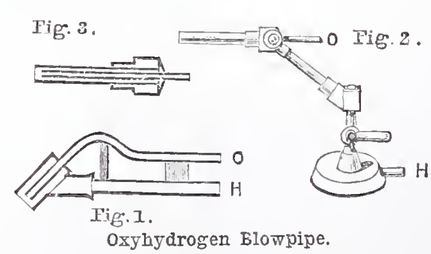
shuts in ice drawer; F, perforated zinc ventilation that opens into shaft, having opening at top under truss, G. Fig. 2, length—A, ice drawers; B, cupboards; C, space between, formed with zinc lining. The ice water trickles down this from ice drawers into receptacle, D, where it may pass through bottom, or be drawn off with tap. E, space for water tank. Fig. 3, bottom of ice drawers formed with laths crossed $\frac{1}{2}$ in. apart. Fig. 4, front elevation with bead and flush panels."

Oxyhydrogen Blowpipe.—H. B. S. (*Liverpool*) writes in reply to T. W. B. (*Barnsley*) (see page 174):—"If you have not yet tried your oxyhydrogen blowpipe, I should advise you not to do so, as, if you use it, you will sooner or later have an explosion. The hydrogen and oxygen should not mix until they reach the nozzle. Besides, you do not require any reservoir like that figured. I give you a sketch of an oxyhydrogen blowpipe that I think will suit you. It is similar to those made by Fletcher, of Warrington. It would be best made in brass, and is intended to hold in the band, for soldering lead sheet, brazing, etc. The blowpipes on stand are similar to the following:—



Oxyhydrogen Blowpipe.

Enlargement of nozzle. O, tube for oxygen; H, tube for hydrogen. In each case you will require a reservoir of each gas, so as to keep up a steady supply.

Trade Notes and Memoranda.

THE *Moniteur Industriel* gives an account of the invention of a glass pen, which is furnished with a helicoid groove to carry the ink.

THE soda engine is gaining in favour in situations where steam is not allowed, or cannot be used. It is employed in the St. Gothard tunnel. The boiler in this engine is filled with a few tons of soda, and when a jet of steam is introduced it produces an intense heat, which gives the motive power. When the soda becomes saturated, the action ceases. A jet of superheated steam from a stationary boiler is then driven through the soda; this drives out the mixture, and the soda is ready for use again.

CARBONISED sawdust, saturated with chemicals, has been introduced into Germany as a filtering and discolouring material. Sawdust is treated first with alum, then with sodium carbonate, and becomes impregnated with a precipitate of aluminium hydrate, which firmly adheres to it. After being washed with a solution of barium chloride until no precipitate is given, the sodium sulphate simultaneously produced is entirely removed, and the prepared sawdust is ready for use. Coloured liquids filtered with it have their colour entirely removed by the formation of lakes with the aluminium hydrates present in the filtering material. Sawdust saturated in this way with barium chloride is used for filtering liquids, from which it is required to remove calcium sulphate, and a sawdust treated with magnesium sulphate, and caustic soda, is used to remove calcium carbonate from a solution.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

Specialities for 1888 & 1889.—Books of New Designs. FRETWORK No. 1, containing 12 Large Sheets, price 1s. No. 2, containing 20 Sheets of larger and more elaborate Patterns, 2s. 6d. Book of Wood Carving Designs, containing 14 Patterns, price 1s.; these are all New Patterns, not sold in any other form, and would, if sold separately, cost three or four times the amount charged. Fretworker's Handbook and Workshop Guide, price 1s. New Designs. All Patterns greatly reduced in price.

Complete Fretwork Outfit, comprising 12-inch Steel Frame, 48 Saws, Awl, File, 4 Designs (with sufficient planed Wood, gratis), and 1s. Handbook on Fretwork, price 3s. 6d., carriage paid. 12 feet Assorted Planed Fretwood, 3s. 6d.

☞ Special Fretwork Design, in commemoration of Her Majesty's Jubilee, size, 36 in. by 26 in., price 2s. 6d.

Catalogue of Machines, Designs, Wood, Tools, &c., with several Hundred Illustrations, and full Instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. Good Fret Saws, 1s. 6d. per gross; best ditto, 2s. per gross.

Eclipse Design, No. 102.

Wall Bracket. Price 5d.

MELLIN'S FOOD

For Infants and Invalids.

TRADE MARK

NOT FARINACEOUS. Rich in Flesh, Nerve, Brain, and Bone Formers.

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

No Food in the market can show such a vast collection of *bonâ-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

USED IN ALL CHILDREN'S HOSPITALS.

WORK

An Illustrated Magazine of Practice and Theory

FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

VOL. I.—No. 31.] SATURDAY, OCTOBER 19, 1889. [PRICE ONE PENNY.

AN AQUARIUM, WITH OPEN FERNERY AND FOUNTAIN COMBINED.

BY C. MAYNARD WALKER.

THERE are very few people, indeed, who do not regard an aquarium with some degree of pleasure, especially if it be tastefully designed, well made, and kept under conditions favourable to the health of its inmates. At any rate, if the latter condition be fulfilled it is a continual source of interest and pleasure, and I have little doubt that if it were more generally known with what ease and how cheaply a practical worker can construct a really good aquarium, and how readily it may be kept in a healthful and vigorous condition, almost every man of a mechanical turn of mind would have one of his own make. I propose in this article helping any such of our readers to this end by giving complete illustrated instructions based upon actual and long experience. And in connection therewith, the reader will permit me, before going further, to refer to a pleasant recollection of my own. It was in consequence of reading, many years ago when a boy, a short description of how to make an oblong aquarium, which appeared in one of the first numbers of THE QUIVER, that I was led to try my hand

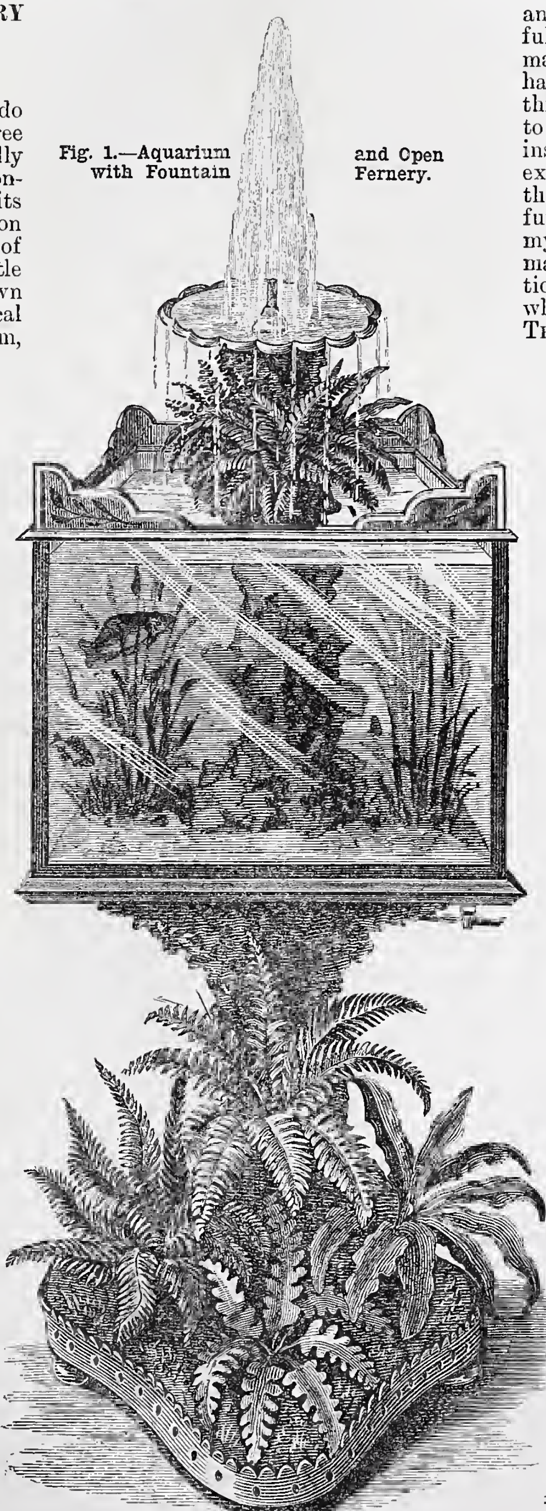

Fig. 1.—Aquarium with Fountain and Open Fernery.

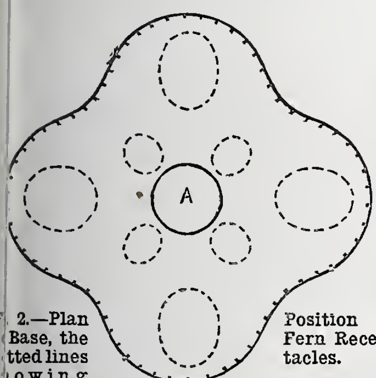

Fig. 2.—Plan of Base, the dotted lines showing Position of Fern Receptacles.

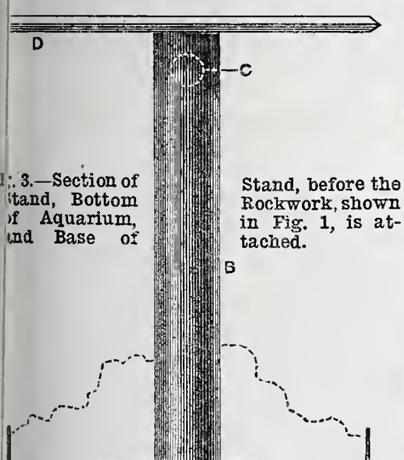

Fig. 3.—Section of Stand, Bottom of Aquarium, and Base of Stand, before the Rockwork, shown in Fig. 1, is attached.

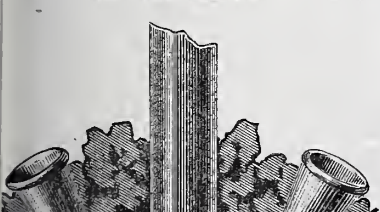

Fig. 4.—Section of Base, showing Method of Building up Rockery for Ferns.

Fig. 5.—Mode of Pocketing Castors before Rockwork is put on. Castors are subsequently bedded in Cement.

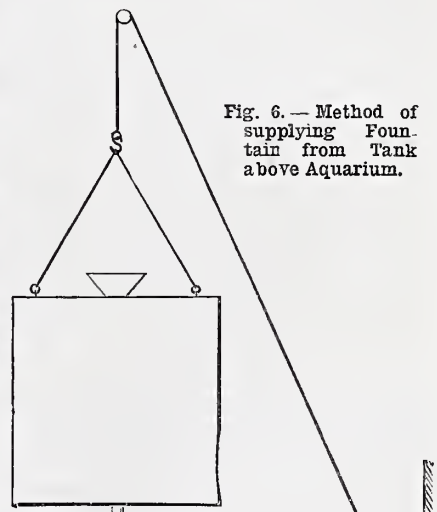

Fig. 6.—Method of supplying Fountain from Tank above Aquarium.

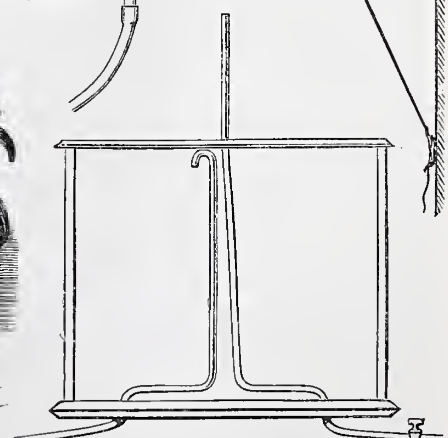

Fig. 7.—Diagram showing Position of Compo Pipes in Central Structure in Aquarium.

at mechanical work in making an aquarium. Since which time I have made a great many of various kinds. And as THE QUIVER and WORK are both published by the same house, it is, perhaps, not unfitting that the writer should return to the subject in the pages of the latter. From the illustration on page 481 it will be seen that the aquarium under consideration is intended to be a bold and somewhat massive article, suitable for standing in a bay window, the centre of a room, or other position where it can be seen to advantage; and although when finished it will be of considerable size, it will be found that the cost for materials will be very low.

The dimensions are as follows:—Height over all, 4 ft. 4 in.; stand (exclusive of castors), 2 ft. 4 in.; bottom of stand from round to round, 2 ft. 2 in. diameter; from hollow to hollow, 1 ft. 6 in. diameter; height of centre rockwork to under side fountain dish, 1 ft. 10½ in.; depth of the aquarium proper, 1 ft. 1 in.; width of aquarium at bottom, 1 ft. 7½ in. These dimensions may be varied, of course, to any extent, enlarged or reduced, but to make it much larger it is somewhat difficult to move if required, and again if much smaller the space is cramped; the writer found these dimensions worked up made a most successful affair in every way. The materials used in the construction are mainly zinc, glass, and cemented rockwork. The angle bar and rebated zinc, for making the aquarium frame, can be bought at any zinc workers, or direct from Messrs. Treggon and Co., Limited, Jewin Street, E.C., and the numbers of the various parts used are the numbers used by them in their catalogue. In making up this design make the bottom of the aquarium first: this consists of four equal lengths of No. 7 sash bar, 1 ft. 7½ in. each, and carefully mitred at each end so as to form when soldered up together a perfect square—an ordinary backed saw will do for this conveniently. The worker will observe that the sash bar has on one side a kind of open seam where the two surfaces of the zinc meet, but are not soldered; it is better that for the bottom these should be soldered perfectly tight, after mitreing, so that they must be so cut that this seam meets the seam on the next one; this being done, you have a square frame with a rebate top and bottom. Now cut a square of No. 10 gauge zinc half an inch smaller than the frame and solder the same strongly to the frame; file up and set aside. Now make the base by taking a square of No. 10 zinc, 2 ft. 2½ in. from corner to corner, centre it, and mark a circle of 3 in. diameter on one side. Now mark and cut out the curves as in Fig. 2, and with a hammer raise a ¼-in. edge all round, which will stiffen up the work and make it ready to receive the ornamental border, which is formed of No. 28 fret (Treggon's), and costs about 3d. per foot run; a smaller size is made at about 1½d., but No. 28 is the best, being bold and strong; this must be soldered so as to be water-tight, or the drainage from the ferns will run on to the floor. The castors should now be fixed. It is most important that castors should be used, as in attempting to move the finished work the strain is very great owing to the weight, especially when filled with water, but with castors it is moved quite easily; nor must they be merely tacked on with solder for similar reasons, but should be pocketed, as in Fig. 5. Make four little tubular pockets and solder in to corresponding holes in the zinc; turn over, fill each with Portland cement of a thick cream, and put the screw or screws of the castors therein, and leave to set hard, taking care that all are on the same level. By this means, when the stand is afterwards made up you will have the castors securely held. You will now require to make the upright centre of stand, which is formed by rolling into the form of a tube a length of No. 10 zinc, 2 ft. 4 in. long, so that when soldered up it makes a tube 2 ft. 4 in. by 3 in. diameter. Having previously marked the 3 in. circles on the under side of aquarium bottom and the upper side of base of stand, solder up, Fig. 3, make a hole about 1½ in. at C, and fill up the tube with small pieces of coke, and then pour in until quite full a batter of Portland cement; this when dry will form a practically unbreakable pillar, and when the other parts are made will be as firm as a rock. Solder in the fountain pipes, Fig. 7, and proceed to build up the rockwork of stand. For this purpose you will require some Roman cement and ordinary gas coke; break up the coke into convenient sized pieces and dip them into a thin batter of cement. Why Roman should be used is that it will take a coating of paint, whereas Portland would require long seasoning; but the latter is much stronger, so that if you propose to paint the work use Roman, if not use Portland cement mixed with sharp sand. Set the work on a level place and see that the pillar is perfectly upright and true to the part you are now working upon; that is, you have got the stand upside down, and from about 3 in. of the edge of D are building up a conical rockwork to the pillar, about one-third of its length, as roughly as possible and yet true; as soon as this is set hard, turn the work right way up, on *a level place*. See that each castor touches the surface of the level place, and see that the whole stands upright, square, and true. This is most important, and the work should be done in a place sufficiently large to get round it and see it from all sides, as when once the work has set firm it cannot be altered to set true. Then build up as Fig. 4, first running in about 1¼ in. of Portland cement and sand, which will make a very strong base; get four flower-pots about 4½ in. in diameter, tilt them on side towards the edge, and fill in all around with cemented coke, taking care that all is well cemented together, and presents a nice rustic appearance. Continue the rockwork a few inches above clear of the mouths of the pots, and then take four pots about 3 in. diameter, and tilt outwards in the same way—between each pair of the larger pots; this will give you two tiers of pots; cover the remaining portion of the upright in the same way, let me again say, taking care to well cement all together, as this part requires to be very strongly made. We now require to complete the aquarium frame. Take four lengths of No. 43 sash bar, 18¼ in. each, and mitre to a square, which should be *exactly the size on the inside with the inside of the bottom;* then for the uprights four lengths of No. 46 bar, 12½ in. long, which solder securely to the frame and to the stand, square and true. Bring to the centre your two pieces of compo (⅜), one for supply and the other for waste; and then glaze the frame with 32 oz. sheet glass, set with putty, made of ordinary putty 1 lb., red lead ½ lb., worked up into a paste with gold size sufficient. Then when well set pour into aquarium to about ½ in. up the glass a layer of *Roman* cement; when set, proceed to build up the centre rockwork, for which purpose the two pipes had better be strengthened by putting in a length of the No. 46 bar tied to them. The waste pipe should extend to about ½ in. of the top, and should be bent down again so that its mouth will be under water when in use, an air hole being made in the top of the bend; this prevents floating objects running down the pipe; both pipes should be soldered in bottom zinc about 3½ in. from edge. The centre rockwork is provided with four pots, set as the upper tier in Fig. 4, at such a height that the bottoms are out of water; and above is fixed a glass dish with a hol in, set quite level and made firm witl cement on top, the supply pipe being fitte with a jet at this end and a tap at th other or bottom of aquarium. The con structive part is now done with the exceptio of the corner ornaments of aquarium show in Fig. 1, formed of the waste pieces o zinc left over cut out with a fret saw.

For finishing, a rich chocolate colour re lieved with lines of gold bronze looks well the rockwork at base looks very effective whe painted a dark bronze, and the ragged edge touched up with gold bronze; the rockwor in centre may be tinted with colour mixe with copal varnish, and the inside corners o the glass should be coated with varnish a well as the floor of the aquarium, and whe thoroughly dry the bottom may have a laye of washed shingle. No live stock excep plants should be put in until the aquariur has become thoroughly seasoned, and it wi save a lot of trouble if the work can be le outside exposed to the weather for a fe weeks, being frequently emptied in th meantime, and the process of painting th outside deferred until the last. Where it convenient a supply of water for the fountai direct from the cistern of course is best; bu where not, a very simple and handy contr vance, Fig. 6, is very useful. A zinc vessel suspended from the ceiling on a pulley-whee and, fitted with india-rubber pipe attache to the supply, is filled and drawn up, and th water when used runs from the waste pi into another vessel or jug, and changed a often as desired.

I trust the foregoing will be sufficient clear in detail to enable any one to make t the design, and would say let no one b deterred from the work, thinking it difficul It is really quite easy, and the more wo there is in it the more value it possesses wh completed.

SOME NOTES ON PLANING.

BY B. A. B.

WHEN the beginner has learnt to sharp his planes according to the instructio recently given in WORK, he will natural want to make some progress in the use these useful tools.

We will try to understand a plane and i mode of action. The cutting edge is arranged that the angle is constant; a chis or gouge can be used in various ways, a held at various inclinations, but the speci feature of a plane is that the cutter is fix by a wedge or a lever and screw. Some our numerous pupils ask why the join uses so many planes; he begins with t jack plane, he then uses the trying pla and after the work is fitted together a glued up, he commonly uses the smoothi plane. Our pupils say, why? Now, t question is reasonable, and ought to answered. The jack plane is used fir because it is a plane long enough to gi some accuracy of surface; it is genera 17 in. long. It is used to take off the ou side surface, and does not need quite su careful sharpening and adjustment as t trying plane, it will do if we take strok of about an arm's length at a time. Now, we may often have very uneven stuff to plane, sometimes slabs axed or adzed into shape, and having an accurately adjusted trying plane; we must take care of it, and economise its use, for the surface of the plane wears uneven on such timber; so our jack plane, which is not called upon for such accuracy, is used first. The trying plane will not then be worn uneven, and it

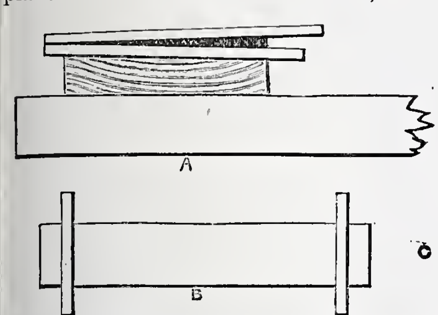

Fig. 1.—Application of Winding Sticks—A, End View. B, Plan. C, Point from which to view.

matters very little if the jack plane is a trifle untrue.

Having reduced the timber to something like accuracy, and also removed the dirt and grit which always deposits upon the surfaces of wood during its exposure for seasoning, and which grit is very destructive to the keenness of the plane iron, with the jack plane, we may take our well-sharpened trying plane and try to obtain a true and finished surface. We shall find it will retain its edge much longer than the jack plane did, because our timber is now clean; and the surface of our trying plane is also likely to retain its accuracy, because our timber is now much less uneven than it was when we began. May I point out the faults a beginner is most likely to reveal as he tries to get his work true? He is extremely likely to take most off the end nearest the bench stop, and he is prone to take most off the corner of the stuff nearest the edge of the bench. This is caused by the fact that the swing of his arms, and, in fact, of his whole body, is in a curved pathway; if he really needs to reduce the front and the near edge, why, certainly; but let him beware of so doing as a mere matter of habit.

Sometimes a piece of wood "lies hollow," as it is often termed, and our beginner may think fit to plane the hollow side first. He begins at the end, and the first stroke sends the wood off the bench, and jerks the plane against the stop, to its probable injury.

We who have seen this will henceforth take care to tuck a thin slip of wood under the end of our stuff, if we *must* plane the hollow side first; if not, we will plane the round side, and if it bends much under our sturdy stroke, we will tuck a piece of thin wood under the middle, taking care that it is not too thick.

We must avoid "winding." What is "winding?" say some of our younger readers. If two of you take a piece of wood in your hands, facing each other, thus:—

Left hand.	Right hand.
Right hand.	Left hand.

Now both raise your left hands and depress your right hands; you thereby compel the piece of wood to be "in winding." Wood often goes "in winding" while drying, and if a door or a shutter is made of winding stuff the consequences are likely to be unpleasant.

Let me explain how to remove this winding. Obtain two pieces of wood about 16 in. long and about 1 in. by $\frac{3}{4}$ in., dimensions are of no importance so that the pieces are straight and parallel. Lay these "winding sticks" across the work and view them; you will at once see which are the highest corners, which are diagonally opposite each other. (See Fig. 1.) Be sure to reduce the thickest of these if there is any difference. If there is much to plane away, most of it may be done with the jack plane.

After the winding is reduced, most likely the stuff is left rounding in the direction of its length. The remedy is to aim at working hollow, constantly watching the effects of the planing, and remembering that the object is not to make shavings, but to make our piece of wood as perfectly flat as possible.

Let us try to understand the reason of this advice to try to plane hollow.

If we imagine a longitudinal section of a plane from end to end we shall find that the section gives us three points (*not in a straight line*), one point at the junction of the front end and the sole, one at the meeting of the sole and the back, and one at the

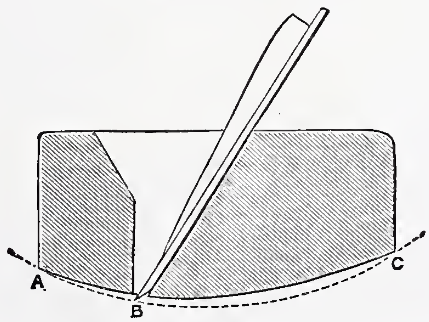

Fig. 2.—Section of Compass Plane, showing three Points, A, B, C, not in a straight line. The dotted curved line is the greatest concavity this Plane will work. Projection of B exaggerated.

point where our section cuts the edge of the cutter, having a projection equal to the shaving we intend to remove. Now, three points not in a straight line must be either the angles of a triangle, or they must lie on the line of a curve. This is what the three points are in the case of a plane; they are in the path of a segment of a circle, whose curvature depends on two conditions: the length of the plane and the projection of the iron. (See Figs. 2 and 3.) Hence a plane can be made about four times as accurate, or rather, one-fourth as defective in accuracy, by halving the projection of the iron. The same increase in accuracy occurs when the length of the plane is sufficiently increased, for we must remember that a plane is an instrument capable of reducing a surface to a small degree of concavity; that is, that although there is scarcely any limit to the convexity that a novice can make with an accurate plane, the most accurate plane ever used on a piece of wood can and often does make a concave surface, and that concavity is limited by the projection of the cutter from a straight line, and the length of the same straight line. In this we must bear in mind that it is longitudinal accuracy we are striving at; the transverse surface of the wood will not be nearly so accurate, however well we may have sharpened our planes, and however carefully set them, inasmuch as the length exceeds the width, so that the truth of our surface will be greater in the direction of the length.

Now, as a truly surfaced plane can make a convex surface (in length), and can make a concave surface, limited as we have seen, we can believe that no tool equally simple and portable can surpass the plane for accuracy of performance.

We are told by opticians that if two flat discs of glass of about equal size are ground together with an abrading substance between, the top one becomes concave and the under one convex; this is just the result of the beginner planing his work—the under surface becomes convex. Now, knowing the amount of hollowing that the plane is capable of is limited, the instructed beginner, however unpractised, sees that to avoid his usual error he must try and plane hollow, limiting the possible error in that direction by having a very slight projection of the cutting edge; the tendency to round off the ends *will* come in, and knowing what to avoid our pupil will be able very speedily to make a fairly flat surface with a good trying plane.

The smoothing plane is small and handy, is easily turned about, and its accommodating shape and size render it fitting for the finishing process, where the trifling use of it is not likely to reduce seriously the accuracy we have attained.

It is most important to so sharpen and set the smoothing plane that the work shall not show plane marks. If the wood has been "tried up" well, probably the mortises and tenons have been truly cut, and the work has been glued up to the workman's satisfaction.

In the final cleaning off, accuracy in sharpening the smoothing plane is most desirable; especially is this the case when the work is to be varnished, for the surface reflecting light as it does, makes every departure from a flat surface most noticeable, and a smoothing plane iron to finish such work (particularly in soft wood where the use of the scraper is out of the question) ought to be very slightly rounded at the corners, enough to avoid the corners projecting from the sole of the plane, and so little as to allow a thin shaving, nearly 2 in. wide, to be taken off with a $2\frac{1}{4}$ in. plane. Such a plane kept well sharpened and the cap iron within $\frac{1}{16}$ in. of cutter, well screwed together, the wedge fitting well, and care

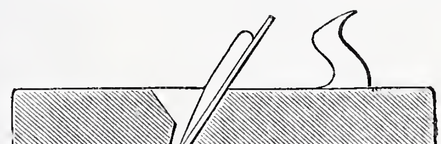

Fig. 3.—Section of Jack Plane, showing three points as in Fig. 1, the depth of curve possible depending upon projection of B. Projection of B exaggerated.

taken to avoid small particles of glue, wood, etc., clinging to the plane, and thereby being forced down on the surface of the work, causing bruises and scratches upon it—such a smoothing plane will leave a surface that will require very little glass-paper to make it fit for the application of paint, polish, or varnish.

My paper may be regarded as affording a simple, but, I trust, clear and intelligible, description of the way to go to work in planing up any piece of wood, and a satisfactory exposition of the reasons for doing so. If beginners in all manual work were thus taught the why and the wherefore of everything that they were told to do, workmen, I think, would be likely to take far more interest in their work than many do at present.

BURGLAR ALARUMS.

BY GEORGE EDWINSON BONNEY.

CONTACTS — DALE'S DOOR TRIGGER CONTACT— MAYFIELD'S DOOR TRIGGER CONTACT—DOORPOST CONTACTS—WINDOW CONTACTS.

Contacts.—The little pieces of apparatus employed to connect the alarum bell with the battery when a door or window is opened, are named "contacts." In their construction are employed tubes or brackets made of brass; springs of brass, or German silver, or steel; small set screws of brass; and insulating blocks of ebonite. The names given to the various pieces denote their uses and situation. These will be seen as we proceed.

Dale's Door Trigger Contact.—Fig. 44 illustrates a door trigger contact made and sold by Messrs. H. J. Dale & Co. The base is made of ebonite, $3\frac{1}{4}$ in. by $1\frac{1}{4}$ in. by $\frac{1}{4}$ in. Two holes are drilled and countersunk in two opposite corners to receive screws for attaching the base to the door frame. A strip of spring brass or German silver, 3 in. by $\frac{1}{2}$ in., is fastened by two screws to the upper part of the base. One of these screws is fitted with a brass collar or washer, and to this one of the branch wires is connected. The strip is bent upward to form a curved spring, and a $\frac{1}{4}$ in. speck of platinum foil is soldered to the spot where it will make contact with the trigger, in the centre of the free strip about $\frac{1}{2}$ in. from the free end. A brass trigger (shape and size shown in the illustration) is loosely held by a pin in a small brass bracket, as shown in the figure. This hangs down perpendicularly, with the finger of the trigger free from contact when the base is fixed to the door frame over the door. On opening the door, its upper part engages with the wedge-shaped piece hanging over it, and the trigger acts like a lever with its finger making contact with the spring above. This part of the finger must also be furnished with a strip of platinum foil soldered to it. As the door is pushed open, its upper edge passes the lower part of the trigger, and this falls down again, out of contact with the spring. The other branch wire is connected to the set screw seen on the left side of the bracket. The bell is set ringing as soon as the trigger comes in contact with the spring. It will be understood that this appliance must be fixed to the door frame *over* the door, in such a position as to bring the top of the door in contact with the lower end of the trigger as the door opens. As the door shuts, it passes under the trigger, but does not bring it in contact with the spring.

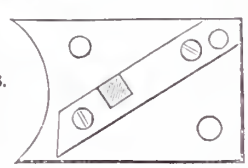

Fig. 48.

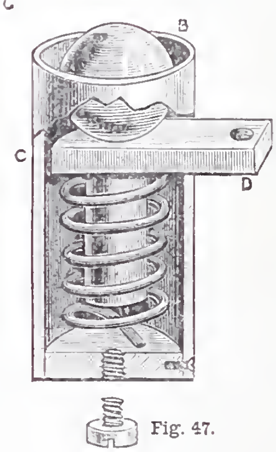

Fig. 47.

Fig. 46.—Doorpost Contact. Fig. 47.—Section of Doorpost Contact. Fig. 48.—Plan of Ebonite Block, E, in Fig. 46.

Mayfield's Door Trigger Contact.—Fig. 45 shows another variety of door trigger contact, made and sold by Messrs. Mayfield, Cobb, & Co., 41, Queen Victoria Street, E.C. It is composed of an angle-shaped brass bracket (D), made out of a piece of brass 2 in. by $\frac{3}{4}$ in. by $\frac{3}{16}$ in., bent at right angles, and drilled with suitable holes for screws, as shown in sketch. To this is attached by screws (the tips of which hold the insulating ebonite block shown) a strip of spring brass or German silver, 3 in. by $\frac{3}{4}$ in. (B), in which is cut a slot $\frac{7}{8}$ in. by $\frac{1}{2}$ in. to receive the wedge-shaped piece of brass, C. This piece of brass is hinged to a small piece of brass soldered to the spring, B, at one end of the slot as shown, and, when thus attached to the spring, the wedge is free to move up through the slot when the top of the door presses against it whilst being shut, but is fixed against the spring when the door is pushed open. The top of the door must, therefore, push the spring upward and bring it in contact with the spring, A, above. This upper spring is made of the same material as the lower spring, but it is fixed to the ebonite block, and is thus insulated from the bracket. The end is also pointed, and bent down so as to nearly touch the end of B; at this point of contact both springs are protected with a speck of platinum on each. One of the branch-line wires is fastened to a screw on the heel of A, and the other wire to the set screw on the bracket, D. This trigger is also fixed *over* the door, as the last-mentioned.

Doorpost Contacts.—Fig. 46 illustrates a form of doorpost contact made and sold by vendors of electric sundries generally. It is made up of (1) a brass plate (A), $2\frac{3}{4}$ in. by 1 in. by $\frac{3}{16}$ in., with a hole drilled and countersunk in each end to receive the screws which fasten it to the doorpost. Half an inch from one end, drill a $\frac{5}{8}$ in. hole, and countersink it on the lower side, or chamfer away the lower edge of the hole until it allows one-third of a $\frac{3}{4}$ in. brass marble to protrude above the surface of the plate. (2) A $1\frac{1}{2}$ in. length of $\frac{3}{4}$ in. brass barrel (C) is soldered to the base plate, A, to form a socket tube for the brass marble, B. This tube has a $\frac{1}{4}$ in. slot cut on the side next the ebonite block, E, to admit the brass cam, D. The inside of the tube is fitted, as shown at Fig. 47, with a strong spiral spring, surrounding a $\frac{1}{2}$ in. brass plunger, to the top of which is soldered the brass cam, D. The tube is stoppered at its bottom end with a disc of brass, kept in place by two or three small screws through the side of the tube. On this bottom rests the end of the spiral spring, and to this is fastened one of the branch wires by the set screw shown in both figures. (3) A block of ebonite $1\frac{1}{2}$ in. by $\frac{3}{4}$ in. by $\frac{1}{2}$ in. (E), cut to the shape shown at Fig. 48, to fit one side of the brass tube, is now to be attached by two screws to the base plate, A. Across this obliquely, as shown in Fig. 48, is fixed a small slip of thin brass, with a speck of platinum foil soldered to the spot where it will come into contact with the corresponding speck of platinum soldered to the upper part of the cam, D, as shown at Fig. 47. To this strip of brass is attached the other branch line. Fig. 49 illustrates another variety of the same appliance, of smaller size, and with a rounded head of brass to the plunger and cam, instead of a brass marble, as at Fig. 46. Let us now see how these contacts are placed in action, and fixed to the door. A hole is drilled in the rebate of the hind doorpost, at any convenient position, to receive the barrel of the instrument. This hole should be sunk deeper than the length of the barrel, to allow for recessing the base plate and give freedom to the set screw at the bottom of the barrel. When this is done, a recess must be cut with a firmer chisel to receive the ebonite block, E, and allow free play to the cam, D. Then the shape and size of the base plate must be marked, and a recess cut to receive it, flush with the surface of the rebate. The branch wires should now be brought into the recess from bottom and side by small holes, and attached in position. See that they are both covered up to the last $\frac{1}{2}$ in. (which must be bared to attach the naked wires to the screws), to avoid accidental contact with the barrel. Then screw on the appliance, and make all good. If we now close the door, its back style will press on the marble and force the cam, D, out of contact with the brass strip on E. Whilst in this position, the circuit of the alarum bell is open, and the bell will not ring; but as soon as the door is open only a little way, the spiral spring will force the cam, D, again into contact and close the circuit. If we left the appliance in the condition it now is in, it would soon get out of order, because the brass marble would wear for itself a recess in the back of the door style. It is usual, therefore, to recess a small brass plate in the style where it comes into contact with the marble, as shown at Fig. 50. A similar appliance, of smaller dimensions, to suit the size of door, may be used for cupboards or French windows.

Fig. 49.—Small Doorpost Contact. Fig. 50.—Piece of Door Frame and Door, showing how to fix Doorpost Contact and Plate to Rebate of Frame and Back Style of Door. Fig. 51.—Window Contact. Fig. 51 A.—Slot for Ebonite Lug. Fig. 51 B.—Ebonite Lug. Fig. 52.—Window Contact—Ball Pattern.

Window Contacts.— Windows are generally considered to be the most vulnerable part of the house defences. Burglars enter more frequently by windows than doors, because they can be opened with least force and least noise. Window contacts are, therefore, made in great variety to suit every probable contingency, and to guard both bottom or top sash, or both together, as occasion may require. Figs. 51 and 52 illustrate a window contact of easy and simple construction for fixing in the rebate of a window frame to either top or bottom sash, or both. The appliance shown at Fig. 51 is made up of (1) a base plate of brass, 4 in. by $\frac{5}{8}$ in. by $\frac{1}{8}$ in. A small hole (for screws to fix it) is drilled at each end, as shown, and countersunk on the face of the plate. Another small hole is drilled and tapped to receive the set screw, S. At a distance of 1 in. from one end is cut the slot shown at Fig. 51A. This slot will receive the ebonite lug shown at Fig. 51B when this has been fixed to the spring. (2) An ebonite block (E) $\frac{5}{8}$ in. by $\frac{1}{2}$ in. by $\frac{1}{4}$ in., to be fastened to the base plate by short brass screws to form an insulating block for the spring, C. (3) A strip of spring brass or German silver 3 in. by $\frac{1}{2}$ in., to form the spring, C. The form of this and the method of fastening it to the insulating block are clearly shown in the sketch. The point of contact between this spring and the base plate may be at the tip of the spring marked X on the figure or at the inner side of the lug, the exact spot being determined by bending the spring so as to touch this spot alone when the spring closes. This point must be protected with a speck of platinum or a small pin of this metal on both base plate and spring. The insulating lug, 51B, is then to be cut out of

Fig. 57.—Section of Bottom Sash Contact. Fig. 58.—Mayfield's Bottom Sash Contact. Fig. 59.—Section of Mayfield's Bottom Sash Contact.

ebonite to the form shown, and of a size to easily slip in and out of the slot in the base plate, whilst the rounded part should be made quite smooth. It is then attached to the spring by small brass screws, as shown.

Fig. 52 shows another variety of this appliance with a marble recessed in the back of the base plate, and kept in the recess by means of the contact spring. This appliance works in a manner similar to that of the doorpost contact (Fig. 46). The point of contact is between the bent tip of the spring and a thin plate of brass on the insulating block. This arrangement gives a certain amount of flexibility to the contact, with a slight rubbing motion, a thing much to be desired in all contacts, to ensure clean bright surfaces at these parts, free from dust. At Fig. 53 is shown in section a modified improvement of Fig. 52, furnished with a rubbing contact. Messrs. H. J. Dale & Co. sell a contact of the form shown at Fig. 51, with all the working parts enclosed in a shoe made of brass and hard wood to protect those parts from dust and damp and other injury. These contacts are neatly recessed in the rebate of the window frame, with the base plate flush with the surface of the rebate, and the recess made deep enough to allow the spring freedom to move. The wires must be brought into the recess through fine holes bored in the frame, where the sash will not come into contact with them.

A very simple, effective, and cheap form of window contact may be constructed by any person familiar with the use of carpenter's tools. A thin plate or strip of copper or brass is recessed in each rebate flush with the surface, 3 in. from the bottom of the lower sash on each side, and also 3 in. from the top of the upper sash on each side, or four plates altogether. The top and bottom plates on each side must be connected to one branch wire, and the top and bottom plates on the other side to the other branch wire. At the top of the top sash at one side, close to the sash cord, fix a curved spring of brass or German silver, and a similar spring to the other side. Connect these together with a piece of cotton-covered No. 18 copper wire, buried in a saw cut along the top of the sash, then puttied and painted. Fix two similar springs to the bottom of the bottom sash, and connect them in a similar manner. When a window is thus guarded, it may be left open some 2 or 3 in. top and bottom (as recommended by Dr. Allinson) without incurring any danger from the entry of unannounced burglars, for, should the thief be tempted by the partly open window to lift it a little higher, or pull down the top sash a little lower, he will bring the springs on the sashes into contact with the plates on each side, and close the circuit of the bell through the wire running along through the top or the bottom of the sash. A similar result is attained by fixing a contact made up of two curved springs, on an insulated base, in the rebate on one side top and bottom, and a connecting bar to the sash. One wire is connected to one spring, and the other wire to the other spring. When the sash is opened wide enough, the connecting transverse bar comes into contact with the springs, and closes the circuit. Contacts for this purpose are sold by Messrs. Mayfield, Cobb, & Co., at 3s. 6d. each.

Should the householder wish to throw open the sashes of his window and draw the Venetian blinds to keep the rooms cool, he can still guard them against intrusion by using Legge's Window Blind Contact, sold by Messrs. T. Gent & Co., Faraday Works, Braunstone Gate, Leicester, at 3s. 6d. each, and illustrated at Figs. 54 and 55. From these sketches it will be seen that the contact must be recessed in the lower part of the window frame with the point of the hook pointing downward. A loop of cord from the blind is passed over this hook when the blind is drawn. Should any person try to raise the blind, the hook will be brought into contact with the metal frame of the appliance and ring the bell.

Fig. 56 illustrates a contact for the bottom sash of a window, made and sold by Messrs. H. J. Dale & Co. Fig. 57 gives a sectional view of the interior, from which it will be seen that the appliance differs in construction from the contacts usually met with. The cap is turned to fit the top of the pin plunger, and is screwed into the top of the barrel to give firmness to this part. Below the head of the pin a spiral spring of brass rests on an ebonite or vulcanite collar, and this spring brings the lower part of the pin in connection with a wire ring below the collar when pressure is withdrawn from the head. This ring is the continuation of a wire which is screwed at the outer end to receive two small connecting nuts. Both ring and wire are held in an insulating chamber of ebonite. A small piece of the bottom of the barrel is bent over the plug of ebonite, and this holds a small set screw to connect one of the wires. It will thus be seen at a glance that all contacts are secure from dust and damp.

Fig. 58 illustrates a contact made for a similar purpose, and sold by Messrs. Mayfield, Cobb, & Co. Fig. 59 gives a sectional view of the interior. This contact presents the novelty of a domed cap, turned to fit the neck of the pin plunger, and screwed inside to fit threads cut on the top part of the barrel. This is made of ebonite, carrying two curved springs of brass or German silver. These springs are insulated from each other by the ebonite top of the barrel. A brass collar is fitted on the pin plunger, and the bevelled edge of this is brought into contact with the springs above when pressed upward by the stout spiral spring beneath, thus closing the bell circuit. The top of the metal barrel is cut away on each side to clear the small binding screws and tops of the springs on each side. The makers claim that this appliance is perfectly damp and dust-proof, and cannot be tampered with by the burglar outside the window. It is fixed (like that shown at Fig. 56) in the bottom frame of the window, so that the lower sash, when closed, shall press on the pin and keep the collar on the plunger from touching the springs. The flanges of the cap are let in flush with the frame, and a hollow is made in the under-part of the sash to fit down closely over the dome. A short brass screw should be inserted in the deepest part of this hollow to press on the head of the pin, and prevent it from wearing a hole in the sash. It will be seen that this appliance meets the requirement of a rubbing contact, and therefore all these parts are kept bright by use.

Readers making their own contacts from the description of them given here, will be able to get the materials from any dealer in electrical instruments. Those I have described are excellent specimens of workmanship, and are made strong, as if to last a lifetime. Nothing less than good material and good fitting should be employed in making these little useful appliances, and all points of contact must be protected with platinum, to prevent the brass from being burnt away by the electric spark which is always caused at these points when contact is broken.

In attaching the wires, see that they are neatly hidden from view, not only to avoid vulgar obtrusiveness, but also to prevent the wires from being broken or being tampered with.

In my next, I hope to show a few traps and dodges to foil the wily burglar, who may know how to damage the ordinary contacts.

BLISTERS IN VENEERING.

BY DAVID ADAMSON.

LET us take blisters, as the swellings resulting from imperfect adhesion of the veneer to its base are called. These naturally are not so likely to occur with caul-laid as with hammer-laid work, still, unless the novice is particularly fortunate he cannot hope to escape them altogether, and they should never be allowed to remain. The sooner they are laid the better, as if the glue has got quite hard and dry, it is a troublesome matter to get them down. The first care after removing veneered work from the caul should be to look out for blisters, and the same may be said before working any surface laid with the hammer. Sometimes the blisters may be so big as to be easily observable with the eye, but it is hardly safe to trust to this, and because anything looks right to pass it as being really so. Blisters may frequently be detected by passing the hand over the surface, but the most reliable and the most common way is to gently tap the veneer with a light hammer head or something of the kind. The hollow sound which is heard when a blister is struck soon shows there is something wrong, and by going over the whole surface carefully all that there may be can easily be discerned. If the novice should fail to discover any difference in the sound wherever the veneer is tapped, he may conclude that it is down everywhere, though of course it may be his want of training which causes him not to notice faulty places. If there are no blisters, for these are by no means necessary though they should always be watched for, he may be very well satisfied. If there are, they will probably show themselves later on, especially when the wood is polished, as very trifling inequalities can then be much more clearly seen.

To give minute directions for laying blisters is, of course, out of the question, and were I writing for experts only, they might very well be left to take care of themselves, and even many novices, who, when they are reminded that blisters are either caused by air between the two surfaces or by an excess of glue, generally the former however, will be able to reduce them without being told how. Still, it must not be assumed that all readers are gifted with such an unusual amount of intelligence—or should I not say conceit?—as to think they can know what to do without being told, and those who attend to the following hints will probably obtain the best results. Perhaps, before going any further, some novices may want to know how big these blisters usually are, as the question has been asked. I am sorry to say I cannot answer it definitely. In the hands of an expert worker they are not likely to be either numerous or large, but with the beginner the case is different, as it is impossible to tell what errors of judgment or manipulation he may not have fallen into. It may even turn out that his veneered work is almost one big blister, and that comparatively little of the work is properly stuck. To give some idea of an ordinary blister, I should say that one the size of a threepenny-bit was small, and that anything over an inch or so across was a tidy size, not quite good enough to take a first-class prize for quality, but quite good enough to take a Liverpool exhibition medal if put in competition and properly arranged. This, of course, does not imply that it is a tip-top blister in point of size, but merely that there are some of less magnitude. It is not, however, the blister but its absence which is desirable. If it is caused by a simple air bubble, it may be laid by pricking a hole in the veneer and pressing this down with an iron warmed sufficiently to melt the glue, the pressure, of course, being retained till the glue has set again. This, of course, is on the assumption that the blister is caused by the air alone, and that there is just the right quantity of glue to do what is necessary. If there is too much glue under the blistered part, it must be squeezed out, the expressive term of "bleeding a blister" being often used to designate this piece of work. The blister must be cut with a sharp edge or point of a knife in order to afford a passage for the glue, which must be first melted and then pressed out with a hot iron. A warmed hammer head, in the absence of anything more suitable, will do very well. Generally the blister will lie flat enough, but in case it does not the cut may be slightly enlarged. Another plan which may be mentioned is to prick a series of holes round near the edge of the blister, and then proceed as before. On a dark veneer it is of very small consequence which way the blister is punctured, but some caution is necessary with the lighter kinds, and I am disposed to favour bleeding by a cut, which, if judiciously made, may almost escape notice or be mistaken for an accidental marking of the figure. The marks caused by pricking round the blister are far more likely to attract unpleasant comment. If the glue has perished, that is, if there is none under a blister, as may happen from a variety of causes, of course some must be inserted, which will be found rather more difficult than taking it out. Even if the glue remains, but has become so dry that heat does not soften it, it will be a job requiring some nicety to moisten it and lay the blister properly. The best way, perhaps, is to prick some moisture in, and then when the glue is sufficiently soft, proceed as before. Blisters, however, should be detected long before the glue has become so hard as to require more moisture, and the last hint will be more useful to indicate to those who have to lay any that may have accidentally been found on old work—to wit, on the aforesaid washstand top. If the blister can be easily reached by a small caul, or, rather, if this can easily be subjected to pressure, it will be found a good plan to lay it in one. The caul, of course, should not be larger than just enough to overlap the blister, as no good and much harm might result from the glue elsewhere being remelted or softened.

A caul for curved work may now be considered, as the nature and work of a caul ought to be pretty well understood from the foregoing. Of course, for plain curves such as a straight cornice-moulding or anything of that kind, there is not much difficulty in forming a suitable caul, but one occasionally meets with some surfaces which, unless they are to be done in considerable quantities, it is practically impossible in the ordinary course of work to make rigid cauls for. The hammer may be, and often is, satisfactorily used in such cases, but when the curves are in all manner of directions a different mode of working must be adopted. The caul, instead of being firm and rigid, must be flexible without being elastic. In other words it must fit itself into every modulation of surface, but should not be compressible by any part of the veneer which may have a tendency to rise. Many substances might be named, but none are more suitable and generally convenient than sand. A bag large enough to cover the work, and of some close material which will not allow the sand to pass through it, must be prepared. This is then filled and heated when required for use. It takes the place of the metal caul, and must be braced up as may be best with pieces of wood which will be fixed down with hand cramps. On the way in which such a caul is clamped down much of its efficacy depends. By the amateur it will seldom be required—nor does the professional worker, with the present fashions in furniture, require it often. Still, there is no knowing how soon styles may not change, and the thorough tradesman ought to be ready for anything that may turn up in his own line of business.

Occasionally, with very sharp curved surfaces, such for instance as a pillar or a column, it may be necessary, to prevent the veneer from splitting, to mount it on thin canvas or something of the sort, but this is so very rarely done that it may almost be regarded as a bit of superfluous instruction to mention it. The sand-caul may be used in all such cases, but where such a thing as a column is being veneered, the wood and hand screws may give way to some binding, such as ordinary chair-webbing, which may be tightly wound round the work. One writer on veneering states that the webbing may be wrapped round the work without a caul, and that by damping and consequently shrinking the binding, pressure will be increased. I don't know that I have seen this plan adopted, but it may be, and as the writer referred to knew what he was writing about, it can only be considered as a practical suggestion not to be despised in case of need.

As marqueterie inlays, *i.e.*, inlaid veneers, are now very much used, it may be said that they should be laid with a caul. Pressure and rubbing with the hammer would be apt to disturb the small inlaid pieces, besides which there are other practical objections.

On panels, square pilasters, or parts of framing where a single line or two of inlaid stringing are required, the veneer may be laid entire and the space for the stringings be scratched out afterwards, in the case of narrow lines the scratch-cutter being just the width of the stringings. Veneered mouldings on the edges of furniture are now so seldom seen that special directions may well be dispensed with; where the worker wants to form any, he will have little difficulty in knowing how to proceed from what has already been said.

It is no doubt well known that the margins of writing-tables, card-tables, etc., are generally finished with veneer. This should be laid before the mouldings are worked, and may be done with hammer or caul. In either case the long pieces, that is those at the back and front of the table, should be laid first, and then the cross-banding or end pieces, which should be within the ends of the others. To prevent shrinkage at the joints, a strip of paper should be glued over these and left till the glue is hard, when it may be removed at any time.

Made-up door frames are done in a similar manner, and I mention this principally to caution beginners against the way in which veneers are sometimes—not so often now as formerly—stuck on the rails, or top and bottom pieces of the frame. The grain of the veneer is occasionally at right angles with that of the solid wood underneath. In other words, it is parallel with that of the door styles, perpendicular instead of horizontal. This, by most authorities, is now considered false construction, and as I think, rightly so. Anyway, without discussing the ethics of veneered door framing, the novice may be told that no one would consider it wrong to lay the veneer with its grain corresponding with that of the pieces on which it is stuck.

It is seldom necessary to lay veneer on end grain of wood, but as it is occasionally so, it will be well to remember that the wood must be thoroughly well sized, I may almost go further and say smeared with glue, in order that the grain may be completely stopped so that it will not absorb more when the veneer is laid.

It is not practicable to mention all the varying circumstances in which veneer may be employed, but enough no doubt has been said to enable the novice to get over any little difficulty he might experience in the general run of work, and if he is in doubt at any time inquiries will no doubt elicit the desired information in the "Shop" columns. Might I, however, as knowing something of the vague character of some of the inquiries frequently put by correspondents, suggest that these should furnish as fully as possible details of the work about which advice is required? Answers frequently require a good deal of thought, and it is impossible that they can be as helpful as the Editor and his staff would wish if inquirers only state half their case. Let them write fully, as by so doing they not only lighten the labour of those who devote their best services to WORK, but they will be helped more than they can possibly be when the questions are so vague that the reply must necessarily be given a good deal in the dark. If the advice and time of capable men are worth anything, they do, at least, deserve to have fair play by knowing exactly what is wanted, either in the way of intended construction or in the avoidance of mistakes in future. I trust that, so far at any rate as veneering is concerned, inquirers will bear these concluding remarks in mind, and it will at all times be a pleasure to the writer "to help a lame dog over the stile."

STENCIL CUTTING.

BY FRED MILLER.

STENCILLING is the readiest way of decorating a surface by means of a perforated plate, and is largely used in house decoration for putting patterns round the frieze, cornice, and upon the ceilings. The design is cut out of some thin material, such as paper or zinc, a pigment is brushed over the plate with short stiff brushes made expressly for this purpose, and the colour passing through the stencil plate on to the surface upon which the stencil is placed, leaves an impression there the shape of that portion of the plate cut away. The simplest kind of stencil we can think of is a circle cut out of a plate, which would leave a round spot upon the wall if we brushed the plate over with colour.

If we cut a few small segments around this circle, not running into it, but each one kept a little distance from the centre, we get a sort of daisy as the flower in Fig. 2. This is an instance of a perfect stencil, for the method and means employed in producing it yield the most perfect result.

Now, suppose we desired to stencil the letter B, and we cut, or attempted to cut, this letter out of a piece of paper, the portions enclosed in the upper and lower loops of the letter would fall out, and we should have an impression, the contour of which resembled the letter B, but detail would be wholly wanting. If we wish to cut a stencil be possible to cut the leaf part of the design out of the plate without reference to "ties," for there is no part of the design that makes a continuous line as in the letter B, and so let a portion of the plate through. But it is important that the stencil should be well held together, for in using it many dozens, possibly hundreds, of times, if the plate were weakened by not having a sufficient number of ties, it would fall to pieces after a little use. There are two ties, A A, in Fig. 2 to strengthen the plate, but such ties form no part of the design; on the contrary, we might say that they rather mar it than otherwise; but in such a pattern as this, itself (thereby avoiding weakening the stencil), but are gradually tapered off, so that when seen at a little distance the leaves appear to *melt* into the stem. This stencil (Fig. 2) was designed by Mr. L. F. Day, and was used as a border, and in order to save time two portions were cut out of the plate so that a double pattern could be stencilled without having to shift the plate. Where a pattern has to be repeated many hundred of times, a great saving of time is effected by having more than one section of the pattern cut. In order to accurately fit the plate on to the portion just stencilled a "key" is cu in the plate, shown at B B (Fig. 2). Thi

Fig. 1.—Example of Stencilled Letter.

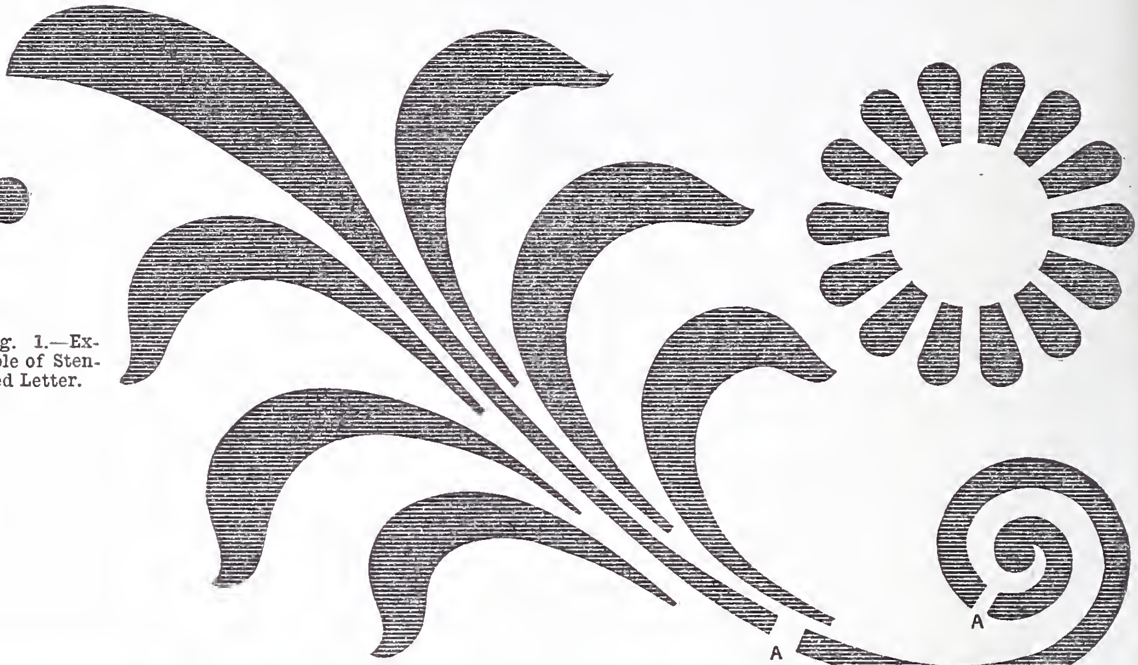

Fig. 2.—Stencil Flower Pattern designed for Border (full size).

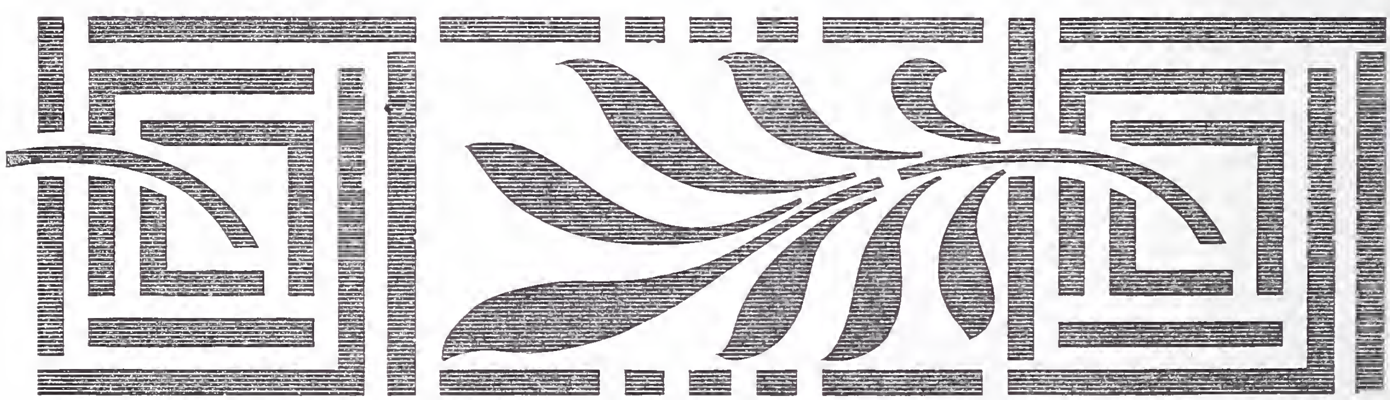

Fig. 3.—Stencil Pattern, showing Combination of Leaf and Old Greek Key Pattern.

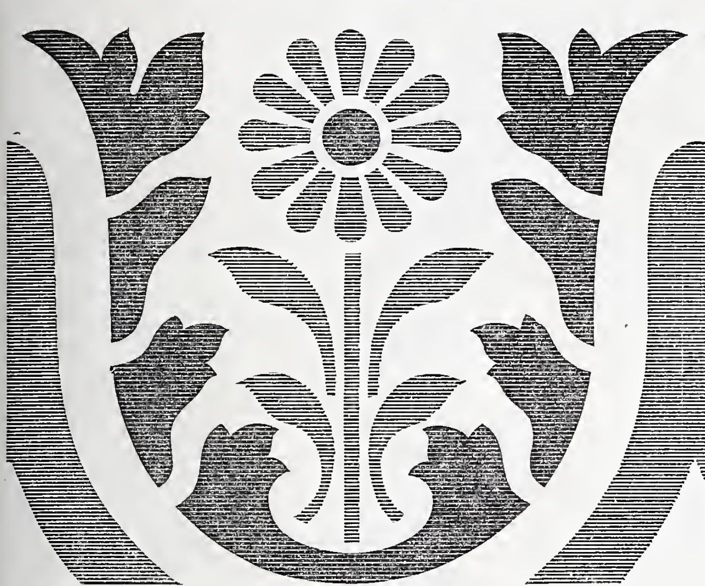
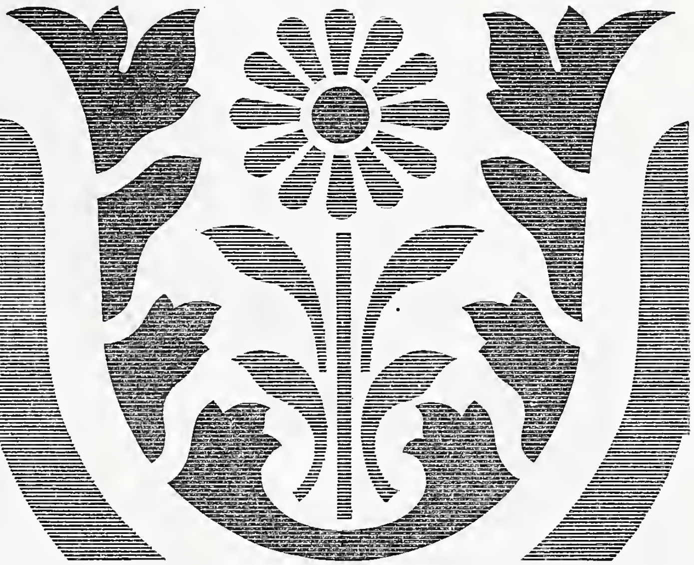
of the letter B, we must "tie" the two pieces that fell out on to the rest of the plate as in Fig. 1, and we can then stencil the letter B, for by not cutting the two loops into the upright, the centre portions are kept in their place. The skill in designing stencils is seen in the way these "ties" are made to actually form an integral portion of the design, so that the pattern actually depends upon the ties for its proper emphasis and expression. But to fully explain myself, let us refer to the illustrations given with this number of Work. We have seen that the flower in Fig. 2 is complete in itself. But the leaf-stalk requires more careful consideration before we cut it, for there are other considerations to be attended to than had to be studied in cutting a flower. It would when placed, for instance, around the frieze of a room, the ties would not be seen. If it is thought desirable to get rid of these ties, a second plate, having the ties *only* cut out of it, is prepared, and when the colour is dry, the stencilling is gone over a second time to fill in the ties. Care must be exercised in getting the plate with the ties on it over the stencilled pattern accurately, and practically I have found it takes little, if any, longer to put the ties in by hand; and it is much more likely to be done by hand without showing than if they are stencilled in. But in patterns placed some distance from the line of sight there is no necessity to trouble about obliterating the ties.

The leaves that spring from the stem, it will be noticed, are not cut into the stem key is stencilled, and when the plate shifted along the right-hand side tl plate is fitted over the key, B B. By th means there are no unequal gaps betwe one impression and another, as would be tl case were the plate shifted along at randoı Remember always to cut "keys" in stenci that are continuous.

In Fig. 3 we have a simple design, which the old Greek key pattern is utilis as a kind of termination to the leaf-stal Such a pattern as this would do for a narro border or on the flat part of a frieze. this design the ties are made to form pa of the design. A good many patterns th have been worn threadbare by long us until the eye tires of them, can be modifi and adapted, and quite a modern feelii given to them. Too many stencil patterns in use are far too trite and hackneyed to be tolerable, and the decorator, instead of using them at all times and places *ad nauseam*, should endeavour to relieve their monotony by importing his own individuality into them. Fig. 4 is another modification of a well-known pattern. This again would be suitable for an "O. G." moulding or a narrow border below the cornice. In this design it is important to stencil the sprig, B, in a lighter colour than the "Acanthus" pattern A. but we must touch on "Using Stencils" on another occasion. The material out of which stencils are cut by decorators is usually cartridge paper, and when the design is cut a couple of coats of knotting varnish are brushed over it (the second one after the first is dry) to make it tough and enable it to wear well and be cleaned. If care be exercised in using paper stencils they will last very well. Draw out your pattern upon thin paper, and transfer it to the material you are about to cut your design out of. carefully, and avoid allowing your knife to go too far and cut more than you want. At the first go off you will find it difficult to keep a mastery over your knife, and cut the curves with freedom and feeling, but a little practice will soon overcome this amateurishness. There is a regular stencil-cutting knife, fixed in a round handle, that can be bought at any good tool maker's for about 9d., and I would advise those who think of cutting many plates to get one. Cut your stencils on a sheet of glass, as the knife travels



No. 1.—Stencil Plate for Fig. 4.



No. 2.—Stencil Plate for Fig. 4.

Fig. 4.—Example of Stencil in Two Colours, requiring Two Plates as above.

Two plates, therefore, are required, A for the acanthus, with the keys, C C, to show where the sprig is to be placed; and B to stencil the sprig and "tongue." Three sections at least should be cut of such a pattern to save time in using the stencil. Here again, though the acanthus is cut up into segments to avoid weakening the plate, these ties are not such as mar the design.

It is possible to stencil in two colours without having two plates by using two stencil brushes, and not having them too large, so that the colour of one part of the plate spreads into that of the other part. In Fig. 2 the flower could easily be stencilled in one tint, and the leaves in another colour; Your knife must be kept very sharp, and have a point so that you can go round your curves with ease, cutting through the paper with one stroke. Be very careful not to cut too far; but should you cut through a tie, you must glue a piece of paper over it. In stencils requiring more than one plate, as in Fig. 4, see that the various sections fit accurately together, and to this end it is well to trace the complete design on tracing paper and transfer the various portions by means of the black transfer paper, marking in the "keys" at the same time. Such forms as the flower in Fig. 2 are the most troublesome ones to cut, and you must not hurry the matter, but cut each petal easily over the smooth surface, and enables one to shape the curved lines with ease. Never attempt to cut on any other material.

Lead foil of the thickness of stout drawing paper I have used; it cuts cleanly and easily, and lies very flat to the wall, and where water colour and distemper are the decorating medium, has certain advantages over paper; but it is much more costly, and, if the ties break, very difficult to repair, so that all things considered I advise my readers to keep to paper. Zinc is often used; but the tyro would not cut this metal, and to get it done by a professional stencil cutter would be a costly proceeding, so we will dismiss it at once.

A stencil looks much fuller on the plate than when it is stencilled, for the thickness of the material has to be taken off all the forms, as the brush, in going over the plate, does not take the colour up to the extreme edge of the design. Therefore keep the design on the side of fulness to counteract this tendency, especially in such forms as stalks and lines, which are apt to look thin and wiry if not cut wide enough.

THE DULCIMER, AND HOW TO BUILD ONE.

BY R. F.

THE Dulcimer, which the Germans call "Hackbrett," the Italians "Cembalo" and "Salterio Tedesca," and the French "Tympanon," is undoubtedly one of the most ancient musical instruments, and the undisputed father of the modern pianoforte.

We have no reliable data as to its introduction into Europe, but it was probably brought to us from the East, perhaps by the Crusaders, for it has been known for ages in Arabia and Persia and also in the Caucasus under the name of "Santir." The old English "Dulsate" and "Dulsacordis" were instruments of which we have no correct information unless they were dulcimers, while the dulcimer of Scripture is still more doubtful.

There is a remarkable resemblance between a seventeenth century dulcimer of Italian make now in the South Kensington Museum, and a modern Georgian santir, as pointed out by Mr. Carl Engel in his "Descriptive Catalogue, 1874."

Dr. Rimbault says, "dulcimer is derived from *dulce melos*" (sweet sounds), probably from the ability of the performer to produce the sweet sounds with the softer side of the hammer or beater with which the instrument is played.

Its use on the Continent seems now to be limited to the gipsy bands of Hungary, but in this country, till within quite recent times, and before it was put in the shade by the introduction of the now ubiquitous cheap piano, it was an instrument in great demand, especially in country places, and many fine performers were to be found whose manipulation was something wonderful. Dulcimer bands, too, were not uncommon, especially in the eastern counties, and generally consisted of a quartette of instruments, composed of first, second, bass, and piccolo or octave. The bass was an instrument nearly six feet long, and strung with heavily bound strings like the bass strings of a pianoforte, whilst the octave was a wee little chap only eighteen inches long. These bands were capable of producing music, especially dance music, of a most go-ahead character, and even performed operatic and other selections with a precision and purity of tone that left little to be desired, the sustained notes being produced by a rapid succession of blows somewhat analogous to that employed by kettle-drummers in the "roll." The unpleasant mixture of sounds caused by the vibration of the undamped strings was, to a great extent, overcome by a judicious application of the soft part of the hand to the strings, but as a rule the music mostly played being of a quick and lively character, did not suffer very much from this "loud pedal" effect.

The recent revival of dulcimer playing is doubtless due in a great measure to the fact that it has been found to make a most charming addition to the piano, and when used to assist at a Cinderella or family dance—when it is not considered really necessary to call in the aid of professional musicians—can render invaluable aid. This, combined with its portability and adaptability for use on board a house boat or yacht, at a picnic or outing, and the undoubted ease with which it may be learnt, justifies the assumption that it is an instrument that has not yet, by any means, seen its last days.

In this and papers to follow I propose to set forth the easiest and best way to build a dulcimer that shall be at once reliable and substantial without being unsightly or heavy, and as portability is a desideratum, we will start on an "F" instrument, that is one that has its lowest steel note tuned to the note  on the piano.

Let us begin then by laying in our stock of wood, and here let me say that it is useless trying to make a good instrument out of inferior stuff; as well attempt the task of "making a silk purse, etc." No; thoroughly good, sound, clean, and well-seasoned wood must be used, or the result will be disappointment and vexation. Tea chests and packing cases will not do, however handy they may be.

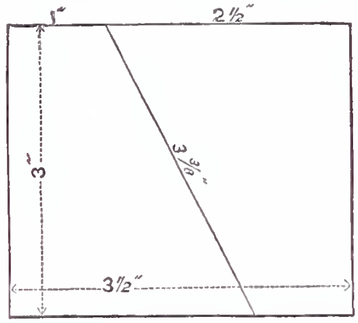


Fig. 1.—Mode of cutting Wood to form "Wrest-pin" and "Hitch-pin" Blocks.

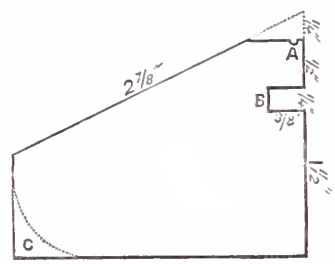

Fig. 2.—Section of Block for "Wrest-pin" or "Hitch-pin" when finished.

The wood we require then is one piece of oak or beech, 18 in. long and 2¾ in. by 3½ in. Beech is the best, as it is "kinder" to work and is not so liable to split. This is for the "wrest-pin" and "hitch-pin" blocks. For the back, about 6 ft. of 9 in. by ½ in.; for the "belly" or soundboard—and this is most important—get 2 ft. 6 in. of ⅜ in. by 15 in. wide best yellow or white pine. It is preferable that this should be in one piece, as a joint in the soundboard should be avoided if possible. Besides this we shall require 6 ft. of 11 in. by ¾ in. for the front and back braces, inside bridges, and front and back facings, and about 2 ft. of 1 in. by 1 in. for inside or lining blocks. All these, with the exception of the belly and pin blocks, should be of the best red or white deal, perfectly free from shakes or knots, as anything of the kind would be fatal to good tone. We have now got all the timber required, except a few feet of moulding and veneer for finishing, which will be mentioned later on.

Now to begin. Cut your piece of oak or beech diagonally from end to end, Fig. 1. This will give you two blocks with sloping faces, which, when planed, should measure 3½ in. across; gauge a mark ¼ in. from the top on the square side of the block, and plane down square to this mark—this will reduce the sloping face to 3 in. In the flat thus formed, shoot a half-round groove, A, ⅛ in. deep and ⅛ in. from the edge, and at a distance of ½ in. from the top edge shoot another groove, B, ¼ in. wide and ⅜ in. deep. The block should now present this appearance, and to give it a finish should be rounded off at the corner, C, as shown by the dotted line, Fig. 2.

Of the two grooves that on the top, A, is intended to take a small brass rod called the pressure-bar, and the one in the side is to take the edge of the belly. Having got out our blocks and seen that the grooves are clean and free from "rags," we will proceed with the back.

Cut off 2 ft. 6 in. of the 9 in. stuff, and another piece of 1 ft. 9 in.; clean them up and shoot one edge of each for joining; the shorter one can be reduced to 7 in. in width or it can remain till the joint is dry. Draw a line across the centre of each, and joint up so that the lines come level, and when thoroughly dry, cut and plane it to measure, 2 ft. 5 in. on the lower edge, 1 ft. 2 in. on the upper, and 1 ft. 2 in. from back to front. If half the distance is measured from each side of the centre line, it will ensure the sides being bevelled at the same angle.

So far our work has been preliminary; in the next paper we will commence the actual work of building.

MEANS, MODES, AND METHODS.

FRENCH POLISH FOR WOUNDS.

RESPECTING the application of ordinary French polish to cuts and wounds as advised in No. 26 of WORK, I have been in the habit of so using that article for years, but it ought to be said that the application at first is extremely painful; it "smarts" so much, that in the case of large wounds the effect would, for a time, be agonising. I find the better plan is, after carefully removing the blood as much as possible, to dust or cover the wound with finely powdered resin, which has a peculiar soothing effect, then to bind or wrap up with rag saturated with the polish. And in regard to the latter, I find it preferable to have it thicker than as used for polishing purposes. This may be very easily obtained by filling a small bottle about three parts full with ordinary methylated polish, and then adding powdered shellac or even resin until nearly full. Shake occasionally until the added gums are dissolved; it will then prove a capital article that ought to be available in every workshop. The resin is a good first dressing. Painters, for cuts, use varnish; copal gum dissolved in oil and spirits for coachmakers; resins for house-painting varnish.—W. G.

RUBBING DOWN OILSTONES.

During fifty years' experience amongst joiners in the metropolis and various parts of the country, I never knew more than one or two men who could keep their oilstones in order without an occasional, and in some cases a frequent, rub down. It is impossible o keep plane irons and wide chisels, etc., rue on a stone, hollow in length or width, nd yet how rare to see a workman's oil-tone but what is so, the old-fashioned plan f rubbing down on a coarse grit slab with and and water being a very tedious and roublesome job. Ah me! how well I emember my apprenticeship days (it was in he forties) when the command was given, 'Bill, rub my oilstone down." Didn't I rumble at that job and no mistake? Rub, ub, and rub, and sweat and rub for an hour t a time. Little more than twenty ears ago, I saw that old-world method ractised at a shop in the neighbourhood of Smithfield where I was working, and it was ot until I came into Lancashire that I earned how such a once tedious job could be lone in a very few minutes by the aid of what s known here as an emery strickle, used by hose who look after carding engines in cotton and woollen mills. For the benefit of those who cannot get an old strickle, I will show how to make an emery board that will quickly level the most irregular oil-stone.

Material required—glycerine glue, coarse-grained emery, and a pine board, say an inch thick, and any size, 12, 18, or 24 in. long, by 4, 5, or 6 in. wide. Take, say, one gill of hot glue, just such as is used for gluing up work, put it in a separate pot or other vessel where it can be kept hot, and add thereto about a dessert spoonful of ordinary glycerine, stirring well. Now take the board, having first of all planed one surface up true, and also bored a $\frac{1}{2}$-in. or $\frac{5}{8}$-in. hole to hang it up by, and lay it face upward upon a large sheet of paper. Cover the surface of the board with the prepared glue, rubbing it in well and evenly with the glue brush. When this is done, without any delay, cover quickly with a thick layer of the coarse emery; bat this down with the flat of your hand all over. Raise the board, shake off the superfluous emery, giving the board a smart rap or two on the bench or table top. Then put aside in a warm, dry place for twelve hours, and repeat the gluing, and covering with emery on the top of the first coat. Rap off all the loose emery, and again put aside to dry. Finally, give the surface a thin coat of boiled oil (with or without the addition of a little black paint), taking care that the interstices between the emery grains are well covered. Let it now rest for two or three days, and when thoroughly dry, it will be found to be a most effective appliance for keeping oilstones nice and level.—W. G.

Cement for Leather Belting.

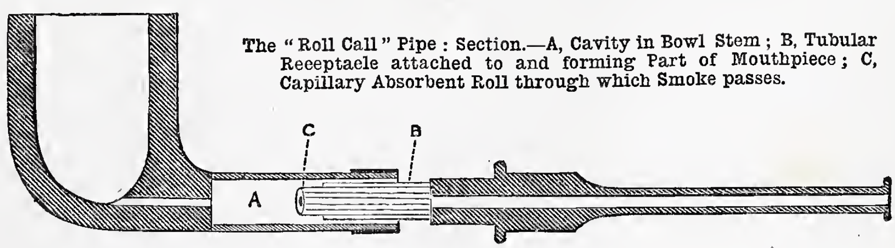
The glycerine glue that is described above makes a capital cement for joining, machine strapping, or leather belting. Power, either of steam or gas, is extending so much in small workshops throughout the country, that many persons, doubtless, will be glad to learn how to piece up broken strapping without having to send a distance and wait for repairs. In my own very modest works, where there is less than a dozen belts running, I find it a very great advantage to be able to repair mishaps to any one of them without any unnecessary delay. Here is my plan. Having first carefully pared down the two ends of the strap to be pieced up, so as to form a lap joint about three inches long, I take a board about three feet in length, and place the two lengths of strap on it so that the joint is midway from end to end on the board. I now temporarily fix the strap to each end of the board by using a hand screw, taking care that the edges of the belt run straight with the edge of the board. Now, first of all, placing a piece of newspaper under the strap at the point of junction, I proceed to glue or cement, as it is termed, the joint with the composition referred to, made quite hot; then driving a couple of $\frac{1}{2}$-in. or $\frac{5}{8}$-in. tacks through the joint into the board, I place another piece of board over the joint, and screw all together tight, either with hand screws, small cramp, or by putting in a vice. Preferably, the whole concern remains thus three or four hours or all night, but, if in a hurry, I unloose the pressure in half an hour or so, take out the tacks, and then stitch with white laces or strong waxed hemp. Joints thus made, when properly dry, are practically unbreakable; the addition of glycerine to the glue preventing the latter from drying hard and cracking, as well as rendering it more adhesive. Where it is exposed to the rain, a teaspoonful of turpentine makes the glue waterproof; that much to a pint of glue.

OUR GUIDE TO GOOD THINGS.

96.—The "Roll Call" Pipe.

Mr. Allen Dewsnap, of 65, Pittes Lane, Glossop, has asked me to notice his "Roll Call" pipe, an invention which is intended to render smoking less injurious and more pleasant than it is when pipes of ordinary construction are used. I have no intention of saying a single word in praise or dispraise of smoking. I do not smoke myself for two very good reasons: firstly, because I do not like smoking; and, secondly, because it does not agree with me. But a great many persons seem to enjoy it thoroughly, and if smoking be really harmful through the nicotine that tobacco contains, it will certainly be useful to make known the existence of a pipe which effectually separates this poisonous and irritating matter from the inhaled smoke, while the fragrant aroma of the tobacco is still retained.

The construction and action of the pipe are shown in the illustration below, which exhibits it in section. It is made in two parts, namely, the bowl and stem, and a mouthpiece which screws into the stem. In a tube, B, at the end of the mouthpiece, a roll, C, of an absorbent substance very much like blotting paper is introduced. This done, the mouthpiece is screwed into the stem, the cavity, A, being nearly filled by the roll, which takes up and absorbs all the nicotine as the smoke passes from the bowl into the mouth of the smoker, the result being, to use the words of the inventor, "a sweet smoke and an absence of nausea, a clean pipe, and one that needs neither scraping nor steaming nor brushing."



The "Roll Call" Pipe: Section.—A, Cavity in Bowl Stem; B, Tubular Receeptacle attached to and forming Part of Mouthpiece; C, Capillary Absorbent Roll through which Smoke passes.

By people who expectorate much while smoking, and to those who suffer from sore tongues, throat, etc., as a consequence of smoking, this pipe will, doubtless, be found a special boon and a perfect cure, and I should imagine its use would be attended with benefit to any smoker, whether he spits or not. The pipe is made of brier, and is fitted with a vulcanite mouthpiece. It is claimed for it that it can be smoked in any position; that it is economical, as all the tobacco is smoked up, and the last whiff is as pleasant as the first; that it is the least offensive of all pipes to other people, as there are no burnt fumes of nicotine to taint the breath or fill a room; and that the roll prevents steam from entering the mouth, and renders the smoke perfectly cool. The price of the rolls is almost *nil*, as twenty-five, or sufficient for more than 100 smokes, may be had for a penny. The pipe and the application of the material of which the rolls are made are both patented. For the price of the pipe, see the "Sale" column that follows "Shop."

97.—Lodge's Patent Self-Locking Cellar Plate.

This cellar plate, the invention of Mr. John Lodge, 24, Shirland Road, Paddington, W., is an important and useful article, inasmuch as it is an advertising medium, by which articles can be

Fig. 1.—Lodge's Patent Self-Locking Cellar Plate.

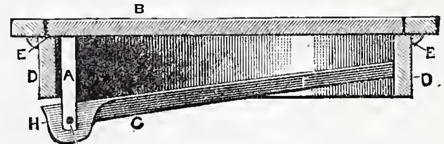


Fig. 2.—Vertical Section of Cellar Plate.

brought under the notice of passers-by, and the names of streets and roads clearly indicated. It seems, however, to be chiefly desirable from the fact that, as the plate is an automatic self-locking plate, pedestrians are in no danger of accidents through stepping on a loose plate not properly put into its place, and the occupants of houses whose cellar approaches are filled with it are insured against entrance in that direction by burglars' boys. The appearance of the plate externally, and the purpose it serves as an advertising medium, is shown in Fig. 1, which speaks for itself; its self-locking principle is shown in Fig. 2. The plate locks itself directly it is placed on the metal ring (D, in Fig. 2) that surrounds the cellar opening, and with the shoulder, E, forms a seating for it. Attached to the under side of the plate, B, is a vertical arm, A, to which a horizontal arm, C, is attached by the pin, G. This arm is just long enough to fall against and grip the side of the ring, D. The end, H, of the arm, C, also butts against the lower surface of the ring, D, and thus affords additional means of preventing it from falling out of the horizontal. The new plate, it is said, has been tested in many places, and has been found to be in every respect simple in action and easily managed, and a safeguard against burglars and accidents to passers-by.

The Editor.

A CORNER FOR THOSE WHO WANT TO TALK IT.

*** NOTICE TO CORRESPONDENTS.—*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

TO ADVERTISERS, MANUFACTURERS, ETC.

*** The Editor of WORK wishes to draw the attention of Advertisers, Manufacturers, Patentees, and Retail Dealers to the following letter from Mr. George H. Bruce, 10, Helena Street, Smethwick, as a proof of the value of WORK as a means for bringing new inventions, machinery, tools, appliances, etc., into notice, and as an Advertising medium. Mr. Bruce writes:—

"I beg to acknowledge the safe return of the gauge and electro lent to you for use in WORK, and to again thank you for the very excellent notice which you so kindly published. As a proof of the extent to which the paper is read, I may say I have received thanks from over forty different towns between Plymouth and Dundee, also from aboard ship, and from Ireland. I shall do all I can to recommend WORK, and should I in the future make anything new to put on the market which would help to make WORK still more valuable to my fellow readers, I will submit it to your approval."

I.—LETTERS FROM CORRESPONDENTS.

Saw Hammering.—J. C. (*London, W.*) writes:—"Your correspondent, in his remarks on saw hammering (see page 333), very rightly states that no two saws, when buckled, can be treated exactly alike; that is the great difficulty, and one which renders it quite impossible for the thing to be placed before the amateur in a readable form. I have had many years' practical experience at the business, and I do not know of anything which is so very puzzling to a beginner, even when in command of the proper appliances. A saw may be what is termed fast or loose, each condition requiring exactly opposite treatment, but the novice could never distinguish between the two. Even when a saw is out of buckle, and what is termed firm, there will occur a variety of bends and twists which are quite distinct from buckles, and require a different-shaped hammer to deal with. Buckles are removed by a heavy hammer with one round face called a 'doghead.' Twists or winds are made to disappear by a hammer with two long narrow faces: one in a line with the shaft, and called a long face; the other at right angles to it, and called a cross face; these and an anvil, and a lot of experience, are the only things that will surmount the difficulty."

Finsbury School of Practical Amateur Mechanics.—MR. THOMAS J. SYER, the Principal of this excellent technical school, which is carried on at Mr. Syer's workshops, 45, Wilson Street, Finsbury Square, E.C., and which is within a few minutes' walk of Broad Street, Liverpool Street, and Moorgate Street Railway Stations, the Tramway Terminus in Finsbury, and the Bank, writes to say that the fresh term has already commenced. Classes are held in cabinet work and carpentry, wood carving and engraving, wood turning, plain and ornamental, metal working, mechanical drawing and coloured plan work, French polishing, upholstery, fret cutting, repoussé work, and tin plate working. Prospectuses with fees, etc., may be obtained of Mr. Syer at the workshops.

An Easily-Made Fret Machine.—ONE IN A FIX writes:—"In No. 21, page 332, W. R. S. gives a method of how to rig up a machine of this kind. Acting on this I started to make one, but cannot see how to work the wheel. I hope W. R. S. will be so kind and obliging as to let me know how it is done, and also how it is fixed."—[W. R. S. is requested to comply with the wish of ONE IN A FIX, and make his meaning perfectly clear.—ED.]

Lock Repairing and Key Fitting.—ERRATUM.—By a misadventure the names of the springs described in the first paper on this subject in No. 21 of WORK, dated August 10th, 1889, became interchanged. The spring shown at G, Fig. 1, is that which is known as the "Scotch Spring," and D is the spring bolt. The "Feather Spring" is the spring illustrated in Fig. 3. This has been pointed out by Mr. Wilson himself, the writer of the article, and several other correspondents, to whom I may say that the passage to which they take exception has been revised by Mr. Wilson. This will be a sufficient reply to IRONMONGER'S ASSISTANT, L. L. (*Salisbury*), and others, whose letters will need no further reply or comment.—ED.

Hinged Bevel for Pocket.—J. G. (*Glasgow*) writes:—"I see a description and drawing of a very handy gauge in WORK No. 23, page 363, for the vest pocket. If a hinged bevel for the vest pocket were made, it would come in handy for many artisans."—[Why not write to the makers of the pocket gauge to which you refer, and ask if they cannot meet your wishes?—ED.]

II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

Paper to Imitate Oak Graining.—H. M. (*Crumlin*).—You can buy this of any one who sells paper hangings.

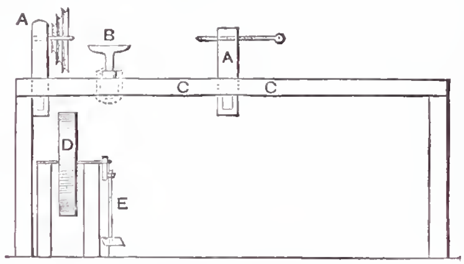
Watch and Clock Repairing.—AMATEUR and NERO.—Before this can meet your eye you will have seen that the papers on this subject are under continuation.

Studio Camera Stand.—DARKIE.—A paper showing how to make this and other camera stands appeared in No. 29 of WORK.

Rubber Stamp Making.—ALBION.—As soon as a competent writer offers his services this subject shall be taken up.

Artificial Leg.—ZOMO.—I cannot undertake to tell you how to make an artificial leg, for I suppose you mean a leg other than that of a mere wooden leg. For anything of this sort the proper person to apply to is Mr. James Gillingham, the celebrated Surgeon Machinist, of Chard, Somersetshire.

Lathes for Everybody.—BEN NEVIS (*Appleby*).—I am glad you like my article on "Lathes for Everybody." I am sure, if you make a lathe of some sort, you will be fully repaid for the labour it will take. It would scarcely be consistent with my object to send working drawings of every part of the complete lathe, as it has to be adapted to existing circumstances, and they are not similar in any two cases. I send herewith a rough sketch, which will explain the position of the various parts, and may be of assistance to you. The bench is an ordinary one on trestles; the top consists of two



Lathes for Everybody.

A, A, Head. B, Rest. C, Bench. D, Grindstone. E, Treadle.

3-inch deals two inches apart; the heads fit into the space thus formed and are secured with wedges, as explained in the article. The grindstone is heavy and driven by a crank and treadle. It occupies the position shown when used as a fly wheel, and can be removed or pushed back out of the way when not in use. A leather band conveys the motion to the pulley. I think you can scarcely fail to comprehend matters, but I will give any other directions you may require with pleasure. The Editor has instructed me to write another article on "Lathes for Everybody." This I will take in hand at once, and describe a simple mandrel lathe. I will remember your suggestion of more detail.—SELF-HELPER.

Alarm Bell Battery.—W. R. (*Bristol*).—The fault you mention is a common one with permanganate of potash in solution. This salt is rapidly decomposed, and a hydrated manganese dioxide is deposited, forming the black mud of which you complain. When used in a single cell, without a porous partition, this mud fouls the zincs, and gives trouble from this cause alone. When about to renew the charge of your cells, use chlorate instead of permanganate of potash, and you will be pleased with the result. Employ half an ounce of chlorate of potash in each cell.—G. E. B.

Galvanic Battery.—GIL PEREZ (*Wakefield*).—(1) The cell described and illustrated by you is similar in every respect to the Bunsen battery described in No. 1 of WORK. You may charge it as there directed for a Bunsen, or with a solution of chromic acid in the porous cell with the carbon, made up as directed in reply to J. R., "Electric Light for Photographic Dark Room." One cell alone, however, will be useless. You must have three such cells, and arrange them in series, to light a very small lamp. (2) If you placed peroxide of manganese in the porous cell together with broken coke, and used a solution of sal-ammoniac in the outer cell, the battery would only be suitable for ringing a small bell, or working a model telegraph instrument, but would be useless for electric lighting. (3) Earth wires are used in electric telegraph systems, but are not to be thought of for your requirements. I would advise you to read closely the three articles on the Bunsen battery in the first three numbers of WORK, and also all the replies to correspondents on this subject in "Shop."—G. E. B.

Plumbing.—SHORTER.—Water is kept back in plumbing by a stopcock—or by what is technically called a stopback—made of clay or new bread. The same thing is arranged in the large cast-iron mains by simply packing the joint.—G. S.

Panorama Tackle.—MACHINIST (*Bath*).—Your only chance of obtaining the necessary drawings for making and erecting the machinery used in working a panorama is by advertising for same in *The Era* and *The Stage* newspapers. A stage machinist, used to working these "shows," would then, no doubt, supply you, if well paid. I certainly know how they are worked, but am not competent enough to write upon the subject. Your first letter did not reach me, or it would have been answered.—H. L. B.

Boot and Shoe Making.—LEATHER.—The introduction of boot and shoe making into WORK has been carefully considered, but if this is touched on, why not include tailoring, hat making, and other kindred subjects? I appreciate your letter, and wish I could see my way to satisfy your wishes, but at present, at all events, it is not possible to do so.

American Organ Building.—GENIUS.—I cannot say with any degree of certainty when these papers will be commenced. I trust you will not have to wait long.

Kaleidoscope.—TOM SMITH.—Indian ink will serve for the back of reflectors, if a thick solution is prepared and smoothly applied with a camel-hair brush. The ground glass circle is to be fixed flush with the inner face of the lid of the object box, in which a recess must be turned or otherwise formed to receive it. The glass is *not half round*, but a *complete* circle, as the dotted line, A B, Fig. 6, refers to the section of box, Fig. 5.—T. R.

Index to Weekly Numbers of WORK.—ELPHYE JANAN.—Your suggestion shall be considered, with the view to its adoption at some future time, if found practicable.

Bicycles Uphill.—A NOVICE (*Southampton*).—I am at a loss to know what your correspondent's difficulty is, as there is nothing indicative in the letter. It simply describes a tricycle of a type now considered out of date, or, rather, out of fashion, the now popular machine being the "Cripper steerer," *à la* handle bar, like the "Safety" bicycle. I may say, however, that a first-class tricycle of the type he mentions will climb hills equal to anything yet on the road, even including the "Safety" bicycle. The side handles give a better purchase for pulling, with the arms in a direct line from the shoulder, than ever can be had with the cross bar in front. When a bicycle comes to a dead stop on a hill, that means a dismount. With a tricycle you may stop and allow your pedals to revolve, say, a quarter of a turn backwards, in order to bring one up for a fresh stroke, when you may again proceed. The principal thing wanted for hill climbing is a good machine, and considerable practice at the work, and a rider who makes a speciality of hill climbing is always immeasurably better at it than one who contents himself with the level and walks the hills. 40-in. wheels, geared level, are not too large for a tricycle, as smaller wheels geared up would be no easier to drive, unless you had gearing to gear them down for hill climbing. I shall be happy to assist A NOVICE in any way I can through the columns of WORK.—A. S. P.

Photography, etc.—F. D. (*Luton*).—I am glad to find that the papers on photography and plating solutions which have appeared in WORK are satisfactory to you. WORK, you must bear in mind, is a magazine of construction and decoration, and that, although the manufacture of photographic appliances will be fully treated, it is not possible to deal seriatim with every branch of the art. When the papers on jeweller's work are commenced, a design for a jeweller's work bench will be given.

Photography, etc.—PALETTE.—Before this reaches your eye, you will have read, and perhaps begun to act on, the instructions given for making a camera. The Instantograph must form the subject of a separate paper. Any question you may wish to ask on the fitting up of lenses will be answered in "Shop." The camera-obscura and its construction must also form the subject of a separate paper.

Gear Cutting.—PENDULE.—Your letter, requesting a paper on this subject, has been sent to a contributor, who will comply with it if possible.

Pen for Ruling Dotted Lines.—H. C. S. (*London, S.E.*).—Your ruling pen seems to be an ingenious contrivance for the purpose in view. I will endeavour to help you in the direction indicated by you. It is a pity that it is not provisionally patented, for the cost of doing so would be only £1.

Printing Frames.—G. P. (*Camberwell*).—An article on this subject will be given as soon as practicable, and special reference will be made to contrivances for printing large cyanotypes. Meanwhile, as you say you do not know what a printing frame is, it may be of assistance to you to know that they are used by all photographers. No doubt any photographer would show you one, and you will then have a very fair idea of what is wanted.—L. J. P.

Hour Glass.—W. E. D. (*King's Lynn*).—I am afraid the subject is hardly a suitable one for an article to be devoted to, and what you ask it is impossible to give in "Shop." I think the best thing you can do is to get a catalogue of carving and fretwork designs from Henry Zilles & Co., whose address you will see in their advertisement. You will, no doubt, be able to pick details from some of the full-sized patterns, which you can combine, to make a stand such as you require. An article on a kitchen dresser is in hand, and will appear in due course.—D. A.

Mediæval Furniture.—T. A. E. (*Newcastle-on-Tyne*).—The subject is referred to in many works, and you can only gain a good knowledge of it from an extensive course of reading. I am not prepared to recommend any one book specially. Your best plan will be to write to Mr. Batsford, bookseller, Holborn, who has a large number of publications on furniture, for his list. You see so much depends on the particular branch you wish to study, that to recommend one book might mislead you. I am sorry to say that your second question, viz., "What period does the style of having straight lines?" is not sufficiently definite to enable me to answer it. If you will supply the words which have evidently been omitted, I may be able to help you.—D. A.

Gold Paper and Mounts.—Anxious One (*Newcastle-on-Tyne*). — It is only by experience that mounts can be properly cut, and the tools are what are known as mount cutter's knife and handle, dividing compasses, iron straightedge, pencil, etc. Gold paper, ready prepared for use, can be bought at City Frame Company, 29, Basinghall Street, E.C. Sixpence per half sheet best gold paper, and postage extra.—G. R.

Cassell's "New Popular Educator."—Ince (*Wigan*).—Cassell's "New Popular Educator" will be complete in forty-eight monthly parts, at 6d. each, or in eight volumes, bound in cloth, 5s. each.

Models for Pasted Papier-Mâché.—W. H. S. (*Southampton*). — Any pattern-maker, joiner, or cabinet-maker would be able to make the moulds for papier-mâché. When many copies are wanted of the same article, it is usual (in the trade) to have a number of casts of the mould made in iron; these are less liable to damage, and, by means of them, the pasting of several copies of the work can be proceeded with at the same time. Tea trays, for instance, being articles wanted by dozens, are pasted on iron moulds.—S. W.

Sign-Writing Book. — Messrs. Brodie & Middleton, artists' colourmen, Long Acre, London, W.C., publish a book on this subject.—H. L. B.

Making Ink. — A Subscriber (*Henley*). — For *black ink*, the following has been recommended:—Bruise 6 oz. of best Aleppo galls, and boil in six pints of water for several hours, adding more water to supply the loss by evaporation. Strain whilst hot through calico into a clean vessel. Add 4 oz. gum arabic, and boil again till the gum is dissolved. Strain again whilst hot into a stone bottle, and add 4 oz. sulphate of iron, previously dissolved in water. Lastly, to preserve from going mouldy, add three drops of creosote for each pint of ink. To appear *thoroughly* black keep for some time before using. A *blue black ink*, but one which appears violet at the time of writing, is made by bruising elderberries, and setting them in a warm place for three days to ferment; straining and adding to each six pints of juice, ½ oz. sulphate of iron, and ½ oz. of acetic acid. A *red ink*, which, it is said, will not lose its brilliancy by use with steel pens, is made as follows: Grind one part carmine with fifteen parts acetate ammonia and fifteen parts water. These are allowed to stand for some time, strained, and then thickened with a few drops of dissolved white sugar. For *blue ink*, the following is said to be good:—To 1,000 parts of boiled water add thirty parts of Prussian blue dissolved in four parts of oxalic acid.—S. W.

Two Speed Geared Cycle.—J. H. B. (*Narbeth*). —In theory, your idea of two gears is desirable, but you are, no doubt, aware that several contrivances for hill climbing power, that is, lower gearing, have been devised and used. They have not, however, been generally adopted, though more than one fully answer the purpose intended. I have used a tricycle with a low gearing in addition to the normal, but, while admitting its occasional advantages for hill climbing, I prefer a light machine without complications. Your specification has, however, been very carefully considered. The plan is, undoubtedly, ingenious, but is open to several objections, though possibly it may contain the germ of something which, if worked by practical cycle manufacturers, might eventuate in success. As it stands at present, I fail to see any advantages over the ordinary run of machines, and I must say that I do not approve of your plan for freeing one wheel when turning corners. I think you will gather from the foregoing that, in my opinion, it would be, to say the least, doubtful whether you would be able to recoup yourself for any expense you might go to. I think your best plan would be to see if you can induce any manufacturer to take up your ideas, but, of course, before doing this, it would be advisable for you to obtain provisional protection. In reply to your second question, I may say that I do not think it at all likely that you would get a patent agent of any standing to give you the guarantee you suggest. He would use every reasonable precaution, and make searches for you, but, of course, he could not take the risk. Unless you are accustomed to patents and specifications, you will find it best to employ an agent, though if you prefer doing without one you are quite at liberty to do so.—D. A.

Ink. — McIntosh (*Highbury*). — Blue black, or purple black inks, become jet black on exposure to light and air, because of the action of the light and air on the iron held in solution with the tannic or gallic acid. If you wish to hasten the blackening process, apply the solution of iron to your paper whilst hot, or heat the sulphate of iron a little before dissolving it. Inks made in this way are not so permanent as those which blacken slowly after being exposed to light and air. You could not possibly separate the ingredients by precipitation, apply them separately, and ensure their combination on paper in the form of jet black ink. Try a strong decoction of nut galls in water thickened with a little gum arabic, as a first solution. As a second, use a solution of sulphate of iron in water thickened with gum arabic and applied hot. If I knew exactly what you aim at doing I might help you further.—G. E. B.

Bookbinders' Tools and Materials.—D. T. D. (*Cardiff*).—You will be able to get binders' cloth, leather, etc., at any respectable bindery in small quantities to suit your purposes. Second-hand binders' tools will not be so easily obtained. Bookbinders' tools are the property of the master, and seldom find their way to the second-hand dealer through the pawnshops, like mechanics' tools. I have seen them, however, for sale in Edinburgh. If you write to Messrs. George Royle & Sons, 5, Lovell's Court, Paternoster Row, London, E.C., they may have some cheap lots to suit you. If you write to the Secretary, Science and Art Department, South Kensington, London, you will get the syllabus for next May examination.—G. C.

Violin Tool. — C. O. N. (*Farrow*). — A purfling tool, like the one I use, is sold for 5s. 6d. by J. Scheerer, Covered Market, Leeds. Another kind is sold by Withers & Co., St. Martin's Lane, London, for 4s. 6d.—B.

Parts of Bicycle.—T. C. (*Chepstow*).—The following makers and dealers will supply all parts and fittings for safeties, and other cycles, either in rough, part finished, or completely finished ready for fitting together:—Brown Bros., 7, Great Eastern Street, London, E.C.; Wilkins & Co., 66, Holborn Viaduct, London, E.C.; Thos. Smith & Son, Ladley Mills, Birmingham; W. A. Lloyd, Waeman Street, Birmingham; Wm. Bown, 308, Sumner Lane, Birmingham. The last is about the best place for all kinds of ball bearings, pedals, and everything connected with the trade.—A. S. P.

Polishing Mahogany.—P. J. S. (*Lambeth*).—The best way to finish mahogany is by French polishing it, if you want a bright glossy surface. The process embraces staining if necessary, to darken the colour, oiling, filling or stopping the grain of the wood, bodying in with polish, and finally spiriting off to get a fine smooth surface without marks. For stain use a solution of either bichromate or permanganate of potash, the strength depending on the colour required. Rub down with fine glass paper after staining to remove roughness caused by the moisture. Oil with raw linseed oil, rubbing it well in with a piece of rag, but not saturating the wood with it. Allow the work to stand by till the oil has become fairly dry, and as long as you like afterwards before beginning to fill in. The best filling you can use is one composed of whitening and turpentine with a little rose pink to colour. Mix these into a stiffish paste, and then rub some of it well into the wood. When you judge this has been sufficiently done to stop up the grain, wipe the surplus away before it gets hard with a clean cloth. The wood is then ready for bodying in at any time, though it is always advisable not to hurry on too fast with any polishing process. To body in use a pad formed of cotton wadding enclosed in a piece of soft rag. Moisten the wadding with French polish and cover it with one fold of the rag. Give this just the least touch of linseed oil, and go over the wood till you have a good body of polish on it. As the rubber dries add more polish, and be careful to cover the wood evenly, rubbing the polish till the spirit evaporates. If necessary, bodying in may be repeated several times at intervals of a day or two. At this stage the surface is smeared and dull-looking, and the final polish is got by spiriting off. This is much the same as bodying in, only spirit (methylated) alone is used instead of polish. Unless you are careful, instead of getting a highly finished surface, you will be apt to remove the previously laid body. Spiriting off is the most difficult part of the process, and requires considerable skill to manage it properly. A series of articles on polishing will appear ere long, meanwhile the foregoing brief directions will, no doubt, be of assistance to you. If, as I conjecture from your second query, you want to polish fretwork, let me advise you to do so before fretting, or if not omit the filling. In the former case you will simply have to touch up the polished surface after the work is completed. If you want very small quantities of thin mahogany, you cannot do better than get it from some local cabinet maker, who will cut a board to any size required, but of course you will have to pay more than if you go to a timber merchant, who, however, will not cut, unless as a matter of favour. The quantity you must take is, however, not excessive, and you will get a great deal more for the same money than you possibly could otherwise by going direct to a timber yard and buying a whole plank. I can recommend D. Witt & Palmer, Drummond Street, Euston Square; Samuel Westlake & Sons, 51, Tabernacle Street, E.C.; or you might try Wm. Bloore, 57, South Lambeth Road; or, W. C. Ware, Lower Kennington Lane, as being nearer to you. I cannot, however, say whether these latter two would supply you. As a guide to you I may say that ⅛-in. plain mahogany may be got from 3d. to 4d. per foot, though of course for fine qualities you must pay considerably more.—D. A.

Engine for Launch.—C. C. (*Hackney*).—Write to Mr. Dugald Clerk, A.M.I.C.E., 13, Temple Street, Birmingham.—J.

Advertisements in Work.—Spes (*Wolverhampton*).—I can only refer you to the reply given to Ad Finem on page 253 of Work.

Violin Varnish.—G. M. L. (*Ashington*).—Amber is only soluble after it has been fused, and is then no good for violin varnish. As varnish making requires both special knowledge and appliances, I should advise you to apply to Mander Brothers, Wolverhampton, who used to make an oil varnish which sets hard and bright in from twenty-four to thirty hours; I think it was made by them on the suggestion of the late Charles Reade.—B.

Tempering Mill-bills. — T. C. (*Chepstow*). — (1) Take two gallons of rain water, 1 oz. corrosive sublimate, 1 oz. sal-ammoniac, 1 oz. saltpetre, one pint and a half of rock salt. The pick should be heated to a cherry-red, and cooled in the above bath. (2) Prepare a bath of lead heated to the boiling point. In it place the end of the bill to a depth of 1½ in., until heated to the temperature of the lead, and then plunge into clear cold water.—J.

Bicycle Wheel. — F. K. (*Lee*).—At that place where the rim comes nearest to touching the fork side, slacken back a few spokes with the spoke grip; then on the opposite side tighten up as many spokes as will pull the part straight. It is, however, quite likely that the spokes at this latter part have got stripped at the screwed ends, or pulled through the rim at the head, in which case all such spokes must be replaced by new ones. F. K.'s best course is to give the machine to a repairer. If he finds, however, that the spokes are all holding good, then he may readily put the wheel right by the means above indicated. To bring it to run dead true, set it revolving, and let the rim touch a piece of chalk. Where the chalk touches, loosen slightly a spoke or two, and tighten one or more on the opposite side.—A. S. P.

Tooth Plane and Paper-Rack.—P. E. (*Ebbw Vale*).—All inquiries are answered as soon as possible, but you must not be surprised at not getting a reply at once. To insert replies immediately is impracticable for more reasons than one, although, if it could be done, it would, no doubt, be a convenience occasionally. A tooth, or toothing, plane is similar in appearance to an ordinary smoothing plane, except that the iron is perpendicular. The face of the iron is ribbed, or rather serrated, for some distance from the lower end. This, on being ground and sharpened in the usual way, gives a sharp saw-like or toothed edge, which is used to roughen the surfaces of wood before they are glued together. You will thus see that though the action is a scratching one, the toothing plane is not the same as the "scratch." One of these, with a special iron, might, of course, be made to answer fairly for occasional use. I do not understand quite what kind of paper-rack you want described. Is it one for keeping stock wall papers in, or for showing them, or what? The thing you ask for may take so many different forms that I must ask you to state more fully what it is intended for, otherwise much space might be occupied in describing several arrangements, none of them suitable. Give particulars as fully as you can, and state space available, quantity of paper kept, and so on. Your other inquiry is altogether too vague for me to answer in a satisfactory manner.—D. A.

Zinc Letters.—T. E. (*Padiham*).—You can purchase the letters and figures that you inquire about at any engravers in copper or zinc, or you could have them cut at any good ironmonger's where they keep workmen on. But why not do it yourself? It is not very difficult work, nor does it require a lot of tools. If you cannot mark out the letters, etc., do as I used to do when a young hand. Get the letters out of auctioneers' bills, etc., the size wanted, paste them on the metal you wish to cut them out of, and chop them out with a small chisel on a flat plate of cast iron, and trim up with a file. Any further information given with pleasure.—R. A.

Parts of Overmantel.—F. M. (*South Hornsey*). —The long turned pieces are spoken of as columns or pillars, the short ones as spindles, and the short ends as knobs. The corner pieces are generally called brackets, but you must understand this word is not exclusively applied to such parts, but is a term of very wide acceptance in cabinet-making districts you refer to. To help you, I name the parts asked about, but as you state the reason for wanting to know them is that the Curtain Road turners would charge you considerably more than the usual price if they thought you a novice, I may as well say that considerably more than a knowledge of the common trade names will be required on your part. Any of the Road people in the furniture line would recognise with "half an eye" that you are not in the trade, unless you have a knowledge of it. Of course, you must expect to pay more for a small quantity, such as you want, than usual (trade) prices. It is absurd to suppose that you could get them at wholesale figures, though, no doubt, several dealers will tell you they only sell wholesale, and have only one price. Take my advice, and order through a local tradesman.—D. A.

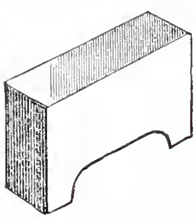
Vulcanite. — E. R. (*Birmingham*). — Vulcanite may be polished when necessary by simply rubbing it with oil and some smooth powder, such as putty powder. The surface will be dull, but uniform, and the easiest way to put a bright gloss will be to go over it with a little French polish or glaze. This I can recommend you as a quick way, though, of course, the work will not stand much rough usage. However, when it becomes dull, you can go over it again with the polish rubber.—D. A.

Pedometer. — W. C. (*Upper Holloway*). — The instrument W. C. requires is a pedometer. It is, I fear, beyond the ability of an amateur to make. It consists of a train of wheels actuated by a mainspring similar to a watch. A lever escapement is so balanced that with each inclination of the body in taking a step the escape wheel is liberated, and the motion is communicated by the train of wheels to the hands on the dial. It thus records the number of steps in a measured mile, and when that has been ascertained it is easy to calculate any distance travelled. W. C. will see from these hints that it requires the skill and knowledge of a watchmaker to construct such an instrument as he requires.—O. B.

Book on Sheet Metal Work.—J. A. (*Grimsby*).—There is a book entitled "The Sheet Metal Worker's Guide," price 1s. 6d., published by Messrs. Crosby Lockwood & Co., E.C. I do not think Warne's publish such a book. If you can get the first volume of Holtzapffel's "Turning and Mechanical Manipulation" you will find a good deal of practical information relative to the working of sheet metals.—J.

Bookbinding.—AN APPRENTICE (*London, S.E.*).—It is intended to carry on bookbinding. A series of practical papers are in the printer's hands, and will appear as early as convenient. Finishing, both plain and extra, will be treated, as the series would be incomplete without it. In the meantime I will be most happy to give AN APPRENTICE any information on gold finishing he may desire, if he states definitely what he wants.—G. C.

Heating Soldering Iron.—E. L. H. (*Begbroke*).—Answering the latter part of your query first, a blowpipe is quite unsuitable for repairing such things as tin cans, kitchen utensils, etc., for this reason: You have, no doubt, seen a tinman soldering with an iron, say, round the spout of a kettle, and noticed that it was done with a kind of rubbing movement. Well, this rubbing seems to do just what the blowpipe cannot do—that is, it brings the metals into more intimate contact, and causes them to adhere; also you cannot guide the metal with the blowpipe so well as with the copper bit, but such jobs as soldering a pin hole, or anything like that, you might manage with a blowpipe, but you will find that you cannot dispense with the soldering iron altogether. With regard to the other part of your query, viz., for a method of heating the iron without lighting a fire or using gas, I am glad to be able to help you. Get a Rippingille's paraffin stove, with not *less* than a 4-in. burner, and a sliding tank. Make, or have made, a sheet iron chimney, like sketch, 3 in. high, to fit over the dome of the burner; rivet four legs on it, or make some arrangement so that it will not topple over. A medium-sized iron will get hot in about five minutes, and the stove is handy for many other things.—R. A.



Heater for Soldering Iron.

Removing Ink Marks from Parchment or Paper.—LANCASHIRE LAD (*Bolton*).—If, as would appear from his letter, our correspondent's error on his plan has been made in *ordinary writing ink*, the stain may be removed by the application of spirits of salts (hydrochloric acid) diluted with five or six times its bulk of water. Solutions of either oxalic, citric, or tartaric acids are said to produce the same results; but in any case the acid must be washed off with clean water a minute or two after application. L. L. is advised to experiment on odd pieces of parchment or paper before touching his plan with acid, as some little neatness is required.—S. W.

Oxygen Gas: "Brin" Process.—C. J. W. (*Beccles*).—Perhaps C. J. W. is not aware that the "Brin" process is protected by patents, and involves special and expensive plant. If desired, I certainly could describe it, but it would take up valuable space, which, I fear, the Editor might object to, as certainly not one in ten thousand of the readers of WORK would be able to carry out the plan. I will, however, direct C. J. W.'s attention to an illustrated article in the *English Mechanic* for July 12, 1889, describing the process. If the information there is not sufficient, I shall be glad to supply any at my command.—O. B.

Electrotyping.—A. W. (*Paisley*).—In answer to your queries *re* moulding, we would suggest that you do away with the frying-pan arrangement at once, and in order to get a practical matrix to cast from (in your small way) make your flong as follows:—Three sheets tissue, one sheet blot, one sheet of brown. After you have beaten in the flong, pack in the whites, and dry off on a copying press heated by gas under bottom platten, bringing the top down hard. After it is dry, cut round and dust with French chalk before putting into casting box.—W. T. R.

Boat Building.—F. G. H.—I have been promised a paper on Canoe-building, but promises, I find, often meet with very tardy fulfilment. I will endeavour to induce some capable writer to take up the subject, but it covers a wide field, and you do not say what kind of boat you wish to try your hand on. Night alarum clocks will also be handled in due course, but it is useless for me, knowing what I have on hand, to make any specific promises. It is satisfactory to know that you and your friends find WORK useful, and that you can say:—"I tried your rational bookcase in No. 15 by Mark Mallett, and have to thank him for his design. I tried it, and made it as good almost, I think, as he could make it himself."

Chairmaking.—CONTENT.—I have an excellent paper, with illustrations, on the method of making a large armchair, usually called an easy chair, by Mr. Adamson, which will soon see the light. I am glad that you also, like F. G. H. and his friends, like WORK, and look forward with pleasure to the appearance of each weekly number.

Polishing Hard Stone.—A. A. M. (*Stockwell*).—Face the stone by working it down to a fairly level surface with the chisel and mallet. If the piece is not sufficiently heavy to remain unmoved under the chisel, fix it to a larger stone with plaster of Paris. Then rub it down with a flat stone, coarse grit, and water. As grit, nothing is better than Yorkshire paving stone smashed up with a hammer. Next rub down with coarsish sand and water, afterwards with fine sand. Finally, polish with putty-powder and a rag. Putty powder—sold under that name at the colourman's—is, we believe, a preparation of calcined tin.—M. M.

Model Locomotive.—W. H. W. (*Scedley*).—One of our contributors, J. H., is describing the construction of such a model locomotive as you require in the pages of the *English Mechanic*.—J.

Grinding Machine.—AMATEUR.—Emery wheels run wet or dry are used for grinding. Write for catalogues to Luke & Spencer, Ardwick, Manchester; L. Sterne & Co., Glasgow; Selig Sonnenthal, Queen Victoria Street, London.—J.

III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

Sketch for Stall.—J. T. (*Middlesborough*) writes:—"Would a kind reader give me a sketch for a stall for to stand in a covered-in market, to show fancy goods, glass, china, and fancy toys, with a racked back, and to lock up at nights, so as not to have to remove the goods, and as little cost as possible?"

Machine for Making Cigarettes.—S. B. R. (*Blackheath*) writes:—"Being a smoker and lover of cigarettes, I should like to have instructions for constructing a machine for making cigarettes. I mean it to be worked like a sewing machine by a treadle, so that you would only have to put in the paper and tobacco, and out rolls a well-made cigarette when the machine is set in motion."

Parchment Mounting and Stains.—MITRE (*Hanwell*) writes:—"Will a reader kindly inform me, through 'Shop,' how I must treat some parchment certificates which I wish to frame and mount? Should they be damped and pasted to a card in the same way as a paper, or do they require any special treatment? I should also be glad to know how to remove some stains."

Pill Making.—J. C. (*Carlisle*) writes:—"May I ask, through the medium of your valuable paper, WORK, if any of your numerous readers can tell me of any firm who deals in, or makes, tools or machines for pill making? or if any one can suggest any simple tool or machine for that purpose, I shall feel very grateful."

Machinery for Breaking up Old Rope.—R. L. R. (*Liverpool*) wishes to know where he can purchase machinery for breaking up old rope and converting it into oakum. He also wishes to know name of makers of the "American Rope and Oakum Picker," which answers the purpose indicated.

Cleaning Engravings.—IVOR (*Bradford*) writes:—"Having some large engravings to clean, I made a wooden tray or 'bath' 40 in. by 40 in. and 3 in. deep. This I lined with thin sheet lead to make watertight. Chloride of lime in solution is used for bleaching or cleaning. I procured the purest lime sold. Yet I find, after a few hours' standing, that the surface of the lead is covered with reddish-brown blotches like rust. If the engraving touches these it is marked like the iron mould stain on linen. Can you inform me how to make the lead impervious to the lime permanently? Would paint or Aspinall's enamel prevent the rust from coming through, or would the paint itself withstand the action of the lime?"

Ink for Posters.—A. J. (*Ilkeston*) writes:—"I should be greatly obliged if any of your readers of WORK would say what kind of ink or paint is used in writing large posters, and also for window tickets."

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Distempering Wood.—F. P. writes in reply to BELL (see page 334):—"Mix 1 lb. patent size with three pounds best whiting, or similar proportions; if glue is used instead of size, consider it four times as powerful for your purpose as the size. You want to 'get up' and grain tables and bedroom suites cheaply, say, in imitation of oak. Proceed as follows: Put cold water into a vessel, then whiting into it and dry ochre sufficient to get the desired shade of ground when dry (determine this by trying a little). When all is moistened, pour off water, and add the hot glue or size. Well stir and strain through a sieve or such like. Dust the articles, and coat with mixture. When dry, give another good coat; this should give, when dry, a hard, solid surface. Well rub down with glasspaper to get a smooth surface (don't rub it all off!), and then grain on it, using water ground pigment in a little beer, and wiping out figure and grain with a stiff brush and wet chamois leather. When dry, give a coat of 'half and half,' turps and varnish; then overgrain, if required, and finish with a good coat of varnish. Any other wood and 'mottling' imitation is done in water. Colour upon the size ground in similar manner; but remember, as in all things, 'practice makes perfect!'"

Trade Notes and Memoranda.

THE 111-ton gun was fired recently at Shoeburyness, and a few results may be interesting. Six rounds, each costing £108, were fired, and projectiles weighing 18 cwt. fired by 960 lbs. of pebble powder were sent twelve miles. The approximate initial velocity was 1,850 ft. per second. The gun was fired by electricity. The concussion broke many windows in the barracks and houses in the village, which is more than half a mile from the battery. A large number of well-known artillerists were on the ground.

A PRIVATE company has been formed, and has obtained the necessary capital for the construction of an electric railway from the town of Lanark to Hamilton. The motive power is to be obtained from Stonebyres, one of the Falls of the Clyde.

IT has been resolved to use the Tivoli waterfalls as a motive power for the electric lighting of the city of Rome. Two thousand horse-power will be derived from this means, and led to Rome, a distance of thirty kilomètres, on the systems of Lipernowsky, Déri, and Blattry, and according to the *Pester Lloyd* this is the greatest distance yet compassed by any similar arrangement. A Pesth firm, Ganz & Co., have undertaken to complete the work.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

MELLIN'S FOOD

For Infants and Invalids.

TRADE MARK **NOT FARINACEOUS. Rich in Flesh, Nerve, Brain, and Bone Formers.**

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

. No Food in the market can show such a vast collection of *boná-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

USED IN ALL CHILDREN'S HOSPITALS.

HOW TO MAKE AN ELECTRIC TIME ALARUM.

BY GEORGE EDWINSON BONNEY.

ONE of the blessings attending the enjoyment of good health and youthful vigour is the ability to sleep soundly and long. It is not only "the voice of the sluggard" we hear complain: "You have waked me too soon, I must slumber again;" for the industrious but weary sons and daughters of toil find the bed all too sweet to leave when duty calls in the early morning. I often smile grimly as I scan the advertisement columns of a newspaper and read there the frequent requirements for early-rising servants. Poor girls! Up late at nights attending to the wants, the whims, or the fancies of their employers, they must be up again early the next morning to cook, to sweep, and dust, whilst their superiors doze in bed and fetch up arrears of sleep. What wonder is it that, one morning, tired nature in the servant refuses to obey the strident tones of the alarum clock! The alarum runs down and she hears it, but the sound only strikes her *dreamy* senses, and she goes on dreaming. For a moment she dreams she is awake and dressing herself, or perhaps lighting the fire; the next moment her senses are benumbed with sleep, and she sleeps on until she loses her character as early riser. Masters and mistresses should exercise kindly consideration for these lapses, whilst us who are older should deal leniently with the late-rising offences of the young, and help them to avoid lapsing into sluggish habits, by providing for them an alarum that will not run down in a few moments, but will keep pegging away until the person to be called gets out of bed to stop it.

Such an alarum will also be found to be of great use to working men engaged in factories and on works where early punctual attendance is rendered imperative to holding a situation. The essentials for an electric time alarum are: 1. An electric bell and battery. 2. A clock of any kind, providing it is a moderately good timekeeper.

The Electric Bell may be of any size or form of the vibrating or continuous ringing type, such as those usually employed for household use. A small bell with a 2½-in.

gong is preferable to one with a large gong, because the sharp sound given by the smaller gong has a better effect in arousing a sleeper than the duller but more mellow tones of large gongs. Where there exists a system of burglar alarums in the house, a bell giving a sound distinct from that of the burglar alarum bell is advisable, and, as these latter are usually large gongs with loud tones, the selection of a small gong for the time alarum ensures the necessary distinction. In the series of articles on burglar alarums recently published in WORK I have given full instructions on how to make an electric bell, and must respectfully refer my readers to those articles if they wish to know how to make the bell for themselves.

The Battery.—If the time alarum is to be set up in a house already provided with a system of burglar alarums or electric bells, we may use two cells of the battery belonging to this system, and connect them up to the time alarum. In the absence of such a battery, two large Leclanché or Gassner cells should be provided. It should be understood here that a small 2½-in. bell may be rung with current from one small cell of either class of battery, and a working man need go to no further expense than to get one cell; but experience has demonstrated the necessity of providing a surplus of power where electric bells are left to the tender mercies of domestic servants. If the bell is only allowed to ring for a few minutes at a time and then promptly switched off from the battery, a small cell will give enough current and last for a year or two; but if the bell is mufled to stop the ringing, and allowed to remain thus for an hour or two, the battery will soon run down, because current is passing through the bell coils all the time it remains muffled. In the series of articles on burglar alarums, I have given directions for making a Leclanché battery, and have shown how to keep it in order.

The Clock.—Being provided with a bell and battery, we may now concentrate our attention on the clock, and it is at this point where attention is most required. As before stated, the clock may be of any size or kind, provided it keeps moderately good time, but preference should be given by the amateur to clocks in wooden frames, furnished with porcelain or enamelled metal dials, and with a door of some sort to cover the face. This class of clock, such as the common American clocks in wooden cases, may be easily altered, and the work will not present any practical difficulties in the way of getting good insulation for the several parts.

To begin with such a clock, then, on which to try our 'prentice hand: access must be first obtained to the works. These, for the purpose in hand, should be held in a metal frame, or at least, the hour hand spindle should run in a metal bearing to which we can solder a wire. A short piece of No. 20 B. W. G. silk-covered copper wire must have one end laid bare, and this soldered to the metal in which the hour hand spindle runs. It matters little whether the part to which the wire is soldered is in front or at the side, or at the back of the works. If the frame is all of metal, it may be at some remote or easily accessible part of the frame. The wire thus soldered to the works must be brought out through the clock case, where it is likely to be least observed, and there connected by a clean bare end with a metal stud or binding screw, or some other piece of metal easily connected to the line wires of the battery. These outside connections of the clock will call for an exercise of the amateur's ingenuity in planning secret or out-of-sight means of connecting the clock with the battery, as it is undesirable to have a pair of binding screws sticking out of the top of the clock or at the sides, and wires running along in full view on the mantelpiece. If the clock has a pointed roof with an ornamental turned brass pillar on each side, these may be taken off, fitted up as connectors for the wires, and then put on again. Connection may be made between the line wire of the bell and the wire of the clock by tightly clipping them both between two tiny brass plates secured to the back of the clock frame by two short brass screws as shown at Fig. 12.

Having secured a metallic connection between the bell and the hour hand of the clock, we must now make an arrangement on the face of the clock to connect the hour hand with the battery when the hand arrives at the time when we wish the alarum to ring. This arrangement must be a surplus hand insulated from the works of the clock, and connected with the line wire leading to the battery. At Fig. 1 is shown a clock fitted with an alarum arrangement on the dial at the right-hand side. This clock was an ordinary American timepiece enclosed in a plain walnut case, and furnished with an enamelled metal dial. The face was protected by a circular glass door set in a brass frame. This I have removed, to more clearly show the alarum arrangement, but its position is shown by the dotted lines. If the clock selected is similar to this, proceed as follows:—Set a pair of compasses to the circumference of the dial, and strike out on a piece of thin sheet brass or sheet copper a semicircle slightly larger than the dial, and from $\frac{3}{16}$ to ¼ in. wide, as shown at Fig. 2. I cannot give the exact dimensions of this part, as it must be obtained by the actual measurement of the dial of the selected clock. It must not touch the dial (if this is made of metal) in any part, but should be close to it without touching, for if it touches the dial it will probably connect the works of the clock with the alarum hand and render it useless. It must also be wide enough to hold the screws employed in fastening it to the clock case, but not so wide as to interfere with the closing of the glass door. Cut this piece out, smooth the edges with a fine file, then drill the holes for the screws. As these will fulfil the double purpose of fastening this part to the case, and also to hold the alarum hand, the holes must be drilled at regular intervals apart, so as to bring the hand midway between the hours on the dial. The hand can then be fixed to either of the screws, and will command in this position the time between any two hours on that side of the dial. For instance, when placed at half-past five as shown on the dial at Fig. 1, it can be shifted to the right so as to meet the hour hand at five o'clock, or at any time between this and six o'clock. If unscrewed from this position and placed between one and two o'clock, it will command any time between these two hours at which it may be fixed.

The alarum hand is shown full size at Fig. 3. It is made of a strip of thin brass, with a small hole at one end to receive the fixing screw and at the other end a pin of platinum wire. This may be of any gauge from No. 16 to No. 22, but it must only be long enough to engage the hour hand, and must be short enough to allow the minute hand to pass over the hand without touching the pin. The screws employed in fixing this hand should be the small flat-headed variety as shown at Fig. 4, obtainable from all dealers in clock materials. Connection is made between this hand and the battery by means of a piece of silk-covered wire, coming out through a fine hole made in the case close under the figure VII, and attached to the brass semicirclet by passing one end of the bared wire around the screw which holds this end of the brass to the case. The other end of the wire is, of course, made fast to a binding screw at the back of the clock, and a wire goes from this to the battery. When the hour hand of the clock comes around to the spot where the alarum hand is set, the two engage with each other, and contact is made between the battery and the bell through the clock. The bell will then go on ringing until the hour hand has swept the alarum hand along over the space which the latter commands (probably during one hour) unless the sleeper awakes and gets out of bed to switch off the bell. A switch for this purpose, shown at Figs. 13 and 14, is generally placed in circuit at some little distance from the bed of the sleeper, such as on the other side of the room, or outside the room door. When time alarums are fixed for servants, the bell is hung in the servants' bedroom, and the switch is placed on a wall or partition outside the master's bedroom door. The alarum can thus be set on going to bed, and the servant must come out of her room to switch off the bell in the morning. During the day, the alarum hand can be turned back out of sight under the frame of the glass door which protects the dial.

In the form of American clock shown at Fig. 5 a different arrangement is required, as there is not any woodwork to which the semicircle of brass can be fixed, and any insulating substance placed on the dial would disfigure it. The dial might be removed and the semicircle insulated from the back of the dial by strips of ebonite or gutta-percha, attached to it by means of short screws. Holes would then have to be drilled through the dial between each figure, near the outer circle, to receive the screws used in connecting the alarum hand with the semicircle beneath, and these holes must be bushed with ivory, ebonite, or bone, to insulate the screws from the metal dial. Few amateurs care to thus disfigure the clock face, and would prefer some other method of fitting up the alarum.

One such method is shown at Fig. 5, as attached to the clock, which is here shown with the door removed for our convenience. The front arrangement to go over the dial, for the purpose of a connector between the alarum hand and the battery, is made up of a lattice work of thin strips of metal, as shown at Fig. 6. To this, at the upper end, is riveted the alarum hand, shown at Fig. 3, whilst the lower end of the lattice is secured by a screw to the pillar, shown at Fig. 7, and this in turn is screwed into a piece of brass to form a bracket foot, as shown at Fig. 8, the whole being then fastened to the back-board of the clock case, immediately under the dial, as shown at Fig. 5. This arrangement will secure insulation of the alarum hand from the metal dial, and provide an elastic and sufficiently rigid arm capable of being elongated to reach the small hours, turned aside to bring the hand in position under the hours from 5 to 8, and shortened or folded up when not in use to place it out of sight during the daytime, when it would be covered by the opaque part of the door.

The lattice work is composed of several strips of thin sheet metal riveted together as shown; the metal may be thin, hard sheet brass or copper, or tinned sheet iron such as tin utensils are made of. The strips should be only $\frac{3}{16}$ in. in width and $1\frac{1}{2}$ in. in length, cut to the shape shown at Fig. 9, and drilled with three holes in each, as shown. The holes should be only large enough to admit brass toilet pins, and these will thus form excellent rivets, with one head already made. The strips must be firmly riveted together, as shown at Fig. 6, but a little play must be allowed to each joint, just enough to make each work stiffly, for if made too loose the arm will not be sufficiently rigid. The number of strips employed must be determined by the length of arm required, which will vary with the size of clock dial, and with the hours to be covered with the alarum hand. The two strips at top, to hold the alarum hand, and also the strips at the bottom to attach the lattice to its supporting pillar, must be shorter than the others, and should be shaped as shown at Fig. 10. The alarum hand should be riveted between the two top strips at the angle where they meet each other. The lower strips may be made larger or have their lower parts enlarged, as shown at Fig. 11, to receive holes suitable for attaching this part to the pillar by means of the screw, shown at Fig. 7. This pillar should be turned out of a piece of brass rod to size and shape of sketch, but the length must be determined by actual measurement on the clock in which it is to be employed, as it should just stand high enough to enable its arm to clear the face of the dial. The lower part of the pillar may be made in the form of a screwed tang, as shown, to screw into a brass foot, Fig. 8, or it may be soldered to the foot. The top part must have a $\frac{3}{16}$-in. hole drilled and tapped to receive the screw shown in the sketch, which must also be turned out of a bit of brass rod to the shape and size shown.

The various parts may now be put together and fixed in position. If the platinum pin on the alarum hand is found to be too long for the minute hand to clear it, the pin must be shortened. If the lattice arm works too freely the rivets must be tightened. If the enamel on the dial is a conductor of electricity, and the arm or hand touches the dial so as to close the circuit and ring the bell, varnish the under side of the lattice and hand with sealing wax, gutta-percha, india-rubber, shellac, or any good insulating varnish. Connect the various parts up to the line wire as directed in the first part of this paper. The brass ornamental pillars on top may be utilised here, or the wires may be carried to connectors such as those shown at Fig. 12 and already described.

I have given here instructions for adapting an electric time alarum to two different types of clocks, and these will suggest the means to be adopted for other larger or smaller ones of nearly the same type, including the old-fashioned kitchen clock. Almost any type of clock may be used by the exercise of a little ingenuity. If fitted with an ordinary striking alarum worked by means of cords and weights, the descending weight may be made to close the circuit of a relay, and throw an electric bell into action ere the alarum has done striking. For this purpose an action similar to that employed in Dale's Indicator Relay, recently described and illustrated in the articles on Burglar Alarums, will be required. A similar action may be employed with an alarum clock in a metal case. Attach one of the relay wires to the metal case of the clock, and the other wire to an insulated spring fixed to the back of the clock near to the T winding key of the alarum. At night arrange the insulated spring so as to come in contact with the T of the key, as this turns around when the alarum runs down; this will close the relay circuit and set the electric bell ringing. These are a few suggestions employed to stimulate the ingenuity of readers who may wish to make a time alarum. Should any difficulties present themselves to any persons wishing to adapt a clock to this purpose, if they will clearly state these to me, together with a rough sketch of the clock, I will endeavour to help them through the medium of "Shop."

HOME-MADE TOOLS.

BY J. H.

Straightedges and Winding Strips.

I now take another important section of tools—those, namely, which are used for the checking of the accuracy of work, and for lining out. In this article I will consider the straightedges and winding strips made in wood and in metal.

Wooden straightedges are, as a rule, employed by wood workers; metal straightedges by those who work in metal. Straightedges, surface plates, and squares are distinguished from other kinds of tools in this respect, that their accuracy can be best assured by constructing them without reference to any pre-existing standards, originating and completing them by a laborious process of trial and error. The fundamental principle is simple enough in itself, but the labour involved is both tedious and minute. The principle may be stated thus:—If three surfaces are mutually and interchangeably coincident, then each of those surfaces must be a true plane. It is impossible that it should be otherwise, and it is impossible that less than three surfaces will suffice by the test of their interchangeability to assure perfect accuracy. Thus, for example, suppose we have one straightedge with its edges planed parallel, and as true in the linear direction as we can get them when checked by the eye, or even by a more exact method still, by laying the straightedge down upon a plane surface—scribing a line along one edge, and then turning the straightedge over and placing its opposite edge beside the same line, when it may appear to coincide. But now, if we make another straightedge, the precise duplicate of the first, and then try edges to edges, we shall most certainly find that the light is visible between some portions, while others are in contact. There will be some amount of rounding and hollowing of the edges, which, however minute in quantity, is to that extent a departure from truth. And though we may alter and modify until we think we have coincidence between two edges when tested in succession by changing end for end, and although this amount of accuracy would be sufficiently approximate for the ordinary purposes of wood working, and also for much metal work, yet it cannot be absolutely accurate. For if a third straightedge be now made, the counterpart of the first two, then it will be seen on trial that the three will not be mutually interchangeable with one another. But by constructing three the coincidence can be made absolute. Thus it is clear that if the edges of straightedges Nos. 1 and 2 are coincident, it may happen that both are slightly inaccurate in opposite directions—that is, convex and concave. But trying the third against both No. 1 and No. 2, it will indicate whether any inaccuracy exists; because it is impossible that it should coincide with two other edges unless those edges are true. In this manner the least traces of inaccuracy may be detected and gradually reduced to an infinitesimal amount. But the same results may be obtained by making two *parallel* straightedges, and using these edges as a check upon each other. Thus, making two straightedges alike in width, with edges at precise right angles with their faces, calling their edges A and B, C and D, they may (Fig. 26), when A and B are brought edge to edge, have the relationship shown in that figure, the curvature being exaggerated of course for purposes of illustration. The trial of these edges alone, therefore, would tell us nothing, because, to all appearance, they coincide. But, reversing the edges they would have the appearance of Fig. 27; also exaggerated. Obviously now we have to reduce the concavity of one pair of edges, and the convexity of the other, in exactly equal proportions, until either edge when tried against the two edges of the other strip are so nearly coincident therewith that no difference can be detected by ordinary tests of wood workers, such as chalking the edges and laying them together. Practically and theoretically the strips are true.

Carpenters, joiners, pattern makers, and cabinet makers usually make their straightedges in pairs as "winding strips;" and it is clear that if two winding strips are in the first place parallel, and then coincident when the positions of edges and ends are changed, there is obtained really the contact of three edges, and as near an approach to accuracy is obtained as is possible or essential. If they are not made as parallel strips, but simply as single straightedges, then it is absolutely essential that *three* be made.

So much for the principle; now for the details. Take first wooden straightedges. They are usually made either of well-seasoned yellow pine or of straight-grained mahogany. No other woods are so suitable. Pine is used for straightedges many feet in length; mahogany for those under three feet.

First, rough out all the stuff, because strips of timber when newly cut out of the board, even though the board is thoroughly seasoned, are apt to curve and warp to a greater or less extent. This is especially the case with mahogany. Jack it over, and preferably let it stand by for a few days, or even weeks. Then plane to gauged thickness and gauged width, and square the ends. Screw the two pieces together side by side; or if screw holes are deemed unsightly, glue the two strips together with paper joints: that is, slips of paper interposed—say one slip near each end, and one about the middle, and glued between the strips. When the planing is done, the joint can be broken, the paper dividing through the middle of its thickness. Finish now the planing of the edges, using a trying plane sharpened very keenly and set very fine; gauge to width with a fine-toothed gauge; check with calipers also, and test for linear accuracy by means of the best straightedge available. If no such straightedge exists, then a trained eye is a good arbiter. Or, having planed one edge as true as possible, lay the straightedge down upon a board, scribe a fine line by that edge, and turn the strip over, bringing its opposite edge close up to the line, when any inaccuracy will make itself seen (Fig. 28), where it is exaggerated, the amount of inaccuracy being half that of the quantity of divergence. If the strips are of considerable length—say from four or five feet—turn them end for end, when perhaps something of the kind seen in Fig. 29, also exaggerated, will be apparent. Now the projecting portions of the strips, those which come in contact with the scribed lines, will have to be reduced, and at the same time the calipers must be in constant requisition to ensure that parallelism of the edges is secured; and the square must also be used, because the edges must be kept uniformly at right angles with the faces.

Having at last done to the best of our ability in getting the strips parallel and straight, unfasten them, and laying them edge to edge by opposite edges in succession, and then changing ends and trying opposite edges again, correct with the trying plane where necessary, still using calipers and square. Practically, most of the work will have been done during the period when the strips were united, and the less that is left to be done afterwards the better.

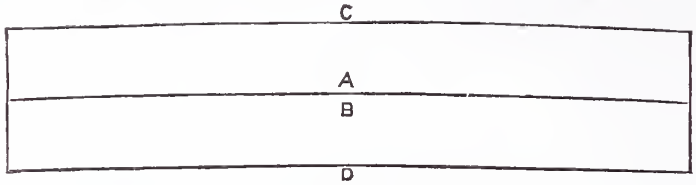

Fig. 26.—Coincidences of Two Parallel Strips whose Edges are not Straight.

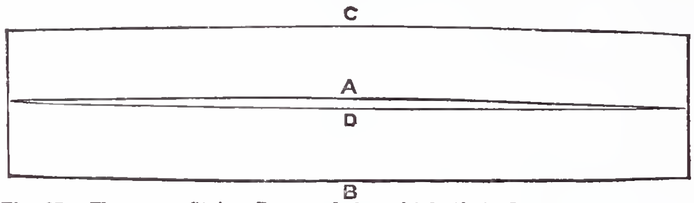

Fig. 27.—The same Strips Reversed, by which their Inaccuracy becomes apparent.

To preserve the wood from subsequent atmospheric influences, it is best to protect the broad faces and ends with an application of shellac varnish. This does not apply to the edges, because they usually have to be chalked. This chalking wears the edges hollow in course of time, and the wood is always apt to warp more or less. It is necessary, therefore, to re-correct winding strips and straightedges every few months.

To prevent wearing of the edges, due to frequent chalking, careful workmen often keep winding strips quite distinct from straightedges, using the former only for testing the amount of winding of stuff, and the latter for checking its transverse truth when planing it over. It is sometimes necessary to make a straightedge so long, or for so temporary a purpose, that it is not desirable to make a couple. Then very fair results may be obtained by laying the two edges in succession against a scribed line, as before described, and also by reversing end for end, and again trying against the line. The errors may be so effectually minimised in this manner as to leave very little to be desired. Another way is to lay the straightedge down upon its flat face, and to strain a chalk line along from end to end, keeping the line away from the edge by about $\frac{3}{4}$ or 1 in., with blocking. Then a gauged thickness strip, carefully tried between the line and edge at intervals, will reveal pretty accurately the condition of the edge. The line must be thin and of equal size, and strained very tightly. Then, for a single long straightedge, it affords a safe method. In the making of long wooden straightedges, very great help is derived from the employment of a true plane. A trying plane recently shot, and with its iron in good order, is a great help to correct results.

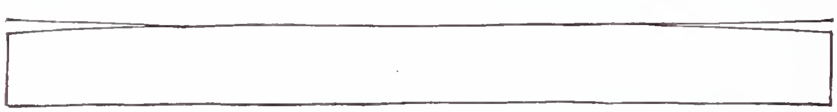

Fig. 28.—Trying a Straightedge against a Line marked from its own Edge.

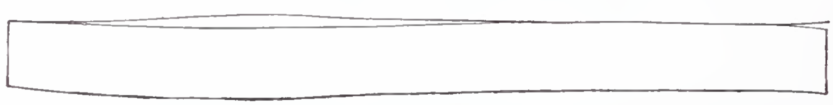

Fig. 29.—Another Example of Trial of Straightedge against Line marked from own Edge.

Taking next the metal straightedges: these are made of steel of moderate hardness, temper, and elasticity. A piece of steel may be thinned down by hammering and so used, but it is better to get a strip of the correct thickness at once. Large shop straightedges and strips are made of wrought iron; very large "master" straightedges are of cast iron, properly stiffened and ribbed. The straightedges to which my present remarks will have reference are those ranging from one to two feet in length, and made of steel plate from $\frac{1}{16}$ in. to $\frac{3}{16}$ in. in thickness. If the plate is not of the correct width, it will be roughly lined out. Centre-pop the outlines of the straightedge upon the steel as a guide for the first stage of cutting out, Fig. 30. Then, if thin, it may be cut round roughly with a cold chisel, or if so much as $\frac{1}{8}$ in. or $\frac{3}{16}$ in. thick, the best plan will be to drill a number of $\frac{1}{8}$-in. or $\frac{3}{16}$-in. holes in close contiguity alongside the lines where the plate has to be divided. If the steel is too hard to stand drilling, it is too hard for a straightedge, and its temper must be lowered, and the metal be annealed to give it equal elasticity throughout.

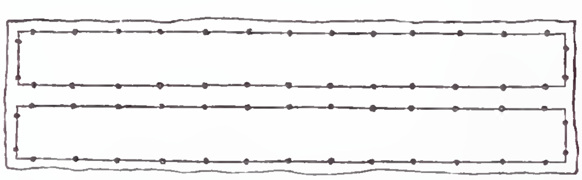

Fig. 30.—Winding Strips Lined out and Centre-popped on piece of Steel Plate.

The edges will now be roughly and approximately filed or ground to width and length. By the time this cutting off and roughing out are done, it is certain that the plate, even if true originally, will no longer be so. Hence, before going into any further details of filing and finishing, the sides must be brought into linear accuracy and perfectly free from winding and unevenness. Probably they may have to be hammered more or less upon a block of iron, or of hard wood set end grain upwards.

The use of a surface plate would be desirable at this stage for the purpose of testing the accuracy of the faces. Failing that, a true lathe bed will answer the purpose. When hammered, draw-filing will have to be resorted to, in order to obliterate the hammer marks; and to ensure reduction to accuracy, bedding on the lathe bed or surface plate will be adopted as a test. During filing, the strip of steel will be laid upon a block of wood, and held steadily between nails driven in around the edges, the wood being clamped in the vice jaws.

The straightedges can be filed now either singly, or both at one time if desired, being united with a particle or two of solder. It will be of much assistance if a light cut can be taken down the edges in a planing machine; but if not, then the next best thing is to use a surface plate or lathe bed as a guide in giving the initial edges to the strips. If the plate or bed is accurate, and the strips are brought into parallelism with calipers, there will be little left to be done afterwards in the way of alteration and correction. But the difficulty of truing up strips is very much increased with every increase in length and in thickness. So that if we have straightedges of metal 2 ft. long and $\frac{3}{16}$ in. thick, they will give us much more trouble than strips 1 ft. long and $\frac{1}{16}$ in. thick. It is difficult to hold the file so that the edge shall be at perfect right angles with the faces, but then allowing the edge to be slightly bevelled in any one section involves a reduction of the edges of each strip to that diminished width. Hence, when we get to the later stages of fitting of the strips, the way to check them together is to lay them side by side and edge to edge on a surface known to be true, and to check the contact of edges in the vertical as well as in the longitudinal direction, and in this way the square will be assisted. During the later stage of fitting, after having used the file until it will no longer afford that localisation of action which is required, we resort to the scrape; and in this way we are able to remove very minute quantities of material. To guide us in localising the action of the file and scrape, a very thin paste of red lead and oil will be smeared along the edge from which we want to transfer contact. At the final stages this must be very thin; in fact, wiping the edge with an oily wiper will suffice. Beyond this, the checking of the various edges until absolute interchangeability is secured will be done precisely as in the case of the wooden straightedge already described.

If any old and experienced hand is inclined to urge that he knows all about the management and manipulation of straightedges, and that it would be difficult for me to tell him anything that he does not know already, let me remind him that it is not for him that I am writing, but for young apprentices whose experience is little more than *nil*, and for workmen who are willing to learn and not above being told.

HOW TO MAKE A PIANO.

BY "NIL DESPERANDUM."

THE SOUND-BOARD—ITS CONSTRUCTION AND PREPARATION—HOW THE BRIDGES ARE MADE—FITTING TO THE BACK.

In my first paper I spoke of the back as being the foundation of the piano. From the foundation we take the next step forward, that is, to the sound-board. While the back is firm and rigid, the sound-board is vibrating and sensitive, so that we have the two extremes. If you look at the interior of a piano, you will see that the sound-board lies immediately behind the strings; it covers the back within the wrest plank and bent side. It is technically named the belly. I suppose the person who named the parts of a piano must have had the names of the parts of the human frame in his mind, for in the piano we have the back, belly, cheeks, legs, feet, and toes. The sound-board fills a very important position in the piano, for without it you would only get the tone of the wire, which would be very poor and weak in itself, as can easily be proved by stretching the string over any rigid surface. When the string is struck with the hammer, the sound is transmitted from the bridge on which the string rests to the sound-board, which takes up the sound waves, and increases the power of the vibrations; so that when a person is playing the piano, the sound-board is in one continual vibration. If you strike a tuning fork on the prongs, and the end is placed on a solid block, very little sound is emitted; but if struck when placed on the panel of a door, its tone is intensified. To show how wood is a conductor of sound, let the reader get a friend to strike a tuning fork on one end of a plank, no matter what length, and he will distinctly hear it at the other end.

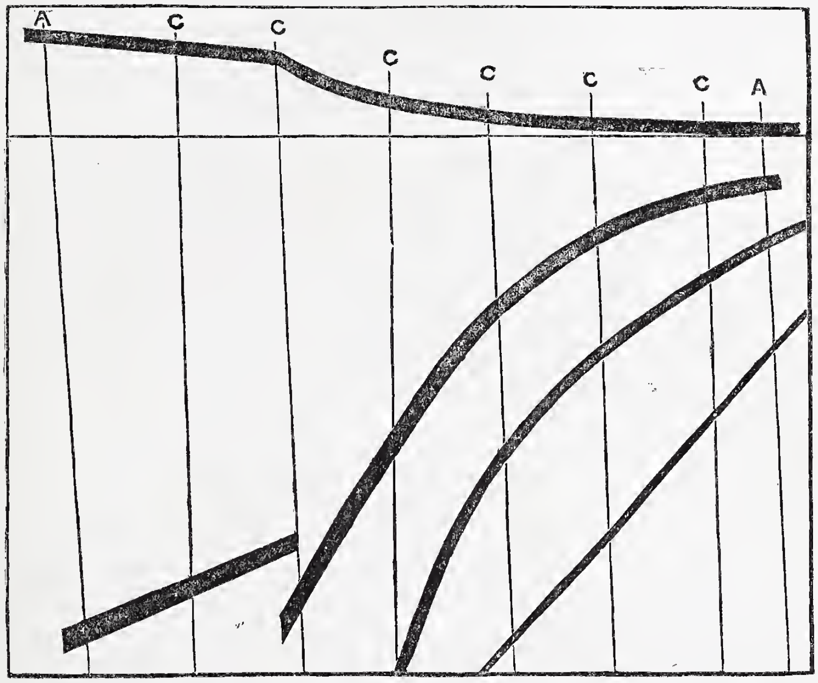

Fig. 1.—Diagram showing Plan of Bridges. (Scale, 1 inch to 1 foot.)

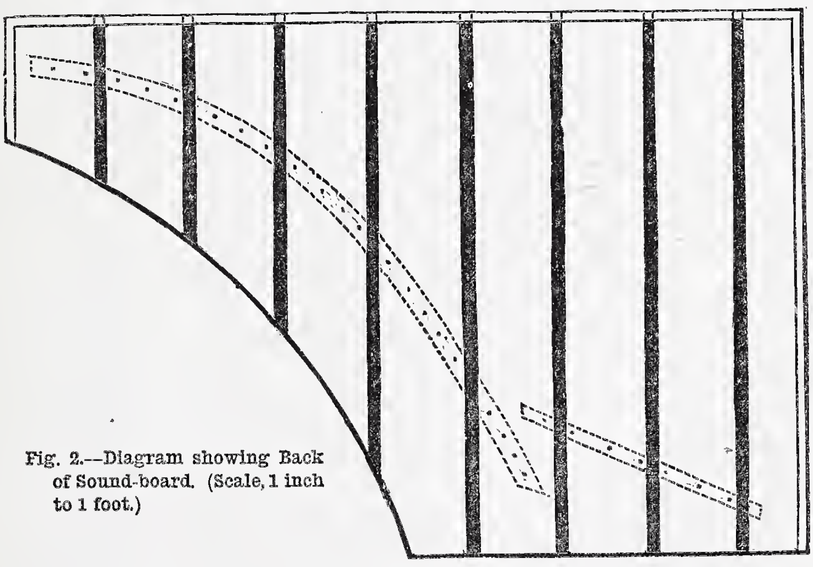

Fig. 2.—Diagram showing Back of Sound-board. (Scale, 1 inch to 1 foot.)

I knew a man who was very deaf—so deaf that you had to write on a slate what you wished him to understand; he had a square piano, and he used to sit playing with the bowl of his pipe resting on the sound-board, and the stem between his teeth, and by that means he was enabled to enjoy his own, or any other person's, playing; the pipe in this case was the conductor. If you take a common fire poker, and tie a piece of string about half a yard long round the head of the poker in the middle of the string's length, then twine the two ends round the forefinger of each hand, place them in the ears, and, bending the head forward, give the poker a swinging motion, and let it strike any object, you will have a splendid imitation of church bells, the string conducting the vibrations to the ear.

I will now endeavour to instruct the reader as simply as possible as to the making of the sound-board. It is usually made from Swiss pine, but can also be made of American pine, or spruce, about $\frac{1}{2}$ inch in thickness, free from knots and shakes, and thoroughly dry. Most timber merchants keep dry material. Having selected the wood, lay the back on the trestles with the plank and bent side uppermost. You will probably find your boards unsound at the extreme ends; if so, cut them off, as it is better to reject them at first than to have trouble with them afterwards. Now lay the boards on your back and cut your first length off; let it run parallel with the wrest plank, and overlap each side of the back $\frac{1}{2}$ an inch, the first board put under the bottom edge of the wrest plank. Now take the remaining boards in rotation, and put together edge to edge; of course, they will decrease in length as you get to the bottom; let them first overlap the rebate of the bent side, so that you have a little to work on. Having done this, make two lines across the whole of the boards in the shape of the letter V, so that you will know their position. Now turn the back over with the wrest plank on the trestles. The reader will probably think there is a lot of turning over; the reason is, that in a factory they have a large board for jointing the belly on, and I want the reader to utilise the back for the same purpose. You will find that your back has two strips of wood across the top and the bottom. Now these will be found useful in jointing your sound-board. Shoot one edge of your first board, and after laying a sheet of paper to keep the back clean, place the board up to the slip of wood mentioned above; put a handscrew on each end to keep it in position; now shoot the edges of the remaining boards, and try to make as good joints as possible. Having jointed them all, get a piece of wood about a $\frac{1}{4}$ inch wider than the intervening space between the bottom edge of the sound-board and the bottom slip, then having made your glue hot and thin for jointing, warm the edges of your wood well, and glue edge to edge on the back, rubbing each joint till you find it bite, then place your slip of wood in, being a quarter of an inch wider than the space; your belly will bulge in the centre. Now by placing a board on the top, and some weight, it will make your joints go up close. While this is drying you may get out your bars; these are made of $\frac{3}{4}$-in. spruce $\frac{1}{2}$ in. wide; these are placed across the sound-board in a vertical direction, one between each bracing, so that you will require eight of them. Plane over the sides after you have cut them out and straighten one edge, and make the other edge a $\frac{1}{4}$ in. round in the centre, graduating to the points; on this edge use the toothing plane, or scratch it with your saw, as this edge has to be glued, and it makes it hold better. When your sound-board is dry you can take it up and remove any superfluous glue that remains with a chisel. Then proceed to plane it over; you can do this while it is on the back, by moving the handscrews to where you are not planing; after planing over one side pretty level, which you can ascertain by rubbing your hand over, then gauge it round from that side about $\frac{1}{4}$ in. in thickness all round, leaving it a trifle thicker at the treble end, also at the bass bottom edge.

Now take a piece of chalk and rub it round the edge of the bent side, and lay your sound-board in its place, which will be a $\frac{1}{4}$ in. below the wrest plank; you can put two pieces of wood on the bottom edge temporarily, about $\frac{1}{2}$ in. long. Now press your sound-board on the chalk line, and that will give you the mark to cut it out, so that it fits in. Having fitted it, you stand the back on its bottom; make a mark with pencil each side of the bracings, and between these marks will be the place for each bar before mentioned. The method of putting these on is by springing a bar a little longer than the distance between the bar and a board or ceiling above, which consequently gives a downward pressure; but it can also be done by gluing one bar in its place at the back, and using another at the front, which must not be glued; for giving pressure, put a handscrew each end of the bars, the round edges to the sound-board.

Before gluing, see that it brings it to a joint; have your glue rather thin and your bars hot. Serve the remainder in the same way. When you have got the bars on, make a line across the top and bottom of them 4 in. from each end; from this point they must be bevelled down to $\frac{3}{8}$ in. from the sound-board, except the bass ones that do not touch the bent side; leave these $\frac{3}{4}$ in. thick at the bottom ends. Now you will have to put fillets on three edges of your belly; these will be of pine 1 in. wide and $\frac{3}{4}$ in. thick for the top and treble one, and 1 in. square for the bass one, graduating it from 1 in. in the centre to $\frac{3}{4}$ in. each end; the top fillet is cut out to fit over the bars at the edge, and these are then glued on; of course, the treble one will just fit the space between the wrest plank and bent side. The sound-board rests on these slips and on the rebate of the bent side.

By reference to diagram you will ascertain the length and shape of the bridges. They are made from beech $1\frac{1}{4}$ in. wide, except the top bridge, which is 1 in. wide and $\frac{1}{2}$ in. thick. When you get your bent side and wrest plank, if you order two wrest planks, one will make your bridges. You cut one edge out to the shape of your long bridge, then gauge it $1\frac{1}{4}$ in. wide from the edge; you will be able to cut out all your bridges from one plank with a little care, cutting up the straight part with a hand saw, and the curves with a frame saw. For the top bridges be careful to keep the flowery side of the wood uppermost; you will see this by observation.

Having planed your bridges, and prepared them for gluing, you can clean any superfluous glue from the back of your sound-board, then take some coarse glasspaper and clean it. Now you will require a pint of white hard varnish; varnish the back twice over, except the fillets and bent side edge, as the glue will not stick to the varnish. Now you must put the sound-board in temporarily, and mark for the long and short bridges, and $\frac{5}{8}$ in. below this line prick through the belly about every two inches with a small bradawl; this is needed when you are putting on your belly bridges. Now get some $\frac{3}{4}$-in. screws ready, and your glue hot and not too thick, so that it will run nicely from the brush; warm your long bridge and glue; put a handscrew on at the treble end, and where you can get others on from the hollow edge; then drive the screws in the holes you have made as quickly as possible from behind; serve the short bridge in the same way.

Now you will want a bottom plate; one made in cast iron for 47 notes will suit you best, and be the easiest fitted. It has three projections on as a rule, with screw holes in, and the bottom of the plate has holes for bolts; the treble end rests on the end of bent side, and the first bass note will be $4\frac{1}{2}$ in. from the outside of the back; this plate must be fitted level. You can bore the holes for the screws through the projections, so that it will go in the same place, as you will want it out to put the belly in. To put the screws in after the belly is in, you must bore centrebit holes through the belly above those previously made. I may mention here that all the ironmongery that is required for the piano may be had from W. Hughes & Co., 37, Drury Lane, W.C.

Now your sound-board is ready to be put in its place. Round the edges bore holes for 1-in. screws for the top and treble and round the hollow edge, and for $1\frac{1}{2}$-in. screws at the bass edge. It would be better to have the assistance of a friend at this stage to help you to glue your sound-board in. Have your glue ready and the screws through the sound-board half way. Warm the edges of the sound-board, and glue all edges except the bottom. Now, as quickly as possible, turn all the screws in their place.

To ascertain the shape of your bridges and their position on the sound-board, you will find by reference to diagram that the bottom edge of the wrest plank is used as a basis for calculating the length of the strings; for this reason it is called the strike line, as the hammers strike the strings at this point. The first note is A, which is $2\frac{1}{2}$ in. from the treble end on the strike line. The first C will be $7\frac{3}{8}$ in.; make a mark at these points. Second C, $13\frac{3}{4}$ in.; third C, $20\frac{1}{8}$ in.; fourth C, $26\frac{1}{2}$ in.; fifth C, 33 in.; sixth C, $39\frac{3}{8}$ in. The last note, which is A, is $47\frac{1}{2}$ in. Take particular care with these measurements, which are all on the strike line, measured from the treble or right-hand side of your back. From the same side at the bottom mark one point 1 in.; second one, $5\frac{1}{2}$ in.; third, $12\frac{1}{4}$ in.; fourth, $18\frac{3}{8}$ in.; fifth, $25\frac{3}{8}$ in.; sixth, $31\frac{7}{8}$ in.; seventh, $38\frac{3}{8}$ in.; and the last, $45\frac{1}{4}$ in.

It would perhaps be easier for the reader if he were to have a sheet of white paper the size of the back, and measure the width of his wrest plank and make a line for strike line. Having made these points, get a straightedge, and make lines from top to bottom intersecting these points.

Now I will give distances above the strike line for the shape of top bridge. The first note, A, runs level with the bottom edge of plank. First C, $\frac{3}{16}$ in.; second C, $\frac{3}{8}$ in.; third C, 1 in.; fourth C, $2\frac{1}{4}$ in.; fifth C, $3\frac{7}{8}$ in.; sixth C, $4\frac{3}{4}$ in.; last note, A, $5\frac{1}{2}$ in. Now for the distances below the strike line for the shape and position of the belly bridge. First note, A, $2\frac{1}{4}$ in. First C, $3\frac{1}{8}$ in.; second C, $5\frac{1}{2}$ in.; third C, $10\frac{1}{2}$ in.; fourth C, $19\frac{1}{4}$ in.; fifth C, $28\frac{1}{2}$ in.—this is the last note on the long bridge. The first note on the short bridge is B, which is $25\frac{1}{2}$ in.; then A, the last, $30\frac{1}{2}$ in.; this bridge is straight and $15\frac{1}{2}$ in. long. On the wrest plank the bridge is placed above the line, while on the sound-board the bridges are placed below the line.

You will see by reference to diagram how these lines are used. Fig. 1 shows the method of obtaining the shape and position of bridges. Fig. 2 shows back of sound-board, the dark lines being the bars and the light double lines slips on the edge.

PRACTICAL HINTS ON MOUNTING OBJECTS FOR THE MICROSCOPE.

BY A. T. SMITH.

TRANSPARENT OBJECTS—PREPARATION—MOUNTING MEDIA—MOUNTING IN CANADA BALSAM—AIR-BUBBLES.

My last article dealt principally with the mounting of opaque objects by the dry method, and we may now, I think, proceed to the second part of our subject, namely, mounting transparent objects for examination by transmitted light.

Objects the most divergent, and, at first sight, quite the reverse of transparent, come under this heading, and by careful preparation can be made sufficiently translucent to enable us to make out the most minute details of their structure. Take, for instance, a piece of coal; who would suppose that anything could be made out of this but the shapeless black mass it appears to be? Yet, by carefully grinding it down to a suitable thickness, it can be made transparent, and its structure can be as clearly defined as the surface of a butterfly's wing.

The different operations involved in the process of preparation of transparent objects are cleaning, hardening, section cutting, staining, and injecting, and it is in these branches of our work that delicacy of manipulation, and, in addition, care in the choice of mounting media, are most essential.

The words "mounting media" in the last sentence at once suggest the primary difference between the operations of mounting opaque and transparent objects. In mounting the former, as we know, the object is simply enclosed in its natural state in a dry air-tight cell, but in the latter case the object requires almost invariably to be mounted in some transparent preservative medium which will permeate its tissues, and, to a certain extent, render the object itself more transparent by increasing its refractive power. The media principally used for this purpose are Canada balsam, gum dammar, and glycerine, with various modifications which will be referred to later.

Since, in order to make a successful mount, it may be necessary to make use of all or any of the processes of preparation referred to above, we will define them briefly before going any further, and leave the more detailed consideration of each particular operation to a future opportunity.

Our dictionary will tell us that the word "cleaning" indicates the action of removing dirt, and a well-known writer has defined dirt as "matter in the wrong place." This definition of dirt suits us exactly, for, from a microscopical point of view, the process of "cleaning" includes the removal of various matters from animal and vegetable tissues, which can hardly be defined as dirt pure and simple—natural oils, fatty and muscular tissues, and colouring matters, for instance.

Some objects are so soft and flaccid in their natural state that they have to be hardened before they can be cut into sections or mounted, and, on the other hand, some objects are already too hard and brittle for our purpose, so that our attention has to be directed to making them soft.

Hardening re-agents are alcohol, turpentine, Canada balsam, oil of cloves, bichromate of potash, and picric acid; and for softening, glycerine, carbolic acid, or a weak solution of caustic potash or soda may be used.

Section cutting involves the art of cutting a section or shaving from a large object sufficiently thin to become practically transparent when soaked in a liquid medium.

Staining consists in colouring the sections, which may at times be *too* transparent, with suitable dyes and re-agents, so as to bring out in strong detail various points in the structure of the object which before were almost invisible.

Finally, injecting indicates the operation of forcing colouring matter into the minute capillary vessels of an object in order to render them distinctly visible.

And now as to the choice of mounting media.

Canada balsam is the microscopist's oldest friend, and when the object will stand the rough usage necessary to adapt it for mounting in this medium, it is the best one to use, because once well mounted in Canada balsam an object may be looked upon as settled for life, for the older it gets the better it looks, and there need be no fear of leakage.

Canada balsam as sold by the druggist is hardly suited for our purpose, as it would take too long to harden. For this reason, a portion should be placed for a short time in an open vessel in a moderately warm oven, care being taken to exclude every particle of dust. By this means the volatile spirit in it will be driven off, and eventually the balsam will become almost brittle. In this state a few pieces should be taken and dissolved in chloroform, and the whole kept in a wide-mouthed stoppered bottle for use. A bottle like Fig. 1 is the best form to use, because the balsam does not run down the outside, and the stopper is not liable to stick as in the case of an ordinary bottle.

The most suitable objects for mounting in Canada balsam are animal sections stained and, or injected, sections of timber and mineral sections, portions of the hard coverings of insects (Coleoptera and Diptera), diatoms, etc.

Gum dammar may be used for the same class of objects, and should be prepared for use by being dissolved in benzine. It is, in some respects, not quite so useful as Canada balsam, being more brittle and liable to crack, though, on the other hand, it is almost entirely free from the objectionable yellow colour of Canada balsam.

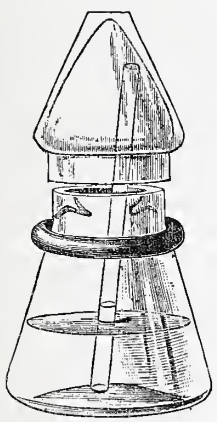

Fig. 1.—Bottle for Canada Balsam.

But I must confess that, for my own part, I much prefer glycerine as a mounting medium with or without modification. My reasons for this preference are—first, because it may be diluted with water to any extent, and, as a rule, will assimilate readily with most animal and vegetable secretions, and thus permit the mounting of an object in as natural a state as possible. This is a great desideratum, and, further, it is absolutely colourless.

The great difficulty with glycerine and its compounds is to prevent it leaking from under the cover glass or out of the cell. It has such an affinity for water and such a strong solvent power, that it is difficult to make a really good permanent mount which can be guaranteed not to leak.

Glycerine jelly is sometimes used for mounting vegetable tissues, and may be made as follows :—Take a small quantity of gelatine, and allow it to soak in cold water for two or three hours, then pour off the superfluous water and heat the gelatine gently until it melts. To each fluid ounce of the gelatine add one drachm of alcohol, and mix well ; then add, in the same way, a fluid drachm of the white of an egg, and boil the whole mass until the albumen coagulates. Now strain through a piece of flannel, and to each fluid ounce of the clarified gelatine add six fluid drachms of pure glycerine and mix ; a few drops of pure carbolic acid should now be added and the whole put into a bottle and allowed to cool. When required for use, the jelly should be melted by immersing the bottle in warm water, and it is as well to warm the slide and cover glass before mounting. I do not recommend glycerine jelly for delicate work, on account of the necessity for the employment of heat in mounting.

Farrant's solution is an exceedingly useful medium for mounting animal and vegetable sections and dissections, but for the latter I always prefer glycerine, either pure or diluted with water and with the addition of a few drops of pure carbolic acid to prevent decay and the appearance of *fungi*. The following is the receipt for Farrant's solution, according to Dr. Carpenter. Dissolve four parts by weight of picked gum arabic in four parts of cold distilled water, and add two parts of glycerine. The solution must be made without the aid of heat, the mixture being occasionally stirred, but not shaken, whilst it is proceeding. When the gum is dissolved, the liquid should be strained (if not perfectly free from impurities) through fine cambric previously well washed out by a current of clean cold water, and it should be kept in a stoppered bottle containing a small piece of camphor.

Some microscopists prefer to filter the solution of gum through fine blotting-paper in a damp chamber and to mix it with the glycerine after straining. This is, perhaps, the best plan, and it certainly gives more satisfactory results. The great advantage of this medium over glycerine jelly is that it can be used cold.

Suppose, now, that we wish to mount a portion of an insect—say the leg of a house-fly or of a beetle—in Canada balsam. Select a glass slip and cover glass, and, placing the object in a drop of water in the centre of the slide, apply the cover glass gently, and examine with the microscope ; we see a densely-black unlovely object, with a number of bristles sticking out of the sides. But now, take the object and soak it for a few hours in a solution of caustic potash or soda, or gently warm it in the same, and a change will come over the scene. Remove all traces of the alkali by washing the object in clean water, and examine again. The black colour will have vanished, and you will see in its stead a delicately-coloured, transparent, brown, horny structure, its surface covered with hairs, and beneath the surface traces of muscular tissue distinguished by minute cross lines.

If there are any particles of dust adhering to the surface remove them by gently brushing the object in water with a camel's hair brush, and then, in order to expel the water, which will not mix with the balsam, immerse the object in alcohol. The alcohol labours under the same disadvantage as the water with regard to the balsam, but it will mix with oil of cloves, which, in its turn, will mix with the balsam. Remove the object from the spirit to the oil of cloves, and leave it to soak there for a few minutes until a slide is prepared.

After thoroughly cleaning a slide, warm it gently over a spirit lamp, and with a pointed glass rod place in the centre a drop of the prepared Canada balsam containing no air-bubbles. With a dissecting needle remove the object from the oil of cloves, and place it gently in the drop of balsam. Take a clean cover glass, and warming it also, place it gently on the top of the whole, as in Fig. 2. Resting one edge of the cover against the points of your tweezers, support the other with your dissecting needle in the manner shown. As the cover glass is

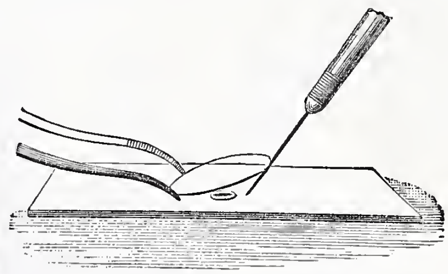

Fig. 2.—Mode of Mounting Object on Slide.

lowered by withdrawing the dissecting needle, the balsam should fill up the space between the centre and the edge of the cover glass, but if it does not do so, apply another drop to the edge and it will at once run in.

If examined now, the object will be seen to be brilliantly clear, and all the points of its structure distinctly visible. The slide should now be put aside in a warm dry place for a day or two, in order to allow the balsam to harden, and if there is any superfluous balsam at the edges of the cover it should then be carefully removed with the help of a rag and a little benzine, left again for a day or two, and then ringed with varnish, when it may be finished off and labelled in the usual manner.

It is necessary to exercise great care in lowering the cover glass on to the balsam in order to avoid the introduction of air-bubbles, but if, in spite of all your care, you find you have accidentally entrapped one of these little nuisances, you can generally manage to induce it to find its way to the edge of the cover glass by pressing the top with a clean dissecting needle. When you have got the bubble outside, the best plan is to bring its existence to an abrupt termination by pricking it with a hot needle, because, if left to themselves, air-bubbles generally die hard, and have a nasty habit of intruding themselves again and again in the places from which they have been expelled.

ON SOLDERING JOINTS IN METAL PIPE.

WITH SOME REMARKS ON BLOWPIPES.

BY R. ALEXANDER.

Importance of the Blowpipe—How to Make Joints—Resin and Grease—Various Forms of Joints — Upright Joint — Horizontal Joint—T-Joint—Soldering with Blowpipe —Benzoline Blowpipe — Gas Blowpipe — Self-acting Blowpipes or Blowlamps — French Patent Blowing Lamp—Regulating Flame Torch Blowing Lamp — Paquelin Lamp.

The jointing and soldering of metal pipes, tin, composition (termed compo for shortness), and lead pipes, will next occupy our attention. Joints in pipes may be soldered with either the iron or the blowpipe ; many people imagine that it is very difficult to solder with a blowpipe, but it is not so, when one has got over the awkwardness that is natural to a beginner in anything. One finds that to work with the blowpipe is as easy as with the copper bit, and it is very essential to a workman to be able to use the blowpipe, for it often happens, in doing a job of gas-fitting, that a fire cannot be had, and, even if it could, joints sometimes have to be made in very awkward places, near the ceiling, between joists, and many other places, where to use the soldering iron is very awkward, and sometimes even impossible. Then the blowpipe comes into requisition, and gets over the difficulty, as the worker will find, easily enough.

It is often a subject of discussion amongst workmen as to which makes the strongest joint, the blowpipe or the iron. My own opinion on the matter is this: That where circumstances are favourable, one is as good as the other, but in awkward places the blowpipe has two to one in its favour, and is far more likely to make a sound joint.

To describe the method of making joints, Fig. 1 is a tampion or pipe opener. This is inserted in the end of one of the pipes to be joined, and the pipe and that held loosely in the left hand and rapped with a hammer or mallet till the end is large enough to admit the other pipe. The inside of the part that has been swelled out (Fig. 2) must be scraped clean and bright; also the outside of the piece that is to be inserted in it. Rub a little tallow round the two cleaned surfaces, and place the joint in position. Sprinkle a little powdered resin on it, and it is ready for soldering.

The handiest and best way of applying the resin is by means of a resin box, Fig. 9. It is a little tin or zinc canister, about $2\frac{1}{2}$ in. high by 2 in. diameter, with a conical top that is removable, and a nozzle that is about 2 in. long and a little less than $\frac{1}{8}$ of an inch aperture at the end. This box is filled with powdered resin, and is the best and cleanest way to carry resin about; a lump of resin thrown loose in the basket, as is often the case, soon crumbles up, and makes all the tools sticky, and wastes the resin as well.

Joints can be soldered with resin alone, or with tallow alone, or even with weak spirits, but I think the resin and grease the best; still, it is as well to know that either can be dispensed with on a pinch. Before proceeding with the soldering part, I will just briefly describe the other joints illustrated. Fig. 2 shows the joint I have been describing prepared. Fig. 3 shows it soldered. Fig. 4 shows a section of it cut longitudinally, showing how the solder has run round it. Fig. 5 shows a method of making a horizontal joint, a kind that often occurs in gas-fitting between joists and along walls. You will notice that one piece is cut slanting; this gives the solder a better chance to flow underneath the other piece than if both were cut square across, the same as Fig. 2. A horizontal joint prepared like this is no longer a difficulty. (For a handy appliance to hold joints, see "Our Guide to Good Things" in this number.) Figs. 7 and 8 show a T joint. The horizontally placed piece has a hole cut in it slightly smaller than the outside diameter of the pipe that forms the T. This upright piece is drawn in a little, and also hollowed out a little on two sides, so as not to obstruct the passage of whatever may have to pass through. It is then pressed into the hole cut to receive it: if it goes in too far a little must be cut off the end.

Now for the soldering part of the process. There are numerous blowpipes and ways of using them. A simple plan, and one much used by gas-fitters, is the ordinary blowpipe, Fig. 10, and a large-sized tallow candle or a bundle of rushes, such as are used for the wicks of rushlight candles. These are procured at the tallow chandler's; they are the rushes that have had one dip in the tallow vat. The best way to use them is not to wrap them up in a piece of brown paper as I have seen men do, but get a piece of $\frac{7}{8}$-in. brass tube a foot long, turn a cap to fit on the bottom tightly, and one for the top not so tight, about 3 in. long. Take enough rushes to comfortably fill the tube and slide, easily push them into the tube, allow about half an inch to project out of the superfluous ends, and slip on the bottom cap.

Now take a strip of blowpipe solder in one hand, the lighted rushes or candle in the other (you must get accustomed to use either hand for either purpose), fix the blowpipe between the teeth, and, bringing the flame close to it, try to blow a pointed flame out of the side of it; you will probably find it rather difficult to keep the flame and blowpipe in correct "juxtaposition," as I may be

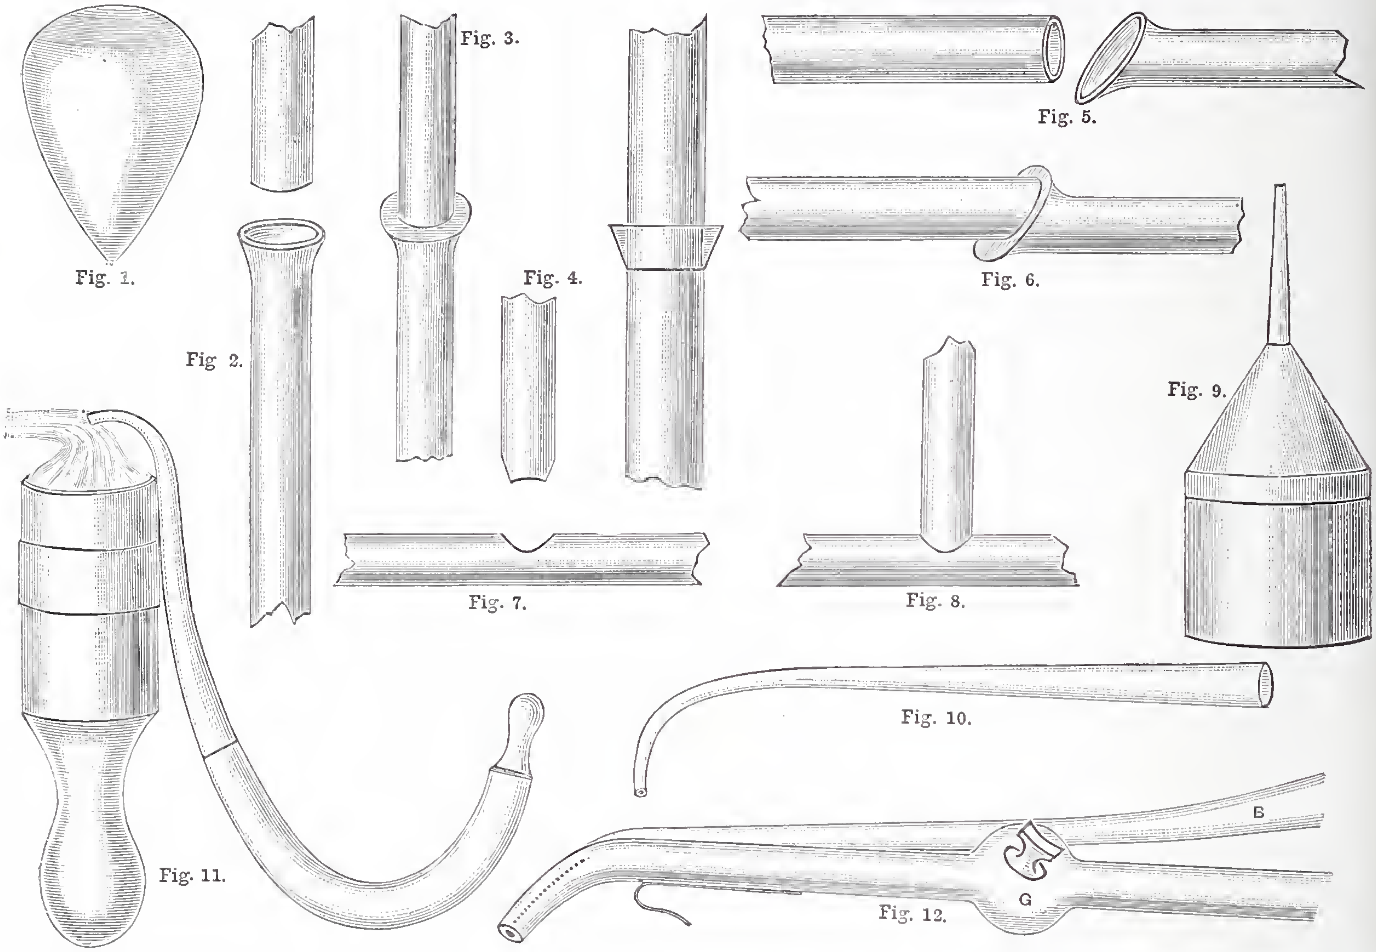

Fig. 1.—Tampion or Pipe Opener. Fig. 2.—Upright Joint Prepared. Fig. 3.—Ditto Soldered. Fig. 4.—Ditto in Section. Fig. 5.—Horizontal Joint Prepared. Fig. 6.—Ditto Soldered. Fig. 7.—T-Joint Prepared. Fig. 8.—Ditto Soldered. Fig. 9.—Resin Box. Fig. 10.—Blowpipe. Fig. 11.—Benzoline Blowpipe. Fig. 12.—Gas Blowpipe.

allowed to say, but you will soon get used to it. Warm round the joint a little, also warm the end of your strip of solder, and just dip the tip of it in a little resin. Then hold the solder to the joint, blow on it, and gently rub it round as it flows under the heat from the blowpipe. Do not blow too long in one place, or the pipe itself may melt, and when the solder has flowed round nicely, cease blowing. Care must be taken not to stop up the pipe, especially very small tubes, such as used for pneumatic bells, for instance.

As the blowpipe just used, or supposed to have been used, is only about 9 in. long, it will be seen that the head and eyes have to be very close to the work, which is sometimes rather awkward. Fig. 11 is another kind of blowpipe which is also much used, and has some good features about it. It has some advantages over the one previously mentioned. The head can be moved about without disturbing the blowing; also, the blowpipe, being fixed to the lamp, is always in the right position for the flame.

It consists of a piece of brass tube, any size, bore from ⅜ in. up to 1 in. will do, about 5 in. long. A bottom is soldered on about an inch up the tube, and a piece of wood put on for a handle to hold it by. The blowpipe is the same as just mentioned, fixed on the side in any way you like; some solder it to the tube, others fit it up with a joint, so that it can be moved in or out of the flame as required. But I think an improvement on either plan is to make a short tube to slip fairly tight on the 5-in. tube, and solder the blowpipe to this. Bend the blowpipe till it is in the right position for the flame, then it is always right, and can be slipped off if wanted. The lamp tube is packed with cotton-waste, and when wanted for use pour benzoline on to saturate it, and then pour off again. It is as well to have a cap of some sort on the top when not in use.

Fig. 12 is a gas blowpipe. This, it is obvious, can only be used in the workshop, or where there is gas to be had. The sketch explains itself. G is the tube that the gas passes along; B is the blowpipe inserted through a hole in the gas tube and soldered along it; it is connected to any ordinary bracket or burner by means of indiarubber tube and a short piece of ditto on the blowpipe, with a bone or tin pipe mouthpiece. This is a very useful tool indeed, and should find a place in any workshop where gas is available.

There are also several self-acting blowpipes, or rather blowlamps. In these there is no blowing to be done with the mouth at all. One of these is the French patent blowing lamp, Fig. 16. This is in shape something like a policeman's lantern with the bull's-eye removed. There is a spherical reservoir on the top, with a filling screw and valve. A small tube leads from this reservoir down to the lamp; the lamp is charged with methylated spirit, and the reservoir on top half filled with the same; the lamp is then lit under it, and in a minute it commences to blow a strong flame—a very useful article. Figs. 13 and 14 show an improvement on this lamp, called the patent regulating flame torch blowing lamp. It is sold by Messrs Rhodes, and is highly recommended by them. By moving the wheel marked A with the thumb (whilst holding the lamp with one hand), the regulator of the wicks can be effectively controlled by the slide, C, and any extent of flame produced. This is a great improvement, as it is often desirable to be able to make a smaller and less fierce flame. There is also a new blowlamp that I must mention. It has not long been out; in fact, I think I am the first to mention it in any journal; at any rate, I have seen no account of it myself. It is the invention of a Frenchman, Dr. Paquelin, and called after him the "Paquelin lamp" (Fig. 15). Benzoline is used with it, and it gives out a very fierce flame. It is sold as a paint-removing lamp, but, thinking it would be useful for many other things, I made some experiments with it. I found that for large lead joints it is first-rate, but it is too strong for anything smaller than 1-in. lead pipe. I recommend our plumbing friends to try it for wiping joints, or for such jobs as cracks in lead roofs, instead of using an iron and metal pot. I am sure they will find it a valuable accessory. But perhaps the most wonderful performance of the lamp is the following: I had a pair of buckles off an officer's belt to alter; the strap loops were too wide for the belt, and I had to make new loops and braze them on to the ornamental buckles. Well, this was rather a ticklish job, with no other means of doing it than the ordinary smith's forge. However, the thought struck me, try the Paquelin lamp. I did so, and the result was better than I expected, and I made a capital job of them, the spelter running like butter. Since then I have brazed a new bow to a key, soldered a silver ring, and sundry other jobs, so can say from experience that it is a capital lamp. So much for its performances; now for a word or two of description.

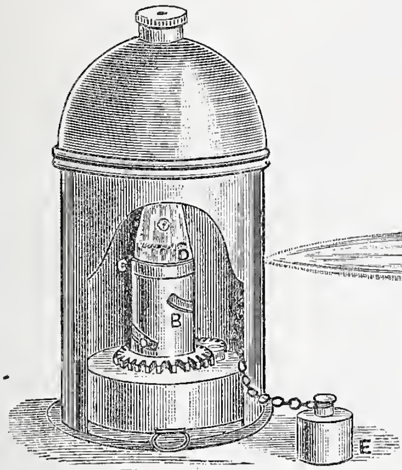

Fig. 13.

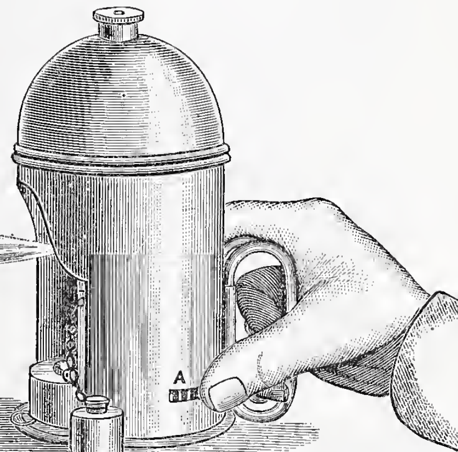

Fig. 14.

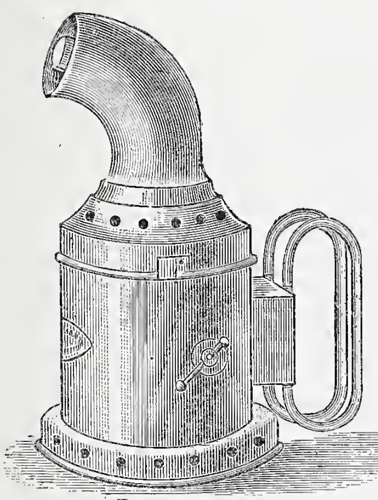

Fig. 15.

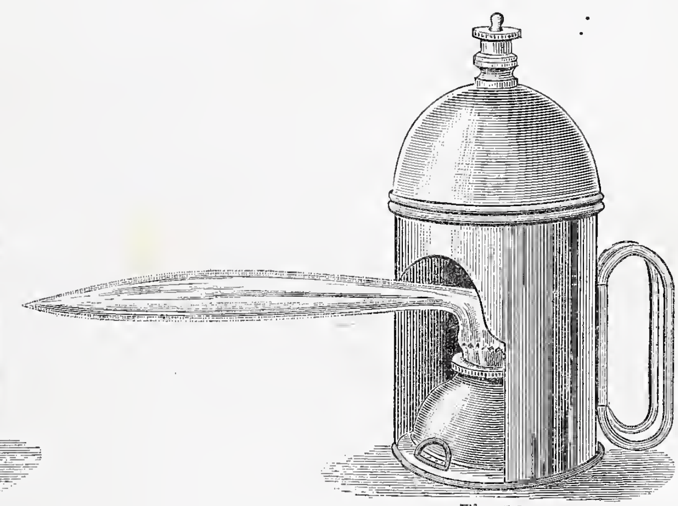

Fig. 16.

Figs. 13 and 14.—Improved French Blowpipe. Fig. 15.—The Paquelin Lamp. Fig. 16.—French Blowpipe.

It consists mainly of three parts—first, a brass body with a wick and some absorbent material inside, and with a capital filling screw with a little vice handle, so that it can be easily unscrewed: a tube runs up the centre of this body for supplying air; second, an inner bent tube of brass, which is slotted to slip over a crossbar, which has a very fine needle-point hole through which the benzoline vapour rushes and ignites at the mouth of the tube; third, an outer tube of sheet iron, which is fixed to a sort of dome which has holes all round it for air; this slips over the inner tube on to the body of the lamp, and is kept in place by a kind of bayonet fastening or stud slot. To set in action remove the filling screw, and fill with benzoline; then stand it upright in some vessel and let as much run out as will; screw up the filling screw, pour a dessert-spoonful of benzoline in the circular trough in the top of the lamp (having previously removed the outer tube), replace outer tube, and light through the air holes; in a minute or two the flame will begin to puff out, and by the time that the spirit in the trough has burnt out the lamp will be in full go. It can be used in any position, sideways, upside down, or anyhow; laid on its handles, with something put through them to keep them from slipping, it will boil a kettle suspended over it very quickly, so that if hard up for a fire you can make your tea or coffee by it.

Having thus described its advantages, I must, to be fair, state that it has a defect. What is that? you say. Will it explode? No; it is quite safe. Will it blow out easily? No; it can be used out of doors as well as in. But its defect is that it makes a great noise whilst working. If you can put up with this it is all right. The English agents for its sale are Messrs. Crowden and Garrod, Falcon House, Southwark Street, S.E., who inform me that they are having a great demand for these lamps, and that they cannot get them fast enough, a proof that I am not alone in my estimation of them.

PRELIMINARY GOSSIP ABOUT POLISHING WOOD.

BY DAVID DENNING.

Probably there are no operations about which there is more popular misconception in connection with the finishing of furniture than the distinction between varnishing and polishing. I do not of course refer to those who are practically acquainted with the furniture trade, or even to those amateurs who have devoted some attention to the subject, but to the large number of people who, when they see a glossy surface on wood, describe the finish indifferently as varnish or polish. The words are, in fact, synonymous in their estimation, and to a certain extent rightly so, for there can be no doubt that French polish is a varnish, though no one who knows anything about it would think of regarding varnish as French polish. Though there is no difficulty to any one who is acquainted with the work in recognising the mode of finishing which has been adopted with any piece of furniture, it is not altogether an easy matter to explain the distinction so that there may be no fear of being misunderstood, for, as has been said, French polish, strictly speaking, is a varnish. No practical man, that is, no man conversant with furniture, would think of confounding the two terms, polish and varnish; but if asked to explain the difference he would probably not be able to do so. The inquirer would most likely be told in effect that varnish is laid on with a brush, while French polish is applied by means of a rubber. This explanation is correct as far as it goes; but it does not go far enough, and even practical French polishers will be none the less capable as executants for knowing at least a little about the theory of the work. By this I do not wish to imply that acquaintance with the theory, with the reasons why certain operations are performed, is essential before a man can be a competent worker, or that a knowledge of theory alone will make him so, but I do say distinctly that the old rule of thumb style of work is not the best possible for the aspirant to skill to be contented with. The man who is satisfied to work solely and wholly in the old grooves is not the one to devise improvements. Now and again he may hit upon some modification of old methods, which may result in improvement, but, taken as a whole, advances in any branch of workmanship emanate from the man who thinks. He takes advantage of every deviation from anticipated results; every accident, every partial failure sets him thinking of the reasons for them. He is not satisfied with knowing that they are, he must go further down and find the cause. He is then able to act intelligently, as a man endowed with brains as well as with eyes and muscles should do. Instead of being a digital machine capable of more or less endurance, he is a reasonable being not deficient in ability to act on his own responsibility when need arises. Traditional methods may be very well in their way, but I would ask any one who is conversant with workshop life, What is the difference between the foreman, or if you prefer it "the boss"—a young man perhaps—and yonder grey-haired, steady-going man, who, though a walking cyclopædia of wrinkles in his trade, has never advanced beyond the journeyman state of existence? The latter knows as much, nay, possibly very much more, so far as manual experience is concerned, than the former, who, however, has the advantage of being able to use his head as well as his hands. In other words he knows something of the theory of his business, and consequently is able to take the lead, to direct others who, either through incapacity or the fallacious idea that head work is only required in the counting-house, or by professional men, have allowed their natural talents to lie fallow.

Although these remarks are made here they are of general application, more especially in a handicraft which, like polishing, partakes a good deal of the nature of an art; or to put the meaning in the plain words of the workshop—knack is the great thing. Without knack, or art, no one can hope to be a good polisher, however much he may know about the materials and their manipulation, and of course the knack of the polisher's craft is not to be acquired without practice. A collection of receipts and instructions is all very well in its way, but I must freely confess that beyond indicating to the novice how to proceed in certain well-defined cases, and telling him the general features of the work, very little, indeed nothing, can be done by any verbal description which will make him proficient. Not long ago a friend was asking me some particulars about French polishing, which he regarded as a mystery rather than an art to be acquired. The mystery certainly exists, though it may not be apparent to the beholder till he actually tries to do the work himself. It then dawns upon him that the way the polish or gloss refuses to come up under his hands is indeed mysterious. It looks such easy, almost lazy, work, albeit somewhat tending to dirty the hands, that the novice may be pardoned for thinking he has not got hold of the right stuff, or that he has been misdirected. Of course, either of these circumstances may be the cause of failure, but it is much more likely to be owing to want of skill. That there is a good deal to be learned in connection with polishing is undoubted, and though much may be explained in black and white, mere written instructions cannot do much more than indicate the course to be pursued when polishing woodwork.

Possibly all this may have a discouraging effect on the novice, as without intending to do so, I may have led him to believe that polishing furniture or woodwork is not to be accomplished satisfactorily without a thorough training in the art. In case any one supposes this, it may be said that everything will be done in these pages to remove difficulties and to indicate right methods of working. The beginner, whether he be amateur or professional, will thus be fairly started, and perhaps it may not be out of place to remind him of the old adage, that "Well begun is half done." Please note only half done, and the other half will rest with himself.

It cannot be expected that the tyro, however clever he may be, will be able to finish his work as well as those who have had the benefit of years of experience. That would be unreasonable, but I may be pardoned for just hinting that some novices are slightly so. They appear, if one may judge from some of their attempts, which have naturally ended in failure, or at least met with very qualified success, to imagine that they ought at once to do as well as the cunning workman with whom the ins and outs of his trade have become almost a second nature. In saying this there is of course no wish to dissuade any ambitious aspirant to skill in French polishing from trying to succeed. The warning is given merely that he may not be discouraged if his first attempts do not reach his expectations. Very likely to an expert they might be satisfactory, that is, when the learner's limited experience is taken into account, although the worker may not be contented. It is somewhat of a platitude to say that excellence can only be obtained with practice, but this fact seems so often forgotten that I venture to do so. What with other articles to which this is preliminary, and answers in the "Shop" columns, it is hoped that no readers of Work will be left in the dark as to what they ought to do and how to do it, on any matter connected with finishing furniture by polishing, whether by French or other process. The wish of all concerned is to make the directions helpful to those who have no other source of information, so that if the advanced polisher should be inclined to think that some of them are superfluous, as they doubtless will be to him, he will kindly remember that I am writing for those who are as unfamiliar with his trade as he is with theirs. Let him imagine he wants to know something about one of these to him unknown trades or handicrafts. He will want to be told as a beginner, not as a journeyman, or even as an improver; no detail will be too trivial for him, and even then he will require to use his brains. Well, the kind of information the skilled polisher would require in other branches of work before he could make a fair start in them is exactly what I aspire to do for those who, however clever they may be in other directions, know nothing whatever about polishing. That polishing is a subject which many readers of Work desire information about is apparent from the many references to it which have appeared in the "Shop" pages. Unfortunately, owing to insufficient details being given in the inquiries, it has not always been possible to answer them so fully as might have been wished, and it is hoped that all difficulties likely to occur to the novices will be anticipated. If not, may I ask inquirers in future to state definitely what they want to know, or at what point difficulty arises; or, in case of failure, if they will describe their *modus operandi* as clearly as they can, saying what the blemish or defect is? I ask this not as a personal matter for the Editor or his staff, but in the interests of inquirers themselves, if they are to be helped as much as the specialists whose duty and privilege it is to answer correspondents would wish to. In making these remarks, reference is naturally made principally to inquiries about polishing. For example, one man says he wants to polish something, and asks how he is to do it. Within the limits of the "Shop" columns it is impossible to tell him what he wishes to know, however much one would like to, for the all-sufficient reason that to do so would be to describe every kind of polishing. No doubt he only required to know of one of them, and that for one sort of timber. Such a question as that supposed admits of only a general answer, but had it been stated whether the inquirer wanted to finish his work with wax, oil, or French polish, bright or dull, together with the kind of wood used, a definite answer could be given. We, that is all concerned in WORK, publishers, editor, and staff, want to help correspondents in any matter which comes within the scope of the Magazine; but how can this be done if some inquirers will not, or do not, no doubt through inadvertence, give sufficient data to go upon? In connection with these remarks, I may say that many of the hints which will be given are based on inquiries from novices who have sought assistance from this and other technical journals. In fact, if I may venture on a personal allusion, there is hardly a detail which will be touched on about which a question has not, at some time or other, been put by a beginner. Thus, however incredible it may seem to the experienced polisher who may not have had the same opportunities of ascertaining on what details beginners want information, I think it may safely be said that all the hints to be given will be found useful, if not in their entirety, at least in great part to the majority of readers.

The question may arise, to whom are the directions likely to be of practical utility? To this, I would say firstly, to those amateurs who want to make and complete any piece of furniture personally; and, secondly, to those artisans and others in kindred trades, such as cabinet making, upholstering, etc., who would find the ability to polish in a fair and reasonable manner an additional source of income.

As is very well known in trade (I allude, of course, to the furniture trade) circles, the polisher's branch of the business is a distinct one by itself. The cabinet maker, the upholsterer, and the polisher are distinct personages, often, unfortunately, totally ignorant of any branch of the business beyond his own special one. Now, I would ask, is there any sound reason for this being the case? Would it not be well for, say, the cabinet maker to be able to do a little polishing when occasion required? Possibly, some of my practical readers may demur to this notion of any man having a right to encroach on the special calling of another. I have no wish to discuss such a question at present, but I do most emphatically say that, at the present time, the tendency is too much towards restriction in the sphere of labour. The artisan, the man, is in danger of becoming a mechanic, a mere labourer in some of our highest crafts. He is clever, or let me say rather an adept, in certain branches of his trade, but he is for all that only a wheel in the great machine, not as he ought to be, a complete piece of mechanism actuated by his head. In country places, and small establishments especially, the "handy" man, the man who, at a pinch, can turn his hand to anything almost with which his trade is even remotely connected, is the most valuable. Therefore I say, without hesitation, that the artisan connected with furniture, who is able to do polishing and all that appertains to it, will command a better market for his labour than the one who ignores everything outside his own groove. As already stated, this applies specially to those in country districts, but, even in the larger centres of population, facility in more than one branch of a trade cannot fail to be of advantage. With these remarks, this preliminary gossip on polishing must end for the present, but in future papers it is intended to treat of the whole "art and mystery" of polishing and its allied operations. All of these, however, cannot be treated "first," but the "Shop" is open to all inquirers who may choose to apply in it.

OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

98.—Patent Pipe Soldering Cramp.

The Patent Pipe Soldering Cramp, of which various forms are shown in the accompanying illustrations, is a speciality of Messrs. Rhodes and Sons, Wakefield, and an appliance which all gas-fitters, plumbers, pewterers, etc., will find of the utmost use to them in the daily work that falls to their share to carry out. It is, indeed, intended to satisfy a want long felt by the trade, and to obviate the difficulties and prevent the loss of time occasioned by the want of an appliance by which ends of pipes to be soldered together might be brought into close contact, and held firm and steady during the process of soldering. The nature of the cramp will be easily understood from the illustrations, from which it clearly appears that it consists of a couple of jaws springing from a common origin, and brought into a relative position in which they are parallel to one another and of the same height. These jaws are regulated by a screw with a butterfly head, so that they are able to be separated to a greater or less degree, and, therefore, able to receive and hold pipes of different diameter. It will also be noted that by their means the ends of pipes can be brought into close proximity, and held in that position until the process of soldering is completed. To use the words of the inventors and patentees, "the Pipe Soldering Cramp is adapted either for gas or water pipes. It is easily applied to tubes of any diameter, as by merely screwing down one end of a tube in the cramp, the other can be brought into contact at once, and rigidly retained by the other screw, when the joint can be rapidly and effectually made. It also accommodates itself to tubes of different diameters, as, for example, $\frac{3}{4}$ and $\frac{5}{8}$ can be as easily held and soundly soldered by means of the cramp as pipes of equal diameter. It is very portable, being never larger than an ordinary hand vice, easily carried in the tool basket, simple in construction, and not liable to breakage." The two smaller sorts, shown in Figs. 1 and 2, are adapted for soldering tin or composition pipe, and are provided with a joint at the back to accommodate pipes of unequal diameter. The cramp shown in Fig. 2 has a bench screw attached to it, by means of which it may be secured to a bench. The larger cramp shown in Fig. 3 is expressly made for lead water pipes and tubes of larger diameters. The cramps are made of best malleable iron. The tin and composition pipe soldering cramp, shown in Fig. 1, is sold at 2s. 6d. That shown in Fig. 2 with bench screw, forming the gas-fitters' screwing cramp, is supplied at 3s. The third form, shown in Fig. 3, known as the plumbers' cramp, may be bought for 7s.; but the same sort of cramp, made in ordinary cast iron, instead of malleable iron, may be had for 5s. It should be said that this cramp is made and supplied in larger sizes and stronger form, so as to be serviceable in the same manner for holding iron pipes while being connected.

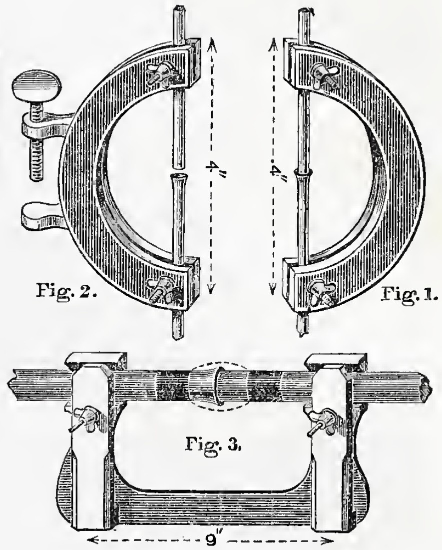

Fig. 1.—Tin and Composition Pipe Soldering Cramp. Fig. 2.—Ditto with Bench Screw, forming Gas-Fitters' Screwing Cramp. Fig. 3.—Ditto, Plumbers' Cramp.

99.—Zilles & Co.'s New Price List.

Mr. Henry Zilles, whom I must heartily congratulate on having developed into Zilles & Co. by a natural process of evolution and expansion, has just issued a monster price list, No. 39, cancelling lists Nos. 32 to 37, which, in their turn, cancelled previous lists. These lists, I may say, contained only selections of fretwork patterns kept in stock by Mr. Zilles, but this giant list of twenty-two folio pages, each measuring 17 in. by 11 in., exhibits every design in miniature that may be made up from the patterns supplied by Messrs. H. Zilles & Co., 24 and 26, Wilson Street, Finsbury, London, E.C., from No. 1 to No. 838 inclusive. These are principally fretwork designs, but a note on the last page enables the reader to discriminate between designs for fretwork, designs for carving, and designs for inlaying and wood painting. List No. 38, I may say, contains a catalogue of cabinet fittings, mouldings, fancy woods, and tools, and is supplied post free at 4d. Mr. Zilles, apparently, has omitted to give the price of list No. 39, or I have failed to find it, so I cannot give it; but this, any reader who will take the trouble to write for the information can ascertain for himself. At all events, when any one has possessed himself of lists Nos. 38 and 39, he will know all about everything that Messrs. Zilles & Co. keep in stock and supply, and will have no difficulty whatever in finding something to suit him in the way of materials, tools, and patterns, unless the multiplicity and variety of designs offered for his selection reduce him to such a pitiable state of indecision that he finds himself utterly unable to make up his mind as to what to choose and have. I must not conclude my notice of Mr. Zilles' specialities without calling attention to "The Amateur," a clever monthly publication of continental origin, issued by him, and which appeals to all fret cutters, wood carvers, inlayers, and decorators of furniture.

The Editor.

SHOP:

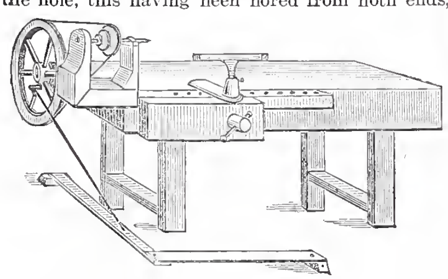
A CORNER FOR THOSE WHO WANT TO TALK IT.

*** NOTICE TO CORRESPONDENTS.—*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

I.—LETTERS FROM CORRESPONDENTS.

An Easily-Made Fret Machine.—W. W. M. (*Glasgow*) writes in reply to W. R. S. (see page 332):—"I would be very much obliged if he would try and explain how to put on the brass rod to the wheel to work up and down, as I don't understand how it is wrought, and I know this will be a great help to those who are trying to construct one of these machines."

Parts of a Lathe.—S. G. D. (*London, N.*) writes:—"I, like J. K. (*Richmond*) (see 'Shop,' page 348), have made my own carpenter's bench, and in addition have made a lathe attachment such as it appears to me J. K. would find very useful. I enclose a rough drawing of the whole arrangement. The headstock and bed are made of 3 in. by 3 in. quartering, a series of holes being cut in the bed (which, by the way, may be made any length), to allow tool rest to be moved from place to place. The mandrel I made out of an old steel spindle that I picked up for 6d.; this I cut short, and cut a screw thread on the end to fasten on the various chucks. The gut pulley is made out of hard wood, and is held in its place on the mandrel by being very tight in the hole, this having been bored from both ends,



Lathe and Bench.

that is, half way through from each end, and meeting a very little out of truth in the middle; this made it very hard to drive the mandrel in, and consequently it holds very securely. Having fixed the mandrel in the headstock, I proceeded to roughly shape up a part of the wood, and form a groove for the gut to run in; as soon as this was done I was able to turn up the pulley properly. The mandrel rests in a simple plummer block in the front. The fly wheel is about 22 in. in diameter. The lathe is a 9-in. centre. The whole cost was not more than 14s. or 15s. I consider WORK is a very excellent publication; subscribers should read every number through, as they will gain an amount of knowledge upon different subjects that is sure to be useful at some time or other, though many of the matters treated upon may not directly interest them. 'Knowledge is power.'"

An Easily-Made Fret Machine.—BLOCKHEAD (*Penicuick*) writes:—"I see in No. 21 of WORK, p. 332, a fret machine by W. R. S. Would he kindly let me know how he gets the brass pipe to run straight up and down when it is connected to the crank, and what size of table, and how made? Does the wheel go round?"

Flour, Emery, Rouge, and Pitch.—MICRO (*Portsmouth*) writes:—"I want to know a simple way to wash flour, emery, and rouge, in small quantities, say, an ounce or two of each; and the best sort of pitch to use for polishing lenses, and whether it should be worked on cloth over the pitch, or the pitch only."

An Easily-Made Fret Machine.—G. P. (*Islington*) writes in reply to W. R. S. (see page 332):—"Explain more fully the working of crank and its connection with the vertical rod. The sketch in No. 21 of WORK is anything but clear. Is there not some error as to the fitting of C with A? I am anxious to construct the machine, and have by me several parts which could be utilised, but cannot at all see how the upright motion is to be got by the present sketch. I thank most cordially W. R. S. for his little invention."

An Easily-Made Fret Machine.—NEMO (*Manchester*) writes in reply to W. R. S. (see page 332):—"I am a subscriber to WORK, and having seen therein a sketch of an easily-made fret machine, I beg to ask a question relating thereto. I wish to know if the bottom end of the brass gaspipe used in its construction is fastened on the crank of the wheel, or how or where is it fastened, as the drawing does not enlighten me on that point."

An Easily-Made Fret Machine.—A. H. H. (*Leicester*) writes:—"The easily-made fret machine in No. 21 of WORK, page 332, by W. R. S., does not seem so easy after all to an amateur. Should like to ask W. R. S. how the treadle crank is fixed to the wheel, and what part the wheel plays in the vertical motion of the machine. I wish that excellent paper, WORK, every success."

II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

Soldering and Frosting Aluminium.—W. E. T. (*Aston, Birmingham*).—Recipes for solder were given in No. 15 of WORK, June 29th, on page 237, and here is another for you to try your hand at if you care to. Aluminium, 6 parts; copper, 4 parts; zinc, 90 parts. Melt the copper first, and add the aluminium; stir it up with a clean piece of iron, then put in a little tallow, and add the zinc; stir it up again, and pour it as soon as you can after it is properly melted and mixed. You see that this alloy, as well as the others, is very much like pewter solder. It should be used in the same way—namely, by "tinning" the edges of the work first; then bring the parts together, and heat them until your solder runs, which it does not do nicely. A piece of aluminium, used as you would a copper bit, will help, I mean by rubbing it along the seam, when your solder runs. You note the flux mentioned in previous paper. But after all, this metal is generally worked up as you have done—viz., pinned it into a bezel; if it is soldered the seam cannot be left with the solder showing (at least none that I have seen is), it must be covered up; therefore bezels are a necessity, and that being so I make them do all the work. Without doubt this want of a solder prevents the use of this metal, and when one is discovered to match aluminium, and be principally made from it (just as our gold and silver solders are made from these metals), then we shall unquestionably use it to a very great extent. It is nearly time this was found out, for aluminium has been in the market for over fifty years, and in the direction of solders we are not a bit advanced, as far as I know, and as I am now placed, I expect that I shall see the results of any great improvement as soon as anybody, even if I do not at first get hold of the methods. As to frosting—I suppose you polished it with water of Ayr stone (one writer recommends a mixture of rum and oil to dip the stone in) and crocus. Then I anneal it and put it in vitriol pickle; it comes out with a fair surface, but I got my gilder to scratch-brush it as well, for my lathes are not powerful enough. It finally came out a decent sort of frosted surface, but nothing like frosted silver. It will not match the surfaces we get on silver, either by frosting or polishing, and I have had several attempts at it myself, besides getting a steam; polisher to try it. Do any of our readers know of better ways of working this metal? If so, will they help their fellow workmen by sending an account of their tried methods to the Editor?—H. J. G.

Egyptian Trellis Work Screen.—T. E. P. (*Cambridge*).—My acquaintance with Egyptian trellis work was acquired in Cairo, and I know of no firm in England which does this work. Mr. Hatoun, dealer in Oriental goods, Mouski, Cairo, is the leading manufacturer of trellis work in Egypt; and I have always found him honest and obliging. Any handy English turner, however, should be able to make what you require, with a little practice. The idea is simple, and a good workman would originate little alterations in detail, which would give variety of pattern. Perhaps H. C. T. (*Newcastle-on-Tyne*), who recently wrote to me on the subject, would communicate with T. E. P., as he has some experience in this work.—C. H. O.

Polishing Picture Frames.—F. B. (*London*).—The best way to finish picture-frame mouldings, whether black or in the natural colour of the wood, is by French polishing, unless, of course, they are gilt or painted. Possibly you are referring to the cheap continental mouldings, which are faced with compo, and, as you say, are finished partly dull and partly bright. You will find it simply waste of time to make these for yourself, as they are sold at such low prices, and always in a finished state. If, however, you wish to polish ordinary wood mouldings in such a way as to resemble them, you must stain and finish in the usual way. You will not have much difficulty in finishing either all bright or all dull, but you will not find it an easy matter if you want some members bright and others dull, and unless you are a skilled polisher, which I take you are not, I do not advise you to attempt this. You will find it almost impossible to get a clean finish, but, if you are inclined to try, you must first polish all bright and dull down the parts you wish dead by rubbing them with a little very fine emery, or similar sharp cutting powder.—D. A.

Furniture.—SLIP JACK (*Liverpool*).—Your inquiry is an admirable specimen of the kind which shows that some information is wanted, but that the writer has not troubled to give sufficient details to enable any one to assist him satisfactorily. I can only guess at the points you want to know about. Whether you want to renovate the leather or the woodwork is not shown in your inquiry, and each requires different treatment. I shall assume it is the latter, but here again I do not know how the wood has been finished nor its kind. To show the importance of these particulars, it may be said that oak wax polished would require very different treatment from mahogany French polished. I am, therefore, only able to answer you in general terms. The work must be cleaned either by washing with soap and water, or with the cleanser composed of vinegar, oil, and glaze (or methylated spirits), already described in these columns. It must afterwards, if necessary, be repolished, using a suitable polish. Very possibly, after cleaning a little glaze may restore the brightness, but, on the other hand, the work may have to be entirely repolished. The liquid "French polishers rub on with a rag" may be either a reviver, a wash to clean, oil, French polish, methylated spirits, or glaze, according to circumstances. Had you sent your address and name, I might have asked you for more details about the furniture you want to do up, and then been able to reply more definitely.—D. A.

Clock Case.—J. M. (*Pollockshaws*).—The dimensions of a clock case must depend on the size of the works. You say you have these, and I can hardly imagine you will experience any difficulty in working from the design alluded to by you. All you have to do is to reduce or enlarge the various parts proportionately, *i.e.*, if you wish to adhere to the proportions shown. You may, however, alter these considerably if you wish, but, unless you have some experience in designing, I can scarcely advise you to do so. If you like to send on the sizes of the works you have, I will give you my ideas of a suitable sized case, but as my ideas may not coincide with yours, I do not know that you will be much assisted by them.—D. A.

Wood for Turning, etc.—J. H. S. (*Brighouse*).—The kind of wood for table legs depends altogether on the sort of table you want to make. Any of the ordinary furniture woods are suitable, and the one that is best for the purpose must be determined by circumstances. You would, for instance, hardly choose mahogany, rosewood, or walnut for a common kitchen table, nor, though pine or beech would do very well for it, you would not regard them as the best for a handsome drawing-room piece of furniture. In your case, as you say you know nothing about turning, I should certainly not recommend you to use anything more costly than pine till you have acquired some skill in the use of your lathe. Table legs are too big for you to make your first attempts with. Try something smaller at first, working on any odd pieces which will be of little consequence when spoilt. You cannot expect to do anything worth keeping at first, so it would be simply waste to begin with expensive wood. You will soon find your ability growing, especially if you get a fair start, and you will then be able to regulate your efforts by your capacity. We must, you know, all creep before we can walk, but I fancy your idea is to walk without preliminary practice. As you do not know anything about turning, I should strongly advise you to get a friendly turner to put you in the way of using your lathe. Papers on wood turning for beginners will appear in due course, and possibly one which may assist you may be published shortly, but to give all the particulars which a novice would require in "Shop," is, of course, out of the question, much as I would like to assist you. Any light wood can be stained mahogany colour, so that pine, American white wood, beech, and others of similar character, would do for your bookcase.—D. A.

Polishing and Staining.—ROUND O (*Arbroath*).—It is a pleasure to answer such a letter as yours, because it states clearly what you want to know, and by describing the process you have pursued I am able to recognise the cause of your partial failure. In the first place you have used far too much oil with the polish, if, as I understand, you have moistened your rubber with one-fourth oil. You should have used French polish alone on the wadding, and just touched the covering with the least trace of oil to allow the rubber to go smoothly over the wood. I can quite understand your plan taking a very long time, and being tedious. You have also, as you appear to think, used far more polish than necessary by filling the grain with it instead of with a cheaper material. As you have watched a French polisher at work you apparently know the routine, but are unacquainted with the materials, so I do not know that I can assist you in a better way than by telling you what these probably were in the case of the counter top you mention. The polisher may have worked in a slightly different way from that described, but if you follow the instructions you will get good results. The counter top was first darkened by the application of raw linseed oil either in its natural state or mixed with some colour. The next material would be a filling, though from you stating that the first was a "thickish compo," I am inclined to think the order of oiling and filling was reversed from that here given, which is the better of the two methods. Various fillers are employed, but you cannot do better than use one formed of whiting and turpentine mixed to form a paste. Some suitable colouring matter to match the wood, if this is of a dark kind, should be added to it—for example, for mahogany rose pink does well. Excess of filling is wiped off before using the polish rubber as above. After you have got the wood sufficiently bodied up with polish use a fresh rubber with spirits only to get the final gloss or shine, but you must be careful not to spirit off all the body. Great pressure is not requisite, but patience undoubtedly is, though you will find this process superior to yours, both in saving time and results. Oak may be darkened in several ways according to the colour required. One favourite method is by fumigation with ammonia, a process about which a paper is in hand, and will appear as soon as practicable. Oak so treated is, however, seldom French polished, being waxed or oiled instead. Bichromate of potash dissolved in water makes another good stain of an orange brown tone. For a purer brown you will find vandyke brown mixed with a little liquid ammonia to form a paste, after which it can be liquefied with water very good. This stain will also serve for walnut colour on birch. Of course you will understand you can get the various stains lighter or darker according to the quantity of water with which they are diluted. Articles dealing exhaustively with polishing are in hand and in preparation. A preliminary paper appears in this number.—D. A.

Carving Tools for Small Work.—A. W. P. (*Leytonstone*).—In reply to your query respecting carving tools necessary for executing the corners of picture frames, given in WORK No. 10, and for small work generally, six cutting tools would be sufficient—namely, three gouges, a firmer, and two narrow flat chisels. Most good tool shops keep an illustrated price list of Addis's carving tools, and by inquiring there you would at once see the kind of tools you think you are most likely to want.—F. M.

Carvers' Tools.—T. V.—In all probability the wood carver to whom you allude as being possessed of some peculiarly formed tools specially adapted for undercutting had them made for him. If you call on or send to Mr. A. S. Lunt, 297, Hackney Road, London, E., he will readily make any shaped tool for you that you may require.

Smiths' Work.—J. P. A.—The appearance of articles yet to come on "Smiths' Work" has been delayed for the preparation of some engravings of examples required to illustrate them. They will be continued, and clear, practical instructions given on the welding of iron and steel. You write:—"I was speaking about the articles to a friend, and told him that, so far, they had only gone into the history of the trade, and as soon as they came to the practical part they would drop off." Your friend is altogether wrong in his ideas on this point. The numbers of WORK that have already appeared are sufficient testimony to the fact that the writers are practical men fully competent to handle practical work, and the writer of the papers on "Smiths' Work" is no exception to this rule.

Stand for Flat Iron.—NO NAME.—A correspondent has sent me a design for stand for a flat iron, but he omits to give name and address. The design is scarcely fit for publication in WORK, but the sender is thanked for the trouble he has taken.

Model Shipbuilding.—ZERO.—Arrangements are being made for a series of papers.

Bird-Cage Making.—ZERO.—I have no article in my possession on making bird cages, but if any contributor sends me a paper on the subject that is likely to prove useful you may be sure that it will appear.

Crystoleum Painting.—H. J. (*Peckham*).—The article on "Crystoleum Painting," which appeared in No. 3 of WORK, page 42, was continued and completed in No. 4, page 58. I am afraid you are not a very close and attentive reader of the Magazine.

Incubator.—C. H. M. (*Barrow-in-Furness*).—A contributor is at work on a paper on the mode of making an incubator, but I am not aware of the capacity of the appliance to be described.

Rubber Stamps for Music.—G. P. G. (*Wakefield*).—I am afraid your idea of printing music by aid of rubber stamps is one that you can scarcely hope to carry out with success. There is music type which is set up just in the same manner as printer's type, and you can get this at a reasonable rate, and would find it answer your purpose. You would have to use your rubber stamps on ruled music paper, and you would, I think, find difficulty in placing your notes either directly between two lines or on a line as necessary. If you followed up the notion, I fear it would only terminate in disappointment.

Plane for Making Pipe Lights.—J. W. C. (*Lowestoft*).—A plane of this description will soon be described in "Home-Made Tools." In the meantime you may obtain one of Messrs. R. Melhuish and Sons, 85 and 87, Fetter Lane, E.C. You will find a nice clean piece of pine free from knots the best wood for your purpose.

Patent for Brake.—W. D. (*Huddersfield*).—Not having seen either drawing or model of your brake for wagonettes and heavy vans, I cannot tell you whether or not the idea is worth patenting. There will soon be a paper entitled "How to Take Out a Patent," and this, I hope, will be of use to you. I cannot undertake to publish drawings of carriages that you may send me, but I will look at them and tell you what I think of them.

Printers and Printing.—H. E. C. (*Wednesbury*).—By Act of Parliament (39 Geo. III., c. 79) printers are required to be registered by the Clerk of the Peace, the fee for which is 1s. The following is the form of notice required to be given:—

To the Clerk of the Peace for the
or his Deputy.—I,
of
within the , do hereby declare that I have a Printing Press and Types for Printing, which I propose to use for Printing at
within the
and which I require to be entered for that purpose, in pursuance of an Act passed in the Thirty-ninth Year of His Majesty King George the Third, entitled "An Act for the more effectual suppression of Societies established for seditious and treasonable purposes, and for better preventing treasonable and seditious practices."
Witness my hand this day of
in the year (Signed)
Signed in the presence of

You will not be liable to prosecution if you print your name and address on circulars, etc. You cannot use the Royal Arms. If you use your own crest or coat of arms a duty will have to be paid—in fact, the duty for using armorial bearings, namely, £1 per annum. If you use a block or coat of arms as a trade mark, you will have to print the words "Trade Mark" with it.

Condensing Pump.—TYRO (*Liverpool*).—The pump should answer for your purpose, and may be worked by hand, but it will be a slow process. If your plunger is one inch sectional area, and you can put 100 lbs. pressure on the handle, it must multiply twenty times, and your hand must move twenty inches for every inch travelled by the plunger. To get 15 cubic ft. of air at 2,000 lbs. per square inch, you must pump in 134 cubic ft. at atmospheric pressure, which will require a total travel of plunger of about 230,000 inches. Of course you can commence with a short leverage, and increase it as the pressure rises. The valves must be very accurately ground in to hold such high pressure.—F. C.

Wood for Greenhouse.—T. J. H. (*Derby*).—You had better purchase some 3-in. by 9-in. yellow deals at 3½d. or 4d. per foot run, and get them cut to the sizes you require. For instance, you say you intend using 3 in. by 1½ in. for the top of your greenhouse. (Do you mean for the rails of the lights, or for the framework?) Get the deal cut 5 flats, which will make six pieces of 3 in. by 1½ in. The standards and sill could be cut 1 flat—*i.e.*, 4½ in. by 3 in. Where do you propose putting the six doors? You can buy the sash bars ready for use at 1½ in., ⅝d. per foot, or 2 in. 1d. per foot, and the match lining for the panels at ⅝ in. thick, 8s. per square, or ¾ in. 9s. A square will cover about 9 ft. by 9 ft., and can be had from 5 in. to 7 in. wide. If you are near Hull I do not know that you could do better than purchase them.—A. J. H.

Domestic Ventilation.—A. W. (*Liverpool*).—I have examined the models and drawings of the domestic ventilator, and think it well adapted to its purpose; it is ingenious, simple, and complete, and I do not know of any invention that anticipates it. I think it will be preferable to retain the two shutters behind the front plate, and it will then afford a clearer way for the current than if one only is used. The case need not be ¼ in. thick, and in fact might be made of sheet iron. The valve, C, will require a stop, to prevent its being thrown too far back by a sudden draught, so that it may be in a position to close if necessary. A. W. should be careful in drawing his specification not to claim too much; it is only in the details of construction that the novelty exists, as the principle has been applied before, and in the same position as proposed.—F. C.

Battery for Induction Coil.—A READER (*Glasgow*).—A pint Bunsen battery will be quite large enough to work your small coil. The cost of a complete cell will be about 3s. The porous cell, containing the rod of carbon, is charged with strong nitric acid (cost about 3d.), and the outer jar with oil of vitriol in water (a wineglassful of acid to a half pint of water), cost ½d. See article on Bunsen Battery in first three numbers of WORK. The vulcanite ends of the coil are easily made. Procure a sheet of ⅛-in. vulcanite, strike out the size of the ends with a pair of compasses, then the hole for the core, and cut out carefully with a thin, narrow saw such as a keyhole saw. Smooth the edges with a rough file, then glasspaper them, and polish as you would polish hard wood.—G. E. B.

Winding Dynamo Armature.—J. C. W. (*South Lambeth*).—From the sketches in your letter I learn that the armature of your dynamo is of the Siemens H or girder pattern. This is most easy to wind. Hold the armature with the commutator toward you, and commence winding the wire on the left-hand side. Work from left to right, placing each coil neatly side by side around the web of the armature. When the spindle is reached, bend the coils on one side until half the diameter has been passed, then bend the coils on the other side to cover the web. See that the covering of the wire is not chafed as it is being drawn tight over the ends of the web. When the first layer is on wind on another, and so go on forwards and backwards until the wire space is filled. Connect the commencing end of the coil to one segment of the commutator and the finishing end to the other segment of the commutator by small set screws near the inner edges of the segments.—G. E. B.

Battery for Coil.—ELECTRICITY (*Leeds*).—You have so mixed up a "galvanic machine" with "a battery," and this with "a bell," in your letter, as to thoroughly puzzle me. You do not describe your galvanic machine, but I suppose it to be an induction coil. You attempt to describe a battery, but here you fail, for the zincs could not work in "two indiarubber bags," and I cannot at all imagine what you mean by "a stop and brake." I can only guess the nature of your newly-acquired property and your requirements, so if I fail to help you it is your own fault, and you must be kind enough to write again, giving a more clear account of your apparatus. I think it possible you have got hold of a shocking coil, and two cells of an old form of Daniell battery, with pieces of ox-gullet for porous cells. This will be troublesome to you, as you know little or nothing about such apparatus. Nearly fill the copper jars with a mixture of a wineglassful of oil of vitriol in a pint of water, and hang the zincs in this from a rod of wood placed across the tops of the jars, so that the zincs cannot touch the copper. Take one connecting wire from one of the copper jars, to one of the connecting screws of your "galvanic machine." Connect the zinc of this cell by means of a copper wire with the other copper jar (the side of the jar itself), then connect the zinc of this second jar with the other binding screw of your machine. If the acid makes the zincs hiss badly, you must take them out and coat them with mercury by the method described in WORK in the articles on the Bunsen Battery, and also in the note on amalgamation on pp. 86-87. When you wish to stop the action of the battery, merely lift the zincs out of the acid solution, leaving this in the copper jars until again wanted. Discard the ox-gullet (indiarubber?) bags altogether.—G. E. B.

Drop Black.—F. B. (*Guernsey*).—Drop black is a kind of ivory black, but of a better description than that which generally goes by the latter name. It is supposed to be made of burnt ivory, but is really burnt bones. Drop black costs about eightpence a pound, while ivory black can be had at threepence. If you cannot obtain it easily use vegetable black for the receipt you refer to in "Tips for Tyros," as it will do equally well. As you do not say what material your frame is composed of, and I do not know what its surface is like, I cannot here give you explicit directions for gilding it. However, if you refer to WORK, No. 8, page 118, you will find a "Tip" which I think will help you.—OPIFEX.

Walnut Fret Wood.—S. O. P. (*Clapham*).—The following are among the best firms for every kind of hard wood in all thicknesses:—C. B. Snewin, Back Hill, Hatton Garden, and Ray Street, Farringdon Road; W. & J. R. Hunter, New Bethnal Green Road; Oliver & Sons, Bunhill Row. There are plenty of veneer merchants in and around Old Street, E.C.—A. J. H.

Shrunk Forms.—PERPLEXED (*Norwich*).—The difficulty experienced by you arises either from the mahogany boards having expanded or contracted, or the paper having stretched or shrunk. If the fault be with the paper, then the stretching will most probably not be regular. This may be discovered after printing first colour by taking sheets from various parts of the "heap," and holding two sheets together up to the light. If the printing fall exactly in the same place on every sheet then the defect must be in the blocks. If they have expanded dry them thoroughly. If this does not succeed, new "register" will have to be made by cutting the boards or relaying the electrotype plates.—J. F. W.

Automatic Machine.—MINER (*Willington*).—Your arrangement will not answer because, while one valve is closing another is opening and letting in a further supply. To make the thing work the top valve must shut first, then the lower valve open, and at the same time open a vent for air at the top of the measuring vessel. The removal of the glass from its stand may by a counterbalance be made to reverse the action of the taps. The arrangements would be more complicated than your sketch, and I doubt if it would pay you better to patent a new contrivance than to hire one like those in use in London for fresh water—½d. in the slot—at railway stations.—F. C.

Repairing Broken Saw.—MINER (*Willington*).—The only way of joining a broken band saw other than brazing is by electric welding, but that probably cannot yet be done in your district. In my own experience I have found it better in the long run to buy a new band saw than to attempt to mend an old one. In the matter of brazing, if well done it may last a while, but the difficulty is to get it well done, and even then near the braze the temper must be lost, and the endeavour to restore it will generally extend the evil, as the brazing will not stand the heat for rehardening.—F. C.

Barometer.—WEATHERGLASS (*Eastbourne*).—Wash the inside of the empty tube with water acidulated with aquafortis (one part nitric acid to ten parts of water) mixed in a small spouted jug. Pour this into the tube, and pour it out again two or three times, then rinse it with warm distilled water, and warm the tube to hasten the drying. Whilst the tube is still warm refill with mercury, shaking this in as you have done before to get all air bubbles out. The mercury may be cleaned by shaking it up and down in a bottle together with a mixture of nitric acid and water of the same strength as that used for cleaning the tube. When the mercury is bright, throw away the acid mixture, and rinse the bottle two or three times with warm distilled water. Pour the mercury into a basin and dry it with blotting paper, and finally filter through a piece of thin wash leather, or through a piece of linen.—G. E. B.

Tondeur Developer.—E. L. H. (*Begbroke*).—The Tondeur developer is probably compounded from a private formula known only to the vendors. Excellent developers are most easily and inexpensively made. Why not make your own? The following will work with most plates:—No. 1, pyrogallic acid, 6 grains; sulphide of soda, 24 grains;

water, 2 oz. No. 2—pure carbonate of soda, ½ oz.; water, 2½ oz. Mix just before use. If the plates are very sensitive, or the exposure overdone, add a grain or two of potassium bromide, or less of the soda solution.—E. D.

Blocking Book Covers.—A. B. C. (*Liverpool*).—If our friend A. B. C. is a blocker he will find little difficulty in working the self-inking press he speaks of. In fact, it is a great deal easier to work than the ordinary blocking press. The table of the press has a to-and-fro movement which admits of great facility in feeding and setting up. When the press is doing inking work, the rollers pass over and repass the stamp by the movement of the table, and thus printed work is done with the same speed as ordinary blind work. The covers are fed when the table is out, and there is less chance of the gold getting rubbed off as in the old process. One or two sides and the back of cases can be done at one operation, using both gold and colour at once. Thus complete covers can be produced at the rate of 600 per hour. It is not necessary to use any size or prepare the cloth in any way to receive the ink. But in the better class of work it is usual to block the cases blind, and afterwards ink them in. The presses register so nicely this can be easily done. Of course, when putting on the ink the press must be cold. Book-cover ink is the proper thing to use, and may be obtained from any printing ink manufacturer. I expect you will get it readily in Liverpool. If not, send to Messrs. Richardson & Co. for a sample tin; use it as thin as possible, but not too thin, else you will not have the fine gloss that you should have. If you are getting a new press the maker will give you all the necessary instructions for working it; or, if you are going to a new place to work one, a glance at the machine, if you are a blocker, will be all that is necessary. I am very pleased to be able to help you; if you find any difficulty write again.—G. C.

Rabbit Hutch, etc.—A SUBSCRIBER (*Kingsland*).—Yes, a description of a rabbit hutch will, it is to be hoped, appear in due course. Full particulars will be given about it, but I cannot speak for the "allschow," as I do not know what sort of a thing this is, and I do not remember to have heard of one of them before. The preparation of dry plates is hardly suitable work for an unskilled amateur, the process being extremely delicate and tedious. However, for the benefit of those who wish to try their skill it will be described some time. For the present there are many articles of more general interest awaiting publication. You are, however, quite right to name any subject which you would like to know about, even though it should not be possible to give the desired information in "Shop," the space for which is limited.—L. J. P.

Renovating Stained Floors.—J. R. (*Liverpool*).—Although you refer to the floor having been stained only, it may be taken for granted that the surface has been finished in some way, probably by varnishing or waxing. If it has been polished with wax then it will most likely be sufficient to wash this off thoroughly with soap and water before applying fresh stain. A varnished floor is, however, more difficult to deal with, and I could only advise you definitely how to act by seeing its present condition. This, of course, is out of the question, so I must answer you in a general way. If the floor is in very bad condition, and you want to renovate it thoroughly, you must either scrape or plane it over. Papering will be superfluous, unless you want to French polish it instead of varnishing it. You may be able to wash the varnish off with turpentine, of which a good deal will be required. Possibly the varnish may have "perished," or been worn off entirely. Are you quite sure that the floor needs restaining? for it often happens that owing to the varnish having gone the impression is taken that the stain has also, whereas a coat of varnish will do all that is necessary. In any case you will not find it so easy to renovate a floor which has been stained as to stain and varnish an uncoloured one. You may not be able to match the stain exactly, for to do so requires the judgment of experience, and unless you can the result is apt to be patchy. I think if I were you, instead of staining the floor afresh I should paint it, using ordinary oil colour, as the appearance will probably be much better. After the paint has dried give it a coat of varnish. You may, perhaps, also attain your object by mixing a little colour, say, vandyke brown with the varnish, and so dispense with either staining or painting separately. If you still want a walnut stain here is one. Vandyke brown mixed to a paste with ammonia and water added till thin enough for use. The "Badger" is used like an ordinary brush, which will do just as well for your purpose. Of course make the strokes, as you call them, uniformly, and remember that the varnish on a floor is not so closely investigated as to cause brush marks of the ordinary kind to be noticed. Don't apologise. It is recognised as a pleasant duty by those connected with WORK to assist amateurs, and you seem rather "down" on yourself.—D. A.

Reversible Lathe.—J. F. P. (*Darlaston*).—In reply to your question respecting the possibility of reverse action of lathe, allow me to say all real self-acting lathes are capable of backward and forward action and stopping without interfering with engine, or shifting the belt from the pulley on which it runs, action and reaction depending, not on the pulley, but on the overhead riggers, and the train of wheels attached to the mandrel or geared into it.—G. E.

III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

Fretwork Picture Frame. — AMATEUR (*Belfast*) writes:—"Would you permit me a little space in the 'Shop' column of WORK to ask if any brother reader could give me a design for fretwork picture frame? If so, he would very much oblige me."

Varnish for Drawings. — A. M. (*Glasgow*) writes:—"Could you suggest a good, hard drying varnish for coating drawings executed in colours on ordinary drawing paper? The varnish is intended to prevent the drawings being soiled by frequent handling, and it should be, as nearly as possible, colourless."

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Drilling Square Holes. — P. P. (*Withington*) writes in answer to A READER (see page 270):—"There are drills in the market that are supposed to drill square holes, but there are none that drill them practically square, the majority leaving the angles round. The one of which I know is composed of four short drills on one shank, all working in the same direction, and close together, the whole enclosed in a square steel casing, sharpened on all sides, with the bevels inward. This drill needs much force to make it penetrate any distance, and unless you have a drilling machine, and a large number of holes to drill, it would not be worth while getting one, as the cost is large, and repairs are often needed. A new drill for square holes has been lately described in the *English Mechanic* as having a 'sun and planet' motion described to cut a clean square hole. Perhaps Melhuish & Sons will bring this to our notice in WORK, if it is found to be all that is claimed for it."—[A tool that will do this kind of work will shortly be noticed and illustrated in "Our Guide to Good Things."—ED.]

Sharpening Carving Tools.—J. W. B. (*Wakefield*) writes in reply to AMATEUR (see page 270):—"I grind my carving gouges almost equally from inside and outside. For the insides I use small emery wheels (such as dentists use), varying the size with the sweep of gouge. In doing this great care is required, so that the temper be not altered. The letter from H. C. (page 268) explains, I think, the reason why carvers do not generally use the handscrew for holding slips, but as I happen to have both bench vice and German screw in my shop, it did not occur to me for the moment that many carvers are without either. As to this method of holding slips being 'amateurish,' I can refer D. D. (page 252) to one of the oldest cabinet carvers who has used this system throughout a working life of over sixty years."

Joiners' Composition.—B. A. B. (*Hampstead*) writes in reply to J. R. (*Oldham*) (see page 270):—"Glue and whiting is frequently used. Glue and sawdust from the wood in use is frequently recommended. Glue and litharge is good for light mahogany. Plaster of Paris mixed with a little glue and venetian red, chrome yellow, and raw or burnt umber is sometimes used, but must be used quickly, and the glue must be thin. I have used a sealing-wax, which is made expressly for the purpose, and can be had in various colours to match different woods, at four sticks for 3d. at several shops near Curtain Road."

Tobacco-Pipe Making.—PIPER (*Manchester*) writes:—"In answer to SMOKE on tobacco-pipe making (see page 222), I must say that there is no book published on the above; but if SMOKE will publish his address, and state what he wants to know, I can, no doubt, help him."

Ivory Walking Stick. — P. P. (*Withington*) writes in reply to W. A. (*Hanley*) (see page 270):—"If you intend to cement it at the broken part, the best thing to use will be the new fish glue (Inventions Exhibition); but it will not stand much rough usage. A better plan would be to drill a hole in each end, and get a piece of round steel to fit; heat it *black* hot, and having filled each hole with resin and knife polish, insert the steel, and hold all in place till cold. This should make a splendid strong joint."

Rickety Table. — W. H. S. (*Willaston*) writes in reply to A. J. T. (*Holborn*) (see page 318):—"Get a piece of wood 8 in. long by 2 in. wide and 1¼ in. thick, which should be planed up. Mark on the piece spaces of two inches; with pencil and square run a line down the centre of the piece; then get a brace and bit, 1½ in. would do, and bore a hole nearly through, according to size of castors; then get a tenon saw, and cut them across into pieces two inches square; take the corners off with a chisel, and place them under the castors on the floor. This is the best remedy that I know of for rickety table."

Spirit Level.—D. J. (*Oldham*) writes:—"Will any reader kindly tell me how to choose a tube for a spirit level, and how to fix it? Level is 9 in. long by 1½ in. by 1 in., with slot 4½ in. by ½ in."

Copying Music.—T. R. (*Gateshead*) writes:—"Seeing such a variety of questions so ably and willingly answered in 'Shop,' I wish to ask if you know of any appliance or quicker method of copying music than by hand with pen and ink? I am in a band, and wishing to have my copy or part always at home, it occurred to me to ask your assistance. I am not a moneyed person, therefore cannot buy a duplicate copy of every piece performed; the time taken up in copying might be more advantageously used upon the instrument, and also to advancement of band."

Trade Notes and Memoranda.

THE oldest steamer in the world, according to the *Steamship*, is lying in Bowling Harbour on the Clyde. The *Industry*, built in 1814, plied for about sixty years on the Clyde, and was finally laid up where she now lies. Last year the engine, a side-lever one with spur wheel gearing, was taken out and placed in the Kelvinside Park at Glasgow. The old boat is fast breaking up, and will doubtless shortly disappear. The engine, however, will show to future engineers what a side-lever engine was like, and how it was connected by gearing to the paddle shaft.

PRIZES to the value of £150, and twenty of the Society of Arts' bronze medals, are offered for objects of art or workmanship to be exhibited in the Arts and Crafts Exhibition in the New Gallery, Regent Street, to December 7th. The work must be the production, not of artists, but of craftsmen, and must have been executed in the United Kingdom, or its dependencies. The objects submitted for competition may be the work of one, or of several workmen in combination, and need not necessarily be the property of the workmen sending them in. Forms of application, and full particulars, may be obtained of Mr. Ernest Radford, Secretary of the Arts and Crafts Society, 44, Great Marlborough Street, W.

As others see us:—"The English shopman (workman) is hardly as reliable as his American contemporary, so far as working steadily is concerned. He takes more days off, his option to do so not being seriously questioned. He is also very tenacious of what he considers his rights, one of which is not to be hurried, and another to do nothing he is not hired to do. If he is a lathesman he could by no means be persuaded to work a week at the bench in an emergency. While the American shopman is usually glad of the opportunity to broaden his field of usefulness, with the idea that knowledge gained in this way will come into play some day, the English shopman will quit his job before he will work out of what he considers his sphere. It is not uncommon in America to see a shopman, with a carpenter perhaps to help him, putting up the counter shafts for and setting some tool which he has to run. In England millwrights must do this. A lathesman does not know how to do it, and he does not want to know how. Insisting upon his doing it would quite likely empty the shop of men. The course of the English workmen does not tend to make mechanics, but perhaps—though we question it—it tends, as is claimed, to make better specialists in the different lines of the machine industry."—*American Machinist.*

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

MELLIN'S FOOD

For Infants and Invalids.

TRADE MARK **NOT FARINACEOUS. Rich in Flesh, Nerve, Brain, and Bone Formers.**

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

No Food in the market can show such a vast collection of *bonâ-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

USED IN ALL CHILDREN'S HOSPITALS.

Prospectus, Pamphlet and Sample, post free on application to the Inventor and Manufacturer,

G. MELLIN, Marlborough Works, Stafford St., Peckham, London, S.E.

NOW READY, price 6d.,

HARNESS'

ELECTROPATHIC BELT

Naturally, speedily, and permanently cures almost all disorders of the nerves, stomach, liver, and kidneys, and is the safest and best remedy ever discovered for

RHEUMATISM

and kindred ailments. Those who have any doubt as to its remarkable healing and strengthening properties should write at once for book of testimonials, or call and personally examine the originals at the **Electropathic and Zander Institute** of the **Medical Battery Co., Ltd.,**

52, OXFORD ST., LONDON, W.

(Corner of Rathbone Place.)

Advice free of charge, personally or by letter. **Write for a Belt or Pamphlet** to-day, before you forget it.

NEW SERIALS.

IMPORTANT NEW FINE-ART WORK.

In MONTHLY PARTS, price 2s. 6d.

The Picturesque Mediterranean. With a Series of Magnificent Wood Engravings from Original Drawings by leading Artists of the day, who have specially visited the Mediterranean for the purpose of Illustrating this work.

☞ *An Exquisite Reproduction in Colours of an* Original Painting *by BIRKET FOSTER, R.W.S., "The Rock of Gibraltar, from Algeciras," will be issued as a Frontispiece to* Part 1.

In MONTHLY PARTS, price 7d.

Cassell's Doré Gallery. Containing 250 of the Finest Drawings of Gustave Doré, with Descriptive Letterpress.

In MONTHLY PARTS, price 1s. (Part 1 now Ready.)

The Cabinet Portrait Gallery. Containing a series of Cabinet Photographs by W. & D. DOWNEY, of Eminent Men and Women of the day, with accompanying Biographical Sketches.

Now Ready, Part 1, price 7d., of

AN ILLUSTRATED SERIAL EDITION OF

The Holy Land and the Bible. By the Rev. CUNNINGHAM GEIKIE, D.D., with Illustrations from Original Drawings by HENRY S. HARPER.

Now Ready, Part 1, price 7d.

CASSELL'S

Illustrated History of India.

With 400 ILLUSTRATIONS.

*** With **Part 1** is issued, free of charge, a Magnificent Portrait of H.R.H. PRINCE ALBERT VICTOR (size 29 in. × 21 in.), beautifully printed in lithography.

Just Commenced, Monthly, price 6d.

The Family Physician. A Manual of Domestic Medicine, by Eminent Physicians and Surgeons of the Principal London Hospitals.

CASSELL & COMPANY, LIMITED, *London; and all Booksellers.*

NOW READY, *price* 1s.

The MAGAZINE of ART

For **NOVEMBER,** *forming the* **First Part** *of a* **New Volume.**

CONTAINING

A Beautiful Photogravure of **"The Last Muster,"** by Prof. HUBERT HERKOMER, A.R.A. (*Frontispiece*).

The National Gallery of Scotland. By WALTER ARMSTRONG. With Five Illustrations.

The Artistic Aspect of Lord Mayors' Shows. By JOSEPH GREGO With Six Illustrations.

"Elizabeth, Countess Grosvenor." By Sir THOMAS LAWRENCE, P.R.A. Engraved by R. BERTHOLD.

Wild Wales. By CHARLES STEWART. With Five Illustrations by the Author.

On Art Professorships. By Professor W. M. CONWAY. With an Engraving by W. E. F. BRITTEN.

"A Maiden of Dreams." Poem by ARTHUR L. SALMON. With an Illustration by C. RICKETTS.

The Philosophy of Laughter: A Study for the Artist. By CHARLES WIBLEY. With Drawings and Sketches by FRED BARNARD.

The Chronicle of Art: Art in October.

PUMP VALVES.

BY FRANCIS CAMPIN, C.E.

BUTTERFLY VALVES—FLAP VALVES—STEM VALVES—STALK VALVES—BALL VALVES—DOUBLE BEAT VALVES—CROWN VALVES—FLAT INDIARUBBER VALVES—INDIARUBBER BAND VALVES—INDIARUBBER SEMI-LUNAR VALVES.

ALTHOUGH in machines of all descriptions every part should be carefully designed and accurately made, and therefore all parts may be regarded as of equal importance, yet are we apt to consider certain details as requiring greater care in their execution than some other parts, those details being such as readily show any defects when in action. So long as a machine can get through its work without any obvious irregularity appearing, dissatisfaction will not arise, although hidden imperfections may exist which materially reduce the efficiency of the apparatus. In pump-work, the weak point lies in the valves, and, therefore, some practical remarks on their construction and duties may prove of service to those who are interested in the details of hydraulic and pneumatic machinery.

The duty of a valve being to allow the passage of a fluid or liquid in one direction only, it is evident that the parts in contact when the valve is shut should fit so exactly as to preclude the passage between them of any of the liquid operated upon, and there are several ways by which this end is sought. If one of the faces is made of some elastic pliable material, such as indiarubber, it will, by adapting its form to that of the hard face with which it is brought in contact, form an air or water-tight valve with any reasonably true surface; but if both the valve and its seat are hard and unyielding, the surfaces of contact must be made exact counterparts of each other in order that they may work satisfactorily.

With regard to all surfaces of special forms, these may be fitted by grinding together with fine emery and finishing off with crocus powder, but to flat surfaces a different process should be applied. The mechanical method of preparing a plane surface is as follows:—In the first place, the surface is made as true as the planing machine or lathe will render it. The surface thus prepared is tested by laying it upon a rigid plate having a true surface, on which a little ruddle has been smeared; the plate used for this purpose is called a surface plate, and is one of the most important gauging tools in the shop. Any parts in the surface under manipulation that are higher than the general level will naturally, by their contact with the surface plate, raise the rest of the work from it, so that the highest parts only will be marked with the ruddle; a slight movement of the work upon the surface plate will effect this marking. The work being then turned over on to the bench, the marked parts are carefully scraped down (a very good scraper can be made from an old three-square file, by grinding the cuts out at the end so as to form three curved scraping edges—not cutting edges) and the work is again applied to the surface plate. More parts will now be found to be marked, and these are to be scraped down as before; at every application it will be found that the marking will extend more continuously over the surface under treatment until at last a uniformly even surface is produced, and both the valve and its seat being thus prepared, a perfectly tight contact may be anticipated.

For very large surfaces I should say that it becomes necessary to apply the surface plate to the work, small ones, easily handled, being made for this purpose. As perfect rigidity is absolutely indispensable in surface plates, they are strengthened by being made with deep ribs at the back, running both longitudinally and across, which impart the necessary quality.

One of the oldest forms of pump valve is the double-flap or butterfly valve shown in Figs. 1, 2, and 3. In Figs. 1 and 2, the valve seat is shown in section to exhibit the apertures through which the liquid passes when the valves are open as shown in Fig. 2, the liquid passing in the direction of the arrows; A A is the valve seat, having in it openings, E, E, shown dotted in the plan, Fig. 3; B, B are valves which work upon hinges, C, their movement being limited by the guard, D; the letters apply to the same parts in each figure; the valves are semicircular in plan. Whenever the pressure below these valves exceeds that above them by the amount of weight of the valves, they will open, closing again as the pressure becomes equalised on each side. For small pumps with a light load of water, these valves serve well enough, and are, therefore, suitable to lift pumps worked by hand at slow speed; but, at a high velocity, the rapidity and violence of their closing would soon damage the seatings and render them leaky if made with metal seats and valves; the valves may, however, be lined with leather, provided the pressure of water is not great. In lifting pumps, the pressure will not exceed 15 lbs. per square inch in addition to that of the water above the valve in the pump bucket.

The weight of a cubic foot of water is almost exactly $62\frac{1}{2}$ lbs., therefore the height of a column of water pressing upon a valve being known, the pressure per square foot upon it will be that height multiplied by $62\frac{1}{2}$ lbs., and the pressure per square inch will be equal to the height in feet multiplied by 125 and divided by 288. The area of escape for the liquid around the edges of the valves will be equal to that of the openings, E, E, when the lift of the outer edge of the valve equals two-fifths of the diameter of the openings, E, E. As stated above, the valve will not open until the pressure of the fluid below exceeds that above it by an amount equal to the weight of the valve. In pumps for water and other liquids, this only requires consideration in the case of suction pumps, in which the weight of the column of water, in addition to that of the valve, must not exceed the pressure of the atmosphere; but for exhausting pumps—such, for instance, as the air pump of a steam engine, or the pumps for exhausting the vacuum pans of sugar refiners—more delicate arrangements must be adopted. If a vacuum is to be maintained, the valve must be of the least possible resistance consistent with its closing tightly enough to prevent a reflux of air, gas, or vapour, as the case may be. In Figs. 4 and 5 is shown a valve, the seat and suction passage being in section, in which the resistance to opening is determined by the angle of the valve seat to a vertical line. If the valve, B, depending from the hinge, C, were hung vertically, it would exercise no pressure upon the valve face, A, and as the inclination of A increases, so will the resistance of the valve, B; D is a guard to restrict the opening of the valve as shown in Fig. 5; E, E are flanges for attachment to the vessel to be exhausted.

The next example shown, shut at Fig. 6 and open at Fig. 7, is a spindle valve, having a conical seat; this valve requires to be ground into its seating to make a true fit. The seat, A A, is shown in section, F F being the part upon which the valve closes; B, the valve, carries a rod or spindle, C C, of which the lower end works through a hole in the centre of a wheel-shaped frame at the bottom of the inlet, between the spokes of which are the openings, E, E, to allow of the passage of liquid; the upper end of the spindle passes through a hole in the guide, D D, which also serves as a stop to restrict the rise of the valve, B; the height of rise necessary to afford an outlet equal to the inlet pipe is one quarter the diameter of the latter. These valves are simpler than the foregoing, inasmuch as the hinge is dispensed with; they have also the advantage that they do not require to open so widely in proportion to width as the previous ones, and will therefore close quicker and with less concussion. Rapid closing in valves has some special advantages which will subsequently be referred to in connection with a larger class of valve. A very compact form of valve similar in principle, but more self-contained than the last, is illustrated in Figs. 8, 9, and 10, the seats in the two former figures being shown in section. Fig. 10 is a plan view of the underside of the valve. This valve, which, on account of its compactness, has been much used for feed pumps, and others that are required to be stowed away in small spaces, is made with a stalk consisting of three wings or ribs cast on its underside; A A is the valve seat, which, besides having its conical part ground to fit the edge of the valve, B, is truly bored out to receive the wings, C, C, C, the edges of which are turned to fit it, and thus act as a guide to the valve. The rise of the valve in this case may be restricted by a set-screw, D, passing through the top of the valve box. The liquid escapes, when the valve is open, between the wings, C, as shown by the arrows in Fig. 9.

A simple kind of valve consisting of a ball, B, ground into a spherical seating in A A, at the top of the inlet, E, is shown in Fig. 11; it is kept in place by a guard, D. Where considerable area is required it has been proposed to agglomerate a number of these valves, but I do not know that such an arrangement has found favour. These valves must necessarily be disproportionately heavy in comparison with their areas; the balls also are somewhat costly, as they must be perfectly true to be of any use at all, and taken altogether they do not seem to possess any particular advantages to recommend them.

Passing from the comparatively small purposes for which the valves above described are appropriate to others of greater magnitude, such as the draining of mines and water supply of towns, we come upon essentially different forms of construction.

In order to make clear what is required of the valves under different circumstances, it is necessary to advert to the actions of the different kinds of pumps to which they are fitted, and this I will now briefly do. The simplest form is the common lift pump, with a flap or butterfly valve at the top of the suction pipe, and another in the pump bucket itself. It occurs most frequently in agricultural districts where there is no town supply of water, though the principle has also formerly been used in connection with large draining schemes. Next is the lifting and forcing pump with a third valve at the outlet to prevent the water discharged under pressure from returning; but this is displaced by the plunger force pump, in which, instead of a packed bucket or piston to draw and force the water, a long plunger is used working through a water-tight stuffing-box in the top of the pump barrel.

Double-acting pumps have pistons worked by rods passing through stuffing-boxes in the pump covers, so that work is done simultaneously on both sides of the piston: drawing on one side and forcing on the other. For lifting and forcing large volumes of water the single-acting Cornish engine has been very extensively used, being one of the most economical in its action, and therefore generally adopted before the era of very high pressures commenced. In these machines a plunger pump is used, having on its rod a box loaded with weights, which in its descent forces the water out of the pump barrel; the pump plunger, together with its "preponderating weight," is lifted by steam pressure on one side of the piston, the other being open to the condenser. The exhaust is then shut and communication made between the spaces above and below the piston, thus equalising the pressure and leaving the pump load free to descend. The pump barrel is filled through the suction valve during the steam stroke. These pumps naturally work very smoothly; as there is no sudden change of motion, the plunger comes steadily to rest, allowing the barrel to fill completely before the down or forcing stroke is made, and if the pump valves act perfectly a full barrel of water is discharged at each stroke.

The valves for such pumps will necessarily be very large to allow the free passage of the water, and the old rule of making the suction pipe one half the diameter of the pump barrel soon became obsolete when the construction of large pumps came into the hands of thoughtful engineers, among whom Thomas Wicksteed stood pre-eminent as an improver of the Cornish engine. To give an idea of the mass of water dealt with, we may take a pump with a plunger 50 in. in diameter and working with a stroke of 11 ft., and such a size is by no means the largest in use. The area of a circle is equal to the radius multiplied by half the circumference, and the circumference is the diameter multiplied by $3\frac{1}{7}$; therefore the area of the plunger section will be 25 multiplied by 50 and by $3\frac{1}{7}$, and divided by 2 equals 1,964 square in., or, dividing by 144, equals $13\frac{5}{8}$ square ft.; multiplying this by the stroke of the plunger, 11 ft., we have 150 cubic feet of water expelled at each down stroke of the plunger, which, as 1 cubic foot contains $6\frac{1}{4}$ gallons, amounts to $937\frac{1}{2}$ gallons per stroke.

The friction of water in pipes varies as the square of its velocity, and the velocity of a given quantity of water passing through a pipe in a given time varies inversely as the square of the diameter of the pipe, therefore the friction of the water will vary inversely as the diameter of the pipe multiplied into itself three times—thus, if one pipe is half the diameter of another, the friction in the former will be sixteen times as great as in the latter; this shows the importance of making the valves and passages as large as possible.

Following the experience of smaller things, these large pumps were at first fitted up with butterfly valves, but their unsuitableness to such a purpose soon manifested itself. The great area of the valve met such resistance in shutting that instead of falling through the water it hung until the return stroke, and fell with the column of water. In such a case as that taken above, where the pump acted against a pressure of 100 feet of water, the weight thus falling would amount to $43\frac{1}{2}$ lbs. on every square inch of valve surface, and would cause a concussion at every stroke that would speedily prove destructive to the machinery. The first method tried to obviate this difficulty consisted in providing air-cocks to admit air under the valves so as to allow of their falling more rapidly by their own weight; but this was obviously introducing a gratuitous leak into the apparatus, and in some cases as much as sixteen per cent. of water was lost at each stroke, causing, of course, a corresponding waste in consumption of fuel. The real remedy was to be found in designing a valve that should close quickly from its own form without requiring any extraneous aid.

To get at the principle involved, let us consider the difference of retarding force of a plate falling flat and one falling edgewise. The force tending to buoy it up and retard its passage through the water arises from the friction of the water passing from the under to the upper side of the plate, and when that plate is flat it evidently takes the water a longer time to reach its margin than when it is placed on edge; there is in short a much greater lateral movement of the water necessary in the former than in the latter case. Suppose the plate to be an inch thick and a foot square, laid flat, when it has displaced its own bulk of water once it will have fallen one inch; if on edge when the plate has displaced its own bulk of water once it will have fallen twelve inches. The conclusion arrived at is, that while keeping a sufficient area of opening of the valve to allow of the free passage of the water, the area of the valve acting vertically must be reduced, and this is done by using the double beat valve shown in Figs. 12, 13, and 14. Fig. 12 is a vertical section of the valve closed, and Fig. 13 of the same when open. A A′ A′ A is a casting bearing two seats, of which the smaller is at the top, A′ A′; these are shown in plan at Fig. 14, where G G shows the lower and A′ A′ the upper seat. These are connected by ribs, F, F, etc.; through openings, E, E, between these ribs the water passes from the underside of the valve, B B, in the direction shown by the arrows. Part of the water passes under the lower edge of the valve, B B, and the remainder over the top seat and out through openings round the centre of the crown of the valve. C is a nut which limits the rise of the valve, the hub, D, coming in contact with it when the maximum rise allowed is reached. This valve affords a very large outlet for the passage of the water, for there is the full area of the bottom seat, and the resistance to the escape is also relieved by the outlet at the top; the pressure being thus rapidly reduced within the valve also aids in facilitating its fall directly the flow ceases. The difference of area of the upper and lower seats will be that opposed to the water, and on this the whole weight of the valve is taken; so this form will require a greater pressure to open than a flat valve, but that is of no moment in comparison with the advantages obtained by its use. These valves are made up to weights of 13 cwt., and sometimes more.

Under very heavy lifts the beat of these valves may be felt at some distance, and in some pumps which were used to force water to a height of 270 ft., I have employed valves of the form shown in Figs. 15 and 16; the letters refer to the same parts as in Figs. 12 and 13, the only difference being in the form given to the valve itself; the idea was to give the valve an elastic form, and also to provide better passages for the water to the upper seat, A′A′.

As soon as it appeared that something different from the old-fashioned valves was needed, numerous inventors arose and patented valves of all sorts. One which may be mentioned here consisted of a series of rings placed one upon another, and having a small disc valve on the top of all, the rings gradually diminishing in diameter upwards. The bottom ring formed a seat for the second, which formed a seat for the third, and so on to the top. This valve closed quicker than a plain disc valve of equal diameter would do, because, the water getting away between the rings did not take so long to get clear of them as to get from under a flat plate.

With the increasing use of high pressure, steam, and high speed engines, high speed pumps have also been introduced, the advantage being found in the employment of smaller and less expensive machinery to do a given quantity of work; therefore valves suitable to quick working pumps have become a necessity. In such pumps we have necessarily all kinds of concussions, for their action may be said to comprise a constant succession of sudden and violent reversals of motion; and if the engine is overrun actual blows will result, for there is a limit to the velocity for the suction end of the pump, which is that of the entering water. If this is exceeded the pump barrel does not fill, and on the return stroke the entering water is struck by the piston or plunger. In order to get the full advantage of the atmospheric pressure, it is desirable to place the pump below the level of the supply, for every foot of lift in the suction diminishes the speed at which the pump may be worked, while we can force out the water as quickly as the power at our disposal will allow.

With such machines it is evident that the natural fall of the valve will be too slow to meet the requirements of the case; the valves, therefore, must be shut by the returning current, the very action which in the large pumps proved fatal to the use of flap valves. In this case then we must design valves that will work in the way required without the resulting concussions becoming destructive. The chief points indicated as necessary are light and elastic material for the valves, large area of inlet and outlet for the water, and no working parts to shake or wear loose. The material that most nearly fulfils these conditions is indiarubber, but it has no strength to support the pressure of liquid over a considerable surface, therefore when used it is necessary to make the valve seat in the form of a grating, so that the indiarubber itself may be sustained against the pressure upon it. The less the lift of these valves the better it is, as the force of closing is proportionally less, therefore a large area, afforded by a considerable number of small valves, will be advantageous. The common form of circular indiarubber valve upon a grated seating is shown in vertical section in Figs. 17 and 18, shut in the former and open in the latter. A A is the seat and B B the valve, which is bolted between the seating and a cup-guard, D D, and secured by a nut, C; the guarding, D D, limits the rise of the valve and prevents its being torn or strained by any unusual pressure under it.

A form of valve in which indiarubber bands are used was designed many years since for use with a Cornish engine raising water to a height of 100 feet in one of the London waterworks. This valve, which gave perfect satisfaction, is shown at Fig. 19—the left-hand half is shown in elevation, the right in vertical section. This arrangement consists of a series of diminishing cylindrical seats, A A A′ A′, in the form of vertical gratings having apertures, C, C, etc., around which are wrapped indiarubber bands, B B, etc.; the water pressure within the valve distends these bands and so escapes around their edges, and the bands immediately contract upon their seats on the relaxation of the interior pressure.

Muddy and gritty water will invariably derange metal-faced valves, inasmuch as some deposit is sure to get upon the seating; to obviate the inconvenience thus caused, an indiarubber valve of the form shown in Figs. 20, 21, and 22 has frequently been used with success; it is, however, only applicable upon a small scale. It consists of a tube, A, which is shown at Fig. 20, in vertical section through the line, C C (Fig 22), on plan at which the lips meet. Fig. 21 shows a vertical section at right angles to the line, C C, at which the lips, B B, meet; these lips are forced apart by liquid passing through, and it is obvious that mud and other clogging material will pass freely through, there being no valve seats on which to deposit. These valves are not suitable for high lifts on account of the yielding nature of the material of which they are composed. The idea appears to be taken from the form of certain valves occurring in the circulatory system of animals.

In the preceding remarks I have sought to put before my readers a description of the various kinds of valves in use in pumps, and to show, I trust clearly, their construction and advantages or disadvantages, as the case may be. I shall be happy to give further information through "Shop" on any point which may seem to require further elucidation.

IRON SOIL-PIPES.

BY W. R.

The rage for speculation which has taken possession of the business men of this age has made itself as evident in the building trade as in any other, and to the driving of hard bargains and close-fistedness of property buyers, can often be traced the reason for the fixing of sun-dried bricks, trashy joists, and, worse than all, defective sanitary arrangements.

Especially is this noticeable in the drainage and sanitary plumbing of modern middle-class houses.

In these, lead as a material for soil-pipes is never used. Cast iron, often badly fitted, has been made to take its place.

Now, every intelligent plumber knows the advantages which lead possesses over iron when used for this purpose. Its resistance to corrosion (when well ventilated), the smoothness of the interior (when drawn, not seamed), its adaptability to jointing—all go to proclaim its superiority over iron.

But yet these builders must use iron, for the simple reason that the people for whom they build will not pay the price for lead. Such being the case, it remains only for the plumber to make the best job possible of the materials to hand.

The two worst faults of iron pipe are its liability to corrosion and internal roughness; these may successfully be overcome as follows :—

Get each length of pipe to nearly a red-heat; this may be done by standing it upright on the plumber's fire-devil or grate in the open air, and lighting a blazing wood fire under it. The pipe should be turned end for end once or twice to make it uniformly hot. When nicely hot, coat it inside and out by means of a long handle tar brush, with a mixture of pitch, tar, and resin in the following proportions :—Pitch, 7 lbs.; coal tar, $\frac{1}{2}$ gal.; resin, 2 lbs.

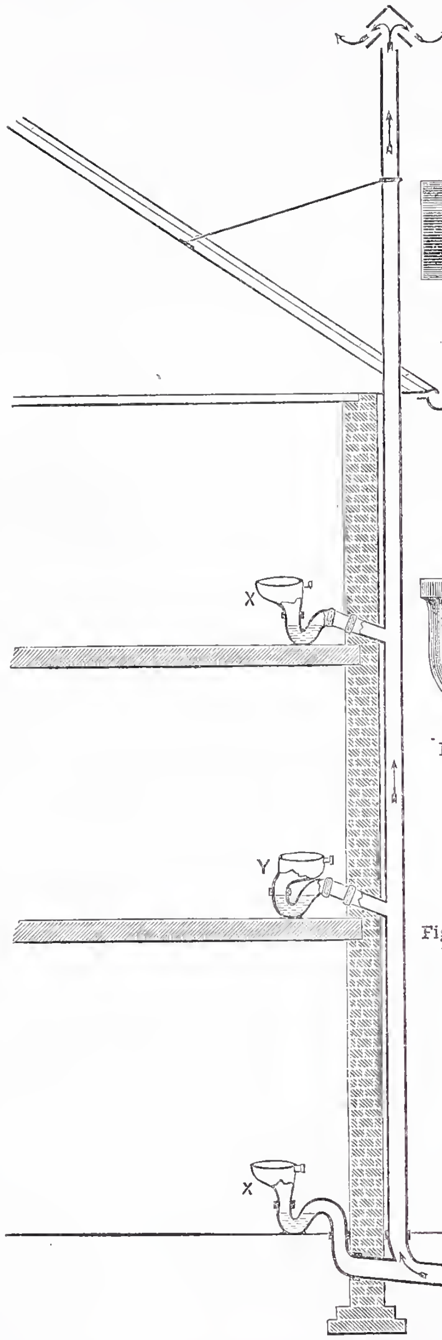
These ingredients should be melted in an iron pot, the pitch and resin first, adding the tar afterwards when the pot is off the fire. When the pipes are quite cold, they will possess a glaze impenetrable alike to water or sewer gas.

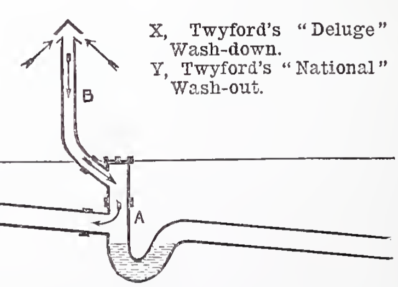
The next thing is the fixing. The pipes should be fastened to the wall as usual by hooks and clout nails through the ears, but every length should have a small wood block placed behind the ears so as to set it off from the wall about an inch (the nails passing through it will hold it in its place), for the purpose of getting the hand round the pipe in jointing. The first length should be placed in the socket of the earthenware bend or junction which has been brought to the surface to receive it. This joint should be made with cement, first, however, placing a ring of tow or flax inside the socket to prevent the cement from running through into the pipe, and thus causing an obstruction.

Before inserting the next length, and, in fact, all above, paint the lower socket with a mixture of red lead and linseed oil.

Paint the end of the pipe to be fixed with the same; now wrap round this end some nice soft tow or flax, and well saturate it with the red lead paint. Put the pipe in it place, and fasten it there. Next caulk i with a thin tool as much tow as you ca occasionally brushing in the paint until th socket is nearly full. Be careful in caulk ing; do not use a hammer, the tool itself wil be quite sufficient, for the ordinary cast-iro pipe will not stand many heavy blows.

Now mix up some red and white lead t the consistency of dough and fill up th socket with it, we squeezing it in to fi up all crevices, an the joint is finishe Joints made in th manner have stoo the smoke test man years after bein fixed, without th slightest leak or crac being found in then





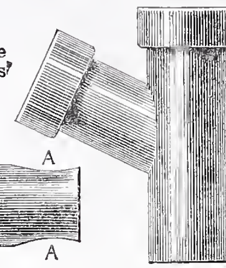


Fig. 1.—Branch Pipe usually known as a "Y-Piece."

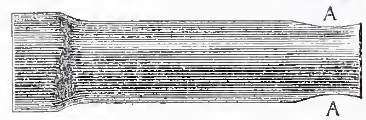

Fig. 2.—Piece of Drawn Lead Soil-Pipe—A A, End compressed to enter Socket.

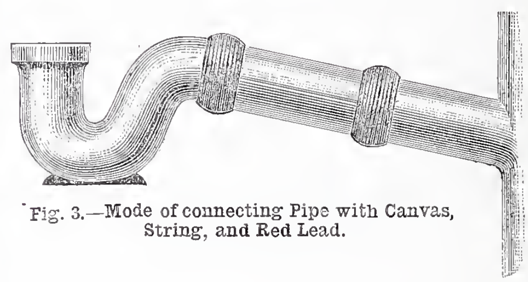

Fig. 3.—Mode of connecting Pipe with Canvas, String, and Red Lead.

Fig. 4.—Connection of Closets with Iron down Pipe and Pipe to Sewer—A, Sewer Intercepting Syphon; B, Inlet for Air.

X, Twyford's "Deluge" Wash-down.
Y, Twyford's "National" Wash-out.

Now as to the co nection for the wate closet, which usuall in these moder middle-class houses is either a "wash-out or "wash-down" pattern. These earther ware closets, by-the-bye, are, generally speak ing, the best sort for use in those position where we often find a large family using on place continually.

Before the soil-pipe is fixed, a hol should be got through the wall on a leve with the floor-line o the water-closet fo a branch to pas through.

The trap shoul then be placed in th exact position it i intended to occupy and temporaril fastened there.

When the stack o iron pipe has nearl reached the hole i the wall, the branc piece should be pu in its position in regard to the closet tra (which, in this case, would be P shape). an the length of the iron pipe taken, which i necessary to connect it with the other pip below.

This branch, or, as some call it, "Y piece," is shown at Fig. 1.

Almost any size can be obtained, but 4-in is generally used for this class of work. O course, this fittin should be coated th same as the rest.

The lengths of pip should then be con tinued to the nex water-closet if ther be one, and then o again above the roo for the purpose o ventilation, as show at Fig. 4.

We shall find ou branch pipe ha barely passed through the wall to the water closet, and is from one to two feet awa from the outlet of the trap.

These must be connected up by means o a piece of drawn lead soil-pipe (not seamed mind) opened at one end to receive the trap and drawn in at the other to enter the iro socket of the branch piece, as shown a Fig. 2.

It will be seen that the smaller end of thi connecting piece is opened out a little. Thi should fit in the iron socket tightly, leaving a space, A A, to hold the packing. Take are that the end of this pipe goes right into he end of the socket, so as not to leave ny space for the accumulation of filth.

This connector should now be fixed, the oints being made with the same materials s the others, but they should not be caulked, s that would cause damage both to the rap and lead pipe. Instead of this, when oth sockets are full, place a thick layer of he mixed red and white lead round each, nd take strips of canvas or calico, and nake a bandage round them.

Saturate the whole with red lead paint, nd then bind on a regular layer of stout string or cord as shown at Fig. 3. This binding will prevent any falling away or racking of the packing, and in a very short ime the whole will set so hard as only o be parted with the greatest difficulty.

In making the drain, a sewer intercepting syphon should have been fixed, as shown at A, Fig. 4, with an inlet for air, B, which should be a pipe about 5 or 6 ft. high, fixed to the nearest wall for support.

There is one thing which cannot be too strongly insisted upon :—*Never carry a soil-pipe up inside a house.*

If these precautions be taken, the cost for workmanship will be but slightly increased, while the causes for complaint against cast-iron pipe will be completely removed.

THE AMERICAN LEVER WATCH.

BY A PRACTICAL HAND.

Waltham, Elgin, or Boston Lever.

The Waltham lever in my opinion is next best in quality and equal in timekeeping to the well-finished English lever. Some will differ from me, I have no doubt, but this was settled a few years ago, after a long discussion in the English press, and was decided in favour of the hand-made English lever on account of its durability.

The Elgin watch, taking its cost and appearance into consideration, is a very strong and useful watch for the working man, far superior to its imitator the common Boston, with its half-finished wheels, the underside of each being left in the rough. Of course the public do not see this, and top plates, etc., are scarcely gilded at all; the few paltry so-called jewels are only on the plate in sight, the under plate is minus. They go fairly well for a time, but the best plan after that is to quit them, or they will be a never-ending source of annoyance and cost. The cases are the lowest mixture of silver, which will scarcely keep bright with wearing; when made in so-called aluminium it is simply brass badly plated. The wearer finds that out in the course of a few weeks. The same price paid for a Swiss silver lever would be money wisely spent. Of course some one must buy them, but my advice is the same as *Punch's* advice on marriage—"Don't."

To clean the above style of watch first take off the hands, hour and minute, with one lift, then carefully raise the seconds hand *evenly* with tweezers so as not to injure the pivot point on which it is fitted; open the inner dome and turn the half-headed screw so as to free the works from the cases; press them out face side. Now hold the movement in your left hand, and draw out the three pins holding the dial in its place; take off the dial and the three dial wheels, as described in page 406; turn over and unscrew the cock or cover to balance and mark the end of hairspring; draw out the pin which holds it in position, and remember which way out, so that in replacing it you do the same; if not you will wonder why it will not go when complete. Lift out the balance and place under glass cover for safety, then let down the spring by turning the winding part a little back, and slip out the click from ratchet notch, gently allowing it to turn down.

Having done this you may now proceed to unscrew the top plate by the three screws

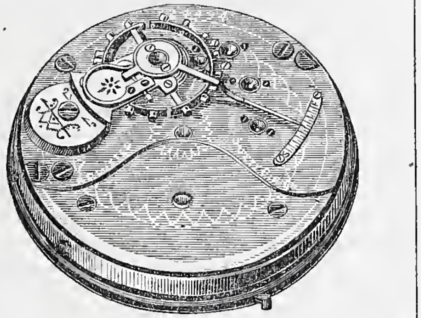

Fig. 1.—American Lever with Top Plate on.

holding it in position, and after examining it well, so that you can remember the position of each part, the top plate ought to be very gently lifted so as not to break or cast any pivot point or other injury; notice the lever, and take out so that you may not drop it and lose it. And so take out each wheel.

One thing in these watches is the ease with which you manipulate the spring barrel; as there is no chain or fusee wheel, in this point they are superior to our watches. There being no chain or fusee work the motion is direct from the spring wheel, for the teeth are around the rim of the barrel. The English makers claim, which of course is true, that by the fusee arrangement the pressure is more equal all the time; the greater leverage when spring is nearly uncoiled. Any one will see that; whereas the American watch must have a longer and exceedingly well-tempered spring to give anything near equal leverage. You will notice, if you listen, that the beat is much weaker when nearly run down.

To proceed, polish the wheels with the brush drawn over the prepared chalk, and also clean plates, using a rotatory motion so as not to show scratches. Many recommend

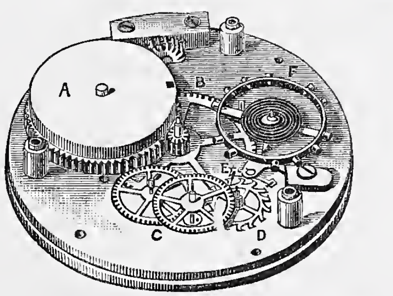

Fig. 2.—American Lever Waltham with Top Plate Removed—A, Barrel; B, Centre Wheel; C, Third and Fourth Wheels; D, Escape Wheel; E, Lever; F, Compensation Balance.

using benzine to dip them in, but unless of the very purest quality the work is unsatisfactory.

Note that it is not advisable to take out the mainspring, for three-fourths of the trade do not, so why recommend it to the amateur; but if you are really of opinion that it must be done to make a thorough job, prise off the lid of spring barrel. Notice the small dots so as to be right when putting it on again; now undo the end of spring in the middle and lift it gradually out, holding the remainder in by your thumb nail, and so gently turning and allowing it to leave; if not, why it will snap off the end at its stud hole. Clean the spring with an oily rag, and brush out the box free from grit; now hook on the spring and gradually work it in as you worked it out. Of course we in the trade do it in a different way, but I am writing for those with few tools, and to describe how would be no use.

When all the spring is in the barrel, put in the centre and hook it on, and try by turning it if it has proper hold, so that when boxed up you may have no further trouble; if it does not grip it, just lift centre out and gently squeeze it inwards. Now replace and try again. Put on cover as previously stated and turn with the key to see if all right; if so, place under cover; having pegged out all the holes clean, touch each one with the oiler, and if you are certain none are worn oval or any jewel broken, cracked, or injured, by such carefulness you may save much time and annoyance.

Having got thus far you may proceed to put together by placing the centre wheel and next the spring-barrel wheel, which works into it and each one; now place on the top plate and guide each pivot into its place; press down, and try if the train runs easy by gentle pressure upon the main-spring wheel; if so, all is right so far; gently raise up the top plate and insert lever pallets with tweezers, using your eye glass. This is not such an easy job to do, but patience will do it, and when all pivots are again in place, also pallet part, then try pressure; and if the pallet moves quickly you may proceed to screw down the top plate; if not, some part is too tight; gently ease the top plate, and try again and screw down. Place on outer plate, holding barrel in position, and screw down with two smaller screws; then as stated before how to clean balance and its spring, replace it, and pin into same mark on the plate; run the pin in *right side*, drop the last coil in betwixt the two studs of regulator, and drop on the cock or cover. Try it to see that pivot is in the jewel hole; if so, screw gently down, trying it all the time by shaking movement, or you may finish the pivot. Try if lever works by using pressure; if not, and balance is locked, or what we call overturned, undo cover, gently raise balance, and just push the extreme outer end of lever towards the other pin and drop balance in again; screw down, and you will find it all right. Now wind up, and the watch will once more be in order; but if the beat is unequal you have not pinned the hairspring to its proper place; partly push out the pin and draw spring a little and try again; if worse, draw the other way until the beat is satisfactory and the pin tight. We have another way to put in beat, but I write so that any may understand; if not, my time and yours is wasted.

Now try the watch for a few hours, and if still working with goodwill replace the dial wheels and dial as previously stated (page 406), and fit into cases; turn the half-headed screw, and replace hands all in correct manner, so that each minute is complete, as the seconds hand denotes. Close cases, and the job is complete and satisfactory no doubt, and in many cases equal to that done by a village watchmaker, so called.

In my next paper I will tell you how to clean the English lever.

BAMBOO WORK AND MATERIAL.

BY DAVID DENNING.

THE trade in bamboo furniture, both useful and ornamental, has of late years made such rapid strides in this country, that no apology need be offered for introducing the subject in these pages with the view of still further popularising it, not merely when made up, but for the workers, either amateur or professional, who may have a taste that way.

For some reason or other, bamboo construction has not received that amount of attention which one would imagine it would have attracted. We are all familiar enough with the appearance of things made partially or wholly of bamboo, but comparatively few are aware of the immense scope this branch of art work affords, and the ease with which the mechanical details can be learned.

Without, at the present time, giving directions for the construction of any specific piece of furniture, a few general remarks will no doubt be of assistance, and perhaps induce many to profit by the designs which will, from time to time, be offered in these pages. In fact, we may consider the subject of bamboo work as virgin ground, which must be surveyed and gone over, ere the practical planting and completion of diagrams can be proceeded with. We may look on the present article as a preliminary canter into an almost unexplored region, of which only some of the salient features can be noted.

We are, perhaps, at first struck by the apparent flimsiness of things made from bamboo; they look so light and fragile that it almost seems as if they could be blown apart.

Further acquaintance, however, shows us that they are by no means so fragile as they appear. The bamboo itself is strong and tough, so that the only source of weakness can be at the joints. That many of the things made of bamboo are not so strong at these parts as they should be, is not to be denied, but with due attention when designing anything for construction in bamboo, *i.e.*, remembering the nature of the raw material and acting accordingly, there is no reason why there should be any inherent weakness in any portion of the work. If any joint or constructive detail is so weak as to render the piece of furniture, be it bracket, table, or whatnot, useless for the purpose which its shape shows it to have been intended for, bad design or workmanship must be blamed, not the material used. It is no use making a pretty thing only, that is to say, unless it is for pure ornament. However pretty to look at, let us say, a chair might be, it is obvious to every well-trained mind that, unless it fulfils the object of chair, the mere prettiness repels rather than attracts. One may admire the design as a design in the abstract, but the futility of the chair causes the beholder to have a feeling akin to pity for those who can admire it. This, of course, is merely an adaptation of the principle that truth is essential to beauty. First truth, then ornament, and if this be remembered, the first great law of art is appreciated. False construction and beauty cannot go together. Now, to the art student, these remarks may seem quite unnecessary, as the principles of them have been inculcated times without number. They are, however, of such extreme importance to the bamboo worker, that insistence on them can hardly be too strong. The worker, to whom they have become almost second nature, is not likely to ignore them, but there are many who seem to think that the highest art is not to hide art, but by artifice to make some material resemble something else. No matter where we look, we find this feeling proclaiming itself in all its hideous vulgarity. "Look at me," says the result of misapplied talent; "you thought I was made of wood—I look like it; but, ha, ha, I have taken you in—I have deceived you. I, through the perverted skill of the artificer who made me, am false from beginning to end; I am in reality made of iron." Well, perhaps exclaims the reader, is not iron as good, as sound, as strong, and useful as wood? Yes, every whit, and, perhaps, better for the purpose of the speech-endowed article above. The material is right, but the wrongfulness consists in trying to make it resemble something else. We may admire, or, let it be said rather, wonder at the dexterity of the artificer, but the feeling is one of pity that he should have gone so out of his way to create a deception. The material and its capabilities must be kept in mind when designing anything.

Now, in bamboo, it is necessary to always remember that it has qualities peculiar to itself. We cannot treat it as if it were so many pieces of wood such as is used in ordinary joinery or cabinet work; it must be manipulated as bamboo not as wood. It cannot be reduced in diameter, but we can select pieces of such a thickness as may seem appropriate. The main portions must be thick comparatively, thick and strong enough to be serviceable, the decorative details being of the smaller and lighter pieces. These can be bent with ease, so that the straight, stiff lines of the main construction are relieved by variety. Then, again, a judicious arrangement of colours afford further scope for the display of taste. However, as the artistic principles involved in bamboo work are not confined to it alone, let us, instead of dilating on them, further descend, or, if the worker who thinks "art all bosh" prefers, ascend to practical work.

"Ah, that's right; he's going ahead now," I almost fancy I hear some one say; or is it the cricket chirping which suggests the words, "and leaving his 'igh hart" notions? Well, my friend, if I have not mistaken the cricket's utterances for your own, let me, in the first place, say that I have no sympathy with "high art" for its own sake; and secondly, without art, no worker can be a master of his craft. I have written a little "art," but I trust not "high art," which, at its worst, is an incomprehensible mystery, even if it is not, as you suggest, "all bosh." If I have unfortunately written anything that is not to be understood, then I plead guilty to having encroached on high art, and freely forgive you for having mistaken what is intended as art, for what is erroneously spoken of sometimes as "'igh hart."

Art and craft must go hand in hand, if our present-day manufactures are to be of any more than merely temporary value, and the more closely the worker can connect the two the better, even in what may possibly be only a passing fashion, such as bamboo furniture.

Well, let us leave the lecture-room, and get right into the workshop. What is the raw material to be? What tools are to be used? These are among the first questions which will occur to the novice's mind. Let them be answered in a general way. You do not want to know about the botanical history of the bamboo, so though a string of scientific, and, perhaps, very interesting, particulars might be given, they must wait. What we have to do is to speak of bamboo as we fin[d] it ready for working up.

Roughly speaking, the kinds may b[e] specified as black, brown, yellow, mottle[d] mahogany, and spotted, according to colou[r] and marking. All the colours are merel[y] approximate, as different sticks, or to spea[k] technically, canes, in a bundle vary co[n]siderably. The artificially coloured cane[s] such as black and mahogany, of course a[re] more uniform than those which are left i[n] their natural state, if we except, perhap[s] the yellow variety. In addition to th[e] plain stained canes, there are some suc[h] as the tortoise-shell with fancy mottling pr[o]duced by artificial means. All the kind[s] are obtainable, either with or without root[s] the rooted canes being the dearer of th[e] two. It must not, however, be forgotte[n] that occasionally dealers run out of sorts, s[o] that the purchaser must not make too su[re] of getting just what he wants at a moment['s] notice. The sizes of the canes vary co[n]siderably, the thickness being from ⅛ i[n.] to 3 in. or more, those most useful f[or] furniture of the fancy kind being from ½ i[n.] or ¾ in. to 2 in. In length, they are fro[m] 3½ ft., the thinner canes up to say ⅜ i[n.] thick not exceeding this, while the thicke[r] ones are cut in 6 ft. and 13 ft. length[s]. Other sizes are also to be met with, but thos[e] named are about the most common. On[e] variety of small canes known as Tonking[s] should not be omitted. Ordinary canes o[r] rattans are also used, and come in hand[y] for a variety of articles.

The prices fluctuate a good deal, and i[t] is impossible, if not out of place, to give the[m] in detail; but the following extracts from [a] recent quotation by one of the principal, i[f] not the chief importer of bamboos, etc., ma[y] be of service :—

Feet					in.		in.	dia.	each
6½	black	bamboos	without	roots	¾	to	1	,,	4½d.
,,	,,	,,	,,	,,	1	,,	1¼	,,	7½d
,,	,,	,,	,,	,,	1¼	,,	1⅞	,,	8d.
,,	,,	,,	,,	,,	1½	,,	1⅝	,,	9d.
,,	,,	,,	,,	,,	1¾	,,	1⅞	,,	10d.
,,	,,	,,	,,	,,	2	,,	2⅛	,,	11d.
,,	,,	,,	,,	,,	2¼	,,	2⅜	,,	12½d.
,,	,,	,,	with	,,	¾	,,	$1\frac{1}{16}$	,,	7½d.

Tonkings from 20s. per 1,000 according t[o] size.

It should be noted that the above ar[e] retail prices at which the dealer referred t[o] is willing to sell small lots, and that i[n] wholesale quantities the figures are corres[-]pondingly less. As some guide to wha[t] constitutes a wholesale order it may be sai[d] that a bale containing 100 canes of a sort i[s] the smallest quantity, and that any fewe[r] or even that number made up of severa[l] sorts, can only be supplied at retail price[s]. In case it may be thought that this i[s] irrelevant, let me say that these particular[s] are inserted as owing to the mention of hi[s] name in a contemporary, the dealer wh[o] quotes the above figures is pestered b[y] numerous letters from persons asking hi[s] *wholesale* prices and favouring (?) him afte[r] a prolonged correspondence with an orde[r] for half a dozen canes.

It will be a great pity if readers of WOR[K] are so indiscreet as to alienate the good-wil[l] of large dealers, not only in bamboos, bu[t] other commodities, by what one can onl[y] stigmatise as "sharp practice." If I ma[y] make a suggestion to the fraternity wh[o] are always seeking to get bargains an[d] buy under value, it is that they shoul[d] remember that time is of some value t[o] men of business and to those who hav[e] something to do, and that by worryin[g] large dealers or manufacturers who ma[y] be willing to oblige the readers of WORK by supplying small quantities, they are likely to do a serious injury to the professional artisan, or even to the amateur, whose proceedings are more business-like and straightforward.

In many of the larger centres of population there are manufacturers of bamboo work who would probably be willing to supply amateurs with such small quantities of the raw material as they are likely to require, but London is the chief market for it. To name any dealers here would be invidious, especially as firms supplying bamboo have already been mentioned in the shop columns.

The tools required for bamboo work are few and simple. A saw of some kind, preferably a small one, is necessary for cutting the canes into lengths. Half-round files of various sizes are also useful, if not indispensable, for shaping the ends to fit against surfaces. This may, however, be managed with a knife alone. Indeed, with patience and a knife almost any piece of bamboo furniture may be constructed, though it goes without saying that the few tools suggested greatly facilitate operations. Several bits for boring are also advisable, though in their absence holes can be made, or rather started, with a gimlet or other suitable tool, and then be enlarged to the required size with the pointed end of a knife. When it is said that unless a thin piece of bamboo is let into a hole bored in another, the usual mode of fastening is by means of wooden pegs or dowels, it will be seen that some contrivance by which these may be cut will be required. The dowels are fitted into the canes, which it may be assumed every one knows are hollow and then let into holes bored partly through the other piece. If this rough outline of the construction is not sufficiently clear to enable novices to start bamboo working, it may be said that in succeeding articles the subject will be more fully gone into, and as illustrations will be given, every necessary detail will be made "as clear as daylight." Glue and nails, it is almost superfluous to add, are required, and having said this, no further remarks are necessary about the appliances used, as those who are familiar with joiners' or cabinet makers' tools will be able to evolve from their inner consciousness the easiest methods of working, while those who are not will soon devise means and become proficient.

One great advantage for the amateur, and perhaps I should say for the professional, worker in bamboo is that there is very little waste of material. The short pieces and odds and ends can be used up till it is hardly too much to say that not a scrap will be left over.

In due course various small articles which can be made up from "waste" will be suggested, so in the meantime the worker who may not have many ideas of his own in this direction may as well keep the bits which at present may seem useless to him.

Bent bamboos have been referred to, and the most casual observer cannot have failed to notice that in many articles made from bamboo the canes are curved. For example, in a table the feet are splayed, not only for the sake of appearance, but to give stability. Now though it might be possible to bend bamboos by hand only, in many positions where the construction is such that the curves are kept from springing out again, the novice will soon find himself in a difficulty in such a case as instanced, viz., in a table leg or foot. The bamboo must not only be bent, but the curve must be retained. The bending may easily be managed by the aid of heat, either dry as from a lamp or by steam. Naturally the former is the easier of the two, and is used by the chief bamboo workers. The bamboo is warmed at the part to be bent by holding it in or over a smokeless flame, in which it is moved about to avoid burning. The cane soon becomes plastic enough to be bent with the utmost facility, and when cold the curve will remain unalterable. A spirit lamp gives an excellent flame for the purpose, but almost any source of heat will do, provided care be taken that the surface of the cane does not get smoked. The heating should be gradual, and on no account must the bamboo be allowed to remain motionless, that is, the flame must not play on any one part sufficiently long to burn the cane. Of course the heat must be applied all over the surface to be bent, and gentle force be used till the desired curve is attained.

Bamboo cannot well be painted, but where nice finish is required it is often gone over with a rubber of polish or glaze.

With these few general remarks by way of introduction to the useful and artistic manipulation of bamboo, the present hints must be brought to a close, and, as it has been said, diagrams and designs accompanied by descriptive explanations will be given in future papers for the benefit of those who, either by way of recreation or from trade considerations, wish to have some acquaintance with the manufacture of bamboo articles.

ENGRAVING ON METAL.

BY NORMAN MACLEAN

INTRODUCTION.

I HOPE I shall not discourage our many readers, male and female, if I mention in the course of this paper a few of the difficulties of this delightful art, followed either as a means of subsistence or as an agreeable occupation for leisure hours.

The practice of engraving is comparatively clean and inexpensive, and its elementary principles are easily learned. By this, I mean that an ordinarily diligent pupil will make such progress as to give him, or her, encouragement to greater efforts. Although I have not come across a workman who of my own knowledge has been self-taught, I have known instances of individuals who have picked up the trade, aided by the assistance of some good-natured workman, and by assiduous practice have so far become good engravers as to have ultimately earned their living by the profession; not perhaps in the highest style of art, but good enough for some mercantile purposes.

The first thing to be considered is the capability for drawing in the learner, who should be able to handle the pencil with ease, as, in the first instance, the subject has to be drawn before it can be cut with the graver. A few terms at the nearest School of Art will be of great use to the young workman, as a knowledge of the principles of drawing will enable the engraver to correct a bad sketch, and also to trace patterns quickly, which in these days of keen competition is an important consideration.

We now come to the requisites for the practice of engraving. A good, strong bench (Fig. 17) sufficiently high to stand at while working at large work—such as a tray, dish cover, or brass name-plate—a good light, and a high stool to be able to sit comfortably when engaged on smaller work, with a box to rest the feet upon when sitting, or when standing on the box, to increase one's height when using the block (Fig. 18) for large hollow ware. This block is fixed, when required, in the hole shown near the edge of the bench, and secured by the wooden nut shown above the block. The block is turned out of beech or elm, and has a slight hollow turned in the top, in which to place a sandbag, and on which the *inside* of the dish cover rests. The engraver, by this means, gets a firm hold of the cover, is enabled to turn it in any direction, and to avoid scratching or bending the side opposite to which he is working.

But for ordinary work which may be done at home the workman may utilise a table, taking care that it stands steadily without rocking, and use an ordinary house chair.

For tools, a very few will suffice at first, but it may be as well to procure all tools likely to be required, as it is a business maxim that "to wait for necessary tools is time doubly lost." Herewith is a list of the tools required by an engraver, with their approximate cost, followed by a list of firms who deal in such tools:—

ENGRAVER'S OUTFIT.

	s.	d.
1 Sandbag or cushion on which to rest the work	2	0
1 Sandbag or cushion, smaller size	1	4
1 ,, ,, ,, smallest size		10
1 best Arkansas oilstone (any price over) ...	6	0
1 dozen Stubbs's square gravers (prices vary), say	2	6
1 dozen graver handles (prices vary), say ...	2	0
1 tracing or etching point (steel, with ebony handle)	1	0
1 Oil can		6
1 Burnisher (steel, with curved end, handled)	1	3
1 Scraper	1	3
½ dozen shading gravers, D threads (handled) Numbers 2, 4, 6, 8, 10, and 12 widths, at 1s. 3d.	7	6
½ dozen plain flat gravers of the above widths, at 3d.	1	6
1 pair Stubbs's spring dividers, say	2	0
Cement block, cement, oil, turpentine, pencil, indiarubber, and pounce bag, say	1	6
Practice plate (German silver, buffed or polished ready for work, about 1 lb.), say ...	2	6
	£1 13	8

BRASS AND ZINC ENGRAVER'S OUTFIT.

	s.	d.
1 Diesinker's chisel for outlining, say		8
1 ,, ,, for sinking the letters, etc.		8
1 ,, ,, wider than above		8
1 pair 12-in. compasses (steel points)	3	0
1 pair large spring dividers	3	0
1 T-square, straightedge, and rule combined, say	2	6
1 Sandbag, 12 in. in diameter when filled, say	4	0
1 Hammer (handled), say	2	6
1 small flagstone, 14 in. by 14 in. by 2 in.		
6 lbs. of cement, at 3d.	1	6
Zinc plate for practice, 3½d. per lb.		
Pumice-stone, water of Ayr stone, crocus, and lampblack for polishing, say	1	0
Archimedean drill and bits	3	6
Files	1	6
Bench vice	7	6
	£1 12	0

MANUFACTURERS AND DEALERS IN TOOLS, ETC., FOR ENGRAVERS.

J. Sellers & Sons, Arundel Street, Sheffield.—All tools. Manufacturers and dealers.

Peter Stubbs & Co., Manufacturers, Lancashire.—Lancashire tools and gravers.

J. Townley & Sons, Bull Street, Birmingham.—Tool dealers.

T. W. Woods, 60, Alderson Road, Highfield, Sheffield.—Threaded shading gravers only.

Starr & Son, Button Lane, Sheffield, Leather Merchants.—Engravers' Sandbags.

Tubbs & Wilkins, Great Hampton Street, Birmingham.—Engravers' cement.

Tucker & Sons, York Street, Sheffield.—German silver, brass, and zinc plates.

Buck & Son, Holborn Viaduct, London, E.C.—All tools.

The above tools are all of the very best quality, and are of the same make as those I use myself, and will cut anything between

Britannia metal and moderately hard steel. If the expense of the above outfit is too great, a smaller quantity may be got at first, the purchaser using his or her judgment as to what may be best dispensed with. The workman now being supplied with tools for a start, I will first deal with the oilstone, as being the most important; as without a good one the engraver cannot whet his gravers in a proper manner. In choosing an Arkansas stone, endeavour to see the whole of the stock of the dealer, and get him to tell you which are the hardest and which the softer stones. Choose a stone 6 in. × 2 in. × 2 in., at per pound weight. The stone should be quite white, without cracks or *yellow veins,* and of the second degree of hardness; such a stone will sharpen any tool in first-rate style, and in moderately quick time. Now take the stone to a cabinet maker, or, if the workman is handy with the chisel, he can mount the stone on a mahogany block (Fig. 5), inlaying it to the depth of ½ in., so that a *gentle tap of the mallet* will fix it. A new stone will not cut very readily, and to make it "bite" scrub it well on the face with a piece of gas-coke and plenty of oil, which will remove a gummy substance often formed on stones when they have been long in stock. The new stone will soak up a large quantity of oil on first being used. Do not forget to clean the stone occasionally, paraffin oil being an excellent cleanser. A useful form of oil can is shown in Fig. 6.

Whetting or Sharpening Gravers.

The method of whetting or sharpening gravers is shown in Fig. 19.

Take a new graver, and break off half an inch of the soft end or tang as it is called; now take a handle—the shortest one you have (Fig. 4)—and gently tap the graver home in the handle, using a bit of brass to stand the point of the graver upon while driving home. A hole is usually left in the handles for this purpose. Put some oil on the stone, and with the finger lay the oil evenly all over the surface. Now take the graver in the right hand and lay it flat on the stone, the bright side or belly of the graver downwards. Place the first and second fingers of the left hand on the end of the graver to keep it in position, and raise the handle of the graver five or ten degrees, still keeping the point on the stone (Fig. 8), then turn the graver slightly inwards and commence rubbing the graver up and down the stone, keeping the tool in the *same position* until the right-hand facet is formed, and then treat the other side of the belly of the graver in like manner. If these facets are formed truly, the line of sight on the belly of the graver and the angle of the newly-formed facets will be in a straight line (Figs. 7 and 14), although of a different level, and will enable the engraver to cut a perfectly straight or circular line at will. If this angle bears to the right hand or to the left hand, it will cause the workman to be unable to follow truly the line which he wishes to cut, therefore he must whet the graver again and again until he can see the

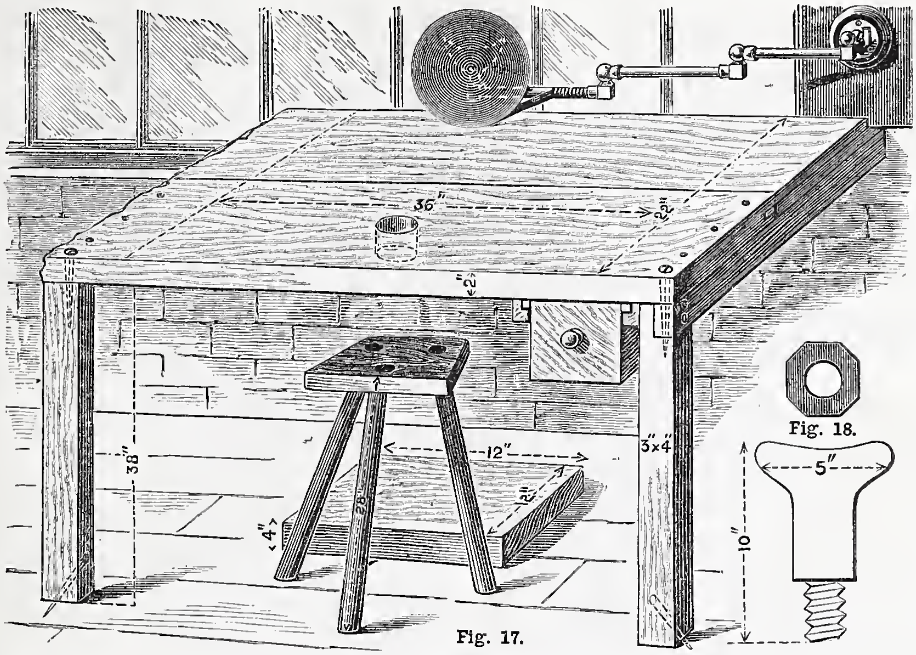

Fig. 17.—Engraving Bench, with Stool, Box for Feet, Gas Bracket, and Shade. Fig. 18.—Block for Large Hollow Ware, as for Dish Covers, etc.

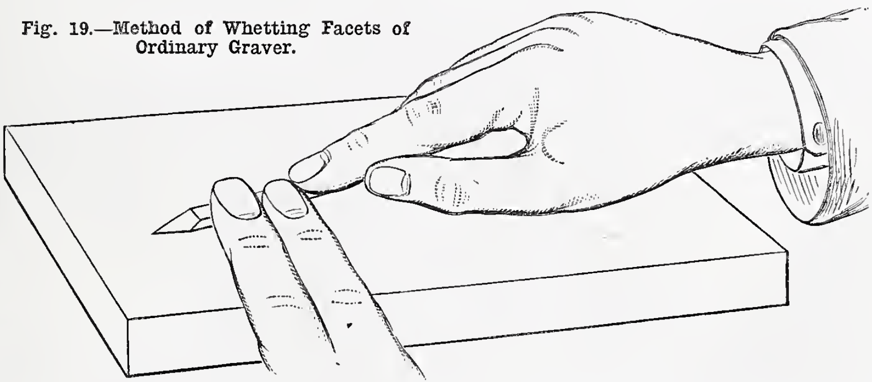
angle of his facets in line with the centre of the belly of the graver. This can be easily seen by holding the graver towards the light and looking along the belly of the graver. This is important, but after a little experience the engraver will be able to whet his tools to suit his own hand, and a little daily practice at whetting will enable him to whet a graver in a few minutes. Now turn over the graver with the newly-formed facets upwards, place the graver on the stone at an angle of 45°, and rub it on the stone until a sharp point is obtained, which may be known by trying the point on the thumb nail. If the point is dull it will slide over the surface of the nail, but if sharp it will cut the nail. Do not rub the stone always in the same place, but use it equally all over the surface, and wear the stone as evenly as possible. The operation of raising the graver handle when forming new facets is termed, "setting off" the graver, and the "set off" of a graver depends upon the kind of work to be done. Thus: the graver we have just whetted is to be used in cutting the plate we are about to mount on the cement block, therefore, being a flat surface and easily accessible, the "set off" of the graver does not require to be very great; on the other hand, if we were about to engrave the bottom of a cake basket (the bottom of which is some three or four inches deeper than the outside edge or mount), we should require a graver "set off" at an angle of 30° to 45°; and in the usual workshop economy of time, these kind of gravers are kept each for its particular purpose, so that it is quite an easy matter to have from fifty to one hundred gravers in use. These and other gravers will be dealt with further on. Meanwhile, should any young workman be unable to get over the difficulty of whetting a graver, if he will send it to me, through the Editor of WORK, I will whet for him a graver as a pattern. It is requested that the postage be paid both ways, as no charge will be made.

To return to the German silver practice plate. These plates may be obtained of a metal dealer at the rate of about 1s. 4d. per pound, according to the state of the metal market. It should be hammered flat by a silversmith, and afterwards buffed or polished, and cut into convenient sizes for mounting on the cement block. This block is a piece of mahogany, 6 in. × 6 in. × 1 in., plain sawn. The cement is called engravers' cement, and may be procured from an oilman. Should any difficulty arise, the cement can easily be made as follows:—Melt in a stone pipkin 1 lb. Swedish pitch—it can be done in an oven; when melted mix 1½ lbs. of plaster of Paris in the pitch while hot, thoroughly incorporating the mixture, and pour while in a liquid state upon the block, spreading evenly all over the surface; now warm the plate, lay it on the cement, and press it down firmly, which, when set, is ready to work upon. When another plate is required to be mounted, the cement can be warmed at the fire, or over the gas, taking care that in the latter case the cement is not smoked or burned. Take also particular care that none of the cement drops while hot upon the fingers, as it inflicts an ugly burn which takes a long time to heal. We have now the plate mounted ready to receive the design or pattern intended to be engraved.

There are many methods of teaching used by professional engravers, which, of course, vary with the individual. Some prefer to start the pupil on the work in hand, such work as tracing from the print, thus making the pupil of use from the first. Others will give the young workman a plate, such as I have described, and having whetted for him a graver, will allow him to quietly get used to the graver in his own way, giving him a few necessary directions from time to time as occasion requires. My own practice is to give to the young workman as great a variety of work as is possible, changing the character of the work frequently, so that it may not become monotonous. Thus, I give a little tracing from the print, cutting, dividing, or "setting out"

Fig. 19.—Method of Whetting Facets of Ordinary Graver.



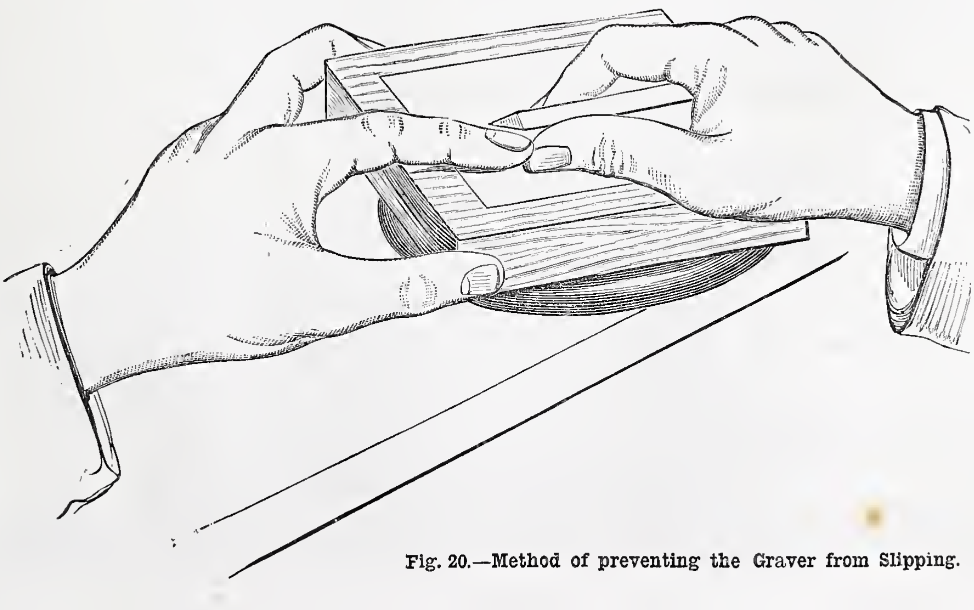


Fig. 20.—Method of preventing the Graver from Slipping.

my own work, with proper intervals for plate practice. However, for a start. take the block and stand it upon the sandbag (second size), B, Fig. 2, and with the spring dividers find the centre in the usual manner, and strike on the plate a number of circles, increasing in size till the outside edge of the plate is reached. Now take the graver in the right hand (Fig. 20), placing the handle in the palm, grasping firmly with the forefinger and thumb. Hold the block with the second, third, and fourth fingers and thumb of the left hand. Thus we have the first finger of the left hand at liberty to place in front of the thumb of the right hand, to guard against the "slipping" of the graver. The workman will now try to cut the smallest circle described on the plate (Fig. 9). He will find this somewhat difficult at first, but with perseverance and practice will soon get into the way of holding the graver. There is nothing difficult about it, except that the holding of the graver in the hand is, perhaps, different to that of any other tool. To resume: now place the point of the graver on the line of the smallest circle, gently raising the graver and pushing it forward till the graver begins to cut. Continue the cut, gradually turning round the plate towards the right hand, cutting towards the left hand, keeping the forefinger of the left hand in contact with the thumb of the right hand. The workman will find that the thumb of the right hand will slide over the work in the rear of the cut; this being the case, a leather thumb stall had better be worn until the end of the thumb becomes hardened. As it is necessary to be able to cut from left to right, as well as from right to left, which I have just described, the second circle must be cut in the reverse direction (Fig. 1, C to D)—viz., from left to right, using the same directions as for the centre circle. By this time the graver, what with slipping about and digging into the metal, will be quite dull, so all that remains to be done to renew the point is to give the graver a few rubs on the stone with the facets upwards, keeping closely to the original angle of 45°. Continue to cut the remaining circles by the above rules, alternately cutting to the right and to the left hands respectively.

The other tools that are illustrated, but to which no special reference has been made above, are a short or worn graver with long handle (Fig. 3); flat graver or scorper, sometimes called a "wriggling" tool (Fig. 10); back and belly of shading graver (Figs. 11 and 12); burnisher of oval section (Fig. 13); back and belly of angle graver for outlining, etc. (Fig. 14); back and belly of round-nosed graver for spotting, etc. (Fig. 15); and back and belly of flat graver (Fig. 16).

Having started the workman in the practice of engraving, I will in my next paper give a few directions to those workmen who have had a little practice, and are familiar with tools, and who wish to know something about lettering on brass and zinc, pewters, etc.

PURCHASING TIMBER.

BY B. A. J. H.

As the purchasing of timber seems to be a difficulty with many amateurs, I will offer a few suggestions, showing how to buy and what to ask for.

Many amateurs are in the habit of getting their timber from builders. This is a great mistake, unless you are willing to pay fifty per cent. more for your wood than if you bought it at a retail timber yard; and as there are now so many of them about London and the provinces, there should be no difficulty in going to one to buy what you require. Of course it must be understood that amateurs cannot buy their timber at the same prices as builders do; but it is possible to get it at a much lower rate than some pay by not knowing what to ask for; and I will endeavour to show how this can be done.

Many make a great mistake by taking a piece of string or tape with knots tied marking the lengths and widths they want. No yard keeper cares for this kind of customer, and frequently has his revenge by altering the knots while the customer is examining his piece of wood. Always take a two-foot rule with you, and should the salesman ask the loan of it, "as he has lost his," be careful that you get it back, as some are not very particular to return them. On the other hand, many customers borrow the rule and forget to return it when they have finished. Avoid unnecessary details in asking for your lengths, such as 3 pieces of 32 in. long, 8 pieces 24½ in. long, etc. Work your quantities out before you go to the yard into as few lengths as possible, such as 1–17 ft. and 1–8 ft., or 2–9 ft. and 1–8 ft. This saves the salesmen a lot of trouble, which they do not care for, and will also ensure your getting the right lengths, as in cross cutting they are not particular to an inch or two, causing much inconvenience if the stuff is cut wrongly. A charge of a ½d. or 1d. is also made in some yards for cross cutting, which they charge on the amount for the timber, and so it is not noticed unless you have asked the price per foot before having the stuff cut. Do not always expect to get just the lengths you want, as few yards have the room to keep every length of all sizes in stock; so it is as well to be prepared with other lengths that will work in for your requirements. For instance, if you wanted some 4 fts. and 3 fts., either 12 ft. or 18 ft. will cut; or ask for any length that will cut. I give a list with prices of the sizes kept in stock at most retail yards, which will be found very useful as a reference. Many writers in giving details of sizes of timber required to make or build greenhouses or such-like often give sizes that are never kept in stock, and upon the amateur asking for them at the yard he is at a loss to know what to take in the place of those sizes not stocked. The technical terms in the trade are often a stumbling block to the amateur, and up goes the price when he asks for a "plank" when he only wants a "batten." These errors mark him as a "green hand" at once. The following are the terms given to yellow, pine, spruce, and white deal, with their relative sizes, that are most likely to be required by the readers of WORK.

A "plank" is a piece of deal from 10 in. in width, and of any thickness, such as ½ in. by 11 in., 3 in. by 10 in., 2 in. by 15 in., and 4 in. by 12 in. A "deal" is 9 in. wide, and from 2½ in. to 4 in. thick, such as 3 in. by 9 in. (this size is generally understood when speaking of deals). A "batten" is the smaller sizes up to 3 in. by 8 in., such as 2½ in. by 7 in., 2 in. by 6 in., 2 in. by 4 in., 1 in. by 7 in., ¾ in. by 6 in., and 3 in. by 1 in; 2 in. by ¾ in. and 2 in. by 1 in. are known as "slate battens," used for slating, etc. Parts of planks cut deep and battens are known as planks and battens, while parts of a deal cut deep are known as boards, such as 1 in. by 9 in., and ½ in. by 9 in. A feather-edge board is thick on one edge and thin on the other, usually ¾ in. and ¼ in. thick, and is used for roofing sheds and garden fencing.

"Quarterings" are such sizes as 4 in. by 6 in., 4 in. by 4 in., 4½ in. by 3 in., 3 in. by 3 in., and 3 in. by 2 in.; and the smaller sizes are called "scantlings," such as 2 in. by 2 in., 2 in. by 1½ in., 1½ in. by 1½ in., and 1 in. by 1 in., etc.; such sizes as 2 in. by ½ in., 2 in. by ⅛ in., 1 in. by ¼ in., are known as "laths." "Floor boards" are generally stocked in the following sizes: 1¼ in. by 6 in. and 7 in., 1 in. by 6 in., 6½ in., and 7 in., ⅞ in. by 6 in., 6½ in. by 7 in., ¾ in. by 6 in. and 7 in. Matching, that is to say, battens which match together lengthways with a groove and tongue, are 1 in., ¾ in., ⅝ in., and ½ in. in thickness, and from 4 in. to 7 in. in width. 1½ in., 1¼ in., 1 in., and ¾ in. by 9 in. planed boards are now stocked at most yards, and the difference in price between the prepared and the unprepared is very little. But in ordering all planed goods an allowance of ½ in. in width must be made on each board for the planing. The following is a list of sizes and prices, which vary according to quality.

PLANKS.

In. × In.	Yellow.	White.	Pine.	Lengths.

5¾	210	9	140
6¼	200	9½	130
6½	190	12	100

If several lengths of one size are required, it is cheaper to buy the planks or deals cut instead of buying them as boards or scantlings. For instance, say you want three 12 ft. 1 in. by 9 in., ask for 12 ft. 3 in. by 9 in., 2 in. deep., *i.e.*, a 12 ft. of 3 in. by 9 in. with two equal cuts through the 9 in., making three 1 in. boards; or six ½ in. by 9 in. ask for a five-cut deal; four ¾ in. by 11 in. ask for a three-cut plank.

In quartering or scantling the deals are cut "flat," *i.e.*, through the 3 in., thus: one flat cut 3 in. by 9 in. = two 4½ in. by 3 in.; two flat = three 3 in. by 3 in.; or one deep and five flat — twelve 1½ in. and 1½ in., and so on. A lower rate is generally charged if the deal is taken, as it does not leave the yard keeper a lot of odd boards, mostly "outside" ones (*i.e.*, those boards cut from the outside of the deal, the rest being known as "inside;" thus there are two "outside" and one "inside" board in a two-cut deal), to get rid of.

The usual price charged for cutting is 3d. per 12 ft. deep cut 9 in., and 1s. per 100 ft. 3 in. flatting; so in asking for three 12 ft. 1 in. by 9 in. you would be charged 1s. 3d. each, while for a two-cut deal (*i.e.*, the same under another name), the price is 3s. 6d.; being 3d. per foot for the 3 in. by 9 in., and 3d. per cut.

Most yards stock pine, yellow, white, and spruce, and sometimes mahogany; but you will find that you can buy the hard woods, such as mahogany, walnut, oak, beech, etc., better and cheaper at those yards where only hard woods are kept. These are sold at per foot super, the price varying according to the figure in the wood. Timber merchants, as a rule, deliver free any reasonable distance if a fair amount is ordered, say 10s. or 15s. worth, although such orders as 5s. are sent home if near the yard.

OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

100.—Nurse's Regulator.

That everything comes, sooner or later, to him who is willing to wait for what he wants, is a saying which borders very closely on being an actual and positive truth, and one with which I have often effectually consoled myself when placed in a position of desire and difficulty, and have endeavoured to console many of my readers who labour under the impression that their wants are neglected and their wishes ignored, because they do not get what they ask for immediately after the ceremony of asking has been performed. Now, for years I have been waiting very patiently for a contrivance that would adjust the plane-iron in any wooden plane as perfectly as it is done in some iron planes of American origin, and I have met with it at last in Nurse's Regulator, which satisfies all my wants and wishes in this respect and leaves nothing to be desired.

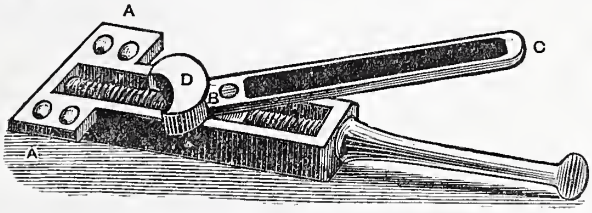

Fig. 1.—Nurse's Regulator for Adjusting Plane Irons.

When I first saw the invention which has been introduced by Messrs. Charles Nurse and Co., Plane Makers and Tool Merchants, 182, Walworth Road, London, S.E., the brass thumbscrew, which shows itself above the top of the plane iron, as may be seen on reference to Fig. 2, put me very much in mind of another plane similarly fitted, to all appearance, which was introduced some years ago, and which, at first sight, I thought likely to answer the end in view, but when I came to remove the wedge and plane iron from the specimen plane sent me by Mr. Nurse and examine the regulator, it soon appeared that the similarity which seemed to exist between the two planes was apparent only, and by no means an actuality. The plane of which I am speaking was an iron plane with a single plane iron, and a piece about ½ in. wide and 2½ in. long was cut in the upper part of the plane iron in the direction of its length to admit of its passage up and down on either side of a piece of iron projecting from the plate on which the plane iron rested, and which carried a screw which worked in a bar with nut in its projecting centre in which the screw worked, and by means of which the plane iron was adjusted. The worst feature of the plane was that the adjusting screw was not made as nicely and truly as it might have been, and the consequence was that the adjustment when effected was soon liable to derangement.

Now I must confess myself to having a strong preference for wooden planes, and a great disinclination to use an iron plane if a wooden one was within reach, but there is a good deal of trying and tapping and looking along the sole of a wooden plane when the iron has to be adjusted, which is simply a matter of course to a professional workman who is handling a plane pretty well every day and all day, but which is decidedly troublesome to an amateur with a minimum of practice, especially if his sight is not so good and keen as it used to be in days gone by. One of the principal reasons for the extensive sale of the American made iron planes in this country has been the ease with which their cutting irons can be adjusted to their work without having recourse to the use of the hammer, and the object of the present invention is to make the ordinary wooden-bodied bench planes, so generally in use throughout this country, equal to the very best American iron planes, as regards the ease with which the cutting irons can be adjusted whilst retaining the distinctive advantages of wooden planes over metal ones.

The general design of the invention is shown very clearly in Figs. 1 and 2, of which Fig. 1 shows the regulator itself and its general appearance, and Fig. 2, by means of a sectional drawing, its mode of application to the plane. Every one who has used a plane and removed the iron for the purpose of sharpening it, will remember that there is a groove in the body of the plane behind the plane iron in which the head of the short screw that holds the two irons together is received. The top of this groove is widened by cutting away a little of the wood on each side to receive the flanges, projecting from the bottom of the brass framework of the regulator as shown at A A in Fig. 1. These flanges are fastened to the body of the plane with brass screws. Lengthways through the frame passes a $\frac{3}{16}$-in. screw, secured both at top and bottom, and terminating at the top in a thumb-piece by which it is worked. Upon this screw works a nut, not very perceptible in the drawing, from which projects a small circular plug, B, by means of which the lever, C, is riveted to the nut, and on which it turns. At the lower end of the lever is a raised semicircular or rather crescent-shaped disc, D, which fits into the round eye-hole always found in planed irons of the English pattern at the upper end of the slot, by which the cutting iron is enabled to be brought down below the edge of the upper iron as it gets ground away, and also to admit of the proper adjustment of the two irons for finer or coarser work. By means of the screw, the plane iron can be easily raised or lowered, as may be required, the lever being used to the parallelism, or otherwise as desired of the edge of the cutting iron with the mouth of the plane. This will be clearly understood by reference to Fig. 2, in which the body of the plane, the wedge, the double-plane iron, and the regulator, properly fitted to the plane, are shown in section. It will be noticed that the planes made by Messrs. Nurse & Co. are fitted with a scroll wedge to allow of its easy removal with a slight tap or two of the hammer. The distinctive feature of the regulator is that it can be easily applied to any bench plane, whether smoothing plane, jack plane, or trying plane, it not being in any way needful that it must be a plane of Messrs. Nurse and Co.'s make to which it is applied. The price of the regulator is only 2s., or 2s. 3d. post free.

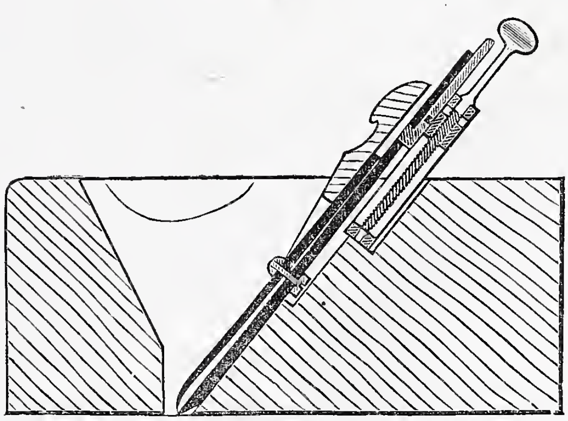

Fig. 2.—Section of Smoothing Plane fitted with Regulator.

I daresay many of my professional readers are well acquainted with Messrs. Nurse & Co.'s name as plane makers, and are quite aware that their name when attached to any tool is an absolute guarantee of its goodness. I heartily wish every tool maker would brand his tools with his own name and not with the names of the retail dealers who merely sell them. Messrs. Nurse & Co. have been plane makers, first at Maidstone and now in London, since 1841. At the International Exhibition of 1862 they obtained honourable mention for the superior workmanship shown in their planes.

The Editor.

SHOP:

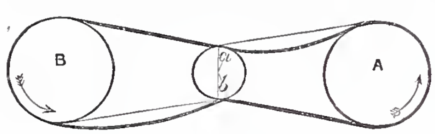
A Corner for Those who Want to Talk It.

*** Notice to Correspondents.—*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

I.—Letters from Correspondents.

Elizabethan Twist.—C. C. E. (*Lincoln*) writes:—"The letter from W. P. W. (page 332) is about a fortnight after date. I have before me, by the courtesy of W. P. W., the piece of pine therein mentioned, which is in no sense an Elizabethan twist. Also I have a spiral cut for me in mahogany, which, though a credit to his ingenuity, is not one either. It seems that we need a definition of an Elizabethan twist. I am informed on the highest authority that it is of Italian origin, and was introduced into England in Elizabeth's reign, and so much adopted for furniture that it received her name. I have specimens of it in chairs made in Italy, and also in others made in her reign. It may be described as a cylinder wound around itself, the whole spiral twisted around an axis contained within itself—the spiral being of such a rate or pitch that one complete revolution extends a length along the said axis, not less than twice its own diameter, and the spiral is such that any section taken at right angles to its own axis or path will be a circle. When I spoke of making a convex curve die into a concave without a break, I was, of course, referring to the twist under discussion, for the operation with a double quarter hollow drill or cutter, for any one definite size, is one of the easiest to any fairly-advanced amateur. The 'pea' in dispute will take a great amount of 'shelling' even by W. P. W. There is, as I intimated in a previous note, no probable difficulty in producing the Elizabethan twist—viz., in a copying lathe, having an iron copy for each rate of twist; but this is not within the compass of an amateur's lathe, and twist from a copying lathe would need, like spokes and gunstocks, to be finished by rasps, files, paper, etc. The work then ceases to be legitimate turning."

Saw Belts Slipping.—J. P. A. (*Walthamstow*) writes *re* belts slipping (page 365, No. 23):—"There is a point not mentioned that is as important as any—that is, the loose side should always be on the top, then the greater the strain the more bite the



Saw Belts Slipping.

belt gets of the pulley, whereas if the loose side is at the bottom there is the more strain, and the less hold the belt gets of the pulley. In the sketch the hold from A is increased by a, and from B decreased by b."

About Work.—A. B. (*Chatham*) writes:—"I quite agree with Kildonan in his protest against enlarging Work and the price. A penny is within the reach of all, and no workman minds paying that for a paper in which he takes an interest; but when it is above that figure, he soon begins to mutter about his not being able to 'run to it,' and 'let them have it that can afford it.' Work is a most valuable paper for the working classes, and, I think, intended for their benefit. I think, therefore, nothing should be done to place it beyond their reach. If not at present, Work will eventually derive its greatest number of subscribers from the poorer classes, and their numbers will more than compensate you for the loss of a few 'imitation gents,' whose hardest work is the bit of carpentering they do for amusement. Those who wish to keep their papers for binding, can easily sew on a cover made of brown paper or newspaper, which would keep their paper quite as clean as a tinted cover from the publisher, and the advertisement page could be pasted over with a picture or drawing. I trust you will not give way to those selfish people who want the paper filled with articles on their own particular trade or hobby; nor do I consider it a good suggestion to give designs and plans of houses, for although a man may make his own boots, clothes, tables, etc., there are very few who have either the time or money to build their own houses. I have now a few suggestions to make in regard to the articles in Work. They are that, while you are giving us lessons in the iron and wood trades, you will not forget those that more nearly affect the home of the humble bread-winner. I refer to the tailoring and shoemaking. When I inform you that I am a journeyman baker, you will not think I am speaking from altogether selfish motives; but how many poor men are there like myself who are always wanting their boots repaired, but can ill afford the three or four shillings charged by the shoemaker? With a piece of leather and a few nails (costing about tenpence), and a few directions in Work, the job is done. Then, again, we could often convert an old suit of clothes of our own into a new one for 'the boy,' if we were only taught how to do it. And lastly, if you would teach us to rivet together our broken earthenware and glass, you will be conferring a great benefit on the hard-working poor."

Combined Bench and Tool Chest.—Mancuniam (*Manchester*) writes:—"I first came across Work by accident, as I was looking for another paper, when I was attracted by the placard of No. 1. So I bought one, and could see it was just the thing I wanted, as I take delight in such things as a hobby. My earlier attempts have been small things, such as a match holder to hang on the wall, or pipe rack, etc., which I have made with a knife; but since reading Work I have got to understand the use of tools, and have bought some secondhand, as I could not afford to buy new ones. The drawing shown in Fig. 1 is what I have made with them;

Fig. 1.

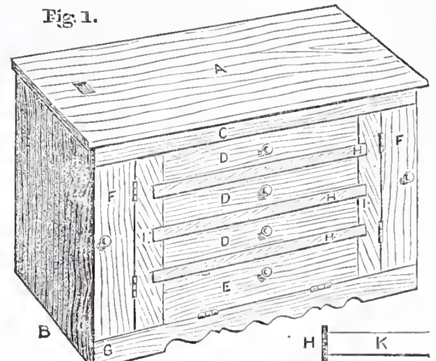


Fig. 2.

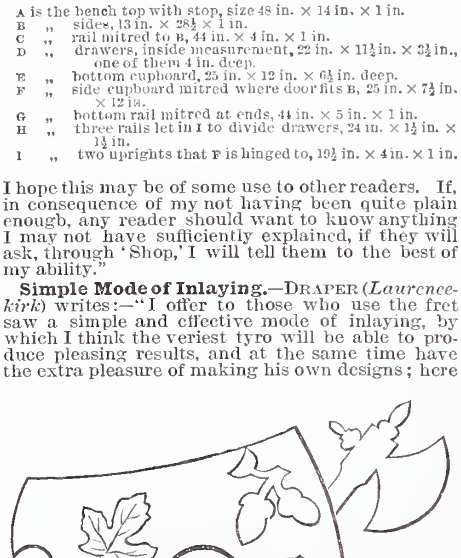
Combined Bench and Tool Chest.

the idea is from Melhuish's Illustration of Tool Cabinet and Work Bench, on advertisement page, which shows that the page is not useless, even to those who can't buy the articles thereon, as some readers complain. It is fastened together by screws, which are sunk below the surface of the wood, then round pieces of wood are glued and forced in, so that the surface is not disfigured; the drawers come over the recess as in Fig. 2, in which H is front of drawer and K the recess. B, C, G are mitred where they meet one another, as is also F, where it meets B, so as to take away the bad look it would have if made to show the cross grain, as I have no bench holder to keep it steady while I plane it. The following is the explanation of Fig. 1:—

A is the bench top with stop, size 48 in. × 14 in. × 1 in.
B " sides, 13 in. × $28\frac{1}{2}$ × 1 in.
C " rail mitred to B, 44 in. × 4 in. × 1 in.
D " drawers, inside measurement, 22 in. × $11\frac{1}{2}$ in. × $3\frac{1}{2}$ in., one of them 4 in. deep.
E " bottom cupboard, 25 in. × 12 in. × $6\frac{1}{2}$ in. deep.
F " side cupboard mitred where door fits B, 25 in. × $7\frac{1}{2}$ in. × 12 in.
G " bottom rail mitred at ends, 44 in. × 5 in. × 1 in.
H " three rails let in I to divide drawers, 24 in. × $1\frac{1}{2}$ in. × $1\frac{1}{2}$ in.
I " two uprights that F is hinged to, $19\frac{1}{2}$ in. × 4 in. × 1 in.

I hope this may be of some use to other readers. If, in consequence of my not having been quite plain enough, any reader should want to know anything I may not have sufficiently explained, if they will ask, through 'Shop,' I will tell them to the best of my ability."

Simple Mode of Inlaying.—Draper (*Laurencekirk*) writes:—"I offer to those who use the fret saw a simple and effective mode of inlaying, by which I think the veriest tyro will be able to produce pleasing results, and at the same time have the extra pleasure of making his own designs; here



Simple Mode of Inlaying.

is one for a photo frame. For this design take a piece of $\frac{3}{16}$ in. oak with rich figure, paste on design with strong starch; pierce small holes at a point in the leaves, and cut out with finest fret saw; put the cut-out patterns in an air-tight tin or box, with a piece of ammonia, and allow them to remain in the box, say, overnight; then glue the edges well (Lépage's liquid glue is the best), and insert the pieces in their respective places. Take a little fret saw dust, and rub well in to fill up the space made by the saw in cutting. See your frame is lying quite level before you leave it to set; after it is quite dry, sandpaper smooth and French polish. Before you glue in the fumigated pieces, allow them to lie exposed for a day, otherwise they will darken the body of the wood. The axe and handle might be fumigated, or a pleasing effect is given by coating the axe with 'diamond' silver powder. If the frame is made of mahogany, darken the leaves by saturating in lime water."

Stencil Cutting.—J. F. (*Elgin, N.B.*) writes:—"I see in No. 23 of Work instructions as to cutting out of stencils (see page 364). I have nothing to say by way of correction as to the method described by R. A., only I find a far simpler and quicker plan which I have done successfully, so I write to explain it should you think it worth your trouble. I should say first it will only be of use when it is zinc that the stencil is to be cut out of. Take a piece of zinc, and instead of painting on the letters, leave them clear, painting all the rest of the zinc, as likewise the ties (it is black japan I use). When it is dry, place it (the zinc) over a basin (earthenware) and pour on a quantity of raw spirits of salt; the letters being clear will fall through as the spirit eats into the zinc; then wash off the acid, and finish off the burr with a sharp knife. I omitted to say, before japanning the zinc, it has to be set up $\frac{1}{4}$ in. all round, and corners soldered. I hope this may be of some use to some of my brother tradesmen. Now, dear sir, what about sheet metal workings? Are we ever to be favoured with anything practical on the above? It is long since it was to appear, but it seems as far away as ever, while things promised but quite recently have appeared, as also things that were never asked for. It is all very well those lessons on soldering for amateurs, but it won't do for those who have learned, or are learning, the art; there is not one apprentice that I have come in contact with but knows all that has been related in those papers before he has been one year at his trade. This with all deference to Work, which I appreciate."

Battlesden Cart.—Homespun (*Tenterden*) writes in reply to Opifex (see page 295):—"In the first place I should recommend the worker to make a full-size working drawing, with chalk, on a plastered wall, or any suitable place, showing both side and back sections; this is of the greatest importance. To draw the wheel, first find the centre, in which drive a bradawl or wire nail, then with a piece of string, and chalk, draw a circle the required size, from which you will be able to see if the cart is likely to balance when finished. While making this drawing, I shall expect the worker to make many alterations until it is to his own satisfaction; when finished he will be able to get all his bevels with the greatest ease. I must now call your attention to Fig. 17 (details Battlesden cart, July 27th): If the seat-rail was 4 in. wide in place of 3 in., it could be screwed on the top of solid sides, which would make the cart deeper if required. If an extra length were left on the bottom of Fig. 13. and turned to the required angle, to screw to the solid side, Fig. 18 would not be required. Before fixing the top sides, or rails, wet them on the in or convex side, holding the outside to the fire; they then can be bent to the required sweep, and fixed without fear of splitting. Over the screws tack a wood valance 2 in. wide and $\frac{3}{8}$ in. thick, plane outside, chamfered to $\frac{1}{8}$ in. at top edge on inside as per section (Fig. 23). Before hanging the tailboard, please read, mark, learn, and inwardly digest the chapters on butts in a previous issue. Previous to fixing the dash, it would be advisable to fix two plates, called bracket plates, made of half round iron $\frac{3}{8}$ in. thick, and about $\frac{7}{8}$ in. wide, to go about 6 in. on front, to hold front corner together, and prevent corner from splitting at A (Fig. 4). The transom, or shaft bar, should be mortised into the shaft $\frac{1}{8}$ in., no more, to prevent it from shifting, as shown (Fig. 10). I should recommend side springs with 3 in. more compass, and a spring block 2 in. deep in the place of 5 in. With his 5 in. block I do not wonder be recommends a solid flap axle, or the spring clips would soon get loose, and the cart would rock about. If any of our readers have succeeded in making a cart from the instructions given by Mr. Opifex, I am certain that they could make their own wheels, and box them, so as to have a vehicle of their own construction. If no abler pen than mine takes the matter up, it would be my greatest pleasure to assist them. I do not wish to commence a hair-splitting controversy, or throw cold water on Mr. Opifex's good intentions; what I write is for the benefit of those who are willing to learn."

An Easily-Made Fret Machine.—E. J. A. (*Reading*) writes:—"In Work for August 10th (No. 21, page 332), W. R. S. has described (?) an easily-made fret machine. I am more than surprised that an Editor of a magazine printed and published by Cassell & Co. should have allowed so much valuable space to have been wasted with a description of such a machine. [Are you? Read on a little further.—Ed.]. How and where is the wheel to be fixed? How, in the name of common sense, can W. R. S. get a vertical stroke if the bar, A, is joined to the arm, C? I can understand its working if the end of the brass bar were made with a straight slot; but in the machine under notice, if the iron guides, B, B, are fixed, I fail to see how W. R. S. can get any stroke. I hope W. R. S. will see the error of his ways."

An Easily-Made Fret Machine.—W. R. S. (*Brixton*) writes :—"HIGHBURY, N., in page 411, says that if the above machine was made according to the illustration it would be impossible to work. He is quite mistaken, considering that the original from which the illustration was drawn has been in use for over twelve months. I shall be quite willing to show it to him at any time he may mention (the Editor has my address). Meanwhile I am anxiously waiting to see the sketch of the machine as corrected by him, asked for by the Editor on page 411."

An Easily-Made Fret Machine.—W. R. S. (*Brixton*) writes in reply to ANXIOUS (*Barnoldswick*) (see page 411):—"You ask how the fly wheel should be suspended. The axle should be fastened firmly to a bench so as to allow the wheel to work easily. In reply to how long the bars of iron should be, mine are eight inches, but they could be made whatever length would be suitable for fixing them. They are both fastened down to a framework, which does not appear in the illustration, and which he must use his own discretion in making. He must remember that the better the pipe, A, works in these bearings the more successful will the machine be. I hope this will fully explain any difficulties which he may have met with, and will be glad to know if he is successful in making the machine."

An Easily-Made Fret Machine.—W. R. S. (*Brixton*) writes in reply to MANCUNIAM (*Manchester*) (see page 412):—"You ask how does C cause A to work vertically? The bottom part of C is fastened to the wheel, and the top part only to the shaft, so that when the wheel revolves the treadle crank pushes up A till it gets to the top, when the crank draws it down, and so on."

Cane Furniture.—J. P. A. writes :—"I made a window stand for flower-pots out of the canes sold for garden sticks. Some were ⅜ in. in diameter and some ⅝ in. Generally there have been six 5-in. pots on each shelf for months, so it bears some weight, and I do not suppose it cost 2s. altogether. I will give my experience on that job, if you think it worth while."—[By all means give your experience in this particular branch of work.—ED.]

Harmonium as Blast for Furnace.—G. H. (*Bradford*) writes :—"No doubt many readers of WORK possess a harmonium or American organ, which they have never dreamt of using for purposes other than charming the savages next door. I am in possession of a small harmonium, and some time ago, wishing to make some brass castings, I conceived the idea of making it act as a blast for my furnace—the kitchen fire. Acting on the spur of the moment I placed the instrument with its back to the fire, bored a hole 1 in. diameter into the reservoir, inserted an iron pipe 6 ft. long, one end of which I put between the bars of the grate, and I had a powerful continuous blast. I have since fitted pipes with suitable bends and couplings, so that my box of music can retain its normal position, and I can at any time attach suitable jets for smelting, smiths' work, brazing, or glass blowing. Further particulars if desired."—[If I possessed a harmonium or American organ I should certainly refrain from treating it as you have treated yours; but, nevertheless, there may be some who might be inclined to follow your example, so I give the latter portion of your letter. The first part I am compelled to omit, partly through want of room, and partly because it would serve no useful purpose to put it into type.—ED.]

Flat or Dead Black.—In reply to F. P. (*Newport, Mon.*) (page 334) OPIFEX writes :—"This correspondent has written a long objection—occupying eighteen lines in 'Shop'—to my 'tip' for quick drying flat black (see page 218), which he characterises as a 'roundabout recipe,' yet it occupies only three and a half lines in the larger type of the other columns of WORK. But although this hundred-galloner grumbles, my poor little tip survives unaltered, as by F. P.'s showing—and he is a professional—drop black, turpentine, and black japan are correct ingredients, for though he substitutes gold size as a binder, and suggests 'any copal oil varnish' as an alternative, which will answer equally well, every one who knows the composition of black japan is aware that it also will answer equally as well as any of the binders mentioned. On the whole, I am obliged to F. P. for his growl, also for having corrected me as to the name of the black. I certainly ought to have written 'drop ivory black,' but thought at the time that every one knew it familiarly as drop black. With regard to the direction that the black should be 'purchased already ground in turpentine,' allow me to point out that amateurs, for whose benefit 'Tips for Tyros' are chiefly intended, do not generally make up their quick black by the 100 gallons, and that it will, therefore, suit them better to grind what they require as they need it. I am sorry to take up so much space in defending my 'tip' from assault, and only hope that all its brethren may prove as much in accordance with 'the results of practical and professional experience and usage' as F. P. has shown this one to be."

Cheap Bell Chuck.—I. L. (*Glasgow*) writes :—"Referring to your article 'A Cheap Bell Chuck,' I would suggest that a diminishing coupling be got from the pipe works without being screwed, or if the tap be sent to the works the smaller end will be screwed by the make, and the larger end left plain; this would give additional strength for screws. Any size can be got on ten minutes' notice; at least it can be got in Glasgow."

Frame for Wardian Case.—J. N. M. (*Salford*) writes with reference to remarks on this subject by W. P. (*Southport*) in No. 19, page 301 :—"I have been hoping to see in WORK something about a wardian case, and having just received my monthly number I have found what I wanted, but not enough of it. I should take it as a favour—and possibly others would—if our friend, W. P. (*Southport*), would explain the *joints* he uses to connect (1) The base of the case. (2) The corner upright astragals to the base. (3) The corner upright astragals to the horizontal astragals. (4) The bevelled astragals to the base and top respectively of the wardian case top. Possibly small diagrams would save much writing and space."

Hand Saw Bench.—J. L. (*Elgin*) writes in reply to B. F. (*Liverpool*) (see page 382) :—"I notice in 'Shop' a description of hand saw bench in which an error has crept in which would overthrow the very first principles of applied mechanics. B. F. says (or is made to say) 'the smaller the pulleys are the greater the speed on saw, but the larger they are the less power.' Surely this is quite the opposite of what he means, for as you lose speed, by using larger pulleys, this will cause a gain of power. I have a bench of same make (my own) by which I do five different processes—viz., ripping, squaring, grooving, beading, and tenon cutting."

II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

Emery Wheel.—J. C. (*Hull*).—You can buy an emery wheel much cheaper and far superior to any that you could make. If you attempt it you will probably have the fragments flying about your head. Churchill, or Buck & Hickman, or Selig Sonnenthal can supply what you require.—J.

Galvanometer.—W. G. G. (*Brighton*). A fully-illustrated description of a galvanometer will be forthcoming in WORK when room can be spared for the article. The construction of coils and galvanic batteries will also receive attention in due time. Space cannot be taken up in "Shop" in showing how to construct galvanometers, coils, and batteries.—G. E. B.

Edison's Chronograph.—R. D. (*Paisley*).—I am told that the needle or stylus in Edison's new phonograph is made of steel, and is fixed to a mica diaphragm by means of a very small nut and screw. Perhaps some reader will kindly oblige R. D. with a detailed account of the diaphragm and stylus of Edison's new phonograph.—G. E. B.

Tire Cement.—BICYCLE (*Rainham*).—A fairly good tire cement at 1s. per lb. from W. A. Lloyd, Waeman Street, Birmingham. Holdtight cement, 1s. 6d. per lb., from Wm. Bown, 308, Summer Lane, Birmingham. Rockbill's cement, 4s. per lb., Wm. Bown as above.—A. S.

Watch Materials.—PORT VICTORIA (*Rochester*).—You can get eyeglasses and watchsprings at Grimshaw's & Co., 35, Goswell Road, Clerkenwell, or at any of the tool shops in Clerkenwell. The best eyeglass I find is the cork frame; they are lighter to hold up, and give to the shape of the eye, and if dropped does not chip like the horn frame. The price is about 1s. each, the horn being about 10d. each. Any material may be had same place.—A. B. C.

Wood.—A. W. (*Hampstead*).—Messrs. R. Melhuish & Sons, Fetter Lane, London, E.C., would probably be able to supply the wood you require. Some years ago S. A. Mitchell, 100, Curtain Road, E.C., used to sell me similar wood, but having no occasion to send him orders lately, I cannot say whether the address would find him now; his prices were reasonable, and the stuff always correct to order, and satisfactory in every respect.—E. B. S.

Mechanics.—NEMESIS (*Manchester*).—The following are two suitable books upon the subjects you refer to :—(1) "Practical Mechanics," by Prof. Perry (3s. 6d.), Cassell. (2) The above, and Rankine's "Civil Engineering," 12s. 6d., Griffin & Co., 12, Exeter Street, Strand, London.—F. J. C.

Painting Iron Bedsteads.—J. R. (*Liverpool*). If, as I presume, you have no facilities for japanning your iron bedsteads, you cannot do better than renovate them with enamel paint. I do not know that any one brand of these has a superiority over all others, so that it would be invidious to name one make to the exclusion of others. If you want to encourage local manufactures, get the "Falcon" brand. Minton's is also another local make. You will find either of these enamels quite equal to Aspinall's, which needs no comment. At Lewis's you will get yet another make, so that you have a choice of at least four, all of which I can recommend from personal use, but I cannot take upon myself to say that one is "the best." There is no particular mode of application that I can tell you of, as I suppose you know enamel, like other paint, is laid on with a brush. Be careful to remove any traces of grease from the work before painting, and if the previous coating is chipped, smooth it down.—D. A.

Hairspring Fixing.—THIRTY-HOUR MOVEMENT (*Liverpool*).—I have always the same difficulty in getting a new hairspring for any of those American movements, and from your query I should say your spring is very much too strong; try and change it for one much weaker at the shop you bought it. If you cannot get one weak enough take the spring from the brass collet in the centre, get a cork larger than the diameter of the spring, and put the spring on a sharp cutting oilstone, and grind the spring down; the cork will keep it flat on the stone. This is a quick and easy plan of weakening a spring, either stock or watch, although it makes the spring narrower, and is inclined to make it wobble in working, unless done carefully. In grinding, press firmly on the cork, and work it in a circular manner, and use plenty of oil with a little paraffin in it, then clean in benzoline, and repeat the dose till going to time; if not successful write again.—A. B. C.

Simple Subjects.—C. E. (*Lydney*).—Your letter is one I should much like to answer with some advantage to yourself, but it is by no means easy to do so, as though you want a description of something simple, you do not say in what craft or trade you want assistance. From what you say I may assume you would find working in wood, *i.e.*, joinery, cabinet making, carving, etc., the most suitable subjects to take up. Of course we want to encourage rising talent, but at your age you really cannot expect to be able to make much. Being, as you say, only thirteen years old, you naturally have still to acquire the very rudiments of tool handling and working, and much as we should like to help you we really cannot devote much space to describing such very trifling things as it may fairly be imagined are within your comprehension and ability. Take my advice if you will, and read WORK carefully. Much that appears in it is doubtless beyond you now, but then, you know, you are not always going to remain "only thirteen," and with increasing years no doubt you will acquire increasing powers. Although you may not yet be able to make many, or even any, of the things described in WORK, you will gain a fund of information which is sure to come in useful when you reach the years of manhood; and I am sure so sensible a lad as you will not be discouraged at being told you must learn the rudiments before you can hope to achieve success. Now supposing you read our articles on jointing up, and put in practice the directions given—in other words, try your hand at joining boards by the methods described. Though you may not by so doing make anything, you are learning a most useful lesson, which will stand you in good stead when you undertake to make a piece of furniture. Certain tools are mentioned in the articles referred to: get and become proficient in them. In "Lessons from an Old Bureau" you will also learn a good deal, though you may not be able to make a bureau yet. In fact, the same may be said about any of the articles which have already appeared or will appear in due course. Try your hand at making a box, and put in practice the remarks about dovetailing, which you will find in connection with the drawers of the bureau. Then, if you do not understand how to use a plane, read the article in No. 20 referring to this tool, and follow the same course with regard to others. By this means you will attain proficiency, and there is no other way, however tedious it may seem. I have answered you at some length, as, though you will see WORK is for workmen, every one must have a beginning, and I am pleased to see one so young as you taking an interest in useful mechanical pursuits. If you will suggest any little thing which might be described for the benefit of yourself and others similarly circumstanced, I will, if a description seems likely to be of general interest, try and arrange for a paper on it.—D. A.

Plough, etc., Plane.—H. S. (*Salisbury*).—Miller's combined plough, fillister, and matching plane is undoubtedly a useful tool, though whether you would find it more serviceable than the separate planes, which it supplies the place of, is more than I should like to say. It is really a point for you to decide for yourself. You are no doubt aware that combination tools, however ingenious, are seldom in every respect equal to all the various things they represent, their greatest advantage perhaps being that less space is occupied by having several things combined in one. As a matter of personal opinion, I prefer the various things combined in Miller's plough, etc., in their separate forms, and in saying this I do so without in the smallest degree reflecting on the efficiency of the combination. Were I constantly travelling about with a quantity of tools, when bulk would be a consideration, I should probably decide in favour of the combination. In case cost may have anything to do with your decision, it may be well to remind you that though the best tools separately would together be more than the combination, this is cosiderably more than you can obtain the lot in lower quality for.—D. A.

Brass Lacquer.—W. J. H. (*Oldham*).—I can hardly understand whether W. J. H. wants a recipe for the making of lacquer or for the application of the same to brass work. If the former, I would suggest that good lacquer can be bought in small quantities cheaper than it can be made by an amateur. But supposing W. J. H. wants it in large quantities, I will, however, try to meet his wants. As there are various colours required for different purposes, it would have been better had he said for what precise purpose he wanted it. 1½ oz. best pale shellac, 1 pint methylated spirit, 10 oz. silver sand, well washed, or powdered glass, put altogether in a bottle, and let stand for a day or two until the shellac is dissolved. It must be occasionally shaken. Let it now stand until quite clear—the fine sand in settling will carry down the other impurities—and pour off. A little spirit may be added to the sediment to dissolve out any remaining gum, and after settlement it may be added to the stock—this we will call No. 1. Take 1 oz. of dragon's blood dissolved in 1 gill of spirits, treating it in the same way as the other—this we will call No. 2. By adding this in small quantities to No. 1 we can get the depth of colour needed. The following recipe is given for philosophical instruments:—Gum gutta 12 drachms; gum sandarach 2 oz.; gum elemi 2 oz.; dragon's blood 1 oz.; seedlac 1 oz.; terra merita 12 drachms; Oriental saffron 2 oz.; powdered glass 3 oz.; alcohol 20 oz. These must be dissolved and treated in the manner before described. The article to be lacquered must be polished until all scratches are removed, and then pickled in pickling acid, then removed and washed in hot water, and dried in boxwood sawdust. Care must be taken that no part is touched by the fingers, as if so every such mark will appear where lacquered. The article must be held in tissue paper of several thicknesses, and heated until it is warm enough to handle comfortably. The exact heat can only be learned by practice; indeed, the art of successful lacquering in all its stages is the result of much practice. The lacquer must be applied by a camel-hair brush in straight lines, and not painted on, and in no place must a second application be made over a previous one, at least until the first is hard.—O. B.

Silvering Glass.—W. J. H. (*Oldham*).—At present there are two principal modes adopted by the trade. First, the old-fashioned mechanical method of mercury and tinfoil; and, secondly, the chemical method. Now W. J. H. simply asks, "How to silver the back of a mirror?" If it is an average size mirror, I do not think he can do so at all, and if he could it would not pay him to do so, as the plant would cost more than the mirror when done. A perfectly level table, say, of marble is required, sufficiently large to take the glass, with a gutter to receive the superfluous quicksilver. But apart from the cost of plant, a great deal of practice is required to evenly distribute the quicksilver over the foil, and then to withdraw a sheet of paper which is placed between the amalgam and the glass. Small pieces of glass can, however, be silvered without much difficulty, as I have found when I have required such pieces, and could not purchase them. On a perfectly level surface—say, a mahogany table—spread a sheet of stout tinfoil; carefully rub out all creases. On this pour pure quicksilver. It is essential that it should be very clean; if there is any doubt about it it should be filtered by being squeezed through chamois leather. With a clean haresfoot distribute it evenly over the foil. Place a sheet of smooth paper on the amalgam, and lay the glass—having been made perfectly clean—on the paper; then, by a firm, steady pull, draw away the paper whilst retaining the glass in its position. By the withdrawing of the paper, what air or impurities may have been in contact with the amalgam will be swept off, and the amalgam and glass will be brought in close contact. It will be understood that no chemical action takes place between the two substances. They simply adhere by contact, and it is clear that if air or any impurity comes between them an unsilvered spot will be the result. The glass must now be placed under pressure for some hours, and then be tilted on its end to drain off the superfluous mercury. I presume this will be all W. J. H. requires. Should he, however, need the process of chemical silvering, I shall be glad to tell him all I know on the subject through "Shop."—O. B.

Book on Heating.—GREENOCK.—The following books may help you: "Warming and Ventilating," by J. W. Baldwin (Spon), 10s. 6d.; "Warming Buildings," a guide to the American practice of warming buildings by steam (Spon), 2s.; "Hot Water Apparatus," engineer's guide for fixing (Spon), 1s.—F. J. C.

Photo.—NO NAME (*Old Kent Road, London*).—There is no publication of the processes for alpha and self-toned paper, they being secret preparations. With respect to the others, "Abney's Instruction in Photography" will supply the necessary information. T. C. Hepworth's "Photography for Amateurs," 1s., Cassell & Co., is also a good book for beginners.—E. D.

Strings to Piano.—NEWSBOY (*Derby*) wishes to tune his piano and also to put on some new strings. The key he names is known in the trade as a tuning hammer. If he writes to W. Hughes, 37, Drury Lane, London, W.C., he can obtain the tuning hammer and the wire he requires. It would be better for him to cut some short pieces off the old strings and send them, then he would obtain the proper thickness. As to the tuning, there would not be space in this column to explain it, but NEWSBOY can order the "Pianoforte Tuner's Guide" through his local music seller. I think it is published at one shilling.—T. E.

III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

Ink Bottles, Where to Purchase.—INK BOTTLE writes:—"I shall be much obliged if any reader of WORK will give me the name and address of any firm of whom I could purchase ink bottles, the same as one buys at shops filled with ink at one penny each."

Small Metal Wheels, Where to Buy.—METAL WHEELS asks:—"Can any reader inform me where I can obtain, either wholesale or retail, small metal wheels, such as are used for wooden horses, engines, and waggons, that we see at our various toy shops?"

Hammered Iron Work, Lessons in.—HIGHBURY wishes to know of any one or any book that would give lessons in the hammered iron or wrought iron work which you see so much about now, or of any school or institute where he could learn it in the evening.

Patterns for Wheel Guards.—CONSTANT READER asks:—"Will any reader tell me the best and quickest method of getting patterns for tin wheel guards for bevel cog wheels for machinery, and shafts both large and small?"

Fluid Cement for Roller Leather.—T. W. R. (*Royston*) writes:—"I shall be glad if any reader of WORK will give directions how to make a fluid cement which will fasten and hold together what is known as 'roller leather,' and harden as quickly as possible."

Attachment of Seams of Waterproof Garments.—A CONSTANT READER asks:—"Will any correspondent oblige me with a receipt for the material with which the seams of waterproof garments are held together?"

Cork Heel, etc.—J. R. writes:—"I shall be much obliged if NITRAM (*Boscombe*) or any other subscriber to WORK would tell me how to make up a cork heel with leather high and small fitting stuff; how many lifts and split lifts; how many to peg down or sew proper place slope in, and draw out at top piece to fit the last to make the heel level with the sole; also flat and medium height; also the draught of shank irons, men's and women's."

Gas Stove, Sketch for.—S. P. (*West Bromwich*) writes:—"I have a lecture room 30 ft. by 14 ft. which I wish to heat with two gas stoves. Can any reader give me a sketch of a good gas stove that I could make myself, with advice as to what kind of burners are required?"

Band Saws.—S. B. (*Nottingham*) writes:—"I have been much pleased with the instructions I have gained from WORK on circular saws. I should be very much obliged if some reader will give a few instructions on band saws, and the cause of their breaking, as I find they often break after one has sawn through the wood. I should also like some instructions on brazing saws."—[Will A. R. (*Scorrier*) oblige, and will he also kindly send me his full name and address?—ED.]

Zither.—J. C. (*Barnsley*) asks for the title of any book that will give instructions how to make a zither?"

Working Drawing of Tram Car.—J. W. F. (*Lancaster*) writes:—"Will any correspondent kindly tell me where I could write for a working drawing of a London tram car with seats on top and spiral staircases? I would pay a good price for a proper plan."

Horse Power of a Windmill.—SCRUTINEER wishes to know how to calculate this.

Packing Case Making.—STUART (*Edinburgh*) will be thankful for any information as to mode of conducting above business on usual trade terms.

Lacquer for Iron and Steel, etc.—STEEL writes:—"There is a blue lacquer, which is used for iron and steel and cheap tin toys, etc., the preparation of which, or where it is to be had, I should like to learn from some reader."

Dies for Taper Tubes.—T. R. (*Gateshead*) writes:—"I should like to know of what material the dies are made of for drawing taper tubes through."

Scotch Glue.—S. J. H. (*Skipton*) writes:—"I should like to know if there is anything to get to make Scotch glue white, so as it will not leave a dark line in the joints of light wood. I shall be pleased if some of our readers could tell me what it is, and where it could be got, and I will do my best to help any one if anything appears that I can solve for any of our readers. Will you kindly put the question in corner of 'Shop?'"

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Insurance of Tools.—G. S. (*Aberdeen*) writes:—"In looking over 'Shop,' in that very good paper WORK, I was rather astonished to see a question put regarding insurance of tools. In Aberdeen here it is not only possible to insure tools, but it is a difficulty to avoid doing it. There is the Northern Assurance Co. here whose agents go through the workshops to try to get the workmen to insure their tools in that company. And in fact there is only one way to get rid of their persistent calls, and that is to say that your society insures your tools. Of course that company may not have a branch in the place where your correspondent's domicile is situated, but I think any insurance company would insure tools if asked to do it. The rate for insuring tools here is 3d. per £1, or 2s. 6d. for £10 per annum. That is in a cabinet maker's or joiner's workshop. Do not think, because I say workmen in shops, that amateurs cannot insure their tools. They can, if they like. The agent just comes and inspects the place where the tools are and its surroundings, and puts the usual queries as to how many are to work there, and number of fires to be used, etc., and if satisfied grants policy. Of course that rate is much higher than that for ordinary house property, but then the risk is much greater on account of the shavings and wood that is always about in a workshop."

Trade Notes and Memoranda.

AT the half-yearly meeting of the Forth Bridge Railway Company held at Edinburgh, Lord Colville, who presided, said that the bridge was approaching completion. The great cantilevers were practically finished, and the central girders were being put into position. The directors hoped to be able to walk over the bridge this month, and if the approach lines were sufficiently advanced, Lord Colville thought that they would be able to use the bridge for goods and mineral traffic early in 1890.

OUR readers may remember the gallant deed of John Smith in May last, who, at imminent risk to his own life, rescued a fellow workman from being roasted alive by a great Siemens steel ingot in the casting pit of the Norfolk Works, Sheffield. The rescued man died afterwards in the infirmary, and John Smith is only now recovering sufficiently to give hope of returning to work. But his bravery has been brought under the notice of the Home Secretary by Commander Smith, and the result is that the hero of Norfolk Works has been granted a second-class Albert medal, which was presented to him by the mayor in the presence of his fellow-workmen. A purse of gold (£20 17s. 9d.) collected by the workmen and £25 added by the firm was also given to the gallant John Smith.

AT present the steel pen trade of Birmingham is flourishing. The weekly average production exceeds 160,000 gross, which consumes from 16 to 18 tons of steel. Of this quantity only about 8 tons appear in the manufactured article, the rest being loss or waste.

THE Swedish export trade in woodwork is steadily increasing, the value of the articles exported last year being £95,000, as against £80,000 in 1887. The chief ports of export are Gothenburg, with £70,000, and Stockholm with £20,000. The largest consumer is Great Britain, with £51,000, being followed by Holland with £10,000, Prussia, £8,000, and France and Belgium with £2,000 each. The export to the Cape was £1,000, and to Australia £700.

PROFESSOR GUNNING estimates the average amount of water passing over the Niagara Falls per minute at 18,000,000 cubic feet. Allowing 62½ lbs. to the cubic foot, this would give a total of 562,500 tons per minute, of which somewhat more than two-thirds would pass over the Horse Shoe Falls.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

MELLIN'S FOOD

For Infants and Invalids.

TRADE MARK **NOT FARINACEOUS. Rich in Flesh, Nerve, Brain, and Bone Formers.**

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

No Food in the market can show such a vast collection of *bonâ-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

USED IN ALL CHILDREN'S HOSPITALS.

Prospectus, Pamphlet and Sample, post free on application to the **Inventor** *and* **Manufacturer,**

G. MELLIN, Marlborough Works, Stafford St., Peckham, London, S.E.

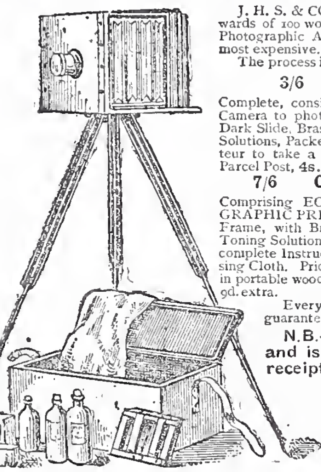
LARGE STOCK AT 100, Houndsditch, London. TERMS—CASH OR HIRE PURCHASE.

J. H. SKINNER & CO., EAST DEREHAM, NORFOLK,

Manufacturers and Importers of Photographic Apparatus and Fretwork Materials.



J. H. S. & CO. have now a large Factory with accommodation for upwards of 100 workmen, which is used exclusively for the manufacture of Photographic Apparatus of every description, from the cheapest to the most expensive.

The process is simplicity itself. Full Instructions supplied with each set.

3/6 The Eclipse Camera Set. 3/6

Complete, consisting of a Polished Mahogany Sliding Bellows, ¼-plate Camera to photograph full-size carte-de-visites, with Focussing Screen, Dark Slide, Brass-mounted Lens, Brass Fittings, Developing and Fixing Solutions, Packet of Dry Plates, and full Instructions, enabling any amateur to take a good Photograph. Price 3s. 6d., or securely packed by Parcel Post, 4s.

7/6 Complete Photographic Outfit. 7/6

Comprising ECLIPSE CAMERA SET, as above; also PHOTOGRAPHIC PRINTING APPARATUS, consisting of Hardwood Printing Frame, with Brass Spring Back, Sensitised Albuminised Paper, Gold Toning Solution, Fixing Solution, Glass Rods, Cards for Mounting, with complete Instructions. Also Hardwood Folding Tripod Stand and Focussing Cloth. Price 7s. 6d. Securely packed, post free, 8s. 6d. If packed in portable wood case, with hinged lid and leather strap, as in illustration, 9d. extra.

Every Set is carefully examined before being sent out, and guaranteed to be in working order.

N.B.—If Apparatus does not give satisfaction, and is returned uninjured within three days of receipt, we guarantee to refund purchase money.

Better Sets, 10s. 6d., 21s., 42s., 100s., and upwards. Complete Catalogue of Photographic Apparatus, one stamp. **J. H. SKINNER & CO., EAST DEREHAM, NORFOLK.**

Wholesale Agent for London—J. MOTHERSILL, 60, Holloway Road, N., and 6, Southampton Row, where Samples may be seen.

Timber Yards, Sawing and Planing Mills covering about Two Acres near Railway Station.

J. H. S. & CO. keep regularly in stock about **120,000 FEET OF FRETWOOD,** solid and 3-ply, veneers, &c., besides a very large quantity of Logs, Planks, and Boards, Carving and Turning Wood, &c., and **200,000 FULL-SIZE DESIGNS for Fretwork, Wood Carving, &c.,** besides an immense Stock of Joiners' Tool Chests, Fretwork Outfits, Drills, Saw Frames, Hand and Treadle Machines, Saw Blades, &c. &c.

Specialities for 1888 & 1889.—Books of New Designs. FRETWORK No. 1, containing 12 Large Sheets, price 1s. No. 2, containing 20 Sheets of larger and more elaborate Patterns, 2s. 6d. Book of Wood Carving Designs, containing 14 Patterns, price 1s. ; these are all New Patterns, not sold in any other form, and would, if sold separately, cost three or four times the amount charged. Fretworker's Handbook and Workshop Guide, price 1s. New Designs. All Patterns greatly reduced in price.

Complete Fretwork Outfit, comprising 12-inch Steel Frame, 48 Saws, Awl, File, 4 Designs (with sufficient planed Wood, gratis), and 1s. Handbook on Fretwork, price 3s. 6d., carriage paid. 12 feet Assorted Planed Fretwood, 3s. 6d.

☞ Special Fretwork Design, in commemoration of Her Majesty's Jubilee, size, 36 in. by 26 in., price 2s. 6d.

Catalogue of Machines, Designs, Wood, Tools, &c., with several Hundred Illustrations, and full Instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. Good Fret Saws, 1s. 6d. per gross ; best ditto, 2s. per gross.

Eclipse Design, No. 102.

Wall Bracket. Price 5d.

THE TAM O' SHANTER HONES

Are Praised by all Classes.

Try one of these famous Hones No clammy oil required in sharpening; use water. Prices, uncased, for Knives, Razors, Plane Irons, Axes, &c., from 9d. to 1s. 6d. each. In neat cases, 1s. 6d., 1s. 9d., 2s., and 2s. 6d. If sent by post 3d. extra, and 4½d. for Joiners and heavy Hones at 1s. 6d., uncased. *To be had at the Ironmongers', Seedsmen, Nurserymen, &c. If they cannot be obtained there, write direct to*

FOLDING COMBINED COOKING STOVE AND OVEN. (*For Description, see next page.*) Fig. 1.—Apparatus shown complete and opened out, ready for use as Oven or Cooking Stove. Fig. 2.—Apparatus shown closed and folded up. Fig. 3.—Apparatus shown cut in half and exhibiting Interior at Back. Fig. 4.—Method of fixing Top and Bottom Centre Rod. Fig. 5.—Diagram showing Corner before being bent and rolled. Fig. 6.—Corner after bending and rolling. Figs. 7 and 8.—Suitable Handles for fitting on Apparatus. Figs. 9 and 10.—Diagrams showing mode of making Saucepan Handles. Fig. 11.—Bracket to support Rod on which Oven Bottom revolves.

A FOLDING COMBINED COOKING STOVE AND OVEN.

BY JAS. SCOTT.

"THE early bird catches the worm." If this is so, it proves that there is not so much good advice contained in the proverb as is generally supposed, for the worm, although an earlier riser than the bird, meets with very great disadvantages from rising so early. But perhaps it may be argued that the "early bird catches the worm" at home, before it—the worm—has started out for its day's business. However, whichever side of the question is right, a great deal may be said both in favour of and against early rising.

My purpose in this article is to lay a few suggestions before the reader, whereby he may profit if he be an early riser. I know several young men who have to start to their work before six o'clock in the morning. One of them is a single lodger, and prepares his own breakfast; the others live with their parents. Now, as it is necessary for them to rise at so early an hour, with the one exception, they have not time to cook their own breakfasts, so that that task devolves upon the mother, who probably retires to rest after she has satisfied her son, and has no need to rise again until two or three hours afterwards. By allowing the mother, or sister, as the case may be, to have her rest comparatively undisturbed, would not encourage idleness, for it may be safely presumed that what is needed to be done will be done.

How nice then for the son when he rises to prepare his own meal without taking up much of his time, and without disturbing the rest of any one else! There are numerous small handy cooking stoves about, and there is no reason whatever to be urged against their use, instead of lighting a coal fire.

I have designed the cooking apparatus here shown so that it can be used as an oven, or for boiling water, and frying any necessaries or luxuries; it can be also compressed, and carried backwards and forwards to work, or stowed away in some corner.

Very little requires to be said about the measurements, the sizes of course being optional. If made 15 in. square, I think that would be a very convenient size. It will be observed that the top and bottom fold together, while the two sides extend outwards. The rods round which the sides are bent should not be very thick, but they must be firm and strong.

Fig. 5 shows how each corner of the back and front should be cut, so that when each piece is bent round the rods they will fit properly, as shown in Fig. 6. Fig. 4 shows the centre rod at the top, the bottom one being similar. They should be a few inches longer than the others, and should be hammered flat at the ends, and bent at right angles; it will then be found that they keep the stove compact. For the benefit of those who do not know, I may as well give a hint for cutting the edges that are to fit round the rods; whatever the diameter of the rods, the pieces which bend round them should be three times the width of the diameter; thus, if the rod is $\frac{1}{4}$ in. thick, the pieces to be cut out at the sides should be $\frac{3}{4}$ in., leaving those pieces projecting (as shown in Figs. 4 and 5) $\frac{3}{4}$ in. wide to bend round them.

I have shown the apparatus as an oven as well for those who may desire it, but I should not like to say I expect it to possess all the merits of the small portable ovens that are now so largely made; but, if well made, I see no reason why it should not answer its purpose satisfactorily. If no oven is required, the stove should not be made quite so high, and the top only should fold in, the two sides and bottom extending outwards.

For the bottom of the oven I have shown two flaps (Fig. 3). Each should be about 9 in. wide, and one should be fixed slightly higher than the other, so as to overlap it. The small iron brackets shown should be soldered on to the inside of the two narrow middle side pieces, while on the outside of these pieces is a small knob, to facilitate opening and folding the entire article.

I should not advise the amateur to try his hand at the saucepans and frying pans. He can buy them already made, and can use his skill by fixing the movable handle I have shown in Figs. 9 and 10. A firm hollow rim should go round the tops of the above named articles, to support them in their positions. Where the handle is to go a piece should be cut out. The handle is an ordinary one, and is fastened into a piece of metal, the end of which has been bent round to the same diameter as the rim. A hole should be made in the rim on either side of the handle, so as to admit a short piece of strong wire to fix the handle in position. Saucepan handles are frequently a source of great inconvenience, and as there is not likely to be much weight brought to bear upon these, I think they will be an advantage.

Fig. 11 shows the shape of the supports to be fixed to the inside of the stove, upon which the flaps composing the oven bottom revolve. Fig. 7 is intended as a handle for carrying the whole affair about; I have not shown it in any of my drawings, but it will be found useful. Pieces are fixed at either side of the stove, one having a slot in it, through which runs the long top piece. A small piece must be cut out of the side of each of the three top openings, to allow the handle admittance; and I believe it will be found that the ventilation through these, when the affair is used as an oven, will be quite sufficient.

I say nothing here about the lamps; that must be left to the reader, as they can be obtained anywhere and everywhere: neither do I speak of the door fastening; the working of it must be apparent to all, and the hinge will be precisely the same in construction as the corners of the stove.

The job should be made in tin, with the oven bottom of iron.

SIGN WRITING AND LETTERING.

BY HENRY L. BENWELL.

THE PREPARATION OF SIGNBOARDS AND THEIR GROUND COLOURS.

SOME time since a practical man recommended the use of American cloth or leather as a surface for the sign writer to work upon. I have never given it a trial, but we all know the material, as it is frequently seen on the cottager's table, and also in many kitchens. I have, I should say, used it for temporary purposes many times, such as a bazaar or fancy fair announcement taking place at a public hall, but in such cases the cloth has merely been stretched on to a frame, and the letters have been painted direct on to the black shining surface. This, though, is a simple expedient as a cheap substitute for a proper signboard, and is entirely different from the method employed by my practical friend, which I will now describe.

The face of the signboard should be covered with the best stout American cloth, which is made to adhere, first of all, to the board with bootmaker's paste, viz., glue, flour, and alum. The cloth must be of sufficient dimensions to lap over the edges of the board where it is closely tacked down all round with *tinned* tacks. Do not on any account use iron or blue tacks, as they rust and very soon rot the fabric. The cloth should dry out perfectly taut and free from wrinkles. We next paint the edges of the board where the tacks are with a good round coat of red and white lead mixed as a further preservative, taking care to keep the front of the cloth surface clean. The mouldings, which have already been primed and received one coat of paint, are next tacked on, and the nail holes, joints, etc., well stopped with putty. The back of the board and the beadings, etc., next receive three good coats of paint made up into a slate colour, with black and white and red lead. The cloth itself, being of a shiny and hard non-porous surface, requires but two thin coats of paint, mixed with equal quantities of copal varnish, raw linseed oil, and turpentine. This first coat must be allowed to get perfectly hard, when it is lightly glass-papered with Oakey's No. 0 or No. 1, and it is then ready to receive its second coat. If the sign is to be written on before varnishing, it should be "flatted" in the same colour as used for the first coats, and, after getting thoroughly hard, it is ready for "setting out" the matter thereon. The medium for binding on the flatting should be copal varnish, which must also be used for finishing off the sign.

I do not myself think this method possesses any lasting qualities. It is, nevertheless, a handy dodge for covering up very old and badly cracked name-boards over shop fronts where the tenant does not care to go to the expense of having a new board inserted.

In concluding this subject, I cannot do better than quote the method employed by Mr. William Sutherland of Manchester, one of the best workers, and a recognised authority on all matters relating to sign writing, marbling, and its kindred arts that we have in the provinces. I shal call attention to the literary work of this gentleman at the end of these articles when recommending an advanced textbook on the sign-writer's art.

"A signboard requires to be as smoothly got up as any other description of painted work, and the clearer the polish or lustre and the freer from nits or grit it is, the better the work afterwards put upon it will look. This is especially the case when the letters are gilt. The smoother the surface the brighter and more lustrous will be its burnish. It should, therefore, be pointed out that, although there will be some extra labour required to get up the work properly its appearance when finished will amply repay the trouble bestowed upon it. . . . . The first thing to do will be to kill the knots, but there never should be any in a signboard, it being always a serious defect for no covering in the shape of patent knotting or glue and red lead, etc., will prevent a resinous knot from showing on the surface if exposed to the sun's rays. And the only effectual cure in these cases is to cut out the knot and let in a piece of sound wood in its place. . . . . For priming, use any of the dark reds or browns red oxide, purple brown, etc., mixed with raw oil. The second and third coats should be brown also, but mixed with one-third turps to two-thirds of oil, having a little liquid dryers added to harden it. All the paint used should be carefully strained before being used, and well rubbed down between each coat. If this is not done, we are apt to accumulate on the surface of the board a quantity of coarse particles of colour and skins of paint which are afterwards very difficult to get rid of. . . . . . To finish the board off with a black ground, we first give the sign a bare coat of black oil colour upon the previous three coats of brown. We then grind drop black in turpentine, stiffish, and then add sufficient japanners' gold size or varnish to bind it, and with this carefully coat the sign over. When this is dry and hard, we finish with one or two coats of copal varnish."

In writing a fresh inscription upon an old signboard, it is frequently found to be necessary to clean off all the old material, and otherwise "doctor" it, before it can be made fit for repainting. The old paint must, therefore, be burnt off with the spirit torch, and the board well rubbed down with some sharp new glass-paper until smooth. All holes, cracks, and other imperfections, should next be made good with white lead and putty, and the knots freshly coated with the usual preparation. The board should now be primed with red and white lead, half and half, with the usual quantity of oil and turps. I am always in favour of this priming for all new work, as it has such protecting power and soon dries quite hard, whilst the oxides of iron and the earths have little or any body in them, and are, consequently, unfitted for withstanding and resisting the climatic changes of any country.

A few words of caution here may, perhaps, be the means of preventing a few young hands from making bad work the result of their first efforts :—

1. Always use raw linseed oil for the face of signboards.
2. Always use pure, uncoloured turpentine.
3. Always use the same dryer throughout a job, and do not use one kind in one coat of paint and another in the next or finishing coat: the different chemical actions of the two substances will not agree, and very likely cause the paint to crack, etc.
4. For the same reasons, always use the same quality of varnish and the best procurable : outside copal and outside oak. The best boatbuilders' varnish will be found an excellent preservative when the board is varnished before lettering, as it is made with the special object of resisting water and the sun's action. As it is somewhat dark, I cannot recommend it for varnishing after lettering or on a light-coloured ground.
5. Well strain your paints and pigments.
6. Do not use boiled oil, except for the back of your signboards.
7. Let each coat get thoroughly hard before applying the next—quite hard, and not merely dry.
8. Also, never rub down with glass-paper until quite hard, and be careful not to rub portions of the previous coat "up" or "clean off," or your surface is spoilt.
9. Last and most important : do not have your paint too thick or containing too much oil. Do not let each coat be too round ; it had better be laid on too sparingly than otherwise. Well work each coat about with the brush in every direction, and finish by "laying off" evenly in one direction and with a light hand, leaving no brush marks. This last remark also applies to varnishing. This rule must be attended to in order to prevent the sign from blistering.

Much might here be said as to the general tints and shades of colour which show off the lettering to the best advantage, but as space is limited, a great deal must be left to individual taste and knowledge. For gold lettering, a black groundwork is always the most effective, as the letters show up plainly at whatever angle they may be viewed from ; this is not so with a white or any other light ground. Gold letters also look well on a dark blue or bronze green groundwork. They also show up wonderfully well, when properly shaded, on a ground of Chinese red. This is the colour used on the mail carts, but, as it is particularly liable to fade when exposed to the light and weather, several coats of "flatting" must be applied, and after the gold leaf has been affixed, it must be well protected with two good coats of varnish. A black letter shows up the best on a white ground, but it may not be generally known that a *white letter* on a *black ground* is a great deal more effective than *vice versâ*. At least, this is the opinion of a great many of our best writers, who have frequently pointed it out to the author of these articles. This is more so the case in very small lettering, and on a limited space containing a lot of matter, such as a "Trespassing Notice Board," or auctioneers and land agents' boards, which generally commence with "This valuable plot of freehold land to be sold for building purposes, etc.," and such like examples. Boards of this class, I confidently assert, can be read much easier and at a greater distance—especially by short-sighted people—if the letters are in white on a black ground. Do not, however, use white lead, but oxide of zinc, or, better still, some Charlton white. That is, of course, if the tube colour is not used, which is the rule for common work of this class. If the tube colour is used, resort may be had to flake white, which is the carbonate of white lead oxidised, and which does not consequently discolour so quickly on exposure to the atmosphere.

With reference to other kinds of grounds, there is a species which one frequently sees lettered upon, especially on shop facias, and that is the marbled or grained surface, which exhibits very bad taste indeed when an inscription is written thereon in the ordinary style. It frequently looks as if the grain of the wood or veins in the marble are springing out in all directions from the letters themselves. I have no sympathy whatever with a grained ground, and would strongly urge the employment of a plain colour, which harmonises with the graining colour around it. If a grained ground is used at all, it should imitate a wood totally different to that which is used for the rest of the work, and also contain a small close grain.

In writing on an imitation marble surface, only one class of letter looks really well, and that is the incised letter, or, rather, the imitation thereof. It is a difficult letter, and wants a lot of skilful handling to look effective and real. If the whole of a shop front is marbled, and the name to be inscribed also on a marble surface, the facia or signboard should be worked in a different marble of a somewhat lighter tone, and so as to resemble an inlaid slab which has the appearance of being let into the rest of the structure.

SMITHS' WORK.

BY J. H.

MEDIÆVAL SMITHS' WORK—THE IRON WORK THAT WAS MADE, AND THE MODE AND METHOD OF MAKING IT.

I NOW intend to take a few of those examples of the mediæval smiths' work which remain in existence, and shall endeavour, in a sketchy manner, to discuss the methods of manufacture adopted. Perhaps the term "manufacture" is not well chosen to express the conditions under which the craftsmen of the Middle Ages gave form and permanence to their beautiful creations—their chastened ideals. Let us say, rather, "methods of fabrication, mysteries of craftsmanship, *chefs d'œuvre* of arts and trades."

In this preliminary section on the work of the mediæval smiths, I think it well to divide the subject under several heads, discussing under each head the characteristics of some special kind of work. In this way I shall take hinges, gates, locks and keys, grilles and screens, arms and armour, and, finally, some miscellaneous pieces of workmanship, as lamps, knockers, etc. But before entering on these, I shall best occupy this present article in remarks of a general character on the methods of operation followed by the old smiths in the fabrication of these various articles.

One of the principles of true art is that of adapting the design to the character of the material employed. Thus, massive designs, which are suitable for stone, are not adapted for works in iron ; and designs, on the other hand, which look well in iron, are not suited to the precious metals. Another principle is that of decorating, instead of disguising and concealing, essential portions of construction. We conceal our locks, hinges, nails, and so forth, as far as possible ; the mediæval workmen elaborated and beautified them, and made their work fit for the vision of the gods.

In the elder days of art,
Builders wrought with greatest care
Each minute and unseen part ;
For the gods see everywhere.

And thus the early hinges covered the whole breadth of their doors with beauty. The lock and key were marvels of workmanship intended to be seen and admired, and a smith would sometimes occupy two years in making a lock. The nails and bolts were also often richly ornamented.

The old iron work owes much of its charm to one element of beauty, the reason of which we may yet not be quite conscious of—I mean its extreme lightness. It is this which, as much as graceful curves and delicate tracery, lends so much charm to the screens and the grilles, the hinges and the door-fastenings, the gates and the lamp-brackets. The exceeding lightness both in weight and in appearance of work done in wrought iron is one of its chief recommendations. Nothing in stone, timber, or cast iron can be at once so strong and so light, or be endowed with such graceful outlines.

If we examine samples of iron work from different countries and ages, we shall see much difference in the degree of finish imparted to them. But finish alone is not, however, distinctive of any one period, and some of the earlier works compare favourably in this respect with those of later dates.

As a rule, the bars from which the old work is built up are more or less rough. They show the marks of the hammer, and have a wavy and uneven appearance. It would appear as though the workmen must, in many cases, have themselves hammered their bars to such dimensions as they happened to require for any piece of work on hand. But there are striking exceptions. The best, perhaps, which I have seen is the pair of gates made for Edward IV.'s tomb at Windsor, the reputed work of Quentin Matsys. It is a wonderfully perfect piece of art, and I am at a loss how to account for the smoothness of finish of the surface of the bars. It has been suggested that the heavier portions are of cast iron. It is possible, but very improbable. The art of casting in iron was little understood at the period when these gates were made. I can only think that these are the work of an exceptionally gifted craftsman, and that by the use of a broad flatter, coupled with almost infinite painstaking, the smooth surfaces which are so much admired were imparted to the bars. But certainly the use of flatters by the early smiths appears to have been very much the exception rather than the rule, for few of the main bars upon which the gates are built up, and very little iron work, indeed, of that type, show smooth surfaces.

Another point is that the file seems to have been quite an exceptional tool. Surfaces could have been rendered smooth by a laborious process of filing, but without saying absolutely that this method was not followed, I certainly can detect no traces of its use. There are an immense number of curves whose outlines could have been rendered much more perfect by filing, which were not so rendered. There are many ornamental edges and faces where a file could have been used to much advantage for imparting regularity, symmetry, and finish, where it has certainly never been used; but the work has been, without question, left just as the chisels, punches, or fullering tools left it. Strong evidence that the file was not used is observable in the remarkable freedom from corrosion which these old works manifest, a clear proof, I think, that the work was left untouched after the hammer, the scale of magnetic oxide naturally adherent thereto affording a better protective coating than any paint.

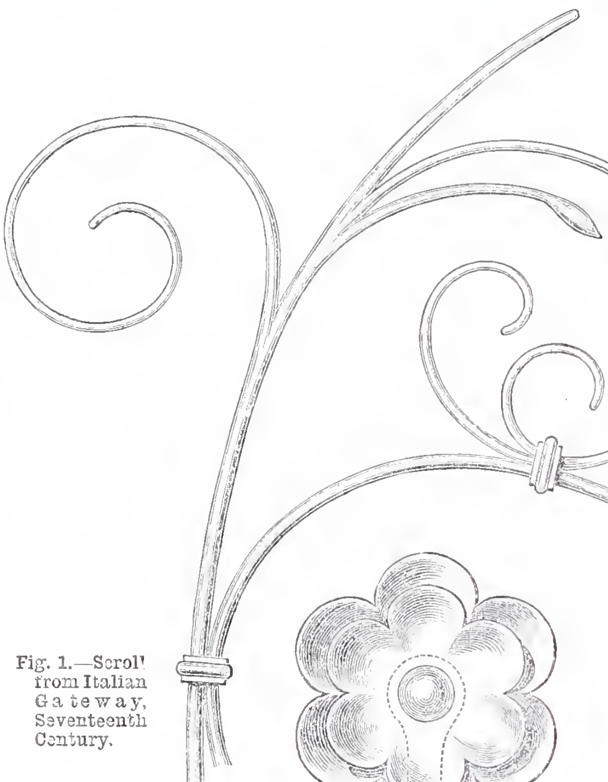

Fig. 1.—Scroll from Italian Gateway, Seventeenth Century.

In the union of parts, riveting and tenoning were the principal devices employed in the craft of the mediæval smiths; the main bars are so united, and so also are the delicate foliage and the flowers. The tenons are mostly used for the heavier bars of the framework, and the rivets for the lighter portions. There is little attempt at concealment of these fastenings. Often where the design lends itself thereto the rivets are made subservient to ornament, their heads being formed into a cupped or semicircular shape.

In large numbers of instances the bars and scroll work are united by means of bands or belts of rectangular, oval, or circular outline. This is a method equally common with riveting, and is used in positions where riveting would not be convenient or possible. Illustrations occur in Fig. 1. The bands are variously secured. In very light works they are often simply bent round without any attempt at welding, or even without their ends quite meeting. In many cases, however, they are so close and fast fitting that they appear to be certainly welded. In the larger work they are riveted in two portions. In numerous instances these are made means of ornamentation, the bands being ribbed as in Fig. 1.

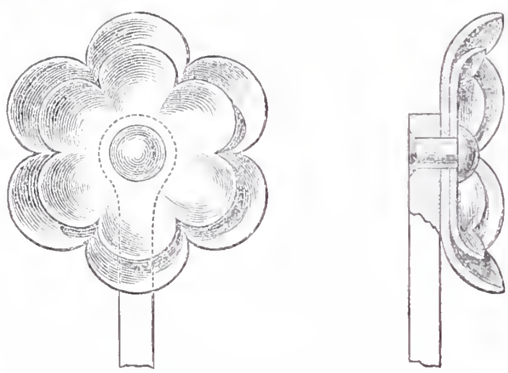

Fig. 2.—Floral Ornament from Italian Gateway, Seventeenth Century.

Another notable feature is that while welding was the exception, swaging down was very common. In large numbers of instances it is quite apparent that a bar of large section has been first taken and bifurcated as many times as there were stems required, and that each of these tongues was then beaten out to required sections, and curved as in Fig. 1, where to all appearance half a dozen separate stems are hammered from a single bar. And expansions made to represent leaves are also often beaten out of the bar. Many stems are of circular section, and it is a difficult task to beat out and curve them also, when, as in many cases, they lie in close contiguity to one another. Even in such work as this, where the inducement to use the file must have been very strong, there is no trace of its employment.

Much of the work of leaves and flowers is convoluted by hammering, the iron being in very many cases not more than $\frac{1}{32}$ in. thick. These leaves are usually riveted on, though also occasionally welded.

The floriated ornament displays much ingenuity, and those who may have ever attempted to hammer, not thin sheet brass, but iron, into floral forms, will appreciate the difficulty of the task. Some specimens of these ornaments are here shown (Figs. 2 and 3). The separate whorls of the corolla, when there are several, are invariably formed of distinct sheets, each cut to outline, and beaten out, and hollowed (see Fig. 2). A torus or base is generally present, and formed by the head of a rivet, which is clenched behind; and this serves to unite the whorls of the corolla to each other, and the whole to the stem as in Fig. 2. Stamens often appear as nails, probably welded in, as they are very firmly set (see Fig. 3). The petals in this illustration appear to have been beaten out of the solid bar. The bar would probably be first divided into five forks, and these beaten into ribbed leaves, which were then bent over.

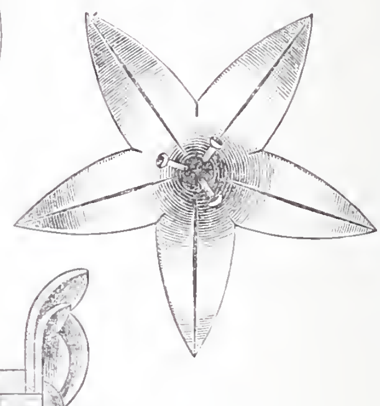

Fig. 3.—Lily, Seventeenth Century.

The beaten foliage is a marked feature of the old work. It conceals many of the unsightly but necessary joints, and much of the plain skeleton of these structures, and the general effect is always pleasing. A candelabrum of hammered iron (Venetian sixteenth century) at South Kensington is thus quite enshrouded with foliage, and this alone catches the casual glance. It is only a close examination that shows the central supporting stem and the scrolls bound thereto, supporting the wealth of foliage. An Italian balustrade (Venetian seventeenth century), also at South Kensington, is entirely formed, save for the top and bottom bars, of cupids and foliage made of hammered iron of about $\frac{1}{32}$ in. thickness, and is made double, the opposed sheets standing out in relief on both sides.

Whatever the method of ornamentation adopted, the secure union of parts is never forgotten. The thin foliage is never without support, usually that of rivets, and the small scrolls and tracery are supported and united at frequent intervals by means of loops or bonds.

The more elaborate scroll work formed from flat bar iron is well worthy of close study. From plain bars of rectangular section the most charming tracery is constructed. Where practicable several convolutions will be formed from one piece of bar, and the smaller the pattern and the closer and more involved the convolutions the greater is the difficulty of bending them enhanced. Little of this could have been done on the anvil—at least, not in the later stages. Much could have been done with tongs and pincers, or with a light hammer, while the work was laid across suitable mandrels held in the vice. And then where much of the tracery is reproduced over and over again, frequent reference to drawings or templets would have been necessary to verify the accuracy of results.

These works are, to all appearance, done by the hammer chiefly. Yet in some of the grilles and gates there is a profusion of panels whose curves are identical in all respects, and in hinges the curved portions which flank the central bar are beautifully symmetrical on each side. Probably, therefore, templets or full-sized drawings would be employed as now, but for the accuracy of the results the workmen must have trusted only to hammer and tongs.

Nor is this all. In the gates and grilles there are mouldings of diverse forms attached to plain bars or frames. We can roll moulded forms between grooved rollers. Not so the old smiths. These mouldings must have been laboriously first chamfered roughly, and then swaged down bit by bit between swages or moulds or dies first carefully prepared. The quantity of material required precludes the likelihood of any other method of formation having been adopted. To these mouldings, and their mode of fabrication, I shall give more detailed notice.

How beautiful were many of these creations! Though the execution of the work is often rude and rough if tested by our modern standard of machine finish and of die-stamping, with their monotonous regularity, yet beauty is interwoven with them all, and the more we study them the greater is the fascination, the more intense the spell of reverence and delight with which we are held in bondage. Though the blacksmith's work is not gaudy, like that of the gold and silver-smith's, or even as that of the brass founder and copper-smith, it still partakes of, and is permeated with, the charm that in some mysterious way is ever associated with the stormy ages when art, science, and learning found an ark of safety within the walls of the cloister, and in the service of the Church.

NEWSPAPER CUTTINGS: HOW TO KEEP THEM.

BY "A COLLECTOR."

Newspapers and magazines contain so many articles of interest to an intelligent workman that it seems a shame that they should in so many cases be consigned to waste and destroyed after being once read. It is true, some of the magazines dealing with subjects of special interest are preserved and bound at the completion of the volume; but I refer more particularly to those odd items of information and practical use which are continually to be found in the daily and weekly newspapers. In as few words as possible I will explain my method of preserving these and arranging them for reference. It is, of course, possible to find other methods which may have advantages in the ease of classifying and finding the cuttings, but, as a rule, they are more cumbrous, and necessitate the use of more drawers or pigeon holes than most of us can command. After an experience of fifteen years, I believe the method I am about to describe will be found to be the most serviceable.

First of all, then, when you read, read with a lead pencil within reach, and mark everything that you want to keep. Don't be afraid of marking, thinking that you can

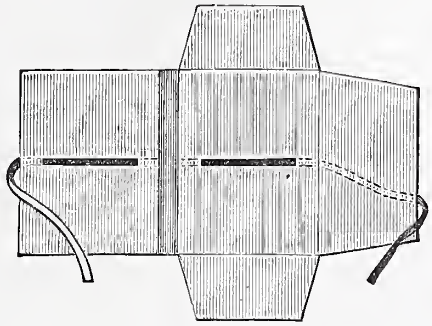

Fig. 1.—Paper Mounted to form Case.

trust to your memory for a certain fact or recipe; when you want it most you will possibly find that your memory is at fault in just some little detail which is of the greatest importance; and remember that it is the man who can lay his hands at once on the information he needs who has the best chance of success nowadays. Mark, then, anything likely to be useful to you. When read put your paper away where it will not be destroyed, and at the week end or first leisure half-hour, take a pair of scissors, light your pipe, and proceed to cut out everything you have marked. Paste these cuttings, either just as they come to hand or,

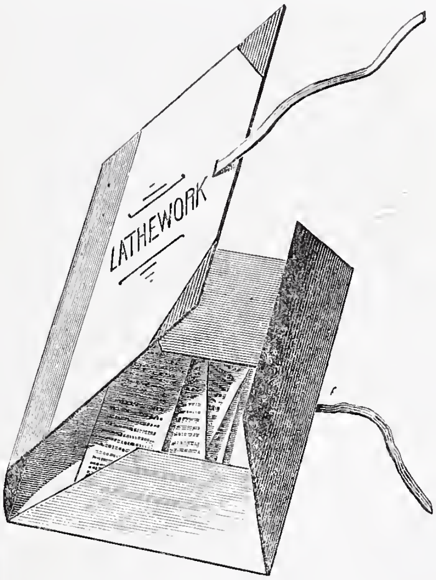

Fig. 2.—Case for Cuttings Complete.

if you have much sense of order, classified as far as you can, into a scrap-book with numbered pages. Those that I use myself are the "Newspaper Cuttings," issued by Messrs. Marcus Ward & Co., and contain two hundred pages each, though smaller ones are to be had. Now then prepare an index in a separate note-book. There is an index in the cutting books named above, but generally it will be found not to have room enough for the requisite entries. Do not skimp your index; make it big enough to last a lifetime, for if you once start it you are not likely to drop it again. Get a good thick note-book, at least an inch thick, and at the top corners of every page place initial letters. It will be found convenient to use the system adopted by accountants in indexing ledgers and other account books; that is, to classify the entries by the first letter and also by the first vowel after the first letter. Thus, "Fretwork" would be indexed on the page devoted to "Fe," "Bridges" under "Bi." Count the pages in your note-book, and then divide them equally amongst the letters of the alphabet, commencing with, say, five pages (or the number found necessary) lettered "Aa;" then following on with Ae, Ai, Ao, and Au. B follows with Ba, Be, etc. This index serves to enter the subjects of all your scraps; and, more than that, any article which you may meet with in your reading should be indexed under its proper heading in such a manner that the book or magazine can be referred to at any future time. The "Newspaper Cutting" books can be referred to as "Sc. I.," or "Sc. II.," signifying Scrap-book I. or II., with the number of the page in smaller figures; while bound books or magazines should have the title and other particulars given more fully. The following examples from my index may make this a little clearer:—

Architecture: Law Court Designs, "Belgravia," Vol. II.; "Builder," end of 1884.
Automata: "Household Words," Vol. IV., 503; "Leisure Hour," 1879.
Foundations: Sc. VIII., 42.
Keyways: Proportions of; Sc. I., 4.

Wherever necessary the item should be indexed under several headings; as, for example, an article on the "Progress of the Manchester Ship Canal," should be referred to under M. S. and C., and *not* under "Progress." I am sorry to say that a valuable weekly journal destroys half the value of its contents by its poverty of indexing, the above item being found only under "Progress," where one would certainly never look for it; while "How to make Glue" is indexed under "How," and never mentioned under "Glue."

The above contains in brief the whole system, and I think I am safe in saying that any one who has tried it for six months will find it of so much use as to be very unwilling to give it up. Sometimes the cuttings relating to one subject will be found to be very long and very numerous. To put these in the scrap-book would be inconvenient for several reasons—they take up too much valuable room, too much time in pasting in, and they get too much separated by other matter coming in between. The plan I use in dealing with these is to make a separate case for each subject, by cutting and folding old mounted drawing paper, as shown in the diagrams. This material I use because it comes most readily to my hands, but if it is not obtainable there will be no difficulty in finding a substitute. The mounted paper is cut to the shape shown in Fig. 1, and folded with the holland side outwards. A piece of red tape, such as is used for bundling papers, is threaded through as shown, and a strip of dark-coloured bookbinder's cloth, glued along the back, serves to keep the tape in position and make the case presentable when put on the bookshelves. With pen and ink print the title on the front cover, as in Fig. 2, and draw the marks across the corners, and the thing is complete. It takes ten minutes to make, does not cost more than twopence at the most, and has quite a respectable appearance.

THE KALEIDOSCOPE: ITS CONSTRUCTION AND APPLICATION.

BY THOMAS RICHARDSON.

The Case and Interior Mechanism of the Compound Kaleidoscope.

[*For Illustrations to which References are made in this Paper, see pages* 424, 425.]

Having completed the wood turning in connection with the plates forming the ends of the case, the next process is that of cutting out the plates to the correct form: first, square the centre lines across the edges, and continue them on the reverse side; then set out the octagon on the front plate, and having removed some of the surplus wood with a saw, pare off the remainder to the lines, keeping the edge as square as possible. The two plates, with the insides facing each other, must now be attached together by a couple of screws passing through on a line perpendicular to M N (Fig. 2), and $3\frac{1}{4}$ in. from the centre, so as not to disfigure the wood where exposed to view. When fixing, be mindful to notice that the centre lines correspond, and also, that the opening in the front plate is concentric with the circle of the same diameter scribed on the back plate, which may now be pared round the edges to match the front, and a $\frac{1}{4}$-in. hole bored squarely through the two plates corresponding to the centre of the milled head, E (Fig. 1); this hole requires slotting in the front plate, but may be deferred till the spindle has been prepared.

The plates can now be taken asunder, and a start made on the metal work. Turning to O (Fig. 2), a brass plate is shown, having a hole in the centre, in which the pinion turns, to which the milled head, C, is attached, and on each side of the central hole a slot is cut in which slide the ends of two steel rods supporting the arms, K, K (Fig. 5). These slotted plates are cut from sheet brass $\frac{1}{8}$ in. thick, $6\frac{1}{2}$ in. long, and $1\frac{1}{8}$ in. wide; notice if they are winding, or bent; if so, lay them on a level surface, and remove the twist with a few skilful blows of a smooth-faced hammer. Drill and countersink the holes for the screws, which may be $\frac{1}{4}$ or $\frac{3}{8}$ in. long, and attach them side by side to the true face of a piece of hard wood. Holding them thus in the vice, file the surface quite level, heat a soldering iron, and tin the ends of each piece; now lay them face to face, bind them together with a piece of fine iron wire, and using sprits of salts for a flux, sweat them together with a heavy piece of red-hot iron. When cold, level both sides, and one edge as straight and square as possible, then the other parallel to it. Scribe a centre line on one face, and dot the central hole with a fine pointed centre-punch; on each side of this dot set off $\frac{13}{16}$ in. with the compasses; dot these marks for holes denoting the inner ends of the slots, and a second pair of dots 6 in. apart for the outer ends, after which the slots may be spaced out for drilling a series of holes $\frac{3}{16}$ in. apart; the drill used for the purpose should be about $\frac{1}{32}$ in. less in diameter than the width of the finished slot. A twist drill mounted in the lathe will be found the most suitable tool for the work, the plates being fed on the drill by means of a piece of hard wood having a deep hole previously bored in the lathe to fit tightly over the centre of the sliding headstock. The dots will probably require to be deepened to prevent the drill from wandering. A line may now be gauged on each side of the row of holes, the distance between not to exceed the diameter of the steel rods. By a careful use of a fine rat-tail file, the holes may be run into each other; then a stout ward file for roughing, and using a dead smooth for the finishing touches. Drill the central hole $\frac{1}{8}$ in. diameter, and leave it to be finished with a reamer. On applying heat, the two plates will separate, and they may now be secured in their places immediately over the centre line, I J (Fig. 2). It is now necessary to prepare the milled heads, B and D (Fig. 5), which act as lock-nuts on the screws cut on the heads, A and C. Of course, the easiest method would be to hold them by means of a self-centring chuck, but failing this, they may be held for turning by driving them tightly into a recess bored in a piece of hard wood which has been mounted on a face plate. If a good fit is secured, it will be found unnecessary to sink them beyond half their depth. Having trued up one side, bore a $\frac{5}{16}$-in. hole in the centre for screwing with the $\frac{3}{8}$-in. brass gas tap. To make sure that it is truly tapped it will be well to enter the taper tap a little way before removing from the chuck, feeding up the back centre as the tap moves inwards, the screwing to be finished in the vice. Each head having been treated in this way, they must be mounted on a suitable mandrel of brass or iron, and the turning completed, finishing the edges by grooving and milling. The heads, A and C, require much the same treatment as the foregoing. They are mounted first with the shanks projecting; should they exhibit a tendency to become loose in the chuck, they may be further secured with three wood screws, evenly disposed round the edge of the recess, or the back centre may be pressed into the service to assist in steadying the shank while it is being manipulated. A hole $\frac{3}{32}$ in. diameter is next drilled and tapered as shown with a suitable reamer. Should the latter not be to hand, procure a piece of $\frac{1}{4}$-in. cast steel about 4 in. long, anneal it by heating to a dull red, and place it in slaked lime to cool. File about $\frac{3}{4}$ in. at one end, square in section, so that it may be turned with a small wrench or brace, then reduce the point to the necessary taper, making it circular in section to begin with, and afterwards pentagonal, which is not so difficult to accomplish as it seems at first sight. Now make it red-hot and plunge into cold water, polish, and hold it over a thick piece of hot iron until the cutting portion becomes of a deep straw colour; cool this portion and still further lower the head to a blue tint, otherwise it will be apt to snap off in use. It now remains to mount the finished head, B, firm and deep in a piece of hard wood as before, and use it as a support on which to finish the outsides and edges of the heads, A and C, after which, rather than resort to force, it will be well to split up the wood in which the former is embedded.

The next in order is the stationary pinion; first, square up the ends of the brass tube to finish $7\frac{1}{8}$ in. long; it is possible to do this with a file, but a superior way is to turn them, fitting a short piece of iron into the end to support the tube lest it collapse under the screw of the carrier, which latter should be small, and may be easily made out of a piece of brass plate $\frac{1}{4}$ in. thick, having a screw $\frac{1}{8}$ in. diameter. The tube is then trued up at one end, and the opposite end next the carrier separated with a thin parting tool. Should the tube prove too short to admit the carrier as above, use thicker iron, with a shoulder to abut against the end of the tube. Now cut off 5 in. of pinion wire, centre it truly at both ends, and turn about an inch at one end, to fit tightly within the brass tube; set off $\frac{3}{8}$ in. from the shoulder, and beyond this turn a bearing large enough in diameter to allow of the central hole in the slotted plate for which it is intended being broached out to fit it. Leaving fully $\frac{1}{8}$ in. for the bearing beyond this, cut a notch with the edge of a small half round file and break it asunder; centre afresh, and turn the remaining portion to fit the opposite end of the tube for about $1\frac{1}{2}$ in.; then $\frac{3}{8}$ in. set off as before, and from this point it is turned parallel for $\frac{1}{2}$ in., after which the remainder is tapered to fit the milled head, C. If the worker is an adept with the file, the leaves of the pinion wire may be so reduced as to leave very little to be done in the lathe, and thus avoid the jarring of the work as the tool meets each leaf or tooth in succession; in any case, it will be advisable to make a somewhat liberal use of the file, always provided that the process is not carried too far. The pinion to which the head, A, is attached is similar to that just described, and slides in vertical slots cut in two brass plates $2\frac{3}{8}$ in. long and $1\frac{1}{8}$ in. wide; the upper ends are cut to the angle of the case to which they are secured by four screws each. The outline of one half is shown in elevation by the dotted line at P (Fig. 2), and they are also shown in section just behind the racks in Fig. 5. The slots must be polished so that the pinion works freely and smoothly within them, and the plates carefully attached to the woodwork, the centre of the slots coincident with the centre line, M N; of course, the wood must be pierced squarely through to admit the tapering ends of the pinions, and for the parallel necks or journals of these latter, four washers must be prepared; all are circular in section, with the exception of that under the clamping head, B (Fig. 5). The washer in question is an oblong plate curved at the top and square at the bottom end, in order to utilise it as a vernier to indicate the angle of the reflectors; it is kept vertical by a long slot, which slides on a pin formed of a small screw, the head being filed off flush after being screwed home. The plate adjacent to the slide may also be attached at this juncture, the figures being deferred for the present, as their correct position can only be determined by experiment when the instrument is complete.

Having proceeded thus far, we may now turn our attention to the spindle connected to the friction wheel, H (Figs. 2 and 5). There are two methods whereby this may be accomplished: the first which suggests itself is to bore a hole in a hard piece of beech $\frac{5}{8}$ in. thick, so that a No. 18 wood-screw will fit tightly within it; wind the screw, which should be about 4 in. long, to the end of the thread, and cut off the point $\frac{1}{8}$ in. outside the wood; unwind the screw, and weld or braze it to a piece of $\frac{5}{16}$-in. round iron, cut off to $9\frac{1}{2}$ in. from the screw-thread; straighten and centre accurately, then replace the wood disc and finish to $1\frac{3}{4}$ in. diameter by $\frac{1}{2}$ in. thick, a very shallow groove being turned on the edge to support a band of red rubber, as sold by stationers to secure note books. Inserting a small screw in the rim of the disc, we may use it for a carrier to reduce the opposite end of the spindle to fit the milled head, E

(Fig. 1), which has been prepared with a tapering hole for its reception. Perhaps an easier way to mount the spindle would be to reduce the plain part of the wood-screw so as to fit a piece of $\frac{5}{16}$-in. brass tube, 9 in. long, and also reducing the long boss or shank of the milled head to fit the opposite end, securing them in position by sweating together, or drilling a small hole for a pin; though sweating is to be used in preference. By using the brass tube for the spindle, we shall gain an advantage in its being shorter, and thus lessen the distance that the head projects outwards from the case. Selecting a piece of brass $\frac{1}{8}$ in. thick, we may now cut out the lever, L (Fig. 2), as shown in the dotted line; it is attached by a screw at its lower end, which acts as a fulcrum. The central hole is broached out to fit the spindle, which has a groove cut $\frac{1}{8}$ in. wide at this point, the lever acting as a key to prevent end-shake, and at the upper end of the lever is a small stud, round which is hooked one end of a tension spring, the opposite end of which is secured by a screw, and the slotted plate, P, cut away to clear it.

Arrived at this stage, it is now necessary to commence on the rackwork. First attacking the fixed pair, R R (Fig. 5), very little difficulty is likely to be experienced in making them a success. Two pieces of rackwork $2\frac{1}{4}$ in. long are cut off, and at each end the teeth are removed, so as to leave a clear space of $\frac{3}{8}$ in.; in the centre of this space a hole is drilled and countersunk for small screws, by which the racks are secured to pieces of oak or beech, shaped as at O (Fig. 2); these are rabbeted to fit over the slotted plates, and it will be noticed that one is $\frac{1}{8}$ in. thicker than the other, and is also cut away in addition to admit of vertical travel in the washer, which resists the pull of the clamping head, B. Passing on to the sliding racks, S, S (Fig. 5), we require for these two lengths of dry beech, 12 in. long, accurately planed true and parallel to $\frac{3}{8}$ in. square. Previous to being divided into 6 in. lengths, mark one face and one edge, and place some distinguishing mark so that they may be kept in pairs, one pair to each end. As only $4\frac{1}{2}$ in. are useful, I must explain that the extra length is to lessen the danger of the wood splitting on account of having to drive screws in close proximity to the end of the piece. The two remaining lengths of rackwork are equally divided, and a space cleared and drilled at each end as before, after which each rack is screwed to a wood slide in the centre of its length and flush with the face. As in the case of the fixed rack above, provision must be made for the washer, and in order to support the rack, and keep it square with the pinion, a slip of wood about $\frac{1}{8}$ in. thick is screwed to the back of the slide, as shown in section Fig. 5; when these are in position, they should slide just clear of the edge of the slotted plate. Now, it will be seen that the lower slide of the two at each end is supported on a piece of hard wood, T, T, $2\frac{1}{2}$ in. long, 1 in. wide, and the combined thickness of the slide and slotted plate in one instance, with the washer added in the other. The exact position of these supports may be found by placing the end of the case on the bench, inside uppermost, and holding the pinion vertically in its bearing; push the lower rack into position, interposing a slip of writing paper, so that the teeth may not engage too deeply, the support being finally secured with a screw at $\frac{1}{2}$ in. from each end, thus clearing the brass clips, *l l* (Fig. 5), which grasp the backs of the upper slides. These clips are of brass $\frac{1}{3}$ in. thick, filed to the outline seen in the dotted line (Fig. 2), allowing $\frac{1}{2}$ in. beyond for bending. If the brass from which they are to be made betrays a disposition to crack on bending to a sharp angle, it must be annealed by making red hot, and plunging into cold water. The hole is first drilled to clear the pinion, then the latter is placed upright, the paper slips intervening between the racks and pinion teeth, and a line scribed on the inside of the brass clip, which must next be bent at a right angle, over the edge of a piece of smooth $\frac{1}{2}$-in. square iron, bent on itself, in order to grasp the brass on both sides when held in the vice. This done, with a smooth file polish the inside of each clip, rounding off the arris or edge so far as it comes in contact with the wood slides. When all this has been carefully carried out, it will be found that the racks will travel smoothly in either direction on turning the pinion with a small carrier or pin vice. Should this not have the desired effect, one or both the racks is too deeply in gear with the pinion, if they are not pinched at the sides. Taking them asunder for examination, it will perhaps be discovered that the cause lies in their not being of an even thickness from the tips of the teeth to the back, which will be exemplified by a careful use of the calipers; the remedy will be to file a little off the wood, preserving the same square edge, but on no account must the teeth be interfered with. If the calipers reveal no discrepancy in the depth, it may be necessary to remove the brass clip and file the surface adjacent to the slides, only be mindful that a very little clearance will give the necessary freedom to the movement. The rackwork is now complete, with the exception of four brass lugs or hinges $\frac{1}{8}$ in. thick, as seen at *k* (Fig. 1), having holes drilled and broached if necessary to fit the steel rods which pass through the arms of the reflectors. To be certain that this hole is exactly central over the slot in which the rod moves, it will be advisable to bring the racks to the end of the stroke, as in Fig. 2, while the holes for the screws are being marked through the countersunk holes in the hinges. In this way it will be immediately noticed if the pinion is out of wind with the rod on each side of it. The surplus wood at the ends of the slides may now be cut away, the lower slides being bevelled as at S (Fig. 1), to clear the sides of the case, the construction of which will be taken up in the next article.

DESIGN FOR A LARGE BRACKET IN FRETWORK.

BY E. BONNEY STEYNE.

Fret-craft is an art so simple, that the rules for its perfect working might be taught in five minutes and set forth in a few paragraphs. Yet the point where it gains value from careful and precise workmanship is not to be reached by one or two trials only. If, however, the amateur worker intends to become a past master of the craft, the motto of the old Romans—*Festina lente*—which is generally translated "hasten slowly," should be his, for undue dilatoriness or overhaste will alike fail to compass his end. Like to a moth fretting against a garment, he will indeed leave traces behind him, not only of spoilt material, but also of useless toil. If the saw is not tight and taut at each reinsertion—if it be not held in a perfectly vertical position—the best result cannot be achieved. Yet, if the design is only wrought with elaborate mechanical exactitude, there is danger of a stiff cast-iron pattern being produced. In all hand-wrought work, the charm consists in the feeling unwittingly imparted by the worker. A machine will make you ten thousand repeats of the same detail with microscopic correctness, but if an artist has to draw a pattern with frequent repetitions, though he be never so careful, he will, if indeed he be an artist, all unknowingly produce slight variations in each.

The leaves of a tree, like as they are to each other, are yet not exact replicas of one shape, even in the simplest formed species. But it is waste of words to try to teach what must be instinctive. Though you argue until doomsday, you shall never convince one who has not already felt it of the subtle quality we call "art." Be sure, that if you fail to recognise the difference between things held to be worthy, and the commonplace wares of to-day, that the joy or sorrow of the artist is not yours. If you see nothing in the marvellous drapery of the Fates (in the marble remains of the frieze of the Parthenon in the British Museum) more than in the drapery also of marble that clothes the weeping figures who are fondling urns in the Euston Road stoneyards, then it would be waste of time to try to instil it. To be able to explain wherein and why they differ is quite another thing, that comes only by education and study, but the feeling must be there ere you can in any way cultivate it.

If you take rough carvings by peasant lads, home-made attempts at decoration by artisans, in some you trace the untrained artist, in others merely the mechanic, who assuredly may rival a machine in his finish, but who will never surpass it in the higher qualities.

A sombre sermon this, you say, on a fretwork bracket. Diluted philosophy expended on a trivial piece of ornamental work, lacking merit in design, and exacting little skill in execution. True, I grant you; but the preacher may be aware of the good, although his infirmities forbid him to achieve it. And if the desire to be inspired with the true and sincere love of beauty for its own sake should begin with a thing that has no claim whatever to such a royal description, it will have served a noble end. If in poor work you put your whole heart into making each curve better than your design, letting every leaf or bud mimic the true lines of nature, which, in the desire to keep the whole simple, is impossible in catering for an unknown army of possible workers, then the artist who drew it on paper will be only too delighted to find himself beaten, and be glad to have provoked the energy that caused the initial effort.

The design, for the necessity of the pages of Work, has been planned to give a large pattern in the limit of a page. In tracing leave half an inch of plain wood between the four parts. Trace and reverse for the second tracing of each part. The bracket to support the shelf can be either a simple one or the whole of design A. The shelf may be shaped to any convenient form. It is best kept square with rounded corners. This yields more room for objects to be carried, and is better than a simple half circle.

The size of the bracket when finished and put together is 17 in. by $15\frac{1}{2}$ in. There is no necessity to say anything about material, as when it is possible to do so the material should be suited to the furniture of the room and the surroundings. The design itself will be found in the next page.

BURGLAR ALARUMS.

BY GEORGE EDWINSON BONNEY.

THE WILY BURGLAR—UNGUARDED POINTS OF THE DEFENCE—BURGLAR TRAPS—LEADBETTER'S BURGLAR ALARM—FLOOR OR DOOR-MAT CONTACT—AMATEUR FLOOR CONTACT ALARM—CLOSED CIRCUIT ALARM SYSTEM—ALARUMS FOR EMPTY HOUSES—CONCLUSION.

The Wily Burglar.—Professional burglars do not always set about their nefarious work in the same way, nor enter the house according to the rules of any concerted system. An open window or open door may generally be relied upon as offering an unresistable temptation to the thief, but he prefers an open cellar grating, a fan-light left unfastened, or scullery window left ajar, to any of these apparent traps. The old bird is not caught with chaff, nor the ticket-of-leave man twice in the same way. As he gets older in his career, he becomes more crafty, and teaches the younger members of his profession the mysteries of his craft. I can quite conceive of such a wily thief studying electricity and making himself well acquainted with electric burglar alarms with a view to turning his acquisitions of knowledge to his own ends. Such a wily thief would examine all windows and doors in search of indications pointing to the presence of alarm contacts, and even invent means for throwing these out of action and so prevent them from giving the alarm.

Unguarded Points of the Defence.—We should therefore endeavour to so plan our system of defence as to leave no points unguarded. Partially opened fanlights may be left in this state if protected with Legge's Window Blind Contact. Scullery windows should always be fitted with a suitable contact, and even the trap-door leading to the roof should not be left unguarded. The cellar-flap or grating may be adequately protected with one of Dale's Burglar Traps fastened to the same with a piece of stout string. Should the thief break the fastenings of the flap noiselessly and attempt to open it, the string of the trap will not fail to ring the bell; and should he discover the string and cut it, he will by so doing release the spring of the trap and cause it to make contact.

Burglar Traps.—These, and the others to be described, are therefore veritable burglar traps, likely to foil the most cunningly devised schemes of the wily burglar, and drive him to despair. Dale's Burglar Trap (shown at Fig. 60) is so named by me because of its cleverly devised double action. This trap is made up (as shown in the figure) of a small brass casting $3\frac{1}{2}$ in. by $\frac{5}{8}$ in. by $\frac{1}{8}$ in., with two pieces bent down in the middle at right angles to form a clasp for the hinged lever below. An ebonite block is attached to each end of the base plate, and to these blocks are fixed brass contact pieces insulated from the base plate. The small brass rocking lever hinged to the base plate is also furnished with platinum points where the ends touch the contact plates. It will be seen that a piece of bent clock spring, D, forms a spring between the base plate and one end of the rocking lever, to keep this from being in contact with the plate at A. This little appliance may be attached by screws to the floor, a post, or any piece of wood at a little distance from the point to be protected. The wire from the binding screw, C, must then be connected to one line wire, and the two wires from A and B to the other line wire of the alarum system. This being done, the bell will ring and continue ringing until the

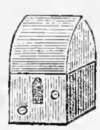

Fig. 67.—Contact Block for Floor Contact Alarm.

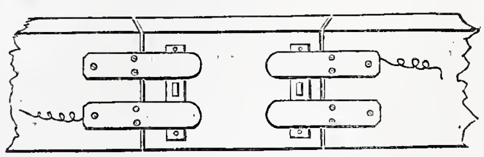

Fig. 64.—Amateur Floor Contact Alarm: Plan of Underside.

rocking lever has been pulled away from B sufficient to keep both ends free from touching either A or B. A piece of stout string is then fastened to the loop, E, and tied to the door-flap, grating, drawer, or whatever we wish to protect. It may be tied to the leg of the table, or of a chair, or to the knob of a drawer, or of a door. Should the article to which it is tied be moved away from the appliance, the lever will be brought into contact with A and start the bell ringing; but should the wily thief discover and cut the string, the lever will be forced by the spring, D, into contact with B, and thus ring the bell. Should he fail to discover the string, he may possibly stumble against it and thus bring both ends alternately in contact. Similar traps are made in cylindrical form for insertion in posts and sills. In these forms a small brass piston working in an ebonite cylinder is kept in contact with the brass casing at one end by means of a spiral spring, until pulled out, when a cross piece makes contact at the other end. These are named "double contacts."

Leadbetter's Burglar Alarm.—This ingenious burglar trap, invented by Major Leadbetter, is shown at Fig. 61, and its internal arrangement at Fig. 62. The external appearance is that of a 3-in. electric bell gong, furnished with a pillar on the top, out of which protrudes a small piston of brass. On taking this instrument in hand we find that the gong is fastened to a brass ring enclosing a disc of ebonite, which forms a base for the gong. The ring is held to the sides of the gong by three small steel set screws, and, on unscrewing these, the dome comes off and reveals the interior arrangement shown in section at Fig. 62. This is most simple. Two small strips of spring brass are fixed to the ebonite base by small screws and bent to form a bridge, coming into contact with each other at the free ends. To the longer and lower strip is soldered (in the middle of the bridge) a small disc of brass raised in the centre to form a cone, the summit of which is hollowed out a little to receive the rounded end of the brass rod or piston. Two short pieces of insulated wire connected to these bits of brass and carried out through holes in the ebonite base, serve to connect them with the alarum system ouside. It will be seen that the pillar on the top of the gong is hollowed out to form a socket, and this fits a ball through which the piston passes. The screwed cap of the pillar is hollowed beneath to form a cup fitting the top of this ball. When, therefore, the end of the rod or piston is inserted in the top of the cone on the contact bridge and the cap of the pillar is screwed down, its hollow cup presses on the ball and causes the rod to press apart the contact pieces below. The alarum is now fixed ready for action. By means of projecting pieces on the ring of the base, it may be fastened by screws to the floor of a room, to a block of wood in a garden, or to a table, or any other wooden support. Pieces of twine or strong worsted are then fastened to the top of the piston (in the holes shown in the cap) and led in any direction from the contact to doors or windows, or to stakes driven in the ground, to which the ends must be attached. If the prowling thief opens a door attached to one of these strings, or if his feet is caught in one of them, the top of the projecting rod is pulled on one side and its foot slips out of the socket on to the contact bridge; these strips at once come into contact, and the bell is set ringing. The contact pieces can be set easily at any time by unscrewing the cap of the pillar and adjusting the rod, and this can be set to almost any degree of stiffness by more or less pressure from the screwed cap on the ball of the piston. These little instruments are sold by Messrs. T. Gent and Co, Faraday Works, Braunstone Gate, Liecester, at 10s. 6d. each. They are said to be most invaluable as detectors of garden thieves, as the strings leading from them can be readily laid among grass and foliage, and so escape observation.

Floor or Door-Mat Contact.—At Fig. 63 is shown the usual form of floor or door-mat contact. The brass barrel of this appliance is furnished with an extra stout spiral spring surrounding the stem of the flat top plunger shown in the sketch. This keeps the plunger in the position shown until pressed down with the foot, when the bottom of the stem comes into contact with an insulated stud fixed in an ebonite disc screwed into the bottom of the barrel. To fix this appliance, a hole to fit the barrel must be drilled with a brace bit in the floor, under the mat; the top part of this is countersunk to receive the lower part of the cap, and then the flanges of the cap let in flush with the surface of the floor. The wires are laid along beneath the floor, and brought up through the hole cut to receive the contact barrel; the ends are connected to the screws shown in the sketch. When placed under a mat in the doorway this appliance serves to announce the arrival of a visitor, and it is also used under the carpet of a dining-room table to enable the host or hostess to summon a servant by pressing the contact with the foot.

The Amateur Floor Contact Alarm.—At Figs. 64, 65, 66, and 67, I give detailed illustrations showing how an amateur may construct for himself an effective floor contact alarm. To do this he must rip up one or two or more floor boards under the doorway, or at any other part of the floor where the alarm is to be fixed. One floor board will be enough, but the area of contact will be enlarged if two or more boards are formed into a kind of trap-door, and then laid down again, for in this case it will be almost impossible for any one to miss treading on the trap. I take, however, one board as being sufficient to work upon for the purpose of elucidating the construction of this alarm. Having taken up the board, mark off an oblong piece on it, just between two joists, at a spot where a person is likely to tread when entering the open door. Cut this piece out of the board, as shown at Fig 66, and thus form a little trap-door with bevelled edges. To the undersides of the remaining pieces of floor board, fasten, by means of short screws, four pieces of thin spring steel or spring brass in the position shown at Fig. 64. When the contact arrangement beneath the floor has been completed, these pieces of board will be nailed down in their places and the springs will support the trap-door as shown in sketch.

Two contact springs will be required for the underside of the trap. The form of these is shown at Fig. 65. Their proportionate dimensions are shown in plan at Fig. 64, and in section at Fig. 66. I purposely omit sizes because these must be obtained by actual measurement on the spot. The springs themselves should be made out of stout spring brass at least $\frac{1}{2}$ in. in width, and the curved ends should have a bit of platinum foil soldered to them where they are likely to come into contact with the contact block beneath the floor. The base plate to which they are riveted must be long enough to span the space between the steel springs supporting the trap, and the springs long enough to reach the contact block as shown in Fig. 66. The contact block is to be made out of a piece of boxwood or of ebonite to the shape shown at Fig. 67, and should measure when finished: height 2 in., width $1\frac{1}{2}$ in., thickness 1 in. The lower part of the block, beneath the tapering part, must be coated with thin sheet brass, with a bit of platinum foil soldered just where the tips of the springs are likely to come into contact with the brass when the trap is pressed down. This block must be fastened to a strip of $\frac{1}{2}$ in. deal secured to the joists and supported as shown at Fig. 66. The floor boards may now be nailed down, and the wires from the alarum system connected to the steel springs as shown at Fig. 64. When the trap is put in its place it should be kept by the tips of these springs at least $\frac{1}{4}$ in. above the level of the floor if intended to be under a mat or carpet. The tips of the contact springs should also be resting on the taper wood part of the contact block. If all has been made aright, the trap will sink when trod upon and the current from the battery will pass by way of the steel springs to the brass springs and the circuit be completed through the metal coat of the contact block.

This form of floor contact possesses the advantage of being easy to construct and keep in order. All the contact points are what are known as "rubbing contacts," and therefore not likely to get rusty or coated with dust. Should any of the parts require attention, the trap can be easily removed and the parts repaired.

The Closed Circuit Alarm System.—To more effectually foil the nefarious schemes of the electrically educated thief, a system of electric alarums has been invented, which depends upon the action of an electro-magnetic relay always connected with a constant battery. This relay keeps the local circuits of the alarum bells open whilst its own circuit remains closed, but should the crafty thief discover the wires and cut them, the circuit of the relay is at once broken, and it then throws into action the local battery connected with the alarum bell. The battery used in this system is a form of the Daniell known as the sulphate gravity battery. In this form, a lead cylinder perforated with small holes at the bottom, and filled with sulphate of copper crystals, forms the negative element in a glass or porcelain cell. In the same cell, suspended near the top from a wooden cover, a massive ring of zinc forms the positive element. The cell is first charged with dilute sulphuric acid, then a saturated solution of copper sulphate is carefully poured into the lead cylinder so as to float the dilute sulphuric acid on its surface. The superior specific gravity of the copper sulphate solution keeps it at the bottom of the cell below the dilute sulphuric acid, unless the cell is shaken or the solutions agitated. This battery keeps in good working order whilst constantly in action, hence its use for this purpose.

If this system is adopted throughout a house all the contacts must have a reversed action; that is to say, they must be made to keep the circuit closed whilst all the doors and windows are closed, but to break the circuit when any of these are opened. No attempt should be made to conceal the ires and connections as it will be an dvantage should they be discovered and ut.

Alarums for Empty Houses.—When well-o-do householders flit to the seaside or to he moor for their summer holidays they annot always leave their houses in the care f servants or care-takers. They therefore ock up the premises and depart in some ear and trepidation lest the house should be roken into during their absence. Messrs. '. Gent & Co. have made arrangements or supplying a specially constructed loud-oned gong to be fixed on the outside of a ouse and connected with the alarum system nside. Notice should be given to the olice that a house is thus protected whilst s owners are away, when they will hold hemselves ready to pounce on the thief s soon as the bell gives notice to them f his intrusion. Of course it will be nderstood that the bell is not placed in a rominent position to be easily seen by the ntending burglar, but it will be best heard f placed high up on the house.

In this series of papers I have not pre-ended to give an account of all the little ontrivances made and sold as burglar larm contacts. Either of the firms men-ioned by me will have much pleasure in upplying any special forms to meet special ircumstances, and to advise on the fixing f the same. I will also endeavour to do vhat I can through the medium of "Shop" to ssist with my advice any reader who may vish to make or repair his burglar alarums. The subject of fire alarms and other auto-natic alarm systems will be dealt with in uture papers.

OUR GUIDE TO GOOD THINGS.

. *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* WORK *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of* WORK *without charge, the notices given partake in no way of the nature of advertisements.*

101.—Moore's Patent Folding Chairs.

A REALLY easy chair is a piece of furniture much o be desired in every house, especially a chair hat is made in such a manner that the inclina-ion of the back to the seat may be varied at leasure from an almost erect position to one hat is very nearly parallel to the floor without ifficulty or much exertion on the part of the perator, and which, when the relative positions f back and seat have been thus altered, is so onstructed as to retain the form which is de-ired and required without shifting either when ouched or sat upon, as is the case with not a ew folding chairs that are said to be secure and table. The best chairs of this kind—best be-ause they satisfy all the conditions that one aturally looks for in an easy chair whose back nay be raised or lowered at pleasure, namely, tability, ease, and comfort—are, as far as my xperience goes, to be found in the Patent Fold-ng Chairs manufactured by Mr. J. T. Moore, of Macclesfield, and sold by any upholsterer in the United Kingdom, or, if not in stock, can be pro-ured from the manufacturer for any customer t short notice. The principle on which these hairs are made varies in some cases, but that vhich governs the construction of most of them vill be understood from an inspection of Fig. 1, rom which it will be seen that the front legs or upports of the chair and the sides of the framing f the back are combined in two large strips f wood that run in one and the same length from the top of the back to the floor, and that the hinder supports are attached to these by bright brass grips, whose hold on the long bars can be released or tightened at pleasure, and which move up and down the back, and thus raise or lower the seat to any inclination desired.

These Patent Folding Chairs are distinguished by different names according to size, form, or fittings. Thus in Fig. 1 an illustration is given

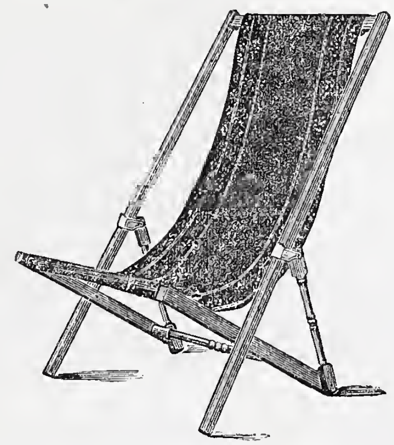

Fig. 1.—The "Waverley" Patent Folding Chair.

of the "Waverley," a luxurious and comfortable hammock chair or lounge chair, nicely upholstered with a strip of carpeting that forms both seat and back, and yields to every movement of the body, to which it affords a strong but most comfortable support. The ends of the framing are firmly planted on the ground, and contain within the straight lines drawn, or that may be drawn, from one to the other, a sufficient area to impart perfect stability to the seat. This chair is said to be one of the best chairs made for use on a lawn or ship's deck, and it can be used when opened out only eighteen inches from front to back, thus rendering it of great utility in cases where room is a consideration. The "Trafalgar" is like the "Waverley" in form and construction, but the frame is more strongly made, and thus perhaps it is more suitable for gentlemen's use as a lounge, hammock, or deck

Fig. 2.—The "Hygienic" Patent Folding Chair.

chair, while the "Waverley" meets the less exacting requirements of the ladies in every particular. The "Pliant," another chair of this class, is placed on rockers, and so are the "Gem" and "Little Gem," most useful chairs, very portable, and suitable in every respect for drawing-rooms, sitting-rooms, and bedrooms, as well as for outdoor purposes. The last-named chairs differ from the "Waverley," "Trafalgar," and "Pliant" in having the inclination of the back regulated by means of a rack on the underside of the seat bars, in connection with the spindle on which the seat bars rest. The "Hygienic," illustrated in Fig. 2, is like the "Pliant," but has a rack at the seat bars and a regulator fastened to the back instead of the grips. When made with arms it is a good nursery chair, and a child may be put to sleep in it. It is specially recommended for invalids, because the peculiar wave-like motion induced by it when in use relieves constipation. "Its action," says the inventor, "is perfect massage without the toilsome labour, and, as prevention is better than cure, the daily use of its gentle, undulatory motion will greatly assist the liver and bowels in securing that vigorous health which is of so much value to every one. A great advantage of this chair is that it combines a perfect rocking chair with a perfect lounge, the restfulness being such that it has many times been used as a bed. THE EDITOR.

MASONRY CLASSES AT SOUTH KENSINGTON.

THE Editor of WORK has much pleasure in saying that he has received the following letter from the Secretary and Members of the Committee for the formation of these classes, dated 17, Shepherd's Place, Upper Kennington Lane, S.E.:—

"DEAR SIR,

"We earnestly request your favourable consideration of the enclosed syllabus of masonry class to be held at South Kensington under the direction of Lawrence Harvey, Esq., F.R.I.B.A., etc., and should you believe the lessons therein are calculated to give a sound knowledge of masonry and construction, and prove a scientific basis of training for masons desirous of rising to the positions of foremen or clerks of works, we respectfully solicit your help to bring these lessons within their reach.

"The Council of the City and Guilds of London Institute either cannot or will not reduce the high fee demanded of $2\frac{1}{2}$ guineas, therefore we the undersigned have formed ourselves into a Committee to receive subscriptions from friends who consider our cause a good one, and tending to raise the general tone and character of a large body of workmen.

"We propose reducing the fee to 25s. each for all bonâ-fide masons, and even this amount, with the addition of railway fare and other expenses, forms a large sum for masons to pay, and it is to their credit that many are now anxiously awaiting the result of this our effort in their behalf."

In giving publicity to it, the Editor has only to add that a letter to the Secretary at the address given above will at once procure for the applicant a syllabus of the classes and a prospectus of the "College of Masons."

SHOP:

A CORNER FOR THOSE WHO WANT TO TALK IT.

PRIZE COMPETITION DESIGNS.

IN reply to correspondents who have written pointing out that engravings of these designs did not appear in No. 30 of WORK as announced, the Editor takes the opportunity of explaining that it was considered to be more useful to readers to give working drawings of them instead of small sketches, as was originally contemplated, and that they will shortly appear in turn with descriptive matter explaining mode of construction, etc. etc.

I.—LETTERS FROM CORRESPONDENTS.

"Muntin," and Suggestions to our Writers. —W. B. (*Liverpool*) writes:—"I observe some correspondence in 'Shop,' No. 27 (see page 428), regarding the derivation of the word 'muntin.' I find it given in Ogilvie's Imperial Dictionary as follows:—'Munt (Scotch), to mount. Muntin, or munting, the central vertical piece that divides the panels of a door.' It is evidently a corruption of the word 'mounting.' May I offer a suggestion as to articles in WORK? There is a tendency in some writers to shorten their descriptions, and to offer supplementary instructions through 'Shop,' if required. The effect is to leave the instructions a little vague, and so much is taken for granted that it is sometimes difficult for an unskilled hand to follow them. That is not satisfactory, and though the deficiencies may be made up in 'Shop,' it is only when some one asks for the details. Besides, you will no doubt have correspondents all over the world, to whom the columns of 'Shop' cannot be of much service in that way. The delays are too great. I regard Work as so valuable that I should be sorry to see its usefulness impaired for want of a little extra trouble on the part of the authors. Many of your readers are no doubt, like myself, very amateurish, and require full and complete details of construction from beginning to end, but observe it has only to be done once. Having given such instructions for, say, a bookcase, camera, etc., in all future designs of similar character, readers could be referred to those instructions for details. Do not think I complain of Work—it is the best value for its price that I have seen for a long time. I do not like to mention names, but Mr. Adamson's instructions about the bureau are the kind that I and many others require. I cannot follow the articles on the camera, kaleidoscope, sideboard, etc., so easily."

Tin Ovals, etc.—A. N. (*Airdrie, N.B.*) writes:—"Being a reader of your paper, Work, I may say I am well pleased with it, also the remarks in 'Shop,' which is a first-class feature in it, and which I find very interesting. I may say I am in the metal stamping line, and am pleased with B. M. Ramsden's paper. I also noticed the fanners in 'Shop,' of which I have made a few before seeing same. The only difference in mine is I have spindle running on centres as underneath, which causes less friction, and can be altered in case of blades rubbing on side, having gam nut on the screws. I may say I have made a fern case and aquarium combined, and seeing inquiries for same, I hope to see papers on it. But, Mr. Editor, would you be as kind as to ask some reader for a description of machine or oval rollers for making oval tin bodies with locked seam, such as mustard and tobacco tins, or makers of same, or put me in correspondence with one who knows? I may say I would give something to have a fast method for forming oval bodies. I hope you will be as kind as to put this inquiry before your readers."

Machines for Current of Air.—Fitter (*Walsall*) writes:—"I have noticed a sketch or two of machines for producing a constant current of air, and I should be glad of the dimensions for making same."

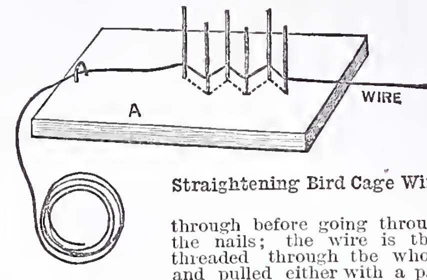
Chamfer Plane.—Apprentice Lad (*Leicester*) writes:—"In No. 20, on page 316, J. W. (*Burton-on-Trent*) writes that he has made a chamfer plane from working drawings published in the *Carpenter and Builder*. I should be very much obliged to him if he would kindly give me the drawing in 'Shop,' so as to make one myself. I think others would like to make such a useful tool too. I am very pleased with Work."

Blacking Gladstone Bags.—R. A. P. (*South Kensington*) writes:—"Seeing in your issue of 24th August (page 365), a paragraph entitled 'Gladstone Bags,' recommending Berlin Black for renovating same, I endeavoured to get some, but found that it is seldom kept in stock by shopkeepers, though it could be got to order, but not less than a gallon. I therefore got some of Harris' Black Leather Varnish, sold by Harris & Son, 33, Beech Street, Barbican, E.C., and found it answer admirably, drying quickly, and it is quite elastic and pliable. Twopennyworth is sufficient for a large bag."

A Hint to Fretsawyers.—C. E. (*Streatham Hill*) writes:—"It may be worth knowing that half a dozen or more exact copies with once tracing can be taken of a design without spoiling the original by placing underneath sufficient sheets of Japanese paper and carbonic paper, and tracing with the end of a needle stuck into a wooden holder. For instance, if six copies should be required, six sheets of the Japanese and three sheets of the carbonic paper would be required, as the latter is prepared on both sides. The paper, being so extremely thin, can easily be removed from the cut work with a damp sponge, provided it has been stuck on with thin paste. Being also transparent, the reverse of a design can be got by simply turning it over. I may mention that Messrs. Isaac Pitman & Sons, of shorthand fame, Amen Corner, supplied me with small quantities of the above."

Wheels, etc., for Mail Cart.—W. P. writes:—"Readers of Work who reside in the North of England and are desirous of building a mail cart can buy their wheels and other requirements of James Henry, 95, Port Street, Piccadilly, Manchester, who supplies wood wheels at 4s. per pair, rubber wheels at 5s. per pair, and other things equally cheap; Alfred Parker, 60 and 62, Great Ancoats Street, Manchester, who supplies rubber tire wheels with axle at 5s. 6d. per pair; and Owen's Toy Bazaar, 84, Ancoats Street, Manchester, where rubber tire wheels may be bought at 5s. 6d. per pair, and spider wheels (without rubber tires), springs, and axle at 7s. the lot. Readers residing at a distance, and unable to get these things in their own locality, should write before making a remittance, giving the height of wheels required and inquiring price."

Straightening Bird Cage Wire.—A. E. D. (*Birmingham*) writes:—"In No. 27 of Work (see page 429) are a few remarks *re* straightening wire, but all have not the use of a set of tinman's rolls, so I take the liberty of sending sketch of a simple method which will straighten any kind of wire, either hard or soft, which I hope will be useful to readers of Work. In the illustration A is a strong piece of wood into which strong nails or pieces of thick wire are driven, not straight but zigzag as shown. A staple is also driven for wire to pass



Straightening Bird Cage Wire.

through before going through the nails; the wire is then threaded through the whole, and pulled either with a pair of pliers or by being bent round a piece of wood or the like; if the wire curls either way the nails are to be hit sideways alternately; the last two or three will suffice. A little practice will soon show how the curl can be broken. And now, in conclusion, allow me to thank you for publishing so useful a periodical as Work. I have taken it from the commencement, and am both instructed and delighted. Long may it flourish is my wish."

Simple Bead Router.—J. M. (*Louth, Linc.*) writes:—"Noticing, as I have in looking through the columns of Work, the many valuable tips and receipts they contain, also about the tools of other trades, which of course I myself am not well acquainted with, it made me think, as I had received some benefit from Work, I could supply

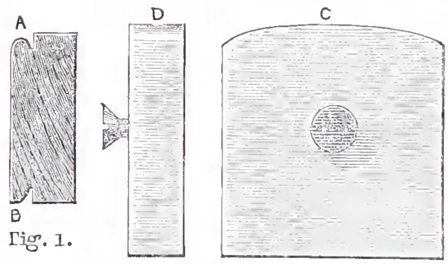


Fig. 1.—Examples of Beading. Fig. 2.—Bead Router in Plan (C) and End View (D).

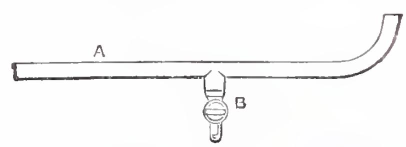
some of our amateur friends, as well as practical friends, with a design for a very simple and yet very useful and cheap tool, which they all could make themselves. It is a tool (of course I call it a tool, though, perhaps, some would not call it so) for making beads on the edge of doors, or any other article that requires a bead on an edge. I enclose sample of beading, also the tool itself. You will notice one bead is finished with just the edge taken off with a smoothing plane (as at A in Fig. 1), and the other at B, just cut with the screw head, and not finished with smoothing plane. The tool itself is shown in plan (C) and section (D) in Fig. 2."

Noises in Waterpipes.—E. G. B. (*Rochester*) asks:—"Can you tell me the cause of waterpipes humming, and a loud lapping noise occurring when water is drawn? How can I remedy the above defect?"—To this query I may reply:—The noise referred to by E. G. B. is caused by turning the draw-off cock suddenly when there is a high pressure of water. The simplest remedy is to have a screw down cock, or have the pipe lengthened thus:—



Noises in Waterpipes—A, Pipe; B, Draw-off Cock.

Microscope Making, Etc.—G. E. G. (*Bradford*) writes:—"The instructions given by O. B. in No. 22 of Work describe the brasswork part most minutely, but nothing much is said about the most important thing (viz., the optical part), excepting a little about the eye piece, which was of great interest to me. He says there is nothing that an ingenious worker cannot do except the few castings in brass. How would the instructions read if applied to the metal work of a clock, and nothing said about the number of teeth, or the diameter of wheels and their mode of action? I consider it just as vague. The metal work to me now is child's play, but the optical part I don't know much about. I should esteem it a great favour if as good a description of the lenses could be given. I don't mean the making of them, but as to their focal positions, diameters, etc. I, when a boy of fifteen, read an article in *Design and Work* respecting the making of a microscope; the instructions given were mostly about the diameters, positions, and focus of the lenses. I procured the proper lenses mentioned from London, and made the thing according to instructions, but was disheartened on the completion, as the definition of the objects was very bad. I then had the opportunity of examining a professionally made one, and found my lenses to be absurd in diameter and as regard to their positions. Now I wish to point out that such descriptions get young lads and amateurs to spend their time and money, until they come to such a disappointment as I did in my first attempt, when the whole thing is given up in disgust. Perhaps I am too rash in not waiting to see if the subject is to be continued or not. However, here are two or three more things that would put the damper on a boy who commenced to make (1) machine for current of air, No. 19, p. 302. It certainly has a slight look of a fan—perhaps a little resemblance to a Capel Mine fan—but driven in the wrong direction the vanes curved the wrong way, and no inlet for the air shown. (2) An easily-made fret machine, No. 21, p. 332. The most vital part not shown, how i the motion given to the saw frame by a cam—eccentric or what; and bow on earth would the connecting rod pass the axle, fixed in the way it is shown? (3) Soldering in repairs of sheet meta utensils, No. 23, p. 354. Now everybody would no know, in attempting such soldering, that the leas particle of zinc left on his iron or solder would giv no end of trouble in attempting to mend a kettle o especially a soft metal teapot; a good solder fo Britannia metal or pewter contains bismuth t make it more easily fused, so as not to endanger th article. This trouble I had to find out at th expense of spoiling a good teapot. I now kee a piece of solder to itself that I use for zinc only as good solder gets contaminated when soldering galvanised metal. I am also very careful to file o all the old facing from the iron after using it fo zinc. (4) Lock repairing and key fitting, No. 21 first page. Our friend says the chisels for chipping out the keys cost about 6d. Most amateurs i attempting chipping metal with such small chisel would soon send their sixpences flying. I had t find out that using a chipping chisel requires good deal of skill. A boy reading that subject, an seeing how simple it appears to be to cut keys would speculate a shilling or two on the tools, an in the end be disgusted at his chisels breaking. admire such a remark as regards buying a chea vice, as I once bought one; the thread stripped i a very short time. I trust you will see what I an aiming at, not exactly being sarcastic, but simpl pointing out that a little more detail and cautio might be put in the subjects to make them mor easily understood by the younger folk, as really m (1) and (2) would make a practical man stud before he could understand what the drawing were meant to illustrate. I think if such drawing were submitted to more practical men before bein cut less time and money would be wasted. I an not reflecting discredit on the whole of the subject as I consider most of them splendidly described. am now nearly thirty, and have always take a paper of this sort since being thirteen years old *Design and Work*, or *English Mechanic*, an now Work, which I consider by far the best fo amateurs. I am speaking for beginners, as yo will see what difficulties I have met by attemptin these things which appear easy to make or d In my opinion every lad should have a hobby an be encouraged, as a very little thing makes hi give it up if everything does not go right, and the he will perhaps turn for the worse. My fathe encouraged me by buying a small cheap lathe for Christmas-box when very young, and used to hel me out of many a difficulty. I now possess facsimile screw-cutting amateur lathe that too the only medal for lathes at an exhibition held i my town. My hobby now is a good help on m weekly salary."—[Your letter contains just th kind of criticism that is desired and courted, an the recommendations given will no doubt b accepted, remembered, and acted upon by those t whom they refer. You must remember, howeve that many a skilled hand, writing on a subjec with which he is perfectly familiar, will omi reference to some necessary point, because i happens to be so well known to himself that h imagines it is equally well known to all for whor he is writing. I endeavour, however, to impress o every writer the desirability and necessity fo being minute in detail, so that those who ar ignorant of processes, etc., under description o discussion may be helped to as perfect a compre hension of them as possible. Whenever a voluntee writer describes and illustrates in "Shop" any thing that is not actually feasible, it is desired tha either queries should be put to elicit better informa tion on any points which may not be intelligible, o a description supplied which clears up anythin that may not be perfectly plain.—Ed.]

II.—Questions Answered by Editor and Staff

Papers on House Painting, etc.—J. H. Y (*Sunderland*).—Articles on house painting and de corating were commenced in Nos. 27 and 29 of Work and these are furnished by one who is both skilled hand at the work and a competent writer Receipts for making varnishes, greases, cements patent driers, etc., will appear in "Means, Modes and Methods" when sent in by correspondents wh have tried and tested them; but I regret to say tha up to this time I have had but very few contri butions to this portion of the Magazine. I canno comply with your request to facilitate an inter change of receipts between readers of Work. Sen me any that you may have by you, and they shal ppear in due course; and, if you set the ball rolling, ithout doubt others will follow your good example.

Shells.—VULCAN (*Greenwich*).—The firm can aim the application of the punches and dies to the irpose without limiting themselves as to size. If ou use similar punches and dies for the same purpose, you infringe the patent, and an injunction to estrain you from so doing can be obtained, even though your punches and dies are of different zes from those used by the patentees.—F. C.

Revolving Stereoscope, etc.—T. G. (*Hatton-Hole*).—I darcsay some correspondent who underands the construction of this instrument will send paper on it, in which case it shall appear for your enefit. With reference to house painting, see bove reply to J. H. Y. (*Sunderland*). A folding ench for amateur woodworkers will appear very hortly, and will be followed by another on the iode of making a good stout and serviceable work ench with convenient fittings.

Book on Sign Writing.—W. F. M. (*Commercial Road, E.*).—The book on "Sign Writing" referred o has been out of print for years.—H. L. B.

Printer's Roller.—J. P. S. A. (*Penryn*).—Without knowing the size of the roller, or the materials f which it is made, it is impossible to give direcions how to renew it. Printer's rollers are generally omposed of glue and treacle, one pound of the ormer to a gallon of the latter. About one-third of he old material could be mixed with the new. The casting is accomplished by pouring the composition into a mould, the wooden or metal stock occupying the centre. As, however, the casting of a roller is a difficult task to any one who has not done it before, we would recommend your having t renewed by a practical maker.—J. F. W.

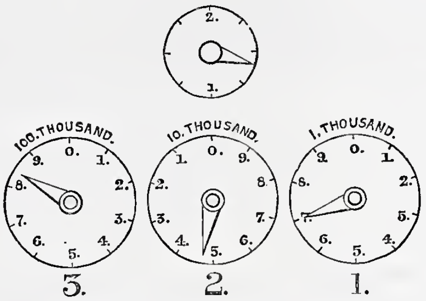
Accumulators.—JAMES (*Peterboro'*).—(1) Start charging the cells with current of a low E.M.F., and raise its tension as the cells get charged. Continue the charging current for thirty hours, or ten hours a day for three days. When, at the end of this time, gas is seen to come off in bubbles from the plates and the liquid appears milky, the charge is complete, and each cell should then have an E.M.F. of from 2·2 to 2·5 volts. Always discharge the cells through a high resistance, and let this be greatest at first if you wish the plates to work well. Always fully charge the cells before commencing a discharge, and do not continue the discharge when the E.M.F. falls below 2 volts. (2) Brown plates are positive plates, and grey plates are negatives. You must have both. (3) Unpasted plates require occasional reversing charges, but this is a delicate task, and should be conducted with great care. The reversing current must be very small at the start, and be gradually increased until the cells are fully charged. A rapid charge or discharge is always liable to scale the plates. See Sir David Solomon's book on the "Management of Accumulators."—G. E. B.

Medical Coil.—H. D. (*Heaton Norris*).—The necessary description and illustrations for a medical coil would take up too much space in "Shop." I may tell you, however, that the primary wire must be wound on by itself, and the secondary wire wound over the primary wire in the same direction. The two should not be connected together. In constructing one with different powers, each power has its own secondary wire. An article or two on coils will be given when space can be spared for them.—G. E. B.

Carriage Varnish.—J. R. (*Glasgow*).—I do not think any one ever makes his own varnish nowadays. For many reasons it would be a very risky experiment, and amateur's varnish would be almost certain to spoil a carriage, etc. As I do not know your requirements I can only advise you to obtain the best carriage varnish from any good oilman at about 16s. per gallon. If, however, I were compelled to make it myself, I should try the following recipe, as the source from which I take it—Spon's Recipes—is most reliable:—"Best pale carriage varnish: 8 lbs of 2nd African copal; 2½ gallons of clarified oil; boil till very stringy; ¼ lb. of dried copperas; ¼ lb. of litharge; 5½ gallons of turpentine, strained; 8 lbs. of 2nd sorted gum anime; 2½ gallons of clarified oil; ¼ lb. dried sugar of lead; ¼ lb. litharge; 5½ gallons of turpentine; mix with the first while hot." This is, of course, for a large quantity, but the various ingredients might be reduced proportionately for small quantities.—OPIFEX.

Solution for Developing Negatives.—AMATEUR (*Oldham*).—To make a concentrated developer dissolve:—No. 1. 4 oz. sulphite of soda; 30 grains of citric acid; 9 oz. hot water; when cold add 1 oz. pyrogallic acid. Call this solution No. 1. No. 2. 2 oz. carbonate of soda pure; 10 oz. water. Call this No. 2. For use take 30 drops of No. 1, add 2 oz. of water, and just before development add 1 oz. of No. 2. This makes a capital developer for most makes of plates. Ordinary clean washing soda will answer in case of difficulty in getting the pure article. You had better try Ilford ordinary plates, and be very careful to use no more light than absolutely necessary for development, especially at the beginning of the process. Both solutions will keep indefinitely before mixing together.—E. D.

How to read the Index of a Gas Meter.—H. N. (*Chelsea*).—The four circles represent the indices of an ordinary dry gas meter. The indicator, or band of circle marked 1, has to travel once right round to register 1,000 feet, once right round circle 2 to register 10,000, and once right round circle 3 to register 100,000 feet. That is to say, that the hand of circle 1 must have travelled once right round before that of circle 2 is on the 1, which will show that 1,000 feet have been used; and the hand of circle 2 must have travelled right round once, and that of circle 1 ten times, before the hand of circle 3 is on the 1, which will show that 10,000 feet have been used, and so on. Now to take the state



Indices of Ordinary Dry Gas Meter.

of meter, commence at circle 1, and whichever number the band is on or nearest to, that will indicate hundreds. You will notice I have put it at 7 or 700. (Bear in mind that it would have to go right round to be 1,000.) In circle 2 you will notice that the hand is between the 4 and 5, but, although it is nearest to the 5, you call it 4, which makes it 4,700. The reason you call it 4, and not 5, is because the hand has not reached 5, but has passed the 4 and about three-quarters, or 700, over. In circle 3, the hand is between the 8 and 9, very nearly half-way, which makes the reading 84,700. The small circle above merely indicates units, and need not be taken any notice of. As the indices of both wet and dry meters sometimes vary with different makers, I will soon put you right if your index does not correspond with the diagram above on receipt of particulars.—E. D.

Plating.—C. E. (*Plainville, Hartford Co. Conn.*).—You are perfectly correct regarding platina plating. It simply means platinum plating. There are no solutions I am sorry to say at present in the market (at least that I could recommend) to plate and oxidise at the same time. You could, however, add a little platinum bichloride to your bath, but it is, as a rule, a little troublesome to work. A good method and solution for oxidising silver is the following:—Take 1 lb. of sulphur and dissolve it in 1 quart of boiling potash solution, prepared by dissolving ½ lb of caustic potash in 1 quart of water (cold). When the reaction following this has stopped and the vessel is cold, pour in sulphur and boil, stirring the solution well, then cool and filter. This gives a fine oxidising solution. If work is too light add little more sulphur and boil, but if too dark dilute with water (with little caustic potash dissolved in it). To use this, well clean the article to be oxidised, then immerse for a minute in this; then dry on a piece of warm iron, and polish with rouge. I do not quite understand what you term the *dull* finish of goods, but if you work with excess of cyanide and small anode the work will darken slightly. The quicksilver method is worked by means of amalgams; either gold or silver is made into an amalgam with mercury, and the work to be plated is covered with this amalgam. The mercury is then volatised off by the aid of heat, which leaves the metal on the article, which then, generally speaking, will bear burnishing. I do not know of the so-called black nickel solution; send me details of its preparation and I will advise. Any further information you or any brother platers may require I shall be very pleased to give. I will also see about another article for the profession.—F. W. M.

Etching Materials.—CUPID (*Castlejohn*).—I have never heard of such a compound as an etching mordaunt. Hydrochloric acid and nitrous acid are the two generally used for etching on copper and steel.—F. M.

Spence's Metal.—J. S. B. (*London, E.*).—Try Billington & Newton, Longport, Staffordshire.—J.

Telescope Tubes.—H. N. B. (*Middleton*).—Let me tell Mr. B firstly that, from actual experience, I can't help him. Though I have dealt with many a "brass telescope tube," I have never needed to blacken the interior of one, for the reason that the blackening is a luxury rather than a necessity. The dull, dead, coppery colour of the drawn brass, in its first unpolished state, I have always found sufficiently unreflective. This for the astronomical telescope; the stops commonly inserted in a terrestrial telescope should render any special darkening of the tubes still less necessary. However, I will give what help my knowledge can. The fumes of burning straw will darken a brass surface, and this is the only homely process that I know. Of satisfactory chemical methods which do not necessitate elaborate manipulation the simplest is this: Dissolve soft copper in nitric acid (scraps of wire covered with the raw acid until they are taken up), and dilute the resultant solution with water. Heat the brass slightly, and apply the solution freely with a soft brush. Then raise the heat of the metal until a sufficiently intense colour is obtained, and finish off with an oiled rag. A considerable degree of heat is necessary to obtain a good finish. Mr. B. may not be aware that a stop that will shut out extraneous light can generally be applied to a telescope without injuring the value of the instrument.—E. A. F.

Size and Glues.—GARRETT (*Dewsbury*).—I am not aware of any work treating specially on the manufacture of these articles, and since I have made special and particular inquiry with those who ought to know, I do not think anything of the kind has been published. Although glue is an article of somewhat ancient usage, size, as now prepared for distemper, painting, etc., is comparatively but a recent development. The gilder prepares the size he uses in "water-gilding" from parchment cuttings, which are put into an iron vessel, covered with water, and then simmered for many hours until all the "virtue" is extracted. The size thus obtained is called "clear size," and is the purest and clearest of any used. The commercial "double" and "extra double," as the ordinary qualities are called, are doubtless prepared from similar gelatinous sources, viz., from the hoofs of different animals, cuttings of hides, and all such refuse of the slaughter-house. In the North of England, I believe, a good clear size is made from tripe-dresser's refuse, trotters, and so on. Although used almost exclusively by painters, in preference to dissolving the glue one's self, the old style in London and other large centres, there must be a good demand to pay for its manufacture on a large scale, since in hot weather size easily putrefies. Young's Patent Size is a much stronger and more transparent make than the two kinds of glue-size before mentioned, and commands a big sale in the metropolis. Various forms also of powdered glue, termed "concentrated size," "size powder," etc., find a ready sale in the trade. A useful account of the method of making glue is, I believe, contained in Spon's "Workshop Recipes," price 5s., published at Charing Cross. The following is a brief description of the process. The hide clippings, hoofs, and such like refuse of the tan-yards are first treated with lime, then dried by exposure to the air, and afterwards simmered in boiling water for a considerable time. The liquid thus obtained is concentrated by evaporation, and when cold and "set" forms a jelly which is cut into blocks. The blocks are then dried by two processes—first by exposure to air in suitable chambers, and afterwards in heated chambers. The process of drying by exposure requires every attention, for change in the weather may spoil the whole batch. The spring and autumn, when the atmosphere is least variable, are the best periods for this drying. Glue in a liquid form is prepared by dissolving the substance in water, and adding alcohol. If GARRETT had given definite particulars I might have assisted him more practically. My advice to him is, get permission to go through a glue factory. If this is not within his reach I may further assist him through our Editor.—F. P.

Tram Car Starter.—AD VALOREM (*Hull*).—Your sketch does not clearly show the action of the foot-brake in regulating the accumulation and distribution of energy, but there is another point which seems fatal to the successful action of your apparatus. Suppose you are running in the direction shown by the arrows in your sketch, and having the friction wheel on the axle in gear with the upper friction wheel of the energy storing arrangement when making a stop, then to make a fresh start in the same direction, the lower friction wheel of the storage gear must be brought into gear with the friction wheel on the axle; unless there is some pawl or detent which is not shown in your sketch, your spring would go down with a rush while you are lifting your friction wheels; in fact, directly the top one leaves the axle wheel. In the arrangement described in the slip you enclose there is evidently a lock of some sort which is released by the pull upon the traces. Your idea of accumulating energy in running down hill and giving it off again is ingenious, but the details do not show how you do it. I should imagine though you would require a long and very heavy spring to make much of this.—F. C.

Exposure Tables.—J. B. R. (*Liverpool*).—There are no tables compiled specially for instantaneous work. Burton's exposure tables are as good as any, but the use of tables of any kind is confined to time exposure.—E. D.

Harmonium.—AMATEUR (*Peckham*).—Papers and plans on this subject will appear as soon as the season for winter work sets in.—ED.

Cricket-bat Handles.—AMATEUR (*Sheffield*).—We are unable to name any shop where cane or whalebone handles are on sale, as they are probably made for "the trade" only; it is likely that they could be procured through any dealer in cricket appliances. But why should not AMATEUR make them for himself? The best cane for the purpose is said to be the male (solid) jungle-cane. This is cheap: in large quantities it may, perhaps, range from £2 to £4 per ton. Whalebone is a more costly thing, and may cost as much as 14s. per pound. The material is merely cut into strips, 3, 4, or 5, as may be desired, and glued together.—A. Y.

Lathe Band.—W. E. H. (*Bognor*).—You ask how to secure the hook and eye of the "gut" band so that it will not come off. The first thing is to get the hook and eye the right size for the gut; have them of such a size that you can screw the gut in, when only very slightly pointed with a penknife or chisel; you should not have to reduce the gut except at the very point. Screw the gut in a vice, slightly grease the end, grasp the hook in a hand-vice, and screw it on without stopping till it comes through; it must screw on rather hard; if you stop it may be difficult to start again; if it won't go on far enough, you can't unscrew it; the only thing is to cut off the end, and bore the bit out of the hook, then slightly reduce the end of the gut, and try again. When you have got the hook on tight, cut away with a penknife whatever bit of gut comes through into the hook; then heat a skewer red-hot, and pass it momentarily through the hook to sear the end; it must be only a quick touch. Now put on the eye the same way. I never have trouble with mine. It is possible you may have bad hooks and eyes with a bad thread; mine come from J. Buck, 56, Holborn Viaduct, as also the gut. You probably know you can tighten your hand by twisting it up a turn before hooking it, and it can be loosened a little by untwisting in the same way, thus you can adjust it to a nicety, according to the weather. The Editor will appreciate your good wishes, and you will soon overcome this slight difficulty.—F. A. M.

Cheval Screen.—W. A. Jr. (*Portglenone*).—Your idea of a cheval screen whereon to display your flower pictures is undoubtedly a happy one. Have you thought of utilising a once popular variety, that is a little difficult to explain without diagram, but is practically the shape of Fig. 2 (page 196), with two panels that draw out, one on either side? Yet I do not know that this is any real gain; it would add to your labour, and need a harder grain than pitch pine possesses, to make the framework strong, and yet slender enough to work in a satisfactory way. I should suggest (as perhaps you intend) ebonising the pine, or enamelling it with white. Either white or black produces a good frame, but the colour of pine, especially in conjunction with gilt moulding, is rarely a success. As a practical hint, I would advise you to use the stout cheap German millboards for mounts, and be quite sure to paste the pictures (or backing paper) on both sides while the paste is wet. If you allow one side to warp in drying, as it most assuredly will on any pasteboard, it is almost impossible to get it to keep quite flat again. So be quite ready to cover each side of the panel, and, as soon as possible, lay the whole under a smooth board, with a few bricks or other heavy weights, to keep it taut in drying. If you could work a moulding of the same wood, and apply it in place of gold (which has always, in these sort of things, a cheap and shoddy effect), I think you would find it in much better taste, or you might rabbet the mount, or tack on a simple beading.—J. G.-W.

Sword Smith.—H. B. (*London, E.*).—You seem to know so well what you want, that it is only the matter of finding a good sword smith (not a mere sword manufacturer). Mr. H. Mole, sword maker, of Birmingham, might give you reliable information; or by a visit to that town, or Sheffield, amongst the sword cutlers, you might try testing blades, and form an opinion of the merit of the tempering. The shape you should supply by a wooden pattern, which prevents any mistake being made by the smith in his work. A single sword of a different pattern would cost more than an ordinary blade. When done you should be sure to try it before the hilt is fixed. The scabbard is unimportant, except for actual service, or to test the best form of suspension to the rider if it be for a horseman. The maker named is sure to use the best steel, as would any sensible sword smith, as it would not cost a shilling more than common steel. £50 is not an out-of-the-way price for a presentation sword, which means forty odd pounds are paid for hilt, scabbard, and fancifying the blade. We are pleased you approve of the way our writers tell readers the how and why of work, and further help learners by telling the how and why of failures. An illustration of logic in work, as well as in words, was given by a sword-smith to a manufacturer. A sword smith, who now is in the United States, was contending with his employer for his claim for better pay. "It is not logical," said his employer, "for you to expect more than any other smith." The smith took up a sword blade made and tempered ready for grinding—*i.e.*, making worse—and fixed it in a vice, and with a sword he had tempered, with one blow cut the other blade in two, with but slight harm to the better blade. "That is my logic," said the workman, scornfully, as he turned away from one whose ignorance was made manifest by his bad sword blade making.—J. C. K.

IV.—Questions Answered by Correspondents.

Tools.—H. C. (*Clapton Park*) writes in reply to G. P. (*Edgeley*) (see page 366):—"The tools he should have to commence with as actual necessities are—a jack plane, a smooth plane, hand saw, 24 in., tenon saw, 8 in.; hammer, turnscrew, oil stove, oil can, three chisels—say, ¼ in., ½ in., ¾ in.; rule, 2 ft.; square, 4½ in.; two bradawls, two gimlets. Your correspondent would find it pay the best to have good tools, and not the cheap ones, and I think he cannot do better than go to Messrs. Syer & Co., of 45, Wilson Street, Finsbury Square, London, who have a good assortment, and where he could also get information practically demonstrated in the use of the tools, if he desires same. I found the firm very obliging in showing the uses of the various tools I have had from them. Of course there are other makers, but I, myself, do not know of one who has a carpenter's shop wherein to try and see the uses of the tools one is buying."

Finishing Brass.—R. L. (*Raheny, near Dublin*) writes in reply to S. H. D. (*Newtown*) (see page 366):—"Gold lacquer, or brass finishers' lacquer, can be got in three shades of colour at most oil shops. To use it on small articles to prevent tarnishing after thoroughly cleaning the brass, warm the metal in a Bunsen burner or spirit lamp, till the back of the hand will just bear it when placed against it; then apply the lacquer quickly and evenly with a soft brush. Do not go over any part twice, or a stain will result. When done pass the article quickly through the flame a few times, and leave to harden. Should the brass be too hot the lacquer will dry or burn at once, and leave marks on the metal, and if too cold the brass will have a foggy or dull appearance."

Removing Ink Stains.—R. L. (*Raheny, near Dublin*) writes in reply to Littleton (*Worcester*) (see page 366):—"To remove ink or iron mould stains from linen, moisten the linen by holding it in the steam from boiling water, then apply weak hydrochloric acid on a piece of stick. When the stain is dissolved out wash the article well to get rid of any acid."

Insurance of Workman's Tools.—Donovan (*Thrapston*) writes in reply to J. K. (*Oxford*) (see page 366):—"You would, I think, do well to join the Hearts of Oak Benefit Society, for by so doing you would (among other things) insure your tools for £15. An application to the Secretary, Hearts of Oak Benefit Society, 17, Charlotte Street, Fitzroy Square, London, W., will procure the necessary forms and information."

Removing Ink Stains.—L. M. (*Putney*) writes in reply to Littleton (see page 366):—"You can easily remove ink stains by moistening them with a weak solution of oxalic acid."

Flour Paste Souring.—A. J. C. (*Finsbury Park*) writes in reply to J. R. (*Skerries*) (see page 238):—"To every half-pint of flour paste (without alum) add 15 grains of powdered corrosive sublimate, and mix well; this, though not attacked by insects, is extremely poisonous.—N. B.—Keep in a covered pot."

Drilling Square Holes.—B. A. B. (*Hampstead*) writes in answer to A Reader (see page 270):—"There is a plan described in one of R. S. Burns' books, which consists of a square steel tube the required size, ground and sharpened inside to a chisel edge. This square tube surrounds an auger, or Jennings' twist bit, which fits the tube as nearly as a round tool can. The bit has an adjustable shoulder, brought into contact with blunt end of tube, so that the bit bores a hole, which the square tube, which is thereby forced into contact with the wood, immediately cuts into a square mortise. A Reader will see that care must be taken to begin the square hole correctly, and that there is a portion of hole left circular."

Regilding Looking-Glass.—F. P. writes in reply to B. N. (*West Ham*) (see page 333):—"As it may probably save disappointment to the worker, allow me to supplement G. R.'s answer to the above by a few lines. Take your frame and clean off dirt, and with it the old clear size; this is a right commencement; but, in nine cases out of ten, a frame requires something else before it can be gold-sized and properly gilded. Nearly all new frames are gilded by water-gilding process (I make no allusion to German lacquered stuff), and, therefore, beneath the exquisitely thin layer of gold we have an absorbent surface. A frame is seldom regilded until some of the gold is worn and rubbed off; and, therefore, to put 'japanners' gold size' upon it without any other preparation, means that the latter will invariably be absorbed into the 'size and whiting' surface underneath, and, consequently, the gold cannot stick. We can touch it up afterwards, of course, but workmanlike methods and amateur makeshifts are two vastly different matters. In any case of regilding, it is always advisable, if not necessary, to give the article, after cleaning, a coat of either French polish or thin 'patent knotting,' applied evenly and expeditiously; or, what is the better job, a thin, bare coat of white paint, made with lead, turps, and a little 'japanners' gold size' in it to dry and harden it. 'Japanners' gold size,' as a medium for gilding upon, is only an 'amateur's touch,' and such as no good job of gilding is done with. Get a little of gilders' oil gold size, spread very barely with a soft hog-hair fitch (working on white paint one can see where one is going), stand it aside, out of dust, until the next day, and then lay on the gold leaf. Wipe off very gently as G. R. directs, and finish with clear size, a bare, even coat, or a weak solution of isinglass, which is more readily dissolved; a pennyworth will do a score of frames."

V.—Correspondence Briefly Acknowledged.

A Reader.—Much obliged to you for your advice, which shall be acted on if found expedient or practicable to do so. J. R. (*Skerries*).—The articles on plans, etc., for building cannot be commenced in the present volume as there are already so many subjects in hand. W. R. (*Old Street*).—I acknowledge the receipt of your letter, which is all that is really necessary for me to do. What you do not care for, others take pleasure in, and *vice versâ*. G. S.—Electric lighting will be treated in Work. Desire (*Peckham*).—Plumbing will be treated in Work in due season.

Trade Notes and Memoranda.

Recently, at Messrs. Beardmore & Company's Parkhead Forge, Glasgow, the casting took place of an unusually large shaft for a dynamo machine. Over seventy tons of metal were run into the mould, which was sunk more than twenty feet into the ground. The casting was of Siemens steel, and will be hollowed to a diameter of twelve inches. When finished the shaft will weigh about thirty-two tons. The dynamo for which the shaft is intended is being constructed to the order of the London Electrical Supply Corporation, and will be the largest in the world. The casting was in every way successful, and would take fully a week for the metal to cool.

A New York correspondent says that besides the clippings resulting from the manufacture of various articles, an immense amount of tinplate scrap is wasted every year in the form of empty tins and other similar objects. Many processes have been devised for utilising the scrap by separating the tin from the sheet iron, but they all failed more or less, either from a technical or a commercial point of view. An American inventor has hit upon the idea of converting the tinplate scrap into nails, and although considerable difficulties had to be overcome at the outset, it is stated that the machinery has now been so greatly improved that it enables a boy to produce nearly ½ cwt. of nails in a day, the cost of the scrap in America being at present about 9d. per cwt.

A Roman correspondent says that the well-known firm of Ansaldo-Bombini in Sampierdarena have recently completed the colossal engine and boilers intended for the Italian ironclad *Sicilia*. The engine is constructed to work up to 19,500 horse power, and it is the most powerful hitherto constructed in Italy. It is constructed on the compound principle, with eight cylinders and four surface condensers. It drives two four-armed screws, which have a diameter of six metres. The weight of the boilers is 500 tons, and the total weight of the engine and boilers is 1,740 tons.

MELLIN'S FOOD

For Infants and Invalids.

TRADE MARK **NOT FARINACEOUS. Rich in Flesh, Nerve, Brain, and Bone Formers.**

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

No Food in the market can show such a vast collection of *boná-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

Taking out a Patent: Example of Drawings to Illustrate Specification.

TAKING OUT A PATENT.

BY C. C. C.

Patents and Patent Agents—The Law of Patents, their Origin and Objects—What may be Patented—How to get a Patent at Least Cost—Obtaining Provisional Protection—Necessary Forms, their Cost—Filling up Forms and Making Drawings—Example of a Specification—Rights under Provisional Protection—Completing the Patent—Forms for this, and their Cost—Making Complete Specification—Expense of a Patent.

"How can I get a patent?" "What would a patent cost?" and "What would be the most ready and economical way of setting about getting a patent?" are questions certain to occur at some time or other to those of an inventive turn. The columns of "Shop" show that they exercise the minds of various of the readers of Work. The writer, who has had some years' experience as an unprofessional patent agent, is in a position to answer these questions, and somewhat more at length than it might be found possible to do in the above-mentioned columns. He can also, if desired, say a word or two about the registration of designs and trade marks.

It is well that all those who invent should have this information. Many an idea of practical value is allowed to remain undeveloped, or it is developed and its fruits enjoyed by others than its originator, solely through the apparent difficulty of securing patent rights. Inventors ignorant on these points are scared by the vague fears of expense, or they may not find it easy to consult a patent agent, since these gentlemen are to be found in large towns only. Many inventors, mechanics by calling especially, have a not unreasonable dread of the charges of professional men. And though it is but just to admit that patent agents are as a class very quick in catching the ideas of their clients, there are few among working people who can explain themselves to a strange gentleman as they could whilst chatting with a friend, or sitting quietly jotting down their ideas at leisure on a sheet of paper.

These considerations being borne in mind, it is proposed in the present article to show how any inventor who can express himself intelligibly in pen and ink, and can make a mechanical drawing, or who has a friend who can help him in either or both ways, may get his patent without the intervention of an "acknowledged agent," and secure his rights without running into any unnecessary or unknown expenditure.

In the energetic little manufacturing town in which the writer resides, inventors among working men are numerous, and he has become an "unacknowledged patent agent" involuntarily. His neighbours have fallen into a way of coming to him with their inventions, not only because he was close at hand and they were not afraid of his fees, but also because, knowing him, they could explain matters freely to him. The "unacknowledged" patent agent will, however, soon be a thing of the past, for a clause comes into force in the present year (1889) which subjects any unlicensed person practising as a patent agent to a penalty of £20, though this by no means affects the right of any inventor to act for himself in procuring a patent. Whilst, however, the writer acted in the capacity of agent, none of his work as such has failed, and he believes he has been successful chiefly because in his specifications and drawings he has kept in view the primary and fundamental objects of the patent laws.

What these are we shall see if we just glance at the origin of patents, as we understand that term in common parlance.

Their history begins in the reign of James I. Before that time the inventor had no protection except by keeping his own counsel. Shrewd men protected themselves in this way, and the consequence was that when they died many trade secrets of more or less value were lost to the community.

This was acknowledged to be an evil, and as a remedy it was enacted in the 21st year of James I., c. III., that if any useful secret were fully described and the description placed on record, its inventor should, upon payment of certain somewhat heavy fees, be guaranteed the sole right to use or sell his invention, during a reasonable time, throughout the king's dominions.

Previous to the year 1624, in which the above Act was passed, the practice of granting monopolies had prevailed in this country. Persons with sufficient influence had been accustomed to obtain for themselves an exclusive right to trade with certain countries, to import certain articles of consumption, or to practise certain crafts. This practice was justly regarded as a grievance by the public at large, though, as it was a source of no small profit to the Government, it was defended by the party of prerogative. It was, however, abolished by the Patent Act, and the system of protecting inventions established in its stead.

But this more equitable arrangement was not without its opponents. It was urged that a patent, during the time that it remained in force, deprived other inventors of their inherent right of making the same discovery for themselves—that the new law was opposed to the law of Nature, by which the way of improvement is alike open to all, and more to the same purpose. Nevertheless, the principle held its ground. The system was initiated by England; after a long interval (in 1790) France followed her example; and since that time the plan has been generally adopted among civilised nations.

It will be seen from the above that the prime object for which Patent Laws were instituted was not the protection of the individual, but the preservation of such inventions as might be of practical benefit to the public, and that the condition on which they offer protection is the complete divulgence of the inventor's secret. The one thing, therefore, that is needful in drawing up a satisfactory specification is *that it shall be plain*, nor is there any statutory form to be adhered to beyond that on the paper furnished to the applicant for filling up.

"What may or may not be patented?" is a question to be asked at the outset. It would appear that nothing has a claim to protection under the patent laws which is not the outcome of thought. No mere natural product is a subject for a patent; but evolve the idea of mixing two or more products, so as to form a new and useful compound, and you have a proper subject. A single metal, as such, cannot be patented, but a combination of metals, as *Muntz's Metal*, is entitled to protection. In a general way it may be said that anything is patentable which can be described as a new and useful art, manufacture, machine, apparatus, or article; any improvement in any of these; or any new composition of substances in such a manner as to be useful. By the statute of James I., manufactures brought from over seas, though old in other countries, may claim protection if new to Britain. But nothing may be patented which is dangerous, mischievous, or inconvenient to the public—nothing which is hurtful to trade or to the public morals. Patents for improvements in patented machines or apparatus are allowable; but if the improvements cannot be made use of apart from the patent machine, the expiration of the first patent must be waited for, unless the two patentees can come to a private arrangement. Finally, the invention must not only be new, but it must presumably be useful and beneficial to the public; a novel curiosity, as such, being no subject for a patent.

Let it be supposed that we are in possession of a patentable idea, and that it is desirable for us to protect it on the most economical terms. We have first to decide on the most fitting title for our idea, and whether we are to speak of it as an "invention" or an "improvement." That done, we may quietly sit down with a sheet of paper before us, and as simply, straightforwardly, and clearly as we can, draw up a description of it. If it will admit of such aids to verbal description, we should make rough drawings as we go on, marking them and our manuscript with letters so as to render reference easy.

While thus engaged we should bear in mind the rule already laid down: that the object of our description and descriptive drawings is so to explain our invention, that from them alone any person may, at any future time, be able to make the article or to perform the process which we are describing. If we do this we do all that the Patent Office requires of us. The most experienced agent can do no more.

We are now ready for the proper forms. It is in almost all cases better in the first instance to secure *Provisional Protection;* that is to say, protection for nine months. During that time we can test the value of our invention in the market, we can sell or make arrangements for working it with other parties, or, if we find reason to think that we have overrated its importance, we can abandon it before the expense of an actual patent is incurred, and in a general way it will give us time to look round us and determine on our future measures, we being as safe meanwhile as if the patent had actually been granted.

We, therefore, go to the Post Office and ask for a Provisional Protection Form, and a paper will be handed to us partly printed and partly blank, and it will have a stamp for which we shall be charged one pound. This paper will be marked A (if we require protection for the Colonies as well as for Great Britain it will be marked A[1]). With it will be given us, free of charge, two other papers, which will be duplicates, and these will be marked B. If these forms do not happen to be in stock at the particular office to which we apply, we can, by ordering them, have them procured for us there or at any other Money Order Office in the kingdom.

For filling up the blanks in these forms we shall find directions in their margins. On the stamped form A the application has to be made; whilst form B is for the specification: that is, for that description of our invention which we already have in draft. The blanks to be filled up in Form A are short and simple, and with the directions printed upon it to guide him no one can well err in filling them. The real work is in filling those in Form B properly. It is probable that our specification will require more space than the form affords, and, if so, we shall have to continue it on other paper, good stout wide-ruled foolscap being used of the same size as the form, viz., 13 in. by 8 in. The accompanying illustrations must be on white, smooth, rolled drawing-paper, also of the same size, and they must be drawn in black india-ink only, such shading as is introduced being in lines alone, for no washes are allowed. The reasons for these regulations with regard to drawings being that they will have to be photographed at the Patent Office. It is also required that the drawings should not be creased by folding; they must be rolled up for transmission.

The drawings, like the specifications, have to be in duplicate, and all have to be signed and dated by the inventor. When ready, these papers have (unless delivered by hand) to be forwarded to the Patent Office through the post. By return an acknowledgment will be received through the same channel; and, if they are found satisfactory, in a short space (probably about a fortnight) this will be followed by an intimation that Provisional Protection has been granted.

Perhaps we shall best show how a specification should be drawn up and illustrated by giving an imaginary example in which some well-known invention is described. Will the reader kindly carry his imagination back to a period when the *wheel-barrow* existed only as an idea in the brain of its originator? We will (without any historical authority whatever) suppose that unknown benefactor to his species to have been an ingenious craftsman of Eboracum, who, when the Emperor Severus was busied on that colossal piece of navvy-work, his rampart across this island, conceived a scheme by which to relieve the backs of his fellow-Britons, and, of course, to put money in his own pocket. He would be entitled to protection, his invention being no mean improvement on the Roman *feretrum* or bier previously used for burdens. His specification might run much as follows. The printed matter on the form is given in capitals or italics.

To be issued with Form A or A¹.
Patents, Designs, and Trade Marks Act, 1883 *and* 1885.

FORM B.

PROVISIONAL SPECIFICATION.

(To be furnished in Duplicate.)

(a) Here insert title as in declaration. (a) An improved vehicle by means of which loads may be conveyed from place to place by the labour of one man only.

(b) Here insert name and full address and calling of Applicant or Applicants as in declaration. (b) I, Caius Constantinus Evans, of 6, Forum Street, in the County of York, in the City of York, Wheelwright and Timber Merchant, *do hereby declare the nature of this Invention to be as follows:*

(c) Here insert short description of invention. (c) I construct of wood and iron a vehicle by means of which one man may readily convey loads from place to place for building or other purposes, and I construct it in the following manner:—

I take two pieces of wood, by preference ash, each about 4 ft. 9 in. in length, 2 in. in thickness, and 3 in. in depth. These I dress, and form one end of each in such a manner that it can readily be grasped by the hand, as shown at A, Fig. 1. These pieces I call the "side-pieces."

In each of these, I cut mortise holes as denoted by B, C, D, the hole B being 21 in. from the end A, while D is 15 in. from the opposite end, C being midway between the two.

I shape three pieces of wood, by preference ash, $1\frac{1}{4}$ in. thick and $3\frac{1}{2}$ in. wide, and cut at their ends tenons to fit the mortise holes above-named. These pieces, which I call "slotes," vary in length, as will be seen by referring to Fig. 2, where they are denoted by E, F, G, the length of E being 22 in., while G is 18 in., and F is of an intermediate length. When, therefore, the tenons on E, F, G, are fitted into the mortise holes, B, C, D (Fig. 1), and fixed by pegs or otherwise, the work will appear as in Fig. 2.

I next make the legs of my vehicle from two pieces of oak plank 3 in thick, of the form shown in Fig. 3, where they are marked H, I, and then fasten them to the side-pieces by the iron rod, K, which passes through them, and which is also shown in Fig. 2, where the legs appear in section. I further secure the legs by the pieces which I call the leg-brackets, two in number, of the form shown in Fig. 4, which are nailed to the legs and side-pieces, as appears at E, E, Fig. 9. And I further strengthen the legs by an iron rod, bent to a semicircle, which is nailed to them, and to the back slote, as shown at M, M, M, Fig. 3.

The body of my vehicle, A B, which is to be placed on this frame, is composed of a flat bed and four slanting sides or boards, all of elm. The bed extends from the front to the back slote, and from side-piece to side-piece, and the side-boards are conformable to it. Fig. 5 shows the front-board, U; Fig. 6, one of the side-boards, N; and Fig. 7, the back-board, X; and these I nail together as shown in Fig. 8. I afterwards nail the body to the slotes, side-pieces, and the sloping sides of the legs; and to strengthen it when so fixed, I take two pieces of wood of the form shown at O, Fig. 6, which I call "front-brackets," and which I nail to the side-pieces and front-board, as shown at O, Fig. 9; and two other pieces, shown at P, Fig. 6, which I call "back-brackets," which are nailed in like manner against the back-board, as at P, Fig. 9. And I still further support the sides by pieces of wood nailed to the side-pieces and into the angles formed by the projecting ends of the back and front boards, as shown at Q and R, Fig. 9.

The distinctive feature of my vehicle is that it has one wheel only. For this I prepare an axle of turned wood about 10 in. in length and 4 in. in diameter in its middle parts. My wheel differs from that of an ordinary chariot, inasmuch as the axle itself serves as its nave. Through the centre of the axle I cut a slot lengthwise about 2 in. long and 1 broad, but slightly tapering towards one of its extremities, and into this I drive an ashen spoke cut to fit it, so that one half of the spoke may project on each side. I then cut a second hole, 1 in. square, through the centre of the axle and broad spoke, at right angles to the first, and drive into it a second spoke in like manner, and trim the outer portions of the spokes down to an equal thickness as they appear at S, S, T, Fig. 9. I then complete my wheel with felloes and an iron tire in the manner usual with wheelwrights. Finally, into the ends of my axle I drive two iron pins, upon which it and the wheel revolve in two staples driven into the side-pieces, as shown at A, Fig. 9.

And the improvements and advantages claimed for this, my invention, are these: that by means of it one man may convey a greater burden, and with less labour than could have been borne in the old manner by two; also that, owing to the arrangement of its two legs, the labourer is enabled to rest, and again to resume his labour without loss of time; also, that its sloping sides allow of loading and unloading easily; also, that its single wheel permits of loads being readily conveyed along a narrow plank; and, also, that by means of a strap passed round its handles and over the shoulders, it permits the weight of the load to be distributed over the body of the labourer in a satisfactory manner.

From the foregoing specification, with its accompanying drawings, it will be admitted that any workman, who had never before seen one, might construct a wheelbarrow (possibly some reader of WORK may be tempted with such plain directions before him to make such a useful article—he may safely do so without infringing the inventor's patent); and if they enable this to be done, they fulfil the fundamental requirements of the patent laws.

In this imaginary specification, the writer has described the supposed invention fully. This is not usually done by Patent Agents when applying for Provisional Protection. Their common practice is to give no more than a bare outline of the invention; or, rather, of its principles, and to avoid drawings if possible. Why this should be we can readily understand. The writer, however, prefers to explain as thoroughly in the provisional as if it were a complete specification, and to illustrate it thoroughly; and for this reason—experience shows that inventors having obtained provisional protection, are apt to put off taking any steps towards completing the patent till the time for doing so has all but expired, when the work may be too much hurried to be done properly. Whereas if the description has been thoroughly made out in the first instance, all that has to be done at this time will probably be to make a copy of the provisional specification and refer to the drawings filed with it. A duplicate of this specification is, upon application, returned to the inventor for guidance; it is, however, better that he should have himself kept a careful copy and tracings of his drawings with their letters of reference. Of course, if he has during this time added anything to improve his invention, he will embody this in his complete specification, and if an extra drawing is required, he will make one on paper of the same size as before.

Should there be anything vague in either drawings or specifications, the specifications, if clear, will serve to correct a vague drawing, or exact drawings will serve to correct a vague specification.

Although an inventor may be provisionally "protected," he is not, strictly speaking, entitled to mark his invention as "Patent." Yet this is generally done, and, so far as we know, only one action has arisen in consequence, when the plaintiff got 10s. damages. The proper way to mark the inventions would be "Provisionally Protected;" but the word "Patent" has been so generally substituted for it that no action at law is likely to arise, unless some brother inventor of a similar article gets spiteful, in which case a jury would probably consider the *malus animus* and give nominal damages.

It should be observed that in the case of an abandoned patent—that is, when the inventor has neglected to complete his patent within the period for which provisional protection has been granted—the Patent Office will not return his specification.

Our Provisional Protection claim is for nine months only, and if, during that time, we have reason to be so well satisfied with the prospects of our invention as to be justified in going to the expense of a complete patent, we must, before that time has expired, apply at the Post Office, as before, for complete specification forms. Two will be given us, duplicates, except that one will bear a stamp, for which we shall be charged £3. These forms will be marked C.

On these we have to make out in duplicate our complete specification, and if, as above advised, we made our provisional one carefully, this will generally be little more than a copy of our former work, except that on the margin of Form C is a direction that the specification must end with a distinct statement of the inventor's claim in prescribed form. If distinct novelties are to be insisted on in different parts of the invention, these will have to be mentioned in the claim. Had our imaginary friend, the inventor of the wheelbarrow, introduced any new thing of importance in the legs or sides of his vehicle he would have to mention them, as well as the wheel, in his claim; but as he would consider the importance of his invention to rest on the single wheel alone, his statement of claim would run as follows:—

"Having now fully ascertained the nature of my said invention and how the same is to be performed, I declare that what I claim as my invention is a vehicle having one wheel only, and that the whole is constructed substantially in the manner above described, and for the purposes stated in this my complete specification." This he will date and sign.

As a result of this second application, we shall obtain security for a term of fourteen years, and the *right* to use the word "Patent." For these privileges we shall have to pay the sum of £150, in addition to that already paid for stamps. This we may do either in two instalments, viz., £50 before the end of the fourth, and £100 before the end of the seventh or eighth year from date; or by annual payments as follows:—Before the ends of the fourth, fifth, sixth, and seventh years, £10 each year; before the ends of the eighth and ninth years, £15 each year; before the ends of the tenth, eleventh, twelfth, and thirteenth years, £20 each year.

It may be useful to know that when an inventor has not the means of properly working his invention and has to secure the help of a capitalist to help him in so doing, the name of the person thus joining him may be associated with his own in the patent.

A FEW WORDS ABOUT SCREWS.

BY JOHN CHARLES KING.

When screws are spoken of, the common screw to be turned into wood with a screw-driver is generally understood by those who hear or read about them. It is of such I now write, with remarks as to the best sorts and the most effective way to get them in and out, with the least possible trouble or injury to material they are used in.

Not a hundred years ago, the screws were so badly made that some coach makers preferred to put countersunk clout nails in the hinges of carriage doors, as the screws were apt to break off at the end of the thread part on extra strain, or if the head impinged a little more on one edge of the countersunk than the other, as the sectional sketch will show; the countersunk of the hinge being iron recessed conically and unyielding to the canted head, not at right angles to the countersunk face. The attempt to use a screw in hard wood had the same effect, but not so great. If the cone of the countersunk were fainter in its angle than the cone of the screw head, the chances of a screw breaking would be lessened, as the neck of the cone of the screw head would take the bearing on one side of the hinge, or wood countersink. The screw, as will be seen (Fig. 1), is bent out of straight at its weak part, and at every half turn round it is bent back when the opposite side of the screw is turned to B, which, in effect, is the same as holding the thread part tightly, while the stem part, A, is crooked first one way then the other, the strain being augmented also by the tightening of the thread part producing a torsion strain on the weak part of the screw.

Hinges of carriage and heavy house doors are here selected for illustration, as the result of a broken hinge screw in a door-post or standing pillar of a coach or chariot, which would obviously be a more serious matter than a small light door, the wood generally of heavy doors and carriages being harder, and the door pillar or standing pillar of a carriage smaller than a door jam or post. A broken screw under such conditions was a serious matter in the olden time, and led to a lot of time-wasting contrivances to extract the part bedded in the pillar or post. It had to be done. One plan was to bore a larger hole from the other side of the pillar opposite the point of the screw, and punch the broken part through the hole; then plug up with a wood pin and glue, which needed a few hours to dry hard before it could be bored into for another screw. Another plan was to drive a clout nail in to fill the hole, beside the broken screw. Sometimes the head would be the trouble. If a blunt screwdriver were driven into a narrow saw cut of the head, half the head would fly off; even impinging on the hole countersink, more one side than the other, would cause the head to break half side off. If too tight in to get out, the remedy then was to leave it, and put in putty, to hide the mischief; but if not quite tight in its bedding, it had to be got out somehow, causing an hour's work, perhaps, in trying, and then probably having the other half of the head break off. To get a tight screw out of a hole without a head was not an easy task, and would puzzle workmen of the present day, with all their

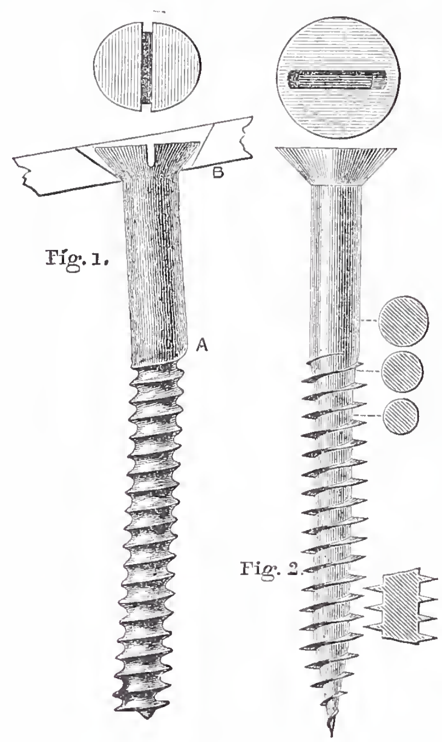

Fig. 1.—Old form of Screw, showing weak points, Fig. 2.—New form of Screw.

handy tools they use for any troublesome jobs. It has to be done, and had to be done a hundred years ago more often than now: that is why countersunk clout nails were used in preference to screws in post-chaise and stage-coach work in many shops, and often in door hinges into oak door posts. As to the headless screw in the hole, we will explain a contrivance to get it out, which was suggested and made by a poor outcast tramp, who was looking for work. This was in the hinge of an iron gate of a nobleman's mansion. The workmen were afraid to try to draw the other screws, as the heads were as brittle as the broken one. The tramp made a fine chisel and cut the stem of the screw to the shape of a triangle, and fitted on a triangular steel pipe stem, like a short length of a padlock key. This he made square on the projecting part for an inch, and with an iron cramp forced this key tightly on the broken screw; while held thus tightly, which prevented it coming off, with a wrench that fitted the square, he turned the screw back at the same time as he turned back the thread of the cramp. It was the keen sense of touch, not eyesight, which determined the degree of pressure of the cramp screw, as the broken part was turned back far enough to enable a small hand vice to grip it, and turn it right out. We may mention that this trifling matter won the poor fellow work, and eventually, by his worth and cleverness, the place of foreman. His name was Crundle, and it may still be remembered by old men in the carriage trade in London.

Screws have been progressively improved since that time, the chief improvement being in the tougher iron used; the next, in the acute chisel edge of the thread; and the next, in the screw tapering to a sharp point, with the thread right up to the tip. The latest improvement is making the stem of the screw smaller than the diameter of the thread part, so that the old evil of having to make a big hole in one piece, to prevent it being "stem-bound" and not drawing, is averted, though a smaller hole is used. The illustration of the screw in Fig. 2 shows this. Finally, the head breaking half off is made almost impossible, as the cut does not extend to the edge of the head, but is as a mortise in it, as the diagram shows, the sharpness of the cutting thread being augmented in keenness at each improvement. It all looks simple enough, and the old remark, "any one could have thought of that," drops short when we refer to the metal of which these are made; it is a mild steel of intense toughness, and they are made by elaborate machinery, so that the "bogy," cost, shall not arise to baulk its introduction, and it is swaged and rolled *cold*. This is one demonstration of the superiority of the metal used; again, the cutting is done laterally, not longitudinally, which makes a feeble thread, so that there is right talent evinced in this improvement shown at the Exposition Universelle by the American Screw Company, of Providence, Rhode Island, U.S.A.

ECONOMICAL ROOF-COVERING.

A NEW MATERIAL FOR ROOFING SUMMER-HOUSE, FOWL-PEN, OR DOG-KENNEL.

BY JOHN W. HARLAND.

I have been much exercised for the last year or two to find some material for covering roofs of temporary structures that should possess the desiderata of inexpensiveness, efficiency, and durability, combined with an ornamental appearance, and which should not be too heavy for the purpose. Not only for my own constructions, but for those of numerous acquaintances, has this question been forced upon me, and I have tried several plans, such as thick brown paper soaked in boiled linseed oil, or laid on the roof with equal parts of resin and Russian tallow applied boiling hot, or with a solution of resin in paraffin. All these methods, however, failed, owing to the sun affecting them; they answer only one condition, *i.e.*, being waterproof, but not heat-proof. Paper treated in any of the above ways is thoroughly waterproof as a lining for cisterns where no heat or frost can attack it, but as a roof-covering is very perishable, though it appears to answer very well at first for a few months. It can be made to look rather ornamental by means of a coat or two of paint, but this soon blisters in the sun and becomes unsightly. It does not keep out the heat to any extent. Slating and tiling are heavy, and necessitate building the roof much stronger, costing in material and time a considerable outlay.

Under these conditions, it struck me that floor-cloth, linoleum, and kamptulicon, might answer the purpose, and, accordingly, the experiment was made; the result was a perfect success. Readers of WORK, therefore, will, no doubt, appreciate some account of the way in which it is utilised. Firstly, floorcloth which has been laid down upon boards wears out at the joints of the boards, and cuts through long before the other parts are worn at all, and very frequently is taken up and replaced by new for appearance' sake, because the pattern gets partially worn off. Even when the greater part is thoroughly worn out, corners and other parts which have been under articles of furniture are better even than new, having had the advantage of long seasoning. There are few houses where, in some lumber room, stowed away, such old cloth cannot be found, and, if not, every furniture broker has pieces of all sorts which may be bought for a shilling or two. The first operation is to cut up the cloth or linoleum into slate-shaped pieces of about 6 in. in width and 13 in. long, rigorously excising every bit of worn-out stuff and every part that has been pierced by tacks. So long, however, as the pattern only is worn off, the cloth is just as good for our purpose as if it were new.

Fig. 1.—Summer-House roofed with Linoleum Tiling.

Having cut a sufficient number of pieces all exactly one size, they may be made more ornamental by cutting off two corners at *one* end, at an angle of 45 deg. or 50 deg. (Fig. 2). My readers have, no doubt, observed that many floor-cloths are of a deep Indian red at the back, others of a terra-cotta hue, others dark, and others lighter stone colour; this should not be lost sight of, for herein lies its capability for ornamentation, for it is the *back* of the cloth we use uppermost.

Suppose, now, the roof is ready to receive the covering: instead of the rafters being slate-lathed, they should be boarded over with thin boards; for this purpose almost anything is good enough—old egg-boxes, "slabs" off logs of timber, or other old stuff, which need neither be planed nor close-jointed: it is merely to support the oil-cloth or linoleum slates.

Now commence by putting on at the eaves with ⅝-in. *tinned* tacks a strip of cloth the whole length, about 9 in. wide, nailing it along the upper edge only, and allowing it to overhang the eaves about 1 in. Then lay the first band or row of your floor-cloth slates with their lower edges flush with that of the strip you have just nailed on, tacking them down only at their lower edges; then lay 4 in. higher up your second band of slates, nailing them only at the lower edges: for these tacks will go through the row underneath as well and thus securely fasten them. Care should be taken that the joints of the second row should come opposite the exact centre of the first row. If care has been taken to make them all one size, you need only measure the first of each row, the rest will fall exactly in their proper places. Proceed next with the third row, the side joints being made to fall in line with the first row and 4 in. higher up, and so on with the next row or band (see illustration, Fig. 2), when you will find that throughout, as in actual slating, you have *three* thicknesses of covering, the lower edge of the fourth band overlapping the upper edge of the first just 1 in., thus ensuring its being absolutely water-tight. If you continue until the ridge is reached, you will thus have to cut the last band of slates but one 4 in. shorter, and those of the last—*i.e.*, the top row—8 in. shorter, so that these all finish at the ridge. Or, if you find that you can utilise other portions of your cloth that will not cut full-sized slates, so much the better, as you avoid waste.

With a little taste and forethought, by laying out your slates on a table, you may add quite an artistic tone to your roof, by arranging, say, two or three different colours of cloth either in bands or patterns and other combinations, the effect at a short distance being quite that of flooring tiles, whilst the peculiar colour harmonises with either the bright greens of spring or the brown and golden tints of autumn foliage.

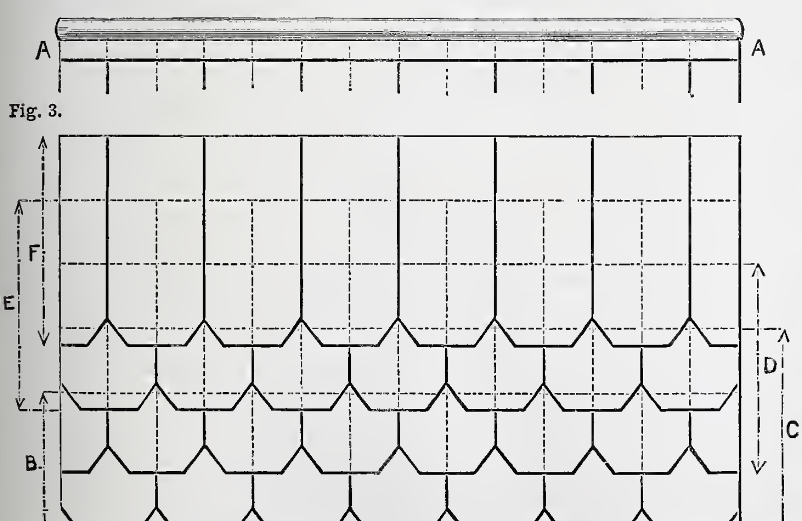

Fig. 3.

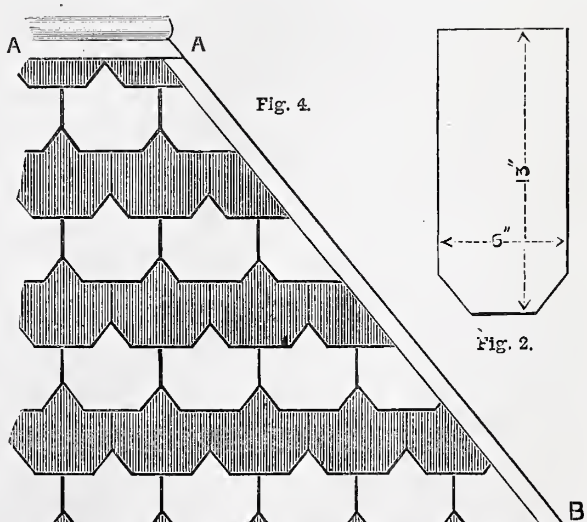

Fig. 4.

Fig. 2.

Fig. 2.—Plan and Dimensions of Single Tile. Fig. 3.—Lean-to, or Side of Span Roof—A A, Ridge Roll of Zinc; B, 9 in. Strip; C, First Row; D, Second Row; E, Third Row; F, Fourth Row. Fig. 4.—Hipped Roof—A A, Ridge Roll of Zinc; A B, Zinc Flashing.

I have hitherto endeavoured to generalise as much as possible for clearness' sake that our remarks might apply to all light, temporary roofs; but it is necessary to point out different modifications entailed by different forms of roofs, viz. (1) a "lean-to" or shed roof, (2) a "hipped" roof, or (3) a "hipped and gabled" one.

In the first (1), the simplest form possible, every alternate row or band commences with a half-slate, *i.e.*, with a piece cut 13 in. by 3 in., instead of 13 in. by 6 in. The ridge slates being cut to finish, as before described, at the wall to which the roof leans, require simply flashing to make them good at their junction with the wall. This is done as follows:—Scrape out the mortar between the two next courses of bricks in the wall just above the roof, and insert the edge of a strip of cloth the full length of the roof, wedging it in with small wooden wedges, say every foot or so apart, and then fill in with Portland or Roman cement, and point the joint over the cloth, or, instead of cloth, thin zinc may be used, tacking down the lower edge here and there to the roof.

In a double shed roof, such as a dog-kennel, the ridge is made by nailing over the top a strip the whole length, overlapping both sides for two or three inches, and over it nailing a ridge roll of wood to keep it well down, which may be grooved at top to receive a cresting if desired.

In "hipped" roofs (2) the oil-cloth tiles have to be cut to the angle at the "hip" rafter, and before the ridge flashing is put on the hip should be made good with a strip of cloth or zinc nailed down over the cut edges of the slates, and the ridge flashing then nailed over its upper end. (See Fig. 3.)

In a "hipped and gabled" roof (3), where the gable roof mitres with the main roof, the "valley" must be laid first with either cloth or zinc about 3 in. on to each roof, and the tiles should be cut to the angle about an inch from the angle itself on both roofs, leaving the valley exposed to view 2 in. wide altogether, thus leaving a clear channel for the water. At the ridge, the strip for making good, whether cloth or zinc, should have a 4-in. piece laid under the mitre joint, or else be twined round one over the other and made good, the ridge roll being also mitred.

Having thus shown how to construct this roof in various ways, let me point out its capability of economic maintenance in good condition. Instead of the trouble and inconvenience of hot tar or asphalte (as in the case of roofing felt), all that this roof requires is periodically to give it a coat of boiled linseed oil, and half its volume of turpentine or terebine laid on as paint. Or, if preferred, it can be painted from time to time either in a self-colour, or in patterns, etc., as desired. In any case, the edges of each tile should be painted over with oil and turps before laying, which leaves them the same colour as before, and preserves them from the weather.

This novel covering excludes heat as well as moisture, is very durable, looks quite artistic, and costs next to nothing. In Fig. 1 is given an illustration of a summer-house roofed with it (from a photograph), which is thoroughly satisfactory and successful.

SOLID LETTERS FOR SHOP-FRONT FASCIAS, ETC.

BY B. A. B.

If it is not going "beyond my last," or, in other words, going from my business into the domain of the author of the excellent papers on "Sign Writing and Lettering," I should like to tell the readers of Work how, owing to Mr. Benwell's articles, I made some solid letters for shop fascia.

First, I ascertained what sized letters would best suit my purpose, and found 7 in. would do well, and that note-paper is just that dimension. Mr. Benwell's outlines of sans-serif served as models, and armed with a pair of scissors, a black-lead pencil, and a straight-edge gauged to the width of the letter I, very little difficulty was experienced in obtaining fairly good, well-formed letters. X gave a little trouble, but note-paper is cheap, and I made another essay. The letters being now cut in paper and satisfactory in shape, were glued to a piece of ¾-in. deal, using judgment to obtain a suitable way of the grain. This was believed to be upright, and all the letters except T, which was formed of two pieces, mortised and tenoned together, were cut out with a bow-saw just outside the paper pattern, so that with sharp chisels and gouges, the wood could be reduced exactly to the size of the paper letter; a shooting-board was found very useful for B's, E's, R's, etc.; a coat of ordinary paint was given to the letters all over, and any fibre which had been left unnoticed before, now that the paint had caused it to show more prominently, was carefully pared off with a sharp chisel, and another coat of paint applied to front and edges of letters. I ought to mention that no stops except full stops were required, and that those were made of square pieces of wood, the sides of the square being the same as the width of the upright member of the letters. The finishing colour was next debated, and some preference was felt for a gilt surface, especially as Opifex had recently given some hints on gilding, but, finally, I decided to have white letters with red edges. For the white, white lead, turps, some crystal varnish, and a little ultramarine were mixed; the edges were painted with white lead, vermilion, and crystal varnish mixed together and finished with a coat of Urquhart's "carmine tint" enamel. These letters fixed on a dark green ground are very satisfactory, and there may be among the readers of Work many who, like myself, would like an effective sign, but are not blessed with very heavy purses, and to whom the alternative is either do it yourself or do without.

Now the letters must be fixed, which reminds me that very small brass plates, such as card-board almanacks and price lists are sometimes furnished with, would be excellent for the purpose, and probably could be purchased of wholesale stationers or ironmongers who stock for fancy leather workers — ordinary ironmongers' plates are too heavy. Being unable to procure suitable plates my letters were fixed with fine wire nails or panel pins well punched in, and holes stopped with white lead, with just a touch of ultramarine blue to match. Such letters can be read with the least possible light, and the coloured edges give a solid appearance as the spectator approaches.

Encouraged by the success attending this attempt, another idea was suggested. Some zinc about No. 10 gauge was in hand, and why not try and cut some letters in that? Still keeping close to Mr. Benwell's outlines, a piece of wood was cut out and carefully squared, every letter was made the height by this one piece of wood, remembering the axiom, "things which are equal to the same thing are equal to one another." Of course, the width of the letters varies from M or W, the widest, to I, the narrowest. S and O were the only difficult letters; U and P, and similar letters, might be cut in part with a centrebit, or marked with compasses; a strong pair of scissors or shears, chisels, gouges, and a half-round file, a hammer to flatten the zinc when required, a mallet, and a flat piece of wood to cut on, are all the tools required.

To make these letters into words, two No. 0 iron rods were taken, and some waste pieces of zinc bent round the rod closely and soldered to the back of the letters, two at least to each letter. Having all the letters now on the rod, they can be carefully spaced and the rod filed, and a bead of solder put upon the spots where zinc and iron meet. The whole can now be painted, and were coloured white as before with a touch of blue in it; but against a bright sky, or when light slates in the full sunlight form the background, white is almost invisible, so red was tried and found a success; the backs of the letters, however, had better remain white. K, R, and other letters, look very odd when seen from the back.

Some people, however, are more attracted by the back and its odd appearance, and so take special trouble to spell out the sign, and, no doubt, remember it the better for their trouble. This is written to encourage the readers of Work to make use of the excellent articles which are placed within their reach; even when, as in this case, the directions are not exactly followed, the spirit or suggestive force of the article is often the most valuable, that is, of course, to those who read with a purpose, and they will find that information they had hardly thought of any value at first becomes almost an inspiration, often becoming a means to an end, a way by which the desired object may be reached.

PLAIN AND DECORATIVE HOUSE PAINTING.

BY A LONDON DECORATOR.

Blue and Black Pigments.

In the preceding paper upon this subject of house-painters' pigments, we considered the most useful amongst the Whites, Yellows, and Reds—both for oil and distemper preparations. Therein was enumerated only those which were requisite or advisable for practical and every-day use, taking the mind of my reader from the starting-point of white, at the head of the scale, down through the yellow and red pigments, and leaving the subject at the intermediary or stationary position of the reds—*intermediary*, since it is the turning-point from light and warm aspects towards the cool tones of blue and black; and *stationary* as red appears to the eye neither an advancing or retiring agent.

Although we are not so fortunate with respect to the number and variety of blues for house painting as is the case with warm pigments, there are enough for our purpose.

Warm schemes of colour, depending for effect upon the reds, are by far more suitable aspects for the climate of this country, in which, notwithstanding occasional long and hot summers, we get a preponderance of cold and cheerless weather; and, happily, with these we are well provided, both from natural and artificial sources. Returning, however, to the pigments of blue, the most interesting and important of these are a variety of preparations known under the generic name of *Ultramarine Blue.* Of all pigments in our use and knowledge the real ultramarine blue is by far the most pure and costly, and has been known and used from the time of the first Pharaohs. Its name is derived from the Latin *ultra*, beyond, and *mare*, the sea; and by the ancient Greeks it was known as Armenian blue. Its true natural source is a precious stone called lapis lazuli, of a beautiful azure colour, marked with fine golden veins, and principally obtained from Persia and Siberia. In the recent Inventions' Exhibition at South Kensington I noticed amongst the Persian exhibits some small table-tops formed from this precious stone; they were about eighteen inches in diameter, and were marked at £90 each. In the Geological Museum in Jermyn Street, London—an institution that is, I am afraid, as little known to the average worker as its contents are equally valuable and interesting—there can be seen small specimens of the stone in its natural state, and then the resultant pigment of ultramarine at its side, as well as figures denoting its commercial value. I will here venture to digress from my subject to earnestly advise any student or worker, whose avocation or inclination brings him into contact with pigments and colours, to visit this comparatively little-known museum and to dip into the mine of information upon all kinds and classes of colours and pigments therein contained—for never will his time, I am convinced, be better expended. Returning to my subject, and looking upon it as a pigment in use to some extent at the present time, I find, in George Rowney & Co.'s catalogue, that four qualities of genuine ultramarine blue are therein quoted, ranging from £3 3s. up to £7 17s. 6d. *per ounce.*

Notwithstanding this fabulously priced article has little relationship to house-painters' pigments, I venture to think that the above brief *résumé* of the real and original blue will not be without interest to my brother-workers in paint.

French and *German*, or factitious *Ultramarine*, is, however, a commodity that most painters are familiar with. It is prepared artificially in a great number of qualities, and retailed, consequently, at an equal variety of prices. It is always sold in the form of a fine powder, at prices ranging from 1s. 6d. to 3s. 6d. per lb. for house-painters' use. It is a most useful pigment, possessing much purity and brilliancy, is permanent, and can be mixed with either oil or distemper paints.

Coming next in order of usefulness we have *Lime Blue*, a cheap powder of somewhat similar colour to ultramarine, but far less pure and strong as a stainer. As its name implies, it is useful only for mixing with water preparations of chalk-lime or whiting (carbonate of lime), and is much used by the paper stainer for cheap goods. It is practically useless for oil paint. A fair quality should be retailed at 6d. per lb.

Prussian Blue is one of our most useful pigments, and is a chemical preparation derived from a mixture of iron and potassium salts of the compound cyanides of iron; or, to put it more simply for the ordinary worker—a combination of Prussic acid, iron, and alumina. It is a blue of much beauty and strength, not quite so pure as ultra, but possessing a slight tinge of green, which, however, makes it none the less useful and beautiful for the painter's use. Some authoritative writers on the subject credit Prussian blue with the property of fluctuating—losing and gaining colour—according to the preponderance of oxygen in the air. Although I do not question their conclusions, the experience of many years' use under all ordinary conditions gives me perfect confidence in its general reliability for oil painting. It gives very fine tints of blue in admixture with white lead; added to black, in small quantities, it makes that neutral appear still more black and intense; whilst its brilliancy and transparency make it very useful for glazing over metals—gold and silver leaf—a process so much used at the present time in decorating Lincrusta-Walton, Tynecastle tapestry, Anaglypta, and suchlike modern relief wall-hangings. Some notion of the strength of Prussian blue as a staining pigment may be gathered from the fact that ½ oz. ground in oil would stain, say, 20 lb. of white lead paint to a decided light blue. It is seldom used in water or distemper painting, as it does not show the same qualities of brilliancy and permanence as when used in oil. Its price is about that of good French ultramarine: it is always sold ground in oil or water, being too hard for the worker to grind or mix it himself from its raw state.

Cobalt Blue is a pigment seldom used by house painters, being about three times as costly as the two last mentioned. It is second only to genuine ultramarine for beauty and purity of colour, and is much favoured for using as a sky blue, both in oil and water painting. It is not, however, nearly so strong a stainer as Prussian blue, but is thoroughly permanent and reliable in oil and water.

Antwerp Blue is a very similar preparation, both of source and qualities, to Prussian blue; used as an oil glaze it is somewhat brighter and greener, but it is neither so intense or so permanent as the latter, either in oil or water.

Indigo Blue is an ancient pigment of the nature of a dye, obtained from herbaceous plants which grow in India and other hot countries, and is usually sold dry in the form of little knobs. The finest comes from Bengal, and the annual value of the total quantity imported into this country is given by one authority at £4,000,000. In its colour qualities and appearance it somewhat resembles Prussian blue, but it is very inferior to that pigment for oil painting. It is for water-colour purposes that indigo is invaluable. It is one of the most useful pigments for distemper tints that we have, and is just as permanent in water as it is unreliable in oil—that is, if good and pure indigo is used. The price, however, prevents its use to any great extent in house painting, being about four times as expensive as French ultramarine.

Blue Verditer, a preparation of copper, is a very pure and pretty light blue. As it is serviceable only in water, and is not thoroughly permanent, its use is chiefly confined to the paper-stainers.

This list of blue pigments is, I think, comprehensive enough for all ordinary, and more than ordinary, requirements of the trade; we will, therefore, now turn our attention to those at the bottom of the scale, viz., the neutral blacks.

Ivory Black is at once the purest and blackest of all black pigments. Its name is derived from the supposition that it is, or was at one time, produced from burning ivory. The ordinary ivory black, however, is prepared by charring bones, in closed vessels, by a very strong heat. It is most often termed "drop black," and this by reason of its being usually sold in the form of drops, or knobs, when in its dry state. It is a very strong stainer in either oil or water, but it is most invaluable ground in turpentine, for producing flat or "dead" black paint, for various purposes. Its price retail is about 1s. per lb.

Lamp Black is, as its name implies, carbon given by the soot from resinous or oily flames, and is obtained for commercial purposes from factories where the preparation of turpentine and tar is carried on. It is a good black, but not so intense as "ivory," being more of the colour of Indian ink. It is very useful in either oil or water, and is quite permanent.

Vegetable Black is a similar article obtained, I believe, by burning vegetation. It is wonderfully light, and therefore rather troublesome to mix and handle.

Black Paint, as it is usually termed, is a preparation of these common blacks, but is ground in linseed oil to the form of a thick paste, very useful for common painting.

Blue Black, as its name suggests, is a pigment of a blue hue of black. Its source is charcoal, and its blue tone results from the thorough burning and levigation it goes through, as well as being due to the wood used in the first instance. It is very serviceable as a water-colour pigment, and is indispensable to distemper work generally. Although it is not much used—that is, the finer kinds—as an oil stainer, it is, nevertheless, useful and reliable as such; its price is about 3d. per lb. retail, for the ordinary dry colour, up to 1s. 6d. for the finest qualities, in oil.

Besides these artificial or burnt blacks, there are occasionally to be met with earth blacks, in the West of England and Wales, as well as black chalk, in their native condition. Generally speaking, they are not very pure in colour, nor do they exist in sufficient quantities to warrant my considering them herein as ordinary black pigments. *Black Lead* is a form of native pigment we all are familiar with, but, notwithstanding it possesses certain estimable qualities of permanence and purity, we seldom look upon it in the light of a painter's pigment.

BLOWPIPES AND BOBS.

BY GEORGE EDWINSON BONNEY.

Blowpipe.—A blowpipe of some sort is a necessary tool in an electro-plater's equipment. The mouth blowpipe has a wide range of usefulness as a soldering tool and as an instrument in the laboratory. An ordinary plumber's or tinman's blowpipe made of brass, and costing from 6d. to 8d., will serve every purpose. This is improved by having a few inches of the mouthpiece silver-plated. For the heavier work of hard soldering, brazing, and smelting small quantities of metals in the laboratory, no better tool can be found than the gas blowpipe made by Fletcher, of Warrington, when worked with one of his foot blowers.

Bluestone.—The name given to copper sulphate on account of its likeness to lumps of blue stone. See *Copper Sulphate.*

Bobs.—These are small wheels made up of discs of leather and other materials fastened together. When placed on the spindle of a polishing lathe and caused to revolve, they are used for abrading and polishing goods to be plated. Bobs are made of thick walrus or hippopotamus leather, or of bull-hide, or of other tough leather, and are then used with Trent sand or glasscutter's sand. For finer work they are made of felt, fustian, or other tough soft textile material, and used with fine sand or some other abrading or polishing material. See note on *Polishing.*

A COMBINED PORTFOLIO STAND AND DOUBLE MUSIC STAND.

BY JAMES SCOTT.

I THINK that the article shown in the accompanying drawings would make a useful piece of furniture for the drawing-room.

As will be seen, it answers the purpose of a portfolio stand, where the music can be stowed when not required, and a double or single music stand.

Being used as a double stand, all the portfolios (required or not required) will have to be taken out for the time being ; but he who has a soul inspired for music will hardly be the one to grumble at this.

As it can be adjusted to any height, this will be found of great convenience, for the musician can then either sit or stand ; moreover, supposing his better (or worse ?) half should have a soul similarly inspired to his own, she can sit or stand opposite to him, at the other half of the stand. But whether they both agree or disagree to play the same tune, there is one thing they must both agree upon, and that is either to sit or stand together. If the one half should feel disposed to stand, and the other half feel disposed to sit, I trust they will both forgive me, for although I suppose it would not be an impossibility to satisfy them both at once, still, I have done as well as I can for the present.

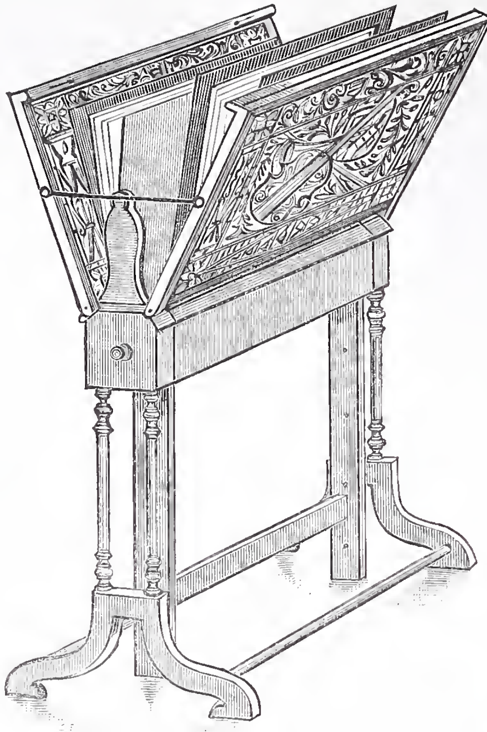

Fig. 1.—Stand with Frames up, adapted to receive Portfolio.

Fig. 2.—Stand lowered with Frames down.

It is customary, when giving a drawing, to describe it in a written article, but although some men—and they are generally professional workmen—say that they do not see the necessity of doing so, it will most always be found that an admirer of any particular design feels an interest in reading about it, although, perhaps, the drawing may sufficiently explain the working of the article.

To furnish a description, then, must be my task.

I will not advise any particular wood for it to be made in, as that must be a matter of choice.

Our blocks at each end must be 4 in. wide, 4 in. high, and 2 in. thick, with a hole bored through the centre of each, to admit the movable peg, which should be about 4 in. long, including the knob.

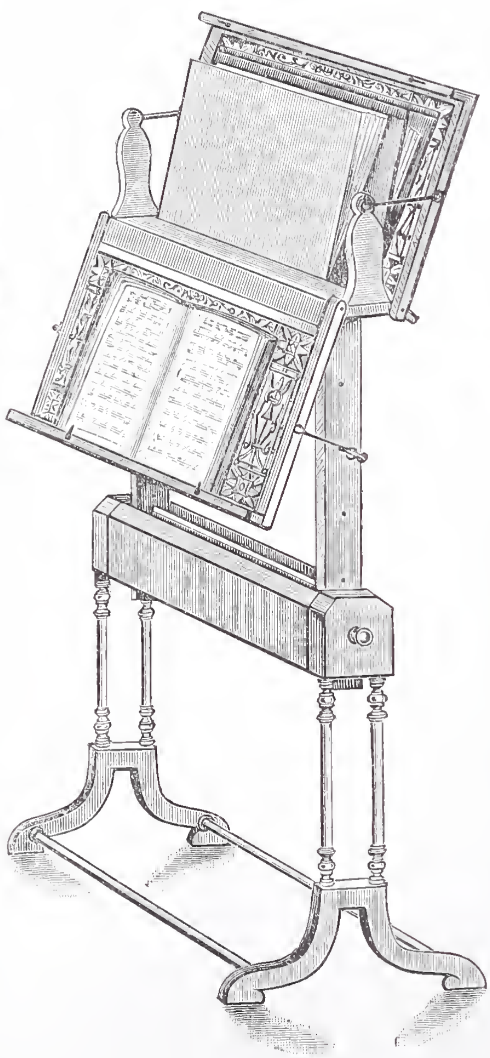

Fig. 4.—Stand with one Frame down as Music Stand, and one Frame up as Music Portfolio.

The turned columns can be obtained at almost any turner's, the four upright ones being 18 in. long, and the two stretchers $12\frac{1}{2}$ in. These must be carefully fitted to the blocks and feet, otherwise, the job will become rickety in a very short time. A word or two as to fixing these columns will not be out of the way, as it is very probable—taking into consideration the numerous letters I have lately read in "Shop"—that there are among my readers several amateurs.

Drill a hole exactly in the centre of the column, place a little sawdust, or other dust, into it, and, after turning the block upside down, place the column in its position, and give the other end a tap; this will cause the dust to be left in precisely the spot where the hole must be drilled. Then have a rounded piece of wood, one half its length, glued into the column, and the other half into the block. Proceed the same with the stretchers and feet, getting them together first. I believe this plan is about the best one to adopt in order to secure strength. Of course, the fixing of the pillars should be left until the top part, with the block at each end, is fastened together.

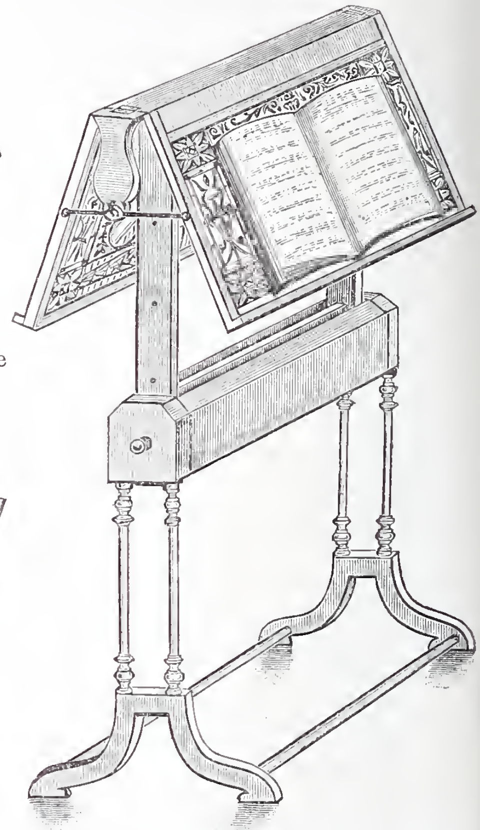

Fig. 3.—Stand raised and in position as Double Music Stand.

Two pieces of wood 12 in. long, 4 in. deep, and $\frac{3}{4}$ in. thick, should be joined to the blocks as shown in Figs. 1, 2, 3, and 4, so as to allow space for the under framework of the movable part to work in. Cut the outside edges off diagonally for $\frac{3}{4}$ in.

Next we have to deal with the bottom part on to which the music frames are fastened. The centre piece of wood should be 16 in. long, $3\frac{1}{2}$ in. wide, and $\frac{1}{2}$ in. thick ; the two outside pieces should be the same length, same thickness, and $1\frac{1}{2}$ in. wide. Round off the outside edges of the two side pieces, and after having canted the two edges of the centre piece, sufficiently fasten the three together.

Our frames must be made of stuff ½ in. thick and 1 in. wide. Each frame will consist of two pieces 18 in. long; and two pieces 14 in. long. The rail which is fastened on the bottom part of the frames is fixed at about 1½ in. from the end of the side rails, to allow for the free movement. Then glue a strip of wood along the edges so as to hold the music. When the frames are ready, fasten them on to the bottom piece at the sides by means of stout pins, so that they will work freely up and down.

The under framework needs little commenting upon; the two side rails must be 30½ in. long, and 2½ in. wide, and ½ in. thick. The cross rail must be a little stouter, the same width, and 12 in. long. These are the lengths before they are joined together.

In shaping out the feet I should advise the amateur to proceed upon the admirable plan suggested by "O. B." in No. 14, page 209. I have drawn my diagrams of the feet and shaped wood to 6-in. scale, so that it is only necessary to enlarge the squares to double their present size.

The squaring method should be practised more than it is, as it is in every respect an excellent plan for reducing or enlarging either pictures or diagrams. Every professional workman should use this mode of procedure in making full-size working drawings from drawings to scale. It saves a great deal of trouble in determining measurements corresponding to those in the original.

I recollect once reducing in this way one of the double-page illustrations in the *Graphic*, of the well-known picture of the elephant demolishing the toll-gate, to about one-eighth the size.

It will be seen that in Fig. 4 I have shown one frame up with the portfolios still resting against it, and the other frame down as a music stand. I think it will be found that the feet are wide enough to prevent the whole affair from toppling over when in this position, provided the portfolios are neither too large or heavy.

With regard to the hooks, if the holes in the upright rails are bored at short distances apart, a long peg can be placed in one at each side to hold them.

When used as a double stand, if it is found that the hooks when linked together do not keep the frames sufficiently firm, and the peg and hole arrangement is not admired, I should advise the shaped piece of wood to be hinged (not glued) to the bottom part; it will then fall down, and can receive the hooks in the same manner as when up, if a peg is fastened on both sides. The fixing of this piece of wood should be left until all the rest is put together. It should be about 8 in. long, by 3 in. at its widest part (see Fig. 6).

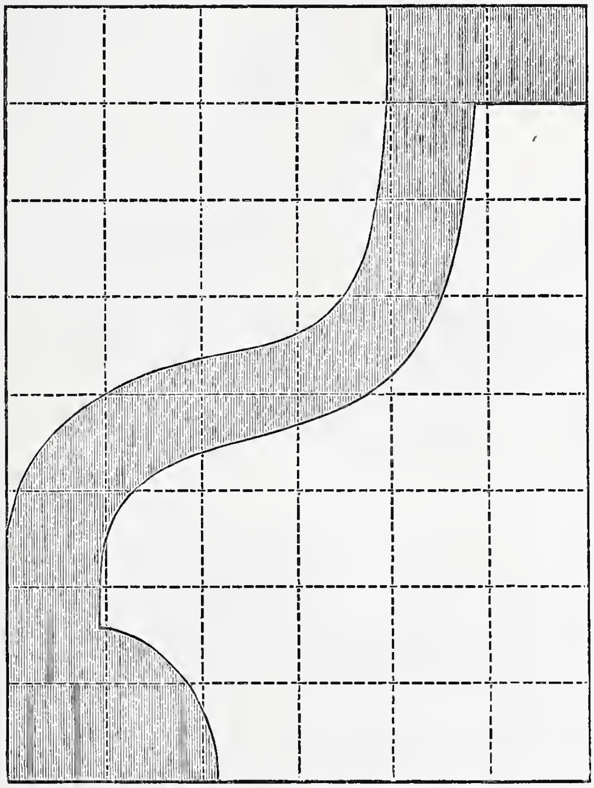

Fig. 5.

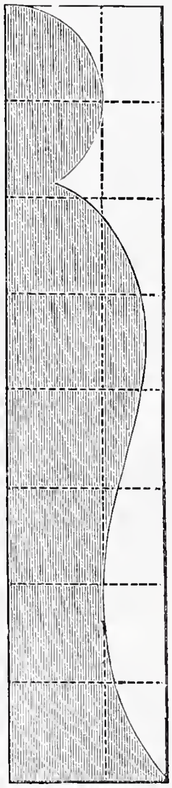

Fig. 6.

Fig. 7.

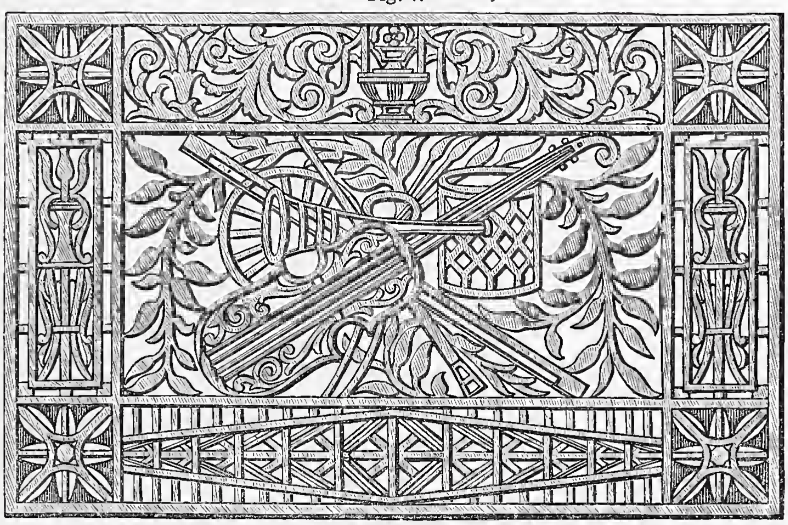

Fig. 5.—Pattern of Feet drawn to Half-inch Scale. Fig. 6.—Pattern of Shaped Upright carrying Hooks, Half-inch Scale. Fig. 7.—Design for Fretwork to drop into External Framing, Quarter-inch Scale.

I must leave the choosing of the lengths of these hooks to the maker, as he can then have the frames to rest at the angle he considers best.

Perhaps it would be best to have the hooks fastened on to the inside of the frame (not on to the outside, as I have shown), cutting away the fretwork to admit them. If this is done, the shaped piece of wood will keep its upright position, supposing it is merely hinged, whereas, otherwise, it would be at a slight angle.

For the hooks to hold the music in its place, read the instructions given by "O. B." lately, or else obtain four pieces of flat iron or brass, 3 in. long, bend the end of each at right angles for an inch, and file it round. They are then ready to fasten in.

I have drawn the fretwork to 3-in. scale; if the cutting of this is above the amateur, any fret cutter would do it for him: or if he did not like the design, and I confess there is nothing particularly new about it, as I have given my attention mainly to the job collectively, he might be able to choose a different pattern from the fret cutter's.

It will perhaps be observed that my drawings represent the article rather wider than it would be if made according to my measurements, but I think that if my description is followed out it will make as conveniently proportioned an article as possible. What I have said with regard to the enlargement of the parts shown in Figs. 5 and 6 applies equally in principle to the enlargement of the design for fretwork to drop into external framing, shown in Fig. 7, which is drawn to a scale of three inches to the foot, called also one-fourth scale, or quarter-inch scale. I have directed the attention of the reader to this pattern, and have said that he may, if he prefer to do so, substitute another pattern for it; this, however, must be in accordance with the size of our design, which, when enlarged into full size, is 16 in. by 10 in. To effect the enlargement, all that the fret-worker has to do is to make a fine tracing of the design, and divide this into squares, half an inch or a quarter of an inch apart, according to his pleasure, the smaller squares being used when the draughtsman has not sufficient confidence in his own skill and powers of reproduction to resort to the use of the larger squares. The reason for this will be apparent when I remind the reader that in the enlargement according to division into half-inch squares, the squares on the full-size drawing would be two-inch squares; but that, if the division of the design be effected by quarter-inch squares, the corresponding divisions on the full-size drawing would be one-inch squares. I have not penned these remarks for the guidance of professional workmen, but for amateurs and any who may find difficulty—and I believe there are many who do so—in working from drawings done to scale and requiring proportional enlargement.

MEANS, MODES, AND METHODS.

KORSHŪNOFF'S PINCE-NEZ SPECTACLES.

OF spectacles, so necessary to many people, the annoyance of their being always more or less wrong in their adjustment is trying and tiring. The Pince-nez is popular from the ready application of the bow-spring holding them on the nose, but in very many cases the plane of the glasses is not truly parallel with the plane of the eye surface; or, in other words, at right angles to the line of vision directed through the glasses. Figs. 1 and 2 show the difference of the planes, which so much depends on the formation of the nose. It is obvious that the plane of the glasses should be adjusted to the orbit of vision independent of the accidental formation of the nasal bones chancing to hold the spring grip of the glass frames rightly. M. Korshūnoff, a Russian engineer resident at Rue Chazelles, Paris, has patented spectacle frames by which their grip on the nose is entirely independent of the plane surfaces of the lens frame, as will be seen by sketches, Figs. 3 and 4.

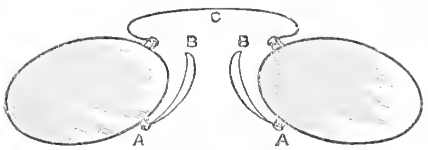

Fig. 3.

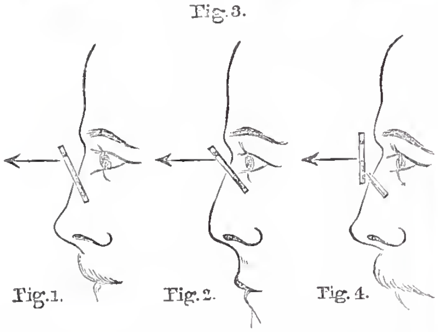

Fig. 1. Fig. 2. Fig. 4.

Figs. 1 and 2.—Difference of Planes of Glasses caused by form of Nose. Fig. 3.—Korshūnoff's Pince-Nez. Fig. 4.—Diagram showing Adjustment of Glasses to the Proper Plane of Vision.

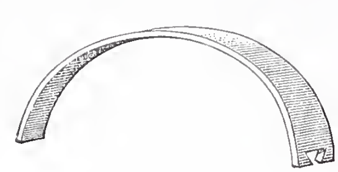
Fig. 3 is a Pince-nez with the usual connecting bow-spring, C, and two spring nose-grips fixed at the lower inside edges of the frame on studs, A, A, which admit of these grips being turned radially on the studs to suit the most fitting position on the nose, and adjust the glasses to the proper plane of vision, as shown by Fig. 4. The mechanical advantages may now be considered; here are three spring grips on the nose, instead of only one, making the "seating" more secure without so much pressure.

This invention was the only new thing I found in this class of goods at the Exposition Universelle, and a busy trade was being done in them, and also fitting to purchasers' own glasses where desired or necessary.—J. C. K.

A HANDY FILE-HOLDER.

The peep into a mate's tool-chest while he is showing his various tools is always interesting to me, and to show mine is often equally interesting to him, and sometimes evokes the remark, "I wish I had had such a tool, what time and trouble it would have saved me!" This was the remark upon showing a "file grip" which was new to him and his shopmates, and not having seen it in any other shop it may be new to some of your readers. Its use will be obvious by the sketch, showing how the whole length of the file may be used with considerable power with such hand-piece, while a handle would be in the way of using the heel of the file.

It is a bit of round iron bent to a hard-cornered curve about 5 in. long and 3 in. high; one end is made larger than the other, and a deep notch filed in it. This grips the "tang" of the file, which at that part is made slightly dovetailed in form, as shown in the illustration at A—a section of a tang. The notch corresponding is slipped on to the tang of the file, and the other end takes a pressure, bearing only on the top side of the file.—J. C. K.



Handy File-Holder. A

OUR GUIDE TO GOOD THINGS.

** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

102.—GRANT'S GAS LIGHT REFLECTOR.

THE handy little article known as "Grant's Gas Light Reflector," made and supplied by Mr. J. T. Grant, Recreation Street, Bolton, is a useful appliance so made that it can be fixed on any gas-burner in a few seconds, and used for the purpose of reflecting and directing the light of the jet of flame issuing from the burner in any direction. Of course it will be understood that it is only intended to be used when there is a glimmer of gas, so to speak, proceeding from the slit or holes in the burner, as the case may be, and not when the gas is turned on to its fullest extent, and the flame, consequently, at its brightest. It is very simple in its construction. A band of metal $\frac{1}{2}$ in. in width is bent into the form of a circle just about 2 in. in diameter, the ends of the band being bent outwards and brought together so as to form a short arm about $\frac{1}{2}$ in. long projecting from the ring of metal already described. Before the band is bent, as described, an indentation is made lengthways along its central line, and this is utilised to receive and hold the edge of a small concave mirror, made apparently of copper and silvered. As soon as the metal ring has been brought round the reflector, two pieces of sheet metal, so cut that the ends, though parallel, are not in the same straight line, but have the connecting piece inclined to each at an angle of about 135°, are attached by means of a brass eye to the projecting part of the band, and on this eye, or hinge, the reflector can be turned upward towards the light, or turned back from it, as may be found necessary. The ends of this portion of the reflector are bent each towards the other in the form of an arc, thus being constituted a kind of clip to grasp the burner. The chief object with regard to its use as a reflector is to afford means of throwing a strong light upon the dial of a watch or clock placed at a distance of 8 or 9 feet, the rest of the room remaining in comparative darkness. This renders the reflector an article that should be prized by householders, artisans, night nurses, and others who may wish to note the progress of time as the hours run by, either through the long night or in dark winter mornings, and for the same reason it will be found useful by invalids or the wakeful. When the reflector is not in use, it may be bent back, as already said, without removing it from the burner. By attaching the reflector to a small stand, it may be made available for a small lamp. Its price is 1s.

103.—THE CLOCK JOBBER'S HANDY BOOK.

This volume forms the seventh of the series known as Lockwood's "Handy Books for Handicrafts," written by Mr. Paul N. Hasluck, as good a guide in all matters pertaining to mechanics and practical work as any man without experience, or with but a little experience, could possibly wish to have. "The Clock Jobber's Handy Book" is a practical manual on cleaning, repairing, and adjusting clocks and watches, and it embraces information on the various tools, materials, appliances, and processes employed in clockwork. It is illustrated with upwards of one hundred engravings, chiefly devoted to the illustration of tools, and the parts and mechanism of clocks and watches. It forms, in fact, a suitable and, it may almost be said, an indispensable companion to Mr. Hasluck's "Handy Book on Watch Jobbing," which also forms one of the series to which the volume now under consideration belongs. "The tools requisite for clock cleaning and simple repairing," says Mr. Hasluck, "are few and inexpensive, and but a small amount of practice will give the necessary manipulative skill. Thus clock jobbing offers an occupation easily acquired by those who have aptitude for mechanical subjects." To this it may be added that, in the eight chapters of which his book is composed, Mr. Hasluck gives sufficient information, clearly written and careful in detail, to pilot the way to successful operations on the part of those who may betake themselves to clock jobbing, either for gain or for amusement, under its guidance.

I have said that the subject matter of the volume is divided into eight chapters, and it may be useful to intending purchasers to show to what part of the subject each of these chapters is devoted. In the first, various forms of clocks are described; in the second, pendulums are considered as the controllers of the velocity of the going trains of clocks, and their regulation, and the various forms of pendulums in use are mentioned; thirdly, the escapements commonly used are noticed; and in the fourth chapter the attention of the reader is drawn to De Wyck's, German, and house clocks; in the fifth, the mode of examining and cleaning an eight-day clock is described; and in the sixth, the minutiæ and manner of repairing are carefully gone through; in the seventh, the treatment of French timepieces is taken up; and in the eighth and last, lathes and turning appliances used by and useful to clock jobbers are reviewed. The price of this useful, well written, and well illustrated volume is 2s.

104.—DYSON'S BEDCLOTHES HOLDER.

It often happens, especially with children, that by their restless movements they will throw off the bedclothes that cover them, especially during the continuance of illness, and that colds in the one case and chills in the other are the inevitable consequences. To prevent this throwing off of the clothes, Mr. Alfred Dyson, 21, Till Street, Bury, has invented a very simple contrivance, which he calls a Bedclothes Holder. This consists of a piece of cord, very much like a piece of thin blind cord, with a wooden button about $1\frac{1}{2}$ in. in diameter at one end, and a piece of wire bent into a fiddle-like form at the other. A loop is made in the middle of the cord, which is used to secure the appliance to the bedpost or rail at the bed-head. The button is then put under the clothes, and the clothes and button are thrust in a little lump through the broad part of the wire loop, and pulled down into the narrow part of the loop, by which clothes and button are securely held. The holder only costs 2d., and is well worth having.

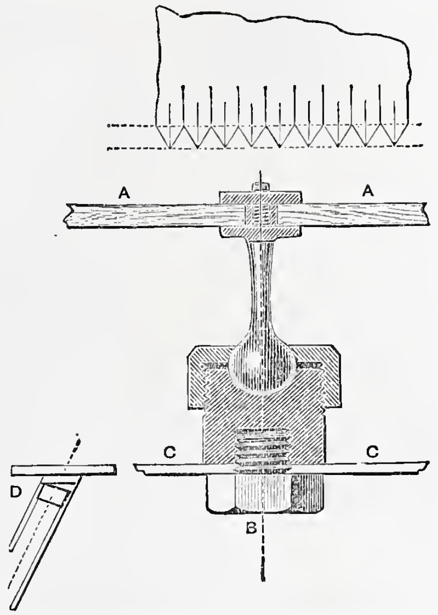
I.—LETTERS FROM CORRESPONDENTS.

Remedy for Severe Cuts: Treatment of ·ruises.—(WORK No. 26, page 411).—MEDICUS ·rites:—"I have been a subscriber to your valuable [agazine, WORK, since it started, and must thank ou very much for the pleasure it has given me. I ave followed with great interest most of its very seful and practical articles, being extremely fond f mechanical as well as of my professional occuation. I certainly think short paragraphs about ow to treat the various little accidents to which very workman is liable, and from some of which ıost will have at times suffered, cannot fail to be f great use. But I should at least hope that these ·ould be correct, and not likely to do more harm ıan good, or to put impossibilities down as facts. 'o begin with, a saw-cut wound would never heal uickly or without suppuration under the treatment ou advise, and it is simply impossible for a finger ut off by a saw to be again united to the hand by ny means whatever. A stiff-jointed finger is ften more than useless to a workman, as it conantly gets in the way, and is therefore more likely) be injured again. I have amputated several ntirely at the patient's own request alone for this eason. In the treatment of bruises the great thing ; to arrest the extravasation of blood, and to keep hat which is already extravasated from suppurang or turning into an abscess. This is generally one by rest, cold, or the application of some oothing astringent or absorbent lotion, and above ll to keep the skin over the bruise whole, as once roken it is almost sure to suppurate. In your reatment you advise rubbing with a hot irritant r the application of leeches, which would probably ust do the harm which is to be guarded against. hope I have not spoken too strongly, but I write his trusting you will be rather more careful in the uture to obtain accurate information."—[The VRITER of the notes entitled as above in "Means, fodes, and Methods" replies as follows to IEDICUS]:—"As to 'saw cuts,' with forty years' xperience, I know they would heal quickly by the ıeans proposed. Of course there would be suppuation; it is essential to eliminate the disorganised issues. As to turpentine, its application is so eneral in railway and other shops that it is esirable its service in emergencies should be nown to all. A finger cut off and replaced at once vill grow, as I know from having seen only ecently an instance. A foreman at a large sawıill was my informant respecting other instances. Bruises may be variously treated as suggested by he writer. Three ways are named. Turpentine s an absorbent. All are good, but for an emerency and generally, turpentine is the best I know f ready to hand. Many others, as arnica, might e named. In bad cases leeches are so important hat the skin being opened for the blood to escape s far less serious than allowing it to remain and be bsorbed into the system. I speak with confidence rom more than forty years' experience of bruises, nd serious ones, some to myself and family and riends, to whom the application of turpentine was he best remedy, and leeches saved from glandular nflammation and its attendant evils. I seek to erve those who suffer harm that may be alleviated romptly, and am convinced of its efficacy by many ıundred cases having passed under my notice. Let those who have been harmed by it speak; let hose who think differently advance something etter. I, as well as your readers, will be thankful. Guessing as to probable results is not an answer to acts."—[Although it seems unlikely that a severed inger would be reunited to the hand from which it had been cut, I judged it as well to permit the notes o which MEDICUS takes exception to appear. I nyself have known a case where the top of the humb was cut off, bound on again, and reunited, out in this there was no severance of bone. I have reserved MEDICUS'S letter until the reply from the WRITER of the notes in "Means, Modes, and Methods" could appear, and I now give letter and rejoinder together.—ED.]

Stencil Patterns.—MR. G. JONES (*East Cowes, Isle of Wight*), whose excellent stencil patterns were noticed in No. 27 (page 427) of WORK, writes:—"I should like it made known to the readers of WORK that instead of a small book of miniature designs, I send to intending purchasers, post free, a roll of full-sized designs, about 400, and price list per dozen, for selection; and if required I also send samples of cut stencils on approval, unless the selection is left to my judgment, when I do my best to give every purchaser satisfaction, and am quite willing to refund money if stencils are not approved."

Bicycle Camera Stand.—J. A. (*Liverpool*) writes:—"Seeing in your paper, WORK, an article on 'Camera Stands,' etc., I would like to bring to the notice of your numerous readers the stand which I have had made lately for myself. It consists of three legs, each of three pieces of thin brass tube, ⅝ in., ½ in., and ⅜ in. diameter by 15 in. long (connected when together by means of brass diminishers, but when not in use for the stand, they telescope into one another), screwed on to nipples soldered on at the right angle to a circular brass plate. The camera itself is fixed to an apparatus



Bicycle Camera Stand—A, Camera Bottom; B, Hexagon Nut; C, Brass Top Plate; D, Leg on top.

with a ball joint, secured when required by a hexagon nut, which is fastened on to the top by means of a tap bolt, as per sketch above. Thus, when the tripod is once fixed, the ball joint can be adjusted in any direction. I have found the apparatus for the camera very handy when mounted on the head screw of my bicycle by means of a stud screwed into it, and as for the stand, it is by far the stiffest and most substantial I have seen, and in addition is comparatively light."

Signboards, Construction of.—W. S. (*Goole*) writes:—"I think the writer of the article on signboards in No. 30 of WORK must have very little knowledge of the subject, and that his ideas of what a signboard should be are entirely and altogether misleading. I have made many signboards in my time, and have painted and written many more, being a sign painter for fifty years, and during that time have never, in my recollection, seen an oak one nor a pitch-pine one. These, I consider, are, especially the latter, the very worst woods of which to make signs. The best wood is good old yellow pine, or, if that cannot be had, any old, dead, well-seasoned white-wood. Why, if your sign were of pitch-pine, you could not keep the paint on it a single week if it were exposed to the sun. The resin would, especially if the board be painted black, liquefy and push off the paint. The cost of mahogany stands in the way of its general adoption, or else this is far superior to even pine. I have recently made one of Honduras mahogany, 17 ft. 6 in. by 2 ft. 2 in., in one piece. It had not a blemish of any description, and the price of the board at the timber yard was 26s. This board will 'stand' for generations. The thickness recommended by your correspondent is out of all reason. My boards I make of ½ in. and ¾ in. stuff—the thinner the better if properly made—and the way to make is as follows:—Place battens about 3 ft. apart, and do not screw or nail them to the board, but rebate the edges and fix loosely with buttons screwed, not too tightly, to the board. This plan will allow for expansion and contraction of the board. Leave the battens a trifle shorter than the width of board so that the cappings will not push off on contraction. Caps, mouldings, etc., I need not notice, as any skilled maker will know all about them. And now about jointing. Never use glue on a sign—use paint instead. If I have a board to joint, I prefer, instead of groove and tongue, a smooth or, as we Yorkshiremen call it, a slope joint with iron dowels. Let all battens, mouldings, caps, etc., be well painted before they are put together. Glue is a terrible enemy to all outside woodwork; its affinity for moisture keeps the parts always wet, and this is, according to long observation and experience, the sole cause of rot and decay in external woodwork. Who ever saw a door begin to decay in the middle of a panel, or a sash in the middle of a bar or frame—always at the joints? Why, the pins with which sashes are secured at the tenons slide out in damp weather of their own accord. Let me have all external woodwork put together with paint."

Subjects in WORK.—T. B. (*Portadown*) writes:—"I think your very interesting paper, WORK, must provide a long-felt want in many homes. At the same time you will pardon one who has worked with his hands on almost every sort of work from childhood, for suggesting that there are some things which it will save amateurs a vast amount of work and expense not to attempt, and which will cost an amateur even more for the materials than the finished article can be produced for. Now take, for instance, piano making. Is there a single reader of your paper likely to begin one, not to speak of the finished abortion? and will the music likely to be got from such an instrument not depopulate the unlucky neighbourhood where such an amateur may reside? In the name of common sense, give us articles that have a remote chance of application. All that kind of padding so prominent in some amateur papers on how to make a turning lathe without a lathe, how to make reflecting telescopes out of bullseyes and lids of tin cans, should be carefully excluded from WORK. There is a big future for your paper if the articles are written to suit the demand, and your subscriber wishes it well."—[WORK is for professionals as well as amateurs. It is not possible for me to cut down the list of subjects to be treated to those which an ordinary amateur workman may be disposed to undertake. It is quite possible for an amateur to make a piano, and a good one too. Men who make such things look rather to the end to be achieved and the pride of having done so rather than the expense to be incurred. I have known amateurs make good violins, and dispose of them at a remunerative price. It is possible to make a turning lathe without a lathe—namely, by rigging up a temporary substitute for one. I have never yet recommended the manufacture of reflecting telescopes out of bullseyes and lids of tin cans in this or any other publication, and I never shall. Lastly, the greater part of the papers that appear in WORK are written to demand. The difficulty is to satisfy popular craving.—ED.]

A "Multum in Parvo" Querist.—YOUNG APPRENTICE (*London, N.*) asks:—"(1) Can you answer the following questions:—(2) How to case-harden, clean and properly? (3) Should like to have a few more hints on cycle repairs and manufacture. (4) How to make a spoke-cutter? (5) The correct way to braze? (6) How can you calculate gearing? (7) Can you tell me a good book on engineering, or where I can learn it in London? (8) Where to get a good tire cement in a large quantity? (9) How to get a good enamel without baking? (10) What do you think will be the go in machines next season? I have taken in WORK for some time now, and am highly pleased with it."—[Ten questions on one piece of paper, and, metaphorically speaking, all in one breath! Please re-write each question on a separate piece of paper, and then you will put it in my power to send each to the member of my staff who may be best able to answer it. You need not repeat the first and last questions. As to No. 1, I may at once reply, "Yes;" and to No. 10, I do not think anything at all about it, as I am not aware that any season sees a decided run on any particular class of machine.—ED.]

The New Water Glue.—F. C. W. (*Bradford*) writes:—"As you have said you would like to have the experience of subscribers who have used the new water glue, I beg to say I have used it a good deal for all sorts of work, and find it exceedingly valuable; for the smaller joints in cabinet work it cannot be surpassed, as it makes a perfect joint. This is the best liquid glue I have seen, and it has the valuable property of being waterproof in addition."

Combination Bedroom Suite.—T. B. R. (*Hull*) writes:—"Being a great admirer of WORK, and an amateur woodworker myself, I should like to make, with your kind permission, a few criticisms and observations upon the 'Combination Bedroom Suite,' by Mr. Scott, in No. 26 of WORK. I hope Mr. Scott will not be offended by my remarks, as I admire his ingenuity in his contrivance. My first objection to the suite is the unsightly appearance the wardrobe door would present when closed, it having to be binged on the outside, thus showing an ugly angular strip the whole length of the door. The projection at the back of the looking-glass is also unsightly. Now what I would suggest as improvements are that the wash-hand basin should be fitted in a drawer in the compartment where the soap dish, etc., are shown—it would thus be out of the way, and not show when not in use. There would also be room in the angles of the drawer for soap dish and brush tray. This arrangement would do away with the door having to open at the side, and I would suggest that the wardrobe closet be made 10 in. or 12 in. wider, and the door open in the front and have a looking-glass panel. If this were done it would do away with the looking-glass shown by Mr. Scott, the fastening for which is so high up (6 ft.) that many people would have difficulty in opening it. The three cupboards at top might then be formed into two, and would be infinitely more useful than at present arranged. The cupboard and drawer at the base should both open in the front, and be either two drawers or two closets of equal length, and if made a little higher one of them might hold the water jug or other utensils used to contain water, and the other necessary conveniences of a bedroom, provision for which does not appear to have been made. One other observation and I have done, and that is that the thickness of the wood used in the construction (at least of the styles of the panels) should not be less than 1 in. thick, and not ½ in. as recommended."

Band Saw Machines and Band Saws for Sweep Work, etc.—A. R. (*Scorrier Saw Mills*) writes:—"There was a time when the jigger was considered a valuable little machine for sweep work, etc.: but when compared with the band saw machine of to-day it is left in the background. A good band saw machine in a factory where an amount of sweep work is to be done cannot be too highly esteemed. I say a good machine because, as in all other things, there are good and bad. A good machine for such work I consider should be heavy, that is, the main frame should be heavy and strong, and the spindle or shaft on which the bottom wheel is keyed should be at the base of the machine; the boss of both top and bottom wheels should be heavy, and the rim of wheels light; the diameter of wheels from 36 to 42 in. for saws up to 1¼ in. wide. The wheels should run quite true, and be covered with soft leather, or, better still, with a rubber band. The top wheel should rise and fall freely as the tension of saw varies; the speed of such a machine should be from 400 to 500 revolutions per minute. The amount of work that can be turned out with a good saw, if properly worked, on such a machine is really surprising. Yet there are some foolish enough even now to prefer the jigger to the band saw; their reason is that the band saw breaks, but I think if they would take into consideration the small cost of a band saw up to 1¼-in. wide, and the amount of work it will do, the band saw would be preferred: for there was never a jigger yet invented that would do as much work in two days as can be done in one day with the band saw. Of course the band saw will break sooner or later, but with care a good saw will last longer than they often do if the machine is of good construction and properly worked. There are many reasons given why band saws break, and I cannot believe a machine has yet been made on which a band saw will run, and not break. I have heard of a saw being worked from 1 in. wide until it is reduced to less than ¼ in. without breaking; but seeing is believing; it may be so. I said above that saws may be worked much longer than they often are before they break. If I were to give all the reasons stated by makers and others why band saws do break, I think I should be encroaching on valuable space, but the following, in my opinion, are two or three of the chief reasons why they break oftener than they otherwise would, when worked on a good machine.

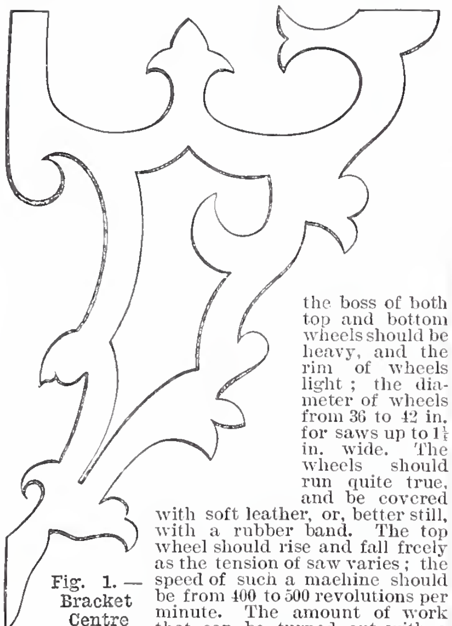


Fig. 1.—Bracket Centre Sawn out.

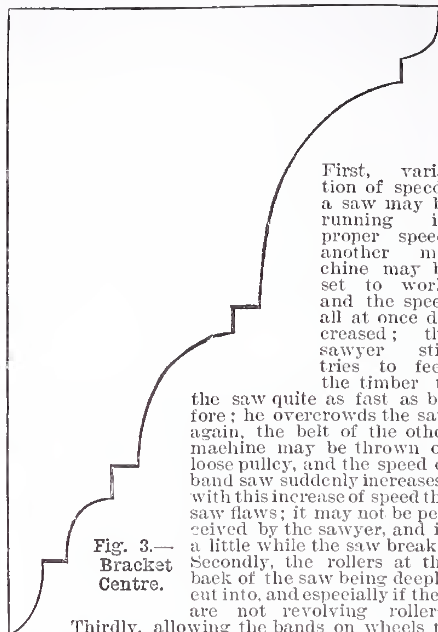

Fig. 3.—Bracket Centre.

First, variation of speed: a saw may be running its proper speed, another machine may be set to work, and the speed all at once decreased; the sawyer still tries to feed the timber to the saw quite as fast as before; he overcrowds the saw again, the belt of the other machine may be thrown on loose pulley, and the speed of band saw suddenly increases; with this increase of speed the saw flaws; it may not be perceived by the sawyer, and in a little while the saw breaks. Secondly, the rollers at the back of the saw being deeply cut into, and especially if they are not revolving rollers. Thirdly, allowing the bands on wheels to become badly worn and hard. Fourthly, overstraining the saw, which, I think, is the greatest cause of band saws breaking. I have more than once ordered half a dozen band saws which have been used chiefly in cutting felloes, shafts, etc., out of ash plank; the saws have been from one maker and ordered to a certain length; one saw has been perhaps ¼ in. longer than the others, so that it could not be strained quite as tight as the other saws; they have been all worked in turn; the five have broken and have been rebrazed and broken again, and the longer saw still has stood good and has not broken. I think this is a good reason why overstraining should be considered the chief reason of the saws breaking on a good machine. With a machine as the above, segments up to 12 in. deep may be sawn, and brackets of any pattern and of any depth up to 12 in. With ⅜ in. and ½ in. saws, we often cut bracket centres, as Figs. 1, 2, and 3, but it will be noticed that the centre of Fig. 1 has to be sawn out, which cannot be done with the band saw; in such a case, a hole or holes should be bored with centrebit, and sawn out with a small hand fret saw. If a band saw is in good working condition, a bracket when taken from the saw will require but little cleaning up: the saw will cut so clean that a little rubbing with glass paper will leave it quite smooth."

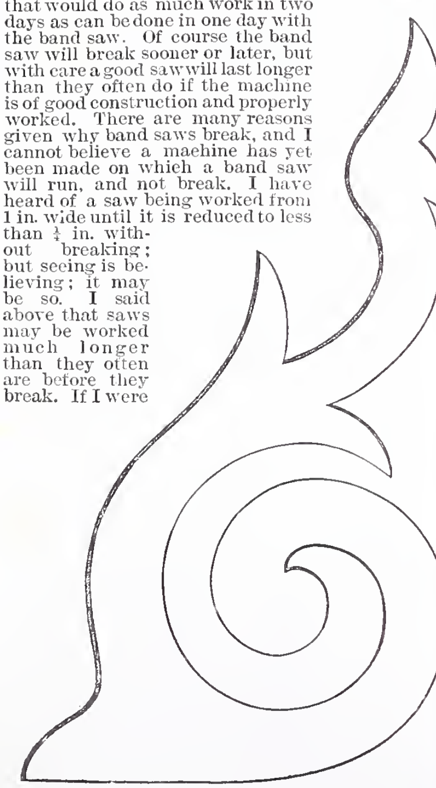

Fig. 2.—Bracket Centre.

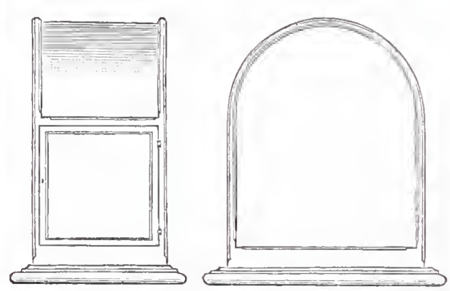
Wardian Case. — C. S. (*Newcastle-on-Tyne*) writes in further reply to W. P. (*Southport*), (see page 301):—"Seeing a sketch for above in No. 19 of WORK, and thinking that another sketch



Wardian Case.

might be of use to some of the readers of WORK, I have enclosed one, which is a copy of a case which I fitted up for my own use. It would be best made of oak or teak. The side glass is in one piece, with small doors in each end for working the interior. It would also need a zinc tray two inches deep to form the bottom. If desirable, I would be glad to send details and full particulars for any of our readers."

Cheap Hearth for Smithing.—A. H. (*Wolverhampton*) writes:—"In reply to A. S. (*Liverpool*) (see page 414) in reference to my reply to BELLOWS (*Gloucester*) in page 302, with respect to a machine for a current of air, I beg to submit the following:—(1) In the construction of a cheap hearth for use with the machine. The hearth will be about 3 ft. high. A. S. will want some sheet iron (20 gauge is about the right thickness). Cut a circular piece o iron 2 ft. 7½ in. in diameter, then a strip (for th sides or rim of the hearth) 4 in. wide and 8 ft. long Turn up all the way round the circular piece ¾ i Rivet the long strip together first, then the bottor piece to the strip, as in Fig. 1. Then you will war four lengths of rod iron 1 in. thick. Flatten th top, and drill a hole through for riveting. The turn the flattened piece back, as in Fig 2. Do th to the four pieces (each to be 3 ft. in length). Riv these on the bottom. Connect a piece of rod iro to the four legs, as in Fig. 3. (2) The tue-iron blast pipe. If A. S. wants one for the water circulate it will be more trouble than one wi a plain nozzle. However, as he asks for the mo of constructing a tue-iron for water, I will expla it. The iron, which should be cast, is shaped as Fig. 4. A. S. had better buy one ready-made. will also be provided with the water pipes. Abo 6 in. long will be the best size for the hearth. T pipe at the top must be connected with the botto of a tank or tub, and the one at the bottom mu come up to the top of the tub. The water go down pipe A. The water becomes heated, a then the steam forces it back up pipe B into t tub again. (3) As to the fan. One 10 in. diameter would answer A. S.'s purpose; the b to be 1 ft. in diameter. The mode of working to as follows. The fly-wheel 2 ft. diameter, and t fan pulley 3 in. A the pipe from the fan; B t exhaust water pipe going over to the top of the tu C feeding water pipe; D tue-iron; E treadle: crank; G fan box; H H supports for fan; I er bar from one leg to the other. Four of these v be required."

Cheap Hearth for Smithing.

Learning a Trade.—Paddy writes in reference)Excelsior's question (see page 413):—"I ean point ut the only way hy which Excelsior ean live nd learn a trade at the same time. He must get n at some good shop as painter's lahourer, and nake up his mind to be *excelsior* in the future, and c is sure to make himself a good tradesman. ;ooks are no use unless you have oeular demonstra- on at the same time, and most painters of to-day ave begun as above, though they may not have ked the discipline. At the same time, like my- elf, he can keep his eyes open on the other trades vith a view to johbing on his own account. This lso is decidedly not approved of, but every right- ninded man wants to be independent."

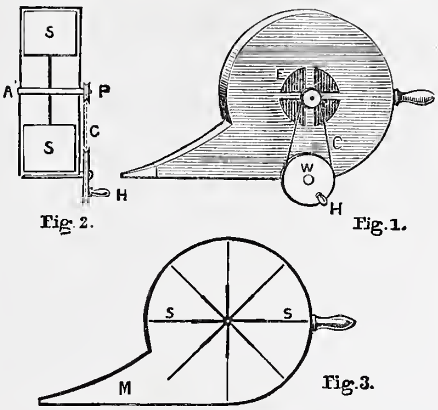
Classes in Carpentry.—B. R. C. (*East Finchley*) vrites:—"I think Amateur (*Bayswater*) (see page 2, No. 19) eould obtain, as I did, 'some elementary nowledge of carpentry' at King's Colicge. I elonged, some eight years ago, for six months, to n evening class (which, doubtless, still exists) vhich met there two evenings a week from half- ast six to nine o'clock, and there learnt to make ome eight or nine different joints, and made myself large hench and tool-box, whieh are now, after onstant use, as strong and sound as ever. The nowledge there obtained, combined with pretty onstant practice in spare moments at home, has nabled me to make in workmanlike manner a ariety of useful, strong, and ornamental articles. he fee, I believe, speaking from memory, is £2 a erm of three months. You receive, sir, so many ommendations upon the manner in whieh you onduct Work, that I will refrain from adding nine, except on one point which I have not seen eferred to yet. It is your light and dexterous touch n letting down the grumblers, as exemplified on age 309 in No. 19, in your reply to R. B. R.'s effusion; t is beautiful."

Classes in Handicraft.—F. S. (*Exeter*) writes:— 'In answer to H. N. (*Kingston-on-Thames*), allow ne to give my little experience with a night elass f drawing for working-men and youths. Having eceived mueh advantage in my trade as brass vorker through a knowledge of drawing obtained t Severn Street Night School, Birmingham, I feel t my duty to encourage others to try that art, nd show in a practieal way I mean to do so hy tarting a penny night elass for drawing, providing verything necessary. First business, to get a room, ree if possihle, with light, and at last the Rev. G. Davis, of Trinity Chureh, in this eity, allowed the ise of a room, and provided gas and firing *free.* Second, I have to obtain drawing boards, **T** squares, ompasses, rubbers, pins, paper, and pencils, with a lack-board and ehalks. These cost me at the rate f £2 15s. per dozen set. On the first night I invited ome of the students to help in the work, and right villingly was it taken up, these to eome half an hour efore time to prepare room, sharpen peneils, ete. And here let me say I only lost three pencils in three nonths. We went on so sueeessfully—increased our umbers to douhle what we started with—that I ould not admit more owing to expense of tools, tc. Only gave up the class owing to lease of remises running out. My generous donor had to ive up. I am thinking of eommencing again in he winter months, and having one night per week or repoussé brass work, if I can get some monetary elp to start. Once start, that is all you require. wish H. W. every sueeess in his work, and am villing to give any advice I can to help him in his ood work."

Model Yacht Building.—Oxygen writes:—"I ee that in the reply to G. H. (see page 269), *re* 'Model ailing vessel,' you say that the writer would natu- rally like to know the taste he has to suit. As I am n ardent model yachtsman, will you allow me to nake some suggestions? I, and probably many ther readers of Work, should like an article on he designing and building of racing model yachts, such as are sailed at Clapham and Kensington; not show models for glass eases and such purposes. Such an artiele I should suggest might be followed up by an artiele on racing model steamers, sueh as one sees in eonneetion with the Manehester Model Yacht Club. I am sure, with the aid of Work, the designing of such would become as popular among amateur meehanics in London as it appears to be n Manchester. No hobby could be more instructive in the mechanieal line, as it would eall into play both the mental and physical eapabilities of the amateur shipbuilder."

The New Waterproof Liquid Glue.—J. B. B. (*Bradford*) writes:—"Your request to your readers to report their experience with the above leads me to write to you. When I first tried it in our pattern shop I formed a poor opinion of its adhesive qualities, but further experiments have caused me to ehange my opinion. If the joint is clamped up hard, and the glue forced from between the joint, the result is failure; if the joint after being coated is simply placed together and left un- disturbed to harden, the result is a good, tight, hard, and thoroughly waterproof joint. I should like it to set a little quicker, but douhtless the makers will improve the glue as time goes on. Meanwhile I have no hesitation in recommending its use in the house or the shop. It is a practical and much wanted improvement in the glue line."

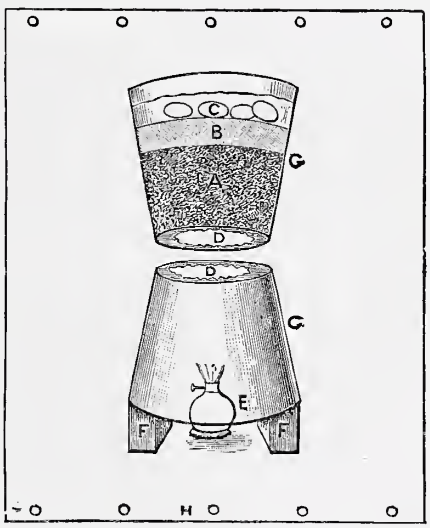
Machine for Current of Air.—A. T. W. writes in reply to Bellows (*Gloucester*) (see page 302):—"In No. 12 of Work, I saw a letter from Bellows (*Gloucester*), asking for a method of making a machine to give a constant current of air. I saw one some time ago, and have represented it here as clearly as I can, to give Bellows and others some idea how it is eonstructed. It is, however, a somewhat clumsy affair to use, and unless well made is apt to get out of working order. Fig. 1 shows it in perspective. Figs. 2 and 3 are two seetional views. H (Figs. 1 and 2) is a small



Machine for Current of Air.

handle which turns the large wheel, W (Fig. 1), round which a eord, C, passes round the small wheel, P (Figs. 1 and 2), which turns the small sheets of metal, S S, whieh are eight in number, and are fastened to the axle, A (Fig. 2), by pieces of wire, the whole of which revolves inside the ease, and blows out a eurrent of air at M (Fig. 3). A space should be left at E (Fig. 1) for the entrance of the air, the axle being supported by two eross pieces. The smaller details may he seen by re- ference to the figures. The one I saw was made of japanned tin, and seemed to work very well, hut I should think one might very easily be made out of wood and eardboard."

Simple Incubator.—W. L. (*Kingsland*) writes: —"In answer to B. F. (*Liverpool*) (see page 302) how to make a simple incuhator, I send a rough sketeh of one easy to make, will work well, and eost next to nothing. All that is wanted is two large-sized garden pots, piece of tin, small lamp, two hricks, fine sand, some flannel, and hox large enough to



Simple Incubator—A, Sand; B, Flannel; C, Eggs; D, Tin; E, Lamp; F, Bricks; G, Pots; H, Venti- lators round Box.

hold same when put together. To make, break out bottom of pots; eut tin to fit in bottom of one at D; then half fill with fine sand (A), top of sand some flannel (B), on the flannel your eggs, on eggs some more flannel. For bottom pot plaee your two bricks in bottom of box, so that your pot rests on them; under pot place your lamp. Then place other pot with sand in on top of this, and your incuhator is complete."

Step Chair.—Ralph E. Scorah (*Urbana, Ohio, U. S. A.*) writes under date of September 2nd:— "In reply to W. W. W. (*Nottingham*) (see page 270), I enclose a eut of a ehair whieh ean be ehanged into a step-ladder. This chair is made and given away to every purchaser of a hutt of plug tobaeco. I do not think it is patented here. Please publish this with full name in 'Shop.'"—[I have mueh pleasure in eomplying with Mr. Scorah's request. I do not engrave the drawings of step-ehair in its two forms of ehair and step-ladder, but I ean assure W. W. W. (*Nottingham*), and any other readers of Work who may be willing to buy a "butt of plug tobacco" in order to get the ehair, that it is a very good-looking piece of furniture. Unfortunately Mr. Scorah leaves us in the dark as to the weight and price of the quantity of tobacco named, and without these particulars it is unlikely that even W. W. W. (*Nottingham*) will respond. I trust Mr. Scorah will forgive my ignorance on this point, hut the United Kingdom is not yet a tobacco- growing eountry, though it is trying to he, and so "tobacco weight" does not yet figure in our "tahles of weights and measures."—Ed.]

Quick Drying of Gelatine Negatives.—E. B. (*Liverpool*) writes:—"In Work No. 29, page 462, I ohserve a reply given to a correspondent on the above suhject which I venture to say is hardly eorrect. Benzine will not do instead of spirit to dry a negative, neither will sulphurie ether. Spirit dries the negative quiekly solely by the powerful attraction which it possesses for water, acting like liquid hlotting paper as it were. Neither henzine nor ether possesses this attraction, and were a gelatine negative soaked in benzine for a week it would at the end of that time contain as mueh moisture as when put into it. Expense ean scarcely apply to articles so cheap as methylated spirit and benzine, the difference in price being only about 2½d. per pint."

Model Locomotive.—W. T. (*Blairgowrie*).—This suhject is receiving eonsideration, and will without douht be taken up and thoroughly treated in Work in due time.

Gasoline.—D. M. I. (*Portsmouth*) writes:—"For the information of your correspondent, J. McW. Iernus (*Tarbert*) (see page 460, No. 29 of Work), I think he eould obtain gasoline from Messrs. Sugg and Co., Vincent Street, Westminster, in small quan- tities. It is one of the lighter paraffins, and is used for making air gas to supply mansions too great a distanee away from gas works to be supplied there- from."

New Water Glue.—J. M. N. (*Bradford*) writes:—"In a recent number of your valuable paper called Work you invited subscribers to give their experience with the 'new waterproof liquid glue.' My experience with this article (which is over twelve months') is that it is a most excellent 'waterproof liquid glue,' and I believe that it will do all that is claimed for it hy the makers."

The New Water Glue.—R. W. (*Shipley*) writes:—"Seeing your article on the new water- proof glue made by the new Glue Company, Shipley, and your request for the experience of those who have tried it, I have much pleasure in stating for the benefit of your readers that I eon- sider the glue invaluable to amateurs; for model yacht building it is a perfect boon, insuring a tight boat, and much facilitating the building process; in fact, by the use of the glue the most unskilled builder is insured a tight eraft. I have also used the waterproof glue with success for domestic purposes, repairing furniture, and even glass and ehina, and eonsider it invaluable for every house- hold, on aeeount of its handiness and other qualities. It requires rather different treatment in use to the ordinary glue, that is, the joint must not be ruhbed, but after being glued simply requires gentle pressure to insure success."

II.—Questions Answered by Editor and Staff.

Tools for Hand Turning.—Bodger.—Yes, you require nothing hut the chisel or gouge and the T-rest for turning such things as egg eups: turners' chisels and gouges are kept at most ironmongers' who sell tools at all, and eost about a shilling eaeh. You should inquire for a turner's shop, and give him a shilling to give you a lesson; that would teach you more about the way to hold a gouge for hollowing out an egg eup than pages of descrip- tion.—F. A. M.

Wood for Cheval Screen Escritoire.—F. J. (*Bristol*).—While fully appreciating your desire to be economieal in the raw material wherewith you pro- pose to construct the cheval screen escritoire that appeared in Work of June 15th, yet I am strongly of opinion that it is false economy to waste good joinery upon inferior stuff, only to find after- wards that all the time and eare lavished is, to a great extent, thrown away. Pitch pine would he, no doubt, eleanly to work, and not unpleasant in its effect. If you deeide to use it, I should advise you to stain it hlack and polish it, and if decoration of the panels hy inlay or earving is impossihle (and with pitch pine it would he practically so), then to try an odd yard of Japanese gold leather paper, or linerusta, and use it on the panels. Pieces the size you require would eost hut a few penee at any good decorator's, for such scraps are sure to be left over in important johs. The form is quite un- suitable for veneer, and I should strongly advise you not to attempt it on a structure so complex as the one quoted. American walnut is eheap, and you ean often buy old mahogany at a second-hand shop, in the shape of some pieee of furniture damaged past repair, that would yet eut up into such a thing as this. If you dislike black a good finish might be made with Aspinall's enamel in a dark peaeoek blue, or even a sealing-wax red. Sequoya wood is as eheap as pitch pine, very pretty, and easy to work, but perhaps too soft to be suitahle for an escritoire. Bearing in mind that accidents in the neighbourhood of an ink bottle usually leave lasting results, I think one may eome back to ehonised wood as the most satisfactory, especially as certain parts, for example, the door frames and the projecting feet, can be cut of harder wood. Your personal thanks I must not overlook, although modesty forbids me to accept them fully. Yet to know that one's efforts are appreciated, and that the pleasure of explaining results in the pleasure of being understood, is an experience that, however often it comes (and the correspondents of WORK are a kindly-disposed set), always comes with a fresh feeling of gratification to yours very faithfully,—J. G.-W.

Books on Plumbing.—SEMPER IDEM (*London, W.*).—You will find the following to be good books on the subject you mention:—"Sewer Gas, and How to Keep it Out of Houses," by O. Reynolds (Macmillan & Co.), 1s. 6d. "Bad Drains, and How to Test Them," by R. H. Reeves (E. and F. N. Spon), 3s. 6d. "Plumbing," by W. P. Buchan (Lockwood), 3s. 6d.

Polishing Cutlery.—C. L. B. (*Tunbridge Wells*).—To repolish cutlery, you will require three wheels about 8 in. diameter, and 2 in. to 2½ in. wide, the edges covered with buff leather. If in possession of a lathe you can use that as a means of revolving the wheels, but it is not advisable to use a good lathe for this purpose, as the grit and dust damage the bearings. If you are going to make a regular thing of polishing, then rig up a proper frame, something like the knife-grinders travel the streets with. The wheels should have a square hole in the centre so as to all fit on one square spindle; they can be keyed on or fixed by means of pins driven through, or holes drilled in the spindle each side of the wheel. Use with the first wheel No. 0 emery and oil, till all scratches and marks are taken out, then use wheel No. 2 with crocus and oil, and polish up on No. 3 with dry crocus or rottenstone, revolving the wheels from you, and working at a good speed.—R. A.

Small Electro-Motor.—J. C. (*Shipton, Yorks*).—I gather from your letter that you wish to revolve a wheel of life, or Praxiniscope, by means of a small electro-motor, worked by a current from a quart Bunsen battery. As you got the battery from Mr. Dale, he will also advise you respecting a motor to be driven from it, if you write clearly, and tell him just what you want. But do not ask for a "Magneto-Morter," as you have in your letter to me. Tell him you want a small electro-motor such as is used in revolving vacuum tubes. It will cost about 15s. As he is a maker of optical instruments, he will also give you the price of a Praxiniscope or wheel of life.—G. E. B.

Electro-Gilding and Electro-Plating.—LEARNER (*Manchester*).—The best book on the subject for a "beginner" or a professional workman is "Electro-deposition," by A. Watt, published by Crosby Lockwood & Co., price 12s. 6d. This you may get for 9s. from a discount bookseller. Be sure you get the latest edition. A cheaper but good book is "Electro-plating," by J. W. Urquhart, published by the same firm, price 5s.—G. E. B.

Electro-Plating.—C. H.—Kindly see reply to LEARNER (*Manchester*), respecting the best book for your purpose. I may say, however, that the subjects you name will be fully treated in WORK in a manner easily understood by everybody able to read. I note with pleasure what you say about boy readers of WORK. It will be always (I hope) my chief concern to so write my articles as to make them quite clear and readable to boys and young men. I write for them specially, and have them always in my mind when writing for WORK. But the boys and young men and apprentices who now read WORK will be, I trust, some day, professional men, and I must write so as to anticipate that time also.—G. E. B.

III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

Steel and Florentine Bronze.—J. L. writes:—"Can any reader give me particulars for steel and Florentine bronze for brass work (gasaliers and gas brackets)? I can work green lacquer, but know nothing of these newer colours."

Riveting China and Glass.—F. A. J. (*Canonbury*) writes:—"Can any reader tell me how china and glass riveting is done? How the holes are drilled? Whether the rivets can be purchased or are made at the time, and how they are secured? It seems to me probable that it is a simple process well within the capability of most men, and would often save the destruction of a useful piece of china, and if the information could be given in 'Shop' might be useful to others besides myself."—[I shall be glad to receive a paper on the subject describing the peculiar drill that is used, how to drill the holes, and how to insert the rivets, from any person competent to write on the subject.—ED.]

Barnes' Foot-Power Scroll Saw.—REMINGTON writes:—"If any reader of WORK has tried or seen working one of Barnes' American Foot-power No. 7 scroll saws, I should be thankful if they would give their opinion of same—as to what thickness it will cut easily, etc.—as I am in want of one for practical workshop use. I don't want a toy. Any particulars as to same would be thankfully received."

Harp.—J. K. (*Glasgow*) writes:—"Would any reader inform me how to construct a harp? I should be much obliged."

Small Pump.—W. R. S. (*Brixton*) writes:—"Would anybody be kind enough to give me instructions for making a small pump capable of lifting about a third of a pint of water at each stroke, and where to get castings for same?"

Book on Brushmaking.—BRUSH (*Tipton*) writes:—"Can you recommend a book on common brushmaking? If not, I should be glad of any information on the subject in 'Shop.'"

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Cement for Billiard Slates.—W. G. writes in reply to CEMENT (*Cork*) (see page 382):—"Gold size and litharge, worked up into a stiffish putty, will answer the inquirer's purpose. It will set as hard as the slate, and be unaffected by heat."

Illuminating.—H. T. L. (*Tufnell Park, N.*) writes in reply to H. C. (*Lincoln*) (see page 318):—"As I have seen no reply in WORK to the above, I venture to make a few suggestions. Presumably H. C. is about to illuminate a testimonial, or possibly write a missal. You do not specifically state which. Rub your parchment or vellum with pounce, and having stretched it as usual, proceed to work. No more suitable colours than those contained in moist pans can be used. If you mean by their not being brilliant that they have not sufficient gloss, add a little gum water together with a little liquid ox-gall; the latter causing the colour to flow more evenly on the somewhat ivory-like surface of the vellum. The colours I use are, viz.—smalt, French blue, cobalt, and sparingly cerulean, carmine, rose madder, scarlet and purple lakes, and vermilion, emerald and oxide of chromium, deep and pale cadmium, lemon yellow and aureolin, vandyke brown, lamp black, and Chinese white. Surely you can obtain a brilliant colouring with these. Don't mix them much, mixing always destroys brilliancy. Use for gilding gold leaf with a gilder's cushion and short-haired tip. I use both deep and pale gold, the pale on raised parts, such as mouldings, etc., the deep on the flat parts to give some indications of shadow. To answer your question and reply to your remarks properly would take up too much space in this column. Procure Winsor & Newton's 'Manual of Illumination' and 'Companion' (1s. each). The style they indicate is the purest and the instruction among the best."

Insurance of Tools.—F. J. (*Kidderminster*) writes:—"I see in No. 27 of WORK, page 429, that T. T. (*Kennington*) wishes to know if there is any office in which he could insure his tools. I know of no insurance office which undertakes this kind of risk, but if T. T. is not already sufficiently covered in cases of sickness, I would recommend him to join the Hearts of Oak Benefit Society, which, in addition to allowing 18s. per week in cases of sickness, and a correspondingly adequate sum in case of death, also provides its members against the loss of tools by fire to the extent of £15, beside other benefits, on payment of an average subscription of 10s. per quarter."

Insurance of Tools.—A. J. THRESHER (15, *Warwick Road, Stoke Newington*) writes:—"In reference to the query of T. T. (*Kennington*) in No. 27 of WORK, page 429, I do not know whether he or yourselves may be aware that by joining the Hearts of Oak Benefit Society of 17, Charlotte Street, Fitzroy Square, W., he can have his tools insured up to £20. The payment to the Society is 10s. per quarter, but in addition to the insurance of tools this includes benefits as follows:—£20 on death of member, £10 on death of wife, 18s. per week during sickness, 4s. per week superannuation, and other minor advantages. On application to the above address, however, full particulars will be sent."

Paint on Leather.—R. S. W. (*Norwich*) writes in reply to J. B. S. (*Nottingham*) (see page 318):—"You want to know how to prepare bag or portmanteau to receive paint so as not to crumble or fall off. This is the preparation: Thoroughly clean the leather with good spirits of turpentine. Then, when dry, give it three good coats of best japan black, the last one to have a small quantity of vegetable black in it to take the browny hue off it. He will find it will last a long time. I am in the trade."

Child's Wooden Toys.—P. P. (*Withington*) writes in reply to W. A. (*Hanley*) (see page 270):—"If he applies to E. May, Buckledge Avenue, Harlesden, London, N.W., for his catalogue, he will get what he requires."

Tool Wanted.—MEDICAL (*Cambridge*) writes in reply to GAUGE POINT (*Paris*) (see page 446):—"For a reliable rule to measure promptly and accurately (to $\frac{1}{16}$ in.) openings and spaces from 2 ft. to 10 ft., I have one which I made a couple of years back, and which has worked satisfactorily, and which I think may possibly be useful to G. P. The rule consists of a scale 1 ft. long graduated to $\frac{1}{8}$ in. and having a sliding bar working along it, after the manner of a cobbler's measure. This sliding piece corresponds accurately with foot-rule when closed, and has a mark $\frac{3}{16}$ from its end which will, of course, fall half way between first and second mark on fixed scale. Suppose, when rule is extended to fit space, the end of sliding bar fall between 6 in. and $6\frac{1}{8}$ in. marks, then $\frac{3}{16}$ mark on bar will show by its position in regard to $6\frac{1}{8}$ in. mark on rule whether $6\frac{1}{32}$, $6\frac{1}{16}$, or $6\frac{3}{32}$ would be the most accurate reading. To the end of my scale are hinged a number of folding rods, as used in ordinary rules, so that any length from $12\frac{1}{16}$ in. to 6 ft. (the extreme length of my rule) may be accurately read. I think GAUGE POINT will be able to adapt this idea to his requirements, but if it is useless to him let him believe that it has been very far from useless to the amateur who tenders it to him."

Trade Notes and Memoranda.

MESSRS. KRUPP have shipped a cast steel gun weighing 235 tons, from Hamburg for Cronstadt. The calibre of the gun is $13\frac{1}{4}$ in., the barrel is 40 ft. in length, its greatest diameter being $6\frac{1}{2}$ ft. The range of the gun is over eleven miles, and it will fire two shots per minute, each shot costing between £250 and £300. The gun is the largest in existence and the heaviest yet exported by Messrs. Krupp.

THE large weigh beam in the engine house at Le[e] Mill, Bacup, belonging to Mr. Henry Maden, suddenly snapped asunder recently, and in a few seconds the massive beam engine, two galleries and the large window were a complete wreck. The damage is estimated at over £1,000.

SIR EDWARD WATKIN has submitted a proposa[l] for a gigantic railway project to the Secretary o[f] State for India. It is nothing less than a railwa[y] from London direct to India *viâ* Kurrachee. Th[e] Channel Tunnel is a portion of the scheme, thoug[h] not an absolutely essential part of it, since th[e] start could be made from Calais or Boulogne. Th[e] railway would proceed direct to Gibraltar, usin[g] the existing lines as far as possible, and the[n] would be introduced a novel feature in the lin[e]. This would be a vast broad-beamed boat capable o[f] taking on board the entire railway train, as [it] arrives at Gibraltar, and delivering it on the rai[ls] at Tangiers. Here the line would strike eastwar[d] keeping along the north coast of Africa, touchi[ng] at Egypt, and proceeding by the Persian Gulf t[o] Kurrachee, where it would join the Indian railwa[y] system. Sir Edward Watkin's project is said [to] have engaged the attention of several emine[nt] engineers and capitalists.

A DUST-PROOF engine has been designed b[y] Messrs. Hanson, Carter & Co., of Quebec Work[s], Bradford, for use in dusty situations as stokehold[s], foundries, and the like. The engine is entirely e[n]closed, access to the working parts being through [a] door provided with a felt edging to render th[e] closure air tight. They are made in three size[s] with 3 in., $4\frac{1}{2}$ in., and 5 in. cylinders.

THE Worshipful Company of Armourers an[d] Brasiers will hold at their Hall in the City [of] London in May, 1890, an exhibition of specimens [of] modern armour (including helmets, breastplate[s] and blades) and of original art works and designs i[n] brass, bronze, copper, etc., to be the work of Briti[sh] subjects, and manufactured since 1st March, 18[8]. Prizes, certificates, etc., will be awarded for me[ri]torious work, special prominence being given [to] exhibits by craftsmen. Full particulars may b[e] obtained on application in writing to Marsha[ll] Pontifex, clerk, Armourers Hall, 81, Colema[n] Street, London, E.C.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, [at] 9 o'clock every Wednesday morning, and should be obtainable ever[y]where throughout the United Kingdom on Friday at the latest.

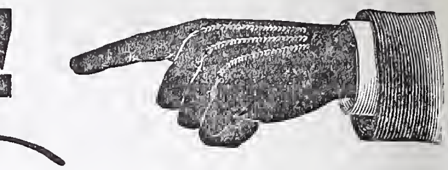
NOTICE ! !



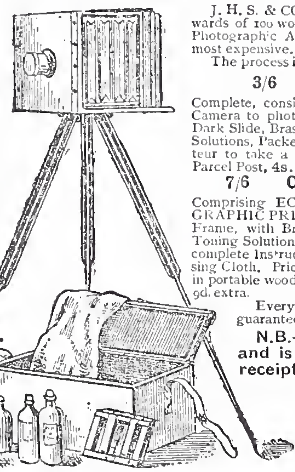
WE are *bonâ-fide* Makers of 300 Varieties of Lathes and other Engineers' TOOLS, many of which were designed for the British Government. Six Varieties of Fret Saws. Numerous Prize Medals. Our new Fret Machine, No. 8, cuts metals or ¾-in. wood: it is having a capital sale. Send 6d. for Catalogue; 2d. for List of Second-hand Tools. New and valuable Book on Turning, 3s., post free. Cash or Hire Purchase. You are invited to call and inspect a Large Stock of above at

BRITANNIA CO., 100, Houndsditch, London.

ALL LETTERS TO BRITANNIA WORKS, COLCHESTER (ENGLAND).

J. H. SKINNER & CO., EAST DEREHAM, NORFOLK,

Manufacturers and Importers of Photographic Apparatus and Fretwork Materials.



J. H. S. & CO. have now a large Factory with accommodation for upwards of 100 workmen, which is used exclusively for the manufacture of Photographic Apparatus of every description, from the cheapest to the most expensive.

The process is simplicity itself. Full Instructions supplied with each set.

3/6 The Eclipse Camera Set. 3/6

Complete, consisting of a Polished Mahogany Sliding Bellows, ¼-plate Camera to photograph full-size carte-de-visites, with Focussing Screen, Dark Slide, Brass-mounted Lens, Brass Fittings, Developing and Fixing Solutions, Packet of Dry Plates, and full Instructions, enabling any amateur to take a good Photograph. Price **3s. 6d.**, or securely packed by Parcel Post, **4s.**

7/6 Complete Photographic Outfit. 7/6

Comprising ECLIPSE CAMERA SET, as above; also PHOTOGRAPHIC PRINTING APPARATUS, consisting of Hardwood Printing Frame, with Brass Spring Back, Sensitised Albuminised Paper, Gold Toning Solution, Fixing Solution, Glass Rods, Cards for Mounting, with complete Instructions. Also Hardwood Folding Tripod Stand and Focussing Cloth. Price **7s. 6d.** Securely packed, post free, **8s. 6d.** If packed in portable wood case, with hinged lid and leather strap, as in illustration, 9d. extra.

Every Set is carefully examined before being sent out, and guaranteed to be in working order.

N.B.—If Apparatus does not give satisfaction, and is returned uninjured within three days of receipt, we guarantee to refund purchase money.

Better Sets, 10s. 6d., 21s., 42s., 100s., and upwards. Complete Catalogue of Photographic Apparatus, one stamp. **J. H. SKINNER & CO., EAST DEREHAM, NORFOLK.**

Wholesale Agent for London—J. MOTHERSILL, 60, Holloway Road, N., and 6, Southampton Row, where Samples may be seen.

Timber Yards, Sawing and Planing Mills covering about Two Acres near Railway Station.

J. H. S. & CO. keep regularly in stock about **120,000 FEET OF FRETWOOD,** solid and 3-ply, veneers, &c., besides a very large quantity of Logs, Planks, and Boards, Carving and Turning Wood, &c., and **200,000 FULL-SIZE DESIGNS for Fretwork, Wood Carving, &c.,** besides an immense Stock of Joiners' Tool Chests, Fretwork Outfits, Drills, Saw Frames, Hand and Treadle Machines, Saw Blades, &c. &c.

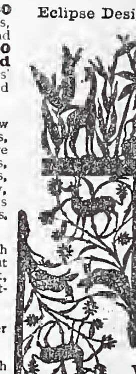
Specialities for 1888 & 1889.—Books of New Designs. FRETWORK No. 1, containing 12 Large Sheets, price 1s. No. 2, containing 20 Sheets of larger and more elaborate Patterns, 2s. 6d. Book of Wood Carving Designs, containing 14 Patterns, price 1s.; these are all New Patterns, not sold in any other form, and would, if sold separately, cost three or four times the amount charged. Fretworker's Handbook and Workshop Guide, price 1s. New Designs. All Patterns greatly reduced in price.

Complete Fretwork Outfit, comprising 12-inch Steel Frame, 48 Saws, Awl, File, 4 Designs (with sufficient planed Wood, gratis), and 1s. Handbook on Fretwork, price 3s. 6d., carriage paid. 12 feet Assorted Planed Fretwood, 3s. 6d.

☞ Special Fretwork Design, in commemoration of Her Majesty's Jubilee, size, 36 in. by 26 in., price 2s. 6d.

Catalogue of Machines, Designs, Wood, Tools, &c., with several Hundred Illustrations, and full Instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. Good Fret Saws, 1s. 6d. per gross; best ditto, 2s. per gross.

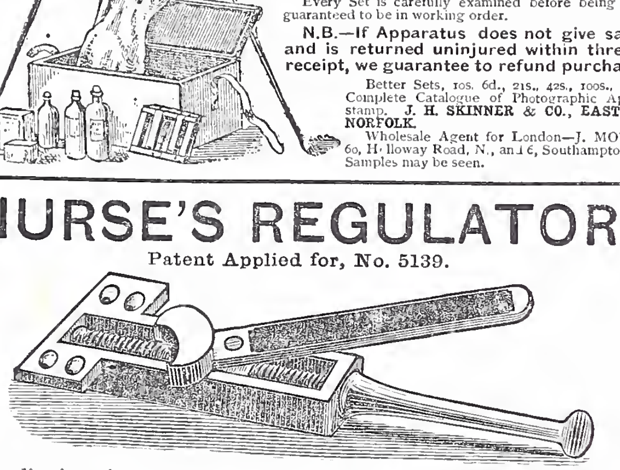
Eclipse Design, No. 102.



Wall Bracket. Price 5d.

NURSE'S REGULATOR.

Patent Applied for, No. 5139.



For adjusting the Irons of all English Pattern Bench Planes. Can be easily fitted to any Smooth, Jack, or Try Plane, without alteration of Irons already in use. Price 2s. each; post free, 2s. 3d.

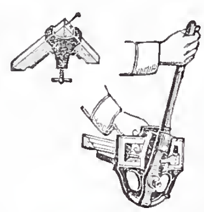
Price Lists free by post on application to Sole Makers,

CHARLES NURSE and CO.,

PLANE MAKERS AND TOOL MERCHANTS,

182, Walworth Road, London, S.E.

(Established 1841.)



PROFITABLE HOME WORK

With BOOTH BROTHERS' **Registered Mitre-Cuttin Machine,** any person, without previous instruction or pra tice, can make a Picture Frame. This Machine is now large used in the Trade, nearly 6,000 having been sold. Wri for Illustrated Circular to the Sole Makers—

BOOTH BROTHERS,

FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

Vol. I.—No. 36.] SATURDAY, NOVEMBER 23, 1889. [Price One Penny.

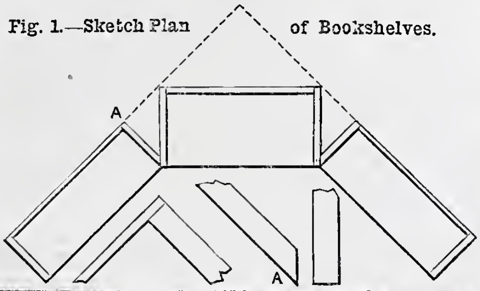
ANGING CORNER BOOKSHELVES IN PAINTED WOOD.

BY PALGRAVE MORRISON.

N arrangement of bookshelves similar to ie one illustrated had long been in my ind; one of its three component parts as made and in use, and the plans of the vo others quite decided, when a room that hoped to secure for my own snuggery iould admit of their being placed in posi-on. The novelty of ie idea was fascina-ng to its inventor, nd offered special dvantages. My un-xpected pleasure on oing into a friend's ooms in one of the 'ambridge colleges, nd seeing the actual et hanging on his all, provoked me to sk, How, when, and hy the shelves in uestion were made? he reply showed that, s usual, circumstances nsightly in them-elves had resulted in ie distinct treatment. or in the room an ld buttress jutted it in the angle of the all, so that no ordi-ary corner cupboard ould fit. This pro-ction being unsightly as hidden in just the ay I had planned for y own shelves.

Apart from any ierit in the appear-nce of shelves so reated—and they are iore picturesque than simple rectangular roup — the vacant pace they leave in the ngle itself would be dmirable for a ven-lating shaft, which, ecessary and health-il though it be, is an nsightly object in a rivate room. It is ften convenient to ave a shaft placed in n angle against an uter wall, but since hen no piece of furni-ire will fit the corner, gives a desolate ap-earance to that part f the room. But a et of shelves in this ishion, whether fitted

Fig. 1.—Sketch Plan of Bookshelves.



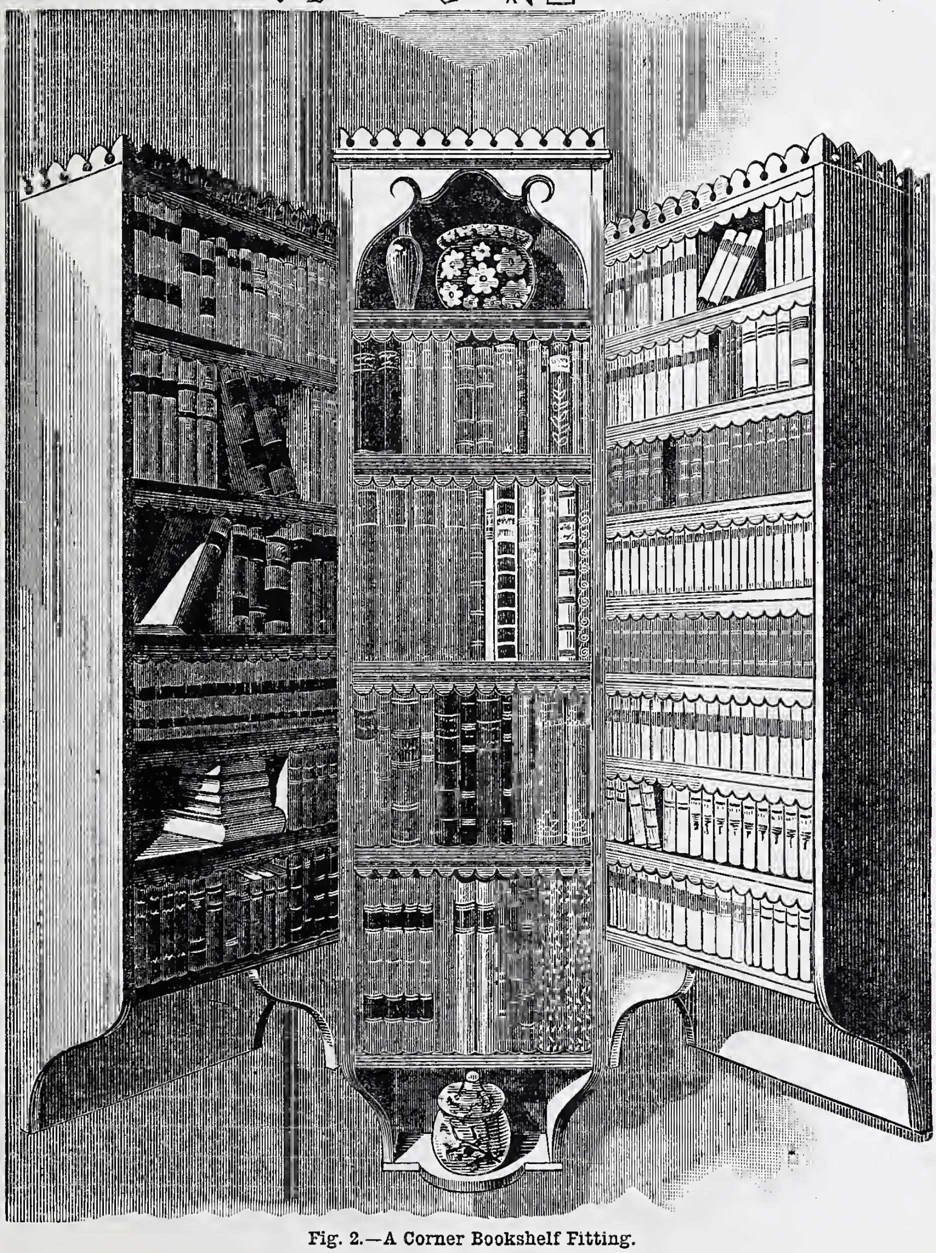


Fig. 2.—A Corner Bookshelf Fitting.

as bookshelves with or without glazed doors, and varied in all respects save the main features to suit the taste of its owner, would solve the difficulty.

It must be clearly indicated that the design offered is purely suggestive; it is not to scale; nor is the arrangement of any of its features a point to be insisted upon. The only structural feature to be followed is that the three separate carcases shall be shaped to form a symmetric group, thus making the whole more portable, saving wood; and more particularly avoid any complicated joinery at acute or obtuse angles.

As a reference to the plan will show, the triple bookcase thus grouped permits the central portion to be deeper, that is, to afford space for wider books, than the wings on either side.

That these wings should be the same height, and harmonise with the central part in their decoration and detail, however plain or elaborate that may be, is perhaps necessary. But that they should be of the same width is hardly needful, for it may easily happen that the obstacle of a door or window will make it more convenient to construct the two wings of different dimensions.

The depth of the side cases is intended to be about (not over) 6 in.; in other words, the uprights and shelves are worked from wood 5½ or 6 in. wide. This scale allows the shelves to be placed at intervals not exceeding 9 in. apart., with a certainty of containing any ordinarily shaped book comfortably.

The central division, being deeper, allows the shelves to be disposed so as to take volumes of larger size. Thus if the wings are 6 in. deep, the central part must be 8½ in. The sketch is in no way to scale; the general effect very fairly indicates the appearance of the complete structure.

The ornamental details to a set of shelves for books are best left out. The books themselves are the fittest decoration. But of course a slightly-pierced caging, as indicated, or a row of small turned spindles, may be used at top. So the top shelf of the central portion may be treated with an arch, leaving space for a bust or vase. The whole is intended to be painted or stained; merely a rough-and-rea ly set for a bachelor's study or professional man's use.

The edge of each wing where it touches the central part is bevelled away as shown in the diagram, so that it appears as if the whole were homogeneous, and not made up of three independent parts.

It is by no means necessary to have such shelves finished in black. I have a similar set finished in bright scarlet enamel, and another in peacock blue, that take their place in the room, and are not a bit staring or out of harmony with the rest; but then in each case the other things accord, so that it is best to recommend every would-be maker to be guided entirely by the future position of the finished thing, and vary size, colour, and decoration as much as he likes; for nothing is so satisfactory as evidence that the design has been subordinated to the needs of its owner, and become, if not an individual creation, at least a pliable adaptation in his hands.

MORE ABOUT POLISHING.

BY DAVID DENNING.

THE novice who has read the "Preliminary Gossip about Polishing Wood," which appeared on page 506, may be inclined to ask whether wood should be polished or varnished, and, following up the answer which will be given in the present article, he will probably want to know something more about the distinction between the two methods of finishing.

Taking up the question which, it may fairly be supposed, would be first put by the tyro who has little more than a vague idea that wood, if not painted, has something put on it to make it shine and improve its appearance, some attempt at a satisfactory reply may be made. Perhaps, however, before doing so it will be as well just to understand what the action of any varnish is, without going into minute particulars. As is well known, varnish when applied is in a liquid state. This liquid is made up of a solvent for the particular kind of gum or resin used in making up the particular kind of varnish required. The surface of the work is coated or painted in some way with the prepared fluid. The moisture evaporates, leaving a film of the resin which has dissolved in it. Wood, or anything else so treated, is said to be varnished. Now, whether this method of finishing is suitable for woodwork depends on circumstances. For coarse work it does very well, but for articles of furniture the process known as French polishing is to be preferred, as finer results are to be got by it. It may, however, be as well to state here that French polishing is not the only method of finishing furniture in addition to varnishing, or even painting. We have, for example, oil and wax polishing processes which, for some kinds of work, are to be preferred to the other, and they will be treated of in due course.

Even choice articles of furniture, from the substantial sideboard to the flimsy fretwork ornament, may be varnished instead of polished; but it must be distinctly understood that a really well-finished surface cannot be got with the former process. This is tantamount to saying that any one who wants to finish a piece of furniture in a suitable and tradesmanlike manner must polish it, and not be contented with the simpler and easier process, which is also more expeditious it may be said, of varnishing it. Where to draw the line between the two classes of furniture, viz., that which will be worth taking some trouble about and polishing properly, and that for which a humble coat of varnish is deemed sufficient, may be safely left to the maker's consideration. Perhaps, as a hint to him, it may be suggested that he will get better results from careful varnishing than from badly executed polishing. There again allusion is only made to French, and not to the simpler wax polishing, of which it may almost be said that it requires no practice, and that it can be done by anybody who has patience.

The only kind of furniture which it may be considered proper to varnish is that made from pine, though even this is frequently French polished. Pine furniture, however, unless it is really well made and finished, is hardly worth polishing—at least, it is not customary to polish it. Like every other wood, it is undoubtedly improved, or, rather, let me say, its appearance is improved, by polishing; but it is obvious that the chief reason for pine furniture being its cheapness, varnishing is in many cases supposed to be good enough for it. The process of japanning, by which much of the cheaper kinds of pine furniture is finished, being akin to painting, does not now concern us, and I, for one, would not be sorry to see it extinct, or, to say the least, very much less employed than it is. The discussion of this is, however, beyond the scope of this series of articles, which will be confined to processes in which the grain or natural figuring of the wood is not hidden, but is simply brought out and improved by a transparent covering. Mahogany, walnut, and all the finer woods used in making furniture should be polished if they are to look as well as it is possible to make them. Enough has now been said to guide the novice in forming an opinion as to when he ought to finish by polishing, and to give him a clear idea of what this is. A little general explanation will be given, after which he will be better able to profit by the more detailed instructions which will follow.

Although the medium used to obtain a French polished surface is in reality nothing but a varnish, it is one of a much finer kind than is generally understood when the word "varnish" is concerned, and probably many of my technical experts may at once be inclined to exclaim that French polish, *i.e.*, the material used, is not a varnish. A moment's consideration, however, will show them that it cannot be described as anything else, and not only so, but that it cannot with accuracy be regarded in any other light. The material known as French polish, were it to be described fully, would be spoken of as a special varnish for French polishing. In colloquial language, however, both the finishing gloss and the material on which, or, perhaps, it will be as well to say by means of which, the gloss is produced, are spoken of as French polish. The material is nothing more nor less than the thin varnish which experience has shown to be the most suitable for producing a fine, smooth, glossy surface by the French mode of polishing. I daresay many of my readers have heard of the celebrated Vernis Martin, which means nothing more than Martin's Varnish, or, as we should perhaps now more elegantly call it, Martin's Polish. This Martin produced a very finely finished surface by means of some material or manipulation which he kept a secret, and which is said to have died with him. This, however, seems hardly probable, or, if his methods were not exactly known and followed, it is only reasonable to suppose that his success induced others in the same line of business to experiment on their own account, and that the result is what is now known to us as French polish. To say that this is exactly the same as the celebrated Vernis Martin is, of course, more than one can do. His materials may have been—indeed, probably were—different from ours. His mode of producing the gloss or polish, perhaps, bore a very slight resemblance to that now adopted; but that he made his reputation by smoothing or polishing a varnish can hardly be gainsaid. Many accounts purporting to describe his process have been given to the world, but it may be doubted whether any of them are absolutely correct, although they may approach very nearly, both as regards materials and manipulation. That the results are good when the somewhat cumbersome processes are followed with skill and ability is an undoubted fact; but the simpler process known to us as French polishing is quite sufficient for all practical purposes, and few, except those who are prompted by curiosity, will care to try any more tedious way of getting similar effects.

The theory that Martin was the inventor of the process which in a modified form is now practised for getting a gloss by mechanical means on a coating of suitable varnish may not meet with general acceptance, but those who urge it have at the least very substantial grounds to build on. This part of our subject is, however, more for the antiquarian than the practical polisher to consider; but even in the humblest of our pursuits it is often interesting to trace the process of development from the first crude idea to the improved processes of the present day. The dirty-fingered French polisher of to-day would likely not be exercising his craft if someone, whether Martin or not is of no consequence, had not observed that a varnished surface might be further improved by polishing. We, perhaps, are rather too apt to consider that when we know all about French polishing practically—that is to say, when we can do the work satisfactorily—everything has been learned. We go as far as the generation which immediately preceded us, possibly even surpass them, or think we do, and then rest satisfied that we have no further progress to make. We have learned all, or acquired all the knowledge which could be communicated, and forthwith sit down in complacent satisfaction, without a thought that improvements may still, at this period of the world's history, be practicable. "Well," says some enterprising polisher, "all this sort of thing, trying to find out improvements, making discoveries, and so on, may be all very well for engineers, electricians, and those engaged in scientific callings, but as for polishing, there is nothing more to be accomplished. That there are certain defects and drawbacks in the way the work is done is, of course, apparent; but then they cannot be avoided, and there is no way of overcoming them." Others again will tell us that they don't see anything the matter with their modes of working, which are quite good enough: they make a living by their work, and what more is requisite? Now, I am quite willing to admit that there may at present be no *known* way of overcoming some of the defects in polishing, but is there any reason why this should always be the case? At one time, and that not so very long ago, the average English polisher, or rather labourer who did the polishing, aspired to no higher gloss than was to be obtained by means of beeswax; and are we now to think that because a better finish can be got that there is nothing superior within the reach of man? True, at the present time we get a very nice surface, or, let me say, it can be got by a competent polisher, and in the foregoing remarks I have no wish to disparage the skill so often shown in finishing furniture; but with all deference to those who have arrived at the highest point of skill, there are defects which show that the craft has not yet attained to that degree of excellence which would warrant one in supposing that further progress cannot be made. Just to give one example of a weakness in the mode of polishing now pursued, let me suggest "sweating," which, as every polisher knows, is a frequent source of trouble and annoyance. It is all very well to say that "sweating"—by which, of course, I do not intend the commercial meaning of the word—is unavoidable, and to give all the reasons why newly French polished wood is liable to it. It may be admitted that with our present knowledge this is so; but is it inconceivable that some improvement might be made which would render "sweating" a thing of the past? I am quite aware that experiments have been made with this intention, and that some of them have been attended with a fair amount of success; but still, the argument remains good that there is still plenty of room for improvement in the details of the work, and it is with a view to stimulating those who are best able to make improvements, viz., those who are professional French polishers, to investigations on their own account that these suggestions are offered. Perhaps it may be thought that after having referred to "sweating" I have some specific against it, or that I have ideas of what ought to be done to prevent it. I am sorry to say I have no remedy to suggest, but it by no means follows that there is none to be discovered. Of course, "sweating" is only named as an example, but other matters in which there is room for improvement will occur to any practical polisher. I know many of these are inclined to regard with suspicion anything claiming to be improvements, but I cannot help thinking that advances might be made by polishers themselves which would be of benefit to the craft, and that those whose experience has shown them how improvements are practicable have a splendid opportunity of disseminating their views in the pages of this magazine. They may be sure that plenty among the readers would try their methods and discuss them; not amateurs merely—for, with all due deference to these enthusiastic workers, they are unable to do so fully—but artisans who have a thorough knowledge of the difficulties to be overcome, and are both willing and competent to adopt any improvement. Perhaps much of the stagnation—which, after all, may be more apparent than real—which exists in minor trades is owing to the fact that, till the appearance of WORK, the means of communication of ideas have been very limited in extent. Trade organs or journals devoting themselves to our particular trade have appealed more to the employer of labour than to the artisan himself. In WORK exists a real workman's magazine, or I would not have ventured to make the digressions I have, and while the amateurs' wants are by no means disregarded, the professional is encouraged to go ahead and let the world benefit by the hints and wrinkles which he has picked up, but which have hitherto seldom got further than his workshop. That there is a vast accumulation of "folk lore" lying almost buried, must be evident to every one who has been much in factories or workshops of any kind, and though in succeeding papers I hope to communicate a general idea of how to wax, oil, or French polish, I can only state what has come under my own observation. As has been stated before, the instructions will at the least explain to amateurs and novices what they ought to do, while those more advanced may find suggestions which will lead to increased skill on their part.

IRON AND STEEL: ITS ANALYSIS.

BY CHEMICUS.

DETERMINATION OF SILICON, SULPHUR, AND PHOSPHORUS.

THIS article is written with the object of enabling those of our readers who possess a knowledge of practical quantitative analyses to make a determination of the silicon, sulphur, phosphorus, manganese, combined and graphitic carbon, copper, etc., in iron and steel. Unquestionably the information afforded by such an analysis is of considerable value, as from it we are enabled, not only to decide as to the suitability or otherwise of the metal for any purpose, but also to account, to a certain extent, for any abnormal behaviour in the same when subjected to mechanical treatment.

For the analysis the sample of iron or steel is brought, preferably, into a state of drillings. This, however, in all instances, is not possible; when such is the case, the sample is reduced to as fine a powder as possible.

SILICON.

When iron or steel is dissolved in nitro-hydrochloric acid, the iron enters into solution as ferric chloride, while the silicon is oxidised into silica (SiO_2), which, by subsequent evaporation of the solution to complete dryness and heating of the residue, is rendered insoluble. Such is the principle upon which the determination of silicon is based.

For the analysis, weigh out four grammes of the sample and dissolve it, with the aid of a gentle heat, in 100 cubic centimetres of nitro-hydrochloric acid* in a porcelain dish of about 500 cubic centimetres' capacity, the mouth of which is covered with a watch glass to prevent loss by spurting. (As regards the actual quantities of the metal taken for the determination of the several constituents, the operator must use his own judgment, being guided by the quantities of the same presumably present.) When completely dissolved, remove the watch glass, after washing any liquid adhering to the same into the dish, cautiously take the solution to complete dryness, and strongly heat, over a Bunsen burner, the resulting residue until it becomes black. Add to the contents of the dish, when cool, 100 cubic centimetres of hydrochloric acid, heat gently to bring into solution, and again take to complete dryness. Make a further addition of hydrochloric acid, and evaporate until a crust commences to form upon the surface of the solution, which dissolve in a few drops of hydrochloric acid. This solution is now diluted with a somewhat large volume of warm water and passed through an English filter paper which retains the silica, or, if an iron be under analysis, a mixture of silica and graphitic carbon, or graphite.* (Invariably small portions of the silica adhere to the sides of the dish, the removal of which is effected by rubbing the same with a "policeman"—a piece of caoutchouc tubing at the end of a glass rod—and rinsing into the filter.) Wash the filter, together with contents, with a hot dilute solution of hydrochloric acid some half dozen times—one acid to three parts water—and afterwards with hot water until the washings give no red coloration with a dilute solution of potassium ferricyanide.

The subsequent treatment of the filter and contents depends upon whether a steel or an iron be under analysis. Should the sample be a steel, the filter and contents are placed in a platinum crucible and ignited, employing at first a low temperature, but gradually increasing to a bright red heat, allowed to cool under the desiccator, and the weight † of the silica, which contains 46·67 per cent. of silicon, determined. If, however, an iron be under analysis, the filter, etc., contained in a platinum crucible is ignited at a heat just sufficient to burn off the paper (the employment of a high temperature must be carefully avoided, as it would result in a loss of graphite), and when this is effected the residual graphite and silica weighed, replaced in the crucible, and again ignited, this time employing a strong red heat, whereby the graphite is burnt off. Finally the weight of the residue (silica) is determined, which weight, as is obvious, deducted from that of the graphite and silica, will equal the graphite contained in the weight of the metal taken for analysis.

The silicon may also be determined by the following method:—Four grammes of the sample, contained in a beaker, are dissolved, with the aid of a gentle heat, in 100 cubic centimetres of dilute sulphuric acid—one part acid to three water—and the resulting solution evaporated until it becomes a white cakey mass (ferrous sulphate), and heavy white fumes are given off. When the beaker and contents are cool, add 250 cubic centimetres of water and heat to boiling, with constant stirring, until the mass of ferrous sulphate has dissolved. The silica and graphite, if the same be present in the metal, are then collected on a filter, washed, etc., as previously described.

The silicas obtained by the above methods should be white, but not unfrequently they are more or less red, due to the presence of iron, which even repeated digestions with hydrochloric acid fails to eliminate. The whiteness of a silica is not, however, a guarantee that it is pure, as, although free from iron, it may nevertheless contain titanium, should the same be present in the iron or steel. To obtain the silica in a state of purity, it is intimately mixed, contained in a platinum crucible, with six times its weight of acid potassium sulphate, and fused, employing

* Prepared by mixing one part nitric acid (sp. gr. 1·42) with three parts hydrochloric acid. It is advisable to prepare a large quantity of this reagent, as it is employed throughout the analysis.

* Steel, practically, contains no graphite.
† The weight of the filter paper ash must always be deducted from that of the precipitates, etc.

at first a low temperature, but gradually increasing to a bright red heat. At the expiration of thirty minutes allow the crucible to cool, remove the lid, and break up the fused mass as completely as possible, then, together with the lid, place in a dish and digest, with constant stirring, with cold water for a considerable time. Withdraw the crucible, etc., after washing, and collect the silica, now pure, on a filter, wash, etc.

SULPHUR.

The methods employed for the determination of this constituent are based upon two principles, viz:—

(*a*) When iron or steel containing sulphur is dissolved in nitro-hydrochloric acid, the sulphur is oxidised into sulphuric acid, which is precipitated as barium sulphate ($Ba\,SO_4$), by barium chloride.

(*b*) Upon passing the sulphuretted hydrogen evolved upon dissolving the metal in sulphuric or hydrochloric acid through a solution of a metallic salt, such as copper sulphate, the sulphur combines with the metal, resulting in the precipitation of a metallic sulphide.

Of the two methods, that founded on principle *a* is the most accurate, but *b* method is the most rapid, and furnishes results which for general purposes are sufficiently accurate.

In determining the sulphur by *a* method, two or four grammes of the sample, according to the amount of sulphur presumably present, contained in a porcelain dish, are dissolved in 100 cubic centimetres of nitro-hydrochloric acid, the resulting solution taken to complete dryness, and the dry mass heated strongly. Allow the dish and contents to cool, and bring the dry residue into solution by the addition of 100 cubic centimetres of hydrochloric acid and the application of a gentle heat. Take the resulting solution to dryness, re-dissolve in hydrochloric acid, evaporate until a crust commences to form upon the surface of the solution, which dissolve by the addition of a few drops of hydrochloric acid. The solution is now diluted with hot water and passed through a filter, which retains the silica, etc., while the filtrate contains the sulphur in solution as sulphuric acid. If the above directions have been carried out the filtrate will be free from nitric acid, and, also, from an excess of hydrochloric acid; two very necessary conditions for the obtainment of accurate results; the former because nitrates are precipitated by barium chloride, and the latter on account of barium sulphate being soluble in acid solutions of ferric chloride. Make up the filtrate, after separation of the silica, with water to a volume measuring 500 cubic centimetres,* add five cubic centimetres of a solution of barium chloride—prepared by dissolving one part of the crystals in ten of water—well mix the liquids, cover the mouth of the containing vessel—preferably a large beaker—and allow to stand at rest in a warm place. After the lapse of at least twenty-four hours, decant off as much as possible of the supernatant liquid, and pass the remainder, together with the precipitated barium sulphate, on to a Swedish filter paper. Wash contents of filter some three or four times with a dilute solution of hydrochloric acid—one acid to six parts water—and thoroughly cleanse with water, then transfer to a platinum crucible, ignite at a strong heat, and when cool determine the weight of the barium sulphate, every hundred parts of which is equivalent to 13·37 of sulphur.

The determination of the sulphur by the method based on principle *b* necessitates the employment of a solution of a metallic salt. A solution of copper sulphate may be employed, which is prepared by dissolving sixty grammes of the crystals in a litre of water.

For the analysis weigh out into the flask, A (Fig. 1), which has a tube, C, bent at right angles welded to the neck, ten grammes of the sample, and insert the caoutchouc cork, through which the safety acid funnel, B, passes, reaching to near the bottom of the flask. Arrange the apparatus over a Bunsen burner, so that the tube, C, dips to a considerable depth beneath the surface of the copper sulphate solution contained in cylinder, D. (D contains 200 cubic centimetres of the copper sulphate solution.) About 200 cubic centimetres of dilute

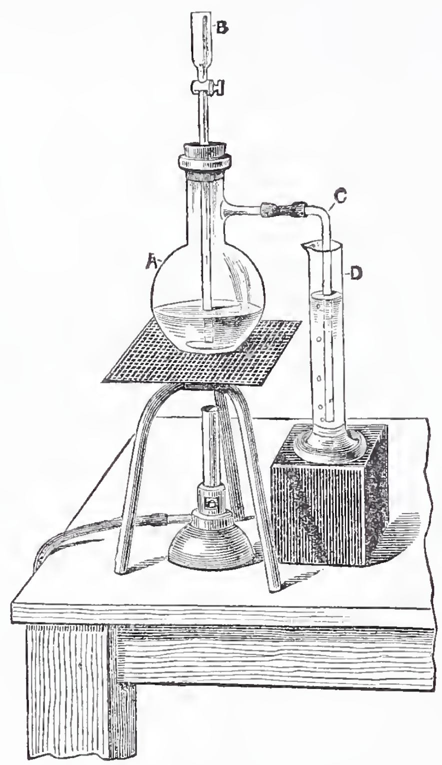

Fig. 1.—Arrangement for Determining Sulphur in Analysis of Iron—A, Flask; B, Safety Acid Funnel; C, Bent Tube; D, Cylinder containing Copper Sulphate Solution.

sulphuric acid—one part acid to three water—are now passed into the flask through the funnel, B; the metal is immediately attacked, sulphuretted hydrogen being evolved, which as it escapes and passes through the copper sulphate solution is decomposed into sulphur and hydrogen, the former combining with the copper, resulting in the precipitation of copper sulphide, while the hydrogen escapes. Towards the end of the operation apply a gentle heat, and when the evolution of gas ceases fill up the flask with warm water, taking care that none be allowed to overflow into D, whereby the whole of the gas is driven over. Then withdraw the flask, washing any of the copper sulphide adhering to C back into the cylinder, and pass the contents of cylinder through a filter. Well wash the copper sulphide on the filter with cold water, then transfer to a porcelain crucible, and convert, by ignition, the sulphide into oxide of copper (CuO), and weigh. Every hundred parts of copper oxide is equivalent to 20·12 of sulphur.

PHOSPHORUS.

The methods of determining this element are far from satisfactory, but that known as the "molybdate" process yields, in our opinion, the best results. The method is based upon the principle that when iron or steel is dissolved in nitro-hydrochloric acid, the phosphorus is oxidised into phosphoric acid, which is precipitated by ammonium molybdate.

For the analysis, take four grammes of the iron or steel, or less should the sample be phosphoric, dissolve in nitro-hydrochloric acid, and separate the silicon as already described. The filtrate will contain the phosphorus as phosphoric acid, but before the precipitation can be proceeded with, the hydrochloric acid must be expelled. With this object the solution, contained in a conical, is mixed with 100 cubic centimetres of nitric acid (sp. gr. 1·42), and evaporated until it acquires a thick syrupy condition. Repeat this evaporation with nitric acid some three or four times. Finally, to the syrupy mass add sufficient nitric acid to cause it to flow freely in the containing vessel, and to the resulting solution, which should occupy a volume measuring not more than 50 cubic centimetres, add 50 cubic centimetres of the ammonium molybdate solution. Thoroughly mix the liquids by agitating briskly the containing vessel, and then allow to stand at rest in a warm place (about 40° C.) for five minutes. After the lapse of this period ascertain, by smell, whether the solution is ammoniacal or acid, and if the former add strong nitric in small quantities at the time agitating well and allowing to stand at rest with each addition, until only slightly acid,* while if acid add ammonia until slightly so Upon the obtainment of the right degree o acidity, allow the solution to stand until th yellow precipitate of ammonium phospho molybdate has settled to the bottom of th containing vessel and the supernatant liqui is clear. Collect precipitate on a tare Swedish filter paper, employing a dilut solution of nitric acid — one acid t five water—to rinse on the last portion and wash filter and contents some hal dozen times with the dilute acid. Finall remove filter paper, etc., to the water oven dry and re-weigh to determine increase du to phospho-molybdate precipitate, whic contains 1·66 per cent. of phosphorus.

The ammonium molybdate solution i prepared by dissolving fifty grammes of th crystals in a litre of water, adding sixt cubic centimetres of ammonia (sp. gr. ·88 and allowing the solution to stand for two c three days and decanting from any precip tate formed.

HOW TO MAKE A PIANO.

BY "NIL DESPERANDUM."

MARKING OFF, OR PREPARING BRIDGES TO R CEIVE THE STRINGS—VARNISHING SOUN BOARD, ETC.

In the two previous papers I dealt with tl construction of the back and sound-boar I must now advance another stage and sho how the bridges are prepared to receive tl strings, or what is technically terme marking off (Fig. 1).

In a pianoforte factory the business the marker-off is to take the back, with tl

---

* This solution must be distinctly acid, but free from an excess.

* The successful precipitation lies in the obta ment of the right degree of acidity. What this cannot be very well defined. It is such, howev that while there is a sufficient quantity of ac present to prevent the precipitation of ammoniu molybdate, there is not a large excess, which wou prevent complete precipitation of the phosphoru

›und-board in position, and to plane the ridges to their proper height, mark the ale, drill and pin the bridges, clean and ırnish the sound-board, adjust the bottom ıd bent side plates, bore the wrest plank, ıd put in screws and bolts. I will describe ; clearly as I can how this is done. See ıat the bass ırs do not ›uch the bottom of the back; they do so, ıke a chisel and ıt the wood of ıe back away ntil they are ılly free. To ›st whether it free, strike ıe long bridge ı the centre

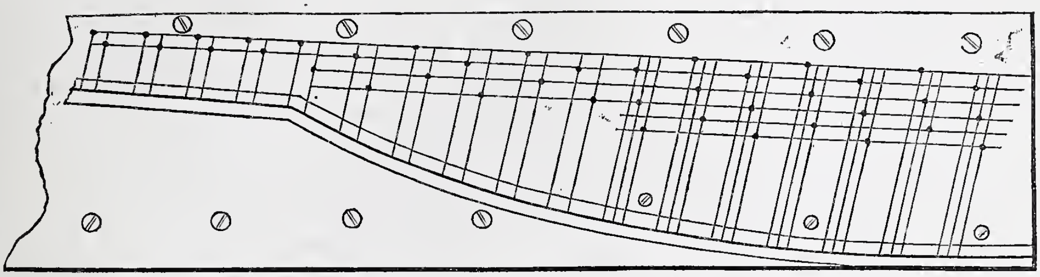

Fig. 1.—Sketch of Wrest Plank and Method adopted for Marking for Wrest Pins.

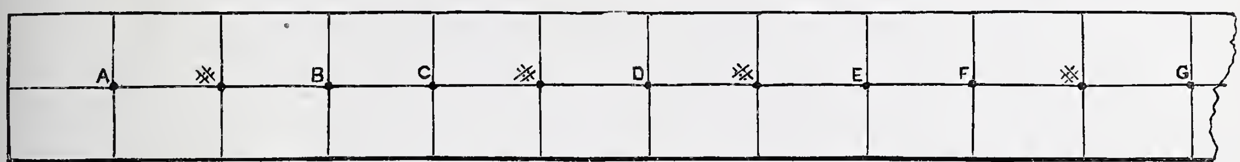

Fig. 2.—Scale for Marking Bridges: actual size.

vith the clenched hand, and it ought to ound like a drum. Now prepare a slip of ›ine $\frac{3}{4}$ in. wide and $\frac{1}{2}$ in. in thickness; this is to e placed round the edge of the bent side on he sound-board, the $\frac{1}{2}$ in. edge to be glued n the sound-board, and close up to the ›ent side. To bend this, you may find it ıecessary to cut some kerfs in with your aw, then put some pins in, to hold it in ›osition until the glue dries. Plane your op or wrest-plank bridges down to $\frac{3}{8}$ in. t the treble, and $\frac{1}{16}$ of an inch lower at he bass end. Now make it straight in its ength, and plane the bent side slip down o $\frac{3}{8}$ in. at the treble, graduating to $\frac{1}{8}$ f an inch at the bottom of the bent side. Now place the bottom plate on temporarily, ecuring it with a hand screw; see that the ›ottom of the sound-board does not touch

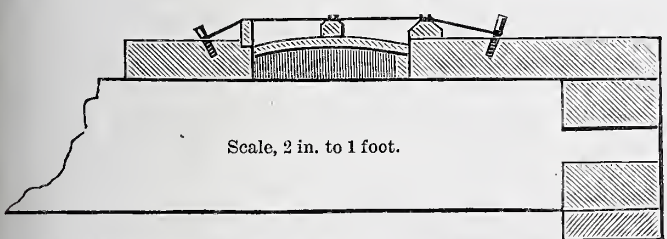

Fig. 4.—End Section of Treble End of Back, showing Sound-Board and Bridges.

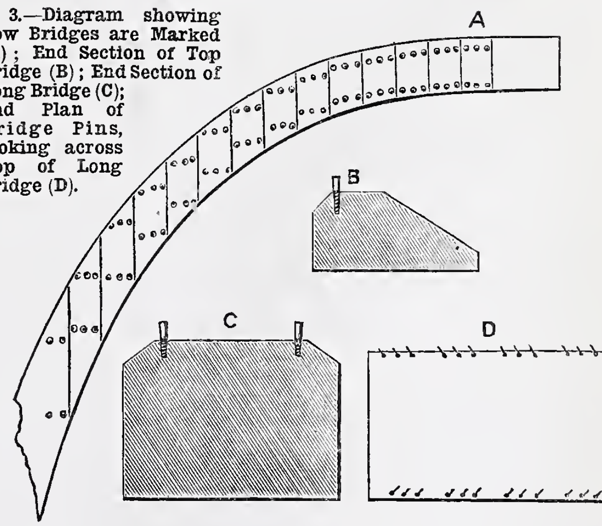

Fig. 3.—Diagram showing how Bridges are Marked (A); End Section of Top Bridge (B); End Section of Long Bridge (C); and Plan of Bridge Pins, looking across Top of Long Bridge (D).

Fig. 5.—Forks for Marking for Bridge Pins: actual size. A, Trichord; B, Bichord.

it. Take a straight-edge and hold it on the plank and long bridges at the treble end, and you will find that your long bridge requires reducing in height; plane it down about 12 in. of its length until your straight-edge is within $\frac{1}{8}$ of an inch from the bent side slip, then move your straight-edge 12 in. nearer the bass, and plane down until it is $\frac{1}{4}$ of an inch; move another 6 in. and make $\frac{3}{8}$ of an inch. Now from this point graduate the slip to the bottom plate. Now place the straight-edge across the bottom end of the long bridge, and make it, and also the beginning of the short bridge, $\frac{3}{8}$ in. above the plate, graduating to $\frac{1}{4}$ in. above the plate at the extreme bass end.

The reason for planing the bridges is that the strings shall have a proper down-bearing, as, no doubt, you have observed the bridge of a violin supporting the strings in the same way.

If the sound-board sinks or the strings lose this bearing, the piano loses its beauty of tone, also making it very thin in power. Now make two slips of wood about $\frac{1}{4}$ in. in thickness, and $\frac{3}{4}$ in. wide, 4 ft. 2 in. long; make them clean on one side; mark one slip top and the other bottom. Gauge a line in the centre of each slip; now take the top slip and mark a line across with a square and marking point $2\frac{1}{2}$ in. from the end, and mark this treble. Now set your compasses to $\frac{9}{16}$ of an inch; start from the mark you have made, and proceed to mark the length of the slip until there are eighty-five marks on it, the space between each being $\frac{9}{16}$ of an inch. Square the marks across, and mark the bottom slip. Make the first mark $1\frac{1}{2}$ in. from the end, and mark it treble. Now serve it the same as the top one, with the exception of the last twenty-seven marks at the bass end; these must be contracted or drawn in, so that they are 1 in. shorter in their space than the twenty-seven in the top scale. This can easily be done by closing the compasses hardly $\frac{1}{16}$ of an inch. Having done this, bore a $\frac{1}{16}$-in. hole with a drill in the gauge line crossing each mark. For convenience it would be as well to mark each note in the following order from the bass end (you can do it with pen and ink): A *, B, C *, D *, E, F *, G (Fig. 2); and continue in the same manner until you get to the treble end of your slips, where you ought to finish with A. Place the top slip under the wrest plank, so that your first note, A, will be $2\frac{1}{2}$ in. from the treble, or right-hand side of your back. Now place the bottom slip at the bottom of back crossing the bent side; fix these temporarily so that they will not move about. The bottom slip will be $1\frac{1}{2}$ in. from the treble end to the first note. Place a piece of wire in the two first holes, and having a stick of black-lead pencil, flattened one side, so that it rests close to the straight-edge, put your straight-edge up to the pins at top and bottom, and mark across the bent side and both bridges; continue this until you pass the bent side, then, of course, take your lines across the bridges. Now set your compasses to $\frac{1}{4}$ of an inch wide, and use them as a gauge; run round both sides of the long bridge, making a mark on the top; also run them round top bridge from bottom side (Fig. 3); now open them $\frac{1}{16}$ of an inch wider, and mark both sides of the short bridge. Now you will have to make a tool as shown in Fig. 5. This can easily be made out of a piece of round steel; flatten one end, and make the prongs with a saw file; the one with the three prongs is for the trichord notes, and the two prongs for the bichord notes. Now take your trichord punch, and place one prong on the first treble line of your top or wrest-plank bridge, the other two prongs being to the left of the line. Punch each one in this way until you have done twenty-two, this will be the number of trichord notes. Now take your bichord punch and punch the remainder with the exception of the last seven at the bass end; these are single notes, so only require one punch mark. You now mark the long bridges. Take the trichord punch and begin with the first note at the treble; place the right prong on the line which crosses the bridge, and the left on the line you made with the compasses, holding the punch in a line parallel with the wrest plank.

You will find that the first twelve notes will run in a line on the bridges, when they will gradually break off. Mark twenty-two with the trichord punch. In the top bridge there is one line of pins, in the long and short bridges there are two lines of pins; now to mark the bottom edge of the bridge, place the right prong on the line you made with the compasses and the left prong parallel with the wrest plank. Of course you mark with the bichord punch to correspond with the top bridge. You may now mark the short bridge with the bichord punch in the line you made with the compasses, except the last seven, which are single notes; serve these the same as the top bridges.

In the trichord you use small bridge pins, bichord middle size, while for the short bridge you use a shade larger. You ought to have your pins before you bore the holes, which is done with a drill stock and bow, or an Archimedean drill will answer your purpose, and are about 2s. each. You can make your drills out of umbrella steel ribs; if they are round, file them so that they have three sides to cut with, which will prevent splitting.

Commence boring the top bridge, using soap on your bit; start at the treble; you can sit on the wrest plank while boring this, and hold your drill in a slanting direction, so that your pins will lean towards the bass. Now bore the long bridge, the top row bore leaning towards the bass, and the bottom row leaning towards the treble; serve the short bridge in the same way.

Having bored all your holes in your bridges, scrape your bridges clean and glass-paper them. Now mix some black lead into a paste with water, and rub with a piece of flannel over the surfaces of the bridges; now rub a piece of round steel over and burnish them. Set your compasses to $\frac{6}{16}$ of an inch; run round the top bridge, using them as a gauge, that will give you a line to work to. Now take a small plane and bevel the bottom edge of the bridge up to the pin holes. Bevel the top side of the bridge up to the line you previously made with the compasses, smooth it well, then varnish with a small brush. Now bevel the bottom edge of the long bridge up to the first hole; also bevel the top treble edge, where the holes run straight; then take a small saw, such as are sold with a brass back and straight handle for 1s. 6d., or a dovetail saw; now sit on the sound-board, looking towards the wrest plank, and begin at the treble end at the thirteenth hole. Hold your saw, and cut in the same direction; your strings will lie across the bridges $\frac{1}{8}$ of an inch the bass side of the hole, down to the hole of the note below, about $\frac{1}{4}$ of an inch deep. You will find these cuts will lengthen as you get down the bridge. After you have cut them all, then take a sharp $\frac{3}{4}$-in. chisel, and hold it half way across the holes and cut the piece out, starting at the treble and going to the end; this is called carving the bridges, and if done carefully looks very nice; see that you clean the side (that you cut with the saw) with the chisel. The short bridge you simply bevel up to the pin holes at the top and bottom edge.

You must now make a bevel in the following manner: take two pieces of $\frac{1}{2}$-in. pine, one piece $1\frac{1}{2}$ in. wide, and the other 1 in. wide, and both 9 in. long. Screw the 1-in. piece across the centre of the other $\frac{1}{8}$th to the inch out of square. Now start at the first treble hole on the top bridge, holding your bevel to the holes in rotation, and marking with a fine pencil across the wrest plank. This is done to mark for the wrest or tuning pins. Where it is trichord, mark a straight line 2 in. from the top of wrest plank, and 5 more below it, with a space of $\frac{5}{8}$ in. between each line. Where it is bichord, you will only require four lines; see that the bottom row of pins are $4\frac{1}{4}$ in. at this point from the top bridge. This is so that the action will have room later on. Take a centre punch, and start at the treble, and punch the first, third, and fifth lines from the bottom; this will be your first note. Now punch the second note; that will be on the second, fourth, and sixth lines. As the grain of the wood in the wrest plank runs straight, this is done to distribute the pins over as large an area as possible. When you come to the bichord, you punch the first and third line for one note, and the second and fourth for the following, repeating it as you proceed. By a little close observation, you will soon see how this is done. Now clean the pencil lines off with a scraper and glass-paper, and give three coats of white hard varnish, allowing each coat to dry before the other is applied. You then clean up the sound-board, and give three coats of varnish.

Next we must turn our attention to the bent side. Run a pencil line round the bent side from the sound-board edge 2 in. From this line, mark towards the treble in short lines parallel with wrest plank across the straight lines previously made, every four until you have marked across thirty-eight lines. Now punch a mark where the lines cross. As you have twenty-two notes trichord in the treble, count this number, and 1 in. behind them make another line, and punch. You can now clean the pencil lines off. Now take a sheet of brown paper, and cut to fit round the inside of slip of bent side, and extend an inch over the holes you have punched. Mark where it crosses each bracing for bolts; get a heel-ball from a shoemaker's, and rub over the brown paper, and this will mark all your holes. This is a pattern for an iron plate to cover the bent side to prevent splitting. You will require to send this to the ironmonger's before mentioned, and order the bridge pins, Nos. 14, 15, and 16, one set and twenty-five over of wrest pins, nine wrest-plank screws and washers, and four 6-in. bolts with nuts, square heads, and sixty hitch pins for bent sides. I have not mentioned screws, as these are generally to be had in most towns, and they are not of a special character.

When you have got your pins, you will know the size to bore the holes; let the bridge pins fit the holes, but not tight enough to split. It is better to bore in a piece of beech till you get your bit the size you require. The wrest pins must fit tight as in tuning; if they were not so, the piano would not stand in tune. Having got your holes bored in your bridges, proceed to pin them (using a small hammer for the purpose); let them stand above the bridges about $\frac{1}{8}$ of an inch, then run over with a file to level them. In boring the wrest plank, use a stock, and probably you will find a $\frac{3}{16}$-in. spoon bit will be the size. You must bore these, standing at top of the wrest plank when the back is on the trestles, and let the bit lean towards you, so that the wrest pin is $\frac{1}{4}$ of an inch out of the upright in its length; this prevents a tendency to fall down, as when the piano is on its bottom, the pins point upward a trifle. Having bored the holes, countersink a little to remove burr off the top. Now mark above the holes the scale you marked on the rods, beginning at bass end, and starting with A and ending with A.

The bent side plate must now be put on so that the holes cover the punch marks; screw on, and put bolts through so that they are level at the back; you can bore in the bracing with a centre-bit for the nut to lie on; now bore your holes for your pins with a small bit, and drive in the bent side. Fix on your bottom plate, put in position by looping a piece of string on the last pin, and see that it comes in a direct line to the bridge. Now hold in position with hand screw, and put 2-in. screws in the projections, and 6-in. bolts in the bottom into the bracings. To find the place for the nut, turn it on the bolt half an inch, then hold it on the bracing opposite to the hole you want it to go in, and strike the nut with a hammer. Now bore a 1-in. centre-bit hole in a little way, and bore through the hole in your plate to meet it, then drop your nut in the hole, and turn your bolt in. Now put some 4-in. screws through the wrest-plank under the top bridge in the bass and over in the treble into the bracings; this will secure your wrest plank at the bottom edge.

PLAIN AND DECORATIVE HOUSE PAINTING.

BY A LONDON DECORATOR.

THE THREE SIMPLE DIVISIONS OF COLOUR—SECONDARY AND TERTIARY PIGMENTS.

I WILL now ask particular attention from the young worker on a few points of a theoretical nature, before I bring my selection of house-painters' pigments to a close with a list of the most useful greens and browns.

In the first place, it is absolutely necessary that the student and worker in paints should clearly understand the difference between the two, oftentimes-confounded terms of *pigments* and *colours*. Colour is but a *sensation* conveyed to the brain by the action of light upon the nerve-fibres of the retina. Independent of our eye-sight colour, literally speaking, is not! When a man is colour-blind, for instance, either to red or green colour, the explanation of this phenomena lies in the simple fact that the retina of his eye is lacking in that independent set of nerve-fibres which, in the case of those with perfect vision, answers to the particular sensations of red or green conveyed to them by light. The blue of the sky, the glorious, golden hues of sunset and the beauteous and sight-comforting greens which clothe the forms of vegetation these colour sensations are individually and collectively due to the same source of reflected and transmitted light, acting in concert with the wondrous attributes of our vision.

Pigments, on the other hand, are those *substances* which, when acted upon by light, absorb certain of the rays of colour therein contained, and, by either reflection or transmission, give forth that particular colour by which, as blue, red, green, and so on, they are known. It will, therefore, readily be seen by every reader that this is not in any way a distinction of terms only, but as much a difference as there is between "substance and shadow."

In the more advanced divisions of my subject it will be at once my pleasure and privilege to further practically consider the nature and action of colours and light. No more interesting or important an aspect of the painter's craft is presented to us than the study and knowledge, to a far greater extent than the preceding few lines may cover, of the laws of colour.

For the present purposes of this paper, I will now briefly draw attention to the *classes* of colour into which our pigments are usually divided. It will be observed that, so far, I have confined my list of ordinary coloured pigments to those of the yellow, red, and blue kinds. These are usually termed the *primary* or source colours; since by judicious admixture and compounding of these pigments, and with the further assistance of white and black, any tint, hue, and shade of colour can be obtained, subject only to the purity and perfection of the primaries so compounded.

I will here haste to state, lest someone learned in "light and chemistry" amongst my readers may consider my selection of the primaries as based on an error in optical science long since exploded, that due attention to the latest and more proven theories of prismatic colour will be noticed in their proper time. My adoption here of Sir David Brewster's primaries is but a matter of literary and practical policy, the best means to present ends.

The primary pigments, then, being the first simple division, and consisting of blues, reds, and yellows, by combining chemically suitable blue and red we obtain purple; with red and yellow we get orange; whilst blue and yellow pigments combine to give us green colours or sensations. These resultant admixtures of any two primaries are termed *secondary* colours; and again by a similar process of mixing, in certain proportions, two of the secondary pigments together we obtain the third distinct class into which we divide our colours, which third division is known as the *tertiary* colours.

My purpose in thus generally confining myself to the primaries in the preceding list of house-painters' pigments will now doubtless explain and commend itself to the reader. With all those pigments at hand almost every variety of colour, requisite or desirable for our ordinary use, can be prepared; some portion of *brains* being, I need scarcely add, usually also required.

Since I have already indicated the results of adding any two of the primaries together, I will here advise the young painter to practically work this matter out himself by mixing some of those pigments together, the appearance and nature of which he is now somewhat acquainted with by the careful study of my simple list.

In compounding painters' pigments there is yet a further matter requiring some little consideration by the worker. Not all of our blue pigments are chemically suitable for mixture with yellows or reds, nor all yellows with reds—in fact, a knowledge of the chemical source and affinities of pigments is almost a necessity to the painter and decorator. As the most brief and simple way of aiding the student, I will now define those ordinary pigments which it is usually advisable *not* to mix together.

For mixing in oil colour paints, chrome is an undesirable pigment, and it is particularly to be avoided when compounding *greens* from *Prussian* or *Antwerp* blues, which latter colours it would eventually destroy. In such an instance, for common use, the best substitute for the chrome would be bright *yellow ochre*, or, as it is often labelled, yellow paint. *Raw Sienna* can also be used with the above blue pigments without much detriment to either. In any case where a bright *mixed* green is absolutely necessary, I may say that the lemon chrome can be used in conjunction with good *ultramarine* blue or *indigo*.

In compounding the secondary colour of *purple* from the blues and reds I have given, there is less danger of trouble arising. For oil painting the best and purest are obtained by mixing ultramarine with *madder lake* (which is a beautiful crimson and transparent pigment equally as permanent as lakes derived from cochineal are unstable), or ultramarine and vermilion will answer. Prussian blue and vermilion give very deep purple, which may be lightened up with white. For common purposes the cheap purple brown is most useful, if required full in strength; but if lighter and pure tints are wanted in oil or distemper, ultramarine blue and vermilion, or, for cheapness, Venetian red, is necessary. Prussian blue in water would *not* suit so well, but indigo could be used if cost was not a consideration.

The remaining secondary, *orange*, is not a colour very much called for. In *orange chrome* or *orange red* we have a bright opaque pigment, but otherwise, like all the chromes, not a commendable article. *Burnt Sienna*, previously mentioned in my list, is a very opposite pigment in both nature and source. It is semi-transparent, reliable, and permanent, and, what also the practical student must always bear in mind, it is, when of good quality, a remarkably strong stainer, like Prussian blue in this respect. In compounding orange colour the reds and ochres I have mentioued are usually bright enough; yellow ochre and Venetian red, or raw and burnt sienna together, give us, with white lead, a good and serviceable variety of permanent orange and salmon tints.

The compounding of the third division of material colours, the tertiary, from either of the two secondaries is a subject I need scarcely here dwell long upon. The student who works at this subject practically will soon find from the foregoing and subsequent remarks those secondary pigments of orange and green which produce the tertiary *citrine*, whether bright or sombre, such as occasion requires. Of the remaining tertiaries, *russet* and *olive*, prepared from the secondaries purple and orange, purple and green, respectively, we have a good supply in the form of simple pigments. Notwithstanding, therefore, the necessity and advantage of the worker being able to obtain any colour by the admixture of the three primaries, it is always most economical to use a simple article of the desired colour when such is to hand.

Having now brought before my readers the simple outlines of colour-mixing, I will here append a selection of the most serviceable and everyday pigments of the secondary and tertiary classes which are to be obtained ready for house-painters' use from the manufacturers.

I need scarcely point out how unnecessary, and almost impossible, it would be for me to include here all, or even one half, of the various greens, browns, etc., which are now upon the market. I take up the wholesale colour list of a Newcastle-on-Tyne manufacturing house and find therein a dozen or more kinds to every primary, secondary and tertiary. The bulk of these merely represent differences in nature, hue, or brightness, and three-fourths of which compositions, each rejoicing in some fanciful, and often incongruous, name, could be as easily prepared by the worker himself who understands that little of the nature and qualities of pigments I have herein endeavoured, I trust not without some success, to make plain and intelligible from every point of view.

Green pigments, chiefly derived from the mineral sources of copper, are very plentiful and reasonable in price. Emerald green is the brightest, and is useful to the house painter both in oil and distemper, in which it aids us to get very clean and bright tints. I well remember when it was used in house painting to a great extent, and when some of the aristocratic residents of Westminster and Belgravia were quite satisfied with emerald green tints on their dining-room or morning-room walls. Nowadays, however, what with Sanitary Congresses and Health Exhibitions, the merest suggestion of green is usually interpreted "arsenic," and since the deleterious nature of such copper greens is certainly a definite source of trouble, everybody can be satisfied with seeing less of them.

Brunswick greens, quaker greens, chrome greens, etc., are all useful pigments, owing their colour to, I believe, their preparation from the same mineral sources as Prussian blue and chromes. Generally it may be granted that they are reliable and fairly permanent for their cost, about 3d. to 6d. per lb. retail; but remembering my remarks about the mixtures of the chromes and blue, the painter will do well to avoid their use for tints with white lead in good and permanent interior work. Bronze, olive, and invisible greens are, as their names imply, deep but richly-toned pigments, very useful for external painting and very reasonable in price. They can be almost as easily mixed by compounding black and yellow pigments, or black, blue, and green, according to the particular hue or "cast" that may be desired.

Since we have a surfeit of greens and yellows it follows that there is little need for citrine pigments: they can be mixed best and easiest from those secondaries. Coming under this heading, however, are usually classed the *umbers*. The most common is usually termed raw umber, a natural ochre found almost all over the world. The best is Turkey umber, and this, after burning, which makes it richer and warmer, when it is known as burnt umber, is one of the most useful pigments. For graining it is almost indispensable, and for all general purposes of painters' and paper-stainers' work it is one of the most valuable aids to soft and modest colouring, both in oil and water processes, we possess. Its price varies, according to quality and preparation, from ½d. to 1s. per pound. Of the umbers and Vandyke brown I shall have, necessarily, more to say in the papers in which I shall deal with graining and other imitations, so I may spare the reader any further remarks on them here.

HOW TO PAINT A STAINED GLASS WINDOW BLIND.

BY FRED MILLER.

PAINTED glass for domestic purposes requires a totally different style of work and design to that intended for ecclesiastical windows. It should be simpler in design and less severe in treatment, and the effect largely obtained by "tracing" rather than by elaborate leading. Church windows (I speak of figure windows) owe their effect to the use of coloured glass, and the disposition of the leads that bind each separate piece of glass into a complete design. In the window blind we propose doing as our first effort at glass painting, the glass is simply cut into squares, say 3 in. and $3\frac{1}{2}$ in. or even 4 in. square, and each square is painted or "traced," as it is technically termed, in a solid brown colour, known as tracing brown. The glass is then "stained" at the back with "yellow stain," fired, and the glazier then leads the squares together and completes the blind.

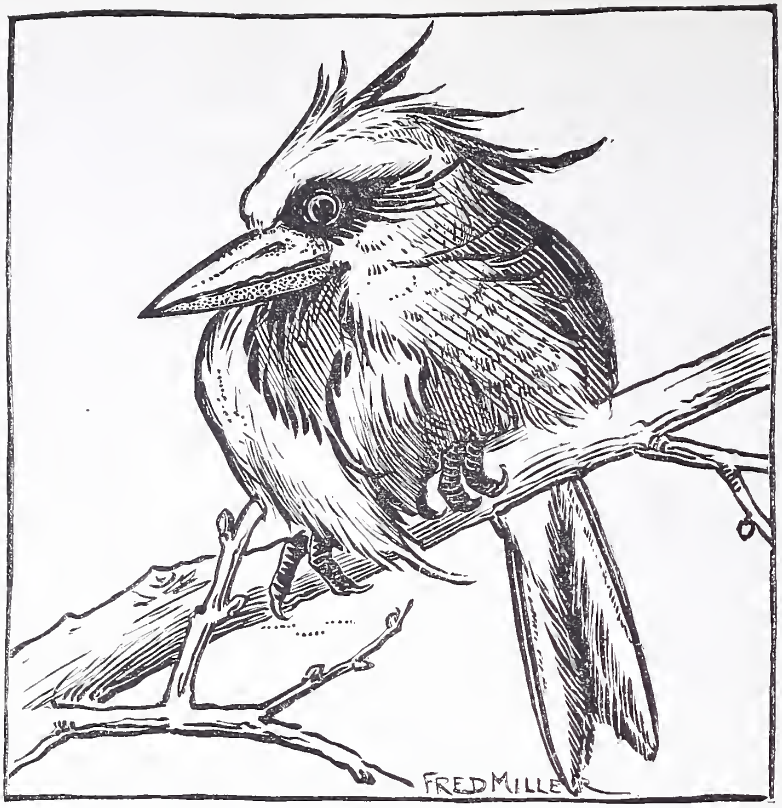

Fig. 1.—Design for Stained Glass: Laughing Jackass of Australia.

This tracing brown and other glass colours can usually be obtained where you get your glass cut, viz., of a firm who produce leaded glass for the trade, such as Pepper & Boyes, in the Euston Road, for I must here assume that my readers do not attempt to do the cutting and leadding for themselves, these both being distinct branches of the work from the painting of the glass, and in the trade are confined to a separate class of craftsmen. You must measure the size of your window, and if you are going to put the glass into a wooden frame, as is usually the case, you must make due allowance for the space occupied by the frame. Get out a piece of paper the size the glass is to be, and bisect its length and width. Assuming that the squares are $3\frac{1}{2}$ in., just see how many you can get in the length, for it does not look well to have to cut down one row of squares; you want to get in a complete number. This can always be effected by slightly altering the size of the square, and sometimes, in order to get a complete number in in the width, it is necessary to reduce or increase the width of each square, as the case may be, in order to work them in.

It is a nice finish to a window blind to have one or two "lines" of glass round the outside, as in Fig. 4, the outside one varied whites, and the inside one ruby. If you tell the glazier to whom you go to get your glass that you want a white and ruby line outside, he will at once know what you mean.

There are many makes of glass, but one I often use myself because of its charming effect is "Anbetti." It has a slightly rough bubble surface (some of it is more "bubbly" than others, and this kind is useful if it is desirable to block out an ugly look-out or prevent people seeing in).

When you get your glass, clean each square very thoroughly with a damp leather, and polish with a dry cloth. Any suspicion of greasiness will prevent the colour taking to it. The tracing brown must be thoroughly ground up, and the most effectual way to do this is to use a glass muller on a piece of ground glass. To every six parts colour put about one part loaf sugar and mix well with the colour. The sugar binds the colour to the glass and enables you to work it easily.

You can tell if you have enough sugar in your colour by putting a little on a piece of glass and drying it. If it dries dead looking and will not rub off by passing a dry finger over it, you know it is then right in consistency. If it rubs off easily put more sugar; if on the other hand it dries shiny and sticky, there is too much sugar, and you must add more dry colour.

Colour improves by being kept, as it then works more smoothly; but keep it out of the dust. When it is hard on the palette you have only to moisten it with water and mull it up again.

Tracing brushes are long black sable writers that come to a fine point, and at the same time hold plenty of colour in their hair. At some brush shops they keep what are known as glass tracing brushes.

Place one of your squares over your design (say one of the designs given in this number of WORK), and filling your brush with liquid colour try and follow the lines of the design accurately, and yet with freedom. Be true to the spirit rather than to the letter of the design, for tracing that looks mechanical is never good. Tracing must be done with feeling, but this only comes of practice, for at first you will feel awkward, and will not be able to get the colour to flow freely from the brush on to the glass.

Fig. 2.—Design for Stained Glass: Toad with Toad-stools.

You want to get a certain body of colour on, for the tracing should be fairly solid so as to be opaque when held up to the light. Remember that glass tracing has to look well when held up to the light. Never work with a dry brush. Always keep the colour fluid, and continually charge your brush with fresh colour, so that it flows freely on to the glass.

Some of the markings on the bird and frog would look better to be less opaque. Such markings are done with colour thinned down with water and put on thinly. An experienced glass painter can produce a charming variety by the use of thinner colour in some portions of the work, for although the tracing must on the whole be opaque, yet it should not

e mechanically so. A semi-
ransparent line here and
here gives variety and takes
way the hard look that
ork has which is equally
olid everywhere. This is
he light and shade of trac-
ng, and though you will not
ossibly be able to attend to
uch points as these at the
utset, it is well to have an
deal before you to keep you
p to the mark.

The beautiful transparent
ellow so constantly seen in
lass windows is produced
y chloride of silver. It is
nown as "yellow stain,"
nd you could doubtless pur-
hase a little of the people
vho cut your glass. It is
nixed with turpentine, with
Venice turpentine added to
oind it on the glass, as we
ised sugar with the tracing
colour, and is always put on
he back of the glass, for this
tain enters chemically into
he glass, under the action of
heat, and has a tendency to
lestroy other colours that
re touched by it. Put the
yellow stain on with camel-
hair brushes, keeping well
within the traced lines so
that when held up to the
light only the particular part of the design destined to be yellow is stained. In the case of the bird and frog "quarries" (as the squares are called), don't stain anything but the bird and frog—*none* of the accessories, such as grass or tree. The squares are now complete, and must be sent to the kiln to be burnt. The heat melts the tracing colour on to the glass, making it permanent, while the silver is driven into the glass and stains it yellow. By the way, I must not omit to say that a thin wash of the silver stain produces a pale yellow, while a heavier wash gives an orange.

Designing.

The treatment of squares with quaint renderings of birds, animals, fish, etc., alternated with ornamental or foliage quarries, is one that gives an entirely satisfactory result. I myself constantly adopt this treatment in my own work, and for large staircase and hall windows the effect is rich without lessening to any great exent the amount of light admitted through the squares. It warms and softens the light and imparts a glow to the walls and furniture, and in cases where it is desirable to shut out the gaze of the curious, painted leaded glass should always be used in preference to the cold, formal, mechanical embossed and ground glass. The variety of tint obtained with the yellow stain is infinitely varied, and has a most beautiful appearance when a large number of squares are leaded together. The squares themselves should be cut out of various tints of white, and the stain takes differently on a greenish-white to what it does on a yellow or grey white, and so on.

In drawing birds and animals for quarries try and accentuate any characteristic of the creature you take a suggestion from. Ornamentalise, as it were, the details of your subject, and get the effect with as few lines as possible. You cannot keep this work too simple in execution. Attempt nothing in the way of light and shade, only so far as it is needful to obtain clearness of form and relief. When you come to stain the quarries you can keep the stain thin in the lights, and darker on the side that would be in shadow. This kind of light and shade produced by varying the stain gives a most excellent result. The more you vary the squares the better, and in window blinds no two ought to be alike. The Japanese books of designs will suggest a good many *motifs* to those who cannot invent for themselves. I have myself drawn a great deal in the Zoological Gardens, and the two designs given here in Figs. 1 and 2 are simply quaint renderings of two Zoo sketches. Fig. 1 represents the Australian bird known as the Laughing Jackass, and Fig. 2 the common Toad with two of the fungus known as toad-stools to form a suitable background. The other two designs in Figs. 3 and 5 represent respectively the blossom of the chrysanthemum and the fruit of the pomegranate conventionally treated.

Alternate the bird quarries with ornamental ones, and do not vary the pattern, as these squares are to be a foil to the animal ones. One window blind might have one pattern, and the other blind the second design. Stain these ornamental quarries very lightly, except the seeds in the pomegranate, and the cusp of the flower. Remember not to carry your tracing up to the edge of the squares, so that a portion is cut off by the lead, but leave a good ⅜ in. all round.

If the entire work has been carefully carried out in the manner indicated above, it may be taken as being a matter of absolute certainty that the glass painter himself will be pleased with it, and his friends also. The liking for the work will grow upon him, and in all probability he will in time proceed from window blinds to windows for staircases and glazed doors, which look very well when treated in this way.

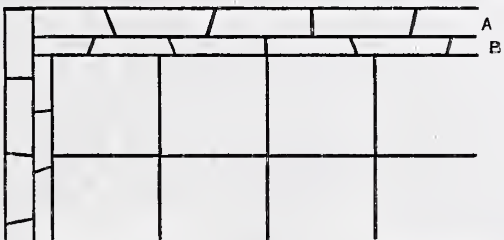

Fig. 4.—Bordering for Blind—A, Varied Whites; B, Ruby.

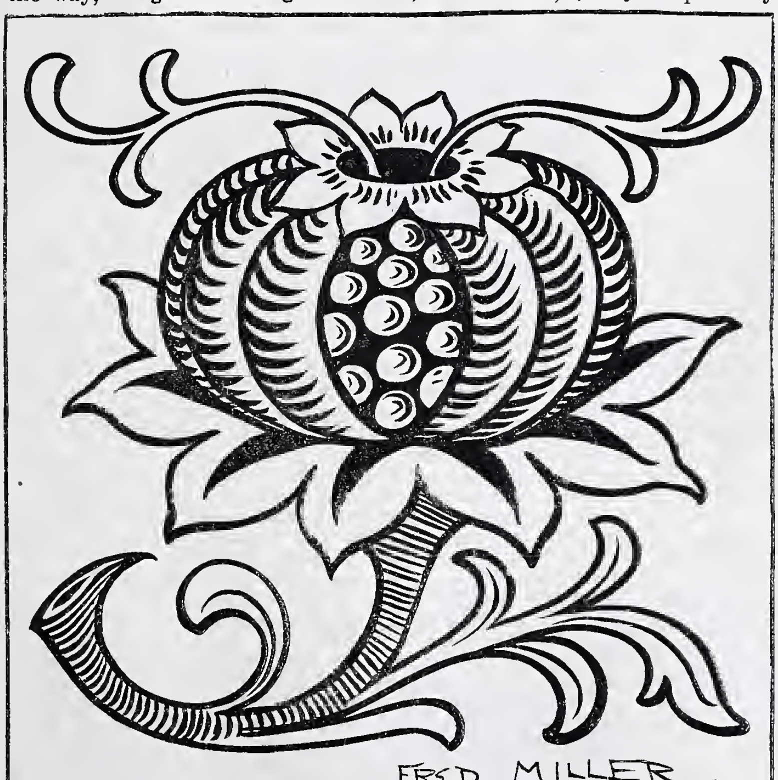

Fig. 5.—Design for Stained Glass: Fruit of Pomegranate conventionally treated.

SOME NOTES ON BRASS.

BY GEORGE EDWINSON BONNEY.

Brass.—Brass is an alloy, composed of copper and zinc in various proportions, as will be seen from the following list. In some varieties of brass a little tin is added. Soft brass, for turning into ornamental articles, contains a small quantity of lead.

TABLE OF VARIETIES OF BRASS.

Name.	*Copper.*	*Zinc.*	*Tin.*
Sheet Brass	84·70 parts	15·30 parts	0
Wire "	70·29 "	29·26 "	0.17
Gilding Metal ...	73·73 "	27·27 "	0
Mosaic Brass... ...	66·00 "	33·00 "	0
Dutch Metal	84·70 "	15·30 "	0
Prince's Metal ...	75·00 "	25·00 "	0
" " ...	50·00 "	50·00 "	0
Muntz Metal ...	60·00 "	40·00 "	0
Bell Metal	80·00 "	20·00 "	0
Pinchbeck	80·00 "	20·00 "	0
Watchmaker's Brass	33·50 "	66·50 "	0
German Brass ...	33·50 "	66·50 "	0
Yellow Brass ...	66·50 "	33·50 "	0

Published formulæ respecting the composition of brass alloys are apt to differ in the proportions of the metals to be employed. Mr. Bloxam gives the proportions of Pinchbeck as 3 parts of copper to 1 part of zinc. Bell metal is given in the above list as composed of copper and zinc, whereas Mr. Bloxam says it is an alloy of copper and tin. It is, therefore, a bronze, not a brass. The colour of brass is dependent upon the proportions of the two metals used in its composition. When there are more than 80 parts of copper in the hundred parts of alloy, a red tint predominates, which is increased as the quantity of copper increases. On the other hand, the colour becomes yellow when less than 80 per cent. of copper is present in the alloy, and the yellow tint gets lighter until 30 per cent. of copper is reached, after which the alloy cannot any longer be regarded as being of a yellow tint, but more nearly approaches that of zinc. The fusibility of the alloy increases as the quantity of copper decreases. This known property is taken advantage of in selecting a suitable solder for hard soldering articles made of brass, the yellow varieties being available as solders for the reddish varieties. Hard solder for brass may be composed of 79 parts of good tough brass added to 21 parts of zinc, using borax as a flux. Further information will be found in article on "Soldering Brass." Brass articles, tarnished or corroded, must have the tarnish or corrosion removed before they can be coated with metal by electro-deposition. It is not enough to scour off the corrosion by mechanical means, since this would still leave minute specks of dirt on and in the surface of the metal, and prevent perfect adherence of the coat of electro-deposited metal. Corrosion and tarnish are, therefore, removed in an acid pickle, made up of a mixture of acids for the purpose in hand. These are sometimes named "acid dips," and also "dipping acids." A good pickle for brass is composed of—

Sulphuric Acid	... ...	$3\frac{1}{4}$ pints.
Nitric Acid	... ...	$1\frac{1}{4}$ "
Common Water	... ...	1 pint.

Mr. Sprague gives the following as the composition of a pickle used for brass, copper, and German silver :—"Water, 100 parts; oil of vitriol, 100 parts; nitric acid, specific gravity 1·3, 50 parts; hydrochloric acid, 2 parts." Mr. Urquhart recommends for "bright dipping" a mixture of exhausted nitric acid, half a pound; water, 1 pint; hydrochloric acid, 3 lbs. The articles must first be cleared of all corrosion by dipping them in strong nitric acid; they are then allowed to soak in the "bright dip" for some minutes, and then well rinsed in clean water to clear off the black slime remaining on them. Mr. Watt gives the following as the composition of a dipping acid to produce a bright and clear surface on "certain classes of work":—

Nitric Acid, Commercial (by measure)	...	1 part.
Sulphuric Acid " "	...	2 parts.
Water	...	2 "

A pickle for "dead dipping" (that is, to give a dead or matted appearance to brass), as recommended by the same author, is composed of "brown or fuming aquafortis, by measure, 2 parts; oil of vitriol, 1 part. To the above mixture a small quantity of common salt is added." This mixture works well on both copper and brass, but it must be used in the open air, where a strong draught can blow the poisonous fumes away from the workman, or else be worked in a "stink cupboard," provided with a flue and a good strong draught of heated air. The fumes are always worse in damp air, as on a damp day or on the near approach of rain. A similar precaution must be observed in the use of the American brass pickle, which is composed of sulphuric acid 2 parts, and nitric acid 1 part only. This is an excellent pickle for brass castings or corroded brass of all kinds, but the articles must be moved quickly in it, and well rinsed in an abundance of clean water the instant they are removed from the pickle. They should then be dried by rubbing or tossing in hot sawdust, when they will assume a nice golden tint. If the pickled articles are to be plated or gilded, they should be well rinsed in at least two waters, dipped for an instant in a bi-tartrate of potash solution, again rinsed, and passed on to the plating-vat without delay. If not wanted at once, they may be left in the bi-tartrate of potash dip, where they will be protected from tarnish.

OUR GUIDE TO GOOD THINGS.

*** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

105.—BEIT'S ENAMELLED ADHESIVE WATERPROOF ADVERTISING PAPER LETTERS AND FIGURES.

AMONG the most useful articles that are supplied as a means by which any dealer may call attention, if he so desire it, to the specialities which he manufactures on the one hand, or sells on the other, there are none perhaps that are more useful than paper letters and figures, for by aid of these show-cards and ticket boards may be speedily prepared in a most effective manner by those who are not possessed of sufficient skill to paint these things for their own purpose, or, to use the proper technical expression, "write" them on card-board or on wood, or even on glass. The best letters and figures of the kind that I have seen for this purpose are "Beit's Enamelled Adhesive Waterproof Advertising Letters and Figures," which are manufactured and supplied wholesale and retail by the Oxford Show-Card Manufacturing Company, 17, Arthur Street, New Oxford Street, London, W.C. These letters and figures are made in all sizes from $\frac{3}{8}$ in. in depth to 6 in., in a great variety of forms, and in gold, silver, and all colours. Rules, corner-pieces, or ornamentations of different kinds, hands, left and right, halfpenny signs, and the sign £, used to denote pounds sterling, may also be had at prices ranging from 1s. per gross upwards according to size, but I may say that sizes, shapes, and prices of letters will be ascertained from the sample price lists which the Company will send to any applicant.

It may interest some readers to know that these letters are cut by aid of steel plates from 2 lbs. to 20 lbs. in weight, according to the size of the alphabet. The paper from which the letters are cut is enamelled and waterproof, so that the letters and figures can be washed, or, if put outside of any window, the rain and weather will not injure them. They are cut by machines to insure uniformity, and the paper can only be purchased in Germany, as nothing resembling it is made at present by English manufacturers. The sheets, in fact, are so large that eight sheets imperial can be cut out of one of them. The letters, when cut, are sorted and bundled up in tens, and many millions are constantly kept in stock ready for use. Being gummed at the back, they have only to be wetted and stuck on any surface, whether of card-board, wood, glass, earthenware, or even iron. The gum used, I am told, is not an ordinary gum, but is a composition which will hold fast to anything, and which, at present, remains a "trade secret." For show-cards and price tickets for shops the letters and figures stand out clear and distinct, and they have the merit of being very durable. They may be used for banners in bazaars, etc., for letter-boxes, for numbering houses, for names on plate-glass windows, sign-boards, bookshelves, and many other purposes. The Company has agents in all parts of the world and the United Kingdom. I mention this because many a general dealer and seller of fancy goods might find it useful to add them to their stock.

106.—WILLCOX BROTHERS' PAPER LETTERS.

As I am writing on paper letters, I may take the opportunity to mention that another very effective kind of paper letters, useful for all indoor purposes and positions where they would not be exposed to the weather, are cut and supplied by Messrs. Willcox Brothers, Paper Letter Cutters, 172, Blackfriars Road, London, S.E. These letters are hand-made, being cut with scissors or knife from plain or coloured paper, six or eight at a time. I have specimens of these letters before me in all colours from $1\frac{1}{2}$ in. to 7 in. in depth, but they are cut in larger sizes than these, even up to 24 in. in depth. Up to 4 in. the price per dozen is 4d. plain and 6d. coloured, but above these the prices range from 5d. per dozen plain and 6d. coloured for letters 5 in. deep to 4s. plain and 6s. coloured for letters 24 in. deep. Fancy cut letters are 1s. 6d. per dozen, and gold and silver letters double the price of shaded letters. Letters shaded in three colours are double the price of shaded letters. Further information as to prices, etc., can be obtained from the makers. The shaded letters are first cut in one colour, and then pasted on to paper of another colour and cut again. Nothing is claimed for them beyond cheapness and effectiveness. Being on thin, common paper they can be utilised anywhere, and can be used on almost any material, and being cheap they can be changed at pleasure when the season may demand it. They may be turned to excellent account for announcements of any kind, and when cut in Church text or Gothic form will be found useful, effective, and cheap as lettering for church decorations. They may be further utilised for announcements of any kind, and especially for concerts and entertainments and meetings of any kind, whether in town or country. The chief points to which to pay attention are the placing of the letters between truly horizontal parallel lines, and equalising the spacing between the letters. Care of this kind bestowed on the work cannot fail to add to its beauty and efficiency when completed. THE EDITOR.

SHOP:

Corner for Those who Want to Talk It.

* Notice to Correspondents.—*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

I.—Letters from Correspondents.

Portable Sketching Tent.—W. A. M. (*Warrington*) writes:—"The enclosed is a rough sketch of a portable sketching tent. Can you tell me if there is one in use at the present time? The idea, as I have tried to show in the sketch, is to combine

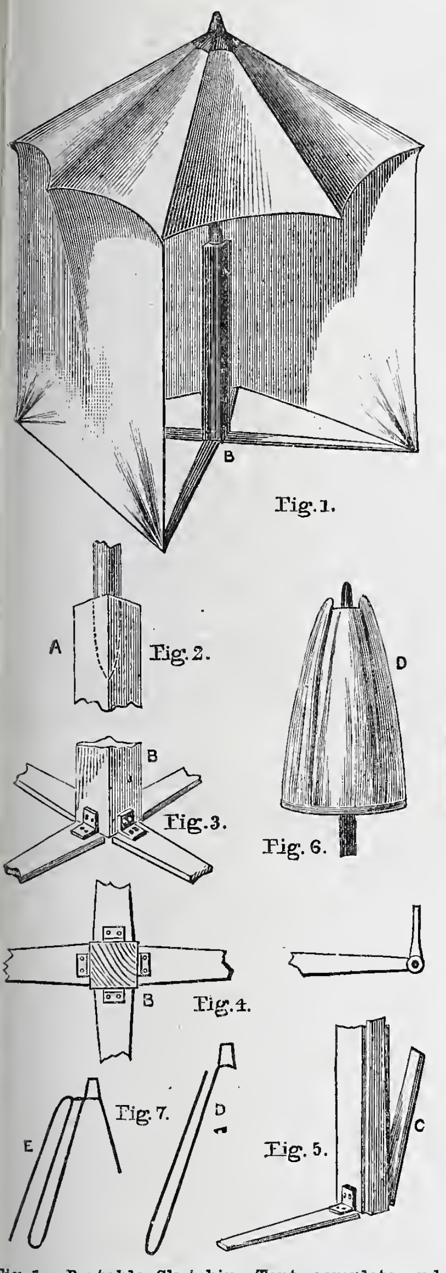

Fig. 1.—Portable Sketching Tent, complete and fixed. Fig. 2.—Top of Socket to receive Umbrella Handle. Fig. 3.—Foot of Upright to receive Umbrella Handle. Fig. 4.—Plan of Fig. 3. Fig. 5.—Bars turned up round Socket. Fig. 6.—Canvas folded up round Umbrella. Fig. 7.—Canvas brought up Umbrella (D) and down (E).

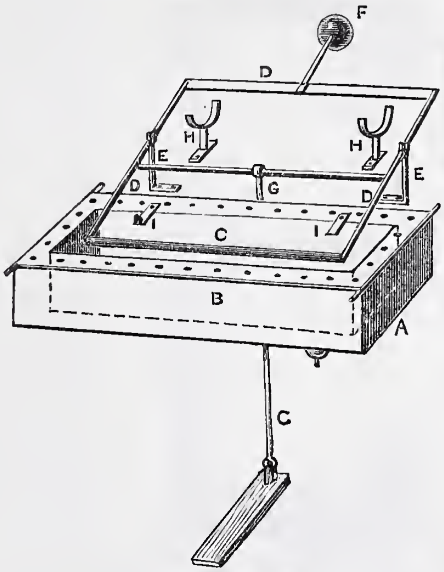
simplicity in working and lightness for carrying purposes, and also the tent to be adapted to be pitched on rock as well as on the soft soil. At A, in the sketch, the umbrella handle fits into the bottom portion. The four horizontal bars are hinged at B, so as to close up. The umbrella covering is brought down, so as to reach the ground, and the corners are fastened to these horizontal bars. Thus these bars serve two purposes: they support the tent on the rock, and also hold the sides of the tent in position. When required to be folded up the canvas forming the sides of the tent could be brought up, as at D, then tied, and the remaining portion brought down, as at E. If there is not one in use now, will you kindly tell me, through your columns in Work, if you think it would be of any benefit to artists or myself to patent it?"—[I do not see exactly what you could claim if you patented your tent. I am sorry to say that I cannot tell you whether or not there is anything of the kind on sale now, except the ordinary umbrella tent about 6 ft. in diameter.—Ed.]

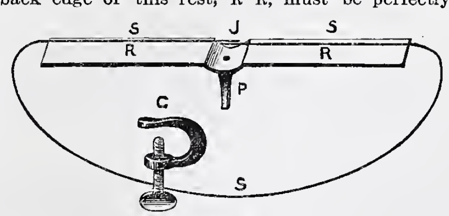
Mounting Calendars.—J. A. G. (*Nottingham*) writes:—"I send a few lines in answer to the inquiry of An Old Gluer for a machine for gluing sticks, being in the same branch at a large firm, and having used this machine for the last three years. Previous to this period, we fanned the sheets out to the width of $\frac{1}{2}$ inch, and laid the sticks on. The contrivance you give is, as you say, very well for sticks that are flat, but, as a rule, they are generally oval, and it would be impossible to lock them up as you would the flat ones. The sketch enclosed, though not a good drawing, may give you an idea what it is; gluing one at



Gluing Machine.

once, you can glue as many as 600 per hour in the machine. The outer pan is iron; the inner or glue pan is copper. The outer pan, of course, is for steam entering at the back with an outlet at the bottom. May be you will see the difference of the parts by letters: A, the outer pan; B, the inner pan; C, the gluing bar; D, frame for carrying bar; E E, loops screwed to bench to carry the frame; F, balance weight; G, treadle; H H stands screwed to bench to hold the sticks; I I, pair of tips to hold the stick while the glue bar or rest comes up from the pan. The bar is only $\frac{1}{4}$ in. thick and 2 in. wide, and the length of pan."

Brazing Band Saws.—A. R. (*Scorrier*) writes:—"Although this is a simple job, there are many that cannot succeed in effecting a good joint. The following is the most simple way that I know of, and I may say I have made hundreds of brazes in band saws. In the first place take a piece of $\frac{1}{4}$-in. or $\frac{3}{8}$-in. iron 4 ft. long, $1\frac{1}{2}$ or 2 in. wide; make it in the form of sketch which I roughly give. The back edge of this rest, R R, must be perfectly



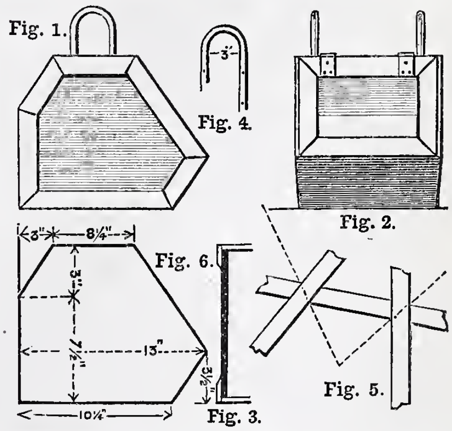
Band Saw Braze.

straight, to which two narrow strips of iron, S S, should be fastened. A piece of iron, P, should be welded, or a hole tapped, and the piece, P, screwed to the centre of the rest so as to hold it in a vice, or insert it into a hole in a small iron horse while the saw is being brazed. Now scarf the ends of saw with a file the length of $2\frac{1}{2}$ teeth. To do this the ends of saw need not to be warmed if the saw is of proper temper. Now place the saw on the rest, keeping the back of saw close against the strips, S S; this will keep the joint straight. Now take four cramps, made as C with thumb screws, and screw on rest, R R, to keep saw in position. Then damp the ends of saw, and take a little powdered borax and mix with a little coarse brass spelter, and place it between the ends of saw, or where they lap at J. All now being ready for brazing, take a pair of heavy tongs and heat them in a fire till bright hot; another lighter tongs must be made black hot. Take the heavy tongs and close it tightly on joint J. As soon as the spelter has properly run this tongs should be slipped off, and the black hot tongs, which has been held in readiness by a boy, slipped on and closed tight for a few moments. Take it away, unscrew the cramps, and lightly hammer the joint on the horse or vice. Then file it a little, and to improve the look of the braze rub it with a piece of emery cloth, and the job is completed. With a little practice a dozen or more brazes may be made in an hour. I may add that no binding wire is required."—[I am obliged for your name and full address, and for your further communications to "Shop."—Ed.]

Combined Bedroom Suite.—J. H. H. (*Oldham*) writes:—"I thank you very much for J. S.'s answer, containing all the information I desired. I enclose a rough tracing from the combination bedroom suite, with the alterations I intend trying to make in it."

Combined Bedroom Suite.

Simple Cheap Coal Vase.—G. W. (*Bournemouth*) writes:—"I send you particulars of a simple cheap coal vase well within the power of an amateur to make, something useful and ornamental. Sizes given are suitable for artisan or small dwelling, and



Cheap Coal Vase. Fig. 1.—Side Elevation. Fig. 2.—Front View. Fig. 3.—Section showing Rebate formed by Moulding. Fig. 4.—Handles, $\frac{1}{16}$ Round Iron. Fig. 5.—Mode of Marking Mitre. Fig. 6.—Size to cut out sides; all measures from back and bottom line as shown, $\frac{3}{8}$ or $\frac{1}{2}$ thick.

may be curtailed or enlarged to taste or requirements; made in pine or mahogany, birch or mahogany mouldings likewise to taste. Those made by myself were pine with birch mouldings, plain iron handles, covered by a saddler with brown leather, for a few pence—may be brass or silver plated—brass hinges, birch moulding 2 in. wide, ⅜ thick, chamfered ⅜, glued on to pine sides (mitred of course), and a few panel pins driven in from back, or bootmaker's rivets ⅜ in. long—nearly same thing. Having prepared sides, mark or gauge a line on back of moulding ⅜ in. from edge. Stick a couple of pins in line for quick guidance. To get the mitre, place two pieces in position, mark from angle to angle, cut and glue on (Fig. 5). When sides are finished, cut any stout piece for bottom 10½ in. long. Nail or screw in rebate formed by moulding (Fig. 3). Lid made same way. With ordinary care a snug, clean job will result. Give a coat of size, *i.e.*, good size thinned with turps. When quite dry clean up (if required) with No. 0 paper and clean turps, and thoroughly varnish or polish if equal to it. Handles are put through the top, and fixed inside with short screws. If of advantage to any one wishing to procure materials, I could supply some sawn in the rough, handles and hinges, pine and birch, 4s. 3d. net."—G. W.

II.—Questions Answered by Editor and Staff.

Bookbinding.—G. F. S. (*Nottingham*).—I hardly know bow to answer your query. You ask for an article or two on Bookbinding. As the space devoted to "Shop" talking is limited, it would be impossible to give lengthy articles. But articles upon bookbinding have been written, and will appear, no doubt, as soon as convenient in the body of the paper. There is no good and cheap book on this subject that I could recommend. Any that I have seen are very much taken up with the history of bookbinding, and describing the bindings of the old masters, who lived centuries ago. This is all very good in its place, but it gives no wrinkle to the amateur to enable him to bind his books. I am quite at one with you regarding the interest likely to be taken in this subject when it appears in our Magazine. You had best make a start to bind your books, and when you come to a difficulty put it down in black and white, and send to "Shop," and I will put you right. Many thanks for your appreciation of Work.—G. C.

Dynamo.—Septimus.—An illustrated series of articles on "How to make a Dynamo" will be forthcoming when space can be found for them in Work.—G. E. B.

Dr. Tibbit's Medical Battery.—J. McG. (*Bootle*).—I am tolerably well acquainted with a dozen or two different forms of batteries, but do not know this. If you will give me some idea of its construction, I will tell you how to recharge it. Perhaps some other reader of Work can oblige you.—G. E. B.

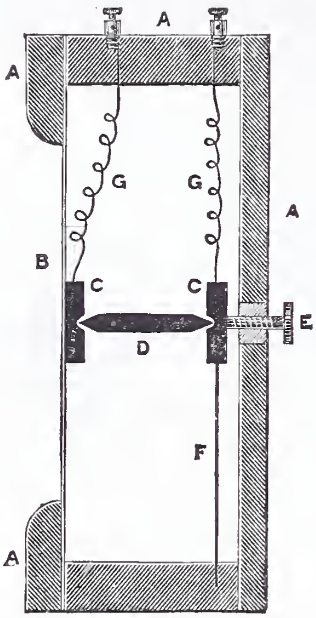
Telegraph Instruments.—H. G. C. (*Liverpool*).—My hands are full of work at present, so I cannot say when the promised articles on telegraph instruments will appear. As you have had several years' practical experience with telegraph instruments, perhaps you can oblige with a descriptive illustrated article on their construction. H. G. C. writes to inform H. D. and others that an excellent book on "The Philosophy and Practice of Morse Telegraphy" may be obtained from Messrs. E. S. Greeley & Co., Day Street, New York, U.S.A.—G. E. B.

Bicycle Materials.—F. W. R. (*Harling*).—1. There are no pliers, properly speaking, for turning spokes. There is a small wrench (Bauer's patent) that turns round objects as well as square: cyclists' size, 1s. 6d., of most tool dealers and cycle shops. 2. Tricycle fittings can be had of many firms. Try Wilkins & Co., 66, Holborn Viaduct, London, E.C.; Brown Bros., 7, Great Eastern Street, London, E.C.; Wm. Bonn, 308, Sunnie Lane, Birmingham, W. A. Lloyd, Waeman Street, Birmingham. Any of the above will supply all requisites. 3. Lines may be drawn of cycle frames and wheels with a large-size drawing pen, provided the colours are not too thick. For straight lines use a straight-edge, or tie a guide to the side of the pen. 4. Boiled linseed oil is used for work exposed to the weather in preference to raw. Raw oil is used for most interior painting and decoration. It is much lighter in colour and thinner than boiled, and therefore does not discolour fine pigments in the same way. 5. In turning slender rods in the lathe the practical turner keeps it running true to the tool with his left hand only. It takes considerable practice to do it, and an amateur could not be expected to do it for a considerable time. For iron work, when the work is of one thickness throughout, there is a guide fixed to the slide rest that travels with it immediately behind the cutter. In wood work for rods all of one thickness, such as broom handles, a hole is bored through a block of hard wood, and a cutter fixed in the hole in such a way that it will take off a shaving. The wood to be turned is first made eight-sided by planes or saw, then a little bit at the end is turned down to the size wanted. The block is now put on to this turned part, the work being now revolved in the lathe. The block is pushed along with both hands, and the rod is thus reduced to the size allowed by the cutter.—A. S.

Flow of Air in Tunnel.—Collier (*Bolton*).—You do not give us the section of the tunnel, so we must assume you refer to a rectangular heading, of which the sectional area would be 6 ft. × 9 ft. = 54 square feet. The cubic feet of air passing per minute will be (assuming it to be equally mixed with smoke in your observation) 90 ft. × 60 seconds × 54 square feet ÷ 23 seconds = 12,678 cubic feet per minute. Your measuring the velocity by the rate of travel of smoke indicates that a charge has been exploded, and therefore the regular current of ventilation disturbed, or otherwise that local smoke has been made that will not quite penetrate the whole current of air, in either of which cases the calculations will not apply. Send full particulars of the method of measuring the velocity, and the section of tunnel (if not rectangular), and you shall have reliable rules to work by.—F. C.

Boat Building.—Paddler.—I should use thin mahogany with a long straight grain, and bend it on to the ribs of the boat, using steam at the bends if required. The slips of mahogany should be about 3 in. to 4 in. wide, or you could use pitch pine. Both look very well. The rivets, etc., can be obtained at any large ironmonger's.—A. J. H.

Microphone Transmitter for Telephone.—W. S. (*Leicester*).—It is somewhat difficult to write and advise upon telephone matters, because of the fact that both receivers and transmitters are so completely covered by patents. But as I see that your receivers are of the "English Mechanic" pattern, and as there is no fear of them coming under the ban of the patentees, I will give you the design of a microphone transmitter, which answers pretty well as a speech transmitter, and is not patented. It was devised by myself, and if it suits your requirements I will be delighted. A wooden case 5 in. by 2½ in., having a round hole in front, closed with a piece of thin wood, to act as a diaphragm; two small blocks of carbon, with a small cavity scraped in the centre of each; a pencil of carbon, pointed at each end to fit into the cavities in the carbon blocks. One of the carbon blocks is fastened with cement to the diaphragm, the other to a piece of springy steel or brass, which is itself fastened in the bottom of the wooden case. The adjustment is made by a brass screw in the back of the box. Wires are fastened to the carbon blocks, and carried to binding screws, which may be placed in the top or back of the box as thought convenient. The sketch is given full size, but the sizes are not very important. There are a great many transmitters, some of them very intricate in the arrangements of the several parts. The one which I have given is just the opposite; it is very simple and easily made, and, providing the batteries and other things are in good order, it will do its work very satisfactorily.—W. D.



Microphone Transmitter for Telephone.—A, Wooden Case; B, Thin Wood Diaphragm; C, C, Small Blocks of Carbon; D, Pencil of do.; E, Adjusting Screw; F, Spring; G, G, Wires to Binding Screws.

American Clock Spring.—Factory Hand (*Brockholes*).—The spring might be made soft at the end by heating to a red heat and allowing to cool, then drill or punch. There is no need to rivet to the arbor, as in winding up; the rivet head, or more properly speaking the arbor hook, will catch in the hole and will hold it quite right. But after you have done it I do not think you will find it stand winding up. The best and simplest way is to get a new spring; it will only cost a few pence—perhaps 9d. at the most—and it will save you trouble. You may get the spring at Grimshaw and Co., 35, Goswell Road, or J. Hunt, 21, Ironmonger Street, St. Luke's, Clerkenwell. Take or send old one for pattern.—A. B. C.

Stains.—A. W. B. (*York*).—Dragon's blood is soluble in methylated spirits, so that you can either make a stain by dissolving a sufficient quantity and diluting afterwards with water, or you can dissolve it in the polish or varnish you may elect to use. With regard to your second question, I should certainly not think it worth while to take the trouble of polishing any piece of pine wood after staining it with dragon's blood. I presume you intend to use this as a mahogany stain, but the colour is far too fiery, and I cannot recommend you to do so. You will get a brilliant red, which is anything but a mahogany colour, though often supposed to be so. If you want a good mahogany stain for your chest, make it up of Bismarck brown, which may either be dissolved separately, or in the varnish or polish. It is a very powerful pigment, so that you must be careful not to use too much of it. As much as will stand on a shilling-piece will probably colour a pint of polish sufficiently for your purpose, though you can add more or less according to the intensity desired. Strain through muslin before using. To get a really nice dark rich mahogany colour on your chest, you cannot do better than stain it with weak walnut stain, and then finish with some of the red polish prepared with the Bismarck brown. Of course you are aware that polishing is more troublesome and difficult than varnishing, but that when properly done the appearance is far superior. I must confess that it seems rather an unnecessary degree of refinement to French polish a tool chest, but for your own purposes naturally you must be the best judge.—D. A.

Gilding Book Edges.—F. J. J. (*Macclesfield*).—There is no special recipe for gilding book edges. I will give a description of the process in common use, and if the querist follows it out I think he will be able to do his work satisfactorily. First then screw the book up as tight as possible in the lying press, between gilding boards, and scrape perfectly smooth with a steel scraper. Then take a wet sponge with a little bole, and blacklead and rub it over the edge, and brush it dry and burnish it with the agate. The bole gives a deeper appearance to the gilding, and if any cracks should be in the edge they will not be so readily observed. The size (which should be one part white of an egg to three parts water) must now be applied evenly with a large flat camel-hair brush, and the gold immediately laid on. After the edge has become perfectly dry it should be rubbed down, and any defects remedied. After this, burnish the edge until it is perfectly clear all over. The best gold leaf is what is known as "deep." The cost of a book is 1s. 3d. It requires a great deal of practice to become a good gilder.—G. C.

Brass Lacquer.—A. H. (*Hull*).—There is no lacquer that will make iron look like brass. Perhaps some kind of bronze would suit your requirements. If the iron articles are gas fittings, for instance, clean them well with sandpaper, and wash in strong soda and hot water. Dissolve 4 oz. shellac and ½ oz. gum benzoin in one pint of methylated spirits, by putting the ingredients in a bottle, and shaking often for two days. Then let it stand for two days, and pour off the clear liquid into another bottle. Now get some bronze green, and mix a small quantity with some of the above lacquer, and paint the iron work, which should be warmed; when dry give another coat. If there are any ornaments, touch them up with a little of the lacquer, and before the latter is quite dry, with a camel's-hair brush dipped in dry gold bronze powder, slightly gild the ornaments; after a few hours the work may be varnished. In reply to M. A. J. J., whose question appears in the same letter, indiarubber may be dissolved in any of the following solvents:—Bisulphide of carbon, benzine, benzoline, chloroform. It is not quite clear from your letter whether you require to cast articles of indiarubber in moulds, or to make indiarubber moulds. If the latter, apply successive thin coats of the indiarubber solution to the article to be reproduced, etc., and thus build up the mould. This, however, is suitable only for very fine and delicate work, and it is impossible to cast articles of pure indiarubber.—Opifex.

Ornamental Work in Lead.—A. K. (*Aberdeen*).—The article you desire to make is, I take it, of the fancy or purely ornamental kind as distinguished from the practical or useful. This being so, your choice of subjects is large, and the selection must depend rather on your own taste and judgment than on external advice, though I must say lead does not seem a very suitable material in itself. You are doubtless aware that it may be used instead of brass for repoussé work, and also for spun metal work. It might also be used instead of iron in imitation of the now fashionable wrought iron fancy articles, such as candlesticks, etc. etc. I cannot, however, advise its use for this purpose as savouring very much of sham production, and imitations are seldom commendable, albeit often ingenious. Perhaps a better way of making something ornamental, and not inconsistent with the material, will be to arrange the lead in form of conventionalised foliage on a wooden foundation. If, however, it is to be artistic work, see that you do not endeavour to get the appearance of some other material. For example, do not try to make your work resemble a piece of carving. Lead has properties of its own; remember these, and let the work show that lead is the material, instead of endeavouring to make it look like something else. I fancy I have heard of lead being used in this way in connection with Jacobean strapwork. If, as I think, you are a plumber, and want to show specimens of your skill at an exhibition, why not prepare something which shall show your proficiency in the recognised lines of plumbing? What you ask seems akin to a painter asking what subject he shall choose, and how it is to be treated, instead of bringing his own artistic perceptions to bear. I know of no book on the subject.—D. A.

Horse-power.—Collier (*Bolton*).—The horse-power of an engine is equal to the area of piston in square inches, multiplied by the effective pressure of steam per square inch in lbs., multiplied by length of stroke in feet, multiplied by number of strokes (that is, twice the number of revolutions per minute), divided by 33,000. The effective pressure is the mean pressure during the stroke, less the back essure. Taking your figures, and assuming the essure you give, 60 lbs., to be mean effective essure, the power will be—

$$\times \underbrace{36 \times 0{\cdot}7854}_{\text{area of piston}} \times \underbrace{60\text{ lbs.}}_{\text{effective pressure}} \times \underbrace{6{\cdot}5\text{ ft.}}_{\text{stroke}} \times \underbrace{2 \times 28}_{\text{No. of strokes}} \div 33{,}000 = \underbrace{673{\cdot}6}_{\text{horse-power}}.$$

ne horse-power is taken as equal to 33,000 foot-lbs. er minute, so we have a short rule. Horse-power quals piston area in square inches, multiplied by iston speed in feet per minute, multiplied by mean ffective steam pressure in lbs. per square inch, ivided by 33,000.—F. C.

Bending Ivory.—W. J. M. (*Liverpool*).—You an bend ivory slightly by immersing it in boiling vater until it gives a little, then clamp it firmly n the position required, and let it get cold. To often it entirely, a solution of phosphoric acid and vater is used; it is immersed until it loses its opacity omewhat; when washed and dried it becomes ard again. But this causes some alterations in it. do not know what, so be careful with it. I know he first is all right, but then I did not have to bend t much.—H. S. G.

IV.—Questions Answered by Correspondents.

Boot and Shoe Making.—Shoemaker (*Somerset*) writes in reply to Boots and Shoes (*Farnworth*) (see page 284):—"I will endeavour to furnish him with the information he requires, and perhaps I shall best accomplish this by describing how I should finish a soleing job. I presume he has a shoemaker's knife, as he 'knows a little of repairing.' I should commence by paring the new sole evenly and in shape with the boot; then rasping it with a rasp, which can be obtained at a leather and grindery seller's for 8d., 8 in. long—this, I think, a convenient size. After this a buffer is used. This can be made from almost any odd piece of steel such as a broken house knife or corset steel. The way to sharpen it is to file it to a semi-circular shape at one or both ends, also file it thin, not thin enough to cut as a knife; then with the back of the shoemaker's knife or awl rub it along the edge with a good pressure; this will have the effect of turning an edge, which does the scraping. Then sandpaper the edge (grasp the sandpaper in such a manner that the thumb will do the work). A burr will now be seen on the bottom. This must be pared off; then with smooth side of the rasp file in an outward direction, taking care to get the edge of sole the desired substance all round. Now take some paste, and spread on the edge, wiping off with a rag and spittle; this makes it smooth. Now ink: ordinary writing ink will do if no other is at hand; this must be allowed to dry, after which is the ironing process. A single iron is used for this work; it is so called because it has only one guide, consequently can be reversed to sole and upper side, and does away with the necessity of a multiplicity of irons. This can be bought at a leather and grindery seller's at a cost of from 4d. to 1s. Black heelball is ironed in to give polish. If the soles are riveted on, the rivets may be filed with the smooth side of the rasp. Now buff (scrape) the bottoms with a buffer made to cut along the sides in the same manner as described for edge buffer; after this freely use No. 1½ sandpaper. If desirable to make what is known as 'a damped down bottom,' an amateur may have some yellow soap (of good quality) dissolved in water till it forms a semi-liquid; use a clean piece of flannel to damp it with. After all the sole is covered, wipe off all that can be wiped off with a dry place in the flannel; allow this to dry. It will now depend on the skill and the quality of the leather whether the bottom is of a good colour or not. Now put some white heelball on the (bottom side) edge, and when the iron is hot melt this so as to make a brown mark on the bottom. Now rub off all heelball with a piece of cloth, and the job is finished. I am afraid I have used too much of your valuable space, but I have tried to act out the 'golden rule.' I wish Work a long and prosperous career. I have taken it in from the first, and have persuaded (successfully) others to take it, and when I met one of them one day, I asked him how he liked it; his reply was 'very well.'"

Lathe Work.—T. R. writes in reply to a Reader of Work (see page 382):—"I am inclined to think it will prove a somewhat difficult job to adjust compound rest on an ordinary lathe to be absolutely certain that a perfect fit will be the result without adjustment in taper work. Where a vernier exists at the base of tool slide, the latter may be approximately set by clamping at the required number of degrees to right or left of zero. Another method consists in using a right and left hand template cut to the angle required, secured with its base resting against the face of the face-plate to a bracket attached to the latter on a radial line with centre of lathe spindle. I always prefer where practicable to do the boring first. Some lathes are fitted with a screw at base of sliding headstock, which is very useful in tapering work between the centres, rendering adjustment easier than by slackening nuts on tool-slide. As the leading screw is ½ pitch, this fraction must be ignored in cutting odd threads as 7 per inch, and the saddle must always travel a certain number of whole inches from the point at which the nut is dropped into gear to the point where the lathe is stopped, and saddle run back to starting point again. You do not state the length of screw to be cut; but say it is 4½ in., then the distance travelled by the saddle must not be less than 5 or 6 in. (no fractions, mind) from starting to stopping. Chalk the lathe bed and the top of wheel on leading screw to indicate the exact position for stopping and starting. In the case of the 4½ threads per inch, this is equal to 21 threads in 5 in., therefore the saddle must run 5, 10, 15, 20 in., or some other multiple of 5 in., as the case may be, before stopping the lathe to run back."

Carriage Paint.—W. P. writes in reply to W. W. W. (*London, S.E.*), No. 28 in "Shop":—"Although you do not state whether the rose pink fades lighter or darker, the following, I think, will meet your requirements. Get some black carriage japan and grind some rose pink in it, then add a very little of Indian or Tuscan red until you get the required tint. To make a better job you might glaze it over with lake at the last coat."

Mounting Calendars.—R. R. & Co. (*Newcastle upon Tyne*) write in reply to An Old Gluer (see page 413, "Shop"):—"Referring to above query, we have a machine in use for gluing sticks for mounting calendars. It is simply an enlarged glue pot made in an oblong shape with water jacket under it, but instead of using a brush having a wooden roller 5 in. diameter resting in the glue with spindle resting in slots at each end with handle at one end to revolve it, the water being heated below with gas, a pipe with holes along being underneath it, the pot should be long enough to admit a roller 2 or 3 in. longer than the longest stick to be glued. The roller (wood) is cut in grooves at distances of 1 in. apart, it not being necessary to glue the sticks all along, saving glue. When the roller resting in glue is turned round the sticks are simply placed one at a time against it, and they take the requisite supply off the roller, which is turned round again as soon as more glue is required. One girl or man can work at each side by placing it in the centre of a bench."

Simple Incubator.—B. A. B. (*Hampstead*) writes in reply to B. F. (*Liverpool*) (see page 302):—"A simple incubator can easily be made, but unless B. F. is prepared to give great attention to the working of it, or can invent or copy a contrivance to prevent the heat fluctuating, he will find it nearly useless. Perhaps he may (if an amateur) copy one of the patented devices; for instance, a small receptacle is made of *thin* metal fitted with a liquid which boils at 103 deg. F., therefore expanding the flexible walls of the receptacle, and

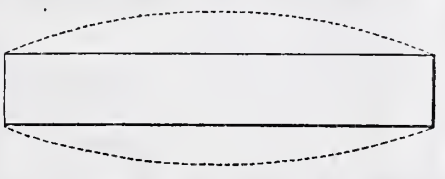


Diagram showing (exaggerated) expansion of receptacle.

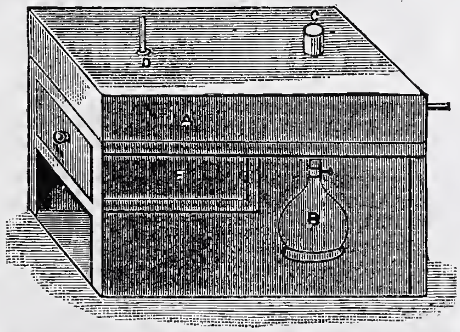
by levers diverting the draught from the lamp; or he might get an electric bell and a special thermometer to make contact at 103 deg. F., so ringing a bell to warn him to reduce the heat. Supposing, however, he has mastered the regulation of the temperature, the rest is easy. Let him make a wooden drawer for the eggs with a frame to carry it. Let the eggs rest on a good thick layer of straw, for some ventilation is needed. The drawer need not be very deep, say, 3½ or 4 in. inside, and had better be lined with tin or zinc, as a little water must be given to moisten the straw from



Simple Incubator—A, Tank or Boiler; B, Lamp; C, Chimney; D, Thermometer; E, Drawer for Eggs. The whole, except front of drawer, to be enclosed to keep in the heat.

time to time. The heat must be applied from the top, and the tin box made into a shallow cover to the drawer case. Let this cover project either at back or side, and have a lamp as a source of heat. There had better be a tube through the boiler, with a movable damper to close it. When open the heat will pass away; when shut will play on the bottom of boiler. Have a thermometer on top of boiler, and then enclose the whole with a wood casing to prevent radiation and loss of heat, admitting a view of the thermometer either by having thermometer upright, the stem passing through a hole in the casing, or lying horizontally with a piece of glass let into the top of casing. There had better be a small ventilator in the drawer front, near the bottom, as air is needed especially during the latter part of the process of incubation."

Fretwork and Carving.—B. A. B. (*Hampstead*), in reply to W. M. M. (*Glasgow*) (see page 446), writes:—"I advise you to write direct to Zilles & Co., because that firm certainly know best as to what patterns they keep in stock, and the prices they charge. A fuller answer would be an advertisement."

Removing Ink Stains.—J. C. (*Ryde, I.W.*) writes:—"In reply to Littleton (*Worcester*) (see page 366), ½ oz. of citric acid diluted in 4 ozs. of water will remove all traces of ink, but not printer's ink."

Copying Tracings.—L. M. (*Putney*) writes in reply to Photo (*Chester*) (see page 366):—"I don't know of any process in which tracings can be copied in black and white by means of gallic acid, but I give a formula from the *British Journal Photographic Almanack* for 1889, which may suit Photo (*Chester*). Make a solution of gelatine, 1 part; water, 15 parts; warm it till dissolved, then well mix with it Indian ink or any pigment desired. Pour it while warm and fluid into a dish, and float paper upon it, and let it dry spontaneously without heat, and away from dust. When dry immerse it in the following solution:—Perchloride of iron, 240 grains; tartaric acid, 72 grains; water, 5 oz. Let it remain two or three minutes, and dry it in the dark. Print under the tracing in the usual way. Develop by immersing it in warm water. The light causes the parts not protected by the lines to become soluble in warm water. The lines are thus rendered black or coloured on a white ground."

Fretwork Picture Frame.—H. B. (*Maida Vale*) writes in answer to Amateur (*Belfast*) (see page 510):—I shall be pleased to send him a very effective pattern for above if he will send me his address."

Pill Making.—G. A. B. (*Old Kent Road*) writes in reply to J. C. (*Carlisle*):—"Being a subscriber, and looking over Work (No. 31, p. 494), asking, through your valuable paper, if any of your numerous readers could inform J. C. (*Carlisle*), or suggest any tool or machine for pill making, I beg to say I am employed by Mr. G. W. Niblett, of 26, Rainbow Street, Southampton Street, Camberwell, S.E., who will be most happy to furnish any requirements in same, as he is a manufacturer with every improvement connected with pill-making machinery."

Cleaning Engravings.—H. L. B. writes in reply to Ivor (*Bradford*) (see page 494):—"What a silly thing to do; of course the lime would act on the zinc. Todd's Victory enamels (Todd & Co., Hull) are recognised by practical men as the best things of their class, as they are a little better than ordinary paint mixed with varnish. Some of their bath enamel or the Chez-Lui bath enamel might stand the lime. But the zinc would require three coats, and the enamelled surface would then have to stand at least three weeks to get quite hard. You should not have lined the wooden tray with anything, but coated it with best shellac varnish. We use this in photography for our large trays, and find it waterproof and acid proof."

Pill-Making Machines.—H. L. B. writes in reply to J. C. (*Carlisle*) (see page 494):—"These may be had from Arnold & Sons, 35 and 37, West Smithfield; or, Burgess, Williams, & Francis, 101, High Holborn, W.C., London; or, Maw, Son, and Thompson, 7-12, Aldersgate Street, E.C."

Carriage Paint.—H. L. B. writes in reply to W. W. W. (*London, S.E.*) (see page 446):—"You must use good colours in carriage painting, and pay a good price for them, or your work cannot stand. I should think brown lake would be about the shade you want, it is not very expensive; try Simpson & Co., London Road, Southwark, for this colour, and say I sent you to them for it. For common work a deep purple brown might do, darkened a little with vandyke. For a purple colour mix white lead, Prussian blue, and vermilion. For dark chestnut, mix light red and black, and use red ochre when you require to lighten colour. For chocolate, mix vegetable black and Venetian red."

Ink for Posters.—Smiling Smudger (*Manchester*) writes in reply to A. J. (*Ilkeston*) (see page 494):—"I have tried several methods of poster writing, but have found the best and cheapest, and certainly the cleanliest and handiest, for an amateur who only occasionally does bill writing, to be ordinary oil paint, easily procurable in tins, mixed with about four times the same amount of benzoline. Use a long-handled round fitch to outline with, filling in with small pound brush. Any colours, such as vermilionette and lemon chrome, not always to be obtained in tins, you may obtain in a powder, or ground in oil; when mixing them add about a twentieth part of oil. Tack the whole of your bill, if possible, to a good plaster or boarded wall, and be careful not to splash the lower portion. I have written some very effective calico banners by this method, besides large pictorial posters, 25 ft. by 18 ft. It will serve equally well for colours, only not quite so thin. Heywood, Deansgate, Manchester, supply a splendid paper for this kind of work, called the 'Mammoth,' size 63 in. by 49 in., price 1s. 6d. the quire."

Varnish for Drawings. — A. W. (*Croydon*) writes in reply to A. M. (*Glasgow*) (see page 510):—"First size over drawings with a weak solution of French gelatine to be obtained at any grocer's or chemist's for about 2d. per ounce; then, when dry, proceed to varnish with the following mixture:—Take equal parts of Canada balsam and turpentine; dissolve by gentle heat in a wide-mouthed bottle, and apply with a broad camel-hair brush."

Ink for Posters.—H. L. B. writes in reply to A. J. (*Ilkeston*) (see page 494):—"The ordinary printers' inks, diluted with paraffin or benzine, are all that is used in poster painting. I am engaged by the Editor to write on this novel subject, and shall commence as soon as time permits, which I hope will be shortly."

Parchment Mounting and Stains.—In No. 31, p. 494, MITRE (*Hanwell*) asks for information on the above. Parchment requires no special treatment for mounting. If you wish to mount your certificates on cards for framing, lay them out on a piece of paper (to keep the table clean), and paste them well with good flour paste, not too thick, using rather a large brush, and going over the parchment as quickly as possible. When carefully pasted, lift the parchment, and lay it upon the cardboard, place a sheet of paper over it, and rub it well down with both hands. There is no need for damping, you will find that the paste will make the parchment quite damp enough. About the stains, however, you should have been more explicit. Some stains may mean much or little, and some stains would require a different mode of treatment from others for their removal. However, you might try oxalic acid and water, or rather water to which a little oxalic acid has been added. I intend to go into the subject of mounting by-and-by if the Editor can find room for this subject.—G. C.

Patent.—PATENTEE (*Leeds*) writes in reply to MINERVA (see page 416):—"'Those who thoroughly understand patents are well aware that this provisional protection is in reality a very questionable monopoly, and that no action for infringement would lie against any one for pirating an invention only provisionally protected.' The above remarks, which appeared in your paper on the 28th inst., are altogether misleading. Section 14 of the Patents, Designs, and Trade Marks Act, 1883, states:—'Where an application for a patent in respect of an invention has been accepted, the invention may, during the period between the date of the application and the date of sealing such patent, be used and published without prejudice to the patent to be granted for the same, and such protection from the consequences of use and publication is in this Act referred to as provisional protection.' Section 15 continues:—'After the acceptance of a complete specification, and until the date of sealing, the applicant shall have the like privileges and rights, as if a patent for the invention had been sealed on the date of the acceptance of the complete specification, provided that an applicant shall not be entitled to institute any proceedings for infringement unless and until a patent for the invention has been granted to him.' Therefore it is clearly evident to any one of ordinary comprehension that not only is the invention fully protected by the provisional specification from the date of that document up to the date of sealing of the patent (provided, of course, that a complete specification is lodged and accepted within the prescribed time), but proceedings for infringement can be instituted for any piracy of the invention occurring within the period covered by the dates of the provisional protection and acceptance of complete specification and sealing of the patent. Most patent agents of any repute advise that it is preferable to lodge merely a provisional specification with the application for a patent, because on a complete specification being lodged and accepted it is advertised, and must be open to public inspection for two months to allow any one to oppose the grant of the patent; but a provisional specification is not open to public inspection during the term of provisional protection—*i.e.*, during the nine months or until the complete specification is lodged and accepted. Another very important reason why it is more advisable to lodge a provisional specification at first is that a complete one becomes public as soon as it is accepted, and if the inventor has not before then applied for his foreign patents he must run the risk and danger of being forestalled by some one patenting his invention before him in those foreign countries where the first applicant can usually obtain a patent, whether he be the inventor or not. Another good reason for lodging a provisional protection first is that if the inventor has not sufficiently perfected his invention in all its details, so that a full and complete specification and drawings may be lodged, he will have nine months in which to fully develop and complete it. It would therefore seem desirable for your editorial department to carefully examine any remarks intended for publication, so as to expunge all mischievous and inaccurate statements, if you wish to maintain the reputation of your paper."

Illuminating. — FAL writes in reply to H. C. (*Lincoln*) (see page 318):—"Vellum, not parchment, should be used for illuminating upon, the latter being quite unsuited for the purpose. Vellum is a most beautiful material, and admirably adapted for illuminations, though care is required in working on it, as it is almost, if not quite, impossible to erase any marks when once made. Ordinary moist or cake colours are the best things to use, assuming, of course, that they are obtained from a first-class house. I use Winsor and Newton's or Roberson's generally with shell, and sometimes leaf gold, and have always found these highly satisfactory. I hardly know what you mean by 'brilliant.' Of course they can be made brighter by giving them a coat of gum after the colours are dried, but I do not think the result would be improved by it. You should, by all means, study the illuminated manuscripts in the British Museum, but if this is impossible, if you will state exactly what you want to know I will do my best to tell you. Some years ago I invented a very simple method of stretching vellum, so as to avoid the cockling which wetting it entails. At this moment I am too much engaged to give the particulars of it, but if you would like to have them, and the Editor is agreeable, I would send a sketch and description to our 'Shop' in a day or two. I may just say that the plan answers perfectly."—[By all means send description and sketch of your plan.—ED.]

Plan for Stall for Covered Market.—B. A. B. (*Hampstead*) writes in reply to J. T. (*Middlesbro'*) (see page 494):—"The conditions laid down are that it shall shut and lock up; to secure this, and to utilise the doors for displaying goods upon, it will be advisable to make the front in four sections, two of which are fixed, and help to form the framing, and two hinged to the outer fixed sections; the ends make of two strong frames without panels, having instead a pair of glass cases revolving on centres fixed in middle of inner edges of top and bottom rails, having bolts inside to fix glass cases, either with their solid backs outside

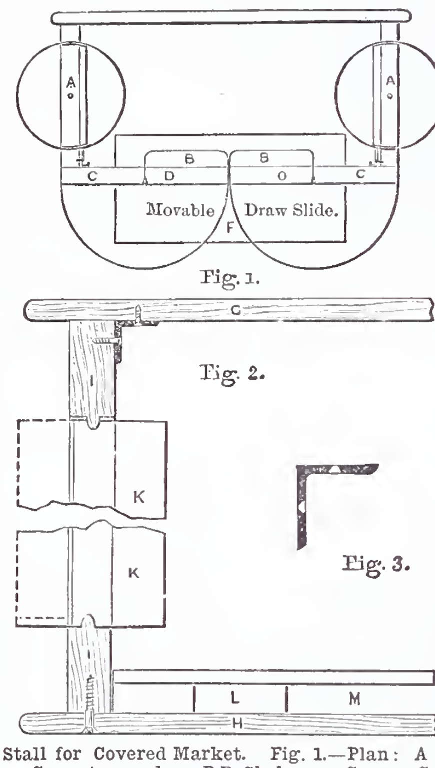


Fig. 1.

Stall for Covered Market. Fig. 1.—Plan: A A, Cases to revolve; B B, Shelves or Cases; C C, Fixed; D D, Hinged. Fig. 2.—Sections of Stall: G, Roof; H, Bottom; I, End; K, Case; L, Ledge; M, Slide. Fig. 3.—Iron Angle Pieces at intervals, important. Not to scale.

or their glass fronts outside as may be required. The bottom I should make of floor board ledged and screwed, having between the ledges a sliding board to draw out in front like a counter flap; over the ledges a false bottom to enclose flap; the back could cheaply be made of match lining not less than ¾ in. thick; top of same, covered outside with prepared canvas such as coach builders cover carriage roofs with. The whole of inside would be best painted white to obtain more light. I do not know if the stall is to go on wheels; if so, some modification might be necessary for what I have called the front, but which, if made as a vehicle, would of course be one of the sides. The whole of the erection could be done with screws or bolts and nuts, and the only joinery would be the glass cases and the end frames; the bottom screwed to ends; ledges of back fitted and fixed thereto; roof screwed from below through angle plates all round at short distances apart."

Ivory Walking Stick. — J. W. (*Liverpool*) writes *re* P. P.'s (*Withington*) reply to W. A. (*Hanley*) (see page 510):—"I will give simple opinion, as I think it will be an improvement—that is, to drill the ends, as P. P. advises, but tap a thread, and screw a bit of wire, level ends nice and flat, and screw wire in each end; that will pull it up to such a joint that it will not be seen."

Trade Notes and Memoranda.

"TYPOGRAPHIA" EXHIBITION AT STATIONERS' HALL.—The lesson taught by even a casual inspection of these exhibits was, firstly, that English letterpress printing was a long way behind continental and American work, and, secondly, that the older means of printing—that is from raised surfaces like type—is, notwithstanding the rapid improvements made in lithography—still very superior for high art reproduction to its younger rival. The causes of foreign excellence are principally the careful culture of apprentices and workmen under continental governments for a long period under systems of real technical education—not the false mockery of it now palmed off in England—a training as thorough as it can be, commencing with the first drudgery of the workshop, practical and manual, and hand-in-hand theoretical teaching, whereby the workman is taught to think out for himself the reasons for his *modus operandi*. American excellence is traceable chiefly to liberality of payment for excellence, attracting technically educated continental workmen to take with them to the States their abilities and culture to a better market than that of their native land. "The British Typographia," a society formed by typographic printers more especially to cultivate and develop their craft and fellow craftsmen so as to bring up English work to the higher standard of foreign work, has logically started off by proving by this exhibition our inferiority and the necessity for immediate action. "Typographia," by every means in its power—by the preparation and reading of papers, by meetings for the interchange of personal experiences and difficulties and their solution, by true technical teaching of those in the craft, whether apprentices or journeymen, and by gradually breaking down the artificial barriers to social intercourse between employers and employed—intends to place England once more in the van in this important branch of reproductive art-work. All who wish to aid in this crusade should send in their names to the Hon. Sec. of the London Branch, Mr. Robert Hilton, 2A, Gresham Press Buildings, Little Bridge Street, E.C.

CHAPTER ON FOLDING TABLES.

BY JAMES SCOTT.

NECESSITY is the mother of Invention;" ut I have also heard it said that Invention not the only child of Necessity, although take it for granted that it is what may be ermed the eldest child. Among the other hildren of Necessity are to be numbered tarvation and Robbery; but although she the mother of these undesirable children, ill there are other mothers who have hildren of the same names, and among iem must be included Idleness.

But I must tackle my subject, instead of thus metaphorically speaking of a well-worn proverb. It greatly worries me when I visit any female relation on a Saturday to see the avoidable trouble to which she is put when house cleaning. First, she pushes tables, chairs, etc., to one-half of the room, and after sweeping and scrubbing, she transfers them to the other part of the room; and, finally, after having exhausted her patience, she places them in their original position. What a blessing if, for the time being, she could summon to her aid some fairy who would stow them away in his waistcoat pocket!

Necessity, then, to a certain extent is the cause of my designing the tables shown in the present article. It will generally be found that the folding tables already in the market are fancy articles for the drawing-room; or, if an extending table, the—sometimes—cumbersome screw dining-table. I have never seen such tables as I have shown to fold. Figs. 1 and 2 will be found the most useful.

I will do my best, then, to give the reader sufficient details to enable him to make any of these tables himself, if he feels so inclined.

Particulars as to wood, preparing, and finishing, are to be found in articles already published in WORK.

Fig. 1 is 29 in. high, from the bottom of the leg to the top of the table. The top is 36 in. square, and is divided into two parts: one 29 in. by 36 in., the other 7 in. by 36 in. The large flap falls downward, and needs to be very strongly hinged to the smaller one.

The legs are turned from $2\frac{1}{2}$-in. stuff, the blocks of which should be 7 in. long. Those attached to the smaller top piece should be very firmly joined. Those on the opposite side must not be fixed at all to the top.

The two end pieces which form the two immovable sides should be $\frac{1}{2}$ in. thick, 5 in. deep, and 31 in. long. This length allows for joining it into the leg block. For the two movable—that is, folding—sides we require four pieces of the same depth and thickness, and each 15 in. long. Two of these form a side, and care must be taken to firmly screw the hinges on. I have shown some of the hinges on the surface of the wood, but they may be so fitted as not to be seen, as my reason for thus showing them is merely to indicate their position.

The top should be $\frac{3}{4}$ in. thick, and should overlap the outside of the leg blocks by $\frac{1}{2}$ in. The framing, according to the requirements, should be hinged and joined to the *middle* of each block.

To keep the table in its expanded position a strip of wood 1 in. thick needs to be fastened on the large flap, underneath, and $1\frac{3}{4}$ in. from its outside edge.

Of course, it is impossible to provide this table with drawers; hence my reason for giving Fig. 2.

This represents a table 4 ft. 8 in. long, by 3 ft. wide, and 29 in. high. The top is divided and firmly hinged in the middle. The framing, etc., of each half is precisely the same, so that it is only necessary to describe one half. I have intended it to have two drawers.

The framing at each side should be 2 ft. 3 in. long, by $6\frac{1}{2}$ in. deep and $\frac{3}{4}$ in. thick (see Fig. 3). The framing on the end should be $6\frac{1}{2}$ in. deep and 31 in. long. This end piece should be so made as to leave a space for the drawer 5 in. deep and 28 in. wide.

Now we require something to keep our table from collapsing when it is extended. First, we must deal with the two backs which come together in the middle of the table, and which can be seen in Fig. 4. It can be a solid piece or cut out as I have shown, but it must have a hole cut through the centre. Fig. 8 shows a thick piece of rounded wood, which, when put through the two holes, will be sufficient to keep the table firm, if it is made the same thickness as the diameter of the holes.

Next, we must give attention to the legs. Each pair of blocks will have to be cut so as to receive the rod (Fig. 7) which passes through the first block and into the second, where it turns in the same manner as a key does in a lock, and will be a firm support for the legs. The blocks should be rounded off on their tops, and connected with the framing by an iron or wooden peg, upon which they work as a pivot. It must be remembered that the deeper the rods are fitted in the blocks, the more solid support they will afford; and if it is not considered too much trouble I should advise the maker to have legs with a block a good distance down, and have another pair of rods to fit into these.

As this table will occupy nearly 5 ft. space when extended, its folding will be a great advantage, as the space it will then take up will only be about 15 in.; so that, perhaps, it will be worth while to spend a good amount of labour on it.

The fancy table represented in Fig. 5 differs somewhat from the usual run of folding articles. In things of such a character, the aim in the design is to supply a table that will fold flat together, without one of its parts necessarily being disconnected from its fellow pieces. Another advantage to be gained by the use of table, Fig. 5, is that it will bear almost any amount of weight upon it when closed.

The top and the bottom board should each be $\frac{3}{4}$ in. thick, the former being 36 in. long by 18 in. wide, and the latter 36 in. long by $13\frac{1}{2}$ in. wide. The four legs should each be 27 in. long, 1 in. wide, and $\frac{3}{4}$ in. thick. The fretwork should be firmly joined between each pair of legs, thus fastening them together. A hole should be bored through the top of each, to admit a rod in each pair 16 in. long. These rods should be fitted in after all the other part is put together.

The framing should be $\frac{1}{2}$ in. thick, $1\frac{1}{4}$ in. deep, and 34 in. long, on each side of the table top, underneath; but no framing must be fastened on the ends. Each side piece should be cut through to allow of the free movement of the rods above mentioned. At 10 in. from the bottom of each leg should be a projecting piece of wood, through which a hole is bored, corresponding with a hole in the thickness of the bottom board, and through which a wooden or iron peg is driven to act as a pivot.

There are numerous methods to enable the table to be kept firm when being used. That which I have shown is as simple as needs be: it is merely a hook, the upper part of which moves in a kind of staple, and secures the legs from falling together.

This table will look well painted in either light or dark enamel. The two larger ones should be made of deal, with mahogany or oak stained or solid legs.

THE REGISTRATION OF DESIGNS AND TRADE MARKS.

BY C. C. C.

Protection of Designs—Drawings Required—Form of Application and its Cost—Classification of Designs—Trade Marks—Difficulty in Finding Novel Ones—Drawing Required—Rules and Information.

The registration of a design is a much more simple thing than taking out a patent. What we have to do in the first place is to provide three pieces of drawing paper, each measuring 13 in. by 8 in., and to make on each a drawing—the drawings being facsimiles of each other—in Indian ink, of the article or pattern which we desire to have protected. On applying for patents duplicates have to be sent in, but in this case *triplicates*.

Should the design be fairly simple in outline or pattern, we cannot do better than make the Indian ink drawings; but should the reverse be the case, and especially if our design will have to be printed for other purposes, time and labour will be saved by having it engraved or lithographed, and having three copies struck off, *without wording or trade mark*. These we may paste upon our sheets of drawing paper instead of making drawings.

We have now to apply at the Post Office for Form E (Patents, Designs, and Trade Marks Act, 1883 and 1885). It will be stamped with a red stamp, across which the word "Design" will be printed in black; for this we shall be charged 10s. In its margin we shall find directions for filling in the blank spaces between the printed matter. These forms are kept in stock at the more important post-offices, but may be obtained through any money-order office on prepayment of the value of the stamp.

In filling up this form, the one point which will specially require attention will be to determine the class to which the design will properly belong. Designs which have to be carried out in different substances, or which are to be applied to different kinds of articles in the same substance, have to be placed under different classes. Thus designs in or on paper generally come under class 5; but paper-hangings are an exception. There is a class for bone and ivory, a class for jewellery, another for metal goods not included under jewellery, and so on. For full information upon this subject it will be well that every person intending to register a design should obtain a little pamphlet of instructions, issued by, and procurable from, the Designs Branch of the Patent Office, at the end of which he will find a table of the different classes and the subjects contained in them. It should be observed that the applicant will have to state whether his design applies to shape or pattern. This is not always easy to decide. The writer has more than once been obliged to claim *both*, and his claim has been allowed. The remaining matters in the printed Form E are so simple that no one can be in danger of making mistakes in filling up the blanks.

As regards the drawings, the stringent regulations laid upon the applicant for a patent are not insisted upon. The drawing or print must be in a permanent ink, but it is allowable to shade it with washes, if these will serve to render the design more distinct and definite.

In addressing communications to the comptroller upon designs, the words "Patent Office Designs Branch" should be used.

Any person seeking to register a trade mark is advised in the official instructions not to go to any expense in engraving until he has ascertained whether the design for that purpose which he proposes to submit will or will not be accepted. In order to learn this he has to procure a form, which he will obtain from the post-office as in the previous cases, make his formal application, and submit his design. In some classes of goods few things are more difficult than to secure a new trade mark, simple as the matter may seem. The writer's experience has chiefly been gained in connection with trade marks for needles. These come under the same class as Sheffield goods (cutlery); no mark will therefore be accepted by the comptroller, the appearance of which in any way approaches a mark already secured by any maker of saws, files, or such-like matters, and though the goods of the needle manufacturer can in no way be mistaken for or clash with those just mentioned, we have known drawing after drawing rejected by the comptroller, because it trespassed in appearance upon some mark used by a member of the Cutlers' Company or other metal worker. To secure a trade mark may therefore be a tedious and expensive affair. We could instance one manufacturer of high reputation in the needle trade who after compassing heaven and earth to find a new and appropriate trade mark, was obliged at last to content himself with a dragon fly!

The form which the applicant will procure will be that marked F. It will have

"Trade Mark" printed across the stamp, and the charge for it will be 5s. It will have blanks in the printed matter to be filled in according to the directions given, and in the middle will be a blank square. With this two other forms (duplicates) will be given to the applicant, each with a blank square in its centre, and in the blank squares of all three papers, drawings of the proposed trade mark must be affixed.

On the stamped form will have to be stated the class of goods for which the trade mark is wanted (for instance, if for needles it would be class 13), date and signature attached, and all three forwarded to the Comptroller of Patents Trade Marks Branch.

When about to register a trade mark, the applicant will do well to procure the small book of rules issued for his guidance, price 1s. It is sold by ten London houses, of which that of Messrs Waterlow and Sons, Parliament Street, is one; in Manchester by Messrs. Palmer and Howe, Bond Street; in Edinburgh by Messrs. A. and C. Black; and in Dublin by Mr. Alex. Thom, Abbey Street.

HOME-MADE TOOLS.

BY J. H.

Joint Boards and Surface Plates.

Joint boards or surface boards are used by engineers' pattern-makers, for the building up of work which is jointed or parted into two or more portions for convenience of moulding. Thus, in making an engine cylinder by the method of lagging, the first half pattern is built up with its joint face upon the board, and afterwards the second half is built upon the first. The reason why a board is used is twofold. First it is usually truer than the bench; which, although true in the sense of being free from winding, is not usually free from local inequalities and roughnesses; and second, the building up of work often necessitates the use of screws, staples, or other temporary attachments which it is not desirable to insert in the bench; and also glue from the glued joints drops down from the work, and would make the bench in a mess. But the joint boards being true can be kept so by occasional shooting, and any disfigurement due to nails or dogs is of little or no consequence.

These joint boards are used for a variety of other operations by wood workers. They not only afford a true basis for building up work, but also for taking vertical dimensions by means of rule and scribing block, checking or adjusting faces with set square or bevel, for lining off centres and dimensions, and sometimes for drawing out work upon. They are to the pattern-maker what the marking-off table is to the fitter.

A joint board (Fig. 1) is necessarily made of several strips of stuff. A piece of board in one width only would shrink and curve out of truth to some extent, in spite of the coercion of stout battens. Making the board in narrow strips, and uniting these with battens and open joints, shrinkage or swelling due to atmospheric influences is so very much localised that the general level remains true for an indefinite period.

A joint board may be made to almost any dimensions according to requirements. It will generally be more convenient to have it oblong. Perhaps the most generally useful dimension would be from 4 to 5 ft. long, by about 2 ft. wide. Supposing it is 2 ft. wide, make it in four strips of 6 in. wide each, or in three of 8 in. wide. It is not necessary to plane to thickness and width, but it is a neater method. At least, the strips should be planed to a parallel width to make the slightly open joints, say $\frac{1}{32}$ in. open, of about equal width throughout. If they are not planed to thickness, then the best plan is to make one face true and gauge and rebate narrow faces on the opposite side to take the battens.

The battens should be stiff. They may measure from 3 to 4 in. in width by $1\frac{1}{4}$ in. or $1\frac{1}{2}$ in. in thickness. They will be screwed to the strips in such a way that a slight amount of expansion and contraction will be allowed to the stuff. To do this, make the screws a slack fit in their holes in the battens. Put two screws from each batten into each strip, arranging them diagonally, and about in the position shown in Fig. 1.

It would be as well to let the board remain at this stage for a few days before planing it over, in order to allow any twist due to the exposure of the new surfaces, and the tension caused by screwing the parts together, to develop itself.

To plane it over true, we require the assistance of a straightedge rather longer than the board, and of a pair of winding strips. In a board of this length there will, unless the stuff is very thick, be an amount of elasticity which will permit it to accommodate itself to some extent to the bench, or trestles, on which it is laid. For this reason the stuff should be thick, not less than $1\frac{1}{2}$ in. in a board of the length we suppose we are making. And always before building up anything upon the board, it should be levelled on the bench or trestles with wedges or blocking pieces, using winding strips and straightedge for the purpose of testing. To plane the board over, in the first place the bench should be true, so that the board may be laid upon it in the most favourable condition. Its surface is then tried with winding strips, the strips being placed transversely near the ends. The straightedge is then tried lengthwise to check condition of surface which lies between the extreme ends just tried with the strips.

The surface may be free from twist as tested with the strips near the ends, but the intermediate portion tested lengthwise may be curved more or less, being either convex or concave. Or the surface longitudinally may be straight, but the ends winding in relation to one another. If the surface is true, not only longitudinally, but also diagonally, when tested over cross corners with the straightedge, then there is no winding. To face the board true, the trying plane must be sharp, and its iron adjusted as straight across as it is possible to work with, and set fine. A board made of well-seasoned stuff, put together in the way described and shot true, should last good in constant use for from six to twelve months without requiring to be reshot.

In making these boards there is no attempt to check one with another as in the straightedges and surface plates, the direct tests of straightedges and winding strips being sufficient for the purposes for which they are required. It is essential, of course, that the winding strips, etc., used in testing be themselves as true as possible.

Surface plates and lining-off tables are made in various forms and sizes. The lining-off table is used by the metal worker for the same general purposes as the joint board of the wood worker. The proper function of the surface plate is of a somewhat different character. Work is marked out on the lining-off table, and small work is built up thereon, or is taken thither for checking the accuracy or otherwise of lines and centres. The true and only legitimate function of the surface plate is the testing of faces and edges to which it is desired to impart the highest possible degree of accuracy. The functions of the two being distinct from one another, they are prepared by different methods. In their general form they are similar, consisting in each instance of a broad plated surface, well stiffened with vertical ribs underneath. But while the lining-off table is simply planed over, and so left, the surface plate is planed, filed, and scraped. The former is approximately true only, the latter absolutely so. The general truth of the broad area alone of the former is of importance; in the latter every minute localised section of area is in the same absolute plane with the rest. The former is easily and quickly prepared, the latter involves the labour of many days, perhaps of weeks.

Unless the aid of a true surface plate already in existence is available, it is absolutely essential to perfect accuracy that three surface plates be made. This, however, is a task in which three skilful amateur metal workers might well engage and take equal shares in the expense and labour.

For all work of large and moderate size, surface plates are made of rectangular and oblong forms; for very small work they are often circular (Fig. 4). In each case patterns are required, and they are to be constructed so that the face shall be cast downwards. It is best for this purpose that the stiffening ribs be only dowelled upon the plate, and they will be thinner upon the top edge than at the bottom. If the plate is large, diagonal stiffening ribs (Fig. 3) will be required in addition to those which run round the edges. If the plate is small, say 15 in. or 18 in. long, hand-holes should be cast in the two end ribs to lift the table by. If large, say two feet or over in length, handles of wrought iron are screwed in (Fig. 2, B). But such tables are only used in large workshops. The design shown in Fig. 3 will answer very well for tables up to about 24 in. long. The drawing is proportional for any dimensions below 24, so that a table of any length, from say about 8 in. × 6 in., which is about the smallest that is worth one's while to make, upwards to 2 feet, can be scaled from the drawing.

The oblong tables are the most useful. The rectangular surface is handier than the circular, and the edges afford a convenient base for the trying of the square across. But many small circular plates are made (Fig. 4). They are then commonly of the form in Fig. 4, the three legs enabling them to stand steadily on an uneven bench.

The making of surface plates is not an essentially different operation from that of straightedges and winding strips.

Having received the castings, grind over the surface and edges to see if they are sound before spending any other labour upon them. Then if they can be planed over in a planer or shaper, so much the better. If not, go to work with coarse file and straightedge until the surface of each is reduced to a fairly level condition.

If the surface plate is of small size, the file may follow immediately after grinding. If it is of moderate or large size, and in any case if its surface is uneven and rough, it must be chipped before the file is employed. The chipping should be commenced with a narrow cross-cut of about $\frac{1}{4}$ in.

in width, cross-hatching the surface with a series of shallow grooves. The truth of the grooves from edge to edge will be tested with a straightedge. Afterwards, the metal between the grooves will be removed with an ordinary broad-faced chipping chisel. When chipping near the edges, do not cut outwards towards the edges lest they become broken out, but strike inwards. Test the general level from time to time with a straightedge, and get it as accurate as possible with the chisel, because it is quicker and easier to chip than to file. It will also be found that by cross-hatching, it is much easier to get below the hard skin, and a truer surface can be obtained in less time than by using the broad chisel in the first place.

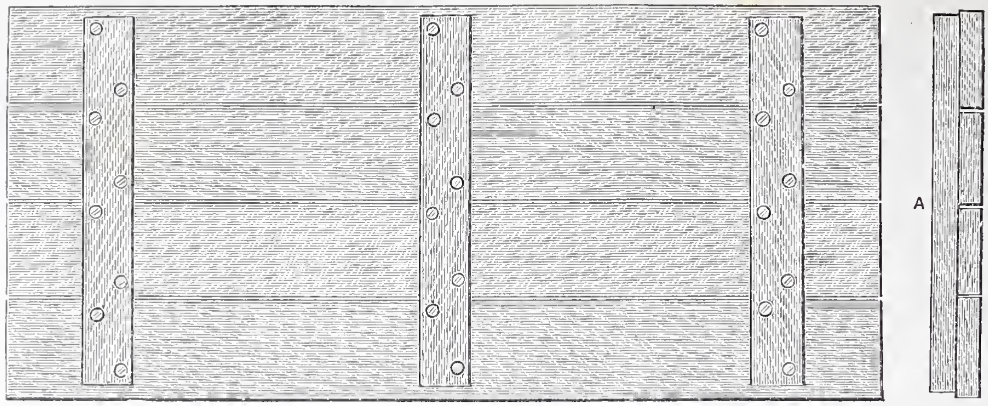

Fig. 1.—Joint Board in Plan seen from the Back—A, End View.

In the first rough stage of filing, when the chisel marks are being obliterated and the surface brought to a general level free from winding and curvature, no special precautions are necessary except the testing with straightedges. When the finer files are brought into requisition, their efforts will have to be more precisely localised, and red lead paste will be smeared over the straightedges, and transferred thence to the surface of the plate.

Not until we have done all that can be done in this manner is there any advantage in testing the plates by mutual contact. This will be done when we are using the superfine file and the scrape.

At these stages we shall get each plate first as true as possible, quite independently of the other, and then test each by the others.

It will be rather surprising when these plates, to all appearance true when tested singly by straightedge, are brought together in succession with red lead on their faces, to note how small a portion of the colour will be transferred from one to the other. Such being the case, we shall have no difficulty whatever in selecting the higher-coloured portions. and removing material with the point of the fine-cut file, and this alone will occupy us some considerable time. By-and-by, when the colour becomes more equally distributed, it will not be easy to localise the action of the file, and it is at this crucial stage, therefore, that the scrape has to be brought into service. By means of this tool the most minute localisation of action is possible, and the only limit to its use is the patience of the operator, as under the action of the scrape the number of minute points of contact made between the several plates increases, the action of the scrape is more and more localised, and the red lead mixture is made thinner and thinner until it is a mere film of coloured oil, and presently even this will be superfluous. It is better in the latest stages to trust simply to the contact of surfaces, the polish produced by the rubbing of the metallic surfaces upon one another being sufficient to indicate the higher points. At the last stage the surface of the plates will be covered with these points, imparting that lustrous appearance common to all scraped work.

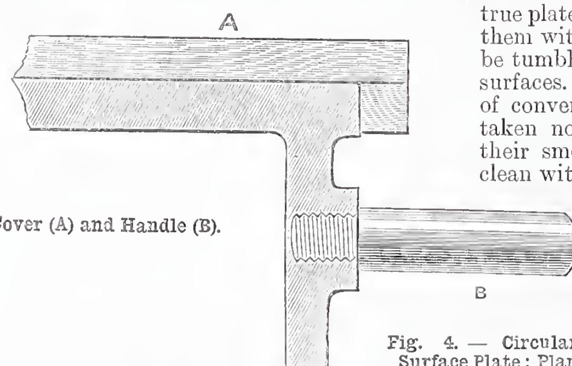

Fig. 2.—Cover (A) and Handle (B).

So intimate is the contact of surfaces in plates which have been prepared with the utmost perfection, that the upper one is capable of lifting the lower. Professor Tyndall attributes this to molecular attraction rather than to atmospheric pressure, because the same effect follows in vacuo as in air. In surface plates not prepared with this high degree of accuracy, there is nevertheless a very sensible force required to pull them asunder. When the plates are put together, the upper one floats for a while on an interposed film of air, and when this is squeezed out, it requires a good pull to separate the plates, unless the top one is slid sideways off the lower one.

After taking so much pains to produce true plates, we cannot do otherwise than treat them with consideration. Work should no be tumbled about or hammered upon thei surfaces. If lining out is done for the sak of convenience upon them, care should b taken not to scratch or otherwise impai their smoothness. They should be wipe clean with waste or with a wiper after us and when not in use should b covered with a wooden cove as shown at A in Fig. 2, in pos tion on the surface plate. Th cover consists of a board car fully jointed if necessary, o account of size, with a ledg screwed on round the edge.

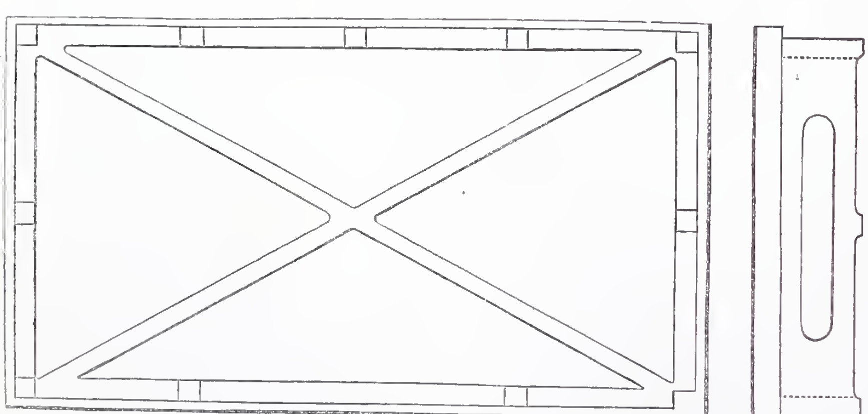

Fig. 3.—Square Surface: Flan from Below—A, Side View; B, End View.

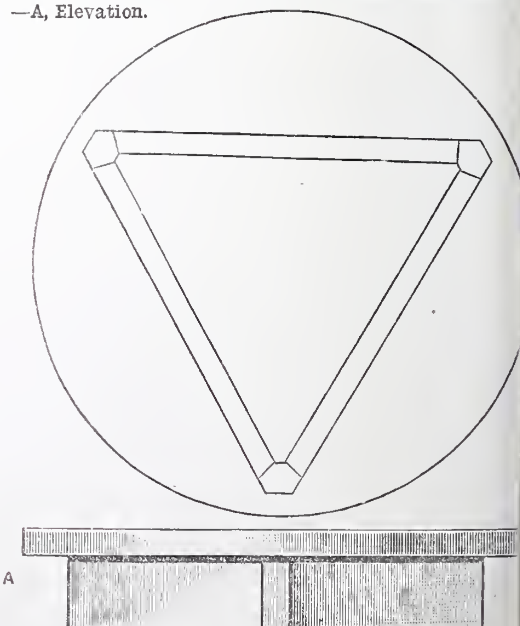

TOOTHED GEARING.

BY FRANCIS CAMPIN, C.E.

HEN one shaft is required to be driven om another, and the relative velocities of e two rigidly maintained, frictional contact not to be relied upon, and, whether for ;ht or heavy machinery, toothed or spur heels must be used, and these so conructed that they move together in exactly e same way as they would were the otion communicated by the mutual conct of their circumferences. To determine ie form of tooth by which the required otion can be transmitted is the question ow before us. In Fig. 1 let E and F present two circular discs of which the of the teeth, will be equal to the corresponding least distance from the points 1, 2, 3, etc. Therefore, to find points in the side of the tooth on F, so that it shall work properly with *dd'*, and remain always *in contact* with it, proceed thus:—Placing the compass-point at C as a centre, open the compasses till the pencil touches the nearest point of the curve *dd'*, and draw the arc *e*9; then take in the compasses the shortest distance from point 1 in circle E to *dd'*, and using point 5 in circle F as a centre, draw the arc 9, 10, meeting *e*9 at 9; in like manner take the shortest distance from 2 to *dd'*, and from the centre 6 draw the arc 10, 11, meeting the arc 9, 10, at 10; then from 3 take the shortest distance to *dd'*, and from 7 as a centre, with it as radius draw —of the accuracy of the solution. It is now to be found what law is established to guide us in determining the suitability of a curve for the sides of teeth. It will be seen that in every position a line drawn from the point of contact of the circumferences of the circles to the point of contact of the teeth will be a radius at that point to the curve *ee'*, and therefore (from the properties of circles) it will be at right angles to the curve *ee'* at that point; and because the curve *dd'* touches *ee'* at the same point, the said line (C*e* for the position shown in the figure) will also be at right angles to *dd'*. We therefore find as the condition to be satisfied in order that the circles, E, F, may be made to revolve by the surfaces *dd'* and *ee'* precisely as they would by the friction

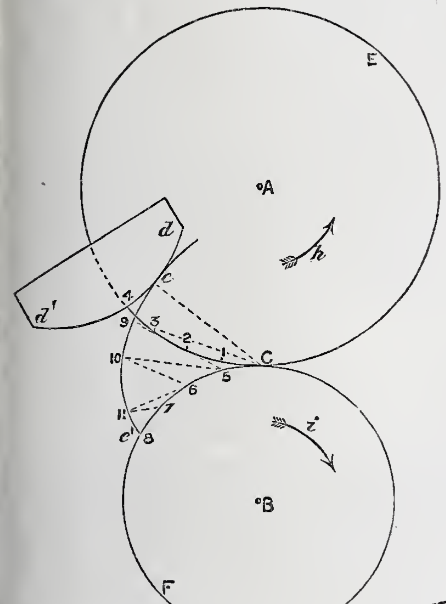

Fig. 1.—Contours of Teeth.

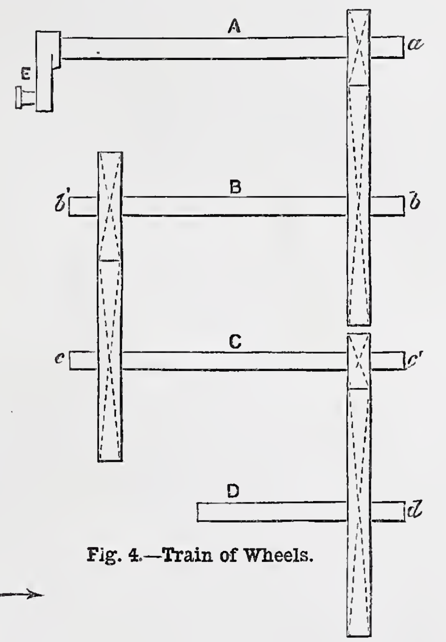

Fig. 4.—Train of Wheels.

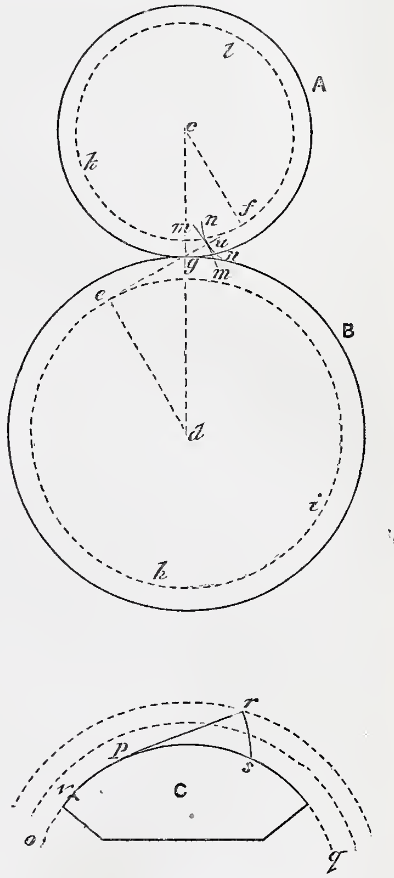

Fig. 3.—Involute Teeth.

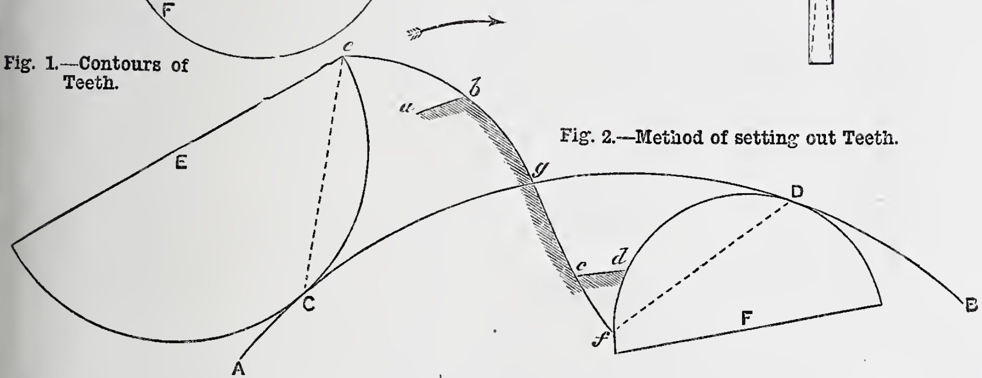

Fig. 2.—Method of setting out Teeth.

:entres are at A and B, and let them be in :ontact at the point C; then, assuming that there is no particular resistance, if one disc be turned, the other will revolve with it by reason of the friction at C. Upon the disc E let there be a tooth, the face of which is shown by the curve *dd'*, which cuts the circle E in the point 4. Divide the arc C4 into any number—in this case four are taken—of equal parts, and mark off the same number of equal parts on the circle F from C, making the arc C8 equal to the arc C4. Now if the disc E be turned in the direction of the arrow *h*, the disc F will revolve in the direction of the arrow *i*, and the points 2 and 6, 3 and 7, and 4 and 8, will successively come together at the point C. Now it is required to make a tooth which, fixed on the disc F, shall, during this movement, remain in contact with the curve *dd'*. It is evident that, at each successive position, the distance from the point of contact, C, to the point of contact the arc 11, 8, meeting 10, 11, at 11; and then the points *e*, 9, 10, 11, 8, will be points in the side of a tooth that will remain in contact with the curve *dd'* during the revolution of the discs through the arc C4. The more of these points that are taken, let me say, the more correctly will the form of tooth be given.

As in this lies the proof that the teeth can be made to work together concurrently with the natural motion due to mutual contact of the circumferences, and therefore can be used to make one disc drive the other in the same manner as, but without, the contact of the circumferences, I strongly advise the student to set this problem out on strong Bristol drawing board, so that it may be made into a working model, this method of investigating such matters impressing their results firmly on the memory, besides convincing the inquirer by the most satisfactory of all proofs—ocular demonstration of their circumferences, is that a straight line drawn from the point of contact *e* of the teeth to the point of contact C of the circles must in every position of the point *e* be at right angles to the surfaces in contact there.

As we may take an infinite number of points between C and 4, it is evident that the radius is continually changing for the side of the tooth, and therefore a curve made up of circular arcs will only approximate to the strictly correct form. There are, however, some curves which may be easily set out which answer exactly to the conditions required, and these, and the methods of applying them, I will now describe, premising, however, that the circles E and F, which would be in contact if there were no teeth, are called the *pitch-circles*, and that the part of the edge of a tooth *outside* the pitch-circle is called its *face*, and that part *within*, its *flank*.

In Fig. 2 let AB represent part of the pitch-circle of a wheel upon which it is required to set out teeth in accordance with the principles laid down above. If upon the arc AB a circular template, E, is caused to roll, and this template is fitted with a tracing-point at *e*, then as the template rolls in the direction of the arrow the point will describe the curve *ebg*, and at each point in the curve its radius will be a straight line from the point of contact of the template E and pitch-circle AB, one of these radii being shown at *ce* in the diagram; this curve therefore fulfils the conditions required for the proper working of the tooth. In similar manner, if a circular template, F, is caused to roll upon the inside of the pitch-circle, and has a tracing-point in its circumference at *f*, it will draw the curve *gcf*, the radius of which also will be at any point a straight line drawn to the point of contact of the circles. Thus we have obtained one side of a tooth, *abgcd*, of which *bg* is the face and *gc* the flank; E and F are termed the *generating circles*, and AB the *base*. In mathematical language, the upper curve *ebg* is known as an epicycloid, and the lower, *gcf*, as a hypocycloid, and teeth thus set out are known as epicycloidal teeth. The same generating circle may be used for both face and flank of the teeth, but this is not necessary; but it is necessary that the faces of the teeth on one wheel shall be described by the same generating circle as the flanks of the teeth on the wheel working with it. If any number of wheels of different diameters are made, and the teeth on all of them are described by the same generating circle—both flanks and faces—these wheels will work promiscuously together, the teeth of any one of the wheels being suited to work with the teeth of any other of them. Before proceeding with the work of practically designing the wheels, I will describe another form of curve which also meets the required conditions, and which has some advantages in certain cases; they are called involute teeth, and their form is described by the unwinding of a thread from the circumference of a circle.

In Fig. 3 let A and B represent the pitch-circles of two wheels, of which the centres are at *c* and *d*, and let the dotted circles *klf* and *ehi*, drawn about the same centres, have their diameters in the same proportion to each other as are the diameters of the circles A and B. Join *cd*; then *g*, the point where the line *cd* cuts the circumferences of the circles A and B, will be their point of contact: *ef*, a line touching both circles *ehi* and *kfl*, will pass through the point of contact, *g*. Let *u* be the end of the flexible line, *ueh*, wound round the circle *ehi*, and also let it indicate the end of another flexible line, *ufl*, wound round the circle *klf*, and at the ends of these lines describe respectively the tooth-edges *mm* and *nn*, touching at *u*. Because *en* is the radius of the curve *mm* at the point *u*, it is at right angles to it at that point; and because that is also the point of contact of the curves *mm* and *nn*, it is also at right angles to the curve *nn*; it also touches the point of contact *g* of the pitch-circles; therefore the involute curves *mm* and *nn* fulfil the conditions required for the edges of the teeth of wheels required for the proper working together of the wheels of which A and B are the pitch-circles. These teeth may be easily set out by means of a template, C, to which is attached by the screw *v* a spring, *vpr*: *opq* is an arc of the circle *ehi*, and the edge of the template C is made to exactly fit it, *t* being the centre. At *r* on the spring is fixed a tracer, by means of which the edge of a tooth, *rs*, is marked.

All the teeth of one wheel will, of course, be of one size and shape, and therefore a template having been made for one it can be used to mark them off all round the wheel.

The object of toothed wheels being usually to transmit work with certain modifications of speed and pressure, it will follow that two teeth in contact will be subjected to the same force, and will therefore require to be of the same strength and thickness; hence in a pair of wheels of different sizes the numbers of teeth on each will be proportional to their circumferences, and therefore to their diameters, and the number of rotations made by the wheels will be to each other in the inverse ratio of their diameters; for it is evident that if two discs are in contact, and the circumference of one is half that of the other, the former must turn round twice to pass over the circumference of the latter; and as the teeth cause the wheels to act in precisely the same way as if they turned by friction of their circumferences, the same will be true of toothed wheels; and, moreover, it is obvious that if one of two wheels has twice as many teeth as the other, the smaller wheel must revolve twice to engage with every tooth of the larger. So the rule for velocities of two wheels working together in gear is—*the numbers of revolutions per minute of the wheels are inversely as the diameters of their pitch-circles*, or *are inversely as the numbers of their teeth.* Thus, if a driving-wheel is 6 ft. in diameter, and the driven wheel is 4 ft., the speed of the driven wheel or *follower* is equal to that of the driver multiplied by its own diameter (or number of teeth), and divided by the diameter (or number of teeth) of the follower.

In a train of wheels the relative speeds of the shafts at each end of the machine—say, that of the last to that of the first or driving-shaft—will be found by multiplying together the numbers of teeth in the successive driving-wheels, then multiplying together the numbers of teeth in the followers, and dividing the former by the latter. For instance, let Fig. 4 represent a train of wheels, A being the driving-shaft, to which power is communicated through a crank, E.

Upon the shaft A is keyed a toothed wheel, *a*, working into a wheel, *b*, which, together with wheel *b'* is keyed on to shaft B; the wheel *b'* gears with wheel *c* on shaft C, on which is also fixed wheel *c'*, gearing with wheel *d*. The drivers in this train are *a*, *b'*, and *c'*, and the driven wheels or followers are *b*, *c*, and *d*. The number of revolutions per minute of the shaft A being given, the number for shaft D will be found by multiplying it successively by the diameters of *a*, *b*, and *c'*, and dividing the product by the diameters of *b*, *c*, and *d*. Let $a = 20$ in., $b = 45$ in., $b' = 25$ in., $c = 50$ in., $c' = 15$ in., and $d = 30$ in., and the number of revolutions of the shaft A = 60 per minute; then 60 multiplied by 20, by 25, and by 15 = 450,000; and this divided by 45, by 50, and by 30, gives $6\frac{2}{3}$ revolutions per minute as the velocity of the shaft D.

The proportioning of the teeth to the work to be done must now be considered, and this will be done on the supposition that the whole pressure transmitted by the wheel falls upon each tooth in succession, and so is entirely supported by one tooth. The tendency of the force will be to break the tooth off at the root like a bracket or beam-end projecting from a wall the same distance as the tooth from the rim of the wheel.

The strength of a tooth to resist fracture in cross-breaking varies as the square of its thickness, and simply as its breadth, and inversely as its length. If, then, all the dimensions are given in inches, its breadth multiplied by the square of its thickness and divided by its length, and the quotient multiplied by a constant according to the material used, will give its working pressure; or, putting it in a more convenient form for use, to find the thickness of tooth required, multiply the pressure in pounds upon it by the length of tooth, divide by the breadth of tooth and by 800, and take the square root of the quotient. This is based upon taking one-tenth of the breaking weight as the safe working load, for a tooth of good cast iron one inch in every direction will break with 8,000 lbs. at its extremity.

There are certain proportions of depth and other dimensions to the distance from centre to centre of the teeth—this distance being called the pitch of the teeth—that are found convenient in practice, and to these for all ordinary work it is best to keep. Calling the pitch 100, the dimensions are relatively as follows:—

Pitch of teeth	100
Depth	75
Working depth ...	70
Clearance at bottom ...	5
Thickness of teeth ...	45
Width of space... ...	55
Play	10
Length beyond pitch-line	35

Working with these proportions, a simple rule can now be found for determining the thickness of the teeth. Divide the pressure upon the tooth by 480 times, the breadth in inches, the quotient will be the thickness in inches. Let a wheel be required to carry a force of 3,000 lbs., the breadth on the face of the wheel being 5 in.; then 3,000 divided by 480 times 5, gives $1\frac{1}{4}$ in. as the required thickness of tooth.

As in the table it appears that the pitch of the teeth should be to the thickness as 100 to 45, the pitch in this case will be $2\frac{7}{9}$ in., and the length or depth of the teeth $2\frac{1}{12}$ in., of which length one inch will be beyond the pitch-line. The pitch having been determined, the circumference of the pitch-circle must be made to fit it. Thus, suppose the smaller wheel of the pair required is desired to be about 3 feet in diameter, that would give a circumference of $3\frac{1}{7}$ multiplied by 3 ($3\frac{1}{7}$ being the ratio of the circumference of a circle to its diameter), equal to $9\frac{3}{7}$ feet or $113\frac{1}{7}$ in. This will not quite fit the pitch, allowing for a little more than 54 teeth; therefore it must be made for either 54 or 55 teeth. If the ratio of numbers of revolutions of the wheels is a whole number, it does not matter which number of teeth is taken; but if it is any fractional number, this must be considered in deciding upon the number of teeth to be adopted. Suppose, for instance, the pair of wheels is required to reduce the speed from 70 to 45 revolutions per minute; then the numbers of teeth in the wheels will be 54 and 84, which give the same ratio inverted. The strain on the teeth of the driven wheel will, of course, be the same as on those of the driver; but it will be greater on the teeth of wheel *b'* than on those of wheel *b*, in proportion as the radius of *b* is greater than that of *b'*. This follows from the law of the lever.

It is a general law that, taking any two points in the machine, the pressures acting upon them will be in inverse proportion to the velocities of those points. To return to our example : if the wheel is to have 54 teeth, its circumference will practically be $112\frac{1}{2}$ in., which is equal to $2\frac{1}{12}$ in. multiplied by 54 ; and multiplying by 7, and dividing the product by 22, the diameter corresponding to this circumference is found to be $35\frac{35}{44}$ in., which is very nearly $35\frac{13}{16}$ in. The circumference is spoken of as being *practically* $112\frac{1}{2}$ in., because, strictly speaking, it is a trifle more; for, the pitch being measured from tooth to tooth in a straight line, it is a chord of the small arc of the pitch-circle between the centre of the teeth. It is practically of no consequence, as in the present case it would not make a difference of one-fortieth of an inch in the diameter.

THE ENGLISH LEVER WATCH.

BY A PRACTICAL HAND.

THE watch that holds its own the world over is made by the firm of Thos. Russell and Sons, Church Street, Liverpool. This watch, that has stood A 1 for such a long period, in fact, since they were first sent out by them—(this escapement was invented by Berthoud)—for accuracy combined with durability has no equal, the cases of 18-ct. or 9-ct. hall-marked gold or sterling silver, centre seconds, quarter seconds, and flyback seconds. The finest work are the £100 repeaters by the above firm—work that can be relied on. Seeing the amateur will have more sense than to meddle with last mentioned style of watches, I need not describe them; many in the trade cannot do this class of work, but place it in the hands of those who make it a speciality. The English lever, with a steel or gold balance, having the fuzee arrangement to equalise the power of the main spring, will, by careful regulation, keep correct time to about one minute a month; and the English-going barrel without fuzee will keep time to a minute or so a week; some may claim more, but I speak fair on the subject.

To clean an English lever, open the front dome, push out the joint pin from the 10 o'clock side of dial, and the movement is then free from the cases; prise off the minute and hour hands both at once, then carefully take off seconds hand; undo the cap and draw out the three pins holding dial; remove dial wheels, as described in Chap. II., unscrew cock of balance, and mark the tip end of hair spring on top plate for a guide in putting together again; draw out the pin and spring, and place under glass cover. Now proceed to let down the spring by placing the key firmly on square of ratchet (dial side), and prise out the click, keeping firm hold of the key; observe a dot on top of barrel arbor and a similar one on the bar: take note of this and the relative positions in resetting the main spring again.

Another way we practise in the trade, but too difficult for the amateur, is to remove the bar across the barrel, keeping firm hold in your left hand; put your thumb on the barrel, take up a small screwdriver, place it in the hole of the cover of the barrel, then press the barrel back until you can unhook the chain, using the thumb before mentioned as a brake to gently let down the barrel (easier said than done); now keep it upright in its place as well as you can, seeing it has only one side to work on: have no fear and you will do it easier. Now lift the spring free from the maintaining power, and all will be right. Withdraw the pins holding the top plate to pillars, raise top plate gently so as not to injure any pinion, more especially the lever; see that it does not drop out unnoticed, as it is liable to do so; lift it out with tweezers. Now notice the parts and the sketch engraved to this chapter, so that you may easily understand the replacing of same. Take out each wheel, and notice the maintaining power near fuzee wheel; do not

lose it, as is too often the case. It is gone in many that come into my hands, and it must be through watchmakers' apprentices or careless men. The ratchet of main spring be careful to put away. Now clean plates, wheels, etc., as described in Chap. II.; hold every part in small squares of paper so as not to soil them in the slightest, the lever being better class work; tap the hair spring with the bristles of the brush, polish the steel or gold balance, peg-wood every pivot hole, and see no jewels are cracked or injured. A piece of clean cork cleans the pivots best, and in polishing plates, etc., keep the brush clean by drawing it over the prepared chalk. I would not recommend the main spring to be taken out and cleaned, but if you choose to do so, see previous chapter. All being clean and in good order, put in the third wheel, then centre wheel, next fuzee wheel and the maintaining power, then replace fourth wheel, and now the 'scape wheel; drop the least possible oil on the top fuzee pivot, place on the top plate, and press gently down, guiding each pivot. Having your eye-glass in position, examine if they all run clear and easy; if so, again gently raise top plate and replace lever pallets with the tweezers, bottom pivot first, and then press down top plate, and try if pallets move quickly by using moderate pressure on the fuzee wheel; now replace the barrel and its bars, of course holding the movement in clean paper; have its position so that the barrel is upwards and towards your right hand; now lift the hook end of the chain with tweezers and pass it under the pillar near the barrel and fuzee; hook it into its hole, which is near the small opening of the barrel cover. So guide the chain with your left thumb and gently wind with the key in your right hand until sufficient is only left under the pillar to hook it into its position on the fuzee part; next replace the small ratchet wheel, and set or turn the main spring up to the before-mentioned dots, which will be about half a turn; then oil the under plate, using very little oil, and slightly tip the pallet ends or two or three of the 'scape teeth; be sure not to use too much: this is the amateur's failing point. Now wind slowly up, guiding the chain into the grooves for the first time; unless you do so, it may miss, and so twist the chain that it will be permanently injured. Do not hurry over this or any part, in fact; some regular workmen will boast how quick they can take down, clean, and replace. Often these men have the work returned, and in the end it takes longer, besides annoying customer and master. Next oil all the top holes and replace balance, fixing hair spring to old position, as stated in former chapter; it should now be in full swing, with what we call a fine healthy beat; if not, some part is too tight or repair is needed. If so, see chapter to come on repairs, which will appear in due course.

If all right, try it under the glass cover four hours or so face downwards, and then if the beat is equal and all right, replace dial wheels, then dial, re-fix the three pins, and now replace the hands. Clean the cases well with rouge and chamois leather, and fit in the movement; push in the joint pin from 2 o'clock side, close up watch, and all is complete. Of course it will require regulating, as its going will be changed by the cleaning; move the regulator a very minute portion, using your eye-glass so as to have the greatest accuracy; it is worth the trouble. Many watchmakers only regulate them for hanging position in windows until called for, but they should be tried in several positions for good results.

AN ORNAMENTAL PLANT STAND.

BY CHAS. E. DODSLEY.

THE purpose of this paper is not to describe a plant stand which may be knocked together in a few minutes, but to show how, with a little care and at small cost, a stand for plants may be constructed—useful, ornamental, and unique—by any amateur in joinery, and, I venture to hope, be a new idea to some who are not amateurs. I take it that one of the primary aims readers of WORK, or, more properly, workers, should bear in mind is, "What is worth doing at all is worth doing well." To any who may be inclined to consider correctness in detail of secondary importance, the following stanza may be helpful :—

"In the elder days of art,
Builders wrought with utmost care
Each minute and inmost part ;
For the gods see everywhere."

The stand as shown in Fig. 1 is similar to one I have had in use now for some twelve months. It has proved very useful, and, as now filled with well-grown ferns, is a graceful decoration to the room.

So much by way of preface. The plan is reduced to one-sixth. As will be seen, it consists of a framework made in two parts: the lower one 3 ft.; the upper 1 ft. 11 in. long; each about 2 ft. high. It is fastened throughout by mortise and tenon, glued. This frame supports three

Fig. 1.—Ornamental Plant Stand, drawn in Perspective on Scale of one-sixth, or 2 in. to 1 ft. Alternative Designs in Fretwork or Splashed Work over Leaves for Panels.

shelves; the lower one, an open board from end to end. This was suggested to me as an improvement, and will prove useful, my own having simply a rail in place of it. The two upper shelves are made of bars, or rails, as being lighter. The panels are of thin wood as used for fretwork, and may be either splashed work over leaves (this I will describe in its turn) or fretworked, as shown in plan. A general idea will be gathered from the foregoing: now to set about the making. In the first place, what wood shall be used? Preferably, either walnut or oak. From a board 4 ft. × 10 in., and when planed 1 in. thick, all the pieces required for the framework may be cut. Care must be taken that the wood is thoroughly dry and seasoned. Mark out, as shown in Fig. 5, the letters corresponding with those parts in the plan. It will be seen that, though the board is 10 in. broad, it is only cut into nine 1-in. pieces. This will allow of the saw-roughened edges being planed so as to measure just 1 in. square. If preferred, the wood may be got ready cut and planed; though I think it more satisfactory to do it oneself. It will be better to make the framework in two portions, making all joints to fit exactly, that the parts may be fixed together and taken apart again as the work proceeds. Take the eight pieces 2 ft. long × 1 in. × 1 in., which will form the uprights or legs, A, A, A, A, and F, F, F, F. These must each be fashioned separately, but may all be placed together and marked out at once. Fig. 4 shows the marking on the bar, each of the eight being alike. At the lower end make a tenon $\frac{1}{2}$ in. deep, 1 in. long, × $\frac{3}{8}$ in. thickness, taking care that each is cut with the grain and not across. Above this a square base 5 in. long, then $10\frac{1}{2}$ in. to be formed into an octagon with equal sides. This will require to be done with a chamfer plane, the top and bottom being finished off with a chisel. Above the octagon, another square like the base, but $6\frac{1}{2}$ in. Each of these squares will have two mortises to receive the side and end bars. The knob at the top gives a finish, and is easily shaped. Above the square mark a $\frac{1}{2}$ in. space, leaving 1 in. to the top for the knob. On either side make two saw cuts across $\frac{1}{4}$ in. deep, and on the lines marking the $\frac{1}{2}$ in. space; with a sharp chisel hollow out, leaving a neck $\frac{1}{2}$ in. each side supporting a knob (as Fig. 3), with a square base, and a square cone with its apex cut off above. When the eight pieces are fashioned as described, take four of hem, and four pieces 7 in. long for bars, , C, and staves, D, D; also two bars 2 ft. 1 in., B, B, for the sides. At each end of hese pieces, with a fine saw, cut a tenon he same size as at the bottom of uprights—e., full breadth of wood $\frac{3}{8}$ in. thick and $\frac{1}{2}$ in. eep. The mortises in uprights to receive hese tenons will require to be 1 in. long, in. across, and $\frac{1}{2}$ in. deep.

t is hardly necessary to ay that the mortises should e cut just within the ieasurements of tenon hey are to receive, so hat when united a firm oint is formed. Much fter-finishing and fitting nay be avoided by taking ains that each measurement is exact; and all cuts, ither with saw, chisel, or lane, cleanly done to neasurements, this being nsisted upon throughout.

The mortises in uprights nust be made in proper rder, or a hole in the vrong side will result. The asiest way is to first fit he staves and end bars. Take the uprights, and 2 n. above the tenon and arallel to it cut a mortise, nd a second one in the op square $\frac{1}{2}$ in. above the ctagon. Unite the staves nd bars with the uprights, nd thus form two ends. Place them opposite each other, and on the inner sides mark the position where the long bars, B, B, will fit in at right angles to the ends. When these mortises are cut, it will be found necessary to cut a square out of one of the tenons at either corner to fit as shown in Fig. 2. The shorter stand forming the upper part is united in the same manner; G, G, and H, H, being jointed into uprights; F, F, F, F, as described above, only in this case there are no staves. Care must be taken that the side bars in this case are fixed in the same line as tenons of the uprights, and the end bars at right angles.

It will be noticed that throughout the sizes of mortise and tenon are the same in each case. If desired, a square tenon might be made with $\frac{1}{2}$-in. side, but the size I have worked to entails less trouble, and if the

Fig. 3.—Top of Upright with Knob.

Fig. 4.—A, View of Upright as marked ready for cutting; B, Lower View when cut and finished.

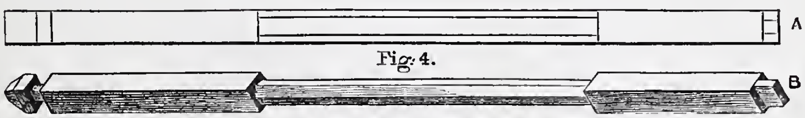

Fig. 4.

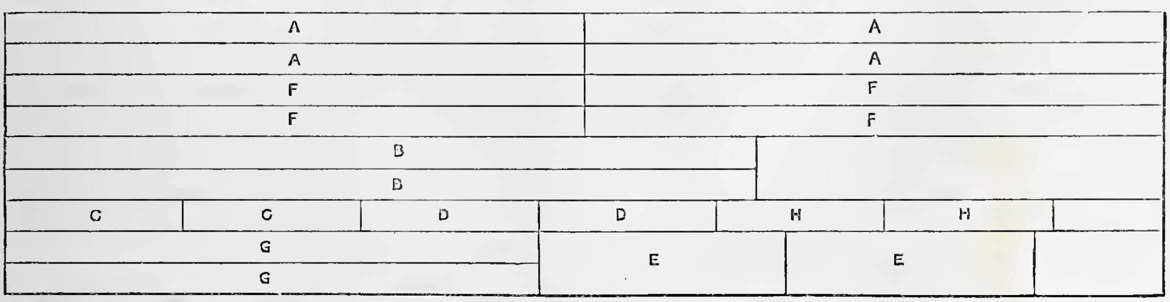

Fig. 5.—Board Marked for cutting all the Pieces for Frame of Plant Stand. Drawn to one-eighth Scale, or $1\frac{1}{2}$ in. to 1 ft. Length of Board, 4ft.; Breadth, 10 in.

mortises are carefully cut, is stronger and quite as neat.

For the feet take two blocks, E, E, and fashion them thus:—In each piece cut two mortises 6 in. apart, 1 in. from either end. Then 3 in. from the ends mark a line across, and from either side of the intermediate space cut a strip $\frac{3}{8}$ in. broad. From each of the four corners of the end pieces thus formed cut a triangular piece, the equal sides being $\frac{3}{8}$ in. Then from the upper edge plane a facet at an angle of 45° the whole way round. Fix the lower stand to the feet thus made; place the top half of stand in the position it will occupy, and mark exactly where the mortises must be made. By doing this a more correct fixing is secured, preventing the danger of any of the parts being thrown out of square when fixed.

We have now in an unfinished state the principal part, in that upon it all the other depends; but without the remaining parts this would be of no use. If cost is to be curtailed, the bottom board may be of pine, stained; as it is below the level of the window, when in use not much of it will be seen. A board 2 ft. 11 in. × 8 in. × $\frac{1}{2}$ in. will allow of any shaped shelf being substituted the worker may desire for the one in the plan. At each end make two tenons 1 in. × $\frac{1}{2}$ in. × $\frac{1}{2}$ in., and 2 in. apart; then make mortises in each of the staves to correspond; that will leave 1 in. at each end of the staves. Lay the board flat, and at a distance of 4 in. from each end mark a transverse line. On each side within these lines cut off a piece 1 in. broad. We now have a board 2 ft. 10 in. long, each end 8 in. broad; the intermediate space 2 ft. 2 in., 6 in. broad. From each of the end oblongs, cut off a triangular piece, as was done with the feet, but now the equal sides being 1 in. Now fashion the length of each side edge with three facets of equal breadth. For the upper shelves six rails will be required, each 1 in. broad, $\frac{1}{2}$ in. in thickness; three for the lower shelf, 2 ft. 11 in. long; three for the upper one, 1 ft. 10 in. long. These are fixed into the end bars at an equal distance apart, leaving $\frac{3}{4}$ in. space between. In each of the end bars make three sockets, 1 in. × $\frac{1}{2}$ in. × $\frac{1}{2}$ in. and $\frac{3}{4}$ in. apart to receive the ends of rails. The brackets beneath the middle shelf are not absolutely necessary, but besides affording extra support and firmness, they give a finish to that part. The four brackets may be made from one of the pieces cut from the lower shelf. Cut four pieces each 4 in. × $\frac{1}{2}$ in. × $\frac{1}{2}$ in.; then take each one singly, and with a sharp knife or chisel, form an octagon in the centre $1\frac{3}{4}$ in. long; then make a mitred joint at each end. These brackets, if glued one end below the long bar, and the other to the leg, and firmly fastened with a long thin screw, add a graceful finish, and render the joints perfectly secure.

Now we come to that part which I always regard as the most tedious and troublesome—viz., smoothing with glass paper previous to polishing. It is well to have three sizes of glass paper handy, Nos. $1\frac{1}{2}$, 1, 0. First rub every piece smooth with No. 1; if any unevenness use $1\frac{1}{2}$ to rub down; then finish all off with the finest. Care must be exercised in smoothing edges and angles to avoid rounding the corners. The more pronounced the angles the greater the beauty of the whole when finished. It is unnecessary for me to describe the process of polishing. The pieces may be polished separately before being put together; and where polished pieces are to be glued, the polish lightly scraped off at the time. To put the stand together, first unite the two ends of lower part, securing them in the feet. Take the bottom board and two long side bars; fix them to one of the ends, and placing the other end in position a few sharp blows with a mallet will secure it. Unite the upper part in the same manner. It will be better to allow the glued joints to become quite set before fixing the upper part upon the lower, and then the brackets as before described; lastly, fixing the rails, which must be glued and secured with a screw at each end.

If the plants have been waiting for a suitable stand, they may now be shown to full advantage, until the panels are made. The panels are of equal height, $5\frac{1}{2}$ in., and $\frac{1}{8}$ in. or $\frac{3}{16}$ in. in thickness. Twelve in all will be wanted as follows:—Four, each $5\frac{1}{2}$ in. long; four, each 6 in.; and four, each 1 ft. 9 in. If the frame is walnut, the panels will form a pretty contrast if made in oak, or *vice versâ*. Every one may not know how the splashed work mentioned in the earlier part of this paper is done. A number of small leaves will be required. Those which have a fine crenate or serrate margin, as rose or birch, or the pinnate fronds of ferns are the most suitable. They must be carefully pressed and dried previous to being used. The panel, being well smoothed with fine glass paper, should have a thin coat of linseed oil rubbed over and allowed to become quite dry. Lay the panel flat, and arrange the pressed leaves as desired, but not overlapping each other, and pin them in position. For splashing, a fine-tooth comb (horn will do) and a tooth brush will be necessary; also some burnt umber ground in water, and a little old beer or a weak solution of potash (about a teaspoonful of liquor of potash to an ounce of water), to mix the colour with. Take a little of the colour upon the brush, by dipping it first into the solution and then upon the colour; draw the comb lightly but quickly over the bristles, holding the brush almost perpendicularly so as to throw the splashes upon the board. It will be better to practise upon a piece of paper first, for the knack is easily acquired. Make the splashes thickest, and therefore darkest, over the leaves, shading lighter and lighter to the edges of panel. When quite dry a thin coat of pale varnish may be applied. If the frame be of oak or light wood, the panels may contrast in dark, in which case the splashing would not answer. If fretworked, in which case more time would be required, each panel might be of a different design, or the long ones one, and the short ones another, as the worker may desire. I give (Fig. 1) a design such as is suitable for either of them. If the panels are made in fretwork, they should be carefully finished off and polished like the rest of the stand. The panels are fixed in slots, formed by fixing a narrow beading in front to the uprights at either end of the spaces, and a similar one at the back, allowing of the panel being easily slid in or out. The front beads should be just to the height of square—that is, 5 in., and flush with the edge. They are glued on, and fastened with very small brass or black nails.

OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

107.—Snaith's Patent Pin and Barrel for Pianos.

Mr. Thomas Snaith, Engineer, 20, Swarthmore Terrace, South Stockton-on-Tees, sends a model exhibiting the mode of appliance of his Patent Pin and Barrel for Pianos, and the Double Key that is used in order to screw down the pin and bring up the string to the required tension. Mr. Snaith regrets to say that he has not been able to induce pianoforte manufacturers to take to his invention. This, however, is no argument against its being a "good thing." The difficulty lies in the manipulation of the double key, which, to say the least of it, is very puzzling at first, because, in order to tighten the string, the outer key is used, and is turned one way, while, to fasten down the pin, the inner key is used, which is turned in the contrary direction. It took me some little time to comprehend and accomplish

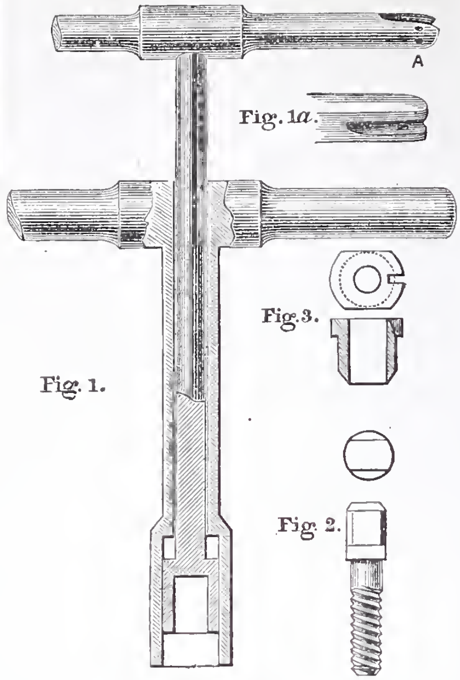

Fig. 1.—Double Key to fit Pin and Barrel with Provisions at End for Bending End of String to fit Barrel. Fig. 1a.—End, A, as seen from above. Fig. 2.—Screwed Pin with Left-hand Screw. Fig. 3.—Barrel with Notch for Strings.

the working of the double key, but when this has been got over, facility in its use will soon be brought about by practice. The engravings show very clearly the nature and use of the pin, barrel, and double key. Fig. 1 shows the double key to fit pin and barrel. In this, as will be seen from the illustration, one key works within the other, the inner and smaller key fitting on and turning the screw shown in elevation and plan in Fig. 2, and which passes through the barrel shown also in plan and section in Fig. 3, this barrel being turned by the outer key, and,

Fig. 4. — Wrest Plank, with Pin and Barrel in Position.

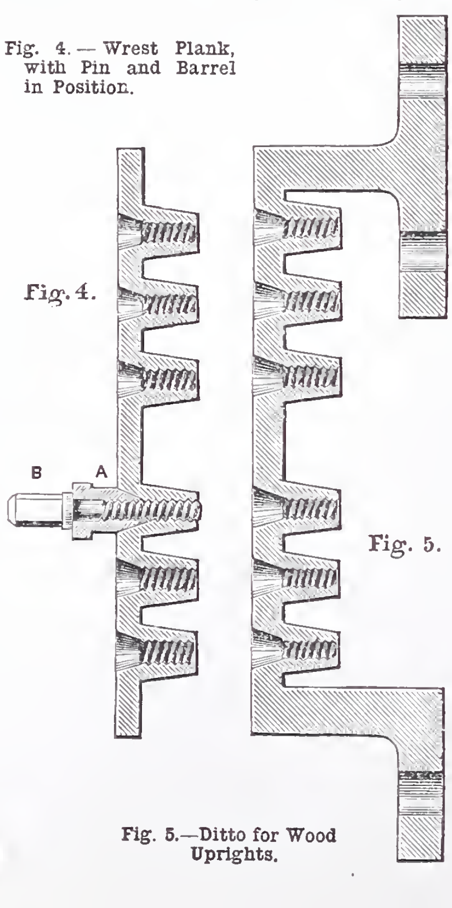

Fig. 5.—Ditto for Wood Uprights.

when turned, tightening the string or wire, the end of which is bent and fitted into a notch that appears on the right of both plan and section in Fig. 3. The right-hand end of the handle of the inner key in Fig. 1 is notched and perforated to afford ready means of bending the wire, as shown in the illustration. Fig. 1a is a view of this end of the handle seen from above. Fig. 4 shows the wrest plank with a barrel, A, and pin, B, in position. Fig. 5 shows a suitable form for wood uprights. Fig. 6 exhibits the arrangement of pins and barrels in wrest plank by means of a top view. When pin and barrel have been placed in position, as shown at B and A, Fig. 4, and the string has been properly attached to the barrel, the key is applied so that the outer part fits over the barrel, and the inner part over the pin. It will be noticed, on reference to Figs. 4 and 5, that the wrest pin is pierced to receive both pin and barrel, the conical end of the barrel fitting into the coned hole countersunk in the brass plate for the purpose of receiving it. The barrel moves freely in this conical depression, and is only fixed when the pin, which passes

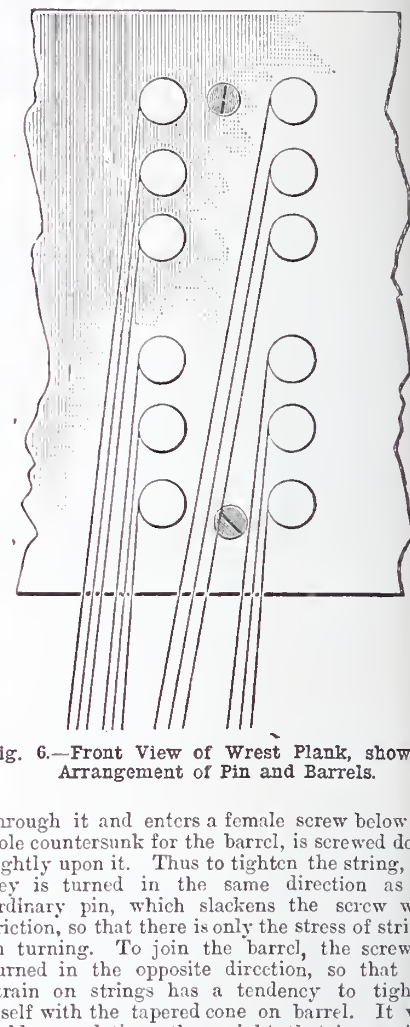

Fig. 6.—Front View of Wrest Plank, showing Arrangement of Pin and Barrels.

through it and enters a female screw below the hole countersunk for the barrel, is screwed down tightly upon it. Thus to tighten the string, the key is turned in the same direction as an ordinary pin, which slackens the screw with friction, so that there is only the stress of strings in turning. To join the barrel, the screw is turned in the opposite direction, so that the strain on strings has a tendency to tighten itself with the tapered cone on barrel. It will hold several times the weight that is required for pianoforte strings. The invention can be applied to iron frames as well as to wooden ones. Readers requiring further information, prices, etc., should apply to Mr. Snaith at the address given above.

As I have just intimated, I do not know the prices put by Mr. Snaith on his pins and barrels in the first place, and on his double key in the second. In all novelties of this kind, involving a departure from the original mode of going to work and the nature of the appliances used, much depends on whether or not the new appliances are cheaper than the old; and cheapness, other things being equal, constitutes a powerful lever to raise them into favour. I fear, however, that the new pin and barrel, etc., are not cheap.

The Editor.

SHOP:

A Corner for Those who Want to Talk It.

*** Notice to Correspondents.—*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

I.—Letters from Correspondents.

Pit Frame Saws.—Pit Frame writes in reply to G. W. (*Bournemouth*) (see Work, No. 21, page 322):—"No doubt you will be surprised at my not answering your queries before, but the fact is I have only just seen them in September's monthly part. If you will look at the title page, you will see for whom these articles are written. The frame described in No. 15 is capable of having large and heavy 4 and 6 in. tired wheels both for lorries and carts. We frequently make them upon ours. Yes, when having my holidays, I have been in good shops both in London, Edinburgh, Glasgow, and in large towns in England, and I have invariably found the frame described is fast superseding the pit. You ask, 'is it intended for amateurs or "pros," as not one in five hundred will undertake such laborious ill-paid work as wheeling.' Indeed, who makes the wheels then? You also say that 'French prepared wood, etc.' This is indeed news to me, as all the prepared wood I know of comes from America, large cargoes of boxes packed with machine-dressed spokes, naves, and even wheels. The set-stick is fixed at the front of the nave, and in the centre with set screw should work about stiffly. Small holes are bored every inch between half-way down the stick from the top. A piece of whalebone is plugged through so far as required for 'dishing' the wheel. The way of securing the nave does not weaken the frame in the least. Evidently you have never seen or used a frame like this before (hence the advantage of taking Work in), so please just make one and have it made strong, so that it will not spring at every blow, as you are afraid it will. You say you could send a sketch of a cheap, simple, secure fastening for nave. By all means please send it, as we are not above learning off brother workers, and I think it would have been better had you sent it at the first instead of querying. I don't know whether you are an amateur or a 'pro,' but I am sure that you must be clever when you made three carriage bodies (carriages not specified) 'with nothing but a piece of hand-saw.' Are you your own master, or were you working for someone? If your other tools are on a par with your piece of saw, I don't wonder at you being disgusted with wheeling, therefore I think the sooner you keep pace with the times the better."

Pen for Dotted Lines.—W. R. R. (*Carlisle*) writes:—"I notice in 'Shop,' Vol. I., No. 31, page 492, a very flattering mention of a pen for ruling dotted lines. Allow me to inform your correspondent, H. C. S. (*London, S.E.*), that he is very late in the field, as I have made and used such an invention for over ten years. Like your correspondent, I am in the same fix *re* 'patenting and its multitudinous costs.' I have several ideas and rough models of self-inking pens for artistic purposes and marginal work, only awaiting some enterprising firm to take them up. I, too, would be glad of your advice, which is of such sterling quality to amateurs. Work is one of the best and cheapest papers extant for assisting the youth of the country in this technical age."

Heating Soldering Irons.—C. P. (*Wanstead*) writes:—"Seeing in the 'Shop' column, page 494 of Work, a paragraph headed 'Heating Soldering Irons,' I should like to give my experience upon the use of oil stoves for that purpose. I had long wanted an oil stove for soldering with, as I have so many small jobs in the summer which are not worth while lighting a fire for, and cannot use gas without a little inconvenience. Having by me a stove called the Beatrice with 4 in. cotton, I thought I would try an experiment with it, so I took the tulk out in front, which left room for two irons to go through to the flame, but to my great surprise as soon as I lit it it began to smoke. I could not turn it up sufficiently to get my iron hot, and the light bobbed up and down, which I think was on account of the tulk being removed. Therefore I replaced the tulk in front and substituted a piece of strong wire twisted so as to hold the iron in place, and let it down from the top of stove nearly to the flame, and I find it answers very much better, but there is still room for improvement."

An Easily-Made Fret Machine.—W. R. S. (*Brixton*) writes in reply to One in a Fix (see page 492):—"No doubt some time before you see this you will have read my reply to Anxious and Mancunian on this subject. I might add that if you live or are at any time near here (Brixton, the Editor has my address) I shall be pleased to show you the machine, from which I think you may get a better idea than from reading pages of instructions. Please let me know if there are any other points on which you require information, and also if you are successful, which I trust you will be."

Prize Competition.—The Editor of Work takes this opportunity to inform A. L. (*Hull*) and other readers of this Magazine that it was found impossible to give in No. 30 engravings of the prize bookcases that would be generally useful to workmen, and creditable as interpretations of the work of those who designed them. The designs with suitable descriptions will be issued in the course of the present volume.

Lathe for Wood.—H. A. (*London, E.C.*) writes:—"In No. 28 of Work, page 444, Stoker gives his opinion of Work, which I heartily endorse, and he tells us how be made, at a very small cost, a lathe for turning wood. I should be extremely obliged to Stoker if he would send particulars of that lathe. I have got a lathe wheel 21 inches in diameter, with crank, and a bit of a framework; it had originally been a jeweller's polishing lathe; the crank is about 16 inches long. If Stoker will kindly give me a few hints how to make it into a turning lathe, he will greatly oblige."

Pinhole Photography.—C. H. C. (*Strand, W.C.*) writes:—"I read with great interest an article in a recent number of Work on pinhole photography. I can add my testimony to that of the writer as to the clearness and good general effect of a photograph taken by this method, under favourable conditions. I recollect how much I was impressed once at a lecture given by Mr. Hepworth on elementary photography. Amongst others he showed on the screen (by limelight illumination) an image—at least 12 feet in diameter, I should think—projected from a slide of the usual size. The picture was of a statue; as far as I can recollect, of some great admiral, in one of our southern seaport towns. It came out beautifully clear, in spite of the loss that necessarily accompanies enlargement, and

I was never more surprised before than when I heard it was taken through a pinhole, the camera being an ordinary chimney-pot hat. I have only one suggestion to make; and that is, that better results, sharper images, etc., are obtained by having a hole perfectly clear from 'burr' round its edges. The writer recommends a visiting card as a good thing. A hole in such a surface, though, could scarcely be free from the above-mentioned defect. A better arrangement still, to the best of my belief, is that told me at a scientific society's meeting by a man who has practised the art a little. It is simply to substitute a thin sheet of copper, to repoussé a small part of it with a blunt point, and then finally make the hole in the thin part thus obtained with a fine pointed needle. The diagram which I append may possibly make things clearer.

II.—Questions Answered by Editor and Staff.

Saw Hammering.—T. O. (*Bootle*).—If any saw hammerer will make himself known to me, and offer to write on matters connected with his trade, I shall be pleased to arrange with him for such a paper as you require, but at present I am without a contributor on this subject, and am not acquainted with any one who could or would write on it. I am sincerely obliged to you for saying you would like Work to be twice the size and pay twice as much for it, but I fear all readers would not be of your opinion. It is true that there would be twice as much room for "Our Guide to Good Things" and "Shop," if the doubling system were entered on, but how about my time, which is pretty well taken up with Work as it is? Could you manage to insure me 120 minutes to the hour?

Turned Trellis Work.—H. C. T. (*Gateshead*).—On comparing the patterns of trellis work sent, you will see that they are so very much like those supplied by C. H. O., and have so much in common with them, that it will not be worth while to publish them in Work. C. H. O. explained that there could be but little divergence from the beaten track in this matter, and you will easily see this on consideration. As I have already explained, novel arrangements might be effected by the combination of blocks (*i.e.* flat pieces of wood in various shapes, such as triangles, squares, diamonds, hexagons, etc.) with turned spindles, but not with turned wood alone, at least I think not. When you have any decidedly original pattern let me have it, and I will publish it, and kindly let me have your name and full address that I may have it in my power to communicate with you if necessary.

Electric Pin.—H. E. (*Leicester*).—Those small scarf pin lamps are a speciality in incandescent lamps, and are sold under the names of "Gem" lamps and "Fairy" lamps. The lamps are lit with current from a small chloride of silver battery. If you can call on Messrs. T. Gent & Co., Braunstone Gate, Leicester, they will probably be able to show you one of the lamps, and instruct you how to fit it to a scarf pin. I see from their catalogue that they also sell a small lamp for special use in dentistry and surgery. I consider the chromic acid single-cell battery the most constant and powerful for your purpose in feeding a small lamp of from $2\frac{1}{2}$ to 5 c.p.—G. E. B.

Alarm Contact for Mat.—A Subscriber (*Stalybridge*).—An illustrated description of door-mat contacts is given in my sixth article on Burglar Alarms. I think this will fully meet your requirements.—G. E. B.

Battery for Induction Coil.—J. Prince.—A pint Bunsen, bichromate, or chromic acid cell is quite large enough to work a coil $4\frac{1}{2}$ in. long by $1\frac{3}{4}$ in. diameter. The number of cells required will depend upon the size of wire used in the primary coil. If No. 18 or 20, perhaps it will take two or three cells in series to fully develop the power of the coil.—G. E. B.

Tinsmith (*Great Grimsby*).—An article upon the construction of self-acting fountain is in hand, and will be published as soon as possible.—C. M. W.

Brazing and Coppersmith's Work.—J. A. (*Grimsby*).—Papers on these subjects will appear as soon as space and opportunity permit. Thanks for your good wishes.

Fronts for Bird Cages.—J. S. (*Coatbridge*).—I am not aware that fronts for bird cages are sold anywhere. At any rate I have never seen or heard of such an article being on sale. The material for cages, as far as wire is concerned, can be purchased, I should say, at any ironmonger's or wire worker's.—O. B.

Fixing Tortoiseshell.—W. J. M. (*Liverpool*).—Tortoiseshell can be fixed together by first filing the edges with a rasp, and then lapping one well over the other; you note that they are to lap, and are not to be placed with simply their edges touching. Then soften both the edges in boiling water, and when the surfaces are soft, place them together and grip them in the vice; but as you say it is for repairs that you want to know, I should advise you to be very careful how you apply the heat, or else you will find that your work has warped considerably.—H. S. G.

Ivory Stains.—W. J. M. (*Liverpool*).—Time stains can be taken out of ivory only if they are not very deep. You will have to remove the very outside of the surface with ground pumice stone and water; then place it in the sun under glass, and try that several times; then if it fails, try a wash of water, 10 parts, and nitric acid 1 part. There is yet another way used to bleach knife handles in Sheffield, where peroxide of hydrogen is the agent, but I don't know of this from any personal experience. If you have pumiced it, then to bring it back again to its former surface, rub it well with whiting and vinegar, or very weak vitriol and water and whiting.—H. S. G.

Soft Steel Solder.—W. J. M. (*Liverpool*).—Is it possible to soft solder steel? Of course it is, provided that you get your work perfectly clean—scraped clean I mean. Then brush the parts that are to come into contact over with chloride of zinc (perhaps you know it under one of these names—killed spirit, soldering solution, soldering acid, or soldering water, fake, etc.; there are any number of names given to it). After brushing it over with the solution, make it hot enough to drive off the moisture, taking care not to smoke, or in any way make the surfaces dirty; now, while it is hot, try and get your solder to hold on; if it will not, add a little Venice turpentine, and use the copper bit. It is a matter of proper application of heat and cleanliness chiefly. When you have it tinned all right, then tie your surfaces together, using a little Venice or solution as flux. Then blow at it, and add solder if necessary; if you do this you will be sure to get your work out all right and soundly soldered. Generally, merely brushing the surfaces with solution and drying them before tying them together goes all right, if your hands and all your soldering articles are clean and free from grease. I have found myself that it is best to use a spirit lamp instead of gas, it is so much cleaner.—H. S. G.

Loose Letters Tray.—G. H. P. (*Stourbridge*).—In reply to your query, the tray requires two pieces 2 and 2 A, two pieces 3. Each of these pairs to be cut in reverse—*i.e.*, one piece of each cut as the pattern, and one with the design reversed. One piece of Figs. 4 and 5. The reason why it is best to cut in reverse is that with a hand saw the two surfaces are not exact facsimiles, and therefore would show a right and wrong side in making up. If you use a machine saw the objection is less.—E. B. S.

Dimensions for Dulcimer.—J. A. (*Barrow-in-Furness*).—The dimensions for a D dulcimer, which is most suitable for playing with other instruments, are as follows:—Width at bottom, 2 ft. 10 in.; width at top, 1 ft. 4 in. Depth from back to front, 1 ft. 4 in. The best wood to use is beech for blocks and bridges, white or yellow pine for belly, redwood deal for back, braces, inside bridges, lining blocks, and top and bottom facings. Sound-hole frets are made of mahogany or any fancy wood.—R. F.

Parchment.—Drennan (*Kilmarnock*).—Before quoting the information relative to the supply of vegetable parchment, I wrote to Messrs. Barker and to Whiteley's, Westbourne Grove, who each quoted it to me as in ordinary sale. There should be no difficulty in procuring it. Wholesale chemists, I know, regularly supply it, and the jam pot covers sold everywhere are a more common variety of the same stuff. It is so infinitely superior to any substitute that it is worth while to be quite sure where it can be easily bought, and if I succeed in purchasing any I will make the result public in these columns.—E. B. S.

Wax.—Constant Reader (*Manchester*).—Although unable to bring any special knowledge or experience to bear upon the question submitted, I am inclined to believe that if, as I understand your letter, the sample of German work sent is such as you wish to get yourself, some composition of the nature of plaster of Paris is that which you must fall back on. In the first place, the colouring process requires a white and absorbent article, otherwise you might experiment with celluloid. This is an ivory-like preparation by which paper, camphor, and acids produce a substance which can be moulded into the most delicate forms, becoming hard when cold. It can be made pliable by soaking in methylated spirit, and is highly inflammable. I think, however, you must try the former composition, and scarcely see why the wax and plaster will not hold together. Is the wax all right? Perhaps the plaster you use is too fine, and sets with too smooth a face, in which case mix a little fine sand to keep a rough face, and thus provide a grip for the wax. Plaster might work more easily if gauged with weak size-water; it would give more time for manipulating. Whiting mixed stiff with strong clear size might be useful, but mixed with glue would be too impure for your tints. I expect that material in general use for your purpose is some composition obtained by trade experiments and practical experience.—F. P.

Jeweller's Soldering.—W. J. L. (*Jersey*) wants to know what hard solder to use to solder a diamond in with, and what will prevent it burning.—For solder, ordinary silver solder will do very well. This he can buy at any jeweller's material shop or refiner's for about 3d. per pennyweight. He need have no fear of burning his diamond, if he carefully paints it over with borax (ground up with water on a clean piece of slate until it is as thick as cream). This being the flux for the solder, it can be applied with the camel-hair pencil at the same time that he places his pieces of solder on the work. Now apply heat enough to properly flush the solder. Never mind about the colour the diamond becomes, but on no account quench it suddenly. It must be left to cool by itself gradually. When it is cold it can be boiled out in "pickle" to get rid of the borax. The diamond will then appear just as it was originally—not damaged in any way, unless there should be a flaw in it. Then that might possibly cause a fracture, but I myself have put some dozens through the fire, and so far without accident—so much so that I should not at all hesitate in this case if I had to do it. so W. J. L. can go ahead without fear. See that your work and your solder is scraped clean, and that your borax is also clean. "Pickle" is about 1 part oil of vitriol (sulphuric acid) and 40 parts water.—H. S. G.

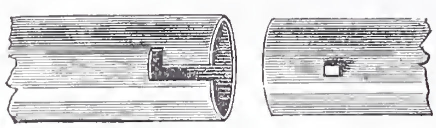
Desk.—W. H. (*Stockport*).—You ask for directions about making a good strong desk, but you have omitted to state the kind, so that I am unable to help you at present. Perhaps you are not aware that many different contrivances go by the name of desk. For example, there is the small portable form which folds up, and the large high clerk's desk. If you will be good enough to state your wants more fully, we will see what can be done to help you. Meanwhile it may interest you to know that papers on both the above-mentioned desks are on my list of subjects, and will be treated as soon as practicable.—D. A.

Camp Table.—J. A. B. (*West Ham*).—It is not possible to give the construction of a camp table within the limits of "Shop." It may be of some assistance to you to know that almost any table which can be folded may be roughly classed as a camp table. There are many arrangements by which the necessary portability can be attained. Perhaps the most general form is that in which the top is in two parts hinged together and attached to folding trestle legs. From the things you wish the table to hold I am by no means sure that you have not described it wrongly, and that what you really want is not a table but a stand of some kind. You might try Silver's in Cornhill, Pound's, or Goy's in Leadenhall Street. The work you name will receive due attention, but it is not so much required as some others which are of interest to the majority of readers. Ask anything you want to know about plumbing, and no doubt some member of the staff will be able to assist you.—D. A.

Bunsen Battery for Induction Coil.—V. R. (*Liverpool*).—(1) The break hammer for an induction coil 9 in. in length by 4 in. in diameter, with a core $\frac{3}{4}$ in. in diameter, may be made out of a disc of iron from $\frac{3}{8}$ to $\frac{1}{2}$ in. in diameter, and $\frac{1}{8}$ in. in thickness. This may be cut off the end of a soft iron rod with a hack saw, and riveted to the spring by means of a small brass rivet. (2) If you want a powerful battery to work the coil for two hours a day only, and then set it aside ready charged for the remainder of the twenty-four hours, do not use a Bunsen, which will require to be taken to pieces when done with, and set up again when wanted. Of course the same charge can be used several times if you follow the directions in my article on this subject. But I advise you to use a single fluid bichromate battery with lifting arrangements for the elements, as advised to J. R. for his electric light. Six cells would, I think, be too much for your coil. Try two at first, and increase the number if you require them. (3) $\frac{3}{4}$ in. is quite large enough for square of carbon. (4) Fill each cell to within $\frac{1}{2}$ in. of the top. (5) Do not put any mercury in the porous cell with the carbon block. A little in the outer cell with the zinc is useful.—G. E. B.

Worms in Wood.—R. J. W. (*Norwich*).—These are difficult to eradicate sometimes as they often arise from the use of improper wood, or wood which has not been properly seasoned. In this case, as the cause lies within the wood it is constantly liable to bring forth more. The worms you refer to seem to be of unusually large size. Are you sure they are not the grubs of some moth which may have found their way in? The best way to eradicate vermin in woodwork is to wash it thoroughly with naphtha or benzine, the latter being, perhaps, the better of the two. Of course you must well saturate the infested parts, as mere superficial washing will not do. Other substances are sometimes used, but if you can't manage with one or other of those named, I am afraid you must give it up as a bad job, or else submit the chairs to an experienced cabinet maker. He would, probably, be able to detect the cause or kind of worm from slight indications which, if you are not a cabinet maker, it is easy to understand might escape your notice.—D. A.

Fishing Rod.—C. H. (*Stockport*).—I almost fancy that one of the Japanese so-called walking-stick fishing rods would suit your purpose. They are light, fairly strong, and very portable. Of course they are no use for large fish, but, from your asking about a bamboo fishing rod and stating that you take long walks, I suppose you want something which can be carried without inconvenience. No doubt you know that these rods are made of a kind of bamboo, and that the pieces being hollow they may be enclosed in each other, the thick or handle piece being the outermost. These rods can be bought for much less money than you could make one. To describe the construction of a bamboo rod such as you could make for yourself without much outlay would require more space



Bayonet Catch.

than can be devoted to the subject just now in "Shop," but the following few hints may be of assistance to you till the subject can be treated at length. The bamboo can be got from Mr. Westbury, Great Dover Street, Borough, London. Either one piece of suitable length must be got and cut into convenient pieces, or you can get several short pieces. Effect the connection by means of wooden pegs fitting tightly into corresponding pieces, if necessary binding the ends of the bamboo, to prevent it splitting, with fine brass wire or even waxed thread. You can also adopt the method of fastening the pieces together by means of a bayonet catch, which I think will be sufficiently explained by the diagram. This joint may be easily formed of thin brass tubing, and is suitable for rods of bamboo or solid wood.—D. A.

Book Backs.—R. M. (*Hyde Park, London*).—To repair the book which has the back off, proceed in the following manner. Take the book and gently strip off all the previous lining from the back, and wash the back with warm water until all the old glue is cleaned off. Procure two pieces of paper, for end paper to the book. They may be white or coloured according to fancy; cut them twice the size of the book, and fold in the centre. If coloured, the coloured side in; paste them down the fold with flour paste (using the fingers) about $\frac{1}{4}$ in. broad, and place them carefully on the book, the fold of the paper flush with the edge of the joint—*i.e.*, the risen-up part of the back of the book. Rub the paper well into the joint, taking care not to cut or tear it any way. When these have become dry put a nice coating of warm thin glue over the back of the book, and allow it to dry. Now get a piece of thin calico or muslin, cut it the length of the book, and about two inches broader. Glue the back again, and lay the cloth on, allowing it to come over equally on both sides. Leave aside to dry after rubbing well to insure the cloth sticking to the back. In the meantime take the back, or as it should be termed the case of the book, and clean off any torn or ragged bits of the old paper or lining still adhering to it. Now take the book and fit it into the case, taking care that the front of the case and book agree. This done, open one of the boards of the book, and with a paste brush paste the end paper and the piece of cloth overlapping from the back; shut the board, turn over the book, and repeat the pasting up on the other side. Put it into a press, or under heavy weights, until dry. If this has all been properly done the book will be as firm as ever it was. I have given the *modus operandi* for repairing a book in the condition assumed from your description. If I have omitted anything or misunderstood you, if you write again as explicitly as possible, I will be glad to help you still further. I would have liked to have known if your book is half bound or full bound in cloth or leather.—G. C.

Fret Machine.—G. W. J. (*Sheffield*).—As you are able to get a straight cut with large saws, I presume the machine itself is all right, for I daresay you are aware that the saw clamps sometimes need adjustment. Very small blades are always more difficult to work with than those of larger sizes. There is such a small amount of metal that any irregularity in the wood has a great tendency to deflect them. Possibly, though not probably, you have got hold of a bad lot of blades, some of which have an undoubted bias towards one side or the other. It is rarely, however, that you will find many in a batch which are defective, and I am inclined to think that your want of success is either owing to your not having sufficient experience to enable you to use very small blades, or what is much the same thing, to your having endeavoured to cut stuff which is too thick, and therefore unsuitable for them. Suppose you try cutting a piece of veneer with as little variety as possible in its texture. Saw across the grain, and see whether the cut is deflected. Are you quite sure that you feed the wood to saw direct without any lateral pressure, and that you have the right amount of tension? Unless you have this latter, which, of course, cannot be as great with a small blade as with a large one, you must not expect to be able to cut to a line whatever the size of the saw may be. If you are doubtful about the quality of the blades you are using, and like to enclose two or three of each size, I will test them on a thoroughly reliable machine, and say what I think of them, in these columns. If you are a beginner, let me, however, advise you not to use very fine blades, say, nothing under No. 1, yet awhile. With a No. 1 or 2 even the finest work can generally be done, and unless you are a thoroughly skilled worker it is a mistake to use the thinnest blades. Practical marqueterie cutters seldom do so. If you are trying them for inlay purposes, as I suppose you are, remember that thicker blades can be used, without the joints showing more, by increasing the tilt of the table. I hope these few hints may assist you, though it certainly would have been a guide to me in advising you if you had stated the thickness and kind of wood you have been trying to cut with Nos. 00 and 000. With regard to overcoming the noise of which you complain, I fear I cannot assist you. Machines with movable wooden arms are more noisy than those with perpendicular movement, and I think it very likely that the noise of yours is no more than might be expected. If it is a new machine it may work more quietly after it has been used for a time. Perhaps lubrication may lessen the noise, as it probably will if this is of a creaking kind. If it is merely what may be called rattling of the parts together, you must decide whether it is only natural to the machine or is caused by defective screwing up. Were I to hear the machine I could soon tell you, but as this is impossible do the next best thing, and get a machinist, or someone accustomed to fit machines, to test it. Before doing so, it will, of course, occur to you that very little machinery of any kind is absolutely noiseless.—D. A.

Medical Battery.—W. E. (*Bath*).—There is a great deal of delusion and misconception afloat just now respecting the properties and virtues of so-called medical batteries. As a fact, batteries in themselves have no effect whatever on the human frame, either curative or otherwise. It has been proved by Dr. W. Stone that the human body presents a resistance of 1,320 ohms. Suppose, now, as you propose, we take a Leclanché battery of 40 cells, connected in series; the E.M.F. of each cell will be 1·60 volts, and the internal resistance of each cell will be 1·13 ohms. Now let us see what current you will be likely to get through your body by grasping the two poles of this large battery. We get the result by multiplying the voltage of each cell by the number of cells, and dividing this by all the resistances of the inner and the outer circuit. It stands thus:—

$$\frac{40 \times 1{\cdot}60 = \ 64 \text{ volts}}{40 \times 1{\cdot}13 + 1320 \text{ ohms}} = {\cdot}00468 \text{ ampères.}$$

I do not think this small quantity of current passing through your body can do you any good. The only result to you will be that you will be relieved of your surplus cash, for the battery will cost alone not less than £5. As you say that your purse is not a long one, in your interest I advise you to have nothing to do with medical batteries. Electricity can be applied as a remedial agent in some forms of disease, but its scope is very limited. When adopted as a remedial agent it is applied generally by means of the induction coil worked by a small battery, and this is named a medical coil, not a medical battery. It is sometimes useful in relieving neuralgic pains, in stimulating the nervous system deadened by partial paralysis, and in eliminating poisons from the body by electrolysis. If you will kindly tell me your ailments I will advise you with pleasure how to act to obtain relief, if electricity is needed at all.—G. E. B.

Gold Bath.—A R. (*Ipswich*).—To get a uniformly rich deposit of gold from an electro-gilding solution, it should be maintained at a standard richness, which may be anything from 15 dwts. to 2 oz. of gold to the gallon of solution. That is to say, if 15 dwts. of gold to the gallon deposits gold of a sufficiently rich colour, we should be careful to maintain it at this standard by paying attention to its condition, and adding gold or cyanide as required to keep this quantity of gold in solution. I suspect your solution has been worked low in metal, hence the poor, light colour of the deposit. Renew it by adding more double cyanide of gold and potassium dissolved in distilled water, until it has recovered its proper richness. Exhausted solutions are best reduced by evaporation to a thick syrup, drying in a shallow dish on a sand bath, and subsequent fusion in a large crucible. The button and grains of gold thus obtained may be alloyed with any other metals held in the solution, and must be refined in the usual way to get pure gold.—G. E. B.

Steam Engines.—SCRUTINEER.—A high-pressure non-condensing steam engine discharges its exhaust steam into the air, or the chimney of the boiler—the steam escaping in puffs; in the condensing engine the steam passes into a condenser, and no escape is seen or heard; the engine will also be fitted with an air-pump. To measure the diameter of cylinder you must have the cover off and measure with inside callipers, or a gauge. The length of stroke you may get from the travel of the piston rod guide block.—F. C.

Hydraulic Engine.—SCRUTINEER.—You have made a mistake, there is no such term as "horse-power pressure." Nominal horse-power is not used in this connection. In no case can n.h.p. be determined unless dimensions are given.—F. C.

Banjo without Brackets.—ALPHA (*Birkenhead*).—In reply to your query for an idea for a banjo without brackets, I beg to inform you that nothing has been invented to equal brackets for stretching the vellum. I heard some time ago of a banjo without brackets, invented, I believe, by a gentleman in Liverpool, but I cannot give any particulars as to the working of it, further than every time the vellum wanted tightening it (the vellum) had to be wetted with a sponge. The very act of wetting the vellum after it was put on would (in my idea) condemn it. I have experimented in that direction myself, but I have not, up to the present, succeeded in making anything to answer so well as the brackets. Therefore, if you want to save time and money, etc., go to work with the brackets. I am sure nothing could look neater than well-made and nicely-plated brackets. The principal thing is to get good ones with a well-cut screw thread, common brackets being dear at any price.—J. G. W.

Lathe for Grinding.—J. J. P. (*Malton*).—Not knowing from your question whether you are an amateur or a workman, I must reply as to an amateur. You do not require a lathe of any special form for grinding, polishing, and scratch brushing; all you want is an ordinary (very ordinary) rough lathe; the grinding wheels, buffs, scratch brushes, etc., can be mounted on mandrel nose, or on iron mandrel to run between the centres. Don't do such work as this on a good lathe; the dust of it is ruin to any kind of machinery with nicely fitted slides and journals. You don't really need a complete lathe at all; if you have the bed, crank, wheel, and treadle, you can fit a pair of wood uprights for headstocks, with a pointed screw through each, pointing inwards, to act as dead centres; then have a number of mandrels, each carrying one or two grinding wheels or buffs to run between these points, being driven by a wooden pulley, which would be provided upon the end of each of the mandrels to receive the band from the fly wheel. Any lathe maker could fit you up a grinding lathe of this kind.—F. A. M.

Patent for Compounds.—L. M.—It is not advisable to sell the compounds until your patent is complete, though there is no law to prevent your doing so. You can drop the patent any time you like; you are not compelled to keep it up.—F. C.

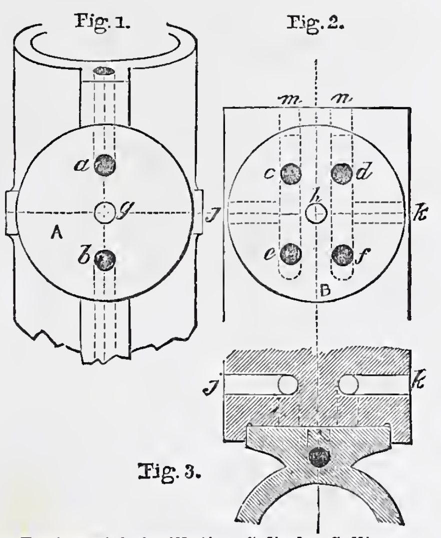
Microscopes.—WATCHMAKER.—I would recommend you to procure a catalogue of a well-known optician. If it is not invidious, I would say that for your purpose you could not do better than to get one of Mr. Lancaster, optician, Colemore Row, Birmingham. As to the price of lenses, a cheap set can be bought for 3s. 6d., but an object lens of short focus and fine quality will run into pounds, but the price of various qualities and powers will be found in any optician's catalogue. As to fitting the cell into the power-tube, if the said tubes were sent to Mr. Lancaster with instructions, it would be most courteously attended to—at least this has been my experience. He has done a good deal of such like work for me from time to time, and I have always found him kind, and his charges exceedingly moderate.—O. B.

Tondeur Photographic Developer.—E. L. H.—The formula for tondeur developer is a private formula, and unknown except to the compounders. If in one solution, the probability is that it is a hydroquinone developer, but without further information it is impossible to say.

Camera Bellows.—JACK OF ALL TRADES.—Several dealers supply parts of cameras. Mr. Tyler, of 58, High Street, Aston, Birmingham, will forward a price list on application.

Cost of Materials and Tools for Camera.—H. J.—The tools requisite are ordinary cabinet-making tools. The following list will be found sufficient: Tenon saw, planes, chisels, screwdrivers, drill, hammer, square, gimlet, and compasses. It is not the tools, but the manner in which they are used. A fit-out of cabinet-maker's tools varies from a few pounds to a few hundreds—there is no limit. As a workman gains in experience, he not only finds the advantage of a variety of pattern tools, but frequently designs special ones for the job he has in hand. It is bad policy to purchase new low-priced tools. Good second-hand ones, chosen with discretion, is probably the least expensive way of getting an outfit. Cheap or low-priced tools are generally deficient in temper, and are altogether a bad investment. The wood can be obtained of most timber merchants, and the metal work from Mr. Tyler, 58, High Street, Aston, Birmingham. Other dealers in photographic requisites also supply fittings. Obtain price list. Cost of completed articles probably two or three pounds; one from the regular makers eight or nine.

Engine with Oscillating Cylinder Callipers.—I think, if you wish to make an engine with oscillating cylinder, and do not know how to arrange the steam passages, you should get a book which treats on the subject, and so obtain more information than can well be given in "Shop" in answer to a query. You might get Powell's book from your nearest bookseller, or you might send 1s. to T. E. Hallewell, 50, Hanover Street, Dantzic Street, Manchester, and ask him to send his working drawing of oscillating engine. If you like it, you can afterwards get a set of castings for 5s. It is almost a pity to make a 1 in. cylinder without a slide valve, and I am afraid a slight sketch such as you ask for might not enlighten you much. The usual plan followed in small model oscillating engines is shown at Figs. 1 and 2. Fig. 1 represents the flange on the side of a double-acting cylinder; the face, A, is got up perfectly flat and parallel with the bore in the cylinder; port holes, *a* and *b*, are drilled leading to top and bottom of the



Engine with Oscillating Cylinder Callipers.

cylinder; also central hole, *g*, to fit the point, *h*, on which cylinder rocks, and which is certain to wear the hole larger and work loose. Now, if the face, A, be brought round and laid on face, B, the ports, *a*, *b*, will come exactly between *c*, *d*, and *e*, *f*, the cylinder being upright; this is the dead point when no steam passes. If *j* be the steam entrance and *k* the exhaust, then *c* and *e* will be steam ports and *d* and *f* exhaust; therefore, if the top of the cylinder swings to the left port, *a* will come over *c* and send steam to the top of the cylinder, whilst port *b* would come over *f* and allow the bottom of cylinder to exhaust. *m* and *n* are holes drilled down to meet the four portways, and are plugged at the top. I would not trust to the point *h* to support the cylinder, unless it were but ⅜ in. diameter, but would sink the surface, B, about ⅛ in., and turn the edge of the flange, A, to fit into the recess, as shown in the sectional plan, Fig. 3.—F. A. M.

Camera Bellows and Lens.—J. S. (*Dudley*) had better write for a price list to Mr. Tyler, 58, High Street, Aston, Birmingham. There is no lens specified. If J. S. would practise folding with a piece of paper, he would find bellows making very easy as soon as the knack was acquired.

Proportions of Quarter Plate and Whole Plate Camera.—G. S.—If G. S. will carefully read the article in question, he will see that "principal measurements" are mentioned, which is intended to mean that the frame of the body, the focussing screen, and dark slide must be made to work 4¼ by 3¼ plates, which is a fourth of the whole plate. The substance of the material may be to the taste of the maker. It is of very little consequence, so long as the inside measurements are right. Old-fashioned cameras used to be much larger and heavier than modern ones. It goes without saying that a small instrument does not require the same amount of strength as a large one. A clever workman will simplify whenever he can do so without interfering with the working capabilities—in fact, brains must be used.

Simple Lathe.—WELL-WISHER.—As you think you could make the lathe described in No. 17 by me, I would strongly advise you to do so, especially as you mean to learn the art of turning upon it. The simpler lathe to which I there referred is that known as a pole lathe, which is a sort justly going to the background. I trust in Part 3 of the series "Lathes for Everybody" to describe a unique lathe, which ought to be a great convenience to those amateurs whose space is very limited. I am glad to hear of your hopes. It brings so strongly to my mind what I felt when I began mechanics. I will be most happy to give you the right hand of fellowship in everything, and trust you will turn out, like me, a SELF-HELPER.

Banjo Making.—DARKIE.—In reply to your request for an article on banjo making, I am quite willing to do my best to oblige you in that direction, provided the Editor is agreeable, and can find room for it.—J. G. W.—[The Editor is agreeable, and will *make* room for it.—ED.]

Second-hand Headstocks, etc.—F. H. N. (*Malvern Wells*).—You can manage in either of two ways: by applying to second-hand dealers in machinery, or by advertisement. If you have plenty of time, go to the dealers in Worcester, or, better still, Birmingham, and suit yourself. If not, try an advertisement in the *Exchange and Mart*. The difficulty here is that the reply may come from so far off that you cannot go to see before you buy; but this is partly overcome by the system of deposit, whereby the price is sent to the manager of the paper, and held by him till the buyer is satisfied, or has returned the goods as unsuitable, when the money is forwarded or returned accordingly. You can easily find out second-hand dealers by inquiry at different hardware shops.—F. A. M.

Moulding Papier-Mâché.—C. H. C. (*Hornsey*).—The method of forming papier-mâché ornaments from pulp with which we are familiar is by using iron moulds, and subjecting the material to considerable pressure. Probably C. H. C. might do well to place himself in communication with the Papier-Mâché Company, London, whose work lies in this direction, and ascertain the process employed by them. We have not their full address to hand, but a Directory will supply it.—S. W.

Cutting Paper Tubes for Boxes.—KROW (*Glasgow*) has doubtless discovered ere this that his query has been answered. We would remind him that some time must necessarily intervene between the receipt of a question and the appearance of its answer in "Shop."—S. W.

Black Japan Varnish.—PAPIER-MÂCHÉ.—Some preparation of Brunswick black has probably been palmed on F. M. instead of the proper article. "Japan" is a word often used by manufacturers to convey the idea of blackness and brilliancy, as in "Japan blacking." He should apply to S. Thornicy, 6, Snow Hill, Birmingham, stating the purpose for which the "black japan" is required, and he will get the proper thing.—S. W.

Battery for Electric Light.—H. A. T. (*Bermondsey*).—Your battery is a single fluid chromic acid battery. Charge the cells with a liquid composed of 1 lb. of chromic acid and 2 oz. of chlorate of potash dissolved in 1 quart of warm water; then add to it 7 oz. of sulphuric acid. Allow this to get cool before charging the cell.—G. E. B.

Statical Electric Machine.—W. M. (*Liscard*).—A description of a statical electric machine would be far too long to be printed in "Shop," and would be almost useless apart from drawings illustrating each part. A series of illustrated articles on this subject will be given in WORK at some future time, but I must ask you to possess your soul in patience whilst waiting for the good time coming, since our "Shop" is now very full of work, and WORK is in danger of being filled with "Shop."—G. E. B.

Electric Belt Links.—TINMAN (*Homerton*).—Cut the links out of 24-gauge copper and zinc plates. The zinc lozenges should be plain oval pieces with a small transverse slit in each end. The copper lozenges should have a small tong or projection at each end, and these tongs must pass through the slits in the zinc lozenges, and then bent back to form a closed hook. The ends of these hooks may be soft soldered, but I do not think this necessary, as there will be no strain upon them when sewn into the flannel. I verily believe you would get as much benefit from wearing a piece of clock chain, or a piece of iron chain, inside a flannel belt, as you will from one of those galvanic chains. You will get more benefit from wearing a simple belt of new flannel than all these quack remedies put together. If you can tell me exactly what you want with such a belt, and what you hope for from it, I will give you some valuable advice from my own long experience. These advertisements are a delusion and a snare.—G. E. B.

Polishing.—M. J. (*Glasgow*).—The piece of work you name may as well be French polished, though if you prefer you may either wax or oil polish. The first-named method will give the highest gloss, and I shall confine my remarks to it. The mahogany you are using being old may be dark enough, but if not you can use a little stain. Oiling will, however, probably be sufficient. Use raw linseed oil, and apply it with a rag, rubbing it well in, and then letting the work stand for a day or two. Then stop the grain with a mixture of fine whiting, turpentine, and a little rose pink for colouring. Rub this well in with a rag, and clean off the surface before the composition gets hard. The wood is then ready for the polish. This you can make yourself, but it can be bought as cheaply. To use it, get some cotton wool or wadding and a piece of soft rag. Moisten the wool with the polish, and wrap it in the rag, taking care that there is only one fold of this between the wool and the wood. Avoid creases on the rubber where it comes in contact with the wood, or you will not get a good finish. The rubber being ready, touch the face of it with a very small quantity of oil, the smaller the better, just enough to make it work smoothly. The wood is then to be gone over with this rubber till there is a sufficient body of polish on it. This you can only learn by experience, but it may be a guide for you to say that the rubbing is continued till the wood has a polish on it, but only a smeary-looking one. After you have got a body on, let the job stand over, and if the polish seems to go or be absorbed after, say, a couple of days, repeat the bodying process. The smears are removed, and the final polish is got by "spiriting off," that is, using a similar rubber to that already described, but without any of the oil and French polish, for which methylated spirit is substituted. In doing this you will have to be very careful not to "spirit off" the body you have previously laid. Continue rubbing till you have sufficient gloss. Such in brief is the process which will be described at length in a series of exhaustive papers on polishing of various kinds as soon as practicable. You will find that the rubber cannot be effectively used on carved parts, which you had better finish with spirit varnish. Paint it on with a brush, and be careful not to lay it on too thickly, or you will get a coarse effect. You are, doubtless, aware that a very good appearance may be got by simply polishing the plain uncarved parts, and leaving the carved work dead by merely oiling it. This is a plan which, as a matter of taste, I should adopt.—D. A.

Aquarium Glass.—AQUARIUM (*Canning Town*).—For the glass for an aquarium 16 by 13 by 14 inches, you had better use what is known in the trade as "32 oz. sheet." For cement for the same see reply to TYRO, page 221.—C. M. W.

Fountain Aquarium. — OUVRIER (*Birmingham*).—The construction of an aquarium with an automatic fountain combined is quite within the reach of any one capable of doing ordinary sheet metal work, and a fully-illustrated article upon the subject appeared in No. 31 of WORK, page 481.—C. M. W.

Safety Cages.—E. J. J. (*Notting Hill Gate*).—There are several inventions patented and in use to arrest the fall of cages in coal and other mines, and in cases where the rope breaks; also similar appliances for securing the safety of passengers in warehouse lifts. There is a very effective arrangement of this kind on the Otis lifts in the Eifel Tower.—F. C.

What to Turn.—CAR (*Carmarthen*).—You have a Milnes' 5-in. lathe with slide rest and tools for wood and metal, also a good set of chucks and a circular saw and table—a very good set of tools let me say—and you wish for patterns, etc., of articles which you can turn. Now with such a good outfit you can make a great many things in wood and metal, but as you are a beginner, begin with wood, and learn to turn in soft wood and hard, laying aside the slide rest and metal-turning tools for awhile. You can hardly do better than begin with tool handles; then go on to boxes which have two parts to fit together, and require to be hollowed out; flat boxes and taller and deeper match-boxes, egg-shaped boxes to hold thimbles, etc.; then make some wooden candlesticks—small ones for wax tapers and large, tall ones. All these things are excellent practice. You might try some Egyptian trellis (see No. 7 of WORK)—very good practice; see also page 281 of No. 18. Holtzapffel's Vol. IV. is a most admirable book, and has many excellent designs.—F. A. M.

Choice of Lathe.—MEDUSA (*Leith*).—You ask advice as to your choice of a lathe for small metal work, including milling, and you mention the Britannia Co.'s No. 14, Barnes' 5½ in., and Price's Universal, which have all been noticed in WORK. Now these are all very good lathes, and it is, of course, a matter of opinion as to which is best, but if you want to do milling I must say that I should in your place go in for Price's lathe with the vertical slide. I would have a long leading screw, a clamp to fix the vertical slide at any height, a bored mandrel, and would ask them to increase the length of the front slide to give more bearing surface.—F. A. M.

Small Motor for Lathe and Sewing Machine.—J. B. (*Keighley*).—An electric motor will do what you want if you have the supply of electricity; if not, you would want a battery, which is far too costly to supply with zinc and acid to answer your purpose. If you can get water from the town main at 9d. per 1,000 gallons, and at 100 lb. pressure per square inch, you might use a "Thirlmere" wheel water motor, which is very cheap, and far the most convenient thing to have, but the water will cost a shilling or two per day. You might have a one-man gas engine, sometimes to be got second-hand for £10, but don't have it in a living room, as it thumps and smells. The gas for this costs a mere trifle.—F. A. M.

"Royal Mail" Cart.—PARENT (*Amen Corner, London*).—A paper on how to construct one of these popular carts for children is given in No. 30.—ED.

Watch and Clock Making.—GOVAN.—These papers were commenced in No. 20 of WORK, published August 3rd last.

Smithing.—I am in receipt of your letter with reference to smithing, and am pleased to find that the papers thereon give you satisfaction. They will be resumed in a very short time, and will include every branch of the trade.

Verge Watch.—W. B. (*Tipton*).—The paper on this subject will have met your eye long before it can light on this reply to your remarks on this subject. It by no means follows that because the first of a series of papers is commenced in any particular number that the second will of necessity appear in the number immediately following. Rest assured that there are always good reasons for doing all that is done in this way, but to give detailed explanation as to the why and the wherefore of the doing to all who ask it is neither necessary nor expedient.

Bookbinding. — BOOKBINDER. — The papers on bookbinding will be commenced very shortly, but I cannot name any precise time. It will not, however, be long now before a beginning is made. I am obliged to you for your good wishes and good opinion of the Magazine as it is.

Modelling in Wax.—WAX.—It will not be possible to give, at all events at present, any description of the methods of preparing anatomical subjects and facsimiles of natural objects in wax. Although it is sought to do as much as is practicable in WORK, still it is beyond my powers to take up every point in the great circle of the sciences as they at present exist.

American Organ.—WAX.—Instructions in building organs of this class will be given as soon as opportunity offers, but to go through every instrument of the kind from the barrel organ of the streets to church organs, and "also the kind to be seen at shows known as military organs," is utterly beyond my power and the purpose of WORK. The use of technical terms in WORK cannot be given up. Ask the meaning of any term that you do not understand.

Wood Screw Cutting Tool.—J. H. E. (*Shepherd's Bush*).—It has been already stated in "Shop" that the London agents for the sale of the specialities of Messrs. Peugeot Frères are Messrs. Alexander von Glehn & Co., 7, Idol Lane, London, E.C., but this, doubtless, has escaped your notice.

Index to Weekly Numbers of Work.—N. W. C. (*Manchester*).—The addition of an index to the contents of each weekly number of WORK is under consideration, but no change in the present form can well be made until the commencement of Vol. II., when, in all probability, many improvements will be effected. A. E. W. and MARKET WEIGHTON are referred to the above reply as an answer to their letters on this subject.

Index to Work.—ALARUM.—An index will be prepared for each volume of WORK. I am glad to find that you are among the many who have derived benefit from the Magazine.

III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

Battlesden Cart. — R. B. (*Fife*) writes: — "Would HOMESPUN (*Tenterden*) give instructions for making wheels for Battlesden cart (see page 524)?"

Carving Woods and Patterns.—J. D. (*Broomhill*) writes: — "Where can different woods for carving be obtained? Also is there any one who enlarges designs according to patterns that may be sent, and from whom models may be hired at a charge per month?"

Terra-Cotta, Monumental, and Portrait Painting. — PIXIE (*Aberdeen*) writes: — "Would you kindly allow me a small space in 'Shop' of WORK to ask if any of the readers or your staff would kindly oblige me with an idea of how to do any of the below-named subjects:—1. A practical treatise on the manufacture of bricks, tiles, and terra cotta? [We cannot teach you how to write a popular treatise.—ED.] 2. How to hang the drapery on an urn for monumental stone-cutting, with a few sketches of the same? 3. How a portrait is painted? And for certain it would do good to more than me."

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Pill Making.—PHARMACIST (*Kingstown*) writes in reply to J. C. (*Carlisle*) (see No. 31 of WORK, page 494): — "If J. C. (*Carlisle*) were to apply to Messrs. Maw, Son, & Thompson, 11, Aldersgate Street, London, they would gladly submit prices, and supply any article or machine used in pill making. There are various forms of pill-making machines in the market, and I feel certain that if J. C. were to call upon any of the chemists in or around Carlisle during their quietest time they would willingly let him see the various forms of pill tiles, rollers, coaters, silverers, etc. He would then be in a position to describe the kind he would require. An ordinary mahogany frame pill machine to roll and cut 24 pills at a time would cost from about £1 to £4, according to fittings. A Pindar's rotary pill machine would cost from 12 to 30 guineas, according to requirements. Graduated pill tiles may be had from 6d. upwards. When only a small quantity of pills have to be made, the simplest method is to weigh out a given quantity of the pill mass, and roll this with the blade of a knife upon a piece of glass or graduated tile to about the thickness of an ordinary writing pencil and divide into equal portions, and roll each between the thumb and forefinger until quite round and smooth. A little practice in this will soon make perfect. Except for very large quantities an ordinary mahogany-frame pill machine is sufficient."

Ink for Posters.—H. P. (*Plaistow*) writes in reply to A. J. (*Ilkeston*) (see page 494):—"You should get your stationer to order a sixpenny or shilling bottle of Mordan's waterproof ticket ink, F. Mordan, 326, City Road, London, E.C."

Lacquer for Iron and Steel.—R. G. (*Birmingham*) writes in reply to STEEL (see page 526):—"Tubbs & Wilkins, Hockley, Birmingham, make the above, all colours."

Working Drawing of Tramcar.—F. C. (*Leytonstone*) writes in reply to J. W. F. (*Lancaster*) (see page 526):—"I can supply you with a drawing of a tramcar as made by the best firm in London."

Trade Notes and Memoranda.

FIVE thousand plumbers are now enrolled on the register of the Plumbers' Company.

THE average number of men employed per diem on the Forth Bridge during the three months of the busiest time was 2,293. Only one fatal accident, and this we are informed was due to the workman's own want of caution, has occurred during the quarter.

THE directors of the Forth Bridge Railway Company recently visited the bridge by the aid of a gangway over the gap at the north girder, and walked on the bridge from the south to the north shore of the Forth. The first to cross were Mr. Thomson, chairman of the Forth Bridge Company and the Midland Company, and Miss Taylor, daughter of General Taylor. They were followed by Lord Colville, chairman of the Great Northern Railway, and Mr. Dent, the chairman of the North-Eastern Company. The party returned to Queensferry by steam barge.

ACCORDING to a recent publication of the Statistical Bureau at Berlin, four-fifths of the steam machinery in the world has been constructed within the last twenty-five years. France has 49,500 stationary boilers, 7,000 locomotives, and 1,700 ship boilers; Austro-Hungary, 12,000 stationary boilers and 2,400 locomotives. In the United States, the steam machinery, exclusive of locomotives, has 7,500,000 horse-power; in Germany, 4,500,000 horse-power; in France, 3,000,000 horse-power, and in Austro-Hungary, 1,500,000 horse-power. There are some 105,000 locomotives in the world.

THE London correspondent of the *Manchester Guardian* says a movement is on foot to establish a house-to-house heating supply, similar to that of gas and water. The system consists in the constant circulation of water at a high temperature and pressure (viz., at 400 degrees Fahrenheit and 250 lbs. on the square inch) from the batteries of boilers at a central station through the supply mains, and back to the boilers by return mains, the circulation being maintained by means of pumps. The loss of heat by radiation has been reduced to a minimum by covering the mains with a non-conducting material. Service boxes sufficient to heat three houses would be placed under the footpaths. From these boxes the house supply would be taken by means of copper pipes. At the end of the copper pipe, and inside the house, is fixed a vessel called a "converter," which permits the water to resolve itself into steam, the pressure of which is controlled by a reducing valve fixed on the copper pipe before it enters the "converter." From this "converter" the house service would be taken.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

A WONDERFUL MEDICINE.

BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

Worth a Guinea a Box.

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.

Prepared only by the Proprietor, T. BEECHAM, St. Helens, Lancashire, in Boxes 1s. 1½d. and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

MELLIN'S FOOD

For Infants and Invalids.

TRADE MARK

NOT FARINACEOUS. Rich in Flesh, Nerve, Brain, and Bone Formers.

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

No Food in the market can show such a vast collection of *bonâ-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

USED IN ALL CHILDREN'S HOSPITALS.

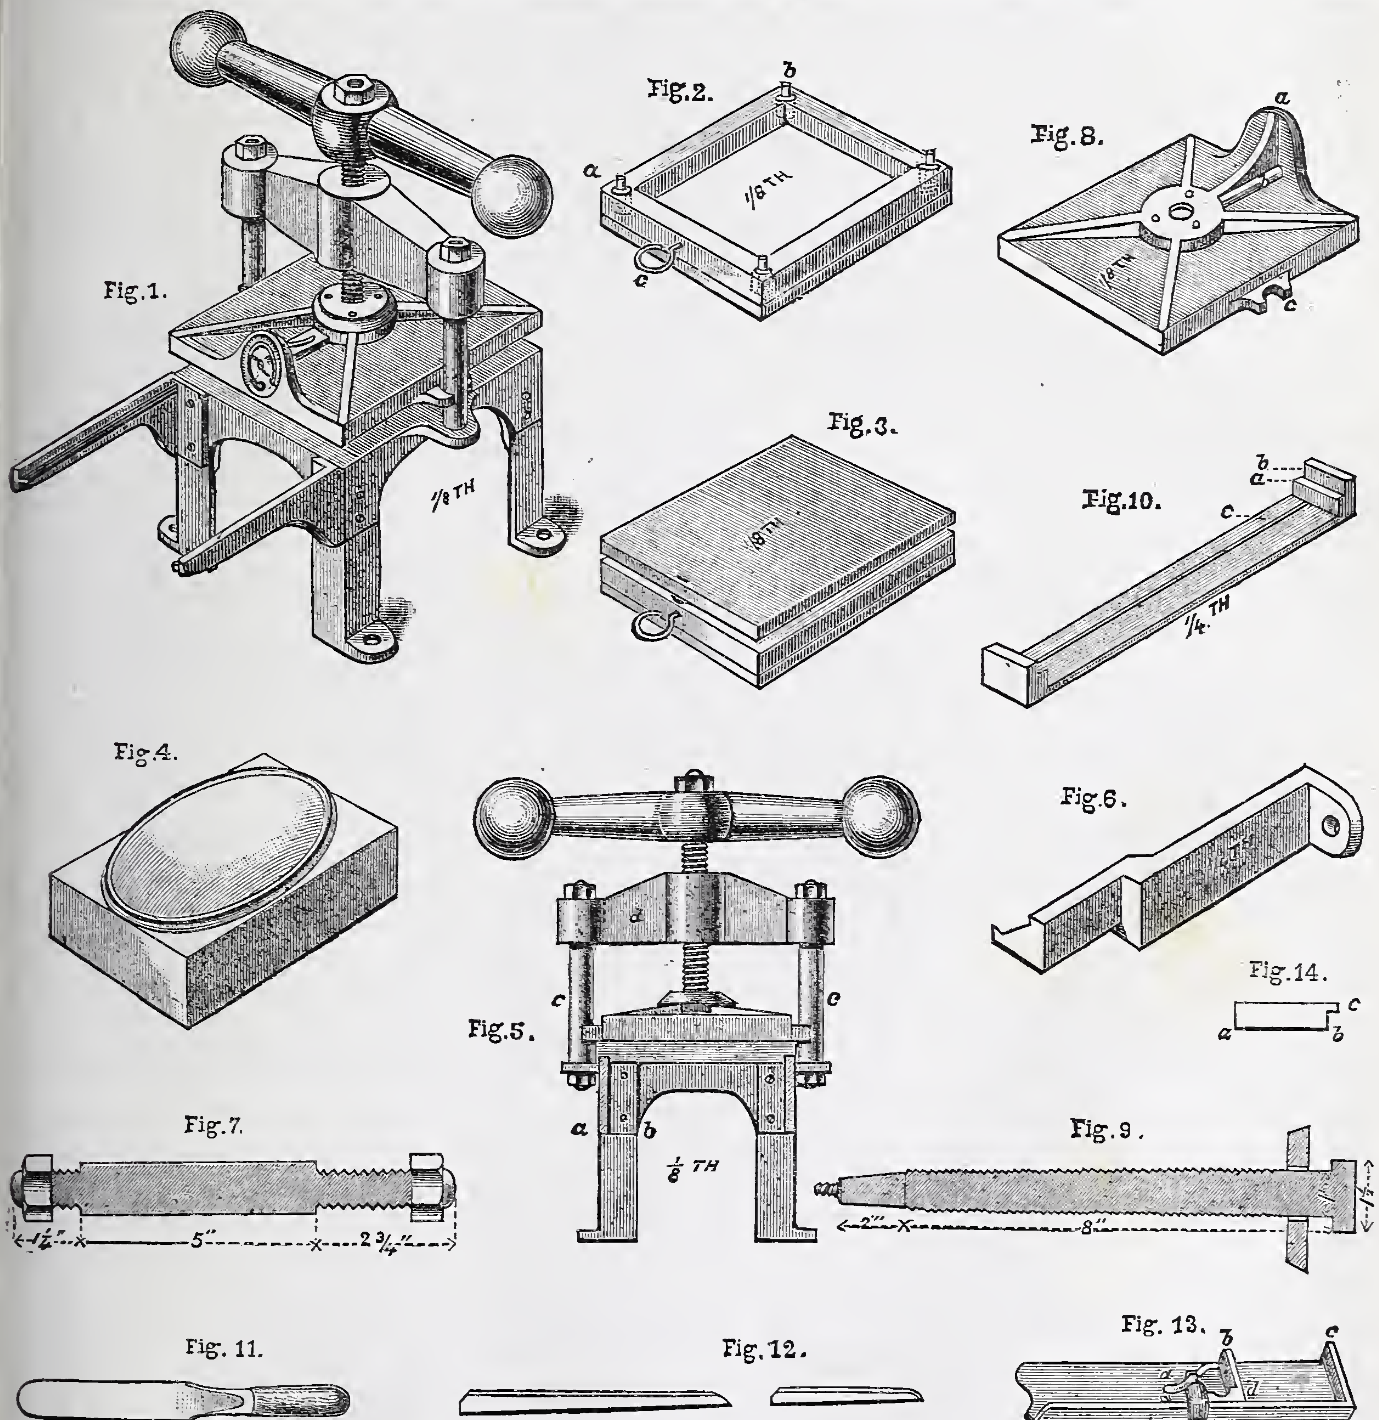
WORK

An Illustrated Magazine of Practice and Theory

FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

VOL. I.—No. 38.] SATURDAY, DECEMBER 7, 1889. [PRICE ONE PENNY.



INDIARUBBER STAMP MAKING. (*For Description see next page*). Fig. 1.—Press for Moulding and Vulcanising. Fig. 2.—Spring Chase. Fig. 3.—Chase with Moulding Plate in Position. Fig. 4.—Oval Shape. Fig. 5.—Elevation of Press. Fig. 6.—Leg of Press. Fig. 7.—Section of Standard. Fig. 8.—Platen or Follower. Fig. 9.—Section of Main Screw of Press. Fig. 10.—Moulding Gauge. Fig. 11.—Palette Knife. Fig. 12.—Side Stick. Fig. 13.—Composing Stick. Fig. 14.—Setting Rule.

INDIARUBBER STAMP MAKING.

BY "QUI VIVE."

Introductory.

In these "go-ahead" days, when almost anything which promises to aid in the economy of time is eagerly welcomed, notwithstanding the fact that many of the most alluring promises are of the proverbial "pie-crust" kind, no excuse is needed for introducing the subject of rubber stamp making. Few offices, even of the most humble pretensions, are to be found without their complement of indiarubber stamps; and even in private life these extremly useful articles have won golden opinions, if one may judge from the numerous advertisements of monograms, linen-markers, note headings, etc. etc., which meet his eye in the periodicals which come under his notice.

The purposes for which india-rubber stamps may be advantageously used are almost numberless, and these handy instruments may be fairly regarded as valuable auxiliaries to the printing press, having their own special sphere of usefulness into which the printing press cannot profitably enter. For the purpose of repeating impressions of the same matter at irregular intervals and in varying situations the solid die has long stood in high favour, and, in the form of the now old-fashioned brass endorsing stamp, is still to be found occupying an honourable position. I am, however, inclined to the opinion that the introduction of indiarubber stamps struck a blow at the older instrument from which the latter cannot possibly recover, the rubber die being not only capable of doing any kind of work for which its predecessor was used, but having also the immense advantage of *elasticity*, by which it is enabled to adapt itself to surfaces so unlevel as to render the use of a rigid metal die altogether out of the question.

When a person handles a well-made indiarubber stamp for the first time, he is, if of an inquiring turn of mind, led to ask by what mysterious process such an apparently intractable substance as indiarubber has been made to yield such beautiful results, and his wonder does not cease if he is fortunate enough to elicit the information that rubber stamps are not engraved but moulded. Indiarubber stamps are not—indeed *cannot* be—made of pure rubber, but of a mixture of pure rubber and sulphur; the mixture being forced into a suitable mould by strong pressure, and in that state submitted to such a degree of heat as will bring about a chemical union of the sulphur with the rubber, and thus produce what is known as *vulcanised* rubber.

The essentials of an indiarubber stamp making plant, then, consist of some means of producing the requisite moulds, and afterwards applying pressure and heat simultaneously to the rubber compound placed therein.

Various attempts have been made to beguile the confiding amateur by offering "complete apparatus and full instructions" for the manufacture of india-rubber stamps, all of which have hitherto been of the nature of the conjurer's explanation of his astounding tricks. I do not, by this statement, intend to convey the idea that satisfactory rubber stamps cannot be produced by such apparatus, for I have personally made some very satisfactory stamps in this way; but, as a matter of fact, chance or good luck enters very largely into the case, and the amateur who succeeds in making a stamp *that will stand the test of hard wear* once out of every twenty trials may be considered exceptionally fortunate in his experience. I purpose in these papers giving such instructions as will enable any person of ordinary intelligence who carefully follows them, to produce stamps equal to any sold by professional makers, and if by inadvertence any point should be overlooked, or the details not made sufficiently clear, a query addressed to me through the Editor will receive due attention in "Shop."

Apparatus.

The apparatus which I am about to describe is adapted for the production of stamps up to six inches by four inches, a size which will probably suffice for most of my readers; but if any require apparatus of a larger size, corresponding additions to the horizontal dimensions given will be all that is needful. The apparatus consists of, (1) printing types and "shapes" of various kinds, according to the fancy of the stamp maker, and a few printers' sundries as detailed below; (2) a specially adapted "chase" to hold the type rigidly during the process of moulding; (3) a moulding plate on which to form the mould and retain the same during the subsequent process of vulcanising the rubber; (4) a moulding-gauge, by the aid of which the moulding composition is spread upon the moulding-plate in a thin and even layer, and (5) a press suitably arranged for use both in forming the mould and afterwards as a vulcaniser. These various pieces of apparatus we will now proceed to consider in order.

1. *The Printing Type and Shapes.*—These may be obtained of almost any printer's broker or type-founder. It is the best plan to confine one's selection to plain type—*i.e.*, type without shading or ornamentation—as, although the finest detail is faithfully reproduced by the rubber, the fine lines soon become choked with ink, and the stamps rendered practically useless. The "shapes" in common use are mostly oval in form, as shown full size in Fig. 4. They may be either solid brass or electrotyped, the latter being the cheaper, but the former the more useful and lasting. "Fancy" shapes to be used in conjunction with type are generally electrotyped, and in this form are substantial enough for the more limited use to which they will probably be subjected.

A supply of "quads" and "spaces"—blank pieces of metal of various thicknesses, and of widths corresponding to the type with which they are to be used—should be purchased at the same time as the type; also a couple of pounds of 4-to-pica "leads"—thin strips of type metal for separating the lines of type—and two or three lengths each of narrow "furniture," pica and nonparcil "reglet," pica "wood rule," and thin "brass rule." A "composing stick" (Fig. 13) will also be required. "Side sticks" (Fig. 12) may be either purchased or made at home. They are tapering pieces of hard wood, generally oak, which are used in conjunction with "quoins"—similar tapering pieces of wood about $1\frac{1}{2}$ in. in length—for firmly securing the type, etc., in the chase, described below, during the process of moulding. It is recommended that both side sticks and quoins be made in the following manner:—Carefully plane up a strip of oak 2 ft. in length, $1\frac{1}{4}$ in. wide, and $\frac{5}{8}$ in. thick, taking care to have the corners square; then divide this parallel strip into two tapering ones, $\frac{7}{8}$ in. wide at one end and $\frac{3}{8}$ in. at the other, and plane up the newly-sawn edges square and true. Now cut off four $1\frac{1}{2}$-in lengths from the smaller end of each strip, and divide the remaining portions into $4\frac{1}{2}$-in. and 6-in lengths respectively, and we have a supply of side sticks and quoins, which only require the removal of the rough edges left by the saw to fit them for use.

2. *The Chase.*—This is shown in Fig. 2, and consists of a plate of cast iron $\frac{3}{8}$ in. thick, planed on both sides, surmounted by a strong iron frame $7\frac{1}{2}$ in. long and $5\frac{1}{2}$ in. wide inside, the frame itself being $\frac{7}{8}$ in. wide and 1 in. deep, with the top, bottom, and inside planed true and square. At each of the corners of the frame and base plate a $\frac{5}{16}$-in. hole is drilled through from the top to the bottom, the holes in the frame being then counterbored to $\frac{5}{8}$ in. in diameter for $\frac{3}{4}$ in. in depth (see Fig. 2).

Four pins are then made of $\frac{3}{8}$-in. rod, about 2 in. in length, and reduced to $\frac{5}{16}$ in. in diameter for rather more than $\frac{5}{8}$ in. in length at one end. These pins are then riveted by their smaller ends into the holes which have been made in the corners of the frame and base plate, thus riveting them together and forming a tray having a flat bottom with the four sides at right angles thereto and to each other.

Before riveting in the pins the holes in the base plate should be slightly countersunk on the underside, and when the riveting has been satisfactorily completed the under surface should be filed level if necessary, and the free ends of the pins reduced so as to project barely $\frac{3}{8}$ in. above the level of the frame of the chase.

Four open spiral springs of steel wire $\frac{1}{16}$ in. thick are then fitted to the annular spaces around the springs in the corners of the chase, these springs being about $1\frac{1}{4}$ in. in length when open, but capable of being compressed level with the upper surface of the frame of the chase. A ring, *c*, is made of $\frac{1}{4}$-in. rod and screwed in the front edge of the chase to form a handle.

3. *The Moulding Plate* consists of a flat plate of iron, identical with that used for the base plate of the chase, with the exception that the holes in the corners are to be of such a size as will allow the guide pins in the chase to pass freely through with the least possible play. The correct position of these holes may be best secured by clamping the frame of the chase and the moulding plate together, and then drilling $\frac{3}{8}$-in. holes through the moulding plate and sufficiently far into the chase frame to serve as guides for subsequently drilling the holes proper to the chase and base plate, which should be clamped together in their turn and both drilled through at one operation. If this operation be properly done, the holes at each corner will exactly correspond, and a very little "easing" of the holes in the moulding plate by means of a reamer will afford sufficient play. The moulding plate in its working position on the chase is shown in Fig. 3. When properly fitted together some distinctive mark should be placed on the front edges of both chase and moulding plate, so that no time may be lost in fitting them together subsequently, when the least delay may be fatal to success, and cause the whole operation of moulding to be commenced anew. Before proceeding further with my description, let me say that the fitting of this part of the apparatus cannot be too carefully performed if the best results are expected.

4. *The Moulding Gauge* is formed as shown in Fig. 10, and may be made of either brass or iron, the former being preferable, not only because of its being readily cast from a

pattern, so as to require but a small amount of finishing, but also on account of its freedom from rust. It is made to ride by the seat *a* close to the edge of the moulding plate, on which it is retained by the guards *b*. The edge *c* is so adjusted that when placed in position on the moulding plate it will leave a clear even space of from $\frac{1}{12}$ in. to $\frac{1}{8}$ in. between itself and the plate.

5. *The Press.*—This is shown complete in Fig. 1, and is somewhat similar to an ordinary letter-copying press. It is, however, necessarily of much more massive construction than copying presses, so that it may be able to retain an approximately equal temperature during the process of vulcanisation. The table and platen, or follower, are each $9\frac{1}{2}$ in. from front to back, 8 in. wide, and 1 in. thick, with their opposing surfaces planed true. Dwarf standards $\frac{3}{8}$ in. thick depend from the corners of the table to the depth of 2 in. below its under surface, the width *a-b* in the elevation (Fig. 5) being $1\frac{1}{2}$ in. To these are screwed legs $4\frac{1}{2}$ in. in length as shown in Figs. 1 and 5. Fig 6 shows the leg in its entirety, and clearly indicates by what means it is attached to the table. The position of the feet, of course, varies as required by the position of the legs. Projecting lugs on the sides of the table support standards of round iron as shown in section in Fig. 7, in which is also shown the dimensions of the standard. These standards are mounted $9\frac{1}{2}$ in. apart from centre to centre, and midway between the front and back edges of the table. The platen, shown separately in Fig. 8, is formed with a central boss 3 in. in diameter, in which is formed a circular cavity $1\frac{1}{2}$ in. in diameter and $\frac{1}{2}$ in. deep for the reception of the head of the main screw, which, with the collar by which it is attached to the platen, is shown in Fig. 9. For the sake of appearance, ribs are made to radiate from the central boss to the corners of the platen. The projection shown at *a*, Fig. 8, is for the attachment of a thermometer, the bulb of which is to be inserted some 3 or 4 in. in a hole drilled lengthwise in the thickness of the platen, which may, if necessary, be made thicker at this part, as shown at *b* in the figure, the diameter of the hole being regulated by the size of the thermometer bulb. From $\frac{3}{8}$ to $\frac{1}{2}$ in. will, however, be large enough. The thermometer may, with advantage, be of the form known as an "oven" thermometer, the external appearance of which is shown in Fig. 1. It is attached to the platen by means of a small central screw, the bulb and that portion of the tube which is at right angles to the circular scale plate being inserted in the hole drilled for their reception. Midway in the length of the platen is placed, on each side, a guide-piece (*c*, Fig. 8), which, partially encircling the standard rising from the table, prevents the platen from twisting when raised or lowered by the screw. The standards (*c*, Fig. 5) are connected at the top by a crosshead, *d*, through the centre of which is formed a female screw to act as a nut to the main screw, which is threaded with not less than 8 threads per inch. Motion is conveyed to the main screw by a weighted lever, as shown, the lever being fitted to a tapering square on the end of the screw.

Brackets affixed to the front of the press, as shown in Fig. 1, will be found very useful to support the chase, etc., from time to time during the preparation of the mould, and also to support the mould whilst being dried.

Having now described the necessary apparatus, I will leave the reader to construct this before proceeding to describe the mode of working, which I will do in another paper.

ENGRAVING ON METAL.

BY NORMAN MACLEAN.

ENGRAVING ON BRASS AND ZINC.

ENGRAVING on brass includes door and window plates, memorial brasses, axle caps, saddlery mounts, beer engines, fender and fire brasses, etc. It is executed in two ways: for small and moderate-sized work with the graver in the usual manner, and for large work by means of the hammer (Fig. 22) and chisel. The latter process requires a greater outlay for outfit, but with this advantage, that the chisel will remove enormous quantities of metal in a very short time, which is, however, counterbalanced by the very great noise made in the operation, which renders the process unfit for home work.

For this reason many engravers prefer to cut the whole with the graver, and, certainly, more correct work can be done, even if it takes a longer time. It will be seen that the outfit for name-plate work includes some extras not required by the ordinary engraver, and possibly some workmen may have tools by them which by a little ingenuity can be utilised for brass engraving.

Brass plates may be obtained at a metal dealer's, cut to size, at the rate of 7d. per pound. They are not flat, and require hammering by a silversmith before they can be engraved. They should also be sand-buffed or rough polished on one side only. After having been made flat by the silversmith, true up the edges (and bevel them if required), using leaden clams in the vice to prevent unnecessary marks, and using the square and straightedge freely during the process. Then send it to be rough polished on one side only. If you prefer to do this yourself, procure a large piece of pumice-stone and plenty of water, and rub the plate (always in the same direction evenly all over the surface) till every scratch is removed. Finish with a large piece of water of Ayr stone, when you will have a fine surface to cut upon.

Now mark out the border, if one is desired. The border is generally a single line with the corners finished ornamentally, the said line and corners cut deeply to hold the wax. Having decided what style of lettering you will adopt, mark in the name with the pencil. To do this proceed as follows: Draw with the pencil a line down the centre of the plate, and also one across the centre of the plate; next count how many letters are contained in the name. Take the centre letter of the top line and roughly sketch it in midway between the centre pencil line and border. Continue to sketch roughly in the remaining letters each side of the centre until they are pretty evenly balanced. Now rule with the straightedge and point (Fig. 23) a line at the top and bottom of the roughly sketched in name, and proceed to draw carefully the whole name, seeing that each letter has plenty of room to stand in, and that the name itself is well balanced on the plate. A few words about the style of lettering for door plates. They should be very legible, and perhaps the best styles for this work are "block letters" and the "Italian," or "writing." I can illustrate my meaning by a little anecdote. At a well-known engraver's in this town there was, and is now, to be seen a large brass plate, with the name and trade of the owner engraved in the highest style of the art. On one occasion I was coming along past this brass plate, when I was stopped by a man carrying a large basketful of work, and who asked me to direct him to Mr. M——'s. (I had noticed the man looking at the plate as I came along the street, and had half suspected that he could not make out the lettering). "Why," said I, "you are looking at his name plate. That is Mr. M——'s place of business." "Well," said the man, "I have seen some thousands of door-plates, but I never came across one that I could not read in my life. This *beats* me." This plate was done in three styles; the name was ornamented Roman, the middle line in German text with flourishes, and the bottom line in Gothic lettering, and not at all easy to read.

The workman, having the plate properly set out in pencil, can now "point it in," using the steel point (Fig. 23). Use the rule for all straight and angular lines, and the dividers and rule for parallel lines, and keep the "block letters" upright, and the "writing" at a moderate angle. The sizes of brass plates vary greatly, from a small plate 4 in. × 2 in. × $\frac{1}{8}$ in., bearing the words "push," "ring," "knock," etc., to door plates 18 in. × 12 in. × $\frac{1}{4}$ in., and it is in engraving these large plates that chisel work comes in with advantage. The plate being "pointed in" ready for cutting, it will require to be mounted on the stone with cement. Before pouring the hot cement on the stone, brush off all the dust and sand that may be adhering to it, and place it before the fire to be thoroughly warmed through, then warm the plate, and lay it on the hot cement, pressing it down so as to make it solid to work upon. This will deaden the sound of the hammering, and resting the stone on the large sandbag will further deaden the sound, counteract the effect of the blows on the chisel, and enable the engraver to turn the work in any required direction (Fig. 21).

In order to outline the letters the operator must first take the chisel (Fig. 25), and whet it at a rather acute angle, and "set off" at about 30°. Commence with the perpendicular lines; outline them boldly as regards depth, holding the chisel slightly sideways, so as to "undercut" the letters. "Undercutting" makes the letter or figure slightly larger at the bottom of the cut than at the surface, and therefore holds the wax more securely. Having cut all the perpendicular lines in one direction, turn round the block and recut the same lines in the opposite direction; this will make the corners square. Then cut the cross lines in like manner. The straight lines will be much more easy to cut than the curved ones, so, until the workman has obtained full command of the chisel, he will do well to cut the curved lines with the graver. The outlining being done, take a chisel nearly the width of the lettering, and proceed to sink the letters to the depth of one-sixteenth of an inch (Figs. 26 and 27). Leave the bottom of the cut as rough as possible, as it tends to hold the wax. This being done, take the scraper (Fig. 24), and remove the "burr" or "fash" thrown up by the action of the chisel. Now take an ordinary graver with a wide facet, and square up the corners, and give a graceful outline to the curves. If the plate is to be mounted on a mahogany block, the four screw-holes must now be drilled and countersunk, which the workman can easily do with the handy Archimedean drill; but if the plate is to be put upon a door, it will be required to have soldered on the back two bolts, which will, by means of nuts, secure the plate on the inside of the door. This must be done before the waxing of the letters is proceeded with. The bolts now being attached, take some turpentine and clean rag, and thoroughly clean all the letters carefully.

The process of waxing requires to be conducted very carefully. The wax made specially for the purpose may be bought at an oilman's; take a sufficient quantity of wax of the desired colour, black or red, and pulverise it in a mortar. Have the plate quite clean, and fill all the cuts with sufficient of the powdered wax, being careful not to let the wax extend all over the plate; then take a camel-hair brush, and gather the wax in a little hillock above the surface of each cut to allow for sinking. Now put the plate into a hot oven and watch it carefully, turning the plate frequently so as to heat it evenly all over. Do not let the wax bubble or boil. As soon as the wax begins to melt take out the plate from the oven, and press the wax in the cuts with a piece of flat iron or steel. It is hardly possible to avoid getting the wax all over the plate, but while the plate is hot it can be wiped off, if it is not too close to the letters.

The plate must now be left to cool gradually. To remove the superfluous wax from the surface of the plate, the water of Ayr stone must be freely used with plenty of water. Rub the stone always in the same direction, lengthways being preferable. The wax being removed, dress the plate with a piece of leather, using crocus, and plenty of common oil to moisten the crocus. A final polish with a piece of soft leather—chamois will do—with lampblack as a polishing medium, will finish the plate and blacken the letters. The mahogany blocks for mounting the plates are made to order by a cabinet maker. But the engraver of small plates is supposed to be able to fix them himself, so that he should be prepared with the necessary tools. Zinc plates, it is scarcely necessary to say, are treated in a similar manner.

Before I conclude the subject of brass and zinc plate work, I must mention two matters which, although not of the greatest importance by themselves, yet, as a whole, will make or mar a brass or zinc name-plate. I allude to the filling of the letters. If a little extra expense be no object, use the very best black or red sealing wax; the appearance will fully repay the engraver for the extra expense involved. My London readers may obtain this best wax at most good stationers', and the cost is usually threepence per stick. The second quality sealing wax is used for very large plates, and is similar to that used by the post-office officials.

The other little matter I wish to impress on the memory of the young workman applies more particularly to cutting zinc. The peculiar nature of zinc tends to "clog" the point of the gravér. To obviate this, and to clear the point for the following cut, I usually have at my right hand a small flat piece of wood, pine or deal—in fact, any soft piece of wood will do—which is screwed down to the bench in a convenient position, so that the engraver may dig in the tool after each cut, and so clear the graver point from the zinc which is attracted by the action of the steel while cutting through the zinc.

THE DULCIMER, AND HOW TO BUILD ONE.

BY R. F.

Completion of the Shell and Fitting of Soundboard.

Now take the blocks and gauge a mark 2 in. from the square edge on the under side, and screw the back on level with these marks with No. 6 screws $1\frac{1}{4}$ in. long. Put in screws at intervals of about 2 in., commencing at 2 in. from the bottom. Grease them before turning them in, as they must come out again before finally fixing on the back. Lay a straightedge across top and bottom, mark off projecting corners of the blocks, and saw and plane them off level, as shown in Fig. 3 by dotted lines.

Now take the back off again, and clean off all burrs or chips that may have got raised, and with some hot and strong—*not thick*—glue, quickly run over two inches of the edge of the back and the underside of the block, and, slipping them together, work them up and down a few times to get a good connection, and drive the screws home. Clean off all glue that has squeezed out, and repeat the operation on the other block. Now fit three blocks of the inch-square stuff $3\frac{1}{2}$ in. long accurately into the angles formed by the back and blocks on each side, glue them in, the first one at a distance of two inches from the bottom edge, A (Fig. 4), and set aside for a day or two to dry.

Our instrument is now beginning to take shape, but has yet to be strengthened by "bracing." First, for the front brace. For this cut a mortise in the front end of each block $1\frac{1}{2}$ in. long, 1 in. wide, and $\frac{3}{4}$ in. deep, D (Fig. 4). Take a piece of $\frac{3}{4}$ stuff, 2 in. wide, and of the necessary length, and cut it to fit accurately into each mortise, and, at the same time, fit perfectly level on the back. The top edges of this brace at each end must come exactly level with the lower edge of the groove, B (Fig. 4). It must not, however, be quite straight from end to end, but must rise $\frac{1}{2}$ in. in the centre, so that the top of the brace presents a slightly arched appearance. This will give the belly a rather convex surface, as it is found that this form gives a better tone, and also presents a greater resistance to the downward pressure of the strings.

When the brace is finished, fit it into its place, and bore a hole in each tenon to take a 2-in. cut clasp, and along the underside of the front edge of the back bore half a dozen holes to take $1\frac{1}{2}$-in. nails. Take the brace out again, and, quickly gluing the tenons and bottom edge of the brace, also the mortises, whip the brace into its place, drive the nails home, and punch the heads in. The back brace is made and fitted in exactly the same way, except that no curve or rise is given to the top edge.

At the risk of being thought too particular or fussy, here let me caution you to clean off all superfluous glue as you go along, or some may be left that will afterwards cause a deal of trouble by giving rise to an unpleasant jarring through cracking or warping off.

Back and front braces having been fixed, the next things to see about are the inside bridges. Without these the belly would not stand the pressure of the strings, but would "swamp," and most likely split. For the treble bridge, take a piece of the $\frac{3}{4}$ stuff $1\frac{1}{2}$ in. wide, and fit it between the front and back braces at a distance of $10\frac{1}{2}$ in. from the left bottom corner and 4 from the left top corner. It should be let into the inner sides of the braces about $\frac{1}{8}$ of an inch, and must be perfectly flush with the top edges of them. The bass bridge is fitted in exactly the same manner at a distance of 3 in. from, and parallel to, the right-hand block. These bridges must be considerably lightened by boring a series of holes through them with a $\frac{3}{4}$ centrebit. Draw a line down the centre of each side of the bridges, and mark off at intervals of $1\frac{1}{2}$ in.; then bore through till the bit pricks, reverse the bridge, and complete the operation, as in Fig. 5. Glue the bridges in and fix with two or three screws from the back.

The "shell" should now present the appearance shown in Fig. 6, in which A represents wrest-pin block; B, hitch-pin block; C, front brace; D, back brace; E, treble bridge; F, bass bridge; G, lining blocks.

Everything is now ready for the fitting of the most important part, the belly or sound board. First take your piece of pine, and carefully clean it up till the edges will just fit into the grooves in the blocks, B (Fig. 2). Now carefully draw a line on your blocks $\frac{5}{8}$ in. from the inner edge. This will exactly correspond with the depth of the grooves, and, laying your board over the shell, mark off the width from back to front, and reduce the board to within $\frac{1}{2}$ in. of this width; lay it on again, and mark off carefully to correspond with the marks on the blocks, and saw off to these marks. Fit the belly in the grooves by sliding it up from the front. You will find that the arched top of the front brace will make this rather difficult, but a little patience, gentle tapping, and easing where necessary, will soon ensure a good fit. It is not required to fit too tight, but only tight enough to prevent rattling; and, having effected this, remove the board again, and at a distance of 7 in. from the bottom edge and $4\frac{1}{2}$ in. from the left side make a dot for the centre of the treble sound hole, and $6\frac{1}{2}$ in. to the right of this make another for the bass. These sound holes are to be of $2\frac{1}{2}$ in. diameter, and may be cut with a pair of cutting compasses, a cutting-out bit, or a very fine-toothed pad saw. If a saw is used, great care must be taken to avoid splintering the edges. The belly must now be thoroughly sandpapered on both sides, and will then be ready for fixing. Glue the top edges of the front and back braces, and along the grooves and also the edges of the belly, and as quickly as possible slip it into its place and fasten it down with $\frac{3}{4}$ brads to the braces. Clean off the front and back edges level with the braces, and clean off also any inequalities of surface that may show. The front and back facings may now be put on. These consist simply of pieces of $\frac{3}{4}$-inch stuff fitted accurately over the front and back edges of the instrument, and when screwed and glued on forming an additional support. The top edges should be raised above the level of the belly $\frac{1}{2}$ in. and the ends must be cleaned off level with the blocks.

Fig. 7 shows front of instrument with facing on, under which dotted lines show outlines of belly, brace, and inside bridges. The description of the construction given above will be easily understood with the aid of the figures. I will show how to complete the dulcimer in another paper.

BRASSING: ITS PRINCIPLES AND PRACTICE.

BY GEORGE EDWINSON BONNEY.

Brassing.—The art of electro-depositing brass upon iron, steel, copper, and zinc, is not only a most interesting subject to the student of electro-metallurgy, but is also of great commercial importance, since the value of articles made with any of those metals is considerably enhanced when coated with brass. This art has only been put to practical use in this country during the last twenty years, although it has been successfully practised in Germany and France for a much longer period. Much of the tinselled imitation gold wires, spangles, and threads used in England are only made of copper wires electro-brassed, and these are imported in large quantities from France and Germany. Brass was deposited by M. de Ruolz, in 1841, from solutions of the double cyanides of zinc and copper. In 1847 M. Charles de Salzede patented a process for brassing and bronzing steel, iron, zinc, lead, and tin. Although Messrs. Russell and Woolrich patented a process for brassing in 1849, Mr. Joseph Steel another in 1850, and Messrs. Morris and Johnson a good brassing solution in 1852, Mr. Napier writes of it in 1875 as being "a process very difficult, although we understand it is done very extensively by means not made public." All who have had to do electro-brassing agree in saying that the process is difficult. The difficulties usually experienced are a tendency on the part of the solution to deposit its copper or its zinc in excess when a very slight change is made in the depositing arrangements, and a tendency to become poor in metal after being worked for a short time.

The cause of these difficulties appears to be in—(1) The unequal resistance to the decomposing effect of the current offered by the copper and zinc salts held in solution. The copper salts are more easily decomposed than the zinc salts; hence, when a current of low E. M. F. is employed, the copper is deposited in excess. Zinc salts require a higher E. M. F. to effect their decomposition than those of copper. (2). The unequal solubility of copper and zinc as anodes in the depositing solution. It matters little whether the anodes are composed of brass or of plates of pure copper and pure zinc: the effect is the same in maintaining the solution at its proper metal strength. The oxide of copper formed at the anode is more readily dissolved in the menstruum of the solution than is the oxide of zinc, hence the solution soon becomes rich in copper, and correspondingly poor in zinc salts.

The remedy for the first difficulty is to employ a battery or other generator of electricity giving a current of sufficiently high E. M. F. to decompose both copper and zinc salts as required. Now, copper can be deposited from its solutions by a current having an E. M. F. of from half to one volt, but zinc salts require current at a pressure of at least one and three-quarters volts to decompose them. These pressures may be represented in the first case by the Smee and Daniell cells, whilst we must have recourse to the Bunsen cell to provide the latter. Hence the Bunsen has been proved to be the best for electro-brassing purposes, because its current has a sufficiently high E. M. F. to decompose both copper and zinc salts in a brassing solution. The relative proportions of the two metals deposited are also regulated by the volume of current or quantity of current passed through the solution in a given time. It has been proved in practice that when a brassing solution is depositing the alloy in proper condition, an alteration in the anode surface exposed to the action of the current will affect the character of the deposit—an augmented surface causing an excess of zinc, whilst a diminished surface causes an excess of copper. Copper is also deposited in excess when motion is given to the articles receiving the deposit, and this is increased with increase of speed. Zinc is deposited from its solutions at the rate of 18·5 grains of metal for each ampère of current passing through the solution in an hour. Copper is deposited at the rate of 18·1 grains per ampère per hour. Therefore an increase in the volume of current would tend to deposit zinc in excess of copper, and this would be brought about by lowering the anode in the solution, and so reducing the resistance of the circuit.

The second difficulty may be met by employing a solvent in the solution which will readily dissolve the oxide of zinc as it is formed on the anode, and form a double salt of zinc easily decomposed by the current at the cathode. In practice it has been found that liquid ammonia best fulfils the required conditions, since it readily dissolves the oxide of zinc, and then yields its metal up to the free cyanide of potasssium present in the solution, forming therewith the double cyanide of zinc and potassium. When, therefore, the workman perceives his anodes coated with a whitish deposit, or when a whitish powder is seen to fall from the anode to the bottom of the vat, he may be sure that the powder is oxide of zinc, and to dissolve this he must add liquid ammonia to the solution until the anodes again work clear.

When, by practice, the right conditions have been found to deposit the desired colour of brass, such as the E. M. F. needed to overcome resistances and force the proper quantity of current through the solution, the most suitable area of anode surface to the work in hand, and the best strength of the solution, these conditions should be carefully maintained, even to the employment of the same gauge of wire for the slinging wires.

Mr. John T. Sprague, in his book on "Electricity: its Theories, Sources, and Application," gives the following "Principles" as a guide to the deposition of brass and other alloys:—

"1. The object to be attained is the deposit of definite proportionate weights of two or more metals; but as the current knows nothing about weights, but measures its work by equivalents, the proportions by weight desired must be reduced to equivalent proportions, by dividing the weight by the electrical equivalent (of the metal). Thus a brass is required containing 64 copper to 36 zinc; $64 \div 31{\cdot}75 = 2{\cdot}02$ and $36 \div 32{\cdot}6 = 1{\cdot}08$ gives the proportion in which the current must divide itself between the salts of copper and zinc.

"2. The solution need not contain the two metals in either of the two proportions, weights, or equivalent; the relative degree can have no fixed law, as it must depend on several conditions, and mainly upon a combined consideration of the facility with which the two salts decompose, and the equivalent proportion required to be decomposed.

"3. Incompatible salts cannot be joined in one solution (that is to say, salts which exchange their constituents or throw down a portion as insoluble), unless another ingredient is to be added which will re-dissolve the precipitate; this latter is often the case when ammonia or cyanide of potassium is to be added, more especially ammonia. In such cases, however, it must be ascertained that these new conditions do not alter the relative conductivity or decomposability of the various metals in solution.

"4. It is of the utmost importance that the metals of which the alloy consists should not have any strong electric relations to each other in the solution to be used. It must be remembered that what is called the electric order of metals is a pure delusion, unless taken in a particular solution, for a metal may be positive to another metal in one solution, and negative to it in another, as this depends upon the affinities of the metals to the other radicals.

"5. It is *desirable* that the several salts should have nearly the same electric resistance, or that these resistances (which partly depend upon the quantity of each salt dissolved) should be proportioned to the relative currents required; but this is not essential.

"6. It is *essential* that the battery power be balanced against the decomposability of the several salts. This is distinct from their resistance. Each chemical combination needs a fixed force to decompose it, and this is effected by maintaining a sufficient electric tension at the plates to effect it. This may be called the *specific molecular resistance*, set up at the cathode only, while the electric resistance lies in the space between the plates. If there is a great difference between the specific molecular resistance of the different salts, the current will tend to reduce the lowest only, and that, perhaps, in a powdery state; in such cases, the only remedy is to have only a sufficiency of the weaker salt present to supply the required deposit, thus forcing the current to act sufficiently upon the more resisting salt."

Mr. Sprague presents in tabular form a list of eight brassing solutions, from which it will be seen that they all contain cyanide of potassium, with one exception. The decomposable salts in solution are, therefore, simply the double cyanides of copper, zinc, and potassium. In the following table the quantities are proportional to each other, and therefore may be taken as grains, ounces, or pounds.

TABLE OF BRASSING SOLUTIONS.

	1	2	3	4	5	6	7	8

Carbonate	—	—	—	—	—	16	1	—
Nitrate ..	305	—	—	—	25	—	—	—

The solutions mentioned in the foregoing table are made up in the following manner:—

1. This is M. de Salzede's solution: Dissolve the cyanide of potassium in 120 parts of the water. Heat the remainder of the water to a temperature of 150° Fah., and add to it, whilst stirring well, the salts of potash, zinc, copper, and ammonia, each separately until all has been dissolved. Mix the cyanide solution with this, and allow the solution to stand exposed to the air for a few days, then work with a battery of two Bunsen cells giving a full current, and use an anode of brass.

2. This is also a solution introduced by M. de Salzede, and is made up and worked in a similar manner to No. 1.

3. Divide the water into two parts. Take one of these parts and divide into four parts, using each to dissolve the several salts in the following manner. First dissolve the copper salt, and add to it half of the ammonia. Secondly, dissolve the zinc salt in the water when heated to about 180° Fah., and add to it the rest of the ammonia. Thirdly, dissolve the potash in its part of water. Fourthly, heat the remaining part

of water to about 200° Fah., and dissolve therein the cyanide of potassium. Then mix solutions 1 and 2; add solution 3, then 4, stirring all the time; and finally add the remainder of the water. Work with a full battery power, using a brass anode, and add cyanide or ammonia when required.

4. This is the solution of Messrs. Russell and Woolrich. Dissolve the copper and zinc salts and the potassium acetate in part of the water; then add potassium cyanide until all the precipitate is dissolved. The potassium cyanide should be in excess, to form free cyanide. Work with a brass anode and a full battery.

5. Dissolve the salts separately, then mix together.

6. This is Messrs. Morris and Johnson's solution. Dissolve the salts separately and mix together, adding the cyanide of potassium last.

7. Dissolve the salts in the water and heat the solution to a temperature of 150° Fah. Suspend a large plate of brass in the solution, and connect to the positive pole of a strong Bunsen battery (three or four quart cells in series); suspend a small rod of copper in the solution and connect to the negative pole of the battery, and pass a current until the solution deposits brass freely on the copper rod. The temperature must be maintained throughout, and the solution worked hot. Add cyanide or ammonia carbonate as required.

8. This is Brunell's solution. Dissolve the salts separately. Add part of the potash solution to the copper and the zinc solutions until a precipitate has been formed, then add enough ammonia liquid to dissolve the precipitate; finally add the cyanide solution. Work with a large brass anode and two or more Bunsen cells, adding ammonia or cyanide as required.

Preference is given by Mr. A. Watt to solutions No. 3, 7, and 8, because these contain ammonia, and this dissolves the zinc oxide from off the anode. Whenever a white deposit is seen on the anode, add a little free ammonia liquid. Cyanide is added when the deposit appears to be deficient in copper, and zinc is in excess. When the solution appears to be deficient in metal strength—that is, holds less than a proper working quantity of both metals—it must be strengthened by adding to it a strong solution of the double cyanides of potassium, zinc, and copper. This deficiency is indicated when the alloy is deposited slowly, and has either an earthy or a greenish hue. When the deposited brass has a dull, dead, or matt appearance, the deposit may be improved by adding to the solution a small quantity of arsenious acid dissolved in a solution of cyanide of potassium. The effect of this addition to a brassing solution is similar to that of bisulphide of carbon on a silvering solution, as it gives to the deposit a bright and lustrous appearance. It should only be added in small quantities at a time when required. The arsenious solution is prepared in the following manner:—Dissolve $1\frac{1}{4}$ ounces of potassium cyanide in half a pint of distilled water made hot on a sand bath, then add, whilst the solution is still hot, 4 drams of white arsenic (arsenious acid), and stir until all the arsenic has dissolved. When cool, place the solution in a glass-stoppered bottle, and label it *Arsenious Solution,* VERY POISONOUS. This poison is even more virulent than cyanide of potassium alone.

Mr. A. Watt (who has had considerable experience in electro-brassing work) prefers a brassing solution made direct from brass. To do this he first dissolves good sheet brass in a mixture of 4 parts nitric acid to 2 parts water, by the aid of heat, until the acid solution ceases to dissolve any more brass. This solution is then diluted with four times its bulk of water, and to this add strong liquid ammonia until the green precipitate first formed is all dissolved, and the liquid assumes a beautiful clear blue tint. To this add a strong solution of cyanide of potassium until the blue colour disappears, and is followed first by a pinkish and then a yellow tint. After this add a little more to form free cyanide, and set the solution aside for twenty-four hours before using. It should contain one ounce of brass to the gallon, and is worked as directed in the preceding paragraph of this article.

Preparation of Metals to be Electro-Brassed.—The various metals intended to receive a coating of brass must each receive special treatment, since all do not receive the brass coating with equal facility. *Cast iron* should be pickled for half an hour in a mixture of sulphuric acid and water, in the proportion of 1 pint of acid to 1 gallon of water. It must then be rinsed in clean water and scoured well with a hard brush, coarse sand, and water, until quite free from black oxide and dirt. When quite clean it should be rinsed in clear water, then in a cold potash dip, again rinsed, and transferred at once to a very rich brassing solution, worked with current of extra high E. M. F. and volume. *Wrought iron* is prepared in a similar manner, but may be brassed in a weaker solution, and with a current of less strength. *Zinc* should be cleaned in a pickle only one-eighth the strength of the above, with two ounces of hydrochloric acid added to the gallon of pickle. It is then scoured in the same manner as cast iron, and immersed in a brassing bath suitable for brassing wrought iron. *Pewter* should be pickled for half an hour in a solution of nitric acid and water, in the proportion of half a pint of commercial acid to one gallon of water. It should then be scoured with a soft brush in fine sand and water, rinsed, and placed in a bath suitable to zinc or wrought iron. *Lead* should be treated in a manner similar to that for pewter, but must be brassed under conditions suitable to cast iron. Only one kind of metal should be placed at one time in the brassing bath, and the slinging wires should be of stout copper wire, so as to offer as little resistance as possible.

Finishing Electro-Brassed Work.—When the articles have received a sufficient coating of brass, they should be removed from the vat and rinsed at once in hot water. This will facilitate the drying, which should be further accelerated by placing the goods in hot boxwood or mahogany sawdust. They should then be brushed with a soft long-haired brush to remove the sawdust, and rubbed with a bunch of clean soft rag or a piece of chamois leather. The goods may now be lacquered or bronzed, or otherwise ornamented, as taste may dictate.

When electro-brassed goods are intended to be lacquered on a golden yellow coating, Mr. Watt recommends that they be finished in a special brassing bath, made up similar to No. 3 in the foregoing table, using copper sulphate instead of the acetate. A few minutes' immersion in this bath will suffice to give a finished yellow coating.

He also says that an indifferent coating on iron or steel articles may be improved by dipping them for a moment in one of the dipping acids for brass, and plunging them at once in cold water. When such metals have received an extra strong coating, they may be thus treated with advantage, the resulting colour of the deposit being equal to that of solid brass.

Much interesting matter respecting the electro-deposition of brass, together with full details of several brassing solutions, taken from French and American sources, and others not mentioned in this article, may be found in Mr. A. Watt's book on "Electro-deposition," pp. 366–394.

THE BUREAU IN GOTHIC STYLE.

BY D. ADAMSON.

HAVING given in previous papers the groundwork or construction of a plain bureau, let us now see how it may be enriched by ornamentation—how, in other words, it may be finished in any characteristic style that may be desired.

It is, of course, out of the question that every style or variety of style can be considered here, for to do so fully in even one of them would require far more space than can be devoted to the subject in its entirety. At the same time suggestions which will, no doubt, prove of service to the novice in directing him how to finish his bureau in a few of the more popular styles may be attempted. The salient features of these will be given, omitting little points which, however interesting to the antiquarian or student of old wood work, would only tend to embarrass the beginner, and perhaps unduly discourage him. For example, much might be said on the minute details by which the Early Tudor is distinguishable from the later Tudor or Elizabethan, and this again from the Jacobean. All are similar, and yet each has peculiarities of its own, not strongly marked in all cases, for it must not be forgotten that in the progress of any art there is no such thing as an abrupt transition from one characteristic style to another. No; the changes are gradual, so gradual that one scarcely observes them passing, and only recognises that there has been a modification by comparing the productions of different eras. Then indeed, the distinctions are apparent, but who can say when first the slight differences which by degrees eventuated in a distinct style were introduced? Even during the last twenty years, while fashions in wood work have been changing with unexampled rapidity, it has been impossible to note the subtle alterations by which one style has superseded another, though the most casual observer cannot have failed to notice that the furniture of to-day is very different from that of only ten years ago. Then the so-called Early English furniture was all the rage, now our leading designers are giving themselves more scope, and the stiff, severe "Early English" has been replaced by what it is hardly too much to say will result, if it has not already done so, in a style as characteristic of the present age as the Queen Anne—which, by the way, is somewhat vague—or the Elizabethan one of former reigns. It will thus be seen that styles, whether in architecture or in furniture—and the two are very much akin—glide into each other as it were. There is no abrupt transition.

Now, although only a few varieties of ornamentation can be dealt with here, the student must not imagine that a bureau, or other article of furniture, cannot be made or finished in any style desired, and as it is possible he may wish to try his hand at designing, the reference made above to architecture will supply the clue. Naturally enough the furniture of any period or country is in harmony with the style of the buildings within which it was placed, so that the designer in adapting old styles to modern articles can find a store of detail by studying the architecture of the corresponding period. This, it will be observed, is a very different matter from copying or reproducing as some might like to do. No doubt if this could be managed difficulties apply it to the modern contrivance, whether furniture or other articles, and lo, we have this in Gothic style, not a copy of a piece of Gothic work, but a piece of work in Gothic style. Herein consists the principle of making anything in any style. Now, let us see how we are to apply this principle in constructing a "Gothic" bureau, bearing in mind that no great elaboration can be attempted, but that the design must be such that an amateur of ordinary skill could execute it. This restriction, of course, confines us within very narrow limits, but not commend it as a suitable style for modern furniture. It may be said that the reason of its failure to do so is an evidence of want of taste; but it may almost, with greater show of reason, be urged that its rejection is a proof of instinctive artistic perception of its unfitness. It is essentially a style for stonework, and in adapting it to modern furniture much of its beauty is lost. Perhaps association of ideas may have something to do with the dislike to pure Gothic domestic fittings, but whether or not this is the case the style has never really taken

Fig. 1.—Gothic Form of Bureau.

would be diminished to some extent, at least so far as designing is concerned; but when furniture is in question it is altogether impracticable. Why? For the simple reason that furniture, as we understand it, is a modern invention. Even that of comparatively recent times is quite out of character with our ideas of taste and comfort, so that the mere copying of old examples would be useless, even if, indeed, there were any to copy. Take, for instance, the bureau. We may want to make one in Gothic style, but we shall look in vain for an example contemporary with it. That, however, does not prevent us making the bureau with Gothic characteristics, for these can be adapted to it. We seize a few, or it may be only one, of the leading features of Gothic ornament, as some compensation for this it must not be forgotten that simple ornamentation properly done is likely to be far more effective than more ambitious work badly executed. A simple rendering of any style can be given, for it is not necessary to crowd in every variety of detail which may be attributed to it, and this remark is, perhaps, peculiarly applicable to the Gothic, which, having been developed principally in work of an ecclesiastical character, is not so well fitted for reproduction in domestic furniture. Certainly Welby Pugin, and one or two other designers, have done their best to popularise it, and have given us sufficient evidence that it is adaptable to work of the highest excellence; but the fact remains that there is something about it which does any substantial position in our homes, and when it is seen in furniture it is generally in a very modified form. In Fig. 1 we see how we may give a slight Gothic character to the bureau without in any way departing from the structural details described, except that the cock-beading round the drawers is omitted. It will be noticed that the edges of the rails between the drawers, etc., are what is known as stop chamfered, an effective, and at the same time a simple, means of giving a semi-Gothic feeling to an otherwise plain piece of furniture. As will be seen by Fig. 2, which shows the chamfering on an enlarged scale, the edges are bevelled till within a short distance of the ends. The front edges of the ends are treated in a similar manner, a stop being made near ıe rails, except on the outer edges, where ıe chamfering runs through almost from ıe top to the bottom. To chamfer evenly nd neatly a special tool should be used, as n ordinary bull-nose plane, though effective ı practised hands, is likely to produce un- ıtisfactory results. The little contrivance epresented by Fig. 5 is so simple both in onstruction and manipulation that the mateur need not waste money on the more laborate planes specially prepared for cham- ering. It compares favourably with any of hem, except, perhaps, that it is not quite so uick in action. This is how it is made. 'wo pieces of wood, say, ½ in. thick, 2 in. or in. wide, and of any convenient length, ave a triangular piece cut out—the angle or ordinary, *i.e.*, square-edged, work eing 90°. Between these two pieces chisel is placed, with its cutting edge lling up the angle as shown by the haded portion of the diagram. The wo pieces of wood are then screwed ogether, and bind the blade tightly. f necessary a little space for this to e in, and prevent any tendency to ıteral play, may be cut. The depth to hich the chisel projects below the apex f the triangular space must be regu- ıted by the width of the intended evel. To use this handy little appli- nce it is only necessary to draw it ackwards and forwards along the edge f the board to be bevelled till it will emove no more stuff, when the bevel- ing is complete. It will hardly be ecessary to say that one of the sides f the triangular space of the stock must e kept continuously against the wood eing chamfered, and that if this ordi- ıary precaution is observed the cham- ers must be regular.

To elucidate the action more clearly o those who may not have grasped the dea in Fig. 5, the tool is shown against he section of the board, A, the edge of vhich has been bevelled to the full xtent of which the cutter is capable. The dotted lines may be said to repre- ent the portion of the chisel between he two pieces of wood which form the tock. The ends of the chamfer or the top must be finished off with a chisel, or neither the little arrangement de- scribed nor any other chamfering tool vill do this.

I do not know whether it will be ad- visable to remind beginners that this portion of the work, the chamfering, may be more conveniently managed before the parts are fixed together, though it may not be absolutely necessary. In Fig. 1 it will be noticed that the drawer fronts have bevelled edges, but if preferred they may be left plain. In this case they should be set back a little so as to clear the chamfers, for the effect would be anything but pleasing were they to be flush with the faces of the rails and ends. In Fig. 2 the relative correct position of the drawer front is indicated in section by B, the projection of the chamfered rail being unmistakable. In the same illustration C represents the section of the bevelled edge of a drawer front. It will be seen that the bevel is sunk slightly below the face of the front, as the trifling break gives a much better effect than if the bevel started direct from the flat. Besides which, it renders clean, true work more easy of accomplishment, especially if the bevel is a fairly wide one, when it would otherwise be a most difficult matter to get a sharp, clearly-defined line. To form the sunk bevel a rabbet plane will be indispensable, for unless the bevel can be cut regularly it should not be attempted, and it is almost impossible to do so by other means without a considerable amount of labour — more than the result is worth. In forming the bevel first mark it all round the front with a cutting gauge, then take a little off on the outside of the line with a chisel, taking care not to let this cut on to the flat front of the drawer. A guide is thus formed for the rabbet plane to work against as it cuts down the bevel, which on the end grain will probably have to be finished off with glass paper. This should be held round a flat, straight-edged piece of wood instead of on the ordinary cork rubber, in order to avoid rounding the edge of the break between the bevel and the flat surface. It is almost needless to say that the upper edge of the plinth should be simply bevelled off instead of being moulded as in the original bureau, and that the edges of the lid should be finished in a similar manner rather than be rounded off.

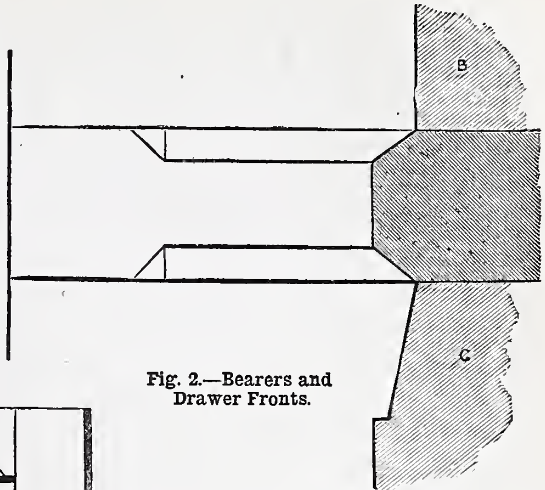

Fig. 2.—Bearers and Drawer Fronts.

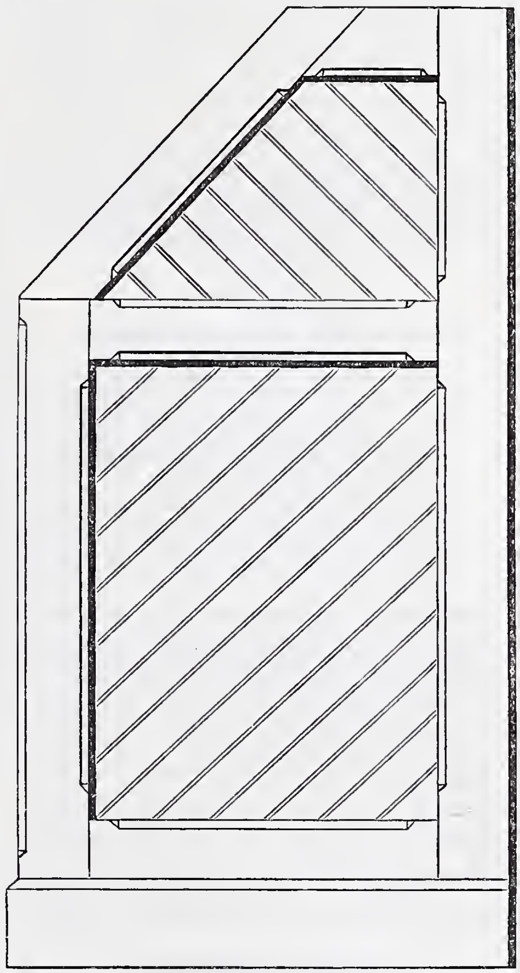

Fig. 3.—Panelled End of Gothic Bureau.

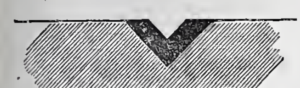

Fig. 4. — Section of V Groove.

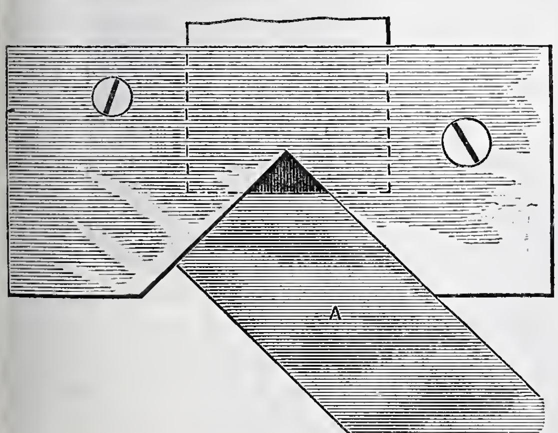

Fig. 5.—Chamfering Tool.

If further adornment to the bureau be desired, we see how it may be managed by referring to Fig. 1, where the lid or fall is represented with the panel sunk slightly below the framing, the edges of which are seen to be stop chamfered. Further, the panel itself may be channelled or grooved as shown by the diagonal lines, in which case it will be as well to let the grain of the wood run parallel with them, instead of from end to end of the lid. The section of the channels or V grooves, as they are commonly called, from their resemblance to that letter, is shown by Fig. 4. They may be easily formed by the use of a plane, the sole and iron of which are shaped to correspond, but as a grooving plane of this kind is hardly likely to form part of the amateur's outfit, the alternative of cutting the groove with a chisel will probably have to be resorted to. If, however, the plane is accessible to any who may not know how to work it when they have got it, it may be said that a guide in the form of a straight piece of wood will have to be temporarily fixed to the board to be channelled. There will then be no difficulty in ploughing the grooves straight and even. To cut the grooves with a chisel is certainly a more serious matter, but with care there is no reason why the work should not be as successfully accomplished. If it is considered to facilitate operations the channelling—which, by the way, should not be too wide, say not over ¼ in.—a small gouge may be used at first, the channel afterwards being brought to its proper shape with the chisel, or with a scratch or router, of which a full description was recently given in these pages. Those who possess a carver's V tool of rather large size may be reminded that they have a ready means of doing the required shaping; but even with its aid the grooves will very likely present an uneven appearance, unless some skill in handling it has been acquired. Provided the lines are straight, though, there is not much difficulty in reducing them to the regularity without which they will be but unsightly blemishes. The useful glass paper must be resorted to. Fit this over the edge of a piece of wood, which has been bevelled to correspond with the groove, and rub till a sufficiently clean channel has been got. By a moderate exercise of patience and even papering, a result which will compare favourably with the more speedy method may be obtained. Of course in rubbing down the groove with glass paper, the piece of wood on which this is wrapped must be held firmly, for if allowed to play from side to side, first sloping one way and then the other, it cannot be expected that a clean, sharp-edged V groove can be got. A little practice on a waste board is advisable before attempting to channel a valuable piece, for however simple the operation may be, a few experiments will show the necessity for care not only in getting the lines equal, *i.e.*, of the same depth and width, but equidistant from and parallel with each other.

For those who want a still more elaborated bureau a suggestion is given by Fig. 3. There, instead of the end being plain it is seen to be panelled, the edges of the framing being stop chamfered, and the panels themselves being V grooved to match the front of the work. The framing may be about 3 in. wide, and should hardly be of less than $1\frac{1}{4}$ in. stuff, which those who are familiar with wood working will know will be little, if at all, over 1 in. thick when finished up. If the framing is made from $1\frac{1}{2}$ in. stuff it will be all the better. The panels should not be of less than $\frac{1}{2}$ in. stuff, which will do very well, as they are not large, and instead of being channelled as shown, they may be bevelled to match the drawer fronts. The framing is fitted together by mortise and tenon joints, which those who have a craze for old-fashioned forms of working will probably think should be fastened by wooden pins running through instead of by the more modern, less barbarous, and equally efficient glue. The panels may be let into rebates run on the inner side of the framing, or be let into ploughed grooves. In the former case they should be fastened in with beads, in the latter the grooves hold them. No glue will be required; in fact, it should not be used to fasten in the panels, for the reasons given when the necessity for allowing for the natural contraction and expansion of wood was referred to. Fasten the panels into the grooves or in the rabbets with glue, and they are almost certain to split, but allow them play, and even moderately seasoned wood may be used without fear of splitting. Naturally, if there is an idea that the wood, from being green or unseasoned, will shrink to any great extent, the grooves or rabbets, as the case may be, must be deep enough to prevent the panels drawing right out of them.

Nothing more need be said about the construction of a "Gothic" bureau, but, no doubt, it will occur to those who intend to make one that pitch pine is the kind of wood which seems the most appropriate for this style. Not that there is any valid reason why it should not be made in any other wood, only somehow or other this plain Gothic wood work is generally associated in one's mind with pitch pine—or perhaps I should say in mine, for I don't know how the idea may strike others—much in the same way that Chippendale's work suggests choice old Spanish mahogany—only the association of ideas, nothing more. Well, if pitch pine is to be the material, see that it is dry and well seasoned, thoroughly so, for, unless it is, it is sure to split, and afford, in a marked degree, an evidence of the way wet stuff "goes." If the novice wants to know what this "going" means, he is informed that the vagaries of wet, *i.e.*, green, or, to use a less technical word, unseasoned wood, are so numerous that space forbids a detailed list of them. It may, however, be said that they are all annoying, and that "going" is only a colloquial abbreviation of "going wrong." Pitch pine is peculiarly afflicted with this tendency, though if care is exercised in the selection of sound dry stuff, it may be used with as little hesitation as any other wood. It only remains to be said that the brass handles and keyhole escutcheon plates, if any are used, should be in keeping with the Gothic character of the work, for unless they are they will, instead of improving it, rather be a detraction.

OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of* WORK *for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of* WORK *without charge, the notices given partake in no way of the nature of advertisements.*

108.—Patent Unbreakable Steel Pulp Ware.

The peculiar ware which I have the pleasure of bringing under the notice of the readers of Work in this number will, I think, be welcomed by all who desire to practise economy at home. It is known as the Patent Unbreakable Steel Pulp Ware, and as far as the word "unbreakable" goes, it certainly merits the name. It is sold wholesale by Messrs. W. B. Fordham & Sons, Limited, 36 to 40, York Road, King's Cross, London, N., who are the sole selling agents for the United Kingdom. It is designed, in a great measure, to take the place of earthenware, and certainly possesses considerable advantages over this material, for it is much lighter in weight,

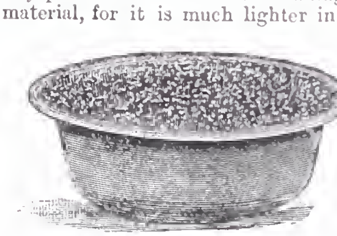

Fig. 1.—Shallow Basin.

and is not brittle or liable to chip. Indeed, it may be dropped from the hand, thrown about, or even dashed to the ground with considerable force without danger of breaking or fear of harm, and it will stand boiling water. At first sight, and on first handling it, it might be supposed to be a peculiar kind of papier-mâché, but this material is neither as strong nor as durable as the steel pulp ware, and will not stand the action of boiling water. Judging from its appearance, the foundation for the material seems to be a fine wire netting pressed into shape on suitable moulds, and then covered with a material which fills all the interstices, the whole being subsequently enamelled or japanned; and I am led to this conclusion by my knowledge of the substance sold as opaque wire roofing, which consists of sheets of wire netting covered on each side by some gelatinous substance. But this is mere conjecture on my part, for I have not yet had an op-

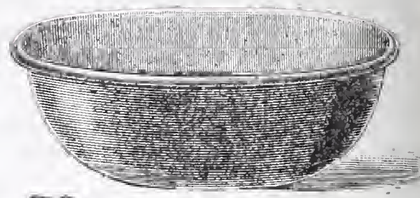

Fig. 2.—Oval Tub.

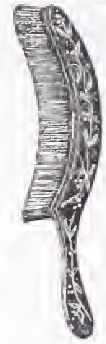

Fig. 3.—Crumb Brush. Fig. 4.—Crumb Tray.

portunity of breaking up a specimen to see whether or not I am right. The surface has the appearance of earthenware, and the patterns painted on it render it highly ornamental. All kinds of articles in general use in every household are made of it, bowls and basins of all kinds (Fig. 1), oval tubs for washing-up purposes (Fig. 2), crumb brushes and trays (Figs. 3 and 4), bread trays (Fig. 5), flower-vases or cache-pots (Fig. 6), waiters (round and oval), sponge dishes and show bowls, which may be supported on brackets sold for the purpose, finger plates, jugs, and all articles comprehended in toilet sets, and plaques, 6, 8, 10, and 12 in. in diameter, suitable for painting, and far easier to paint on than porcelain. Prices range low, and compare favourably with japanned goods and earthenware; thus the crumb brush and tray, shown in Figs. 3 and 4, are supplied at 36s. per dozen, or 3s. for

Fig. 5.—Round Bread Tray.

Fig. 6.—Flower Vase: latest shape.

the brush and tray, though I am not able to say whether this is the wholesale or retail price. Sellers of fancy goods would find these articles a valuable addition to their general stock, and likely to command a ready sale on account of the durability of the material as well as satisfactory appearance.

The Editor.

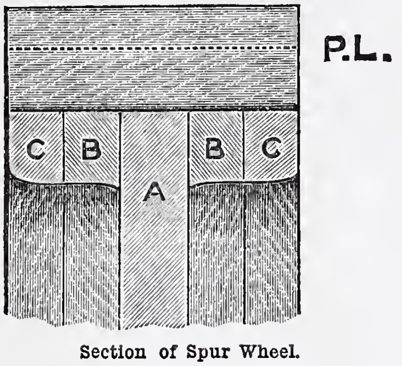
I.—Letters from Correspondents.

The Labour Laws.—"J" writes:—"From a recent report presented to the House of Lords on the laws affecting the hours of adult labour in various Continental and other countries, we gather a large amount of information on this deeply interesting question, and we are confirmed in our opinion that the average British workmen are better off all round than those in any Continental country. We subjoin a few notes jotted down in the course of perusal of this paper, thinking they will be read with interest by all those who, like ourselves, are personally interested in problems relating to the hours and conditions of labour. In Austria-Hungary the law limits the duration of work in mines to a shift of 12 hours, 10 only of which must be spent in actual labour. For factory hands the limit is 11 hours, exclusive of hours for rest and meals. Sunday rest is to be observed. These provisions may be subject to modifications in certain specified cases of emergency. In Hungary there is no general law affecting the hours of labour, and in some cases consequently they are excessive. A day's work of 10 to 12 hours is the normal, but in some industries and localities the working day extends from 12 to 15, and even 18 hours. Sunday rest is not prescribed, and the factories working on Sundays and holidays are 25 per cent. of the whole. There is no law in Belgium regulating or limiting the hours of adult labour, and great variations exist in consequence. In the mining districts the average day is 12 hours, but women are often employed 13 or 14 hours in loading trucks and similar heavy work. Cabinet makers at Ghent and Brussels often have to work 17 hours a day. Railway guards are often on duty for 15 or even 19½ hours at a stretch. Brussels tramway drivers work from 15 to 17 hours daily, Bremen from 10 to 17, and often half day Sundays. Brickmakers 16 hours in summer. In sugar refineries from 12 to 13 hours. Eleven hours is considered the average day's labour in the majority of trades in Belgium. There are a number of labour decrees in France, but as they mostly affect particular trades, no brief general statement can be given. But the report states that, as a rule, it may be said that Frenchmen in factories are present at least 14 hours out of every 24 in the shops. And it must be borne in mind that there is no compulsory observance of Sunday, and no day of habitual rest. Neither in Germany, Spain, Sweden, Turkey, nor in Denmark or Russia, are there any laws limiting the hours of labour. In Russia it is stated that they vary from 6 to 20 hours, but in the majority of cases, estimated at 80 per cent., the hours of labour are 12 and under. Manufactories with 12 hours daily labour number 36·8 per cent., those with 11 hours 20·8 per cent., those with 10 hours 18·1 per cent., with 8 hours 1·6 per cent., with 7 hours 0·4 per cent., and with 6 hours 0·2 per cent. Night work is pursued in 247 establishments. But the majority open at 5 a.m. and close not later than 9 p.m. In Saxony there are no laws affecting hours of adult labour, but the normal working day consists of 11 hours, exclusive of meals. In Switzerland the law limits the normal working day to 11 hours, reduced to 10 on Saturdays and holidays. There are numerous laws in the United States affecting the hours of labour, subject to various exceptions. We can only summarise a few of these. In New York mechanics work 8 hours; in most cities of the State nearly all mechanics and all connected with the building trade work 9 hours, except on Saturdays, when 8 hours is the rule. On the street and elevated railroads and in cities of over 500,000 inhabitants 10 hours is the normal day. In New Jersey hours range from 53 to 60 hours per week; in Rhode Island 10 hours daily; in Maryland an average of 10 hours; and the same in Virginia, North Carolina, Tennessee, Arkansas, Louisiana, and Missisippi, where there are, however, no legislative enactments. In California 8 hours is the day limited by statute, which statute, however, is constantly evaded, so that some of the trades which are unorganised work 12 or 14 hours daily. These examples are selected from a large number given in the report, and they take no account of exceptional cases which are recognised by the statutes. They also apply only to adult labour, but there are a large number of statutes regulating women and child labour, which in some countries is very severe. On the whole, the organised trades of this country may congratulate themselves on holding the best position among the European workmen, and second to none in the matters of hours of labour, second only in remuneration to that of the workmen in comparatively new countries like the States and our Australian colonies."

II.—Questions Answered by Editor and Staff.

Patterns of Spur Wheels.—H. L.—In reply to your inquiry "how to make patterns of wheel and pinion, wheel to have 44 teeth, pinion 13, pitch $\frac{5}{8}$ in., width $1\frac{1}{2}$ in.," you will cut the pinion pattern from solid mahogany, but not the wheel. The latter should be built up in overlapping segments, and the teeth glued on. The sizes of your gears will be thus:—wheel, 44 teeth $\times \frac{5}{8}$ in. pitch $=27\cdot5$ in. circumference $=8\frac{3}{4}$ in. pitch diameter; pinion, 13 teeth $\times \frac{5}{8}$ in. pitch $=8\cdot1$ in. circumference $=2\frac{5}{8}$ in. pitch diameter; your teeth will measure $\frac{5}{16}$ in. in length below pitch line, and $\frac{7}{32}$ in. in length above pitch line. The diameter of the wheel rim therefore before the teeth are put on will be $8\frac{1}{4}$ in. The wheel section is shown in the figure. The plate, A, may be made of a single thickness of wood, properly with one or two open joints, or it may be built in two thicknesses of segments with joints radiating towards the centre and overlapping—that is, made to break joints with one another like bricks in a wall. Upon each side of this plate build two thicknesses of sweeped segments, B and C, also with breaking joints. Then turn the rim to the section given, giving no taper, or at least no more than just sufficient to let the square touch tight and slack on top and bottom faces. The teeth will be either worked to shape first and fastened on afterwards, or glued on as rough blocks and marked out and worked in place. In the first method the teeth may be worked successively in a wooden templet block of the same



Section of Spur Wheel.

section, and glued to the rim by their centre lines, the rim being pitched out carefully. In the second the blocks will be glued on rough, turned when dry, flush with the wheel faces, and to the diameter of the tooth points; struck out on both sides and worked through with gouge and chisel, using a rebate plane for those portions of the faces which can be so got at. Their linear accuracy will be tested with a thin straightedge narrow enough to go between the teeth. A little very careful glasspapering will follow by way of finish. The pinion is best worked from a solid bit of stuff, the grain running in the same direction as the teeth. The block when turned will be therefore simply a solid wheel blank of $3\frac{3}{16}$ in. diameter, upon which the tooth shapes will be marked to be then cut through with gouge and chisel. The correct shapes of the teeth are obtained by the application of cycloidal curves. That is the pitch line of the wheel or pinion, as the case may be, is the base upon which a generating circle or circles are rolled for the development of suitable cycloidal curves for tooth flanks and faces. The dimensions of the generating circle may be properly varied with the sizes of the wheels and the nature of the gear desired. But a general rule is that it shall not be of larger diameter than the radius of the smallest wheel of a set. And a fundamental rule is that in mutual gears the same circle which strikes the flank curve for a wheel must be used to strike the face curve for its pinion, and that used for striking the flank curve of the pinion must be used for striking the face curve of the wheel. It is not necessary that both circles be alike, but a different circle may, if desired, be used for the flank and the face of the wheel, or of the pinion. In practice, however, it is usual to make use of a single describing circle throughout. Then any number of wheels in a set so designed will work together correctly. The best application for patterns for good delivery is common shellac varnish, made by dissolving shellac in methylated spirit, and applied with a brush. Vermillion, red lead, or lamp black are often mixed with the clear varnish to impart greater body, and render the surfaces of the pattern harder and more durable.—J.

Gilding.—B. P. (*Haverfordwest*).—Our friend wishes to know "how to finish mat gilding so that it will look bright and stand dusting." The question at once conveys to any experienced worker in gilding how very little the querist understands of the subject. To fully answer B. P.—however much one may desire to help and enlighten the perseverant worker in these columns—would occupy all "Shop" of this issue. Nevertheless, I trust he will appreciate the brief explanation, and that which only space herein will permit, hoping that, in time, room may be found in Work for a complete and exhaustive treatment of both "water" and "oil" gilding. Our correspondent's question refers to the former process, which involves a distinct trade and calling. Mat and burnish are the two treatments applied to picture-frame gilding, the former meaning a "dead" or dull surface of gilding, and the latter, as the word implies, gilding finished with a very high gloss or burnish. To obtain these two results special knowledge and personal experience is necessary—in fact, the tuition common to an apprenticeship—and the various stages through which mat and burnish gilding have to be brought ere arriving at a successful job are of such a nature that letterpress cannot practically teach them. Mat size and burnish size can be purchased from any dealer in gilders' materials; they are then in the form of a thick paste, the former a pink colour, and the burnish a slaty grey colour. Before a frame can be gilded it has to be gone over a great number of times. When the gilder receives it in the plain wood and "compo," he first coats it with "thin white," viz., prepared gilder's clear size with a little gilder's whiting added; then all dents and crevices are stopped with a putty made from whiting and strong size. After this the frame has four or five successive coats of white, but with a greater proportion of whiting than the first coat, care being taken to keep the shape of the frame clear. It will be understood that each coat has to be thoroughly dry ere adding another. The white will then be about the $\frac{1}{16}$ of an inch in thickness, when it is rubbed down to a smooth surface with water and pumice and other hard stone, shaped to suit the form of the members composing the design of the frame. This process requires care and experience especially. When dry it is rubbed with very fine sandpaper, and now it is ready for the coating with size—viz., the mat and burnish which has been already prepared and diluted with parchment size. Four or five consecutive coats of size is necessary to get a good surface, and this, when obtained, is washed with soft linen rag and water to get the parts to be left mat quite smooth. When the desired surface is obtained and thoroughly dry, the mat parts are gilded by wetting a small portion with a large camel-hair pencil and laying the gold leaf upon it. The gilder then blows with sufficient force to cause the water to pass from under the gold leaf, when, by the strength of the coatings of size underneath, the gold is firmly held when dry. Piece by piece the leaf is laid until the mat parts are finished, when, after careful examination and repairing of faulty little places, it is sized and thus finished. Burnish size—the only, so to speak, mysterious part of the business—is a curious compound of curious things, such as, I believe, pipeclay, blacklead, size, suet, red chalk, etc., the preparation of which is still one of those reminders of the "good old times"—namely, a "trade secret." Briefly, its nature is such that, when spread upon rounded surfaces and after the gold leaf has been laid, as in mat gilding, upon it and has become quite dry, it does not become hard and brittle, but allows its component parts to be rubbed and worked up under the gold to a very smooth and brilliant surface. As the brilliancy of any gilding depends solely upon the smoothness of the surface the gold leaf is laid upon, the burnish of water gilding is thus explained. The tool, or burnisher, used is a polished piece of flint or agate, mounted in a suitable handle and formed in various sizes to meet the different shapes of the frames. Ormolu, as gilders term it—in further answer to B. P.—is a richly coloured preparation of spirits of wine used for adding, in small proportion, to the last coat of parchment size which is given to all gilding with gold leaf, and for the purpose of giving the size a rich and golden colour. I trust our correspondent will appreciate this effort to explain a most difficult subject, and one, as before said, which cannot be taught by book.—F. P.

Cabinet in Fret Cutting.—A. D.—If you will re-read the paragraph at the top of column three, first page of Work, I think you will see how it is done. But in case that account is not clear I will repeat it. First line the back of the wood with a piece of printed matter, preferably a picture. Then having mounted your tracing of the design as usual for fretwork, drill the needful holes for the insertion of the saw, with a fine drill, and always in the corner or at an acute angle, close to the saw cut that is to be. Hold the saw rigidly upright in working, save all the pieces cut out, and having stained either all the bits, or the fretwork, as you prefer (not both, of course), replace the pieces after gluing the saw cut edge of each. If a fine saw is used, the glue itself will suffice to fill the crevices of the saw cut. The picture at the back is simply a guide, like a dissected puzzle, to assist in replacing. I should work the whole on a piece of glass to ensure a level surface, and put all the pieces in the back.—J. G. W.

American Organ Building.—W. S. J. (*Wandsworth*).—I have already sent in the first of my papers on American organ making, and it will appear as soon as arrangements can be made for commencing the subject. "The American Reed Board Agency," No. 2, Oseney Crescent, Camden Rd., N.W., will supply you with fittings. Write for price list.—G. N.

American Organ and Harmonium Building.—Vibrator.—See answer to W. S. J. (*Wandsworth*).—G. N.

Bellows for American Organ.—Organ.—See answer to W. S. J. (*Wandsworth*). The construction of the bellows will be fully dealt with in the first and second papers on "American organ making."—G. N.

Harmonium.—A BEGINNER.—It is impossible within the limits of this answer to give sufficient instruction to enable you to make a harmonium with two sets of reeds. If the Editor sees fit, I may possibly give a series of articles on the subject at some future date. But why not make up your mind to construct an American organ? It would prove a most interesting task, and papers on the subject will appear shortly.—G. N.—[At some future time.—ED.]

Organ and Harmonium Building, Book on. —SPECTATOR.—I do not think there is any work on American organ and harmonium making and repairing published. I have never heard of any book on the subject.—G. N.

American Reed Organ.—SHANG (*Scotland*).—The peculiar characteristic of the American reed organ is its sweetness of tone, and it is undoubtedly this feature which has made it such a popular favourite in this country. It would be difficult to name the principal makers without giving the whole list, as they all claim to be the best in the market. The best English organs are quite as good as the best American, and will generally last longer. I can supply you with the name of a good maker if you write to me through the Editor.—G. N.

Preparing Vellum.—PERSEVERANCE will find all his queries answered, at as much length as the limits of "Shop" columns will permit, in a recent reply to PUZZLED under the above heading, which appeared in No. 25, page 397.—M. M.

Leather for Concertina Bellows.—CONCERTINA.—You will get all the materials for concertina bellows from Messrs. Wallis & Son, Euston Road, London, Messrs. Kohler & Sons, Edinburgh, or through any music-seller who cares to order them for you.—H. D.

Hardening Steel. — TANCRED. — Please read carefully the remarks about working steel in article on "Swords," and try to fancy that there is a sort of law-governing inorganic matter which workers must be guided by. For instance, if you hammer one part of your tool much while cherry red hot, and another part much while black hot, you produce unequal tension of fibre of the steel; if you leave it to be chilled on the shop floor, this again affects the fibres — molecular structure is the scientific term. To heat a chisel thus damaged in the grain, and to chill it for hardening, and heat it again for tempering in that state is to ensure a twist in a flat thing, or a crook in a round thing. Follow the direction about heating and drawing sword blades if you forge your chisels. If they are forged already you must take the chance, but use a muffle—an old bit of iron pipe makes one—pack chisel with charcoal dust; when red-hot, pass it into a brine bath that has an inch of linseed oil floating on the top of the water, but the simple water bath ought to serve in most cases, if the steel has been fairly well worked, to make the chisel.—J. C. K.

Wood Carving Tools.—A. W. P. (*Leytonstone*). —Six cutting tools would be sufficient for carving wood picture frames: 3 gauges, a primer, and 2 narrow flat chisels. Most good tool shops keep an illustrated price list of Addis's carving tools, and by inquiring at one you could see at once the kind of tools you are likely to want.—F. M.

Hydraulic Motor.—C. G. O. (*Truro*).—Room cannot be spared in this department of WORK to give you a useful detailed account of how to make a hydraulic motor. I should advise you to fully study the subject by the aid of the lessons on hydrostatics in "Cassell's Popular Educator," and by reading such works as Mahan's "Water Wheels or Hydraulic Motors"; Donaldson's "Water Wheels"; or Cullen's "Practical Treatise on the Turbine." Any of these books can be obtained from Mr. Calvert, 99, Great Jackson Street, Manchester, if you cannot obtain them through your local bookseller. You may also learn much concerning the various types of hydraulic motors now in use by studying the illustrated catalogues of Messrs. W. H. Bailey & Co., Hydraulic Engineers, Albion Works, Salford, Manchester. Their little water motors are the pink of perfection, but you must have the water delivered to them at the right pressure to work them properly.—G. E. B.

Magneto Electric Bell.—NORTH (*Newcastle-on-Tyne*).—The generator for a magneto electric bell is simply a small magneto-dynamo with its armature wound with very fine wire, and made to revolve at a high rate of speed in the field of a powerful magnet. You may get such a machine from Messrs. T. Gent & Co., Braunstone Gate, Leicester. Space cannot be spared in "Shop" for a detailed and an illustrated description enabling you to make one.—G. E. B.

Improvement of WORK.—H. P. (*Kilmarnock*). —I am obliged to you for your kind suggestions about a cover, but as all these things naturally occur to us here as well as to readers in all parts of the country, I can assure you that all these matters are carefully considered and adopted if found to be feasible.

Eiffel Tower.—OHIO.—Reliable sketches of this structure will be found in the *Illustrated London News* and *Graphic*, if you search files of these papers.

Boat Building.—OHIO.—I cannot say with any certainty when papers on this subject will appear. As yet nothing has reached me, although I have been promised articles on building steam launch, canoe, etc. It will give me the utmost pleasure to redeem my promises on this point, when contributors who have undertaken to write on the subject enable me to do so.

Coal Mining.—COLLIERY DEPUTY.—I am afraid it will not be possible to go into coal mining in WORK, at all events just at present, in such an exhaustive way as you seem to require, but whenever any paper is sent me on improvements on the system at present in use, and on the appliances used, it shall be carefully considered with a view to insertion.

Kaleidoscope.—A. H. C. (*Birmingham*).—You must kindly bear in mind that the writer of the paper on his newly invented kaleidoscope is a busy man, and has but a very limited time for writing. His second paper, illustrated with very elaborate engravings, and his third paper also, have appeared before this reply meets your eye, because at the present moment it is simply impossible, owing to the demand for replies in "Shop," to find room enough to satisfy querists immediately. I greatly regret delays, and can only say that means of relieving the congestion are under consideration.

Bees and Hives.—J. J. B. (*Darlington*), BEE KEEPER, and other correspondents.—The series of papers on apiarian appliances, which I have now in hand, will include instructions for making hives, extractor, etc.—APIS.

Frustum of Cone. — CUBICAL CONTENTS (*Willesborough*). — Calculate the contents of the whole cone, and deduct the top. The rule is, divide the difference of the cubes of the two diameters by the difference of the diameters simply, and multiply the quotient by the height and by 0·2618. The cube of 14·5 is 3048·625, that of 7·5 is 421·875, and the difference of these cubes is 2626·75, which divided by 7 (the difference of diameters) gives 375·25, which multiplied by 0·2618 and 10 (height) is equal to 982·4 cubic inches.—F. C.

Engraving on Metal. — COUNTRY WATCHMAKER.—Articles descriptive of engraving on metal copiously illustrated are in my hands and will shortly appear. You must kindly bear in mind that where so much has to be done comparatively within narrow limits, it is not possible to deal with everything at once. Nor is it possible to give immediate answers to queries, owing to the great pressure on the space allowed, which is the utmost that can be given at present, and the necessity that exists for going to press some time in advance of publication. An answer has been given to your previous query on this subject, but the appearance of the answer in WORK depends, as I have said, on the space at command.

Printing.—T. E. N. (*Islington*).—Your letter contains a proposal to write a series of practical articles on this subject. It requires an answer by letter. You give your address, it is true, but append initials instead of full signature. Please write again giving name.

Gardening.—F. J. L. (*Chumleigh*).—It will not be possible to give directions either weekly or monthly for operations in the garden in WORK. There are many papers specially devoted to the subject, and then again there is Cassell's "Popular Gardening," a complete and exhaustive work, touching on every branch of the subject, which you might purchase with advantage, and which, if such a course be desirable to you, you might acquire by degrees, as it is published in monthly parts as well as in a complete form. WORK is a Magazine mainly dealing with construction and decoration. Appliances used in gardening come within its scope, but not the routine work of the garden.

Icing and Piping Cakes.—H. G. (*Paddington*). —You ask if I "have any idea of giving a few lessons on the ornamentation of cakes, technically called in the baking trade 'icing and piping,'" and you remind me that I "promised to give all kinds of work attention." It is true that I did so promise, but although WORK is a Magazine that treats principally of construction and decoration, there never was any intention of going into the construction and decoration of cakes. Moreover, if I mistake not, there is a special trade paper in which such subjects, I should think, would be fully and properly treated.

Model Ship.—J. B. W. (*Wolverhampton*).—There is so much pressure on the space allotted to descriptive papers and articles, that it is not possible to go into Model Shipbuilding, at all events at present. The best book you can have on the subject is "Model Yacht and Boatbuilding," published by Gill, 170, Strand, London, price 5s.

Glass.—W. H. (*Rawtenstall*).—To bore holes in glass use an ordinary drill, lubricating with turpentine and camphor.

Polishing Hall Chairs.—M. F. (*Balham*).—The best and most satisfactory way, if you are able to manage it, will be to re-polish your chairs entirely, cleaning and washing them well first. If the present polish is very bad it will be well to remove it by scraping, or with methylated spirits. So much depends on the condition of the chairs that without seeing them it is impossible to advise you definitely. Very probably a polisher might be able to renovate them by just touching up the defective parts with a rubber charged with polish in the usual way. Whichever course you adopt remember that no filling will be required, as the grain is already stopped. For the rest the process is just the same as if the chairs were "in the white," that is, unpolished. If the discolouration in the seats is caused by grease your best plan will be to scrape them, but from the doubt you imply as to the cause of this, I am almost inclined to think it may be owing to the natural darkening of the wood, in which case you need hardly try to remove it. By looking underneath you will probably be able to decide whether the discolouration is natural or not. You might lighten by washing with a solution of oxalic acid in water, after removing the polish, but you are more likely to do harm than good. If the marks are so conspicuous as to be an eyesore, suppose you darken the rest to match by mixing a little suitable colouring matter with the polish, or by staining, if you should be unable to get a deep enough tint without.—D. A.

Drills.—AMATEUR (*Edgware Road, W.*).—I am afraid you will find it useless to attempt to make these, as they can be bought so cheaply, and you are evidently not accustomed to the work. The material used is steel, which you can get of suitable quality and in quantity from Aird & Anderson, Whitechapel, Liverpool. After shaping the ends they must be brought to the proper degree of temper; so you will see as, you are only wanting a few drills, that the game is not worth the candle.

Blueing Gun Barrels.—AMATEUR (*Edgware Road, W.*). — This work is quite unsuited for an amateur. The barrels are prepared by oiling, and then placed in a chamber or receptacle where they are heated to a certain degree.—D. A.

Copying Apparatus.—W. C. B. (*Queenboro'*).—The process you ask about is evidently one of the "graphs." Any stationer will procure you the apparatus as well as the special ink required, but if you prefer to make it you can easily do so. The main ingredients are gelatine and glycerine with a certain amount of water, but to these several other ingredients are often added. For a few copies you will find ordinary glue melted as usual and a little glycerine do very well. The glue alone soon dries, and the glycerine is added to keep it moist, so you will see that proportions may be altered according to circumstances. I never use anything but this simple mixture, which can be re-melted whenever required, and a little more of either glue or glycerine added as desirable. The ink I always buy ready made as it is better, though it may be prepared by dissolving some aniline dye—purple is the best—in hot water. You will find the following a very good way of making a "graph." Soak some gelatine, obtainable from any grocer, or fine glue, in cold water till it becomes quite soft, and having poured off the surplus water melt it with heat. Take care not to burn it by placing the vessel directly on the fire. When quite melted add glycerine in about the proportion of four to one of the solid gelatine, and thoroughly incorporate by stirring. Pour the mixture into a shallow tin tray, such as the lid of a biscuit box and leave it till cold, when it is ready for use. Be careful to avoid the formation of air bubbles, which must be removed before the composition sets by pricking them. You will also find the following a reliable recipe, though more complicated:—Gelatine and sugar, 1 part each, 2 parts sulphate of barium, 4 parts water, and 6 parts glycerine. If you mix more than is required to fill your tray keep it in a tin canister for future use. After a time, what with washing off ink after printing and general deterioration of surface, the compo in the tray ceases to give good copies. It should then be scraped off, and re-melted either alone or with some of the fresh stuff with the tin, by letting this stand for some time in hot water. By this means you can use the compo over and over again. After using wash the surface over with a soft moist sponge to remove the ink, and when not in use keep the composition covered, both to keep it free from dust, and to prevent evaporation of the moisture.—D. A.

Copper Plating.—MINER (*North Wales*).—To copper plate with pure copper a number of large copper plates you will require a large vat filled with a solution of copper sulphate, a number of copper plates to be used as anodes, and a strong current of electricity obtained from very large battery cells, or a large electro-plating dynamo, the last being preferable. Before I can give you efficient advice, I must know the size and number of the plates to be coated. It will also be well to let me know whether you have access to a plating dynamo or not, and also what motive power you have at your command. If you do not know anything of the art, you should get a book and learn first how to deposit copper. Space cannot be spared in "Shop" for a full description, but the subject in all its details will be treated in WORK in a series of articles.—G. E. B.

Prints Transferred to Wood.—G. W. (*Chester*). —You must be prepared to encounter disadvantages if you seriously intend to pursue your idea of transferring prints from paper on to wood panels. (1) If you succeed in obtaining a satisfactory set-off the whole thing will be only a reversal, which will, in figure subjects, be very ridiculous. (2) The print which you use for the experiment will be irretrievably ruined. I have heard of a plan, but cannot vouch for its efficacy as I have not tried it: it is to saturate the paper on which the picture is printed, with tartrate of potass; then to pass a printer's roller charged with ink over the face of the print. The preparation of the paper is supposed to enable it to resist contact of the greasy ink, leaving the lines of the engraving fixed to receive it, and to transmit impressions. My reply to J. G. in No. 23 bears also upon this subject.—J. H. W.

Filter Bed for Conditioning Yarn.—W. B. (*Bolton*).—There are many forms of filter beds, or damp cellars, as they are called, but I will give the one that has given the best results out of many I have had to do with. It is rather an awkward thing to advise on, unless one could see the situation or the condition of things as they now stand, and I would suggest that persons asking questions that certain conditions would alter, should give the fullest particulars when asking the question. But to the question on hand: the first thing to do is to determine the floor line, then dig or clear out the soil to a depth of 2 feet below the proposed floor line. Should you now come to a good solid bottom of clay, you can commence to construct the bed, but should the bottom not be clay, or not a good clay bottom, then you must go 4 inches deeper. When that is done, you must puddle 4 inch of clay in, and level off, and lay in drain pipes to be connected with a pipe to the lodge. You will then lay in 3 inch of round stones, such as you see in brook beds. Should you get them from a brook, they must be washed before putting in your bed. They should be riddled with a riddle of $1\frac{3}{4}$ in. mesh, and the smaller ones that go through will be wanted later on. You now put a layer of sand about 1 inch deep, then comes the smaller pebbles or stones 3 inch deep. You now put 1 or 2 inch deep of charcoal or gas carbon, that can be got from the gas-works. You lay on 7 inch of sand, and the bed proper is made. You now put a brick floor on the sand, and the bricks must be put on their edge and laid half an inch apart from each other all round. You put fine pebbles, that have been washed, in the spaces between the bricks. You can now lay on your water supply, which must be a slow but constant one, at distances 16 ft. apart, and regulate the water so that you always have the top of the bricks level with the water. You will soon find out how to get at that. Should there be anything more you wish to know, ask.—J. W.

Gilding on Gilt Mounts.—L. M.—Gilt or bronze mounts are made by using good glue free from grit, which is spread evenly upon the card or surface to be gilt, and bronze powder dusted on through a sieve. It is a dangerous process to health, and I would advise the amateur to buy his boards ready bronzed. He will find it cheaper.—G. R.

Rust on Pianoforte Strings.—Cheviot wishes to know how to remove the rust from the strings of his piano. Take out the front or top door, also remove the bottom door, under the keyboard. Then unfasten the buttons, and pulling the action forward, lift it out carefully, then you will be able to get at the strings. Now provide yourself with a piece of soft leather, one pennyworth of flour emery, and a little paraffin oil. Slightly damp the leather with a few drops of paraffin, and sprinkle on the faintest suspicion of emery; rub up and down the steel wire. Do not touch the copper strings at the bass, except the ends which are steel. The rust on the coils round the wrest pins should be removed with a strip of leather put round the coils, and pulled up and down. Serve the bolt-heads in the same way. To prevent a recurrence of this, pulverise some camphor in a little lard free from salt, put a little on a piece of leather, and rub over the strings. Also see "Hints on Preservation of Pianos," in No. 9 of Work.—T. E.

Photographic Lens.—R. C. D. (*Aberdeen*).—You ask for a "tip" as to the making of a lens, and though I could throw my reply into the form of a *résumé* of the common process of grinding such a lens, I am sure that the reply would be of little practical value to you. For two or three shillings, Lancaster, of Birmingham, or any maker of cameras at popular prices, would sell you a lens that would be exactly what you want, and which it would take years of patient labour on your part, if I understand your letter rightly, to learn to make. Practically this is the best information I can give you. Evidently your idea as to the "various kinds of glasses, and how they ought to be placed in the tube," is of the simplest degree, and consequently any discussion with you as to the construction of a complicated photographic lens would have to be begun at its most elementary optical stage.—E. A. F.

Sign Writing.—F. W. B. (*Bristol*).—The specimens of old English lettering given in No. 19 of this journal were drawn expressly for publication in Work, and taken from the best available source. The example sent by F. W. B. is not true old English, but a cross between the old black letter and Anglo-Saxon. The formation of the various alphabets vary in almost every town in the kingdom, and each writer forms his letters according to his own individual taste. Controversial matters of this sort, however, do no good to any one, and I must decline to enter into them with F. W. B. At the same time, I am always willing to answer a plain and practical question. As to the £10 per week, there are many men in town who undertake the best contract work who earn more than this even, but, of course, 30s. is nearer the mark in the case of the ordinary country journeyman. It is, however, to the former ideal I hope to see the industrious student reach. The remarks about amateurs and outside competition is "baby's talk." It is the same in all trades, and nowadays it is simply the "survival of the fittest." If F. W. B. intends to insinuate I am writing for amateurs, he is mistaken, as I do not consider it work an amateur is likely to take up.—H. L. B.

Ink for Ticket Writing.—Paradox (*Southport*).—The following is a good receipt:—Rub thoroughly together eight parts lamp-black, sixty-four parts water, and four parts finely pulverised indigo. Boil until most of the water has evaporated, and then add five parts gum arabic, two parts glue, and one part extract of chicory. Boil again till the consistency of paste, then run into wooden moulds that are rubbed with olive oil. It is the addition of too much gum arabic that causes the ink to crack on the tickets.—H. L. B.

Mounting Pictures.—J. T. (*Burton*).—The best method, and one always adopted by good photograph mounters in the trade, is as follows: Damp your photograph upon clean glass face downwards, and starch the back evenly, which is prepared by putting, say, six pieces of best white starch, procurable from any respectable oilman, in a basin and mix to a thick paste with cold water, then pour sufficient water—must be boiling—to form a thick paste, and use when cool. Paste is fatal to photographs; when starched lay upon your card, and rub down with blotting-paper, and you will have it dry for use in five or ten minutes.—G. R.

Wood Mitre Cramp.—J. H. (*Blackburn*).—I cannot advise you with respect to making a wood mitre cramp. As a sort of substitute, I should suggest placing a cord round the frame when glued together, and laying on the bench, placing a piece of round wood like a hammer handle, and twist it up tight as you please. This is the best method I could devise, but perhaps some brother amateur on reading this will give you his experience of making a more practical home-made mitre cramp.—G. R.

Polishing Mahogany.—J. M. (*Glasgow*).—Some papers on polishing are in the printers' hands and will soon appear. Replies to all queries submitted are obtained as speedily as possible, and are then handed to the printers to be put into type for appearance in Work. Owing to its very large circulation, each number of the Magazine goes to press considerably in advance of its date, and hence it sometimes appears that an unreasonable time elapses before the inquirer gets his answer. If you could pass a week in the Editor's office you would find that everything that can be done to expedite matters is done.

Continuous Fountain in Small Aquarium.—J. M. (*Glasgow*).—Fountains must be supplied from a height considerably above themselves. Thus, supposing the aquarium to stand on the floor of a room, the cistern which serves as the source of supply should be somewhere near the ceiling. The fountain will work as long as there is water in the cistern, and the continuity will depend, therefore, on the maintenance of the supply.

Dulcimer.—Grandfather.—A series of papers, conveying instructions for making dulcimers, will be commenced shortly, and in these will be given information on every point on which you ask assistance. It will be useless to go over the ground twice, first in a detailed reply to yourself, and then in the articles.

Cock, How to Grind in.—S. G. (*London, S.E.*).—To grind in a cock, take out the plug and wipe off any grease that may adhere to it, and after dipping in water, sprinkle a little burnt sand on it. Now insert the plug in the shell of the tap, and turn it backwards and forwards, but be careful not to put pressure on the plug when turning it back. Take the plug out occasionally, and sprinkle more sand on when required, and continue this until the plug bears equally all round, which will easily be seen by the appearance of the metal. Finish off with a little whiting and water. Finely powdered Bath brick may be used if the sand is not procurable, but on no account use emery powder, as it cuts the metal.—T. W.

Disinfecting Books.—J. M. (*Edinburgh*).—Sulphur fumes will make an excellent disinfectant for books, but in using it you must not subject the books to any degree of heat, as the heat will spoil the binding. Leather-bound books will crack, and cloth will blister. It will be best to put the books in a box, and carry the fumes from the burning sulphur through a pipe into the box. The arrangement of the box, etc., will be an easy matter. After disinfecting, it will be well to wash the binding over with glaire—*i.e.*, white of eggs beaten up until quite thin. If you had stated the style of binding of your books, I could have given more definite information. Querists should be explicit with their questions, as it is sometimes difficult to get at what is really wanted.—G. C.

Cloth Binding, Restoration of.—Anthropos.—It is impossible to restore cloth covers of books that have become faded through use. Bookbinder's cloth is never washed, for the simple reason that washing spoils it. The best way to restore cloth-bound books is to re-bind them. The information necessary for doing this is forthcoming in the pages of Work. In the meantime you may freshen them up a little by coating them with glaire—*i.e.*, the whites of eggs beaten until quite thin. Do not attempt to dye the covers of your books.—G. C.

Book Cover, Best Material for.—W. H. B.—The best material for a book cover, whether it be red, green, or blue, is morocco. If the book is a small one, let the skin be as thin as is consistent with strength. The materials used for binding depend very much upon the nature of the book and the taste of the owner. I should have preferred a little more information in this respect than your query contains.—G. C.

Re-painting Clock Dials.—G. C. H. S.—There is no more difficulty in doing this than in engraving a dial, or painting the name on one. The chief thing required is that you have had practice enough beforehand to obtain some skill with your tools. You say you use a spirit varnish. If you mean a paint made with colour and varnish, such as Brunswick black or Aspinall's, then you should be able to get the fine lines all right, providing you have a good brush, and that you know how to draw or paint sufficiently well. For your present job, you might try and get a steady line by using a ruler to guide your pencil; but, after all, painting dials is a special line, and here in London they can be sent to a clockmaker's material shop, and they get it done. However, there is no reason why you should not paint a dial yourself properly, but you must practise first, and if you study Mr. Benwell's papers on Sign Writing, you will get a good many hints as to materials, etc., for really it is very nearly allied to a sign painter's job, is'nt it? Now, as to the solution that you have seen used to clean gold and silver work when tarnished by fire, it is composed of 1 part sulphuric acid, or vitriol, as it is also called, and 30 or 40 parts water. The same proportions of nitric acid (aquafortis) and water (1 in 30 or 40) are sometimes used, but the first here given is the best. They are usually known under the names of "vitriol pickle" or "nitric pickle" in the workshop.—H. S. G.

Colouring Small Bed-room.—J. C. (*Holloway*). Nothing is too trivial for "Shop" to reply to, providing a useful and reasonable question is asked. You say you understand making white-wash; then so also do you the making of blue-wash. Perhaps, however, your plan and the house-painter's may scarcely be identical, so I give you brief instructions on the mixing. Respecting your "unwelcome guests," a room so inhabited should have every particle of wall-paper stripped off it, and everything washed off the walls with hot soda-water until the plaster is quite clean. If the trouble is confined to certain spots, saturate the parts well with carbolic acid, or petroleum is useful. If general, give the walls—after all holes and crevices are stopped with plaster-of-paris—a coat of strong patent, or glue, size with some carbolic acid or turpentine in it (about 1 gill to 1 gallon of size). Then, for finishing coat for light blue or grey walls, you will want, say, 14 lb. whiting, say 6d.; 1 lb. of glue, 6d.; and $\frac{1}{2}$ lb. lime blue powder, about 3d., total 1s. 3d. Put the glue in 1 quart cold water, to soak over night, and when soft, stand over the fire until dissolved. If you can conveniently get ordinary double size, it is the simplest; 4 lbs. of this is necessary, and the cost about 4d., and it will only require dissolving with a little water added, but don't make it very hot. Put, say, one quart cold water into a vessel, then the whiting into it. When the latter is soaked and soft, pour off water from the top and put in the lime blue, well mixing with the hand or a stick. When the two are thoroughly incorporated, add the quart of warm size or diluted glue; thoroughly mix the lot, and then it is ready for use. Remember that all colours made from whiting dry nearly half as light as when wet; also that the distemper, or colouring, works best when cold. A half-pailful should do a small bedroom.—F. P.

Canvas and Cardboard for Painting on.—V. N. (*Manchester*).—I am not certain of the precise proportions of the paint with which the working side of canvas is covered, but it could be prepared without very much trouble, I believe. In the first place, however, the canvas, as it is called is made specially for the purpose, free from roughness and uneven surface. Again, the manufacturers do not coat it with a brush, as you or I should have to do, but the white paint is rolled on—hence, freedom from brush marks, and a perfectly distributed coating. The cost of good prepared canvas retail is about 2s. 9d. per yard of 27 in. wide, and so on in proportion to width. You will, therefore, see that, by the time you have bought the special fabric, purchased your materials, and accomplished your purpose, you would not effect much saving—in fact, the mounted canvases can be bought at so reasonable a price that I do not believe it would pay to prepare one's own, either in small or large quantities. Presuming, however, that you have a piece of canvas, or any similar fabric, it would require to be stretched, if only permanently, and then coated with strong, warm patent size. When thoroughly dry, one good coat of paint made from white lead and light copal varnish, well mixed to a stiff paste, and then diluted with turpentine to a consistency which we can spread freely, would give a non-absorbent surface suitable for oil-painting. Whether the amount of "body" the one coat contained would be sufficient to fill up the "grain" of canvas is, of course, entirely dependent upon its degree of texture. After spreading the colour generously with the brush, you would have to stipple it with a large tool to properly distribute the colour, or, better still, cover a paperhanger's roller with cloth, and roll the colour over quickly and evenly. Winsor & Newton, the royal artists' colourmen, make a prepared "Academy" board which is non-absorbent. It has a good hard and smooth surface, and appears only to be rolled with one or two coats of "flat" paint, such as above. If your boards are of a cheaper kind, and rougher and more porous in surface, you might with advantage give two good coats of size previous to painting. The paint can be stained to any desired colour, so long as little or no oil enters into the mixture, in which case you will get too glossy a surface, and it will not harden so well.—F. P.

Care of Bellows.—WHEELWRIGHT.—The proper way to keep your bellows in good order is to fill them with air, then chain the top up, leaving the bellows distended until you wish to work them. If they are new do not oil the leather, as it will only harden and cause the leather to be stiff. Dust the bellows often, especially in the crevices, as fine ash or grit settles in and causes the leather to wear into holes. In some shops they only suspend the bellows at the week end and holiday time, also dusting it often. Others leave theirs down, occasionally dusting it. The consequence is that the creases in the leather caused by constant pressure is the weakest part in the bellows. I presume the long bellows you have bought are second-hand ones, as those who now go in for new bellows buy the circular ones, as they are easier fixed and take up less room. If your bellows have been oiled and the leather is stiff, chain the top up and give a thorough good dusting, then wash the leather several times with warm water. When dry rub the leather well with dubbing made from the following recipe:—Get ½ lb. of tallow and melt it, then pour in the tallow 1 pint of train oil. Mix well together. Another recipe equally as good:—Get ½ lb. of mutton suet, melt in an earthen pot in the oven, then pour through a sieve into a large pot. Into this liquid fat pour 1 pint of raw linseed oil, and mix well together. In cold weather this dubbing should be warmed before using, and can be applied with a brush or a flannel rag. If the bellows are used from Monday to Saturday it can be cleaned and dubbed every twelve months.—W. P.

Small Lathe for Bench End.—E. W. M. G. (*Malvern Link*).—What use do you intend putting the lathe to? If you wish to turn pieces about the size of the first joint of your thumb, a lathe 8 inches long might do it, but for a larger piece of work it would be quite useless. However, I would be far from discouraging you, and, by all means, make a lathe, but let it be longer than 8 inches. Such a small thing, except after the manner of a watchmaker's throw, would never pay for the time spent on it. Why not make a lathe the whole length of the bench, and so that it could be removed when not wanted? something like the first I described in "Lathes for Everybody." If you make the heads of that very microscopic, it might be confined to a space 8 inches long. Although I am not the writer of the reply, page 332, WORK, yet I may be permitted to suggest that the table E E could be attached to a separate pillar and not to the guides, D, to which it appears to be fastened in the drawing. The pillar could be made in two, with a joint which could tilt the table, or a semi-circular piece of metal could be attached to the under side of the table with slots in which the fastening screws would work. It is not easy to make a tilting table which acts really well and scientifically.—SELF-HELPER.

Clocks in Fretwork Cases.—YOUNG CLOCKMAKER.—I am sorry to say that I do not understand your details at all. I gather you want to know if your cases are large enough to take chime quarter movements. To that I can say "yes, plenty," an ordinary chime movement being about 8½ by 7 by 4 bells in height, extra say 3 inches, and now beyond this I am fogged, as I do not see what you want mitre wheels on pin wheel and centre wheel, as these trains are made in the usual way, with a third train added generally on the left for the quarter work, and all three trains being inside the plates; but if you have never seen a chime quarter clock, let me advise you to get Britten's "Watchmaker's Handbook," as on page 259 there is a good drawing half full size of a movement showing all the dial work, etc., and trains, and on page 258 giving full details of trains, etc. The book consists of 384 pages of useful matter to all interested in watch or clock work, whether young or old, amateur or professor; the cost is 5s. If you cannot afford one, I will lend you mine for a week to copy out the necessary matter if you will pay postage both ways and return it.—A. B. C.

Sideboard.—A. J. (*Ingrow*).—Certainly, you are quite right to put any questions on matters coming within the scope of WORK to us, and I trust you, like many others, may derive increasing benefit both from answers and articles. We cannot, however, undertake to reply privately as you suggest may be done to you, the "Shop" columns being intended not only to help individual inquirers in any difficulty that may occur to them, but to be of utility to readers generally. I am glad you send sketches, for however rough they may be, drawings are of great assistance in enabling a suitable reply being given. It seems almost a pity to make such a piece of furniture as the sideboard of pine, but your reason for doing so is certainly a cogent one, and there is no reason why a pine job should not be sound and good. I certainly should not advise you to paint and grain it. This finish, which in any case I am not fond of, would make your sideboard suspiciously like a common kitchen dresser. If you must paint it, let the finish be plain—*i.e.*, ungrained; but I would much prefer the alternative of staining and French polishing. I am not sure whether you do not contemplate marking (or graining) with stain. In thoroughly practised hands this may occasionally be to a limited extent, allowable; but the effect is rarely good, as work so finished has generally a common tawdry appearance, especially when done by any one without great experience. The carved trusses under the drawers can be bought; but I do not think you will find them any improvement on some more simple ornamentation which you could make up yourself. They are, in fact, rather tawdry than otherwise. You might, for instance, substitute a flat or turned half pilaster planted on the doors. A flat pilaster would look better if finished with a few beads or flutes, either of which you can easily manage with the aid of the scratch described in No. 7 of WORK. The same tool you will also find useful in ornamenting the drawer front, which I think, you had better make flat instead of curved, as shown on your sketch. This, however, is more a matter for your personal consideration, and you will, of course, to some extent be guided in the details by those of the small cupboards you intend to put on the sideboard. The two doors in the centre will do very well with looking-glass panels, but it is entirely a matter of personal taste whether you have them of this or of wood. Glass looks brighter and lighter, but generally the doors of sideboard cupboards have wooden panels. Transparent panels of course would only be used if you wish the contents of the centre cupboard to be visible, and unless they are ornamental you would not want them to be seen. A suitable length (provided the space is sufficient) for the sideboard will be 6 ft. It may, however, be made as small as 5 ft. with the four doors shown. In anything under this you had better make it with only one in the centre, which should be wider than the ends. The depth from back to front on end of top should hardly be less than 1 ft. 8 in. for 6 ft. length. If it is shorter reduce depth say, 1 in. for each 6 in., down to 5 ft. If your room will take it, and you want plenty of cupboard space, these dimensions may be increased, as there is no definitely fixed rule of proportion, and those given are merely approximate. The height of top should be about, or a little more than, 3 ft. For the substance of the stuff I should say that 1 in. (in pine) will be best for most parts, panels, drawer insides, and such like being less. A good deal, however, depends on how you intend setting out the work, and I can only advise you generally. You may want a thick massive looking top all solid, in which case 2-in. stuff would not be too much, or you may prefer using a comparatively thin top lined up to give the appearance of thickness. In connection with this I need hardly tell you to study the article on lining up, which has appeared in our pages. You will also find the articles on artistic furniture, and jointing up of use in giving you many hints. I think you will find the appearance of your sideboard improved if you raise the cupboard a few inches on turned columns, instead of placing it direct on top as in sketch. The side brackets also strike me as paltry-looking, and you will find the whole look much better, and not involve a great amount of extra labour if you carry the sides up to the top of the small cupboard, finishing them off with a little carving or moulding to match that on the back of it. One or two shelves should be fitted, screwing them from behind and the inside of the cupboard. They will be useful for books or ornaments, and if you support them by brackets or columns at the corners, you will have a handsome piece of furniture. As a suggestion for you, and to make my meaning clear, a sketch is given, which, without going into details sufficiently shows the intention. Instead of turned columns to the shelves, these are shown with rounded corners, and supported by a small bracket. If there is anything else you want to know about as your work proceeds, send us word and we will do what we can to help you.—D. A.

Lathe and Joiner's Benches.—W. T. C. (*Dundee*).—Yes; both these subjects will be treated in due course.

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Horse Power of a Windmill.—G. C. (*Nunhead, S.E.*) writes in reply to SCRUTINEER, see page 526:—"I send a simple formula for calculating this:—

HP.=Horse power.
V.=Velocity of wind in feet per second.
A.=Total area of sails in square feet.

$$HP. = \frac{A.\ V.^3}{108,000}.\ "$$

Lacquer for Iron and Steel, etc.—J. H. B. (*Kingstown*) writes in reply to STEEL (see page 526):—"On page 525, No. 33 of WORK, STEEL will find under heading 'Brass Lacquer' a formula for making a varnish which is called No. 1. If to this STEEL adds some aniline blue, previously dissolved in a little methylated spirit, he will have a very fair blue lacquer, which may be applied with a soft brush. The articles before being painted over must be perfectly clean. By using other shades of aniline instead of blue any colour lacquer may be produced."

Brass Lacquer.—BRASSOLINE (*Glasgow*) writes in reply to STEEL (see page 526):—"STEEL wants to know where to get blue lacquer for tin toys, etc. He can get blue or green; there are different grades. I think grade K K is the best at this address. The name of it is Brassoline. The Frederick Crane Chemical Company, 22, Newhall Hill, Birmingham."

Tuition in Carpentry.—G. W. M. (*Westbourne Park*) writes in reply to AMATEUR (*Bayswater*), see page 302:—"You can obtain tuition in carpentering at the Anchor Institute, Johnson Street, Notting Hill Gate (opposite the Free Library), during the winter session, which lasts from September to March. If you write to the secretary be will afford you every information."

Trade Notes and Memoranda.

WE take the following from the *Journal of Chemical Industry*:—Glycerine is used in tempering steel and iron. The specific gravity of the glycerine may be varied between 1·08, and 1·26 at 15 degrees Cent., by adding water, according to the composition of the steel. The quantity of glycerine should be from one to six times greater than the weight of the pieces to be plunged into it, and its temperature may be varied from 15 degrees to 200 degrees Cent., according to the hardness of the metal. The harder the steel to be tempered, the higher should be the temperature of the glycerine. To increase the quenching power of the bath various salts may be added. Thus, when a harder temper is required, protosulphate of magnesia may be added in quantity from 1 to 34 per cent. of the liquid, or from ¼ to 4 per cent. of sulphate of potassium. For a softer temper, 1 to 10 per cent. of chloride of manganese, and 1 to 4 per cent. of chloride of potassium may be added. The principal advantages to be derived from these methods are:—(1) The temperature of the aqueous solution of glycerine may be varied within wide limits, the boiling point of pure glycerine being 290 degrees Cent. (2) Owing to the fact that solution of glycerine dissolves most salts that are soluble in water, the quenching properties may be varied by readily dissolving in the bath such salts as suit the kind of metal to be tempered and the degree of temper required.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

MELLIN'S FOOD

For Infants and Invalids.

NOT FARINACEOUS. Rich in Flesh, Nerve, Brain, and Bone Formers.

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

No Food in the market can show such a vast collection of *bonâ-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

. USED IN ALL CHILDREN'S HOSPITALS.

Prospectus, Pamphlet and Sample, post free on application to the Inventor and Manufacturer,

Popular Cookery Books

Published by Cassell & Company.

THE LARGEST AND BEST COOKERY BOOK.
Cloth, 7s. 6d.; Roxburgh, 10s. 6d.

Cassell's Dictionary of Cookery. Illustrated throughout. Containing about 9,000 Recipes.

40th Thousand, now ready, price 1s.; post free, 1s. 3d.

Cassell's Shilling Cookery. Containing 364 pages, crown 8vo, limp cloth.

Just ready, cloth gilt, gilt lettered, price 2s.

Cassell's Popular Cookery. This valuable work contains 364 pages, crown 8vo, with Four Coloured Plates.

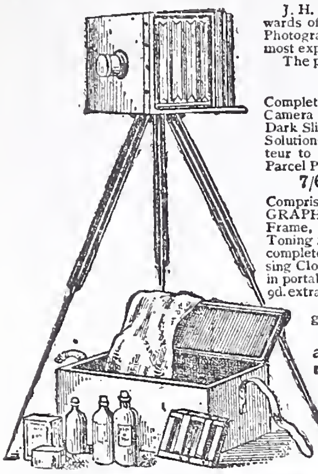
Cheap Edition (20th Thousand). Cloth gilt, 3s. 6d.

A Year's Cookery. By PHYLLIS BROWNE.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

J. H. SKINNER & CO., EAST DEREHAM, NORFOLK,

Manufacturers and Importers of Photographic Apparatus and Fretwork Materials.



J. H. S. & CO. have now a large Factory with accommodation for upwards of 100 workmen, which is used exclusively for the manufacture of Photographic Apparatus of every description, from the cheapest to the most expensive.

The process is simplicity itself. Full Instructions supplied with each set.

3/6 The Eclipse Camera Set. 3/6

Complete, consisting of a Polished Mahogany Sliding Bellows, ¼-plate Camera to photograph full-size carte-de-visites, with Focussing Screen, Dark Slide, Brass-mounted Lens, Brass Fittings, Developing and Fixing Solutions, Packet of Dry Plates, and full Instructions, enabling any amateur to take a good Photograph. Price **3s. 6d.**, or securely packed by Parcel Post, **4s.**

7/6 Complete Photographic Outfit. 7/6

Comprising ECLIPSE CAMERA SET, as above; also PHOTOGRAPHIC PRINTING APPARATUS, consisting of Hardwood Printing Frame, with Brass Spring Back, Sensitised Albuminised Paper, Gold Toning Solution, Fixing Solution, Glass Rods, Cards for Mounting, with complete Instructions. Also Hardwood Folding Tripod Stand and Focussing Cloth. Price **7s. 6d.** Securely packed, post free, **8s. 6d.** If packed in portable wood case, with hinged lid and leather strap, as in illustration, 9d. extra.

Every Set is carefully examined before being sent out, and guaranteed to be in working order.

N.B.—If Apparatus does not give satisfaction, and is returned uninjured within three days of receipt, we guarantee to refund purchase money.

Better Sets, 10s. 6d., 21s., 42s., 100s., and upwards. Complete Catalogue of Photographic Apparatus, one stamp. **J. H. SKINNER & CO., EAST DEREHAM, NORFOLK.**

Wholesale Agent for London—J. MOTHERSILL, 60, Holloway Road, N., and 6, Southampton Row, where Samples may be seen.

Timber Yards, Sawing and Planing Mills covering about Two Acres near Railway Station.

J. H. S. & CO. keep regularly in stock about **120,000 FEET OF FRETWOOD,** solid and 3-ply, veneers, &c., besides a very large quantity of Logs, Planks, and Boards, Carving and Turning Wood, &c., and **200,000 FULL-SIZE DESIGNS for Fretwork, Wood Carving, &c.,** besides an immense Stock of Joiners' Tool Chests, Fretwork Outfits, Drills, Saw Frames, Hand and Treadle Machines, Saw Blades, &c. &c.

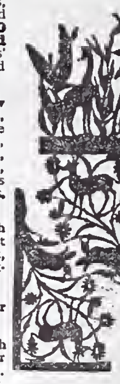
Specialities for 1888 & 1889.—Books of New Designs. FRETWORK No. 1, containing 12 Large Sheets, price 1s. No. 2, containing 20 Sheets of larger and more elaborate Patterns, 2s. 6d. Book of Wood Carving Designs, containing 14 Patterns, price 1s.; these are all New Patterns, not sold in any other form, and would, if sold separately, cost three or four times the amount charged. Fretworker's Handbook and Workshop Guide, price 1s. New Designs. All Patterns greatly reduced in price.

Complete Fretwork Outfit, comprising 12-inch Steel Frame, 48 Saws, Awl, File, 4 Designs (with sufficient planed Wood, gratis), and 1s. Handbook on Fretwork, price 3s. 6d., carriage paid. 12 feet Assorted Planed Fretwood, 3s. 6d.

☞ Special Fretwork Design, in commemoration of Her Majesty's Jubilee, size, 36 in. by 26 in., price 2s. 6d.

Catalogue of Machines, Designs, Wood, Tools, &c., with several Hundred Illustrations, and full Instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. Good Fret Saws, 1s. 6d. per gross; best ditto, 2s. per gross.

Eclipse Design, No. 102.



Wall Bracket. Price 5d.

TOOLS.

BUY from the MAKERS, the Oldest Established and the Best House in London. Stock kept for Carpenters, Wood Carvers, Turners, Fretworkers, Amateurs, and Mechanics.

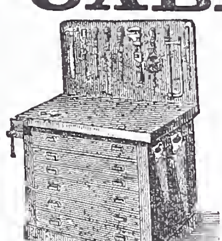
TOOL CABINET.

COMBINED **Tool Cabinet** AND **Work Bench.**



PRICE, WITH TOOLS COMPLETE, **£8 10s.**

Or Cabinet fitted with Vice and Bench Stop, but without Tools, **£5.**

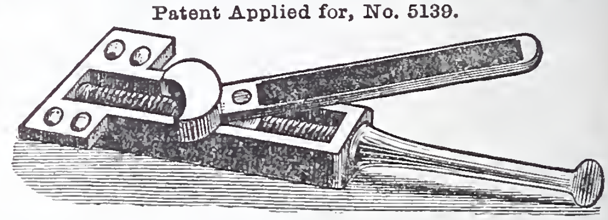
This Combined Cabinet and Work Bench is made of Polished Ash, with Solid Beech Top or Bench, 1¾ in. thick, and is fitted with Iron Parallel Vice, and with Bench Stop for planing. It has a back board with rack for holding Tools, and 5 Drawers, as shown in illustration. It is 34 in. high × 36 in. wide × 17 in. deep from back to front. It is fitted up with 43 best Tools, such as we sell to Mechanics, and specially selected for general work. All of full size and fully warranted. A List of Contents will be sent on application.

NOTE THE ADDRESS—

MOSELEY & SON, 323, HIGH HOLBORN, W.C.

NURSE'S REGULATOR.

Patent Applied for, No. 5139.



For adjusting the Irons of all English Pattern Bench Planes. Can be easily fitted to any Smooth, Jack, or Try Plane, without alteration of Irons already in use. Price 2s. each; post free, 2s. 3d.

Price Lists free by post on application to Sole Makers,

A WONDERFUL MEDICINE.

BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

Worth a Guinea a Box.

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.

Prepared only by the Proprietor, T. BEECHAM, St. Helens, Lancashire, in Boxes 1s. 1½d. and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

A SEMI-GOTHIC MUSIC CABINET: HOW TO MAKE IT.

BY JOHN W. HARLAND.

Every one who has experienced the difficulty of finding any particular piece of music or dance or song that may have been the topic of conversation or the subject of a request to play, must have concluded that instead of piling up a heap of music sheets in dire confusion it would be an infinite improvement to establish and preserve a system whereby any given piece could be instantly found.

The merest reflection will show that some receptacle which would permit of classification, as well as preserve the music clean and intact, alone fulfils these requirements. And here in passing let us record the unfitness of the ordinary paper upon which music is printed to withstand ordinary wear and tear, owing to its want of fibre.

The first governing consideration in planning a cabinet to hold music must of course be the exact size of sheet music, and the space that it will occupy in bulk. Now the average size is found to be very nearly $14\frac{1}{2}$ by $10\frac{1}{2}$ in.; and experiment will show that whilst some editions contain 4, others 6, 8, or 10, and some even 12 pages, that the average number of pieces laid one upon the other is about 30 to one inch in height. The next point to think about is how to classify the different sorts of music—as, *one*, sacred music, waltzes, other dances, songs, operatic music, pieces; or, if preferred, *two*, sacred songs, sacred pieces, waltzes, polkas and mazurkas, quadrilles, gavottes, and other pieces, comic songs, sentimental songs, &c., or any alternative classification, according to the exigencies of individual preference and the preponderance of any particular sorts.

By far the most convenient way of keeping music is to make a series of trays of the above size in which to lay the pieces one above the other—each tray devoted to some specific class, with the generic name on the front conspicuously painted on a slip of ivory or even written on a slip of paper pasted on and varnished.

These trays may be made—according to the taste of the individual or the facilities he or she possesses—of millboard covered with cloth with flaps similar to the cases used in the musicsellers' shops which keep the music free from dust, or of light hard wood such as mahogany or walnut, dovetailed together and polished, either with or without flaps to exclude dust.

Thus amateur bookbinders, apprentices to binding, or those who have relatives in these or similar branches, can more readily carry out our first suggestion; whilst amateur cabinet-makers, carvers and gilders, or other workers in wood, can select wood as their more convenient material.

In any case, the outer receptacle for receiving the trays must be, as it is an article of furniture, either of wood or its alternative papier-mâché.

This opens up an enormous field for originality of design—every conceivable style may be employed, every combination of finish called into requisition. Our province, however, is merely to indicate what we may term the base of construction, and to suggest ideas, leaving to our readers the option of carrying out their own deduced plans therefrom, and to stimulate them to strike out fresh designs on our skeleton models. Nor do we confine those who wish for even greater ingenuity and originality than this to our views, since we believe that the mere interchange of ideas is often, nay generally, "productive of wit in others," as our great and venerated Shakespeare says.

To those who are too immersed in other affairs, who are too young and inexperienced, we feel we are fulfilling our self-imposed duty in giving a comparatively easy design to carry out, suitable rather for the music-room, the school-room or library, reserving for another article the treatment of design suitable for drawing-rooms in the "Queen Anne" style.

Our illustration shows a side elevation, a front elevation, and a section of a semi-Gothic cabinet, severe in its simplicity, which may be easily carried out by any one who can use carpenters' tools, at a minimum cost for material; the more aspiring may go to the expense of walnut, brown oak, mahogany, or even rosewood; whilst those whose self-restraint empowers them to content themselves with plain deal—stained, ebonised or even painted—may do so, and thus economise sufficiently to carry out other projects suggested in Work, reaping twice the pleasure and double the self-improvement they would secure in lavishing upon one only of our suggestions all their spare cash and labour.

The upper part of our design shows the music cabinet proper, but as it would be extremely inconvenient to place it on the floor, as well as giving a very insignificant appearance to it as a piece of furniture, we place it on a stand or pedestal, utilised as a sort of cupboard for "*bound-up*" music, fitted with a shelf. There are now-a-days several valuable although cheap forms of music of smaller dimensions than ordinary sheet music, printed from type instead of plates, such as the *Musical Budget* and others, and another size termed "Bijou." To provide for these odd sizes—between the upper parts of our cabinet and the lower, or pedestal portion—we place a drawer into which these publications can be put, as also any MSS. sheets (which are invariably smaller than printed plates, averaging $10\frac{1}{2}$in. by $8\frac{1}{2}$in.). Students' music-slates and pencils may also find a convenient resting-place in this drawer. This breaks the elevation into two distinct portions, the drawer symmetrically forming a parallel to the plinth of the lower half, giving coherence to the design.

Any second storey, so to speak, of any construction, should be, of course, not so high as the first storey, but as the most important consideration as to height is governed by the second storey—*i.e.*, the tray-holder—we must now decide the height of the upper portion, which should be made separately so as to lift off the pedestal, being much more portable than if made in one piece. By making it separate we are enabled to make the lower portion wider, and thus add to the general symmetry of the whole, which might otherwise give an appearance of greatly excessive height accompanied by narrowness.

Frame up two frames of 3 in. by 1 in. stuff for styles, and $4\frac{1}{2}$ in. top rails, with 3 in. bottom rails, all grooved $\frac{1}{4}$ in., $\frac{1}{4}$ in. deep, also 1 in. thick.

Before gluing, make two panels, diagonal $\frac{1}{2}$ in. matched boarding, rebated $\frac{1}{4}$ in. to flush at back, so that when in place they may finish $\frac{1}{2}$ in. at reveal. Stop-chamfer 1 in. short of styles and rails, except at top, which, as shown in side elevation, is to be carved to a four-centre arch, taking care that the joint of the second board from the bottom of the panel bisects the angle of the lower back corner of the frame exactly; the rest will follow if the drawings—which are drawn to $1\frac{1}{2}$ in. scale, that is one-eighth full size—are carefully enlarged to full size.

Then proceed to frame up similarly two other frames for the pedestal, $3\frac{1}{2}$ by 1 in. styles, top rail $3\frac{1}{2}$ in. by 1 in., bottom rail 4 in. 1 in. Note that the styles should be left 6 inches longer than where the lower rails' lower edge comes, so as to afford fixing for the plinth, and allowing the mortise to be of the full depth of lower rail (or if preferred made into two mortises) to give superior strength.

This remark also applies to the frames of the upper portion, as the "orms" drop into the upper part of the pedestal, so as to retain it when so placed in its intended position, the upper mortises in both should be gauged at least an inch below the upper ends of the styles, so that the "orms" may be sawn off flush (see dotted lines in section). Instead of leaving the panel so long in the upper part and making the drawer an indistinct portion of it (see *b b* and *d d*) the "orms" may be left 5 in. longer and the panel be made 5 in. shorter, as is done in the drawings, and a sub-plinth planted on them $\frac{3}{4}$ in. in thickness. The "orms" at top of each, may, instead of being sawn off flush, extend advantageously one inch above the top edge of rail to allow of the moulds being planted on the rails' top edges, instead of their faces, thus giving double strength and concealing the joint so made (see dotted lines in elevations), but the moulds must then be of course 1 in. broader, and be recessed opposite the "orms" 1 in. back. Next make the frame for the top of the pedestal, which should be of inch stuff 2 in. broad, to allow of being wrought into a thumb-mould, at front and at sides, left plain at back except the rebates to receive the back boards above and below. The inner faces of this frame should be left square, the opening to be of exactly the same dimensions as those of the interior of the pedestal; it must be mortised to receive tenons made in the upper orms (as shown) of the side frames of pedestal to be afterwards glued and wedged thereon, and also recessed so that the lower orms of the upper portion may fit into it firmly and securely without shake.

The bottom of the pedestal requires no framing, being glued and screwed to under-side of the side frames on under-side of the bottom rails, recessed opposite the lower orms of these, to which the plinth, mitred at front corners, is fixed.

The top of the upper, or cabinet portion, will form sufficient frame, if it be mortised, to receive tenons cut in the upper orms of its side frames, and may be glued and screwed to the upper edges of the top rails of these. It should project at front and sides sufficient to allow it to be "stuck" into the mould shown, and to be thicknessed out by the upper members of the moulding previously got out and mitred, to be afterwards planted on, to form base for the parapet balusters. The bottom of the cabinet proper, which also forms the top of the drawer cell or compartment, need not be framed, but should consist of $\frac{1}{2}$ in. stuff like the top, cut through for the lower orms of side frames, and glued and screwed from below to the lower rails of same, projecting, as shown, in front and at sides, to be worked into a small thumb-mould, and should be thicknessed out to 1 in. at front flush with front face of side-frame styles underneath it, for the front of drawer to close upon.

The two portions, upper and lower, being thus put together, having at the back been rebated $\frac{1}{2}$ in. × $\frac{1}{2}$ in., the backs of the proper size, consisting of $\frac{1}{2}$ in. stuff, may be glued and screwed into the rebates. No stronger construction is possible: when put together, if the glue perishes, the various pieces are held together otherwise by being socketed, as it were, immovably into one another. The plinth at bottom of pedestal, and the sub-plinth of upper part, can now be planted on, glued, and, if desired, further secured by being screwed from inside to the orms against which they are planted. The plinth, as shown in section, however, should, for the sake of saving material, have between itself and the lower orms of the pedestal a piece of wood glued to both, through which the screws, if used, should pass, by which a ½ in. plinth will suffice. Both plinth and sub-plinth should be mitred at front, the sub-plinth only to short ends and to the rail alluded to, so as to leave an opening for the drawer; for which drawer runners should be made and provided, fixed flush at top with lower edge of sub-plinth.

It is advisable now to plant on to the upper part of the music-stand or cabinet the upper members of the moulding, which stands upon the thumb-mould, that forms the top frame of the pedestal. (See section.) The upper edge of this moulding must be flush with the under-side of runners for the drawer—*i.e.*, ¾ in. above the upper side of the thumb-mould framing which forms the top of pedestal, the join of this moulding effectually concealing the fact that the upper cabinet lifts off the pedestal between the thumb-mould and the upper members. Now make the drawer of the dimensions shown in the drawings, but, of course, modified by possible slight inaccuracies in previous work. It ought to *fit* its receptacle with that workmanlike truth that all good work exhibits, so as to exclude every particle of dust without being too tight to pull out easily, or so loose as to shake as it is pulled out. It should be made of ¾ in. stuff planed true to ⅝ in. sides, dovetail grooved into 1 in. front, finished to ⅞ in., grooved to receive ½ in. bottom, ¼ in. by ¼ in. groove, bottom tapered to enter, and slotted to receive ½ in. back, extending from top edges only to the said groove of bottom. It may also be grooved ⅛ in. deep and ¼ in. wide for a partition, if desired to separate "Bijou" from 'Bouquet" music; or it may contain a tray for slate, etc., music below.

We now come to the trays for upper portion, which consists of a bottom, ends, and back only. (See section.) These trays should be very accurately made, the sides and backs dovetailed together and planted on the bottoms, well glued on, and screwed from below while the glue is still hot. In the exact centre of the front of the bottom of each tray, glue inlet strip of wood (or ivory, if preferred), to carry the name of the class of music each tray is destined to hold; these trays, like the drawers, sliding in and out easily, but without shake, made so accurately as to ensure a workmanlike fit. Any tray may then be withdrawn, laid upon a table, pieces readily found therein, replaced, and the tray put back in any of the positions made in the cabinet. As shown in the drawing, these trays should be about 2¼ in. in depth, and rests may be inserted, glued and sprigged to the sides, ¼ in. square, to carry them and serve as runners, the under-sides of the runners being chamfered on their lower edges, as shown in drawings.

At any height preferred in the lower pedestal, a shelf may be fixed by letting it into a groove made to receive it in the sides, and further secured by a couple of screws through the backboard. The height shown in the drawings, however, appears to us to be the most appropriate to the design, as it does not divide it equally, but gradually reduces the interval of the spacing in an artistic ratio.

Crowning the whole piece comes the parapet, consisting of turned balusters (as shown) surmounted by a cap-moulding.

The front of the drawer which shuts against the previously described framing requires as a finish to be chamfered at the edges at an angle of 45°, and fitted with a handle or drawer-pull. The one shown in the drawings, being carved from a piece of 1½ in. wood, accommodates itself to the design better, perhaps, than a bought one.

This completes the construction; it only remains to finish the exterior. To give a bit of artistic colouring corresponding with the other furniture in the room, and also to keep dust from the pedestal's contents, make a curtain of any preferred material and colour, attach six rings to it of brass, electro, or turned of the same wood as the cabinet, and fix (as shown) a rod of same wood, of brass or electro-plated, by similarly recessing the top of the front edges of the styles at each side, and planting on ornamental brackets, similarly recessed, to hold the rods in position, finishing at each side with projecting button, turned of same wood, and at same time concealing ends of rod. Brass tube, either lacquered or plated, can be cheaply obtained from Evered's, Winfield's, or any other gas-chandelier makers; the rings at most ironmongers; and the brackets can be secured with one ornamental-headed screw at each side, enabling the rod to be removed and the curtain renewed, or, in some cases, as in that of chintz, washed, starched and ironed, and replaced.

IRON AND STEEL: ITS ANALYSIS.

BY CHEMICUS.

Determination of Carbon, Manganese, and Copper—Total Carbon.

Carbon may be contained in iron either in chemical combination—combined carbon—or in the free state—graphitic carbon, or graphite; and it is upon the conditions under which it exists, as also the amount present, that the classification of the metal into wrought iron, cast iron, and steel depends. When the metal containing the carbon in the two conditions is treated with a salt, the base of which is reduced or displaced by the iron, both the combined and graphitic carbon are deposited in a state of proximate purity, and may be collected, and the real amount of carbon determined, by combustion. Such forms the principle upon which the methods of determining the "total carbon" are based. The separation of the carbon may be effected by a large number of salts, amongst them a solution of the double chloride of ammonium and copper. The re-agent is prepared by dissolving 500 of the salt in a *litre* (1,000 cubic centimetres) of water.

For the analysis, ten grammes of the sample contained in a beaker are digested in the ammonium-copper chloride solution—twenty-five cubic centimetres of the re-agent to every gramme of the metal—until complete disintegration is effected. Should the liquid become colourless, or nearly so, a further addition of the ammonium-copper chloride solution is made. The action is accelerated by the application of a gentle heat, but care must be exercised that the liquid does not approach boiling, which would result in the silicon acquiring a gelatinous condition, which considerably retards the subsequent operation of filtering. The iron enters into solution as protochloride, while the combined and graphitic carbon, and invariably metallic copper, are deposited. To get rid of the latter, add a small portion of hydrochloric acid, more of the chloride solution, and digest. Complete solution of the copper having been attained, collect the carbonaceous residue on a filter constructed as follows: Take a piece of glass tubing, 1-in. diameter and 6-in. long; contract one end, and loosely plug up this narrowed portion with glass-wool, on the top of which place a layer of finely-divided asbestos, and wash with water, so long as any of the asbestos continues to run through. Wash the contents of the filter with a hot dilute solution of hydrochloric acid, and then with hot water, until the washings, when acidified with nitric acid, give no opalescence with silver nitrate.

For the determination of the real amount of carbon contained in the impure carbonaceous residue obtained as above, either a dry or moist process of combustion may be employed. The former method being the most complicated of the two, we shall employ the moist process due to Ahlgren, the principle of which is that upon treating the carbonaceous residue with sulphuric and chromic acids, carbonic acid gas, CO_2 is formed.

Rig up an apparatus similar to that shown in Fig. 2, and to flask D transfer the carbonaceous residue together with the asbestos filter. This is accomplished by inverting the filter tube in the neck of the flask and gently pushing it out, employing as little water as possible to rinse in the portions adhering to the sides. Having connected the flask with the rest of the apparatus, and closed the pinchcock A, add through the stopcock acid funnel 150 cubic centimetres of dilute sulphuric acid—one part acid to three of water—and 20 grammes of chromic acid crystals dissolved in a little water; close R, and apply a gentle heat. The carbonaceous residue is immediately attacked by the acids, with the production of carbonic acid gas, CO_2, which, as it escapes, is freed from any chlorine and moisture in passing through the tubes E, F, H, and is finally absorbed by the caustic potash solution—one part of the alkali to two of water—contained in the bulb tube K, the weight of which has been carefully determined and noted prior to the commencement of the experiment. As the evolution of the gas diminishes, gradually increase the heat until heavy white fumes make their appearance in the body of the flask, which may be taken as indicating that the operation is at an end. The operation ended, remove the source of heat, open pinchcock and draw a current of air, which, in passing through the tubes B, C, will be deprived of carbonic acid and moisture, through the apparatus by means of the aspirator P. When the apparatus is quite cold, detach the tube K, and weigh. The increase in weight represents the carbonic acid, CO_2, which contains 27·27 per cent. of carbon, on the weight of metal taken for analysis.

The tube M, containing calcium chloride, is attached to collect any water of the caustic potash solution which may be driven off by the heated gas. It is weighed prior to commencement of experiment, and also at conclusion, and any increase in weight deducted from first weight of potash tube.

To test the purity of the re-agents, it is advisable to perform a blank experiment.

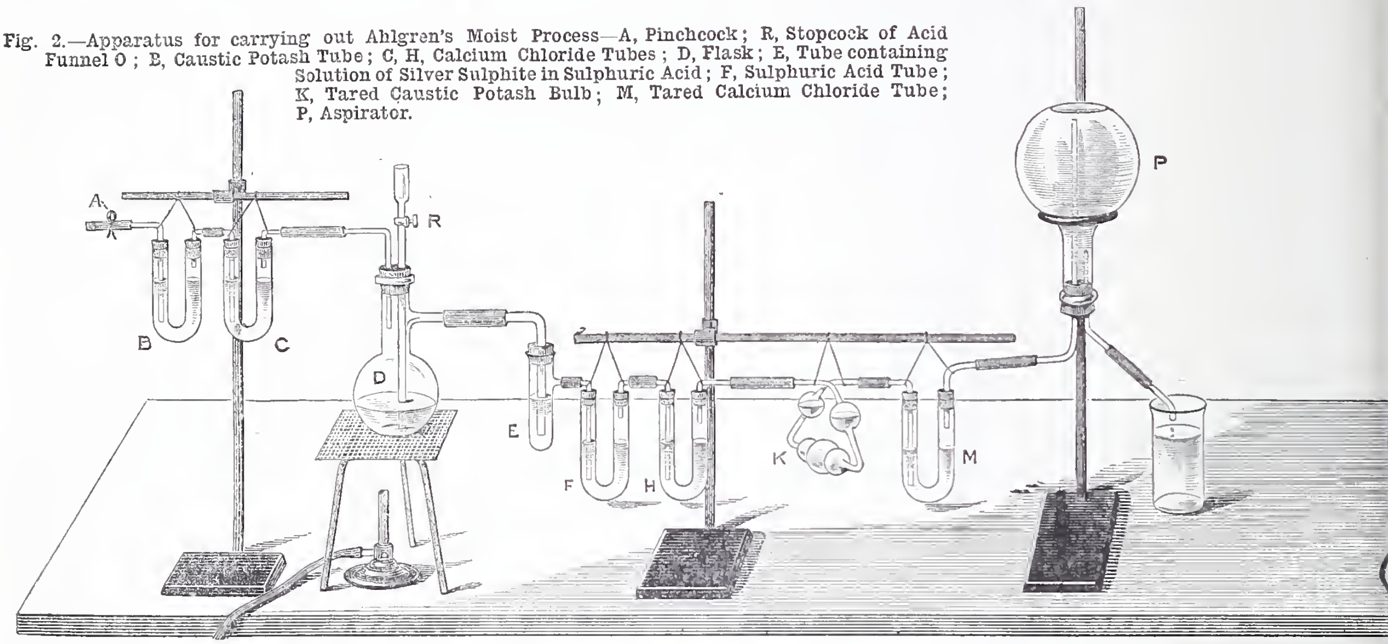
COLORIMETRIC DETERMINATION OF COMBINED CARBON.

The carbon in the state of chemical combination—combined carbon, as it is termed—possesses the property of imparting to a nitric acid solution of the metal a brown colour, varying in intensity in accordance with the amount contained in the metal. This forms the principle of Eggertz's colorimetric test: a rapid, easy, and fairly accurate method. As a means, however, of accurately determining the combined carbon the method is very limited, as the results obtained with specimens containing over ·75 per cent., or have been hardened, are untrustworthy. For the execution of the test it is necessary to possess "standard" steels, in which the combined carbon has been accurately determined, and these should be of the same make and contain as near as possible a like amount of carbon (combined) as the samples to be analysed.

The *modus operandi* of the method is as follows:—In a test tube $\frac{1}{2}$-inch in diameter, 6 inches long, place ·2 gramme of the steel to be analysed, and in a similar tube the same weight of the standard steel. To each add 5 cubic centimetres of nitric acid, sp. gr. 1·20 (free from chlorine), and when all action is at an end, immerse the tubes in a vessel containing water maintained at a boiling temperature. After the expiration of from fifteen to twenty minutes, simultaneously withdraw the tubes, dissolving any crust adhering to the insides by causing the hot solution to flow over it, and cool by immersion in a vessel containing cold water. Procure two graduated tubes, of 50 cubic centimetres capacity, divided into $\frac{1}{10}$th, of equal calibre, and pour into one of them the solution of the standard, rinsing in the last portions with cold water,* and dilute until the volume occupied is a power of the carbon contained in the same. Thus, a standard with ·40 per cent. of carbon would be diluted to a volume measuring 8 cubic centimetres, which is the ·05th power. After dilution, thoroughly mix the solution by closing open end of tube with thumb and inverting a few times. The solution of the steel being analysed is now transferred to the other graduated tube, the last portions rinsed in with the least possible quantity of water, and the liquid mixed *without dilution*. Upon comparing the colours of the two solutions by holding them side by side, the standard on the left, with a piece of white unglazed paper behind them, before a window, it will be found that the steel under examination is, in all probability, of a darker colour than the "standard" solution. Should such be the case, to the former water is cautiously added in small quantities at a time, the solution being mixed and the colour compared with each addition, until equality of tints is obtained. The number of cubic centimetres occupied by the solution, when this is obtained, multiplied by the power to which the "standard" is diluted, will equal the per centage of combined carbon.

Should it happen that the "standard" be darker than the solution of the sample under examination, the volume of the former is doubled, the tints made equal as before, and in reading off only half of the volume occupied by the steel under examination taken.

Fig. 2.—Apparatus for carrying out Ahlgren's Moist Process—A, Pinchcock; R, Stopcock of Acid Funnel O; B, Caustic Potash Tube; C, H, Calcium Chloride Tubes; D, Flask; E, Tube containing Solution of Silver Sulphite in Sulphuric Acid; F, Sulphuric Acid Tube; K, Tared Caustic Potash Bulb; M, Tared Calcium Chloride Tube; P, Aspirator.



GRAPHITE, OR GRAPHITIC CARBON.

A more accurate method of determining the graphitic carbon than the one described under the estimation of Silicon, is as follows:—Digest four grammes of the sample, contained in a beaker or dish, at a gentle heat for some considerable time with 150 cubic centimetres of dilute hydrochloric acid, and when the metal is nearly dissolved add a large volume of strong hydrochloric acid, and continue digestion. Upon complete solution of the metal, dilute and collect the insoluble matter, graphite, on a tared filter paper, which, together, with contents, wash with hot water, dilute hydrochloric acid, and a solution of potash to remove the silica; lastly, wash with alcohol and ether to remove any hydro-carbons; remove filter paper, etc., to the water oven, dry, and re-weigh to determine the graphite.

A small quantity of silica is invariably contained in the graphite obtained as above. To determine the same, the filter paper and contents, after weighing, contained in a platinum crucible, are ignited at a strong red heat for some time, and when cool the weight of any residue determined, and deducted from the first weight of the graphite.

MANGANESE.

For the determination of this constituent 2 grammes of the sample are dissolved, with the aid of a gentle heat, in 75 cubic centimetres of nitro-hydrochloric acid, the resulting solution transferred without loss to a flask of three litres capacity, and the liquid made up with hot water to a volume measuring two litres. To this solution is then cautiously added a solution of ammonium carbonate (dissolve one part in eight of water), in small quantities at a time, until it remains cloudy after brisk agitation. (Should a decided precipitate make it appearance, it is dissolved by the addition of a few drops of hydrochloric acid.) When this is obtained, add 150 cubic centimetre of hot ammonium acetate, bring the liquid to boiling (but do not boil for any length o time), and allow to stand at rest until th precipitate of basic acetate of iron has com pletely settled. Pass the clear supernatan liquid through a large English filter paper receiving the filtrate in a porcelain di throw on the precipitate with the la portions, and wash filter and contents* wi hot water containing a little ammoniu acetate. The filtrate contains the mangane but on account of the small quantit usually present in irou and steel, it advisable to cousiderably reduce, by evapo tion, the volume of the same before p ceeding with the precipitation (of cou any precipitate that may come down duri this operation is removed by filtratio This having been done, to the concent ted filtrate contaiued in a flask, wh quite cold, add a sufficient quantity bromine to cause it to acquire a dark bro colour, and to the brominated soluti ammonia until strongly ammoniacal, bris agitating the containing vessel upon t addition of each re-agent. This results the precipitation of the manganese hydrated peroxide. Heat the solutiou

* Throughout the determination *cold water* is employed.

* As the complete separation of iron and man nese is a difficult matter, it is advisable to disso in the least possible quantity of dilute hydrochlo acid the basic acetate of iron precipitate on filter, and alter dilution to re-precipitate the i with ammonium carbonate, etc., as before. T precipitate collected on a filter, well wash the filtrate mixed with the first and the combi filtrates concentrated, etc.

boiling, collect the precipitate on a filter paper and well wash with hot water. Transfer filter paper and contents to a platinum crucible, ignite at a strong red heat, whereby the precipitate loses water and is converted into tri-manganic-tetra-oxide, Mn_3O_4, every hundred parts of which is equivalent to seventy-two of manganese, and when cold, weigh.

Owing to the large bulk of iron through which the manganese is diffused, and also to the presence of organic matter in the re-agents, a small quantity of iron invariably remains in solution, and is precipitated along with the manganese. It is therefore necessary to test the precipitate for iron. This is done by dissolving it, after weighing, in a small quantity of hydrochloric acid, withdrawing a drop of the liquid at the end of a glass rod, and bringing in contact with a drop of a weak solution of ferrocyanide of potassium, spread on a white porcelain slab, when, if a blue coloration is formed, iron is present. Should such be the case, the remainder of the solution is diluted with the water, made neutral with ammonium carbonate, and the iron precipitated with ammonium acetate; the solution then heated to boiling, the basic acetate of iron collected on a filter, thoroughly washed, converted by ignition, contained in a crucible, into ferric oxide, Fe_2, O_3, and weighed as such. The weight of the ferric oxide thus obtained is deducted from the weight of manganese precipitate.

It is more satisfactory to determine the iron colorimetrically, which is performed as follows:—Prepare a nitric acid solution of iron of such a strength that one cubic centimetre contains ·0014 gramme of ferric oxide, Fe_2, O_3. This may be conveniently done by dissolving 1·004 grammes of pianoforte wire (containing 99·70 per cent. of iron) in nitric and diluting to one litre with water. Dissolve the manganese precipitate to be tested in a small quantity of nitric acid and a few drops of hydrochloric acid; transfer the resulting solution to a Nessler's cylinder, make up with cold water to a volume measuring 50 cubic centimetres, add four drops of a dilute solution of ferro-cyanide of potassium, and thoroughly mix the liquids. In another cylinder place one cubic centimetre of the standard iron solution, dilute to 50 cubic centimetres, add four drops of cyanide solution, and, after mixing, compare the tint with that of the manganese precipitate solution. Should the tints of the two solutions be unequal, a greater or less quantity of the standard iron solution is taken, diluted, etc., until the quantity required to produce equality is obtained.

Copper, if present, would be precipitated along with manganese, and its removal may be effected either previous to the precipitation of the manganese or from the precipitate itself. The former method is treated on under "Copper." If the separation of the copper be effected by the latter method, the manganese precipitate, after weighing, is dissolved in the least possible quantity of dilute sulphuric aeid, and to the resulting solution pure metallic zinc added; a mutual exchange takes place, the zinc entering into solution as sulphate, while the copper is deposited in the metallic state. Immediately the zinc has dissolved, decant off the liquid, wash the copper thoroughly (by decantation) with water, dry, and weigh.

COPPER.

Copper being, as a rule, present in such small quantities, a somewhat large quantity of the metal must be taken for the determination.

Dissolve at least ten grammes of the sample in nitro-hydrochloric acid, and separate the silicon by the method already described. Dilute the resulting filtrate to a volume measuring one litre, cool the solution, add sufficient sodium sulphite to reduce the whole of the iron from the ferric to the ferrous state,* and then heat to boiling, until all sulphur dioxide is expelled. Through the solution, while hot, pass a current of sulphuretted hydrogen to saturation, close the mouth of the containing vessel, and allow to stand in a moderately warm place for three or four hours. The copper is precipitated as sulphide, $Cu_2 S$; it is collected on a Swedish filter paper, and washed half a dozen times with water containing sulphuretted hydrogen. The filter paper is then pierced, and the precipitate completely rinsed by means of a fine stream of dilute nitric acid delivered from a wash bottle into a beaker or flask, some strong nitric acid added, and the whole digested at a gentle heat until all has entered into solution with, perhaps, the exception of a little free sulphur, which is removed after dilution of the liquid by filtering. The solution is now heated to boiling, and while at this temperature the copper precipitated, by the addition of a solution of caustic potash, as copper oxide, CuO, which is collected on a filter, well-washed with hot water until free from alkali, ignited, and weighed. Copper oxide contains 79·85 per cent. of copper (metallic).

*To determine whether reduction to the ferrous condition is complete, withdraw a drop of the solution, after the expelling of the sulphur dioxide, at the end of a glass rod, and bring in contact with a drop of sulphocyanide of potassium, when no red coloration will be formed should reduction be complete.

THE WATERBURY WATCH—LONG AND SHORT WIND.

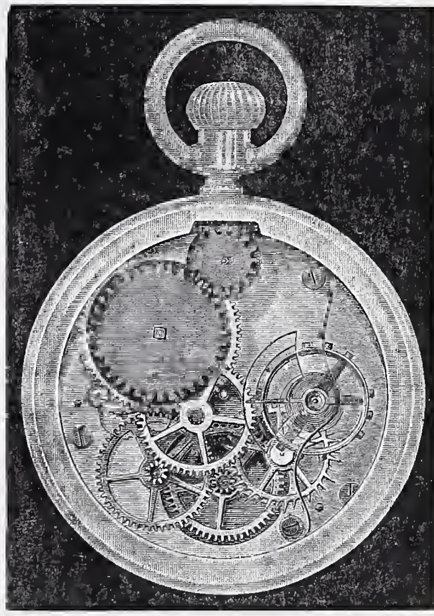
BY A PRACTICAL HAND.

This watch, now so well known, has the merit of cheapness. The long wind (see sketch) Waterbury is an excellent timekeeper—in fact, equal to watches costing ten times the price. The long wind has a peculiar motion; the whole movement turns round inside the cases—the plates, wheels, etc.—its long main spring being fixed in the centre, and the winding whereof is rather tiresome—a performance accomplished by turning the stem within the bow of watch, requiring 80 to 100 turns, unless you wind up several times during the day. But this plan is now surpassed by the short wind, thereby placing them equal to any other. They have a good clear dial, and a very superior style of case in nickel silver, which wears remarkably well if used with ordinary care; but no case will keep smooth if worn, as too many are, in a pocket with small articles, keys, coins, etc. A pocket lined with wash-leather is best—the watch is always bright, and will last years longer. But no one can expect these cheap watches to last like old verges and levers which have seen three and four generations; people now want changes different to their forefathers.

In that case these watches will fill all modern requirements, and they are extensively worn on both sides of the Atlantic.

How to clean and repair them. (Though the public are strictly enjoined on the inner dome "not to remove it by undoing the three screws unless you are a watchmaker"; but still, hundreds will and do look inside, like the lad who cut open the bellows to see where the wind came from.) First thing after the amateur unscrews those screws and raises the inner dome, out flies the immense spring, like a large serpent. This utterly astonishes them; many have been brought to me in this stage, with all tied up in a handkerchief or sheet of paper—they dare go no further; and the parties who sell them, agents in England, put up notices, that no one is authorised to clean or repair them, and, as a rule, will not sell you a duplicate part or spring; but I could always get them.

Well, to commence: unscrew the three screws and lift one side of the plate gradually up until you can slip a thin piece of steel or other article on the spring, holding it firmly down with your thumb; now lift off the dome entirely, and you will see how the centre of spring is adjusted to a notched stud; turn the stem winder to see how the ratchet works by holding the stud firmly and lifting out the click from the ratchet inside; you can now let it down, which is



New Waterbury Short Wind; J Series.

rather a tiresome process. When down, notice particularly how the outer end of the spring is fixed: in fact, just sketch it on a piece of paper, as you may forget, seeing that the extreme end is used to act as a stop in overwinding. Now lift it out and the centre—be very careful, or you may snap the end which hooks on. You have now its simple works before you; few wheels—the long spring saves the use of wheels. Put pressure on the main wheel, and see the duplex escape how it works; every other tooth goes into a detent in the staff of balance, the other tooth holding it until the next is ready, and so on until the thirty hours is complete. Now take off the glass front, and unscrew the screw that holds the stem winder, and the works will now come out. You see the simplicity of arrangement; this has gained it its great popularity, and the few wheels are here which you were cautioned not to look in at, for why? We in the trade know the reason.

Give every part a good study, and then proceed to unscrew, and, as in my previous description of the Horizontal, take and brush every wheel and the plates — you cannot injure their plates, for they have none; Of course it cannot be expected; no more can you find jewels, so see to the pivot holes if any are worn oval (this in time will be the drawback to the Waterbury); when all is clean and ready for fitting, examine all the teeth of wheels to see none are bent or grit in betwixt, clean the balance and its spring, as I previously stated (see former chapters), oil the pivot holes, and replace the few wheels. You cannot possibly make a mistake (except in the new Waterbury, which has a going barrel same as the American Lever; the only difference is the escapement.

After replacing wheels, adjust the top plate and balance, try it by pressure on centre wheel if the motion is all right. The class of long wind you can only test inside their cases; so re-fix the movement and pass the centre coil of spring around the hook. I must praise this hook, it is superior to our English small affairs. Now replace cover, hold it on with your thumb to keep spring in or it may bounce out and so trouble you; give it a good many turns with the stem winder, and now you will hear it tick, for they have really a good healthy beat. I remember the first I had; I wore it a week or two to try it. The first night I wound quite two minutes, and a cold night it was; I hung it up where I usually kept my gold centre seconds. But oh, what a row! I could not sleep, nor could my wife; so I placed it in a drawer of the dressing-table, but that helped the sound, so I got out again in the cold and thrust it into my slipper with sock after it, and now it was about equal to centre seconds; so I slept. I was told of one that they threw out of the window in disgust; but I fancy watches better than that.

Replace the three screws, spring on the back, press on the two hands at their proper time, for they do not turn one another. It will require regulating, the regulator you will see under one of the spaces around dial; it changes—you may find it at six or three o'clock, etc., that is through the movement revolving in the cases. The short wind is same as all watches.

SIGN-WRITING AND LETTERING.

BY HENRY L. BENWELL.

Colours Used by the Sign-writer.

I gave in a previous chapter a full list of tube colours as put up by the artists' colourmen, but a great many of these colours are hardly used by the sign-writer, nevertheless he has the list for reference and guide. I now append a short list of the colours which are absolutely in request by the sign-writer, and from which he can get, by mixing, a large assortment of other tints and shades.

THE SIGN-WRITER'S PALETTE.

Raw Sienna.	Gamboge.
Burnt Sienna.	Yellow Lake.
Raw Umber.	Green Lake, Nos. 1, 2, 3, 4.
Burnt Umber.	Emerald Green.
Vandyke Brown.	Vermilion.
Ultramarine.	Indian Red.
Prussian Blue.	Venetian Red.
Indigo.	Crimson Lake.
Yellow Chrome, Nos. 1, 2, 3, 4.	Scarlet Lake.
Yellow Ochre.	Rose Madder.
Ivory Black.	Flake White.
Vegetable Black.	White Zinc.

There are a few other colours which are best purchased in the dry state, in fact they are not always found in tube colour list. These are Chinese red, Persian red, orange lead, and a few more, and they can frequently be made good use of, and often save the use of some of the more expensive tube colours. It must be distinctly understood that this list of colours is for lettering only, not for painting the surface of sign-boards, and that it refers to tube colours. Of course, the workman can buy some of his colours in the dry state, but those which are most difficult to grind are always found purer and finer when purchased in tubes, than those procured ready ground in bulk. In looking down the above list, the novice must not for one moment suppose that he need purchase a full supply to commence with, in fact, he may only select those most useful to his individual taste and requirements, and add others as he wants them. There are again four shades in chrome yellow and green lake respectively; do not purchase all, however, but start with Nos. 1 and 3. By using discretion and practising economy in this way, may be the means of preventing a good few halfpence being thrown away on plant that cannot become of immediate use to its owner.

As every workman, to be perfect, and able to excel in good workmanship, must not only have a thorough knowledge of his tools, but also of the materials he manipulates, I shall now give a slight analytical description of the most common colours amongst those I have already enumerated, besides a few colours used for ground surfaces, which may be reckoned somewhat dangerous to the permanency of our work.

White Lead.—As this colour is one of the most frequently used colours in all kinds of painting, and also one of the most faulty, it deserves first notice here. It is made by suspending rolls of ordinary thin sheet lead over malt vinegar or pyroligneous acid, in close vessels, the evaporation from the acid being kept up by a steam bath underneath. The lead is thus reduced to a white powder ready for being ground up with linseed oil into a paste. White lead improves by keeping, and I would strongly advise sign-writers and others who undertake particular and delicate work, to stock it for at least twelve months after purchase. Very pale and old linseed oil should also be used in the thinning, otherwise it will probably soon discolour, which is its greatest fault. It is however, about the best pigment we have for preserving wood, etc., from the effects of the weather.

Flake White is a very pure white indeed, and not at all likely to discolour; it is on this account generally used as a finishing coat over previous ones of white lead.

Zinc White is an oxide of zinc, but it does not possess so much covering power as white lead. It however retains its colour, and is a very pure pigment. "Charlton white" manufactured by Messrs. J. B. Orr & Co., London, S.E., is, I believe, a species of zinc white which has the advantage of possessing as much covering power as white lead. This paint has been used with the best results.

Ivory-black is made from ivory turners' dust. This is placed in a covered crucible, and exposed to a great heat, which, after a certain period, turns it to a beautiful jet black. The inexperienced, like myself in such matters, must be cautious to see that they are not put off with a very inferior article when purchasing this pigment. This inferior colour is known in the trade as bone-black, and is made by treating bones in a similar way to the ivory, and it is very often sold as ivory-black by unprincipled tradesman for the sake of a largely increased profit. To make sure, therefore, of obtaining ivory-black, go to a good house, and pay the the best price. Mr. Callingham, a sign-writer of many years' experience, informs us that ivory-black, the deepest and purest of the blacks, being somewhat hard, requires very careful grinding, and that unless ground very fine it will spoil our work. It is best ground in turpentine, and diluted for use with turpentine, gold size, and a little varnish. In drying it will become dull, so that it should not be used unless it has afterwards to be varnished, which will bring it back to its original intensity. It is a difficult pigment to manage, as, if it is thinned down too much with turpentine it will not bind, so that when the varnish is applied it will rub off on to the rest of the work and spoil the whole. Ivory-black, when purchased unground, resembles "drops," and is sometimes called "drop-black," but bone-black is got up in the same way, so great caution is required.

Vegetable-black has now taken the place of lamp-black. It is sold in a very light powder and requires no grinding, being free from any gritty substance. Patent driers may be added for drying purposes, and it may be used on work that has not afterwards to be varnished.

Burnt Sienna is an earth of a very rich transparent red-brown, and is used for glazing over gold leaf and shading. It works well on gold leaf when mixed with a small quantity of ox-gall. It should be thinned with copal varnish, nót turpentine; and gold size may be used as a drier; it, however, dries better than raw sienna, and is very permanent, as it is not liable to change by the action of light and oxygen, nor by damp and impure air.

Raw Sienna is rather an impure yellow, but has more body than the ochres and is also more transparent. By burning it becomes deeper, and is then the burnt sienna mentioned above. It has also the same properties as burnt sienna.

Raw Umber is an ochre brought from Italy; it is a good drying colour, and does not injure other colours with which it is mixed. It is used in graining.

Burnt Umber is the former pigment burnt. It is a good drier in oil, and is therefore often used as such. It is very permanent, and is sometimes used instead of Vandyke brown.

Vandyke Brown is a rich deep transparent brown, a colour good for glazing and for "markings" on gold. It is a bog earth, and not a very good drier. It is permanent.

Ultramarine when perfectly pure is about the most expensive colour we have, but the sign-writer uses generally French ultramarine, an inferior product, which will, however, stand pretty fair when protected with oils and varnish. It may be deepened with vegetable-black, and when mixed with white makes a pure tint.

Prussian Blue is a good working and staining colour and a quick drier.

Indigo possesses great body, and is a good glazing colour. It is not very durable, and is injured by impure air.

Lemon and Orange Chrome.—These pigments, when of best quality, are chromates of lead, and are very pure and brilliant; they have good body and covering power, and make good tints when mixed with white. When used in oil they must be protected by varnishing, especially if exposed to impure air, which in time will turn them black. They make the so-called gold colours, but must on no account be intermixed with Prussian and some other blues in making greens, as chromate of lead will destroy these pigments. The yellow chromes are made in three shades, known as Nos. 1, 2, and 3; the No. 4 shade is the orange chrome, a deep rich colour. The shades are varied by increasing the chromate for deep orange, and lessening it for the pale yellows. These colours are injured by damp and impure air, sulphur fumes and hydrogen; but the orange chrome is said to have more lasting qualities than its near neighbour, orange oxide of lead. The chromes are useful colours, but require careful and skilful handling.

Yellow Ochre.—Not a very gay colour, and is best purchased in tubes, otherwise it is not thoroughly ground. It is an earth found in most countries, and of all shades, from the warm yellow of the Oxford ochre to the pale straw yellow of the French earth—the latter often used for "old gold" shades, etc. The ochres are not liable to change through any chemical actions, and may, therefore, be considered permanent.

Green Lakes.—These are very useful and powerful colours, sold in tubes; they are not noted for permanency, so want well protecting. They may also be purchased in bulk ready ground in oil.

Emerald Green is, perhaps, *the* sign-writer's green, the tube colour being the best to work with. It is a copper green upon a terrene base, very useful for brilliant work. It has not much covering power, and is a bad drier in oil, therefore requiring gold size or patent driers. It is a safe pigment for retaining its colour.

Vermilion can be had as a fine dry powder, free from grit, and is a very brilliant colour in oil. The best quality only is permanent, and that is a sulphuret of mercury. Chinese red, or vermilion, is of a deep crimson tone, but with bad covering power, and, unless well protected, will soon fade from the action of light and impure air.

Indian Red.—Peroxide of iron, procured from the iron ore mines of Bengal. It makes pleasant tints with white, is perfectly permanent, and possesses great body. It may also be used as a ground colour, or as a shade tint with vermilion. For a ground colour it may be mixed with turpentine, 4 parts; varnish, 1 part; when it will dry very quickly.

Venetian Red.—This colour is obtained as a native earth or as a bye product from sulphate of iron in the manufacture of acids. It is exceedingly cheap, but permanent, but must be procured ready ground in oil. It is useful as a ground colour.

Purple Brown, although not mentioned in the list, is much used by sign-writers as a ground and shading colour; insist, however, on having purple brown, and not common oxide of iron. It is rather a bad drier in raw oil, and requires the addition of patent driers or a little varnish. It has good covering powers, especially over a slate colour, but has little or no body.

Lakes, Crimson and Scarlet.—These are brilliant transparent colours, chiefly used as glazes. They make beautiful tints with white, such as carnation, and are then, of course, opaque. Strong light, however, soon discolours lake, and also the tints made therefrom. As a protection, a finishing coat of varnish should be given.

Rose Madder is a beautiful, rich, and permanent red, although very expensive. It is used on the very best work, and is procured in the usual tubes. It is a good tint colour.

I have now taken the pains to convey to the workman some idea of the bases and composition of the various pigments he works with. Although this has taken up the whole of a chapter, I feel it will be space well occupied, as unless the workman has a certain amount of knowledge concerning the colours he uses, and their liability to change or fade under certain conditions—or, on the other hand, their power of permanency, and the destructive qualities of some pigments towards others when coming in contact with them—no man can hope to execute permanent and satisfactory work. This subject is far from exhausted here; in fact, a book could be written upon this matter alone, and would prove, indeed, a great boon to the house and general decorator.

Some few years back a friend gave the writer a copy of Field and Davidson's "Grammar of Colouring" (Crosby Lockwood & Co., 2s. 6d.), but, unfortunately, it has, up to now, been hardly looked at by him, partly through pressure of work, and partly through so much other reading matter engaging his attention. In this book appears to be much matter of use and interest to the sign-writer, a very valuable feature being some tables of pigments showing at a glance—(1) Those pigments, the colours of which suffer different degrees of changes, by the action of light, oxygen, and pure air, but are little, or not at all, affected by shade, sulphuretted hydrogen, and foul air; (2) Pigments the colours of which are little, or not at all, changed by light, oxygen, and pure air, but are, more or less, injured by the action of shade, sulphuretted hydrogen, and impure air; (3) Pigments, the colours of which suffer from all of these causes; and (4) Pigments whose colours do not change from any of these actions, nor by the action of lead or iron.

Such information as this, it need hardly be said, is invaluable to the most simple worker in colours, and the sign-writer should certainly possess a copy of these interesting tables.

SOME HINTS ON WOOD-CARVING.

BY D. ADAMSON.

The suggestive ideas for carved panels, etc. shown by the illustrations will be welcome to many readers of Work, not only among amateurs, but among professionals who wish to get hold of good workable designs. These are from the clever drawings of Mr. John Law, a Liverpool carver of ability, and without entering into any long description of them or giving minute details of the way to work them up, a few general remarks may not be unappreciated by the younger portion of our readers.

Perhaps at first sight some of those who are not able to draw well may experience some disappointment at not finding the particular design they would like to carve of a suitable size for the panel they wish to decorate. They are hardly likely to want to reproduce it in a smaller size, though for some dainty piece of work in close-grained wood there is much scope for ability, and it must be remembered that the value of carved work does not depend altogether on its size. However, the well-known plan of dividing the design to be copied into sections by ruling lines each way, *i.e.*, from top to bottom and across, and marking the panel, or, the same thing, the paper on which the enlarged drawing is to be made, with an equal number of squares, but proportionally larger or smaller is equally applicable for reductions as for enlargements.

Necessarily the tools must be properly sharpened. Without wishing to find fault with amateurs, it cannot be denied that but few of them keep their tools in proper order, even if they have ever had them so. Carving tools as ground and sent out from ordinary tool-shops, or prepared for work by cabinet-makers, etc., are seldom as they should be. The sharpening of the edges is almost an art by itself, as, altogether apart from the keenness of the edge, the bevel is of the utmost importance. One often sees tools which, though sharp, are certainly not fit for the carver's use, simply because they have been ground and sharpened on the back only instead of being sharpened and bevelled away from the front as well.

Then the size of the tools, both blades and handles, supplied to amateurs is too small. I do not now refer so much to width across, because this must necessarily vary, as to length. Roughly speaking, to obtain proper command of the tool it should measure about 12 in., equally divided between blade and handle.

Another defect with unskilful carvers is the way in which they hold the tools when cutting. It is no use attempting to do good work by holding the tool in one hand only, whittling away the wood as though a penknife were being used. The tool should be firmly, yet freely, held with both hands, the left on the blade and the other on the handle. This should always be done by those who wish to carve the wood only; but if their intention is to spoil the work and test the cutting powers of the steel in their own fingers, let them hold the panel down with one hand, by preference in such a position that if the tool, weakly held in the other one slips it will go straight into the flesh. The design—after sticking-plaster has been used—can then be studied at leisure without a desire to proceed more actively towards its completion. In connection with this, may I caution amateurs against the dangerous practice many of them have of walking about their workroom with a tool in their hands? When the tool is not actually in use it should be be laid on the bench or table, and not be carried about. With a keen edge an accident soon happens, and, instead of, as one sometimes sees in classes where carving is taught, one pupil, perhaps going to speak to a fellow-worker with a tool in his hand, it should be laid down. Carrying a carving tool recklessly is almost as reprehensible as pointing a gun at a person on the chance that it is not loaded.

It is an oft-repeated piece of advice not to use glass-paper, either in preparing the wood to be carved on or for finishing the work; but in spite of all that has been said against it the temptation to smooth up with paper seems too strong to be resisted. I raise here no objection to the novice using as much glass-paper as he likes, only I do not say that it will be without serious detriment, both to the tools that are used subsequently, and to the work itself. Spoil the edges by using paper while the work proceeds, and spoil the work by papering it up after the tools are put away. It is useless to protest against glass-paper any more than it is to urge the necessity of keeping the tools sharp, so I don't attempt to do so just now, but I state what the consequences will be.

That tools should be learned by beginners is perhaps such an axiomatic bit of advice that it may be considered unnecessary. Instances are not wanting, however, that novices sometimes do aspire to carve without knowing anything more about the names and scope of the various tools than that one of them has a red bit of cotton tied round it, and that when they want to make a certain cut they must use the other with the white thread; such pupils don't advance much, unless gifted with an amount of ability which their bad memories seem to deny. Some people seem to find an insurmountable difficulty in distinguishing between a chisel and a gouge, as great as that which some—females chiefly, such as charwomen and domestics—have in knowing that the uses of a chisel and a screwdriver are not identical. Well, in case any would-be carver reading this does not know his tools let him learn them. It may take some time; still, the thing is to be done—with perseverance. As a young sky pilot was told lately when he asked if carving could not be learned without knowing the tools first: "It can't be done, and there is no artificial aid to memory."

I have touched on a few of the difficulties, absurd and commonplace as they may be, which sometimes occur, and in conclusion I may remind all that wood-carving is an art in which, though the rudiments may be imparted, proficiency can only be acquired by practice.

Although given ostensibly as designs for the carver's use, there is no reason why the repoussé worker should not avail himself of them, if not in their entirety at least by taking them as motives. Fig. 9, if nicely carried out, would make a panel equally as charming in hammered brass as in wood, and the same may be said of Fig. 7. In case the use of these or other designs as motives for other patterns, or, perhaps, shapes and sizes, has not been understood, this last-named (Fig. 7) affords an excellent illustration of what is meant. Let us assume that a drawer front, say one of much greater length in proportion to its breadth than that shown. All we have to do is to elongate the pattern, or perhaps repeat it twice without showing any break between the two, and we at once have what at first sight would appear to the casual observer to be a new design, but which after all is merely the original design treated to meet the exigencies of the case.

MILNES' NEW SELF-ACTING SLIDE AND SCREW-CUTTING LATHE FOR FOOT POWER.

BY AN ENGINEER.

MR. H. MILNES, of Ingleby Works, Brown Royd, Bradford, has been making lathes for about thirty years; he makes for use in engineers' workshops a very sound and serviceable tool, which, for the 5-in. centres size, is £4 lower in price, and which he calls Class B. The lathe herewith illustrated is the 5-in. lathe of Class A; it has extra care bestowed upon it, and appears well worth the £28 charged. The maker's description of his new "Self-Acting Slide and Screw-Cutting Lathe, to be Worked by Foot-Power," is as follows:—Strong bed fitted with removable gap piece, and mounted on strong iron standards; double-geared headstock with eccentric motion to back-gear; steel mandrel of warranted accuracy, with adjustible *hardened* conical bearings running in *hardened* steel bushes; driver chuck, face plate, and cone centres; cylinder poppit-head with steel screw and accurately fitted spindle; strong self-acting sliding saddle with recessed cross-slide; hand surfacing motion, and quick return by rack and pinion; compound slide-rest graduated for turning taper or conical work to any desired angle; Willis' universal tool-holder; steel leading screw, full length of bed; full set of twenty-two machine-cut change wheels; calculated table of pitches for screw-cutting; reversing motion for cutting right and left hand threads; speed cone for gut band; strong turned crank-shaft running on anti-friction centres of hardened steel; chain and roller treadle motion and heavy turned driving wheel; hand rest with eccentric fastener and two top rests; travelling back stay; foot-board; driving band; and all the necessary spanners. The lathe can be used for cutting long spirals; its approximate weight is 8 cwt.

"These lathes are well proportioned and highly finished, and have been carefully designed and speeded especially for the use of scientific instrument makers, opticians, electricians, and any light engineering business where accuracy and delicacy is required; their parts are carefully balanced, and run easily. The leading and other screws are made of steel, and cut to Whitworth's standard; the sliding parts are got up to true surfaces with the scraping tool; the teeth of the wheels are cut by machine from the solid, and work smoothly, quietly and without tremor; the mandrel bearings being of hardened steel and carefully fitted, the friction is reduced to a minimum, whilst the durability and retention of accuracy is much increased."

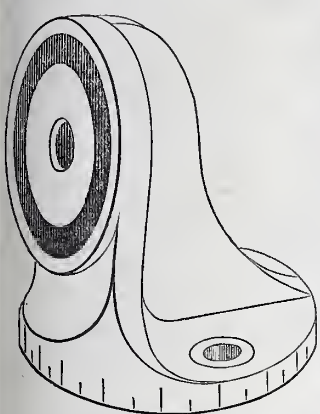

Fig. 2.—Swivelling Bracket for Holding Slide Rest in Vertical Position.

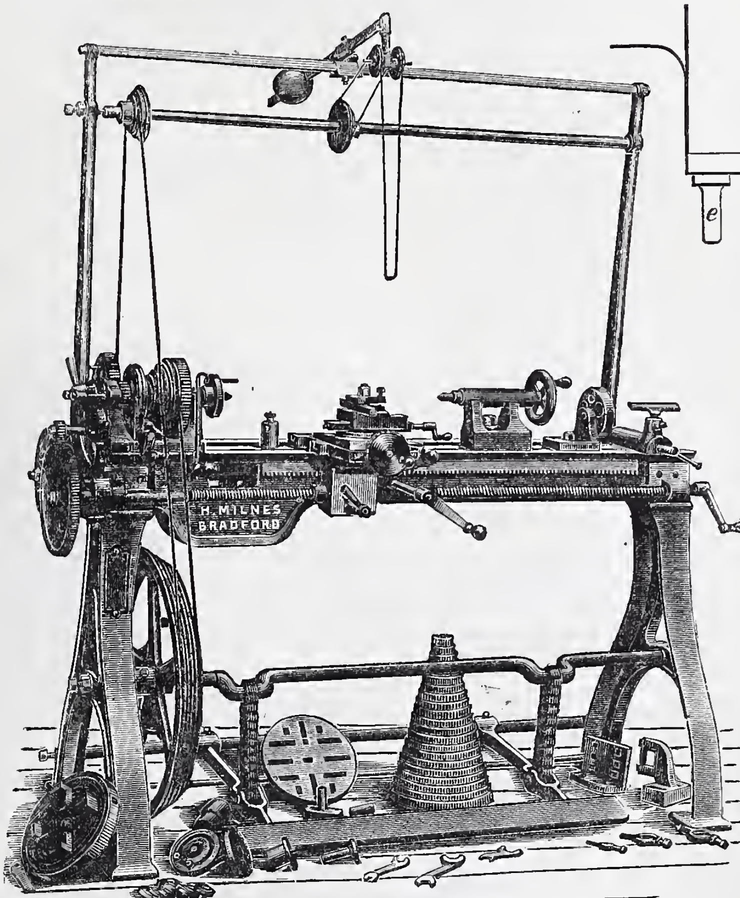

Fig. 1.—Milnes' Self-Acting Slide and Screw-Cutting Lathe for Foot Power.

The following apparatus can be added if desired:—Overhead for ornamental turning, £5; division plate and spring stop, £1 2s; worm-wheel and tangent screw, with micrometer head and index, £3 5s.; hollow mandrel, 14s.; cone plate or boring collar, £1 2s.; loose head centre, made to move sideways for turning long tapers, £1 15s.; quick withdraw motion (to withdraw tool in screw-cutting before running it back for another cut), with improved feed regulator, £1 12s. 6d.; angular and swivelling bracket for mounting top slide of rest vertically, £1.

Having been a customer of Mr. Milnes, the present writer feels pleasure in testifying to the honesty of his work and the straightforward way in which he conducts his business. One cannot expect to get the polish and high finish of the most expensive work at such a low figure, yet these lathes will do good and accurate work, turning and boring parallel and surfacing flat. The moving headstock fits well between the shears, and the cylinder fits into its place so closely that it is scarcely necessary to clamp it with the pinching screw. The necks of the mandrel, after being hardened, are ground on dead centres by a revolving lap, the thread of screw on mandrel nose is cut by a revolving cutter, and a $\frac{3}{8}$-in. hole can be bored through it. The reversing motion is so constructed that the largest change-wheel can be put upon the mandrel as required for cutting spirals of quick pitch; a spiral of one turn in six inches can be cut, and a screw as fine as ninety-six threads per inch. The 5-in. lathe with extras is shown at Fig. 1; it has a cone pulley with five grooves or rises in it, there being five grooves to match them on the fly-wheel; there is another groove in the fly-wheel turned in a ring, which gives a still slower speed, for this, a separate band is required, which runs to the largest speed on the cone pulley; so that there are altogether six speeds without and six speeds with the back-gear. The twelve speed ratios obtained are, from largest groove on wheel to smallest on pulley:—

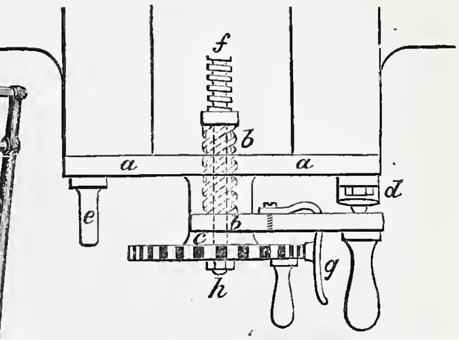

Fig. 3.—Apparatus for Quick Withdrawal and for Regulating Depth of Feed.

1st,	1 revolution of crank		to	8	of pulley.
2nd,	,,	,,	,,	6½	,,
3rd,	,,	,,	,,	5	,,
4th,	,,	,,	,,	4	,,
5th,	,,	,,	,,	3	,,
6th,	,,	,,	,,	2	,,

If the back gear be thrown in, the speeds are:—

1st, 1	revolution of crank		to	1	of pulley.
2nd, 1¼	,,	,,	,,	,,	,,
3rd, 1½	,,	,,	,,	,,	,,
4th, 2	,,	,,	,,	,,	,,
5th, 2½	,,	,,	,,	,,	,,
6th, 5	,,	,,	,,	,,	,,

Thus the fastest speed gives eight turns of the mandrel for one revolution of the crank, suitable for small work in wood; whilst the slowest requires five treads to make the mandrel turn once. Great care is taken to ensure easy running. The overhead motion adopted is similar to that made by Mr. Evans, and is far superior to the form Mr. Milnes formerly made, with the single tension pulley underneath the drum.

The bracket for mounting the top slide of the rest in a vertical position is a very useful addition; it is shown at Fig. 2. The upper part of the slide-rest having been taken off at the quadrant, it is bolted upon the vertical face of the bracket; the two are then placed upon the lower part of the slide-rest, so that the lower flange of the bracket is fixed where the quadrant flange of the rest was. The upper slide of the rest will now be vertical, and can be swivelled round to any angle in a vertical plane; whilst the bottom flange allows of its being swivelled round in a horizontal plane. Thus mounted, the slide-rest may hold a strong driller taking a slot drill, and drill out the slots in a face-plate, etc. Or, with the bracket turned round to a position parallel with the face-plate, it will hold the driller pointing across the lathe-bed, so that a round-edged milling cutter can be brought down upon a tap or rhymer (fixed between the centres) which it was required to flute; by swivelling round the bottom plate, the cutter might be placed at an angle as for fluting a twist-drill, the feed being given by the lead screw as in screw-cutting. A frame for holding cutters for the teeth of wheels could also be clamped to the slide-rest while in a vertical position, which could then be adjusted for height, or slewed round for bevil or skew gearing.

The quick-withdrawal is the last addition to be noticed. This is useful for two purposes. First, it enables the workman to set in his tool by a known quantity, measured in hundredths of an inch. Second, it enables him when screw-cutting, either outside or inside threads, to withdraw his tool before running it back for another cut, with the certainty of being able to restore it to exactly the same position. The old and clumsy way of making chalk marks on the boss of the screw or handle only admits of an approximation, and the wonder is it prevailed so long. Fig. 3 gives an idea of the arrangement as made by Mr. Milnes. On the front of the saddle is bolted a gun-metal casting *a*, *a*, which forms the foundation of the apparatus, and in the boss in the centre of this casting is cut a quick pitched screw thread; *b b b* is a crank handle, on the long boss of which is cut a screw to fit into this boss; these parts are so arranged that when this screw comes home up to the shoulder, a little half sphere carried by the spring *d* drops into a recess sunk in *b*, and so holds it from accidental displacement; yet not so firmly but that it can be raised by a moderate pressure of the hand. The traverse screw, *f*, passes through the boss of *b*, which forms the collar in which it works; endlong motion is prevented by a solid collar on *f* in one direction; and by the nut *h* in the other. The wheel *c* goes on to *f* and turns with it, being secured by nut *h*; this wheel has thirty notches cut in it, into which takes a tooth or spring *g*. The pitch of screw *f* is $\frac{1}{10}$th of an inch, so that if spring *g* be released, screw *f* can be moved by the handle on *c*; one turn equals $\frac{1}{10}$th-in.; one notch equals $\frac{1}{300}$ths of an inch, etc. To withdraw the tool in screw-cutting, so as to clear the thread before running back for another cut, lift the lever *b b* by means of its handle, and throw it over to the left till it rests on the pillar *e*; rack the saddle back to the beginning of the thread you are cutting, then restore *b b* to its first position, so that spring *d* snaps into its place; withdraw spring *d*, and pass two or three notches to give the depth of the next cut. For inside threads, the arm *d d* would rest on the pillar *e* while the cutting is done, and would be thrown over to the right to withdraw the tool from its cut. Perhaps it might be better to have a spring like *d* on each side.

With regard to the hollow mandrel, as some may not understand its value, it may be well to explain that when short articles, such as screws, are being turned from the end of a rod of iron or steel, if there is a hollow mandrel having a hole bored through it large enough to take the rod, it can be passed in through the chuck and lie in the hollow mandrel whilst only enough for one screw projects from the jaws of the chuck; when one screw is finished and cut off, the rod is simply pulled a little further out and grasped again, thus saving the wasted ends which result when the bar has to be cut into short pieces.

OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

109.—Stanley's "Odd Jobs."

Stanley's "Odd Jobs," as the curious-looking appliance shown in Fig. 1 is called, is about as useful a *multum-in-parvo* combination tool as a workman can find to add to the tools that he usually carries in his basket when he is sent for to do repairs of a general character in a house, or to the furniture that is found therein. If it be asked—what can be done with it, it may be pointed out that, when used in combination with a carpenter's rule, it embraces in itself no less than ten different tools which are constantly in use day by day and day after day—from Monday morning till noon-day on Saturday—in every town in the United Kingdom, inasmuch as it supplies in itself a try square, a mitre square, a T square, a marking gauge, a mortise gauge, a depth gauge, a mitre level, a spirit level and plumb, beam com. passes, and an inside square for making boxes and frames, thus performing the functions of ten different tools, as it has been already said. The form and appearance of the appliance will be gathered from

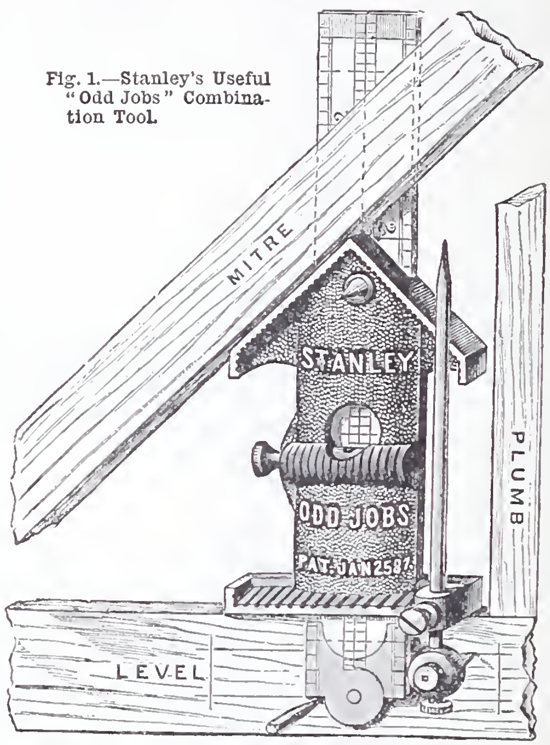

Fig. 1.—Stanley's Useful "Odd Jobs" Combination Tool.

Fig. 2.—Whitehouse's Patent Unbreakable Bits.

the illustration, so there is no occasion to make any remarks on these points here, beyond saying that it is nickel-plated, and as, when thus finished and furnished with a level, as in Fig. 1, is sold in America for 75 cents, so its value on this side of the Atlantic may be set down as being from 3s. to 4s., giving a margin for cost of freight and other charges on its passage from West to East. Its exact price, however, may be ascertained by sending a postcard to Mr. H. A. Hobday (late Hobday and Tovey), Tool Merchant, Cutter, and Hardware Factor, 46, High Street, Chatham, whose house has long been famous as an emporium of tools and appliances for the building trades of all kinds, good and cheap.

To return to the "Odd Jobs," the mode of attachment to a carpenter's rule will be seen from the illustration, the rule working in a broad groove formed in the back for its reception, and in the position shown it will be found to do duty as a try square or as a T square, with a long or short tongue, as may be required. It will be noticed that the top is so formed as to resemble a gable roof, the two sides forming a right angle; thus, when a piece of wood is laid on one or other of the sides, a right-hand or left-hand mitre can be marked on the wood, the tool, and rule, thus together forming a mitre square. The pointed steel rod on the right hand is a scratch awl. It is converted into a marking gauge by setting the point or pencil at any required distance from the square end of the stock. A mortise gauge also is obtained by putting an additional point or pencil in one of the angles on either side of the circular joints at the head of the rule. Thus, by moving the whole along the edge of the wood on which the square end of the stock rests in the illustration, two parallel lines are traced on its surface by the points, as shown. A graduated depth gauge is furnished by extending the rule downwards from the square end of the stock. It will be noticed that there is a steel point projecting from the face of the appliance at the mitred end, this forms a centre from which a circle can be described as with a beam compass ranging from $1\frac{1}{2}$ to 13 inches in diameter. The steel rod in question is shown on the right of the tool. When a small circle is required, this steel rod should be reversed and inserted in the arm bored for its reception the reverse way to that in which it is shown in the engraving; this brings the point or pencil nearer the centre-point. A circle ranging from 13 to 25 inches in diameter can be struck if the rule alone is used as radius with a pencil in the angle at its head. This explains its use as a beam compass. Its utility as a spirit level and plumb, and as an inside square, is too obvious to require explanation. A trial with the tool is the best way to judge of its merits.

110.—Whitehouse's Patent "Unbreakable" Bits.

These bits, which are also supplied by Mr. Hobday, of Chatham, are considered by American workmen to be "a perfect tool," and by English ironmongers to be "the bit of the future." It is said that one "unbreakable" will wear out several of the ordinary bits. The superiority to the latter in point of construction may be seen from Fig. 2, and a trial will soon convince the most sceptical of their value. They will start and finish clear, bore straighter, last longer, are much stronger, and are the only twist bits with which a hole can be enlarged. They are well adapted for boring felloes, and are invaluable for deep boring, as, by giving about two back turns to loosen the screw, they draw out the cut wood, thus saving much time in re-starting. They are made in ten sizes varying from $\frac{1}{4}$ in. to $1\frac{1}{4}$ in. in diameter, ranging in price from 1s. 6d. for the first four sizes to 2s. 10d. for the largest size. If sent by post, an extra charge of 3d. is made. The set of ten complete is supplied for 18s.

The Editor.

SHOP:

A CORNER FOR THOSE WHO WANT TO TALK IT.

*** NOTICE TO CORRESPONDENTS.—In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of WORK in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

I.—LETTERS FROM CORRESPONDENTS.

Oxyhydrogen Blowpipe.—OXYGEN writes in reply to T. W. B. (*Barnsley*), page 174:—"I note that up to the present no reply has appeared in WORK to the above query. No doubt T. W. B. has by now obtained the information he required elsewhere. But allow me, for the benefit of other readers of WORK whom it may interest, to say a few words on the subject of the oxyhydrogen blowpipe. As to the arrangement illustrated on page 174, I may simply say I should not care to be anywhere near it when tried. T. W. B. appears to be hardly aware of the dangerously explosive mixture he would get in the small chamber B. An oxyhydrogen blowpipe to be safe must not admit of any possible mixture of the gases before they reach the nozzle. Bad accidents have occurred through the explosion of such a mixture as T. W. B. would get. Readers of WORK can hardly improve on the oxyhydrogen blowpipe manufactured by Fletcher, of Warrington, and I do not think it would be possible for any one to make one for double Fletcher's prices. An oxyhydrogen blowpipe is a far more delicate instrument than T. W. B. appears to imagine. It will melt all metals, even platinum, and easily fuses silica, and such like almost infusible substances. To use one satisfactorily, the oxyhydrogen must be compressed in cylinders, as the pressure obtained with the old-fashioned gas bag, etc., is not sufficient. When using the blowpipe, first turn on the hydrogen gas (coal gas does equally well) and light it. Then very carefully turn on the oxygen, taking care not to turn on too much, or whatever is being heated will immediately catch fire, particularly if iron or brass. When heating metal the blowpipe should not be allowed to hiss. The smallest of Fletcher's oxyhydrogen blowpipes can make a piece of thick tool steel white-hot in a few minutes, and—if properly used—on cooling the metal will not be nearly so much burnt as it it had been heated in a forge. Should too much oxygen happen to be turned on, there would immediately be a very fine pyrotechnic display, the steel being on fire. I have seen holes an inch in diameter burnt in quarter-inch steel plate in two minutes, a splendid tool for burglars. From this it will be seen that an oxyhydrogen blowpipe is much different in use to an ordinary blowpipe."

Powerful Rip Saw.—ARTIST IN WOOD writes in reply to (*Highbury, N.*), page 411:—"The rod at the corner of the machine is part of the treadle, and is made firm to the cross rocking bar. The top end of this rod moves backward and forward when the machine is in motion. The D rod (for cut see page 348) moves with it and so moves the fly wheel. The treadle is down as shown in the sketch. I use this form of treadle for very heavy work that is a high speed machine. If you want the saw to cut 4-inch deal make the bench low and wide from back to front, so as to give more rise and fall to the treadle. The handle on C wheel should be fixed 3 in. over the edge of the wheel in such a way that it will clear the crank pin to give more leverage. The treadle should be made very strong.

Rubbing Down Oilstones.—A. G. (*Newcastle-on-Tyne*) writes:—"In your issue of October 19th, No. 31, on page 490, W. G. has an article on 'Rubbing Down Oilstones.' I think you will agree with me that it takes a lot of preparing, etc., although it may be very good in its effect, but I have a method which I learnt in dear old Norwich some years ago, which is this:—Get a piece of P. K. P. glass (which is rough on one side) about 12 in. or 14 in. square, which can be got for the asking, then stick 4 nails into the bench, 2 on either side, which will hold the glass while you rub the stone across it, and in five minutes you can rub the hardest stone perfectly level and true. One piece of glass will last for years."

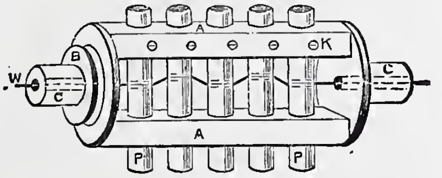
Ear Drums.—DEAFNESS (*Pallasgrean*) writes:—"If any of the readers of WORK have used or are using Nicholson's Patent Ear Drums, would they say in your valuable paper WORK if they are a success, and if there is any danger in using them? I have read so many cautions against putting anything into the ear that, although I much want a remedy for deafness, I fear to use them, although having them on hand. They are very expensive—£2 11s. 6d. for gold-plated ones."

Wire Thread Fret Saws.—Messrs. Moseley & Son, 323, High Holborn, W.C., write, for the information of all who have been making inquiries respecting them, that they now have them on sale. Inquiries as to sizes and prices must be made of Messrs. Moseley & Son, as they have not furnished me with these particulars.

Hair Spring Fixing.—A. B. C. writes:—"On page 525 (November 2nd), column 3, eleventh line from top, 'stock' should be 'clock.'"

Parts of a Lathe.—P. C. (*Bedfordshire*) writes in reply to S. G. D. (*London*), see page 508:—"I should like to know if fly wheel of lathe by S. G. D. is wood or iron, and if the axle is fixed to bench, and also if it is necessary to provide brass or any bearings for mandrel to run in?"

Straightening Bird-Cage Wire.—GIVE & TAKE writes:—"Reading through your editorial on the above in WORK, in 'Shop' No. 27, page 429, put me in mind of a simple tool used in America, but apparently not generally known here; and if my very crude sketch (I cannot draw) is deemed sufficiently clear, the following is a description and its use:—AA is cast from a wood pattern, in which B, pulley, and CC, shaft ends, are concluded. Through each end of shaft a ¼-inch hole is bored, which serves as centres upon which to truly turn up ends, so as to run smoothly in hardwood standards. PP are five hard wood round pegs to



Wire Straightener.

fit their respective holes in frame. KK are small screws to tighten on to pegs. Through centres of pegs a $\frac{1}{16}$-in. hole is bored for wire, W, to pass. For working, you commence by threading your wire through the left hand or pulley end of shaft, and on through pegs and right end of shaft (I conclude you have mounted machine in its standards). Gently tap the second, third, and fourth pegs, out of line, opposite directions, and tighten small screws down on pegs to keep in place. Set frame revolving by strap on pulley, whilst you steadily draw with pliers, the wire through pegs. No matter how crooked or kinky wire was previously it comes out perfectly straight. You can use any wire, or thickness, up to $\frac{1}{16}$ inch, I have not tried thicker. I like WORK very much, and send this on the chance of being useful to others, as I like to give and take."

Sheet Metal Working.—RODNEY (*Newport, Isle of Wight*) writes:—"I have carefully read WORK, and find it just what is wanted in these go-ahead times. I have derived a deal of knowledge in years gone by from Cassell's 'Working Man's Friend and Family Instructor.' I consider this quite a boon to the rising generation. Having worked in the sheet metal line myself, I was pleased with the drawings, etc., of various soldering irons in No. 17. We did not learn geometry. In handling our soldering irons we used to get out a small brass plate, thus—with a square hole to fit the shank, and fit this down on the ferrule and rivet, with burr at the bottom. This, of course, being larger than the

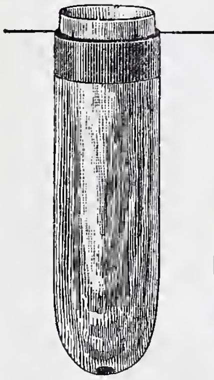


Fig. 1.—Ferrule.

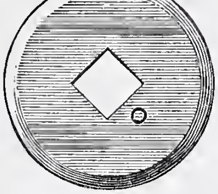

Fig. 2.—Brass Plate.

ferrule, secured it. Another way is to nail on the wooden handle before you drive on the ferrule a tin band, say, ½ in. longer than ferrule. After driving on ferrule rivet over on top end the ½ in. of tin, and that will secure the ferrule. I see in No. 20 St. Mungo (what's in a name?) wishes for a book that deals exhaustively with sheet metal. The best I know of can be obtained from Mr. R. H. Warn, 54, Marquis Road, Camden Square, N.W. This was the address where I obtained mine some twenty years ago. I may say the price of hook is 10s. 6d. (thirty-two plates). I wish you success in this useful WORK."

II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

Tempering Steel.—J. T. (*Manchester*).—To take the temper out of steel, heat it to a low red, and allow it to cool gradually in air. To re-temper it again, heat to a low red, and quench in water; then if the article is small, raise the temperature on a bar of hot iron until it is of the shade of colour required, and quench in water or oil or other special hardening mixture.—J.

Swaging Square Iron into Round.—J. C. (*West Bromwich*).—The art of swaging consists in heating only that portion of the iron which requires to be swaged, and in first roughing to approximate shape with the hammer, and then finishing off between the top and bottom swages. In swaging by steam the shape would be first roughed out under the steam hammer, after which the swage tools would be put under the hammer.—J.

Blackening Zinc and Steel.—W. H. M. (*Accrington*).—Japanning is one mode of blacking which, if done at the right temperature, is very permanent, but it is not a stain. You may stain steel black by getting it hot in the flame of a Bunsen burner and then dipping it in oil. I do not know of any method of staining zinc and should therefore japan it.—J.

Oiling Parts of Watch.—E. B. (*Dartmouth*).—You are rather mixed about the watch, as there is no lever cylinder watch. Each is a separate escapement, the lever having an extra piece between the escape wheel and the staff in the cylinder watch. The escape wheel works directly in and on the part on which the balance is fitted. The scape wheel, too, is different, being of steel, and having the teeth raised on little stalks, so to speak, the lever scape wheel being nearly always of brass, and having radial teeth, or nearly so. But now as to oiling. Oil all pivots, including the barrel, where the barrel works round on the arbor (not where the arbor comes through the plate if a three-quarter plate); likewise the escape wheel teeth whether lever or cylinder (but not the ruby pin if a lever). Keep the hairspring and pins between which it beats perfectly free from oil, or you cannot regulate it. Do not oil the other wheel teeth nor the pinions, and above all do not give too much, especially to the balance staff or cylinder pivots, or to the scape teeth, and use good oil. If you use too much, and it is bad, it will run all over the place and away from the pivots, and then that is as bad as giving none, and if bad it will turn like glue and stick the wheels up that way. Use Ezra Kelley's watch oil. That I find to be best.—A. B. C.

Crests, Monograms, etc., Book for.—R. M. E. (*Sunderland*).—I do not know of any book in which is combined crests, monograms, coats of arms, and decorative border work, but I should recommend you to get Fairbairn's "Crests," published at 50s.; also either Renoir's or Lillie's "Monograms," sold at 9s. 6d. and 6s. respectively, by Rimell of 91, Oxford Street, W., where you can obtain Fairbairn's "Crests" for 30s. Books containing decorative borders are also to be had there. I advise you to try Burke's "Peerage," to be obtained secondhand at about 12s., or some work on "Heraldry," for coats of arms, etc. The best book I know of on water colours is Green's, published by Rowney & Co., Piccadilly, W., at 5s. in one volume (cloth) or in three separate volumes at 1s. each. Noble's is another good book at 1s. by the same publishers.

Anodes of Aluminium Nickel.—J. J. P. (*Malton*).—If you will communicate with the Secretary of the Aluminium Company, Limited, 115, Cannon Street, E.C., he may be able to give you some information respecting this alloy, and where it can be obtained. If you fail to get it there, try Messrs. Henry Wiggins & Co., Metal Refiners, Birmingham.—G. E. B.

Galvanic Battery and Coil.—F. D. (*London, E.C.*).—This subject shall receive my attention in an article or two at an early date.—G. E. B.

Garden Hammock.—BON FILS (*King's Norton*).—An illustrated paper giving full instructions on making netted hammocks will be forthcoming when room can be found in WORK for its publication. G. E. B.

Scale for Stops for Chamber Organ.—J. C. (*Leeds*).—The following would be a fair scale for the stops you mention suitable for a chamber organ:—

	C C.	Tenor C.	Middle C.
Open diapason	4¾ inch.	2⅝ inch.	1⅝ in.
Principal	2⅝ inch.	1⅝ inch.	⅞ in.

Octave couplers, etc., will be fully described in papers on organ building when they appear.—M. W.

Model Yacht Construction.—SPINAKER.—It is not possible to commence instructions on this subject yet awhile, but you may rely upon it that when the matter is taken in hand, it will be dealt with in a sufficiently comprehensive manner to embrace the three specialties of construction—hull, rig, and classification.

Wire for Coil.—COAL MINE.—The sample of wire sent is No. 28 B. W. G., equal to ·017 in decimal wire gauge. Two layers of this, if covered with silk, would do for the primary wire of your small coil, and you might then fill up with about 4 ounces of No. 38 B. W. G. silk-covered copper wire. You will not be able to get a very powerful coil on a bobbin only 3½ inches in length. The best results from this size will probably be obtained by using a ⅝ inch core of soft iron wires. Use No. 20 size, straighten them, make up into a compact bundle tied around with string, soak in melted paraffin, cool the bundle, then unwrap the string. For primary, use No. 20 B. W. G. silk-covered copper wire in two layers. For secondary, use from 4 to 6 ounces of No. 36 B. W. G. silk-covered copper wire wound on as a reel of cotton is wound. Insulate each layer with foreign post paper soaked in melted paraffin. The prices of the wires are as follows:—for silk-covered copper wire, No. 20, 5s. per lb.; No. 36, 1s. per oz.; No. 38, 1s. 4d. per oz.—G. E. B.

Indiarubber Stamps.—W. A. W. (*Redditch*).—You will have seen that a paper on Rubber Stamp making by a contributor has been given in No. 38 of WORK.

Pill Boxes—their Prices.—INVENTOR.—Write to Messrs. Maw & Co., Druggists' Sundrymen, Aldersgate Street, London, E.C., stating your requirements, and they will furnish you with prices of boxes in cardboard or in wood. You need not be at all afraid that any reader of WORK will think you are going to set up as a druggist because you want some pill boxes. You have not given me your name and I have not named the town in which you live, as you may see.

Process Blocks.—P. McL. (*Glasgow*).—You will find the method of making process blocks described in "Modern Methods of Illustrating Books" (The Book Lover's Library), published by Elliot Stock, 62, Paternoster Row, London, E.C.

Book, Stationery, and Fancy Goods Business.—CONSTANT READER.—I regret I cannot help you personally or through readers of WORK in the direction indicated.

Plaster Casts from Nature.—OMEGA.—This subject will, I trust, be taken up and effectively dealt with in Vol. II.

Brass Finishing and Relacquering.—PADDY.—I am glad to learn that WORK is so useful to you. The subject you mention will be taken up as soon as opportunity offers. Meanwhile, any question you wish to ask in relation to it shall be answered.

Property Repairing Company.—RANGOON.—I am afraid that neither I nor any of my staff can tell you where to obtain the prospectus of any company so named. The only property repairing companies that I know are building firms.

Lubricating Oil for Bicycle.—F. F. M. (*Edinburgh*).—Yes, neatsfoot oil is rather thick, and not so suitable for your purpose as sperm. To get rid of the sediment you had better try straining or pouring off the clear portion after prolonged exposure to sunlight, for the purification of oil by the ordinary commercial process is beyond an amateur's capability, but surely in such a place as Edinburgh there can be no inducement to prepare your own oil. You will be able to buy it quite as cheaply and far more satisfactorily than you can by refining a small quantity. Were you living in an out-of-the-way district I could understand you wishing to try your skill as an oil refiner, but for an inhabitant of "Auld Reekie" to do so seems as if the old proverb "Time is money" had lost its force. With regard to your remarks on photography I think if you will turn to the back numbers of WORK you will find that you have no occasion to wait either patiently or otherwise for the subject to receive attention. Many important papers connected with it have appeared already. More will be given in due course, meanwhile as you confess to being "photographic mad" I can hardly wonder at your wanting them quickly, but "bide a wee ma frien'" Even the meenister ye ken canna cram a' his sairmon into a wee bittie talk but maun just tak it in three pairts, or aiblins wi' mony subdivisions an' we feel constrainit to dae the same wi' phōttōgraffy, which ye will allow is a subject which natterally divides itself, not only into three, but into a muckle number o' heads, sae mony in fac' that ilka ither subject wad hae to be pit aside for lang years to come were it to be "treated exhaustively" the noo. Aye echo as many suggestions as you like—we allow you.—D. A.

Paint for Blackboards.—W. T. (*Padham*).—Although I am not certain of the precise nature and component parts of the mixture used for blacking the boards by the manufacturers of school requisites, I have used the following kind of paint, and it has answered perfectly. Procure ivory drop black, ground in turpentine (retail, about 1s. per lb.), dilute this with japanner's gold size, or copal varnish—preferably the former—and a little turps. Being already ground in turps, you will find the black will not require a large quantity of gold size to reduce it to proper working consistency, which is that of a thin, watery paint. If you prepare the boards from the white wood, give them one good coat glue size, then afterwards two coats of oily, dark, lead-colour paint, or common black, and finish with one or two coats of the drop black as above; spread it quickly and don't let more than 24 hours intervene between the oily ground and the flat, lustreless black. At schools they usually freshen up the boards with writing ink and a cloth, but I have used the black above described for music boards, which had afterwards to be lined out into the five-bar staves. They have, therefore, not been touched or so rubbed up, and as the boards I did have been in use for years, I can recommend the above process and mixture as quite reliable, and such as one professional worker can offer to another. If you can't get drop black, use ordinary lamp-black, well mixing it first with gold size—japanner's, mind!—and then thinning down with turps.—F.P.

French Polishing in Lathe.—LEO.—The probable cause of the ridges of polish in places, and absence of polish in others is over-saturation of the rubber. Do not moisten the rubber so much and you will most likely find the result better. If not, describe your process in detail, that I may be enabled to locate the fault more precisely. At present I can only surmise it.—D. A.

Tool Dealer in Manchester.—H. M. D. (*Silsden*).—You might try Grimshaw, 71, Oxford Street, Manchester. If he has not got the things you want no doubt he would obtain them for you. I am afraid this information is too late to be of use to you on your present visit, but really with every wish to render assistance it is not possible to answer a question written on a Monday, and consequently not received before Tuesday morning, in the same week's issue.—D. A.

Box for Games.—A. F. S.—To give particulars in "Shop" would occupy far too much space, but your suggestion is noted, and in time will be acted on, as no doubt a description of the construction of a box for games would be of use to many readers. Thank you for your good wishes.—D. A.

Child's Cot.—T. L. (*New Brompton*).—This subject cannot be treated of sufficiently fully in "Shop," but it will be a satisfaction to you, and doubtless to many other young family men, to know that a paper on a "child's cot" is receiving the serious consideration it deserves. It is not, however, "similar to the beds in the sick bay on board ship," by which I suppose you mean a "swinging cot," but no doubt will be equally useful.—D. A.

Villa for Fret-cutting.—SEMAPHORE (*Newton St. Boswells*).—I do not remember ever having come across a fretwork design such as you want. I have looked over all the British and foreign design catalogues which I have, but the nearest thing I can find is one described as an "old German house as a cupboard." The size is 18 in. wide by 8 in. deep by 16 in. high. It appears as Nos. 810 and 815 in Zilles' No. 39 catalogue, which, as you go in for fret-cutting I would advise you to get, as you can hardly fail to find something to your taste. Thanks for your nice friendly letter.—D. A.

Inlaying Silver Stringing.—W. A. (*Blackburn*).—Real silver stringing may easily be imitated by using strips of pewter and placing them in lines or grooves cut in the wood foundation. The difficulty consists principally in making these incised lines, which of course, form the pattern. The metal being soft, is hammered till it completely fills and fits tightly within the grooves, a little glue being used to ensure perfect adhesion if necessary. You might also ornament your banjo handle with various coloured stringings of veneer or the so-called mosaic bandings, which I dare say you know are composed of pieces of veneer arranged to form a geometrical pattern. Quite right, continue to purchase WORK, and get the back numbers too. They will well repay you for the trifling outlay.—D. A.

Fixing Tiles in Framing.—MACDUFF.—I should think that the plaster of Paris will stand at least as much heat as the wooden frame and back. The tiles being held by the frame on one side do not require much support, but if you are not satisfied with plaster alone mix it with some size or glue. If the design permits of it being done the best plan is to have a rabbeted rail between the two rows. This, of course, would not look well if you have painted the tiles to form a complete picture, as I imagine you have.—D. A.

Secret Dovetailing.—MECHANIC (*Tue Brook*).—Yes, secret and other varieties of dovetail joint will all be described, and the instructions will doubtless be as useful as those on dowelled, etc., straight joints, which have recently been treated in these pages.—D. A.

Plate Shelf.—SIGNALMAN (*Bebington*).—No directions have yet been given for making a set of plate shelves, but the subject will be treated in due course, as it has been down on my list for some time awaiting a favourable opportunity. Glad to welcome you as a new reader, but why not get the back numbers? you will find them an invaluable aid in your mechanical pastimes.—D. A.

Marble Slab for Washstand.—COPSE (*Lewisham*).—For a single slab you will probably do better by going to a good cabinet maker than by going to a marble merchant, who would probably not care about letting you have one at wholesale price. I am supposing that you want to get it ready polished and finished, as you will hardly find it worth while to attempt this part of the work. If you wish to deal direct with the marble merchant I can recommend Mullis, Scrutton Street, Finsbury, or Wilkins & Sons, Pentonville Road, who both make a specialty of marble tops. Any marble mason in your own neighbourhood would, no doubt, supply you equally well. Price depends a good deal on quality, thickness, etc., but you might take 15s. to 20s. as approximate figures for the ordinary kind. St. Anne's, Rouge Royal, and the fancy varieties, would cost considerably more.—D. A.

Wax Ends.—COPSE (*Lewisham*).—Unless you have seen these being prepared it is not easy to convey the information. The bristles and thread are brought together and then twisted, the thread being of course waxed. Any cobbler will show you, and you will learn more from him in a couple of minutes than from a column here.—D. A.

Template for Bracket.—F. D. (*Liverpool*).—I hardly understand what it is you want to know, and at first was inclined to regard your letter as having been written ironically, for you draw the outlines of a template and then ask how to make and use it. I am, however, constrained to consider that you really do ask for information, and I am only sorry that you, like a good many others, have not put your full address. It is contrary to practice to write direct to correspondents, but in your case I should really like to have made an exception, and seen you when lately in your neighbourhood. I think it will be sufficient to say that to use a template you have only to lay it on the wood or other material of which it is to give the outline and mark round it. Thus a straight edge or flat ruler is a template for a straight line. Any material of convenient thickness will do to make the template of—cardboard, thin wood, thin metal, or even stout paper. If you still do not understand give your full address in next letter.—D. A.

Timber Seasoning.—LEO.—In preserving the timber of a tree, as ash or elm, for turning, I should think it would be best to cut first and then stack. Care must be taken in stacking to get all the laths used of even thickness, and placed exactly over each other. Stack in a dry place where the air can pass through the pile. I think it would be better to cut the trunk only into the boards, and not into the squares as required, as it will be better for stacking.—A. J. H.

Electro-plating, etc.—G. R. S. (*Plymouth*).—I shall have much pleasure in giving you advice on all matters relating to electro-plating. On turning to page 31, in our issue for March 30th, you will see an advertisement of the electro-plating and gilding outfit, noticed in "Our Guide to Good Things" of April 20th. It is there advertised as being sold by Richard Melhuish & Sons, Fetter Lane, London, E.C. for 25s., carriage free. You will find Mr. Watts' book on electro-metallargy, recently noticed in "Our Guide to Good Things," the most practical and cheapest text-book on electro-plating. I do not know the process for enamelling bicycles. Perhaps some of our readers who may know how to do this, will oblige G. R. S.—G. E. B.

Straightening Wire.—G. A. M. (*Walworth*).—To straighten long lengths of steel, iron, brass, or copper wire, draw them between rows of French nails or steel spikes driven into a board as shown by the following zigzag row of dots: ˙.˙.˙.˙.˙.˙ Pass the wire in and out the spikes and pull it through by means of a pair of pliers. If the wire is tinned, coppered, or plated, it will not stand such treatment. It should then be straightened by rubbing with a piece of canvas. A wire-worker once taught me to straighten wire in this way:—Fasten one end of the wire in a vice or to a firm bench; rub the bends and kinks out of it by rubbing the wire to and fro with a piece of canvas held in the right hand, whilst the wire is held in the left. By the exercise of pressure on one side or other of the wire as it is being rubbed, it may be made quite straight.—G. E. B.

School for Practical Electricity.—DESIRE (*Peckham*).—If you apply to the Secretary of the City and Guilds of London Institute, and tell him exactly what you want, and how you are situated, I think he will be able to advise you respecting the course you should take to get a knowledge of practical electricity and chemistry. A few winters ago I got some very good practical lessons through this source in the metallurgical laboratory at King's College. A course of lessons and lectures will be given there during this winter, but I do not know the fees for the special subjects you name. Information on this subject, however, will be freely given by the Secretary at King's College, Strand. Address him by letter, or see him personally at the office.—G. E. B.

Electrotypes, etc.—F. J. I. (*Bristol*).—1. The specimen of letter sent is not printed from an electrotype, but is reproduced by lithography, that is an impression or a copy of the letter is made on a lithographic stone and printed from this on paper. It could not be done so well or so cheaply by the electrotype process. 2. When taking an impression in wax from a forme of type, it is necessary to employ a machine to obtain equal pressure on all parts of the wax mould at the same time. 3. I use best blacklead or plumbago. I have not tried finely-powdered tin. If you wish to try it, this is the method for its preparation.—Grind up some tin foil very fine in a porcelain mortar with honey. Wash out the honey with boiling water, and collect the fine particles of tin, which must then be dried for use. I have tried with success the metallic mixture employed by bottlers of liquid to cool the corks of their bottles, etc. You cannot smelt pure copper in an ordinary fire. The temperature must be high enough to heat the crucible to a glowing whiteness. Dissolve the granules of pure copper in dilute sulphuric acid by the aid of heat, and continue the heat until all excess acid and water has been driven off in the form of steam. Set aside the liquid to cool, when it will form crystals of sulphate of copper, and you can use these in your coppering solutions. 5. I am not in the secret of how the diagrams that appear in "Shop," are made, but suppose they are drawn and engraved on boxwood blocks and printed from these, or printed from electros taken from those blocks. 6. I shall leave the Editor to deal with you in respect to what you have written about him, and shall not be surprised if you get a bad quarter of an hour. Respecting myself, I never forget that I am writing to amateurs and for amateurs, but I have to remember that professionals read WORK, and I have to write for them also. If I use technical terms not familiar to you I shall be obliged to you by your asking an explanation of them, and this I shall always be most happy to give in "Shop."—G. E. B.

Tempering Chisel.—CHISELLER.—Files ought to make good chisels; your mode of tempering is correct, and the obvious remedy for their softness is to quench at a darker straw approaching a tinge of brown or purple. You cannot get the precise grade of temper required, except by drawing or letting down.—J.

Organ Materials.—F. R. (*Manchester*).—Organ requisites of every description can be obtained of Mr. T. Willis, Tower Organ Works, Minories, London, but probably you could get them in Manchester, and thus save cost of carriage.—M. W.

Hand Power Dynamo.—J. J. P. (*Malton*).—This correspondent asks:—"Is there to be had a small dynamo electric machine equal in E. M. F. to six large cells of Bunsen battery, and which can be driven by hand power?" I am afraid this question does not convey to me the requirements of the writer. A dynamo may give a current equal in E. M. F. to six Bunsens, and yet be entirely unsuitable to the purpose required, as it may be anything between a small machine for giving shocks, firing a fuse, or working a telegraph instrument, and a large plating dynamo capable of depositing several pounds of nickel per hour. The first might be easily turned by a child, whilst the second would require motive power supplied by a steam engine. The querist must therefore tell me what he wants to do with his machine, or else tell me the volume of current in ampères, as well as the desired E. M. F. of the current required, before I can give him a useful reply. Small dynamo machines to be driven by hand may be had from Mr. Bottone, Carshalton, Surrey, or from Mr. Alfred Crofts, Dover. When ordering, state exactly what you want.—G. E. B.

Electric Work as a Means of Living.—J. C. F.—I fear you would not succeed in getting a living by the proposed means. The prime cost of fitting up a small electric light installation to light up even a very small village would far exceed the resources at your command, although you might obtain water power to drive the dynamos. You would also require more than an amateur's knowledge of electric bells to enable you to master the technical details of electric lighting. My advice to you (and others like you who have an idea that they can get a living by electric work) is, stick to your present employment as a means of living, and supplement this by doing small jobs in spare time, in fitting up electric bells, making and repairing small electrical instruments, and doing little jobs in electro-plating, such as may come to your hand. Get books meanwhile, and study the principles of the science whilst putting these into practice. After some time, if you find that the electric work increases enough to make a living out of it, then throw up the old work, and stick to the new entirely. I am writing a series of articles on this subject likely to be useful to you and others.—G. E. B.

Electric Alarum Clock.—HANDY MAN (*Southwark*).—A paper on this subject is now in the Editor's hands, awaiting space for publication. You will require a 2 inch or 2½ inch electric bell of the continuous ringing type; a switch to connect the bell with the battery at night, and to switch the bell off in the morning; a two-cell Leclanché or Gossner battery; a few yards of cotton-covered No. 18 or 20 copper wire; and a fairly good clock. This last will be most convenient for alteration if enclosed in a wood case. Two types of clock are illustrated in my article, and suggestions are given for fixing the alarum appliance to other types. If you have a system of electric bells already in the house, you may use the same battery to ring the alarum bell, but I advise a separate small bell with sharp tone distinct from that of other bells in the house.—G. E. B.

Enamelled Paper Letters.—JOINER (*Hull*).—If you had read our "Sale" advertisements from week to week you would have found that Beit's Patent Enamelled Adhesive Waterproof Advertising Paper Letters, Figures, etc., are to be obtained at the manufactory, 17, Arthur Street, New Oxford Street, London, W.C.

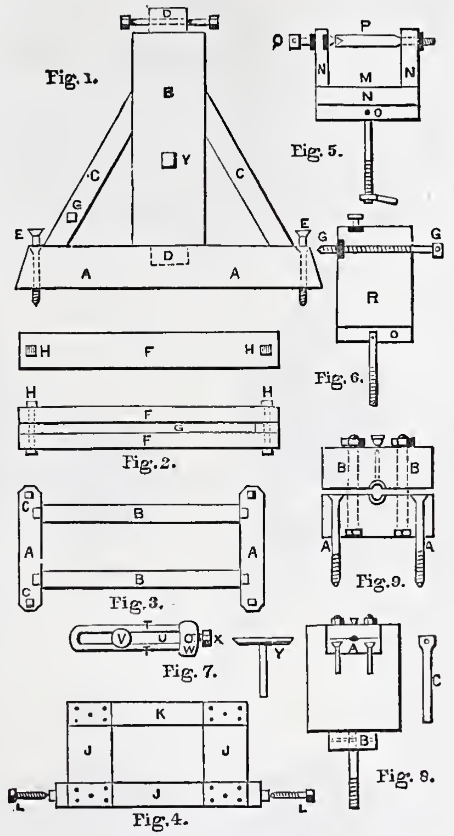
Sign Writing.—A. G. A. (*Primrose Hill, N.W.*).—The paper to which you refer is merely common tissue paper, rubbed over with white wax and pressed on to the gold leaf. I shall describe the method later on in the "Sign Writing" articles. It can be had ready prepared at any colour shop, and is known as "transfer gold leaf."—H. L. B.

Picture Framing Requisites.—J. H. (*Blackburn*).—I regret I do not at present know of any house near your town for picture framing requisites, but you should consult the local directory for the information required, and compare prices.—G. R.

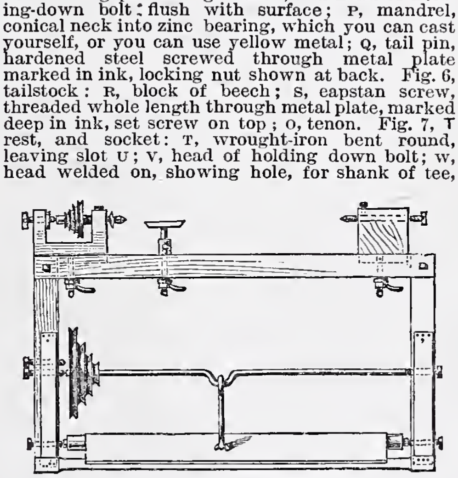
Knife for Mount Cutting.—J. H. (*Blackburn*).—There is a special knife made for mount cutting, which can be obtained, I think, for 1s. the blade, and 1s. 6d. the handle, from the City Frame Company, 29, Basinghall Street, London, E.C. This firm will doubtless forward readers of WORK a set of their moulding and mount samples on application if applicants will pay carriage.—G. R.

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

A Rough Lathe.—J. H. N. (*Malvern Wells*) writes in answer to J. K. (*Richmond*) (see page 348):—"I send a few rough drawings of parts which he will understand, being an amateur carpenter. I hope it will not take too much room in 'Shop,' it may be useful to others that want such a thing. Fig. 1, end view of the standard: A, one of the feet; B, upright tenoned into A, at bottom D; D, on top of upright, tenon for bed to bolt to, showing bolt; E, bolts for floor. The two square heads of pins marked in ink—Y, for crank shaft, S, for treadle shaft. Fig. 2. F, bed, top and side view; G, slot between bed for tenons on bottom of headstocks to fit in; H, bolts for bolting bed to tenon, D, on upright, B. Fig. 3, showing stretcher bar: B, mortised into feet, A; C, bolts for floor. Fig. 4. I, treadle shaft; J, connecting pieces; K, footboard, dots showing screws; L, pins for hanging shaft points into holes, drilled in heads of coachscrews, screwed into ends. Fig. 5. M, wood, cut out of headstock for pulley, pulley not shown; N, showing shape to cut wood; O, tenon for bed, dot showing pin through tenon, and head of holding-down bolt flush with surface; P, mandrel, conical neck into zinc bearing, which you can cast yourself, or you can use yellow metal; Q, tail pin, hardened steel screwed through metal plate marked in ink, locking nut shown at back. Fig. 6, tailstock: R, block of beech; S, capstan screw, threaded whole length through metal plate, marked deep in ink, set screw on top; O, tenon. Fig. 7, T rest, and socket: T, wrought-iron bent round, leaving slot U; V, head of holding down bolt; W, head welded on, showing hole, for shank of tee, marked, Y; X, set screw. Fig. 8, front view of headstock: A, metal bearing, coned; B, tenon, dotted lines showing pin through holding-down bolt; C, holding-down bolt, showing hole for pin to fasten into tenon. Fig. 9, bearing for mandrel, in two parts: A, wood screws through bottom piece into headstock, heads countersunk; B, tightening bolts, square heads let into bottom piece, shank up through both bearings nutted at top, oil hole between, showing cup at top. If a slide rest is added, you will be able to do metal turning. There is a die chuck in No. 13 of WORK (page 204), which you can make, it would be useful for metal turning."



Parts of Lathe.



A Rough Lathe.

Lathe Work.—BRUM (*Keighley*) writes:—"In answer to a READER OF WORK (*London, N.W.*) on 'Lathe Work,' No. 24, page 382, I would say that to set a compound rest for taper turning all he has to do (providing his rest is marked in degrees) is to turn it around from left to right to any angle he wishes for male taper, and the opposite way, to the same angle, for female taper. In cutting 4½ threads to an inch, leading screw ½ pitch, the nut will gear right at every 5 inches of the leading screw, stopping lathe at end of cut before taking saddle back. But it would be easier and quicker in the case of short screws to have a reversing belt, and run the lathe backwards without taking the nut out of gear. To cut 7 or any whole number of threads to an inch the nut will close right at every inch of the leading screw, but the lathe must be stopped before taking nut out of gear. To keep the lathe going constant he must put a chalk mark on the leading screw near wheel plate, and one on the face or driving plate when the nut is in gear, and ready to take the first cut up the screw, and then he must take care to drop the nut in gear when the chalk marks are again in the same position. If a READER OF WORK does not understand this, or if his compound rest is not marked in degrees, I will try and make it clear to him if he will ask."

Polishing Vulcanite.—M. A. L. writes in reply to E. R., see page 493:—"First get all coarse marks out with F F emery paper, and then use Oakey's O paper, which will leave the vulcanite dull, but without any marks. Next get a piece of soft felt and glue it on to a piece of wood (the size of which is all according to the work to be done); rub a piece of candle upon the felt, and then sprinkle with powdered rotten-stone, and well rub the vulcanite with it, and a fairly good polish will be the result, which can be improved by again rubbing the vulcanite with a piece of soft cloth, using oil and rouge, which will bring a splendid polish; then rub all grease off with turpentine, using a soft rag, and finish by rubbing with soft part of the hand. Care must be taken not to make the vulcanite too hot by rubbing too hard, or else it will be spoilt."

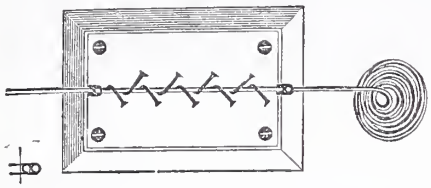
Band Saws.—C. S. B. (*Hoxton*) writes in reply to (*Nottingham*), see page 526:—"The causes of band saws breaking are manifold, the most frequent of which is the improper adjustment of guides, and the tension; also insufficiency of set causing saw to heat, and when no provision is made on the machine to take up the slackness caused by saw expanding, it sags so much above the guides that it is almost certain to go. This kind of breakage is also caused by top wheel overrunning the bottom or driving wheel when the wheels are heavy, but for some years there has been made a machine with built-up wheels similar to a bicycle wheel, being exceedingly light, so reducing this danger to a minimum. It is this cause probably which breaks your saws when finishing a cut, especially in heavy timber, and perhaps fresh also. As to brazing your saws, that is a very simple matter indeed, but one requiring some care to prevent your saw being overheated. I have seen a 30 ft. saw ¾ in. running well with five brazes in it, and the tools used for making the joints were a 1s. pair of bellows, four bricks, and a pennyworth of charcoal for fuel. But more depends upon the workman than the tools for this as many more jobs. The way to start a joint is to thoroughly clean the saw, then, without touching the ends where the braze is to be, lap them one inch, putting a little clean wet borax between, and binding joint firmly with iron wire (using as little as possible to keep the ends in place, as this has to be filed off afterwards). Now wind some brass binding wire over and amongst the iron, and wet all with your borax and water paste. I should have mentioned that you must hammer the set-down of your laps, so that the ends lie perfectly close together. Remember that the less brass you get between joint the stronger it will be. Now for heating your braze: this can be done in many different ways—best by a gas 'injector' blowpipe on charcoal. I find no perceptible difference in the quality of the steel afterwards, though it is said to do steel no good to use gas upon it. Another way is to use a foot blower or small bellows. Get four bricks or pieces of stone or iron, and arrange them thus. Lay two sides down on an iron plate with a space about 3 in. between them. Now lay your saw upon these two with the joint you wish to braze stretching across the space. Put the other bricks upon the saw to keep it in position, and pack charcoal round joint and blow till brass runs; gently draw saw tight, and let cool, take out and scarf down joint. Some recommend scarfing first, but I prefer doing it after brazing, as you stand a chance of getting a thin joint if done previously, and it slips ever so little. By this means you will soften but a very small length of saw beyond the actual braze if you are careful, and it will stand as long as any part of the saw."

Band Saws.—F. C. (*Leytonstone, E.*) writes:—"In reply to S. B. (*Nottingham*) *re* band saws (see page 526) I should think the cause of breaking after cutting through the wood would be contraction in cooling. The friction of cutting makes the saw hot, it lengthens, and the spring tightens it. After cutting it cools and contracts, but the saw breaks, as it is not strong enough to stand the resistance of the spring."

Copying Music.—See page 510. — A number of copies can be done from one copy by means of the autocopyist. The best of these apparatus is made by Fordham & Co., of London.

Fretwork Picture Frame.—W. B. (*Wigan*) writes in reply to AMATEUR (*Belfast*), (see page 510 'Shop'):—"I can inform AMATEUR where he can procure a very elaborate design for a fretwork picture frame, if he wishes to purchase one, size 18½ in. by 22 in., which can be enlarged if desired; price 9d., from J. A. Lambert, Bank Buildings, Carnforth; design No. F 47. I am making the frame now, so thought it might fall in with AMATEUR's wishes."

Straightening Wire.—W. J. W. (*Whetstone*) writes:—"In answer to query of G. C. in No. 27 of WORK, if he does not wish to go to the expense of a set of rollers, the enclosed sketch is a simple method of straightening wire, and can be made in a few moments. All that is required is a piece of mahogany or oak, 12 in. long by 6 in. wide, and about an inch thick, two staples (the exact width



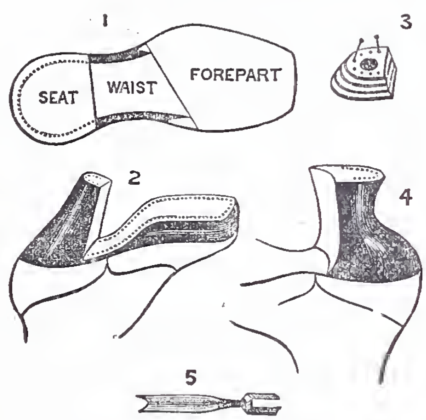
Wire Straightener.

of wire to be straightened) and some French nails, the staples to hold two pieces of wire, as per sketch. A staple is then fixed in each end of the board, and a piece of wire stretched between them and fixed at each end. This is a fixture (the wire to be straightened runs along the top of this). The nails can now be fixed each side of the fixed wire alternately, the board screwed to bench, and it is complete.

Attachment of Seams in Waterproof.—C. S. B. (*Hoxton*), see page 526, writes in reply to A CONSTANT READER:—"This is simply done by means of a solution of india rubber cuttings in naphtha or bisulphide of carbon. You can obtain it ready for use at any rubber dealers, if a small quantity only is required, cheaper than making it yourself."

Aquarium.—W. H. D. (*Bromley-by-Bow*).—See No. 31 of WORK. Alter measurements, and discard such details as you do not require.—C. M. W.

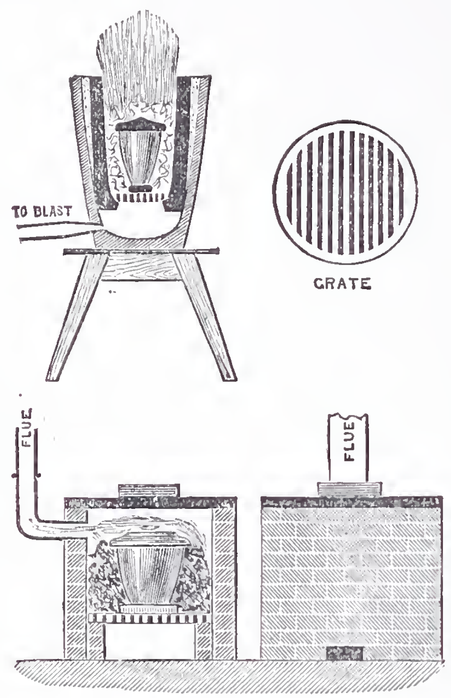
Cork Heel, etc.—H. G. (*Bishopsgate*) writes in reply to J. R., see page 526:—"J. R. does not state what description of boot he wants heel for. If it is for a person with a deformed foot, it would have to be made in proportion to the substance of the sole. If he is not in the trade, he will find it very difficult to make. I will give him the idea. Fig. 1 shows the sole, the dotted lines where the heel is to be built; the first lift should be the same size as the seat, and each succeeding lift should run gradually smaller. Supposing Fig. 2 is the heel desired, which is for a person with one foot shorter than the other—we will say shorter by 3 inches—then the heel would have to be built that height, that is 3 inches. By looking at the diagram you will see the



Cork Heel, etc.

shape required. Put on one split lift only. Fig. 3 shows 4 lifts in position, and the way the nails should be driven in. The breast of the heel should be slanted towards the forepart in proportion to the height. Should the heel be wanted light, punch through the lifts after the heel is built with a half round chisel (Fig. 5) and fill in with cork. Fig. 4 is a Wurtemberg heel. If you are to make the heel on wood lasts, put the first two lifts on with ⅝ pegs, next 4 lifts with inch heel-screws. Should the lifts be stout put three on with inch, and so on. Explain in next number what you mean by the draught of shank irons."

A Small Furnace.—H. B. S. (*Liverpool*) writes in reply to G. T. M. (*Liverpool*) (see page 253), and D. C. (*Huddersfield*) (see page 476):—"You wish to have a small furnace to melt iron and steel. If you can afford it, one of Fletcher's injector furnaces would be the best thing you could use, as it requires no fixing, would stand on any table on an iron plate, and is connected to a gas bracket; the fuel is gas, and air is blown into it by means of a foot-blower giving constant blast. The cost of small size is 11s. 6d. for furnace and 21s. for foot blower. But supposing you want to make your own furnace, there are two plans open to you. 1st, with draft; 2nd, with blast. 1st, with draft, you will require a cellar or outhouse of some kind to build your furnace, as it is not removable, and likewise you must have some means of putting up a long flue, and carrying it into the open air; your furnace will be one similar to those used by brass founders, only need not be sunk into the ground. You have not given me the amount of metal you want to melt, so that I cannot give you sizes; but you can, perhaps, make your own sizes. Build the furnace of fireclay bricks, and perfectly square is a good shape. Leave one brick out at the bottom for draft hole. Cement the bricks together with fireclay instead of mortar, build up a little inside the furnace on opposite sides only, to support the grate. The grate may simply rest on this. It should be a square grate and of strong make to withstand the heat. The flue will have to be of wrought iron for some distance up, but sheet iron will do for the most of it. The flue must be long enough to get up sufficient draft for a white heat. The top of the furnace may be made of a fireclay tile made in one piece with a square hole in the centre large enough to put in and take



A Small Furnace.

out the crucible, and through this hole the fuel is put, the hole must be covered with a fire clay tile when working. 2nd, with blast, get a brass-founder's pot of plumbago, to hold, we will say, 80 lb. of metal, and a smaller pot that will fit inside the large one, and rest within 2 in. of the bottom; these will cost about 10s. Drill a taper hole in the side of the larger pot just at the bottom, 1 in. at outside, and about ¾ in. inside (it is easily drilled with ordinary bits). Take the small pot, and knock the bottom out gently with hammer and chisel, leaving a rim about ½ in. wide all round; get a strong iron grate, such as are used for sewers, to fit the bottom, and rest on the rim. Place the small pot inside the larger one, and pour sand in between. Rest them on a stool covered with an iron plate or stone. All you want now is the bellows, which may be one of Fletcher's, a blacksmith's bellows, or a fan machine as figured in 'Shop' three or four times, and a nozzle tapered to fit the hole. By this arrangement the outer pot may last for ever practically, the inner one will require replacing now and again. I have used a furnace similar to the one last described, and I found that with sufficient draft, I could melt the fireclay crucibles easily. Plumbago crucibles are best, and one of the latter furnaces will melt 4 or 5 lbs. of metal at a time. Put a small fireclay tile on the bars to rest the crucible on, or it will be cooled down by the blast, and ironfounder's coke is the best to use. The latter is the better furnace, as you can get almost any heat by increasing the blast; besides, it is portable, and requires no chimney."

Band Saws.—F. C. (*Leytonstone*) wishes to add to his reply to S. B. (*Nottingham*) in page 621:—"I should judge your machine is of bad construction, saws of inferior quality, and your speed very limited, as your saws break so quickly. Have you an appliance for canting the top wheel transversely? Saws may be tight on the back or on the tooth edge, when the strain will be greatest on the tight edge. Cant the wheel if possible so as to get equal strain the whole width of saw. This is a very important point in the working of band saws. I hope remarks on band saws, which may reach your eye before this appears in 'Shop' will be useful to you and many others of our readers."

Trade Notes and Memoranda.

ONE of the most popular features of the meeting of the British Association was Mr. Baker's description of the Forth Bridge, a triumph of engineering skill, before which the Eiffel Tower almost sinks into insignificance. As a measure of its strength, Mr. Baker mentioned that six of the largest ironclads yet built, weighing each from 12,000 to 14,000 tons, might be safely suspended from its six great cantilevers, while the size of its spans is so great that two Eiffel Towers laid horizontally and joined together at the centre would just span one of its openings. This great work, we may add, is now complete.

In view of the ensuing session of Parliament the Board of Trade has, it is stated, already received over 300 applications for provisional orders for the electric lighting of various towns in Great Britain, the whole of which, if granted, will require the sanction of Parliament next session before they can become operative.

UNTIL recently, the tallest chimney in America was at Newark, New Jersey, and was 335 feet high. A chimney 340 feet high has, however, been recently built at Fall River, Massachusets, it is 340 feet high, 30 feet square at the base, and will furnish draught for the steam-making plant of four new factories.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

A WONDERFUL MEDICINE. BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

Worth a Guinea a Box.

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.

Prepared only by the Proprietor, T. BEECHAM, St. Helens, Lancashire, in Boxes 1s. 1½d. and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

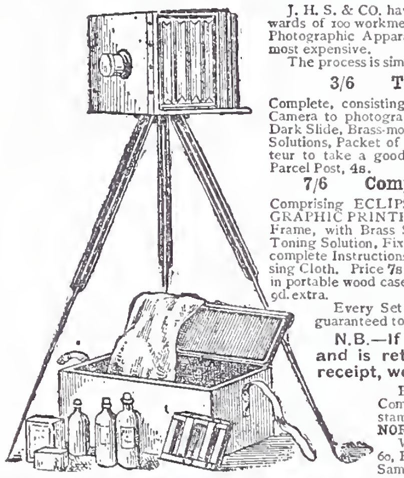
Manufacturers and Importers of Photographic Apparatus and Fretwork Materials.



J. H. S. & CO. have now a large Factory with accommodation for upwards of 100 workmen, which is used exclusively for the manufacture of Photographic Apparatus of every description, from the cheapest to the most expensive.

The process is simplicity itself. Full Instructions supplied with each set.

3/6 The Eclipse Camera Set. 3/6

Complete, consisting of a Polished Mahogany Sliding Bellows, ¼-plate Camera to photograph full-size carte-de-visites, with Focussing Screen, Dark Slide, Brass-mounted Lens, Brass Fittings, Developing and Fixing Solutions, Packet of Dry Plates, and full Instructions, enabling any amateur to take a good Photograph. Price 3s. 6d., or securely packed by Parcel Post, 4s.

7/6 Complete Photographic Outfit. 7/6

Comprising ECLIPSE CAMERA SET, as above; also PHOTOGRAPHIC PRINTING APPARATUS, consisting of Hardwood Printing Frame, with Brass Spring Back, Sensitised Albuminised Paper, Gold Toning Solution, Fixing Solution, Glass Rods, Cards for Mounting, with complete Instructions. Also Hardwood Folding Tripod Stand and Focussing Cloth. Price 7s. 6d. Securely packed, post free, 8s. 6d. If packed in portable wood case, with hinged lid and leather strap, as in illustration, 9d. extra.

Every Set is carefully examined before being sent out, and guaranteed to be in working order.

N.B.—If Apparatus does not give satisfaction, and is returned uninjured within three days of receipt, we guarantee to refund purchase money.

Better Sets, 10s. 6d., 21s., 42s., 100s., and upwards. Complete Catalogue of Photographic Apparatus, one stamp. **J. H. SKINNER & CO., EAST DEREHAM, NORFOLK.**

MELLIN'S FOOD

For Infants and Invalids.

TRADE MARK

NOT FARINACEOUS. Rich in Flesh, Nerve, Brain, and Bone Formers.

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

No Food in the market can show such a vast collection of *bonâ-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

USED IN ALL CHILDREN'S HOSPITALS.

SILICINE GLASS PAINTING.

HOW TO PAINT A WINDOW IN IMITATION OF STAINED GLASS.

BY F. B.

MANY of the readers of WORK are, no doubt, acquainted with one or several of the various kinds of transparent coloured paper sheets which are now being sold for the purpose of being affixed to windows in imitation of stained glass. Some of these are highly artistic, and, if applied with taste, form a pretty decoration for windows. They are affixed without much trouble, and fairly permanent, provided proper care is used in laying them on. They are inexpensive, and answer their purpose admirably in all those cases where nothing is aimed at beyond shutting out an unpleasant view or effecting a temporary or unpretending decoration quickly, without any great expense, and without any great exertion. They will, however, scarcely satisfy those who wish to be original and to give play to their own artistic tastes and personal skill. It is to this class of readers that I will endeavour to describe briefly a method of decoration for windows, screens, etc., which was introduced some time ago as "Silicine Glass Painting," being, as the name implies, a process of actual painting. The effect is, as near as any imitation can be, that of real stained glass, but while, in the latter, the colouring matter is permanently fused with the glass by firing or baking in specially constructed kilns, in Silicine Glass Painting specially prepared paints are applied in the same manner as oil paints would be to canvas or water-colours to paper, but with the admixture of a certain vehicle, called "Silicine," which not only renders the colours perfectly transparent, thereby greatly adding to their brilliancy, but also firmly unites them with the surface of the glass.

This, in a few words, is the principle of the process. The *modus operandi* is simple enough :—

If you wish to paint a window, you will, first of all, have to choose your design. Much, of course, will depend on the situation of the window, its size, and also the degree of your aspirations.

You would, naturally, choose a very different design for a drawing-room window from that which you might think suitable for the hall or staircase. For large panes of a staircase window, a bold and heavy design would be more effective; while, in a dwarf blind of a sitting-room window, more detail might be introduced to advantage.

In the former general effect is wanted; in the latter repeated and closer inspection of the work may be anticipated. For a first trial I should recommend a simple geometrical design, to those especially who have not had a very extensive practice in the handling of the brush.

In accordance with the design, we must now decide on the kind of glass to be employed, for I may here mention that it is best to use separate sheets of glass, that can afterwards be fixed into the sash, in addition to the pane that is already there, and without disturbing the latter.

I have painted windows on the original glass in the sash, but sadly regretted having done so in each case.

Any kind of glass can be used, but I prefer to use the rough kind with a wavy surface, known as "Cathedral" glass, and I should certainly recommend the use of it, except in the case of designs with elaborate details. Cathedral glass is most effective, owing to its uneven surface, which breaks the rays of the light, whereby a remarkable amount of life is imparted to the colours, and, as it does not permit of objects behind being seen through it, the outline of the design is not disturbed by any foreign object shining through. In cases where the latter quality may be objected to—for instance, when the view into the street or garden is desired to be preserved by only partially painting the window—of course, ordinary window glass has to be used. For landscapes, flowers, or figures, painted minutely, ground glass is to be recommended. This material produces pleasing effects of great softness.

Let us assume we have chosen a geometrical design—say, something similar in character to Fig. 1—and decided on cathedral glass as the material. First of all, it is necessary to have the glass for each pane cut to the exact size, so as to fit readily into the sash. This is important, as it is difficult to cut the glass when painted without injuring the work. In cases where the existing panes are not puttied in, but held in place by means of beadings, the measurements should be taken after the beading has been removed, as the same beading will serve for fixing in the painted glass as well.

If there are more panes than one, they should be properly marked and numbered, as even panes of apparently the same size often vary just sufficiently to make an exchange disappointing. Now, having ascertained that the dimensions of our material are quite correct, we will proceed to trace the design on the glass. It is a good plan to draw the design on paper first, and to colour it in water-colours, in order to get an idea of the general effect. When the drawing on paper is ready place your glass on top of it (as indicated in the sketch of the easel used for this kind of work in Fig. 4), with the side to be painted on (that is, the side which will face the glass already in your window) downwards. Secure the paper to the glass by means of strips of gummed paper, or a drop of gum at the corners, to prevent the copy from shifting during the process of tracing. The latter is done with Indian ink and an ordinary drawing pen. If the glass has first received a coating of silicine medium very much reduced with spirits of turpentine, and the same has got quite dry, the ink will not run, as it is liable to do on glass not so prepared, especially when it has not been thoroughly cleaned. It will be noticed that the parts in Fig. 1 marked A, B, C, D, are all different. Of course it is not intended that they should be so painted, the idea being to show four different styles of easy groundwork in the same drawing. Any one of these four styles can be used throughout, or two of them in pairs; for instance, style A for the top of each pane, and style C for the bottom; or one each in reversed order, forming this figure—

A C.
C A.

When the outline is completed remove the copy, and the glass is now ready for painting.

The following colours and materials are required. They can be obtained through any respectable artists' colourman.

Colours for silicine glass painting—yellow (6d.), red (1s.), rose (6d.), blue (6d.), light brown (6d.), dark brown (6d.), black (6d.). Of rose, yellow, and black, it will be as well to get two tubes at once.

1 bottle of silicine medium (1s. 6d.).

1 bottle of silicine gloss (1s. 6d.).

1 flat camel-hair brush, in tin, 1 inch wide.

1 camel-hair mop, No. 6 or 7 size.

2 or 3 fitch hair brushes for oil colours, flat sizes, 4, 6, 10. These should be made of short hair, or what artists call "brights."

1 or 2 round fitch hair brushes (sizes 2 and 4).

2 ox-hair riggers, say, sizes 6 and 12.

1 china palette, 1 palette knife, 1 brush washer filled with turpentine.

Besides the above an easel of a peculiar construction and specially made for this kind of work, shown in Fig. 4, may be found useful, but can be dispensed with if economy is to be studied. The foregoing is all that is required for simple designs such as represented in Fig. 1. For more elaborate and minute work, a few fine red sable brushes, and a steel scraper for taking out high lights, and softening shades, would have to be added to the list, while for very large work a few large flat camel-hair or fitch hair brushes in tin would be required.

Now let us return to our work; we have left it ready for painting. We shall require good light, and should have a small table placed near a window, seating ourselves facing the same. The light must not, however, be too glaring, or it will have a bad effect on the eyes. If you have bought an easel, we will fix the glass into it, the side with the Indian ink outline downwards, and place it on the table, which should be covered with white paper or a white cloth, in such a way as to bring the glass into a desk-like slanting position. If you have no easel, a very simple rest is easily constructed by passing two stair-rods through two pieces of deal board, as shown in Fig. 5; the whole standing on the lid of a packing case, an old drawing board, or such like, two nails in front of the edge of the glass preventing it from slipping. An ordinary rest for fire-irons will form a ready-made rest for your glass, if you do not care for the stair-rod and deal board contrivance.

These preparations being completed, ascertain that the glass is scrupulously clean; if not, there is still time to give it another wipe without interfering with the outline, the latter being on the other side of the glass. Now prepare the first colour you intend to lay on (say the yellow in border of Fig. 1) by squeezing a small quantity on the palette, pour on a few drops of silicine medium, and well mix with a palette knife. This point is very important, as on it depends the general effect of your work. If the medium is used too sparingly or insufficiently united with the colours, the latter when dry present a dull and semi-opaque appearance, instead of being brilliant and perfectly transparent, as they will be when properly applied. Lay on the colour evenly and thinly with a flat fitch hair brush, taking care to completely fill the outline, especially the corners. Any little gaps left blank look very ugly, and quite spoil the effect when the work is finished. You may perhaps find at first, that by laying the colour on thinly you do not get the desired depth. If so, do not be tempted into loading the colour on, but allow the work to dry and then apply a second and even a third coat, until you get the desired depth of colour. This remark applies especially to rose and red, and as the manipulation of these two colours requires a little patience and practice, I have avoided large surfaces of deep scarlet in marking out the colours for Fig. 1. Where scarlet does appear it is produced by alternate layers of red and rose, until the desired depth is reached. The other full strength or flat colours are laid on in the same way as described above, and will offer no difficulty. Peacock blue is mixed with blue and a little yellow, purple is obtained by mixing about 10 parts of rose with 1 part of blue. I may here mention that blue is remarkably powerful, and whenever you have occasion to mix it with any other colour, you should add it little by little, or you may have to waste too much of the weaker colour in trying to counterbalance the excess of blue. Having filled in all the flat colours, we proceed to wash in the tints in the parts A, B, C, D, and also the groundwork in the centre, unless you prefer to let the flower appear on a blank ground. For producing the light shades, reduce the strength of the corresponding colours by adding more medium. For laying on these rather liquid shades a camel-hair mop is preferable. Apply as evenly and thinly as you can, and allow to dry a little, but not completely; then with the tip of your finger go over the painted surface, which should feel just a little sticky (tacky), dabbing it gently all over until every unevenness has disappeared. I need not say that this operation must be confined to one colour at the time, and that the tip of the finger must be well wiped before a fresh tint is begun.

The ground of the oblong spaces between the yellow and brown border is left blank, the thread line pattern being painted in dark brown with a fine fitch hair brush. Dark brown should be mixed with rather more medium than the other colours. At this stage the work should be left alone until it is absolutely dry. This will probably be the case in twenty-four hours, but under certain circumstances it may take two or three days. When quite dry, paint in all the lines or bars imitating leading with black, using an ox-hair rigger, but laying the colour on thick and solid, so as to be perfectly opaque when held up against the light. Special attention should be paid to this point, for it will be readily understood that leading partially transparent would be a poor imitation of the real article. The black lines may be broad and bold, and so far from disturbing the design they will add to the effect. This will soon be apparent if one half of a pane is quite finished off and compared with the other half without leading. The joints of lines should be painted without sharp angles, as shown in Fig. 3.

I may here mention that, in cases where one design is spread over a window with several panes, sash bars may be completely ignored. They will not to any extent interfere with the general effect. When the leading is absolutely dry and hard, give the whole a thin coating of silicine gloss, using a flat camel-hair brush or a large mop. The painting is now finished, and when dry is ready for glazing. The Indian ink lines can now be washed off, and the panes fixed into the sash by means of narrow beading. The painted side is of course to face the glass already in the window, so that the painting itself is really between two sheets of glass, but the latter should not touch. To prevent this, a few narrow strips of cardboard should be glued between the edges.

Fig. 2 is a design for an over-light, that could be adapted to almost any front door, giving either the number or the name of the house. In this case the outline of the figure or letters could be painted with flake white, or first with silicine black, and gold bronze enamel over it, so as to be visible also by daylight.

I shall be glad if many will be induced to try their hands at Silicine Glass Painting, and have no doubt that after having mastered the little difficulties that may present themselves at first, all will be pleased with the result of their labour and patience, and feel encouraged to attempt work of a more elaborate character. I shall be happy to answer any inquiries about Silicine Glass Painting in "Shop."

ON CAUSES OF FAILURE IN AMATEURS' AND APPRENTICES' WORK.

BY B. A. BAXTER.

In these days, when amateurs flourish and apprentices diminish in numbers, work good, bad, and indifferent is done in large quantity, and I feel sure, from a wide and long experience, that, in many things, the amateur has the advantage.

Such periodicals as this, and others, especially cater for him; so much so, that the professional worker is often able to obtain hints, helps, and often real instruction from such papers, while there are few exclusively professional papers or books that help the young apprentice who is desirous of obtaining a mastery over his work.

Beginners often—in fact, always—add to their own difficulties by indifferent performance of the previous operations.

This is an argument for carefulness in every department of work, for materials badly cut out are sure to be more trouble to make up, while the worker gains no extra result from his increased labour, and shaping the badly cut stuff may result in reducing it below the required dimensions. It would be well, therefore, if, taking one tool first, the apprentice gained a fair mastery over it before trying to succeed with another. The plane is, perhaps, the best tool for a commencement. Articles on its use have appeared in WORK, and a staff of enthusiastic helpers are always ready to give instructive replies to any definite queries.

In advising the use of the plane as the first tool to be mastered by a beginner, we are not ignoring the fact that the work must be sawn out before it can be planed, but merely suggest the advisability of getting some freedom in the use of one tool rather than endeavouring to master several tools at quite the onset. If, however, the use of the saw is first practised—as, indeed, it often is—let our young friend accept the decision of those who instruct him, and try as quickly as possible to become a good sawyer. He will be appreciated in any shop and by every workman, for a lad who saws well is all too rare.

If my young friends whom I am now addressing will try a simple experiment, they will be able to take a position which will enable them to saw truly, and, as the ability grows, they will be able to saw truly in any position and in any attitude. Let a plumb line be hung before the lamp, and the marked timber be so placed that the shadow of the plumb line coincides with the mark on the wood to be sawn. Now, if the saw is used in such a position that its shadow is a thin line falling along the mark on the timber, all is well, and the wood will be cut correctly. This method has the advantage of constantly giving an indication of the sawyer's accuracy or want of it, but it has the serious disadvantage of requiring artificial light, and supposes one light is in use. For those who work by daylight, the good old plan of trying with a square from time to time must be adopted, the only drawback being that its *sufficient* use is so tedious that it is very difficult to persuade beginners of its necessity.

A few trials made with its very frequent use, coupled with careful observation of the position of the elbow, will soon help the sawyer over the difficulty. He will find the elbow requires to be neither too close to the side of his body nor extended too far away, but must move in a path over the line marked on his timber. I have said nothing about saws and their characteristics, as "J. H." has recently given a full and correct description of these indispensable tools.

If the learner has to mark out as well as saw the wood, another source of difficulty is presented. A beginner never seems able to divide a board into a given number of equal parts. Even if he can saw on his line, he finds, after they are sawn, variations of width so considerable as to demand much reduction by planing before the pieces are reduced to uniformity of dimensions.

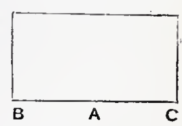
It stands to reason that, if lines, equidistant from the edges and from each other, are drawn on a board, and if the saw divides truly to the lines, that the outer strips will be a trifle wider than any of the inner ones, though the fact is often forgotten or not known. If the saw itself makes a "kerf" $\frac{1}{8}$ in. wide, the outer strips will be $\frac{1}{16}$ in. wider than the inner ones, supposing the marking and sawing both to have been done as accurately as possible. The reason is obvious on consideration. The board, being equally divided by lines, each strip may be expected to lose the thickness of the saw "kerf," except the outer strips, which only lose half that amount.

An easy way to divide a board into several pieces without calculation may not be known to the younger readers of WORK. Take your rule and decide on how many divisions you wish to make. Say the board is over 10 in. wide, and you wish to divide it into seven parts, lay the rule across at such an angle that 14 in. of the rule extend obliquely across the board, then prick off every 2 in., and you have the required division.

Never saw a little way and leave off to begin again at the other end, hoping to do better, for if you went astray before, cutting from the other end will not mend matters, whether the fault is in the workman, the material, or the saw. Even a trifling error in angle becomes a serious one when an opposite error is introduced at the other end of the same cut. The knowledge that an error in sawing is apt to increase, and that the saw-cut, though not the error, is to continue to the end, will help the beginner to endeavour to return to the line as soon as he perceives he has left it.

Some saws have a tendency to go wrong—a sort of obliquity of evil tendency; such saws are either "in-winding" through having been strained, or are badly sharpened or unevenly set. Frequently, however, amateurs cut against a nail which only touches one side of the saw, and takes therefore the set away from that side of the teeth. Have the saw sharpened as soon as possible; let not the amateur believe that saw is trustworthy after such treatment.

Passing over the planing of which we have treated, one other pitfall of beginners' handicraft is the want of system. We have often seen a beginner plane the edges of a piece of wood, having a square to guide him, and get first one angle right and then another which alters the first, or the opposite angle correct, although the sides are not parallel. Now, a beginner will never square a piece of wood in this way, but, by means of a system, he will soon be able to do it well. Let him do it in the following way, whether it is a long piece of square timber or a drawer front, or end of a packing case:



Plane edge A as correctly as possible, and mark the angles B and C square: then, if necessary, gauge the remaining side parallel to the first, but by no means alter A after you have squared either angle.

The beginner ought to remember that, as the angles of a four-sided figure added together amount to four right angles, deficiency in one angle causes redundancy in some other, and that want of parallelism in opposite sides causes variation of angle. Another golden rule is the principle of triangles. Remember that if the sides of a triangle remain unchangeable, the angles are also unchangeable. This, though so easily said, is of the greatest practical importance, and, when the learner is reminded that every four-sided figure may be regarded as two triangles, the importance of the foregoing will be seen to be much increased.

The workman who has any special line always tries to contrive some special tool or appliance that will help him. If the amateur or the beginner tries to do the same, the endeavour will be of the utmost benefit to him, and the result will be seen in increase of resource, in greater speed and facility of execution, and improvement in the quality of his work.

SMITHS' WORK.

BY J. H.

EARLY HINGES ON CHURCH DOORS—IRON GATES OF MEDIÆVAL AND MODERN TIMES.

THE study of the early hinges of our church doors is a deeply interesting one. They are a poem in iron, coming to us from times when every man did that which was right in his own eyes; times of lawless violence, times of fusion of Saxon and Norman, ages of warrior prelates, and periods of gradual settlement of races, and of growth of the arts of peace. Designed primarily to afford the greatest possible security and strength to the church doors against heathen invaders, they gradually developed, with the advent of more peaceful times, an overflowing wealth of floriated ornament. Originally rough, the work of the hammer and of the punch only, they acquired more and more finish as the file and the drill were brought into requisition.

There are no examples of Early English hinges so barbarously simple as our plain strap hinges formed of a single bar of iron clamping the door. The simplest type is that of a central strap flanked by a semicircle on each side—a crescentic form—and one which flourished during two or three centuries. There was good reason for the adoption of such a form. The church was the common sanctuary in turbulent Saxon and early Norman times; and since its doors were liable to be beaten in by insurgent hordes, the great hinges, stretching right across and covering almost the whole of the faces, sustained and strengthened the wood. Utility at the first, then, was the prime condition studied by the smith, and ornamentation was almost disregarded. The early hinges are therefore massive and rough—some of them very rough—the curves ungraceful, and the hammer marks everywhere apparent. But even then some rude scroll work or foliage was commonly formed at the termination of the straps. And this afterwards became developed into the highly ornate forms seen in the classic

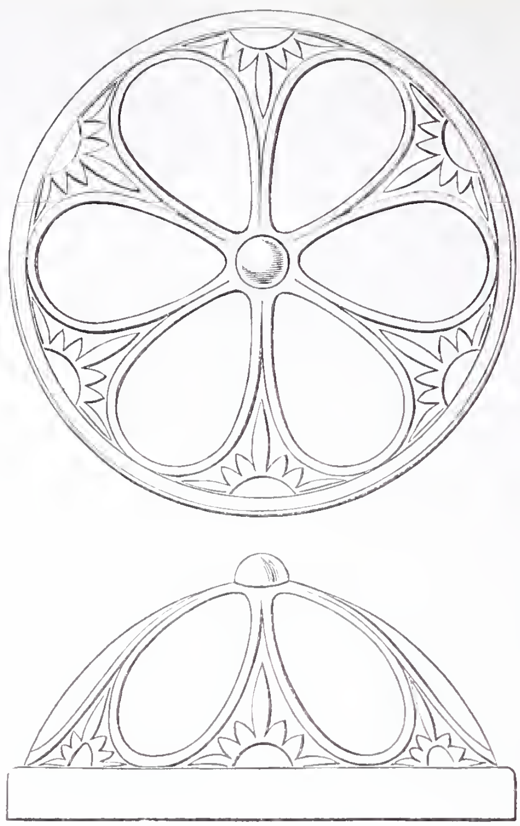


Fig. 4.—Boss on Nail Head.

English styles of the twelfth and later centuries.

It is believed that the elaborate wealth of scroll ornamentation of the classic style is a survival and evolution from an early period when the insides of the church doors were strengthened with a kind of armour plate, formed by the interlacing of bars, in the forms of scrolls and lozenge patterns. When the need for defence passed away, this wealth of ornament was transferred to the outside of the doors, often filling up and covering the whole of the space available between the hinges. An example of this elaborate ornament occurs in the cloister doors of Durham Cathedral.

The ancient hinges were, therefore, not only beautiful but strong. Covering, as they did, the whole breadth of the door, they clamped its boards together so that there was neither any possibility of splitting the doors nor of wrenching them off their hinges.

There are three principal styles of these ancient hinges: one in which the main straps which clamp the door together are flanked by curved straps of semicircular form; another in which the flanking straps are in the form of flowing curves; and a third in which they are foliated. Examples of the first kind occur on the hall doorway of Merton College, Oxford, shown in Fig. 8; of the second on the Church of All Saints, Leighton Buzzard; and of the third at Liège. Birds, dragons, and animals appear on many of the hinges. Those of Dartmouth church are remarkable—two huge animals, lions or panthers, covering the whole breadth of the door. The idea of the artist is evidently to represent them as among the branches and foliage of a tree, and, though stiff and conventional, the effect is very striking.

The English classic type of hinge consists essentially of a central stem or strap with branching scrolls, with or without intermingled foliage. Sometimes the scrolls are suppressed, and floriated ornament predominates. The vine is the plant which in conventional forms appears chiefly. It occurs in the horse-shoe and scroll forms, was common in England and France, and excellent examples occur at Leighton Buzzard, Eton, Bray, Uffington, St. Mary's, Norwich, St. George's Chapel, Windsor, Chester Cathedral, and the Chapter House, York. By the eighteenth century the lily, the thistle, and the passion flower had nearly superseded the vine in hinge work.

From the fact that there is great similarity between the hinges of the English and of the French churches, Mr. Starkie Gardner argues that the French works were made in England and exported. It

is singular that no tradition exists of the origin of the vast hinges of Notre Dame in Paris, except that which ascribes them to the devil. If made in England, national pride might well cover their origin with oblivion.

Wyatt, however, says that the doors of Notre Dame were executed at the beginning of the thirteenth century. They are the largest in the world. In connection with these doors, Sauval, in his *Antiquités de Paris*, gives an account of Biscornette, a smith of the sixteenth century, who appears to have done some repairs to the doors of Notre Dame. He is said to have entered into a compact with the Evil One to obtain his assistance in the working of the hinges, but that when it was requisite to execute the centre door the diabolical help failed him, because through it the sacrament was wont to pass. This illustrates the wonder in which his productions were held by his contemporaries. The secret of his methods died with him, for nobody ever saw him work. Hinges similar to those of Notre Dame occur at Beauvais, Chartres, Nantes, Chalons-sur-Marne, and other towns.

It is often hard to say whether parts are drawn down out of the solid or welded. Both methods were in use, and different men would probably pursue different methods. Then there was a good deal of surface grooving, evidently done with a chisel, probably when the iron was cold or nearly so. The punch also must have been extensively used to produce the little depressions and tiny circular bosses which abound on the floriated ornament.

Examples of hinges occur all over England as well as on the Continent; few localities are without these relics of the past, and an hour may be profitably spent in a study of their details.

Fig. 8.

Fig. 9.

Fig. 8.—Upper Hinge on Door of Merton College, Oxford. The Lower Hinge being similar to the Upper Hinge, reduplication is unnecessary. Fig. 9.—Enlarged Sketch of one of the Bosses on Door.

More wonderful than the great hinges are the iron gates of mediæval and modern make. These are very abundant both in our own country and on the Continent. It is almost impossible to reproduce their lovely tracery except by photography. They must properly be seen and studied, for all description fails. The finest example in this country are the gates of the tomb of Edward IV. at Windsor, now inside St. George's Chapel, just beneath the Queen's pew, and within the altar rails. Formerly they stood without in the cloisters on the other side of the wall, and the sockets in the tombstone in the cloisters in which the gates were formerly stood are still visible, though now filled up. The work in these gates is of so elaborate and delicate a character that I am sorry not to be able to reproduce them entire as they stand.

Tenons and pins are the principal methods by which the several portions of these gates are held together. The main framework is very strong, and it is probably because of the massive character of the principal bars that cast iron has been thought to have entered into their construction. The vertical ribs are tenoned into the top rail or parapet.

Upon this strong framework the compartments and canopies with their delicate traceries are attached. These canopies are crowded with the finest and most beautiful tracery, and I cannot conceive how they were formed except by stamping or by casting. It is of course impossible to say by mere inspection of the surfaces whether these are cast or wrought. They may be either; they are very smooth, but they must have been either cast, or stamped in dies, because it would be impossible to forge them by any mere sleight of hand. Immediately behind each of these bays there is a sheet of iron of about $\frac{1}{16}$th in. thickness, and to these sheets horizontal plates are attached, and these become the backing or supports for the delicate columns and tracery. Oblong holes are punched through the sheets, and tenons from the plates pass through and are pinned upon the back side. Tenons stand out from the brackets of the pillars, and passing through the plates are secured with pins above. These details are not apparent at a casual examination from the front, but have to be searched for.

Although some gates have a much plainer appearance than others, it does not follow that the more ornate specimens necessarily demanded greater skill than the simpler ones. Even the most involved work, when we come to analyse it, becomes resolved, if we may use the term, into very simple elements. The groundwork once built up, the rest is a matter of detail; tedious it may be, but nevertheless a question of time mainly. Matters of detail are repetitive; bars, scrolls, foliage are bent, swaged, riveted, welded, and where panels are multiplied the general uniformity proves the use of templets or dies. But the smiths loved their work, and so was its tedium beguiled.

Fig. 4 represents a frequent method of ornamentation adopted. It is a boss, or nail head, from a door in the City of Toledo, and is fifteenth or sixteenth century date. It is about 4 in. in diameter. Specimens of such *repoussé* work in iron must have been very difficult to make, although it is possible that if several were made at one time, a pair of dies may have been laboriously manufactured.

A method of crossing tracery which I have observed in several instances in bars of round section is by perforation (Fig. 5). A hole is punched through one bar, into which the crossing bar is threaded. The act of punching would spread the metal, without removing any, but in some cases it would appear as though the punched bar had been slightly upset before punching to keep the cross sections on each side of the hole about equal to that of the original bar.

The crossing of bars whose edges are in the same plane is often effected by means of half lap joints. Notches are cut out of the bars, each notch to one half the width, and of the same breadth as the thickness of the bar, and these fitting into one another give the appearance as of scrolls growing out of one another (see Fig. 6, B), which is a portion of an Italian gate of the sixteenth century. Bars of circular as well as of flat section are treated in this manner, and the joints are so close that they are only discoverable by close scrutiny. In the figure, A is one of the belts so common in work of this kind.

The method of attachment of the fleur-de-lis panelling to the cross bars in Fig. 7, which is that of an Italian gate sixteenth century, is shown by the section at the top left hand corner; portions of bar are bent to pass through mortises in the bar A, and embrace that portion of the scroll work B in contact therewith.

Fig. 8 is the upper portion of the very fine hinges on the doorway of the hall of Merton College. The lower portion being nearly a duplicate of the upper part, it is omitted in the drawing.

Fig. 9 is an enlarged view of one of the floral bosses of the hinges (Fig. 8), and well illustrates the style of the work.

There are two beautiful specimens of recent smiths' work in the South Kensington Museum. They are of Prussian make, and were shown at the Paris Exhibition of 1878. They are truly magnificent specimens of workmanship. Their finish is perfect. But they are not a whit better in this respect than the gates of the tomb of Edward IV. This is saying a very great deal indeed; for we must bear in mind the vast difference in the appliances for work available at the present day in comparison with those of five or six centuries since. Moreover, the work in the gates at Windsor is very much more delicate than that in these Prussian gates. These are however beautiful specimens of which every workman or firm should well be proud. It is extremely difficult to detect the joints. The heavier parts appear to have been tenoned, and the scroll work is bound with loops or with rivets.

Park gates and railings were executed in wrought iron before the use of cast iron became common. Specimens of large and comparatively recent gates occur at the Clarendon Printing Office, Oxford, and at Hampton Court, and at several localities about London. But with these we are scarcely concerned at present.

INDIARUBBER STAMP MAKING.

BY "QUI VIVE."

Mode of Working.

Assuming that we are about to make a straight line stamp, we proceed to set up the requisite type in the composing stick. We first take a piece of thin brass rule and form it into a "setting rule" (Fig. 14, p. 593). It is best to have a set of these of the respective lengths of 2, $2\frac{1}{2}$, 3, $3\frac{1}{2}$, and 4 in. from a to b in the figure, the corner c being left projecting so that the rule may be readily removed from time to time, as required. Grasping the composing stick in the left hand, the back of the hand being away from the body, we select a setting rule from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. longer on its shorter edge than the length of our intended stamp, measured in the direction of the lines, and drop it by its shorter edge into the "stick," the slide b of which is to be adjusted to the length of the rule by means of the thumb-screw, a. Holding the "stick" with the corner marked c somewhat elevated, we take the type answering to the first letter of the stamp we are about to make and insert it, face upward and with the nick or nicks which will be found on one side of the type towards the open side of the "stick," in the corner of the "stick" marked d. The type so placed is retained in its place by the thumb of the left hand while the type next required is selected and placed in position, and so on until the first word is completed, when a "space" of medium thickness is placed in the stick to separate the first word from the second, which is set up or "composed" in the same way. When all the words forming the first line have been set up we "justify" the line by inserting "quads" or "spaces" as may be required at each end of the line so that both ends of the line of type may be equi-distant from the sides of the composing stick. We now insert a "lead" of suitable length, and then removing the setting rule from its original position we place it upon the "lead" just placed, and proceed with the setting up of the next line, and so on until the entire stamp or series of stamps has been set up. If any adjustment of the spaces between the lines should be considered necessary, this may now be done by inserting additional leads or pieces of "reglet" where required. Great care must be taken to set the type upright on their "feet," as the end opposite to the face is called.

The type has now to be transferred to the "chase," which is prepared to receive it as follows. The chase is placed on an inclined plane, such as a desk lid, with the corner a (Fig. 2, p. 593) uppermost, that is, in the position occupied in the figure by the corner b. A 6-in. length of the narrow "furniture" is then laid against the left-hand side of the chase—inside, of course—followed by a similar length of "wood rule." Pieces of "furniture," "wood rule," and pica "reglet" of the same length as the setting rule we have been using are next laid in order against the bottom side of the chase. The setting rule is now placed in its first position in the composing stick and a lead placed against the line of type last set. The type, etc., are now firmly grasped between the fore-fingers and thumbs of both hands and carefully slid out of the composing stick, the remaining fingers being used to prevent the type from falling sideways out of their proper place. Still grasping the type firmly they are steadily lowered into their position in the lower corner of the chase. We next apply lengths of reglet, wood rule, and furniture similar to those already used to the unprotected sides of the type, and then proceed to fill up the vacant portion of the chase to within 1 in. or $1\frac{1}{4}$ in. of the upper side and end, taking care to so arrange matters that the type shall be as nearly as possible central in the chase. Finally, we place "side sticks," broad ends towards the lower sides and taper edges outward, against what we already have in the chase, and with a couple of suitable "quoins" to each side stick wedge the whole together slightly with the fingers. Our work must now be carefully examined to discover and rectify any mistakes which may have been hitherto overlooked, after which the "forme" of type is "planed" by placing thereon a perfectly level piece of some hard wood, such as beech, and while moving it about on the face of the type, gently striking it with a wooden mallet. Any leads or spaces which may have risen during the planing operation are now to be carefully pushed down and the "forme" firmly "locked up" by driving the quoins with the mallet, a spare side stick being used in the absence of a proper "shooting stick" for the mallet to strike upon. A little petroleum is now lightly brushed over and into the interstices of the type, and we are ready for the next operation.

We have now to prepare the mould. For this purpose we shall require a supply of the finest plaster of Paris, and of the "moulding composition" sold for the purpose by all the wholesale stamp-making firms, also a thin solution of dextrine in water. We must also provide ourselves with a "palette knife" (Fig. 11, p. 593), a jam pot or some similar article, and a flat piece of slate, with a piece of fine cambric or muslin, a little smaller than the inside of the chase in which our type has been secured. Having all our materials by us, we take a small lump of the moulding composition and knead it well on the piece of slate. This done, we take about as much plaster as we have of compo, and mix it in the jam pot with sufficient dextrine solution to form a thick cream, which must be immediately well mixed with the kneaded compo by means of the palette knife. This mixture should be moderately stiff, but not so hard as to crumble, and should be capable of being spread on the *under* surface of the moulding plate with the palette knife. This we now proceed to do, the moulding plate being turned "wrong side up" for the purpose. The layer of composition should be laid fairly level, and about $\frac{1}{8}$ in. in thickness. A little petroleum should now be applied to the bevelled faces of the moulding gauge, which should then be placed on the moulding plate and slid backward and forward over the composition until the layer of compo is rendered perfectly level and free from cracks or holes. The piece of cambric or muslin must now be laid on the face of the type, and the moulding plate with the composition on its under surface placed in position on the chase. Both chase and moulding plate are then placed in the press, and the platen lowered until a light impression, showing the general outline of the stamp, is produced. The cambric will, of course, prevent anything like a *clear* impression; but this must now be removed, the type once more oiled, and an impression taken with the naked type. This should be repeated several times, each impression being made slightly deeper than the preceding one. The entire operation should be so timed that the final impression is taken when the compo is beginning to set, but the actual time required can only be learned by experience, as it varies with the condition and mode of preparation of the materials, the temperature and dryness, or humidity of the air. Assuming our operations to have been successful, we shall now be in possession of a mould which is the exact counterpart of the type from which it was taken. This mould should now be carefully examined for errors, for although a careful examination of the forme was made before we began our moulding operations, such an error as the reversal of a type may have escaped our notice through the forme being itself reversed. Now, however, the mould shows everything right way up, and so enables us more readily to detect errors which may have escaped previous notice. Should an error be discovered another mould must be made. The mould is not yet fit for use, but must be most thoroughly dried, as any moisture remaining in it would most probably lead to its destruction during the vulcanising process. The drying must be done very gradually to prevent the splitting of the mould by the too rapid generation of steam. It is effected by placing the plate bearing the mould face upward on the brackets attached to the press, and placing a suitable gas-burner underneath; one of Fletcher's numerous patterns will be found to answer the purpose admirably. Another burner may with advantage be used to heat the press simultaneously with the drying of the mould. In order to protect the mould from dust during the drying process, it is advisable to cover it with a bent piece of sheet iron or tin. When perfectly dry—which may be tested by laying any cold polished surface in momentary contact with the mould, and observing whether or not there is any appearance of steam on it upon its removal—the irregularities of the surface, if any, are rubbed down with a file or a piece of sand paper wrapped round a flat piece of wood or cork as used by cabinet makers in smoothing their work. All dust produced in this levelling process must be carefully brushed and blown away. This done, the mould is lightly but thoroughly brushed over with a little French chalk, all traces of dust being carefully removed as before.

Our mould is now ready for the rubber. This is prepared in sheets about $\frac{1}{8}$ in. in thickness, and may be procured from the same sources as the moulding composition. Take a piece of the prepared rubber, somewhat larger than the required die, and brush it carefully on both sides with French chalk. Take also a piece of smooth tin plate about $6\frac{1}{2}$ in. by $4\frac{1}{2}$ in., and well rub it also with French chalk. The heat of the apparatus should now be looked to. The press, the platen of which should have been firmly screwed down, should be heated to about 290° F., and the moulding plate should be so hot that drops of water allowed to fall on it from the finger tips roll off without spreading or leaving any trace, but should not be hot enough to blacken a shred of the rubber compo laid thereon. Both press and moulding plate being properly heated, the platen of the press should be raised about an inch. The prepared piece of rubber is then to be laid on the mould and the smooth piece of tin plate on the rubber. Now slide the whole into the press, and as soon as the temperature, as shown by the thermometer, has fallen to 285° F., screw the platen down into gentle contact with the tin plate, and gradually increase the pressure as the rubber is felt to yield. When well pressed down leave the press untouched for from twelve to fifteen minutes, unless the temperature shows a tendency to rise, in which case extinguish the gas-burner, and complete the operation without the gas being further used. The rubber should now be removed from the mould, and will probably be found of a dark drab or slate colour, solid, and extremely elastic, showing that the operation has been successful. If, however, the rubber remains light-coloured and soft, readily retaining the impression of the finger-nail, the temperature has been too low; if black or hard, the temperature has been too high; if spongy, the pressure has been insufficient. In either case the vulcanising process must be repeated with a fresh piece of rubber, and such modifications of the process as are indicated by our previous experiment. The finished die may be washed, if necessary, with water and a moderately stiff nail-brush. It is now ready for mounting, which may be effected by the aid of a solution of shellac, such as that used for fastening down linoleum, a small addition of methylated spirit being made if the solution should be found too thick. The mounts may be procured at any of the wholesale stamp shops.

My task is now complete, and I conclude with the hope that all who attempt the manufacture of indiarubber stamps from the foregoing instructions will be as successful as I have been; they are certain to find it a fascinating occupation.

LATHES FOR EVERYBODY.

BY SELF-HELPER.

A Good Wooden Lathe for Carpenters—The Fixed Headstock, Poppet, and Hand-rest.

I will take for the subject of this second paper on lathes one which I designed, and partly constructed, for a clever carpenter of my acquaintance. He wished to have something more beautiful-looking and better finished than the somewhat crude machine I described in the first paper of this series, and I was willing to comply with his wishes. For the woodwork I recommend good seasoned mahogany, thoroughly baked, so that there will be little chance of its shrinking and warping when the machine is finished. Every part should be most carefully made, and worked at with plane, file, and sandpaper until it is as smooth and true as the finest piece of cabinet work. It should then be French-polished, which will serve the double purpose of giving it a nice finish and stopping the pores of the wood to prevent them from absorbing moisture, and thus swelling and throwing things out of truth. If mahogany is judged to be too expensive for the entire lathe, the headstocks, or at least the running headstock, might be made of it, and the rest of some less expensive wood—beech, say, or any other hard wood not prone to warp.

My friend used beech largely, and the machine is giving every satisfaction after more than two years' work.

The important thing is to have the wood quite dry, so that it will not warp, and, when finished, to French polish, or varnish, so as to stop the pores.

I will not enter here upon the various advantages and disadvantages of wood and iron as materials for lathes. It will be very evident to any one who considers the matter carefully that many people would be debarred entirely from the possession of a lathe if it had to be made of cast iron, while others of an engineering turn would find it equally difficult to make a good job of wood.

The entire efficacy of a wood-turner's lathe depends upon the truth of a few parts, and, if these are right, it matters little as to what the rest is made of.

I will be somewhat more particular in describing this lathe than I was in the first paper, both because it is a more worthy subject, and also one or two correspondents complained that, in my last, I did not enter enough into details. I will, therefore, describe in order the construction of the (1) fixed headstock, (2) the poppet, (3) the hand-rest, (4) and the stand, including fly wheel, treadle, etc. I follow this order because the first mentioned is the most difficult; and, therefore, if a man succeeds with it, he will find the rest of the work comparatively easy; while, if he finds it beyond his power, he can pitch it into the fire and get rid of the whole thing without having the mortification of breaking up the stand also. If he began with the stand, he would probably succeed in making it, and perhaps not find, until too late, that the headstock was beyond his power.

If any of my readers, however, are fairly handy with tools and persevering, there is no fear of their failing. I may say that the height of centres is 5 in. and the bed is 5 ft. long. Figs. 1 and 2 are side and end views respectively of the headstock. It consists of four pieces of wood, all truly planed to 2 in. thick. Two of the pieces are like Fig. 2; of the other two, one is 12 in. long and 5 in. wide, and one is 12 in. long and 4 in. wide. The figures show how these pieces are mortised together. The wide piece has two tenons passing into each end, and the narrow piece at right angles to that has two others, so that there are four mortises at each end, each mortise being about $\frac{3}{4}$ in. by $1\frac{3}{8}$ in. This work cannot be too carefully done, as on it depends the whole perfection of the lathe when completed.

The two long pieces which are at right

angles and form the base of the headstock should fit closely together, and be glued, and, as an additional security, I passed a couple of $\frac{1}{4}$ in. bolts from the top down, as shown in Fig. 1. I may mention, in passing, that I used engineers' bolts with hexagon heads, which were turned and burnished.

When my carpenter friend brought this job to me (for I got him to do the woodwork at home, I acting as architect and engineer), it did not please me at all.

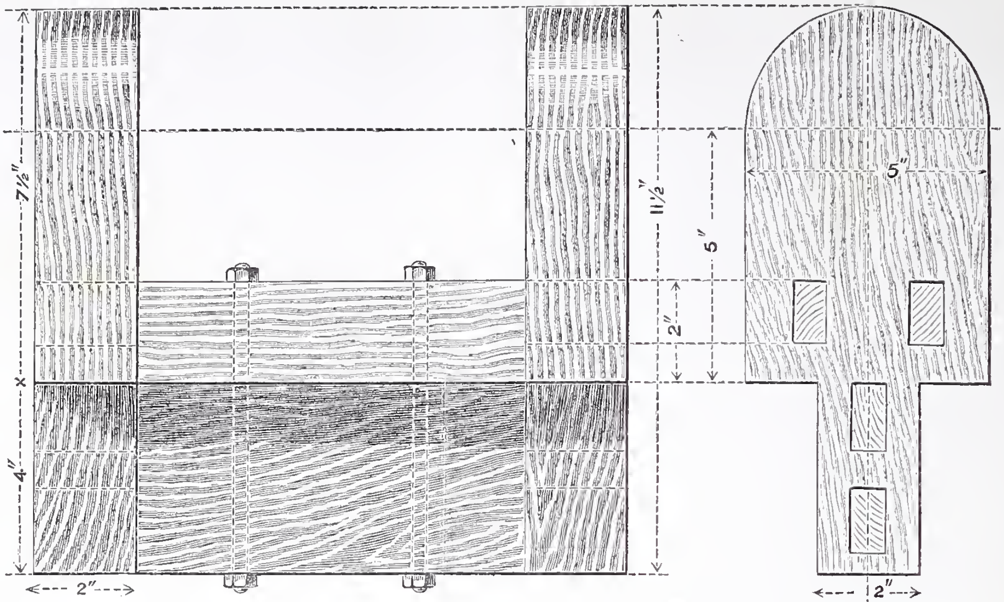

Fig. 1.—Fixed Headstock: Side View. Fig. 2.—Ditto: End View (two like this). Scale, 3 in. to 1 foot.

The tenons did not fit perfectly, as they should do, and the shoulders were in some places so far from their bedding that I could put the corner of a sheet of paper between; the whole, in fact, was not as one piece.

I accordingly, after growling a bit, sent him to the forge to get two pieces of iron made like Fig. 3. I then set him at them with a file until they were quite flat and smooth, and with the edges nicely bevelled at one side of each, so that they could be placed one at each side of the headstock. They were secured by six $\frac{3}{8}$ in. engineers' bolts. I may mention here that when the headstock was finished all but the polishing, I took the iron plates off and japanned them while the woodwork was being polished. This japanning I executed by covering the irons thickly with black japan and putting them in the kitchen stove until they were quite hard, black, and shiny. They were very satisfactory.

The holes for the bolts I drilled in the lathe, half from each side of the headstock, as it requires some care to have the plates exactly in the correct positions. Some would prefer to sink these into the wood, but I let them stand out. They are made of iron $1\frac{1}{2}$ in. by $\frac{3}{8}$ in. If the mortising of the parts of the headstock be properly done, these iron strengthening plates would be unnecessary. I mention them here lest any one should make a mess of his work and be tempted to give it up. The mortising will be of secondary importance if the plates are used.

The next part which I shall describe was most distinctly my own work. It is shown in Fig. 4, and consists of the mandrel, collar, tail screw, and its two screwed plates.

The mandrel (M) was turned from a solid piece of Bessemer steel $8\frac{3}{4}$ in. long. The dimensions are as follows:—

Nose, $\frac{3}{4}$ in. long, $\frac{3}{4}$ in. diameter, screwed Whitworth; front cone, $1\frac{3}{4}$ in. long, tapering from 1 in. to $1\frac{1}{4}$ in.; next cone $\frac{1}{2}$ in. long, tapering from $1\frac{1}{4}$ in. to $1\frac{1}{2}$ in.; body, 6 in. long, $\frac{7}{8}$ in. diameter.

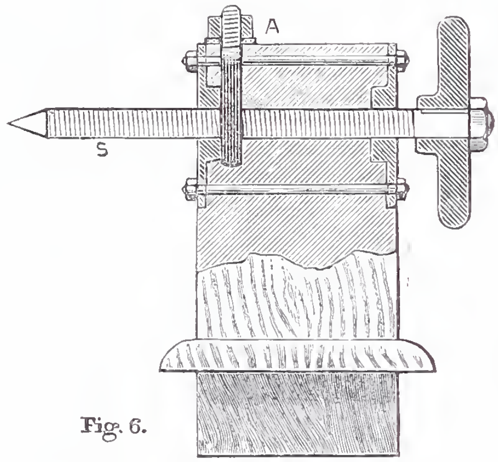
The tail screw is cast steel, 6 in. long and $\frac{3}{4}$ in. diameter.

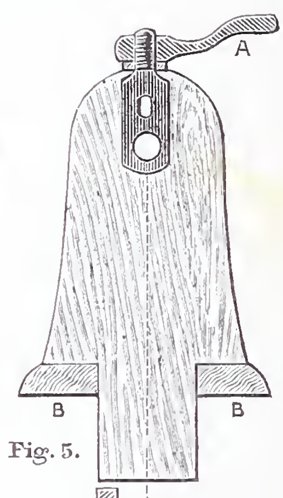
The collar (C) is made of gun-metal; the hole is coned to fit mandrel perfectly, and turned to $1\frac{3}{4}$ in. in the front parallel part, while the flange is 4 in. in circumference and $\frac{3}{8}$ in. thick.

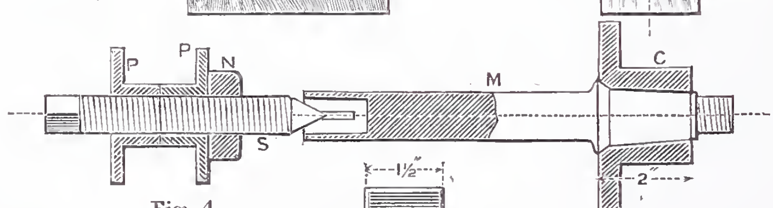
The two plates for the tail pin are also gun-metal, the flanges being 3 in. diameter by $\frac{1}{4}$ in. thick, and the body $1\frac{1}{8}$ in. bored out for $\frac{3}{4}$ in. screw. All the flanges are round, so that they could be turned in the lathe. They were also nicely finished with beer and a burnisher.

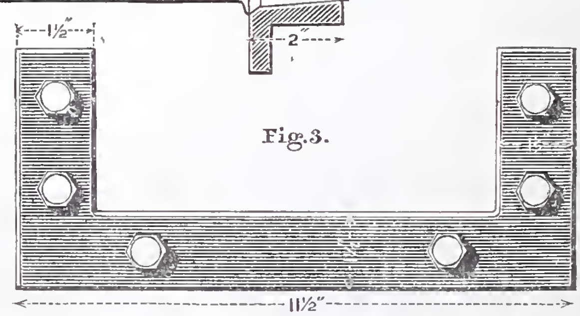
The mandrel has a piece of cast steel let into the tail end, which is hardened, and thus wears much longer than the soft Bessemer steel would. Note the small hole in the centre so that the point of the screw (S) would not wear away.

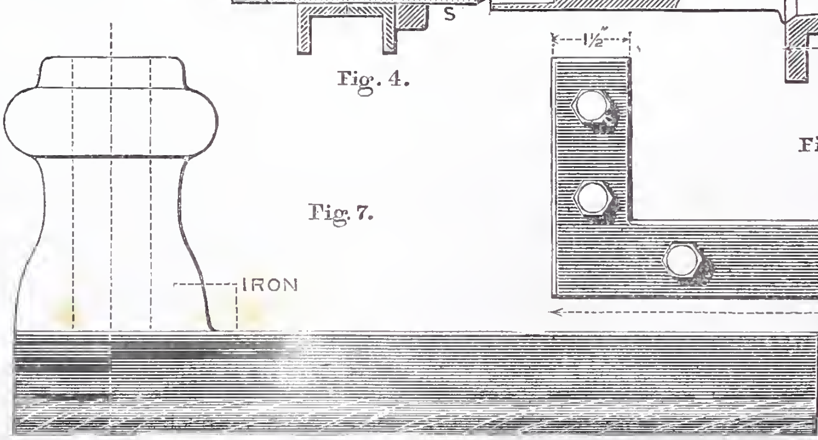
To make the mandrel, cut off a piece of steel or iron the required length, viz., $8\frac{3}{4}$ in.; then centre it truly at both ends, bore a $\frac{3}{8}$ in. hole 1 in. deep, and plug it with a piece of the best cast steel, turned, and with the centre upon which it was turned outwards. Then enlarge the











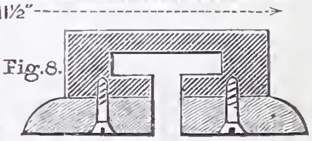


Fig. 3.—Iron Stay for each side of Headstock, $\frac{3}{8}$ in. thick. Fig. 4.—Mandrel, etc.—M, Mandrel; C, Collar; S, Tail Screw; P P, Plates; N, Lock Nut. Fig. 5.—Poppet: End View—A, Locking Handle: B B, Slip. Fig. 6.—Ditto: Front View—S, Screw. Fig. 7.—Hand-rest. Fig. 8.—Section of Hand-rest. Figs. 3, 4, 5, 6, scale, 3 in. to 1 ft. Figs. 7, 8, half full size.

ole in the cast steel until it is about in. outside and tapering to an angle of 5°. The little hole in the centre should previously have been bored about $\frac{1}{8}$ in. liameter and $\frac{3}{4}$ in. deep. The best way to aper the hole is with a rosebit made to the orrect angle and running truly in the lathe.

Next harden the centre by heating the nd of the bar to a bright cherry red and lunging into water. All that remains to lo now is to turn the mandrel to the required dimensions given above.

The casting for the collar (C) is chucked n a wooden chuck, bored out inside to fit he mandrel, and then the outside is turned while it is running on its mandrel. If there s a tendency to loosen, as there probably will be, a nut and washer could be put on he nose during most of the turning, and it will effectually prevent the collar becoming oose.

The tail screw is turned from 6 in. of in. square steel; $\frac{3}{4}$ in. is left square at one end, and the other end is tapered to 55°. The screw ought to be cut in a screwing athe.

The plates are of gun-metal, and are turned like the collar on their own screw, or they might be run on the nose of the mandrel and turned there, the screw being the same. I may mention that four of these plates will be required, two for the poppet and two for this part.

The collar is let in flush with the wood of the headstock, so that its two inches of length will bring the front end flush also with the front of the headstock.

I may mention here that the mandrel projects nearly $\frac{1}{8}$ in. beyond the collar before the shoulder is reached. This is shown plainly in Fig. 4, but it is not quite so plain that the mandrel is sunk in at the back what it projects at the front.

The pulley was made of a piece of ebony, the largest of the four speeds being 5 in. and the smallest 2 in. It was covered at each side with a plate of gun-metal 2 in. diameter, and nicely turned and polished; the speeds were each $\frac{1}{2}$ in. wide, and would take $\frac{3}{8}$ in. gut, but $\frac{1}{4}$ in. was quite enough.

The mandrel, with its collar and tail screw, might now be inserted in the headstock, but there would be a greater chance of accurate work if this were postponed until the framework is completed, which we will therefore do.

I may say that, if the mandrel and the other engineering part of the work are beyond the power of any of my readers, most engineering firms would supply them complete for a comparatively small sum. The Britannia Company, Colchester, will send an estimate on referring them to the number of Work in which this appears.

The Poppet.—This is simply a block of wood 4 in. by $3\frac{1}{2}$ in. and 9 in. long. It is shaped somewhat more beautifully than the fixed headstock, as can be seen in Fig. 5.

The screwed plates can be seen in Fig. 6, through which the long tightening screw passes, the latter 8 in. long, $\frac{3}{4}$ in. diameter, with a hand wheel keyed and nutted at one end and tapered at the other. It would be better if the bosses were turned out instead of in, as shown, and the castings need not be sunk into the wood; they are secured by a couple of $\frac{1}{4}$-in. bolts passing through both. The locking arrangement is peculiar and satisfactory. A piece of iron $1\frac{1}{2}$ in. × $\frac{3}{8}$ in. fits into a mortise cut in the poppet to receive it, as shown in both figures, and the screw passes through a thread cut in it. It is evident that the tightening of the locking handle will effectually jamb the screw. It is well to have this arrangement near one of the washers, for, if it were half way between them, it would tend to bend the screw.

Another thing to be noted is the slips shown at the shoulders. I find that an end grain never runs very well along the bed, and so I hit on the plan of having a slip at each side with its grain at right angles to that of the poppet, which makes it run smoothly.

Every part of the poppet should be most carefully finished as before, the woodwork as smooth as glass and highly polished, and the iron and brasswork burnished, the spokes of the hand wheel being japanned.

I have gone somewhat too quickly, though, in describing the poppet with metal work all complete. The position of the screw can best be found, as in the other headstock, when the frame is made. I will, therefore, suppose that the iron and woodwork are separate until then.

The Hand-rest.—It is difficult, if not impossible, to make a satisfactory hand-rest socket of wood only. I therefore got castings for the socket and T's., but an ordinary $4\frac{1}{2}$ in. socket, price about 1s. 6d., would do very well. I got the sole filed true, and the entire casting cleaned nicely. Then I bored the hole $\frac{3}{4}$ in. diameter for T's, and fitted a $\frac{1}{4}$ in. set screw, and japanned. I was afraid that the iron sole would bruise the bed, and so I fitted strips of wood $\frac{1}{2}$ in. thick to the sole, fastening them on with screws tapped into the casting. This effectually prevented any bruising taking place. The T's were turned in the shank and then filed up and japanned, the shanks and tops being left bright. One was 8 in. long and the other 4 in., the shanks being 4 in. long in each case.

Figs. 7 and 8 show the socket all except the set screw, which is partly at the side, fitting into the ring seen near the top.

In another paper I hope to describe the frame, fly wheel, treadle, and how the position of mandrel and screw are to be determined, and to give a drawing of the complete lathe.

WATCH REPAIRING.

HINTS FOR AMATEURS WITH FEW TOOLS.

Should a lever watch go too fast or slow when the regulator is at the extreme point, unscrew the cock, and unpin the spring from stud; if too slow, gently turn the collet (that part which holds hair spring to balance staff) so that the point end of spring goes $\frac{1}{4}$ of an inch, say, nearer to A from B (Fig. 1), then replace so that end of spring will be that distance also from the mark you made on plate, as stated in the cleaning of watch, in pages 517 and 583. Now repin it to stud on top plate, and replace cock, and screw down; listen now if it is in beat—your ear will be in practice now, and should be able to detect when out of beat. When I go into a friend's house and hear at once the clock out of beat, how it jars on my nerves! I must set it right before I can rest. How people can endure or not know passes my comprehension. I need scarcely tell you if the watch goes too fast; do the reverse to what I state above: turn towards B.

Should the spring be pinned in extreme length, the best plan is to unpin spring at collet—this is risky for amateurs, but try it; a new one will only cost a trifle—and with a small cork pointed just press it on the inner coil on a fine oilstone; a few rubs will reduce it, and, of course, weaken it; now repin it carefully and level; do not turn collet; now refix to stud on top plate to mark made, and screw down cock; it will now go slower and require regulating. Lever watch rubbing causes it to stop and go on again, thereby destroying its time-keeping qualities; listen to it, and you will hear a rubbing and chafing noise: this often proceeds from the one side of hair spring being set out of truth, not level all round the balance, and, of course, touching occasionally the balance in its vibrations, gives an unsteady motion and occasionally stops the balance, which in a short period, by motion of the wearer in walking, starts it again with perhaps a loss of time, several minutes. It is very annoying to the wearer. The remedy is a very easy matter. Draw out the pin and cast it away; proceed, and make a neat, carefully-pointed new one,

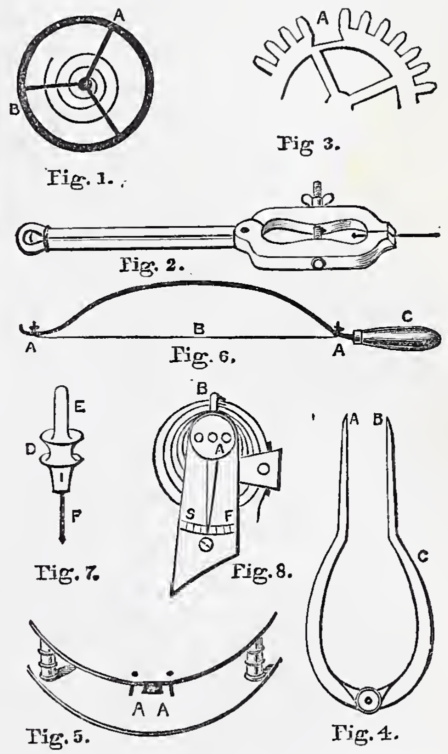

Fig. 1.—Hair Spring and Balance Staff. Fig. 2.—Pin Vice. Fig. 3.—Repairing Broken Tooth of Toothed Wheel. Fig. 4.—Tool made of Common Soft Compasses for adjusting Escape Wheel. Fig. 5.—Top Plate—A A, Banking Pins. Fig. 6.—Drill Bow—A A, Holes for Gut; B, Gut; C, Handle. Fig. 7.—Drill—D, Reel; E, Top; F, Drill. Fig. 8.—Regulator—A, Circular Part; B, Pin.

nice taper, not stunted: this is done by filing well back; see that hair spring now lies level; if it does not, when unpinned take balance and spring out, and gently draw down the side until level; when at rest, use the tweezers, not your fingers, or moisture may rust the spring. Now replace and fix with new pin, and it will be, no doubt, quite level; replace cock gently on to top pivot, screw down while the balance is vibrating, as this ensures you that the pivot is not being injured. Listen to the movement at work, and the rubbing will be gone.

Same applies to horizontal movements as well, except spring is on the top of balance; in this case it often happens that spring rubs against the cock.

Broken Ruby Pin.—This job an amateur cannot do; but take it out as described in page 583, and hand it over to the watch tool shop jeweller, who in nearly all cases does them for the trade; the charge will be reasonable, being quickly done by those accustomed to that special work.

Broken Pivots.—Do as above, because you could not make a clean job even if you had the tools, which are costly. Many who have served their apprenticeship cannot make a clean job, often a botch; so have a pivot drilled in on a new pinion, but it will require movement for the depth.

Broken Teeth.—By accident (but how often astonishes me; nevertheless it does occur) a tooth or two may be damaged or broken; this work the amateur can manage. You may not have a small vice, but the useful tool, the pin vice (Fig. 2), will hold the wheel as well. This appliance for making new pins costs 1s. 3d. and 1s. 6d., according to size. Place the damaged wheel with teeth injured to front, just clear at the mouth, and proceed with a fine-cut narrow file; cut away the damaged teeth (do not press too hard, or you may break the file), and so cut it dovetail, as at A in Fig. 3. Now take a piece of old broken wheel same size of teeth, etc., if you have such; if not, any watchmaker will oblige you with one, as we have abundance in the trade. Cut it exact size, finish neatly, and fit in; then clean both on the *underside*, being the side which will not show; now solder with blow-pipe and pure solder; do this neatly, without a heavy patch of white on the wheel. File up, and make the best job you can of it by burnishing, etc. Should you be unable to procure a piece of old wheel, take a piece of brass, hammer it well, file smooth, and then fit and solder as above. You will only have two teeth to cut, which, if care is used, will be a neat job. Be sure to burnish new teeth well, so that they run as easy as any of the others. Try the mended wheel with the wheel that runs next to it; if no stop is observable, then all is right.

Broken Chain.—Take it up and examine how neatly it is made; use your eye-glass, see that every other link is double, and then single: the single one is sure to be the one whose eye is broken; so take next single and double link joined, and file the rivet head; then place it upon hammered lead, and with a fine blunted needle tap with hammer until the rivet comes out; do same with the other link. Now you can join the two, single betwixt the double, and with a piece of fine steel wire or a softened needle, put through holes, cut off close, and rivet on smooth piece of steel; trim up neat, and no one can tell where repaired, and the odd link or two minus will be no detriment to the movement. Should a hook be broken, take chain and get a new one right size, then rivet as above. They cost 1d.; cheaper by the dozen, of course.

Bent Teeth, Hands, and Pivots.—Sometimes a tooth or two get bent, so that in trying motion of movement every turn of a certain wheel there is a sort of brake power on. Notice wheel in its revolution: at what part, make a dot with ink; now take out wheel and see it at that place with eye-glass. You will find a tooth or two bent; such is often the case with present make of watches. Not so old verge watches; the wheels in last century were made of metal that had been used for years in smelting fat, etc. So careful were our forefathers that this metal was also well hammered before using it; and then, as you find in old verges, the wheels are firm and good, neither easily bent or broken. The verge is the best made watch; yet, except its escapement, some even have such a preference, they have them converted to levers; and they are worth it if of nice shape, and not damaged by careless usage. Wheels are cast and cut by machinery with such rapidity that it would astonish old watchmakers long since at rest.

To set the teeth perpendicular pass a thin knife blade to the root of adjoining sound tooth, and gently raise the faulty one, and so on with the next, until all are perfect; now replace, and try it; if all runs sweetly, the job is complete.

Bent pivot — not often so, except escape wheel or balance. This is done by carelessly trying to force the watch to go, using anything handy, pin, nail, or pencil, thereby casting balance or escape wheel out of truth; the horizontal is generally the sort injured; the balance has a *wobble;* when in motion take it out, and with the tweezers very carefully raise it to the perpendicular position it ought to have; now try it thus. There is a tool for the purpose, but an amateur need not go to the expense; buy a pair of common compasses, such as schoolboys use, costing 1d. or 2d. per pair; they are soft, so will bend any shape; make them the shape shown in Fig. 4, and at A and B dint or drill a hole slightly at the inside, *exactly* opposite; now place in the cylinder pivots of balance, and just close so as not to press too tight, but sufficient to keep it from dropping out; now at C, to nearly touch the rim of balance, hold a small neat piece of wire, and see, when turning balance around, which part of rim comes nearest; mark that place and take it out, and bend the pivot at that side (under or top as the case may be) from the marked part. Now try it, and if rim nearly touches alike all round, the trouble is removed; replace it in the movement, and it will run even now. Before injury, always remember in bending a pivot to do slightly once or twice instead of too much at once, it will save a breakage and expense.

In the trade we use a small piece of brass with a hole drilled to fit the pivot, and by holding this in small pliers, and raising pivot, no injury is done to the smooth surface, but with care the tweezers will do.

Bent hands you can rectify with the tweezers, and a good eye for straight lines; if it is the seconds hand which may not be level on the barrel part, raise or lower the side as the case may be; this often stops a watch; by touching the dial at one side also causes it to go inaccurately. Sometimes, in fact, nearly always, the pivot is bent upon which the barrel of seconds hand goes; straighten it as previously stated.

Should a pivot hole be worn egg-shape or too large, rind it out a little larger, then procure at the watch material and tool shop ready-prepared bushes, pivot-drilled; fit in, cut off even, and gently tap with small hammer until level and neat; pass the point of fine needle in the bush hole to free it from any irregularity.

Broken Main Spring.—Should the spring be only broken at the outer coil, in or near say to $\frac{3}{4}$ of an inch of the hole, you can use such spring again; hold the end in small gas flame to temper equal, for say 1 to $1\frac{1}{2}$ in. up it, then punch or drill a hole to fit the pin inside spring barrel; we use a special spring punch in the trade, but an amateur's time is not of that value, and he need not go to the expense; dress up round the damaged end neatly and workmanlike, and fit in as previously described; should it require a new spring by being broke at the inner coil, which is generally the case, take it to the tool shop, and get one same strength, width, etc., and when in the barrel, if it more than half fills it, you will have to take it out; break off the quantity you consider will fit; don't take off too much, or it will not work the thirty hours; so also if too large it has not room to expand; surest way is to notice the old one before removing drill-hole, and fit as above stated.

Some amateurs might desire to go to the expense of a spring winder; it has a nose-piece similar to the centre piece, holding inner coil of spring, called the barrel arbor; this rotates by turning a handle, and so winds up spring small enough to drop into the barrel; when it catches the outer hook it is done quickly, and the spring is not injured as in the other plan.

Broken Square.—To set hands with, take off the dial and dial wheels; pass it out from dial side; being, of course, a horizontal or Swiss lever, the inside centre wheel will not be disturbed; that you must already know, if you have cleaned one; then take old part and movement to procure one same size; it will cost you a mere trifle; press it in, using the small steel washer again; then fix on dial wheels and dial; the minute hand may not quite fit; file end a little or rind the hand; it cannot be far from fitting; refix in case, and the job is complete.

Should a lever watch have too large a swing—in fact, if an American one—it will overturn, being so powerful, and having club-shaped scape teeth, so stop the movement; to remedy, draw the two banking pins a little nearer so that the pallets are not in full play; do not close them too much or you go to the other extreme—just the merest shade; if the swing is greater when movement is in a horizontal position, the ruby pin must touch.

In watch or clock repairing a drill is very useful, and the bow, though old-fashioned, is the best; the archimedean drill is not so good; amateurs can easily fit up a cheap drilling apparatus. Procure a stout piece of wire 15 or 18 in. long, shaped as in Fig. 6, and drill or punch holes at A and B; fix in a first violin string, and fit on handle at C, costing 1d. or $1\frac{1}{2}$d.; bow is complete. Now take a small empty silk reel, plug a piece of hard wood, E, as per sketch, through hole in D, and drive a strong sewing needle, shaped at point as a drill; you may do this neat with your eye-glass; you can fit up three or four various sizes for watches and clocks. For the holder and presser left hand, take a square of wood (hard), $1\frac{1}{2}$ by 3 in., 1 in. thick; dent a small hollow in the middle for E to work in when drilling; now wrap bow string once round D, and place top square of wood on; gently press while drilling; it is a mistake *to press too hard*—you may break the best of drill-points thus; you will be fit up at a small cost.

Broken Click or Ratchet.—At winding-up part take it out; have a new one, do not tinker with the old one by repointing, etc.; a new one costs so little; it is best plan to get same size, and you can easily fix it on.

Lost dial wheel is a very awkward job, so is a damaged dial, but care will remedy both, even by an amateur. Take off dial and procure a wheel to fit, as all sizes are kept; with patience this can be got over. There are two points to study, this wheel doing double duty.

For a new dial take old one, and from the stock on hand, if you can fit it; it will only cost 1s.; if a new dial specially made, 3s. Notice if centre hole and seconds hole are correct, and outer circumference feet; of course you cannot expect to be right, so drill two holes in plate for them. For appearance to a watch, a new dial is worth cost and trouble; many a good lever looks ıltry with chipped or cracked dial; new al in retail shop is 7s. 6d. to 10s. Of ourse, time in fitting, but charges are eavy. If a silver or gilt dial, being only fit on surface plate, it is an easier job, as ıey are only pressed on to old frame; it is ardly worth while regilding or silvering, ıey never look so well as new, the figures re botchy.

Broken Regulator in Part.—Holding last oil of spring, unscrew the two small screws olding circular part on (but previously ake cock off, or you may slip and break alance) at A, Fig. 8, and file top head of roken pin at B, for it will be that which is ıjured; then draw it out and make a new ne; rivet it in at top, having it fixed in nall pin vice; sometimes, but very rarely, ıe index point is broken by someone not t to handle a watch; if so, get a new one t tool shop to fit cock, very reasonable in rice. This completes what I think an mateur is capable of doing.

OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

111.—New Patent Extending Clothes Prop.

This is another speciality of Messrs. W. B. Fordham & Sons, Limited, an illustration of which is given in Fig. 1. It consists of two pieces of wood about 6 ft. long, 2 in. wide, and 1 in. thick, one end of one piece being cut into a point so as to enter and hold in the ground when in use, and one end of the other in a notch to receive the clothes line. The two pieces slide one on the other in zinc bends, and may be extended from 6 ft. to any length, by 6 in. up to 11 ft. When drawn out to the desired length the pieces are fixed by means of a peg, which passes through holes bored in each slip, 6 in. apart. The material of which the prop is made is white deal. It occupies but little room, and may be put away in any spare corner. When not in use it may be taken apart and the two slips laid on the back of two chairs, thus making up a handy drying horse. The props are sold at 9s. per dozen.

Fig. 1.—New Extending Clothes Prop.

112.—Economy and Advantages of Gas.

Any one who is interested in the subject of heating and cooking by gas, will do well to send to Messrs. Thomas Fletcher and Co., Thyrma Street, Warrington, for a small pamphlet written by Mr. Fletcher himself, and entitled, "Economy and other Advantages of Gas as a Fuel for General Domestic Use." It proves very clearly the value of gas as a heating medium, and supplies illustrations of all kinds of appliances used in warming, cooking, laundry work of all kinds, and apparatus for coffee roasting at home, heating water for baths, and many appliances used in mechanical arts and trades. Much useful information may be gathered from its pages.

Several of our readers engaged in soldering, who have from time to time inquired for heating apparatuses, might turn their thoughts more towards gas. THE EDITOR.

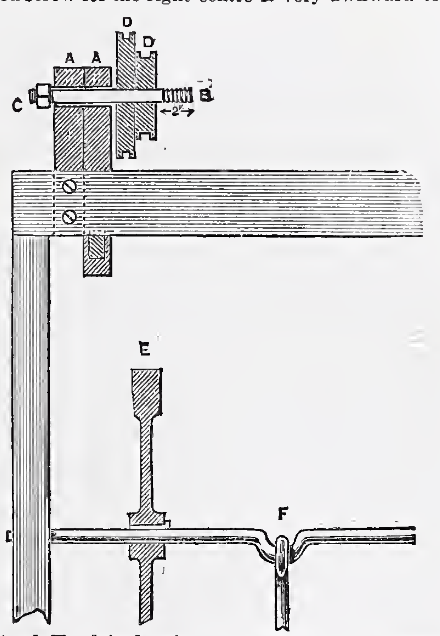
I.—Letters from Correspondents.

Lathe Making.—Bernardo writes:—"I and a friend of mine have constructed a lathe with arrangements very similar to that one previously illustrated and described in Work. Instead of using a grindstone we use an iron fly-wheel and crank shaft with treadle. The mandrel is of steel with a thread cut on it for 2 in. at right end and 1 in. at the left end. On the mandrel a pulley with two grooves is fixed by driving in wooden keys, flats having first been filed on the mandrel. A nut is placed on the left end of the mandrel. This is the only thing to keep the mandrel in its place. Can you suggest a means of preventing the mandrel moving endways to the right without causing much friction? We put an iron washer between the pulleys and the fixed headstock, but this causes a good deal of friction. The length of brass tube encasing the mandrel and forming its bearing is five inches. Is this too long, for the bearing gets very warm when the lathe has been going for five minutes at 650 revolutions a minute? We drilled two holes from the top of the headstock down to the brass tube, and then drilled a small hole through the brass tube for oiling. Would it be advisable to file a channel in the upper part of the inside of the brass tube so that the oil could flow all along the top of the bearing? Is 650 revolutions per minute a sufficiently high speed? Can you give me any guide for speed for different kinds of wood and metal? Is it advisable to harden the nose of the mandrel (I mean the right-hand end) so that it may cut a thread for itself in a wooden chuck, and if so how must it be hardened, and how must the end of the thread he finished so as best to cut its way into the wood for the chuck? I find the bed screw for the right centre is very awkward to



Fixed Headstock, etc., of Lathe—A A, Oil holes drilled to Mandrel; B, Mandrel; C, Nut; D D, Wood Pulleys fixed on Mandrel; E, Fly Wheel; F, Crank.

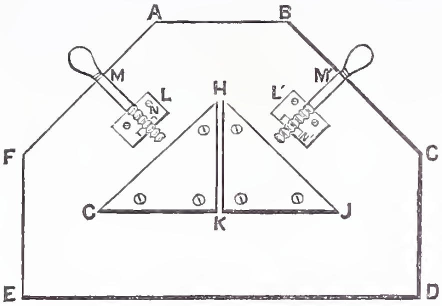
get to correspond to the centre of the mandrel, and that if it is correct when just the point is out, when screwed out an inch or so it is wrong again. I suppose I am in fault for not having drilled the hole for the bed screw straight, but I tried several times, having plugged the previous holes with a pin of wood. Could you suggest a simple and cheap easily-constructed centre, where the point itself might slide in a bearing, and be only pushed, not directed, by the screw? These are all the questions I am going to ask you. I expect you will exclaim 'I should just think they were enough.' I hope I shall not have trespassed too much on your valuable time and space, but having had no previous experience at this sort of work, save a little turning on lathes driven from shafting, I am rather at a loss in the above matters."—[To the above questions put by Bernardo the following reply is given by F. A. M.:—"You and your friend have exercised considerable originality, and, though I must find fault with your arrangement, do not on that account be discouraged, since you may learn more from a mistake sometimes than from a success. You have taken your ideas chiefly from the lathe described on page 261, which is called a 'dead-centre' lathe, because both centres are still, or 'dead,' whilst the work revolves upon and between those centres. Now the dead-centre lathe is by far the easiest of construction, and it is very good for one kind of work, viz., that kind which is turned between centres, such as tool handles, spindles, as of watches, little shafts, etc., but you have evidently perceived that it is unsuitable for what is called 'chuck work'—that is, hollow and other work turned without the support of the backcentre; *en l'air*, as the French turners call it, because it turns in the air with no support but the chuck which holds it. Therefore, instead of bringing the mandrel to a point, fixing it firmly in the head, and allowing the pulley to turn upon it, as advised by Self-Helper, you have screwed the end of the mandrel, fixed the pulley upon it, bushed the headstock with brass, and arranged a kind of running centre, or ordinary lathe, of bad form. Having gone so far, you should have gone further still by separating the two blocks of which your headstock is made, and fitting the pulley between them, to avoid the unnecessary overhang of your nose-screw. No wonder your mandrel moves endways. You want a turned collar between the pulley (as you have it) and the brass bush, then at the other end a second nut to lock with the other, and between these and the back end of the bush a washer fitted on a feather so as to turn with the mandrel. I would cut away all the middle part of your 5 in. length of bush, and have only 1 in. at each end. I fear, however, it will be difficult for you to make a good job this way. It would have been easier to make a back-centre headstock. You are 'falling between two stools,' as the saying is. 650 revolutions per minute is fast enough for large work in wood, but rather slow for chessmen, handles, etc. The speed must be reckoned according to the diameter of the work. Have mandrel pulley $\frac{1}{8}$ or $\frac{1}{10}$ the diameter of largest speed on fly-wheel for wood turning. Speeds for turning a 1 in. bar in brass, 450 revolutions; cast-iron, 140; wrought iron, 130; steel, 70. You ask whether it would be a good plan to harden the mandrel nose and form it like a tap so that it might cut its way into wood chucks. Rather startling! Still, if the nose were quite small, say, half an inch diameter, it might be possible, especially if you make it 2 in. long. The usual length would be $\frac{5}{8}$ in. However, you might try it 1 in. long with that object, and file 3 deep grooves in the end with a round file, the grooves to extend $\frac{3}{4}$ in. so as to leave $\frac{1}{4}$ in. of full threads; then harden only the end, as far as the grooves extend. When fitting a chuck, stop when it is screwed up as far as the grooves on the nose, and use a narrow chisel to true up that part of the chuck which comes up against the shoulder of the nose-screw. You seem to have no shoulder to screw the chucks up to. This shoulder is essential; it is called the face of the mandrel, and the part of the chuck which comes up to it the face of the chuck. As to the alignment of the headstocks read my paper on 'How to Test a Lathe' on page 50."—F. A. M.]

Purchasing Timber.—A. R. (*Scorrier Saw Mills*) writes:—"I was pleased with some remarks in No. 33, page 522, of Work, by A. J. H. on the purchasing of timber. I hope A. J. H. will excuse me for correcting an error made in reference to 3 in. deals. A. J. H. said if you want 12 ft. 1 in. by 9 in., ask for 12 ft. 3 in. by 9 in. with 2 equal cuts. Deals are generally cut in deal frame, the saws wasting from $\frac{1}{8}$ in. to $\frac{1}{4}$ in. full. This means in 2 cuts $\frac{1}{4}$ in. full waste of timber, therefore each plank or board would be but $\frac{7}{8}$ in. full, and 5 cuts in a 3 in. deal. Instead of there being six $\frac{1}{2}$ in. plank there would be six $\frac{3}{8}$ in. full. Often tradesmen come into the yard, and want four $\frac{3}{4}$ in. boards from a 3 in. deal. It's absurd. If it was possible to cut the deal with saws not stouter than a cobweb, there would be some waste. Such men, I think, leave their thinking caps at home—that is, if they have any to leave."

Folding Stove and Oven.—Dealer (*Leeds*) writes:—"As a common-sense reader, I wish to make a few remarks in reference to Mr. James Scott's folding combined cooking stove and oven. I certainly agree with the construction and dimensions of it, but my experience leads me to think it would be better made of light sheet iron and done over with Brunswick black or some other preparation, instead of made of tin, as the heat would disfigure its appearance, especially if it is to be carried about as Mr. Scott says. And, as for the brackets, I should think they would be much better riveted on instead of soldered on, because where there is heat enough to cook anything there is heat enough to melt the solder off, and they would be an everlasting trouble."

Brazing Band Saw.—A. X. E. (*Nottingham*) writes in reply to G. (*Salop*), page 396, No. 25:—"I may say I braze about four or five a week on an average with a machine by Duncan & Mills, of Oldham, who deal in a variety of setting and sharpening machines for hand saws, etc. I have used it for about two months now, and never had one bad joint. Mr. Duncan himself taught me how to use it; he travels with the machines and teaches all purchasers. The price of a brazing machine I may say is under 30s., and I can braze one joint in half an hour, more or less."

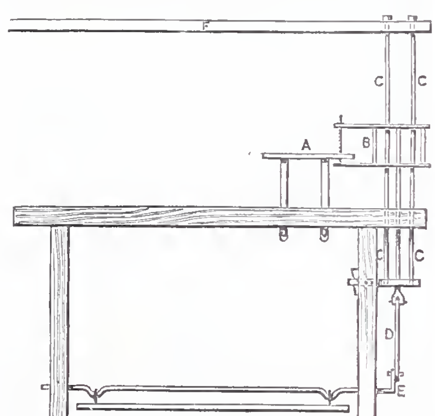
Combined Mitre Block and Corner Cramp.—KILDONAN writes:—"The following makes no pretence of being anything else than a 'means to an end,' and experienced craftsmen are respectfully requested to shut their eyes if they are inclined to be critical. Having some pictures to frame, and having neither a vice nor corner cramp to aid me, I hit upon the expedient now humbly offered. By its help I have



Combined Mitre Block and Cramp.

been enabled to mitre my corners perfectly, and the most expensive and complicated tool can do no more. A B C D E F is a piece of well-seasoned beech or other hard wood, about 1 in. thick. This forms the base of the block. G H J is a triangular piece of similar hard wood screwed firmly to the base by stout screws. The angle, G H J, is a perfect right angle. H K is a saw kerf perpendicular to G J, and bisecting the angle, G H J. It is evident that a piece of moulding laid along H G, while the saw runs in the kerf, H K, will make a perfect joint with another piece laid along H J, and sawn in the same way. Getting hold of two half-inch bolts, M and M', with nuts an inch square, while the length of the screw thread just allowed an inch of play, I sunk the nuts, N and N', into the two short pieces of hard wood, L and L', through which holes are bored to allow the bolts through. L and L' are then firmly attached to the base at a convenient distance from and perfectly parallel to the sides of the block, H G and H J. The diagram is not drawn to scale. Every man can suit the dimensions to his means and requirements. My own block is not even planed, the essential points being accuracy in the angles and edges. If, as in my case, the screws are short, and narrow mouldings to be joined, blocks of wood can be placed between them and the screws. Having applied the glue, bring the corners carefully together, screw up tight, drive in a nail at each side, and your corner is complete."

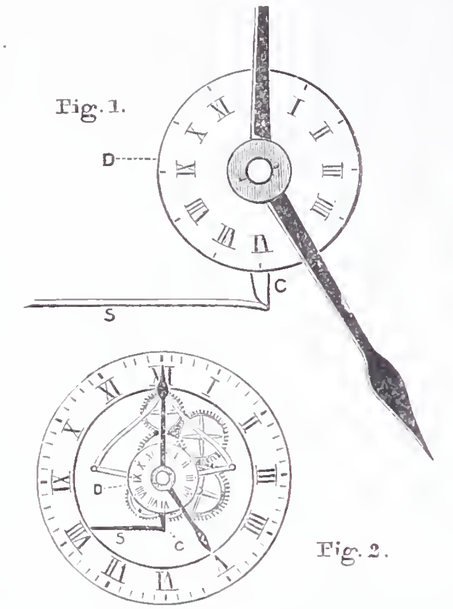
Fret Saw.—A. A. (*Coventry*) writes:—"It appears to me that ARTIST IN WOOD and W. R. S. have taken great pains to give us methods of fitting up saws for fret cutting that will not work. For instance, what gives the up stroke in ARTIST IN WOOD'S saw, and how does W. R. S. get over the throw of his crank? I enclose a sketch of one that



Fret Saw—A, Table; B, Saw Frame; C, Guide Rods; D, Piston Rod; E, Crank; F, Beam.

will work, and work well too. It is entirely home-made, the guide rods being old brass bedstead tubing, the piston the rod of a beer engine pump. The saw I made out of a watch spring. The frame of the saw is ¾ in. ash, and the piece at the bottom of guide rods to steady the piston is ash also, firmly mortised into the upright and wedged. When the saw is not in use I unscrew the top of D, and push the saw up to the beam out of the way. It has a stroke of ten inches."

Electric Time Alarum.—J. W. O. (*Paddington*) writes:—"Having seen in WORK No. 32, page 497, Mr. Bonney's description of how to make an electric time alarum, I have taken the liberty to write to you and try to explain how I have made one for myself, which I have had in use for this last six months, and it has never failed. The clock is one in which the works are visible in a wood case. First of all, I cut a small circular disc of brass one inch in diameter, except at one part. I have left a small piece protruding barely ¼ inch long, so as to make a connection with a small brass spring. On this disc I have marked the hours the same as you often see on an alarum clock, with six o'clock exactly over the little catch. I have drilled a hole through the centre of this disc, and fastened it on to the back of the hour hand firmly, but so that I can easily turn it round to any time I wish. To set it I turn the disc round till the hour I want is opposite the hour hand. The spring is made of a narrow thin strip of brass. This I have fixed to the inside of the case and bent it out, taking care it does not touch the metal work of the clock, but so that the end (which is slightly bent downward to allow of the catch rising on it easily) is exactly under six o'clock, and will press



Electric Time Alarum. Fig. 1.—D, is the Disc full size; S, the Spring; C, the Catch. Fig. 2.—Disc fitted on Clock.

gently against the catch when it comes round, so as to connect the current, but so that the catch can pass easily over it without stopping the hands. It is about 35 to 40 minutes passing over (quite long enough to wake anybody). I have brought the wire which is connected to the works and the other from the spring inside the case to two small metal plates let into the bottom of the case at the back, and these stand on two similar ones with a slight spring in them, to which the line wires are attached. These last two are fixed on the mantelpiece, so that the clock can be shifted at any time without having to disconnect any wires or disfiguring the case with terminals, etc. It is joined up to the bell, which I made myself, with a switch; so all I have to do is to switch it on or off. I have drawn a rough sketch of the disc and the clock face to show how it is fixed. I mostly employ my spare time of an evening in this way. I have taken in WORK from the beginning, and have found it very useful, and I wish it every success. I hope I have not encroached too much on your valuable time and space."

Jewel Case Tools.—C. T. (*Edinburgh*).—The best place for you to go for the tools you require is Buck's, Tottenham Court Road, London.—G. R.

Violin Making.—VIOL (*Cork*) writes:—"I complain that you are keeping the fiddle-makers a long time in suspense. We expected the violin article sooner."—[The articles cannot appear until the second volume of WORK.—ED.]

Dulcimer Instruction.—J. McF. (*Edinburgh*) writes:—"I am glad to see a little more about how to make a dulcimer. I may say I have one, but I cannot make a start to play it. May I ask R. F. if there is an instructor for the dulcimer? If not, could R. F. or ALPHA tell me where I could get a few tunes marked out, which I would gladly pay for?"

Levelling Oilstones.—W. H. D. (*Birmingham*) writes:—"Your issue of October 9th gives a description of a board prepared with emery for levelling oilstones. The method is no doubt an effective one, but I think it would not find much favour with amateurs owing to the trouble of making the board. The plan I have had in use for a number of years is as follows:—Get a sheet of coarse emery cloth, say 2½ in. size, which may be bought at an ironmonger's for one penny; tack it to a flat board by the four corners, or it may be glued to the board. You have then a board ready for use quite as good as the board mentioned above. A few minutes' rubbing will soon show its effect on an uneven oilstone."

Dresser, Perambulator, and Mirror.—H. (*Bishopsgate*) writes:—"I notice in WORK th you take an interest in those who persevere, s thought I would send you some rough sketches what I have made as an amateur. By trade I an bootmaker. Fig. 1 is a dresser which hold tea-service of 48 pieces. I made this of deal, w the aid of a keyhole saw, an iron chisel, and shoemaker's knife. The spindles are of mahoga I then stained it and polished it. I have be

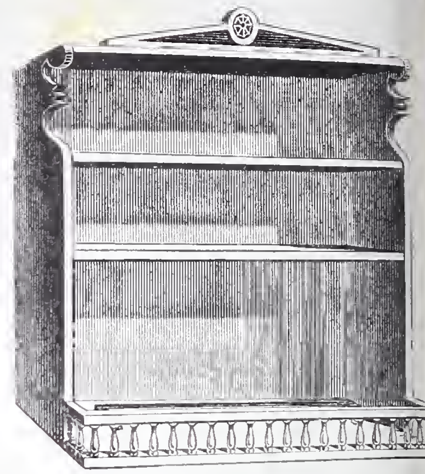


Fig. 1.—Dresser.

offered 20s. for it. Fig. 2 is a clockwork peraml lator. The wheels, which are iron, and 5 in. diameter, I bought, made the carriage, enamell it black, and lined it red. The handles are ma

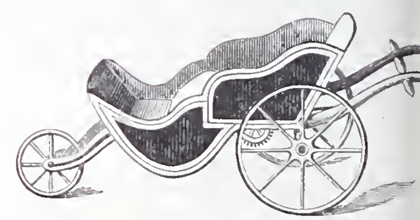

Fig. 2.—Clockwork Perambulator.

for a doll to run behind it. Fig. 3 is one of a pair mirrors covered in red plush, with a gilt frame in. by 11 in. I am also pleased to inform you tha have made a deal table with flaps, turned legs, a casters, which is 56 in. long and 51 in. wi and as solid as a rock. I have also a linnet's ca which I made of mahogany. If I want a waistco I purchase the cloth and make it myself; or a s of clothes for my little boys, I make it myself. N

Fig. 3.—Mirror in Red Plush.

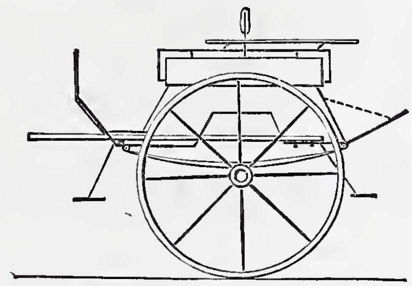
I am waiting to see the design of the bookcas which you gave a prize for, so as I can make myself. I have never worked at any of these trades they are all my first attempts, and they have turne out successful, and if you can find space in you journal for this letter, I think it will encourag your readers to try to do likewise. It often puts shilling or two in my pocket when my own trad is slack."

.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

Engraving Door Plates.—X. L. S. R. (*Falrk*).—I should advise you, before you commence riously to try and engrave, to wait until some papers i the subject make their appearance, which I trust ill be shortly. To help you meanwhile I give you a iort sketch of the method used. First, of course, ou must prepare your metal. This is done by filing ie surface off the brass, then using pumice stone remove the file marks, and finishing with emery oth. You then have your plate ready for work. he tools you must use are chisels specially made r the purpose, which can be had at Buck's, in ottenham Court Road, or any other tool wareouse. You must sharpen the end of your chisel ist as you would your knife, and then rub the ce until it is the shape of a diamond. We should lvise you to get an engraver to show you his iols; you would then understand the setting of iem better than by any description we could give. ext draw your name on the brass with a steel oint. We should advise you to commence with lock letters, these being easier to engrave. You ust then outline your letters with your graver, eing careful not to use your hammer too hard, or ou will cut too deep. When you have engraved ie outline, next cut out with a broad chisel sold r the purpose, and touch up the letters with a and graver. To wax in, heat the brass from nderneath, and put the wax on till you have overed the letters, being careful it does not boil. ou must then pumice off the wax, and polish your rass by using fine emery, rotten stone, and oil. I annot tell you more in the space at my disposal, ut will answer any questions you like to ask on ie subject.

Gilding on Satin.—T. P. (*Redditch*).—I must wn that unless it were possible to see the kind of rticles your inquiry refers to, it is hardly safe to ffer you very definite instructions both for hand nd press. I have, however, gilded monograms nd so forth upon morocco leather, fancy cases, tc., so that the subjoined may be of assistance to ou. Draw the design upon a thin piece of white aper, then carefully prick through the lines with a in, and pounce the design through with chalk, f upon dark surface, or with finely-powdered charoal if upon light, the powder being contained in little muslin bag, the texture of which, when apped over the design, will allow the contents scaping through the pinholes, marking the patern upon the article. Care must be taken that he pounce—that is, the pricked drawing—does not hift in the least. If you wish to paint or gild ipon silk or satin the same directions will suit; ut, of course, the fabric would have to be evenly xtended upon a flat surface, or by some kind of tretching frame. Having successfully transmitted he design to the article we must make the surface ion-absorbent before gilding upon it. Procure ither japanners' gold size or quick-drying variish—that made specially for baths—and rub up inely with a palette knife, a little dry middle hrome, and mix it thoroughly with the vehicle ised. Now, with a fine sable pencil carefully paint n the design, if necessary using a few drops of urpentine with it to enable you to work it the etter. It is not advisable to use much chrome, nly sufficient to well stain the varnish or size so hat we can see nicely where we are going with the rush. When thoroughly dry we can pencil on the old size which is to hold the gold leaf. You can ither use japanners' gold size or gilders' oil gold ize. The first is cheapest and quickest; the latter as more burnish, and is more durable. In either ase add a very little of lemon chrome, so that we see that nothing is missed, and paint it on in the same manner as before, but only a bare coat. If japanners' is used it will be ready for gilding in about half an hour; if oil size, the work is sized one lay and gilded the next. In pencilling on the gold size keep just within the edge, if possible, of the first coating. Use English beat gold leaf, about ls. 3d. per book. If you are not able to use the tip and cushion, let the leaf of gold drop gently on to the size, slightly press it down with cotton wool, and after standing for a little time give a final gentle rub to burnish it, and clean off the superfluous gold. If I had a quantity of small fancy articles to gild—leather or satin—I should draw the design on thick note paper, cut out a stencil of it with a very fine and sharp penknife upon glass, and thus stencil the pattern on, if necessary putting in any fine strokes with a sable pencil afterwards. All this you will see requires a little art and much careful and practised manipulation. I hope you may find this useful to you.—F. P.

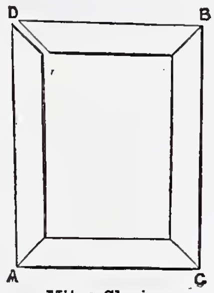
Village Cart, Dimensions.—AN AMATEUR.—The name "village cart" is applied to vehicles of various patterns, but I assume that the one you require is something like the annexed sketch; also that you require a medium, or "cob" size, as your description, "a cart for four persons," might apply to a vehicle for a small pony, or to one for a large horse. The directions for building a Battlesden Cart, No. 19, page 295, will serve for a vehicle of this pattern with a little adaptation. The supplementary sides are rectangular, and are set perpendicularly to the sides, instead of being "pitched," as in the Battlesden. The front foot-board is also different, being much deeper, and attached by two strong stays running the full depth of foot-board, and under the body about 18 in. The length of sides at top should be about 3 ft., and at bottom 5 ft., their greatest depth being 16 in. The bottom should be about 28 in. wide inside measurement. The sides to be pitched at an angle of about 97 degrees with bottom, which, with the same arrangement for supplementing the seatage, as in Battlesden, will give ample width at top. The supplementary sides to be about 9 in. deep



Sketch of Side Elevation of Village Cart on $\frac{1}{4}$ in. scale.

by 3 ft. 4 in. long. Two straight springs 4 ft. long, $1\frac{1}{2}$ in. wide, with 5 plates, will, I think, be sufficiently strong for this trap. The shafts should be 6 ft. in front of the transom, and sufficiently long to run back almost the full length of the body, as in Battlesden.—OPIFEX.

Mitre Cutting.—AMATEUR.—Mouldings are usually of a long length, and not moved in machine with such ease. It is well to cut them at required lengths first, and then trim with the machine, being careful to sight them up exact—that is, place sight edge (or that which is nearest picture when framed) to edge, and see that they are both of an exact length, long and short sides. The machine has regulating screws to get the exact pitch of 45°, or it is as well to join the short sides to the long at A and B, and let them set. Then, in the third joint at C, you can see if it requires a little off. When the third joint is made, the fourth, at D, should meet within $\frac{1}{4}$ in. It will then close in making the last joint, as shown in accompanying diagram.—G. R.



Mitre Closing.

Removing Old Paint.—THREE LEGS.—Glad to learn you find WORK so useful, and hope this may further assist you. By the way, if you find it difficult to get your weekly issue, why not subscribe direct—three months for 1s. 8d., including postage. The article you mention is one of the ordinary house-painter's charcoal-burners. Respecting the lime and soda method, this process, especially for wood that was required to be stained afterwards and not painted, would have been undoubtedly the best. As to the mess, house-painting isn't usually the cleanest of work for one's hands; but with ordinary care to prevent the hands getting burned there is nothing very unpleasant about the task of removing paint. If the woodwork has mouldings on it, the lime is by far the best, since with the burner the most prominent parts would get burned before the heat could perish the whole of the paint on more recessed portions. If you have any more to treat, mind you get fresh dry lime, use plenty of soda, and put the mixture on with a palette, or broad knife, in the form of a paste; after standing a few hours it should then easily scrape off clean to the wood. Well wash the woodwork with cold water, and when dry, coat it with vinegar, using a brush as in painting. The vinegar is to kill the chemical action of any of the resolvent that may be still left in the grain of the wood, and which would otherwise perish the new paint, etc., put upon it. The usual difference in the appearance of the burnt-off work is that some of the priming remains in the grain of the wood, and therefore the surface would not be so absorbent as the lime treated portion, and you would find yourself unable to get a uniform colour. I rather advise painting and graining (plain-combing) in your case, but if you must have stain, try the following:—Rub it all down with glasspaper, and coat the lime-burnt portion with vinegar; when dry give it all a good coat of warm glue, or patent size; this will make all the surface non-absorbent. Purchase some ordinary oak varnish (remembering the price should govern quality); or, better still, that known as "hard-drying," or "church oak," also some turpentine and a few pennyworth of burnt umber in oil. Take equal parts of varnish and turps, mix and stain with umber to desired colour; if you want a more yellow colour use raw sienna for staining; strain before using, and spread carefully and evenly, brushing it the way of the grain. When dry, finish with one or two coats of varnish, or you may give it two coats of stain. Water stain is out of the question under the circumstances of the two surfaces; but were it cleaned right off to the wood by lime, etc., then after vinegaring, you can stain with water stain, and after this two coats of size and one of varnish. Any paint brush, as large as suits the size of your surfaces, will do, providing that it is quite free from dust or paint, and that the hairs don't come out in using. The darker the stain the better the job in your case, I feel sure.—F. P.

Angular Advance of Eccentric.—W. R. W. (*Blaenavon*).—You can work the position out geometrically, or determine it by the following formula:—

Let $a°$ = angular lead of eccentric.
d = distance in inches passed over by valve when piston is at top of stroke.
t = travel of valve in inches.

Then

$$\text{Cosine } a° = 1 - \frac{2d}{t}$$

To use this find the value of $1 - \frac{2d}{t}$ and look out the result in a table of cosines; the angle opposite it will be that required.—F. C.

Water-Wheels.—SCRUTINEER (*Bolton*).—You may find the horse-power (h.p.) of water-wheels from the following rules:—

Undershot Wheel.

Let V = velocity of water in feet per second before acting on wheel.
V = velocity of water in feet per second after acting on wheel.
Q = quantity of water in pounds per minute passing wheel.

(Note.—One cubic foot of water weighs 62·3 lbs.)

$$\text{H.P.} = \frac{Q}{6,440,000}\left\{V^2 - v^2\right\} \text{ for radial floats and}$$

$$\text{H.P.} = \frac{Q}{4,000,000}\left\{V^2 - v^2\right\} \text{ for curved floats}$$

Overshot Water Wheels.

Let h = height in feet of water in pen-trough above that in tail race.

$$\text{H.P.} = \frac{Q.h}{55,000}$$

Breast or pitch-back wheels.

$$\text{H.P.} = \frac{Q.h}{44,000}$$

Turbines.

$$\text{H.P.} = \frac{Q.h}{50,000}$$

F. C.

Bronzing Ferrules.—ANGLER.—To bronze ferrules, reels, etc., for fishing rods, the brass should be turned smooth and bright. The best results cannot be obtained without a lathe finish. The parts must be perfectly free from taint or grease, so should not be handled. Use fine emery cloth and a good speed, and hold the work when finished with a perfectly clean piece of old linen, etc. To make the bronzing mixture, take some new iron filings—about as much as will fit on a shilling—1 oz. of hydrochloric acid (spirits of salts) and $\frac{1}{2}$ drachm of arsenic. Pour the acid upon the iron filings in an earthenware vessel or glass, and let it stand for half an hour. Dissolve the arsenic in a tablespoonful of strong vinegar, and mix with the acid and iron. Strain the mixture through a piece of linen, and bottle for use. As a little of this liquid goes a long way, the above quantity will be sufficient for a good many articles. Now heat the brass moderately by holding it over the flame of a spirit lamp, or better, let the flame play upon the metal while running in the lathe, and while hot apply the bronzing mixture. The best way to do this is to make a small pad of clean rag, and tie it on the end of a piece of wood, wet the pad in the mixture, and hold it to the work as it revolves. The colour will immediately appear, and the pad should be applied until the desired shade is obtained. When sufficiently dark, hold a piece of dry rag to the work until it assumes a good polish, when it may be removed from the lathe and is ready for lacquering. Procure some pale gold lacquer and a flat camel-hair brush, heat the work slightly, dip the brush in the lacquer, and remove excess by drawing the brush across the edge of the cup, etc. Give an even coat, avoiding passing the brush over the same place twice. When dry, again heat, give another coat of lacquer, and hold near a hot fire, or place in a moderately hot oven for a few minutes, and then lay aside till cold. During the process of lacquering the fingers must not touch the surface to be lacquered, but when finished and cold the work may be handled freely. Should a lathe not be available, clean and polish the work with fine emery cloth, dip in a strong solution of pearl ash or washing soda, rinse well in clean hot water, and when dry dip the work in a mixture of strong nitric acid, 2 parts, sulphuric acid, 1 part, to which add a pinch of common salt. Dip for two seconds, and then rinse well in a pailful of clean cold water. If at all cloudy, dip again as quickly as possible, and again rinse. Dry the work in hot boxwood or beech sawdust, and then apply the bronzing mixture with a brush, from which point the operations are the same as in the first process.—OPIFEX.

School for Practical Electricity.—DESIRE (*Peckham*).—The City and Guilds of London Institute has opened an evening department at the Technical College, Finsbury, for instruction in mechanical and electrical engineering, technical chemistry, applied art, etc. The session commenced on September 30th, and the fees range from 6s. to 30s. for the session, inclusive of charges for use of laboratories and workshops. For further particulars apply at the College, Leonard Street, City Road, E.C.—G. E. B.

French Polishing.—J. P. (*Hackney*).—There are one or two books on French polishing, but they are better adapted to professional than to amateur polishers, and I think you will derive at least as much information from reading the hints given in these columns as from any book I know of. You see in "Shop" the little difficulties which beset an amateur are brought forward week by week, and many of them are such as could hardly be anticipated by any one writing a treatise, although they can be explained and errors pointed out. Thus the mistake you have made seems to be that you have used the same rubber for both bodying and the final spiriting off. Try a fresh one for the latter, with a very little spirit, without polish or oil. Use a few, say, four or five, layers of the covering rag between the wood and the moistened wadding. As the outer one dries, remove it, and so on with each in turn till you get a smooth and permanently brilliant surface. Of course you can hardly expect to get this without practice, but by attention you will no doubt see a marked improvement by degrees. Never be afraid to tell us of your difficulties in any description of work, and describe your procedure fully. You may be assured that if one member of the staff cannot assist you another will.—D. A.

Nominal Horse-Power.—SCRUTINEER (*Bolton*).—In these days nominal horse-power is a very uncertain and unsatisfactory expression, as there is no fixed rule about it; in the English Admiralty it is dropped altogether. Formerly when engines ran at low pressures and fixed speeds, the term was commercially convenient. In the Mercantile Marine the rule is very uncertain, most makers having their own, and all of them being arbitrary. Before the introduction of compound engines and high boiler pressure, it was a common rule to allow 30 circular inches of piston area per N.H.P.:—

$$\text{N.H.P.} = \frac{(\text{Diameter of piston in inches})^2}{30}$$

After that period, for compound engines where D = diameter in inches of low-pressure piston and d = diameter in the same of high pressure piston—

$$\text{N.H.P.} = \frac{D^2 + d^2}{33}$$

Neither of these rules takes any account of length of stroke or boiler pressure. To allow for the latter some makers reduced the divisor from 33 to 30, as the steam pressure was increased from 60 to 80 lbs. per square inch. For high-pressure engines the following rule has been used: let D = diameter of cylinder in inches, and S = stroke in feet:—

$$\text{N.H.P.} = \frac{D^2 \times \sqrt[3]{S}}{20}$$

For your first example, compound engine, cylinders 24 in. and 38 in. diameter

$$\text{N.H.P.} = \frac{D^2 \times d^2}{33} = \frac{1444 \times 576}{33} = 61{\cdot}2\text{—N.H.P.}$$

2nd, Condensing engine, cylinder 15 in. diameter—

$$\text{N.H.P.} = \frac{D^2}{30} = \frac{225}{30} = 7{\cdot}5 \text{ N.H.P.}$$

3rd, High pressure engine, cylinder 18 in. diameter, stroke 4 ft.

$$\text{N.H.P.} = \frac{D^2 \times \sqrt[3]{S}}{20} = \frac{324 \times 1{\cdot}58'}{20} = 25{\cdot}59 \text{ N.H.P.}$$

F. C.

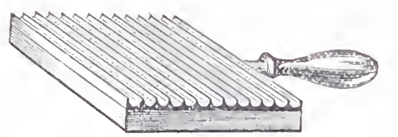
Materials for Oak Graining.—J. H. G. (*Bridgwater*).—The processes and materials used in all kinds of imitations of wood will duly be described later on. As you understand "plain painting thoroughly"—which I am pleased to know—it will only be necessary for me to give you a general idea of the ingredients used in mixing graining colour, so that you can adapt them to your particular requirements. Whether light or dark oak is desired, the colour of the ground, that is, the last coat of oil paint, must be in tone with the graining colour; if the former is made a decided yellow cast the latter should be of a rich or golden shade, and not too hard a contrast of shade between the two. There are many different methods of mixing graining colour for producing the best class of work, but for ordinary work the subjoined will do. Graining colour should always be clean and semi-transparent, easily used with the ordinary paint brushes, so that one can first spread a fair quantity, and then be able to manipulate it with combs, etc., before it commences to set. Procure two ounces of patent or liquid driers; add equal quantities of raw linseed oil and turpentine, up to nearly one pound; thoroughly mix, and then stain to the desired colour by adding ochre and burnt Turkey umber ground in oil. For medium oak, burnt umber alone gives a rich, transparent colour, whilst some grainers will substitute raw sienna (Terra-di-Sienna) for the ochre. Raw umber alone makes a good stainer for very light oak, and very rich tones—seldom advisable or necessary, however—can be obtained by introducing a little burnt sienna. I recommend mixing the liquids and driers together first, and afterwards staining to the desired colour for two reasons. We can judge how much we want for our purpose, and thus prevent waste, whilst the plan of staining the mixture and trying it until satisfactory, gives us thorough control over the colour and shade. The average painter will take a quantity of umber, driers, and usual liquids, and knock it up together with the usual result of having to thin it down to double the quantity before it works freely, and is right in colour, thus having a lot left, and probably wasted. The proportions given make a graining colour which will stand, if necessary, for about two hours before being combed, and should then dry in about eight hours (indoors). If desired to set and dry more quickly, use more turps, and, of course, driers. It should be about the consistency of thin soup, and be strained through muslin before use. I should think you could get graining combs in Bridgwater at any dealer in painters' goods; if not, there are plenty of shops in Bristol. If preferring to obtain through the post, write to Pavitt & Sons, 70, Southampton Row, London; or to Crowden & Garrod, 62, Southwark Street, London, S.E. Steel graining combs are sold in various widths—from 1 in. to 3 in.—and degrees of fine and coarse vein; they are usually retailed at 1½d. per inch and 2s. 6d. per set of twelve in tin case. I wish you every success, and also advise you to look out for the articles now being written on your subject.—F. P.

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Flour Paste Souring.—DILETTANTE (*Glasgow*) writes in reply to J. R. (*Skerries*) (see page 398):—"Though rather late I will give him a recipe which I am sure he will value. I have seen many paragraphs on paste in your paper, but have never noticed the preservative I use mentioned. The substance is corrosive sublimate; 15 grains to a pint of paste is, I think, the proportion. Mode of use, crush to powder and dissolve in a little hot water; then pour paste over it from your pot or saucepan, stirring briskly to mix well. Of course, corrosive sublimate is a deadly poison, and is difficult to procure, but it is worth the trouble. As to danger, I have used paste so prepared for years, and never had a mishap, though I always apply it with my fingers. This should not be done if any cuts are about the hands. I believe my paste would keep good for years—certainly till it is far too hard to use."

Wheels.—R. B. (*Largoward*) writes in reply to G. W. (*Bournemouth*) (see page 332):—"You say that machine-made materials for wheels can be bought almost as cheap as in the rough. Will you kindly give address where material can be had?"

Pill Making.—B. C. D. (*Kilburn*) writes in reply to J. C. (*Carlisle*) (see No. 31 of WORK, page 491):—"I don't know much about the subject, but I saw a man making pills about a dozen years ago. The apparatus that he used was very simple. It was made of two pieces of wood about 6 inches square and 1 inch thick, with a piece of brass let into one face of each piece. The brass was scooped out in a series of semi-circular grooves. Each tool was provided with a handle, as shown in the sketch, which



Pill-Making Machine.

represents one of the tools. The way he used the tools was to first flatten out the paste, and then put it between the brass faces so that the grooves came just opposite each other; then press both tools together so as to cut the paste into a series of round bars; the bars were then taken out and put across the grooves, and the process repeated so as to cut the bars into little bits; then they were worked about between the tools till they were made as round as was possible."

A Cutting Drift.

Drilling Square Holes.—The Britannia Company (*Colchester*) writes (see page 270):—"It is one of those ideas which some may think of value, but it is much easier and quicker to drill a round hole and then drive a drift into it, to cut it square, than to drill a square hole. Some unfortunate inventor patented the above mentioned appliance, and, like many a hundred other victims of the inventive faculty, found only the honour of being a patentee to result from it."

Spirit Level.—G. M. (*Sheffield*) writes in reply to D. J. (*Oldham*) (see page 510):—"If the slot you mention is in the wood, you will require a 4-in. tube ⅝ in. thick; although called 4 in., the length, with the nipple at each end, is nearly 4½ in. You fix it as follows:—Fix a board quite level, place your level on it, put some putty or plaster in the slot, and press the tube in. Then screw on the top piece of brass, taking care not to shift the tube; if it does move you may press the high end down a little."

An Easily-Made Fret Machine.—W. R. S. writes in reply to W. W. M., BLOCKHEAD, G. P., NEMO, and A. H. H. (see page 508):—"The wheel is fastened to the axle in the ordinary way, and made to revolve in either direction. The connection of the treadle to the wheel is the same as that of an ordinary sewing machine, except that the bottom part of C is also fastened by a bolt to the wheel; the top part is only fastened to the pipe A. The size of the table is immaterial, but it will be better to carry it back as far as the slide D."

Trade Notes and Memoranda.

M. YVES GUYOT, Minister of Public Works, has prepared a scheme for a Paris underground railway, which he intends to present to the Chamber early in January. This scheme differs widely from that prepared by M. Bailhaut, and rejected by Parliament. It is far less gigantic than the scheme presented by his predecessor, and does not comprise any State subvention. A syndicate of credit establishments have, he affirms, presented themselves offering to carry out the scheme without any support from Government. The proposed line would start from the Place de la Madeleine, and, passing under the main boulevards, would reach the Place de la Bastille and the Vincennes Station. Thence it would be carried as far as the terminus of the Paris, Lyons, and Mediterranean Railway. Then, crossing the Seine, a little above the Isle St. Louis, follow the Rue de Rivoli, and thus reach the Place de la Concorde and its starting point, the Place de la Madeleine.

J. H. SKINNER & CO., EAST DEREHAM, NORFOLK,

Manufacturers and Importers of Photographic Apparatus and Fretwork Materials.

J. H. S. & CO. have now a large Factory with accommodation for upwards of 100 workmen, which is used exclusively for the manufacture of Photographic Apparatus of every description, from the cheapest to the most expensive.

The process is simplicity itself. Full Instructions supplied with each set.

3/6 The Eclipse Camera Set. 3/6

Complete, consisting of a Polished Mahogany Sliding Bellows, ¼-plate Camera to photograph full-size carte-de-visites, with Focussing Screen, Dark Slide, Brass-mounted Lens, Brass Fittings, Developing and Fixing Solutions, Packet of Dry Plates, and full Instructions, enabling any amateur to take a good Photograph. Price 3s. 6d., or securely packed by Parcel Post, 4s.

7/6 Complete Photographic Outfit. 7/6

Comprising ECLIPSE CAMERA SET, as above; also PHOTOGRAPHIC PRINTING APPARATUS, consisting of Hardwood Printing Frame, with Brass Spring Back, Sensitised Albuminised Paper, Gold Toning Solution, Fixing Solution, Glass Rods, Cards for Mounting, with complete Instructions. Also Hardwood Folding Tripod Stand and Focussing Cloth. Price 7s. 6d. Securely packed, post free, 8s. 6d. If packed in portable wood case, with hinged lid and leather strap, as in illustration, 9d. extra.

Every Set is carefully examined before being sent out, and guaranteed to be in working order.

N.B.—If Apparatus does not give satisfaction, and is returned uninjured within three days of receipt, we guarantee to refund purchase money.

Better Sets, 10s. 6d., 21s., 42s., 100s., and upwards. Complete Catalogue of Photographic Apparatus, one stamp. J. H. SKINNER & CO., EAST DEREHAM, NORFOLK.

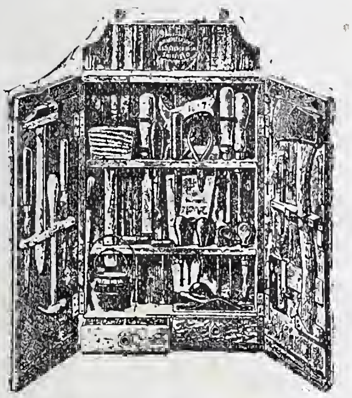
OBSERVE THE FOLLOWING GENTLEMAN'S *Registered* TOOL CABINET, PRICE £2 2s. each.

Size, 21 in. high by 14 in. wide, made of Polished Oak, with Two Drawers, and with Lock and Key, and with two Loops to fasten it to a wall.



The above is a strong, well-made Cabinet of polished Oak, and every tool is full size, serviceable, and warranted. The contents comprise such tools as are usually required for repairs, &c., in a household, and the investment of its small cost will soon be saved by the work done with them.

IT CONTAINS TOOLS AS FOLLOWS:—
Mallet,
Chisel,
Gouge,
Axe,
Two Hammers,
Saw,
Three Files,
Two Turnscrews
Square,
Claw Wrench,
Pliers,
Two Gimlets,
Two Bradawls,
Pincers,
Glue Pot and Brush,
Plane,
Compasses,
Nails & Screws.

ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, St. Helens, Lancashire, in Boxes, 1s. 1½d. and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

TWO FOLDING ARM CHAIRS.

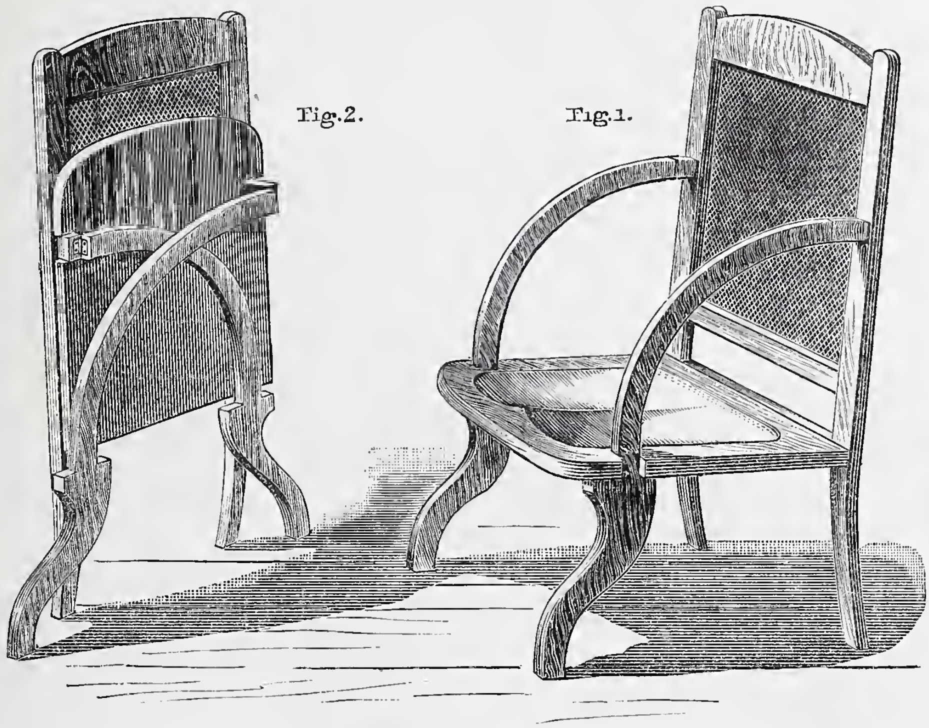
BY JAMES SCOTT.

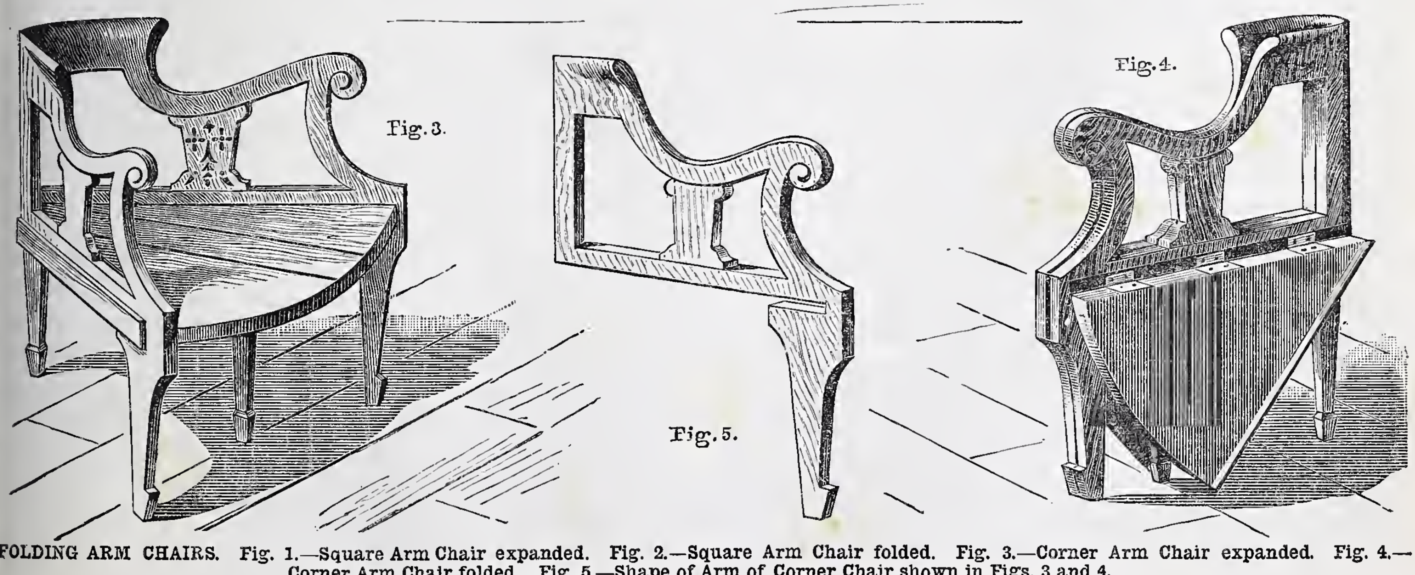
There are to be found among that mysterious community called the Public certain persons who declare that they really detest such things as folding chairs. If, however, the truth could be extracted from them, I think it would be found that the true reason is not because they *are* folding chairs, but because they always have a nasty habit of squeaking when being sat upon.

Now, in the sketches here shown are two folding chairs which will not be so liable to give way to this objectionable habit, as I have designed them to work upon hinges; and the bending of these will not create so much noise as wooden connections do. There is nothing particularly new in the patterns of these two arm chairs; the originality consists in their method of folding.

Dealing with Fig. 1, I will give what I consider the most accommodating sizes; it must be remembered, however, that if made for personal use, dimensions should be studied a little, and altered accordingly. The height from the floor to the seat is 16 in.; length from the back to front of seat, 18 in.; width of seat, 20 in.; height of back from seat, 22 in.

The back should be prepared first, and should be the same width from top to bottom. The seat is next made in two pieces, one piece to fit between the two back feet, and the other forming the seat proper; these are securely hinged to each other. Each arm is in one piece with each front foot, the shaping of which will be the most difficult part; but as it is not my purpose here to give instructions on wood working, I shall presume that my readers can handle a few tools skilfully. The arms can be of any size, but whatever they are, it must be borne in mind that each will have to be a quarter of a circle in shape. If they are 12 in. distance from the back, they will have to be cut out of a circle 24 in. in diameter: and if at 15 in. from the back, the circle from which they must be cut will be 30 in. in diameter; these are outside measurements. Whatever the dimensions of these arms may be, a piece must be cut out of the seat on each side to admit them; and it is by this means that the seat is enabled to rise up against the back. The arms also have to be made to fold one over the other. This is effected by cutting one arm through at 1 in. distance from the back, and the other at 2 in., and hinging them. Fig. 2 shows the appearance of the chair when folded.





FOLDING ARM CHAIRS. Fig. 1.—Square Arm Chair expanded. Fig. 2.—Square Arm Chair folded. Fig. 3.—Corner Arm Chair expanded. Fig. 4.—Corner Arm Chair folded. Fig. 5.—Shape of Arm of Corner Chair shown in Figs. 3 and 4.

Fig. 3 has somewhat the look of what is termed a corner chair. A very comfortable chair can be made by following the design. As with Fig. 1, I will give the most appropriate sizes. The height from floor to seat is 16 in.; height of back from seat, 16 in.; height of arms, 9 in.; seat, from back to front, 18 in.

The seat should be made first, and must be some part of a circle. A circle should be drawn on the board to be used, and the size considered best marked off, from the centre to the outside, and cut out. A piece about 2 in. wide should then be cut out along the middle of the seat, making the seat into three pieces. The two larger parts are then hinged, one on each side, to the middle piece.

Underneath the middle piece, and a few inches from the centre of it, should be fitted a leg. A back-foot, in length from the floor to the top of the back, should also be joined into it. It should be fitted so that the ends of the arm pieces may close nicely against it when they are hinged. The length from back to front of these arms will be just a little more than that of the seat. Fig. 5 shows how they should be made.

At each end of the seat should be a rim, to prevent the arms from slipping off.

The banister under each arm is entirely a matter of choice. These chairs should be made in one of the hard woods, and polished; and if the hinges are in good working order, and strong, and are properly fitted, no complaint will be made of the chairs squeaking.

HOW TO MAKE A PIANO.

BY "NIL DESPERANDUM."

STRINGING, TENSION, PITCH, AND CHIPPING UP.

THE pianos of to-day are strung much heavier than they were formerly, and consequently the back is made stronger to resist the greater tension of the strings. If I may say so, it has been a battle between the strength of the back and the tension of the strings. If the piano has to stand well in tune, of course the back must be the stronger. If one of the old pianos were strung with the wire we now use, it would simply collapse. The theory of stringing requires that each octave, starting from the treble, should double its length, but if that were carried out in the piano under our consideration, we should have a 16-ft. string for the lowest C. Of course, that is impossible in a cottage piano, so the difficulty is surmounted by increasing the thickness of the wire and obtaining lower notes. When a string is struck with the hammer in the piano, it causes it to vibrate a given number of times according to its length and tension, the higher the note, the greater number of times it vibrates. It is said by writers on acoustics that sonorous vibrations lie between 16 and 38,000 per second of time. This seems a large number of vibrations in so short a space of time, but it can be proved by at least six different methods. In a 7-octave pianoforte, the extreme bass A corresponds to about 27 vibrations, and the extreme treble A to 3,480 vibrations per second. The theoretical pitch, as it is termed, is the pitch accepted by acousticians as the natural one, being 512 vibrations per second for pitch C, each octave lower decreasing by half: thus, 512, 256, 128, 64, 32, and each octave higher increasing by double the number in a second. The fork by which pianos are usually tuned is of a higher pitch than this, giving 519 vibrations per second, and called the philharmonic. Some use a higher pitch still, called the diapason normal, giving 522 vibrations per second.

Before commencing to string the instrument, take a strip of cloth listing (such as tailors cut off the edges of their cloth) and glue on the top of slip, which is round the bent side, and also glue a strip on the top edge of bottom plate; this is for the strings to lie on to prevent jarring. Now take a pen and ink and mark the gamut over each note, commencing with A at the bass end, and marking it the same as the marking off slip. The treble and tenor notes of the piano are strung with steel wire, and the bass notes are steel with copper wire wound round them. The steel wire and the bass strings can be had from the ironmonger before mentioned. Now mark under the notes the sizes of your wire, count 6 notes from the treble and mark 13, and then mark again in the following order:—10 notes of 14 wire, 6 notes of 15, 6 notes of 16, 21 notes of 17, 3 notes of 18, 2 notes of 19, 2 notes of 20, 1 note of 21. You will require a $\frac{1}{4}$ lb. of all these sizes, with the exception of 17; of this you will require $\frac{3}{4}$ lb. Now you will require to take a scale from your back for the covered bass strings; this you do with a sheet of newspaper. Lay it on the back so that it covers the short bridge in its width from the bass end, and is over the top bridge and the bottom plate; now take your heel-ball and rub over the pins gently on your top bridge, short bridge, and bottom plate; this will give the size for the string-maker.

When ordering your strings, say you want them about 4 lbs. weight. You may now commence to string your back; see that it is laid evenly on your trestles, one under your wrest plank, and the other under the bottom. You will require a tuning-hammer to turn the pins, also a pair of pliers to cut the steel wire. The best place to obtain these or any tool for pianoforte making is at Buck's, Tottenham Court Road, W.C. You will also have to use a hammer to drive in the pins. As you will know by marking the wrest plank, you start at the treble end with No. 13 wire, the first 22 notes being trichord. Your centre string will need a loop on the end; this is looped on the front row of pins. Take your wire, and having put a piece of wire of the thickness of the hitch pin in your bench vice, hold the end of it with your pliers, and give it a couple of turns round the wire, and then slip it off the wire, and while holding the loop thus made, finish it off by turning the short end round it. Now put your loop on the first pin in the front row on the bent side, pull it tight with your pliers, carry it over the bridges, and three inches over the hole where you require the pin, if you make a mark with a file or your pliers three inches from the point, you can measure your wire to this mark. Having cut your wire, put the end in the hole in your wrest pin and turn the pin round to the right until the wire is coiled round it two or three times; then drive the pin into the wrest plank with your hammer until the coil is a quarter of an inch from the plank, then tighten it by turning to the right; now put the end of your wire in a wrest pin and repeat the operation of coiling. Drive this pin into the first hole in your wrest plank, and take the wire round the first pin in the second row in the bent side and over the bridges; cut off and put round a wrest pin, and drive it in your third hole of the wrest plank; this will complete one note. The remainder are done in the same way until you get to the bichord; of course the middle string is left out. Take care the sizes are put on as you marked them on the plank; the sizes will be marked on the paper the wire is wrapped in.

When you have got all the steel wire on, then put on the covered bass strings; these you will find are threaded on a wire, with loops on the ends. Take off one note of two strings from the end where they are the thinnest; put the two loops together, and the one that is farthest away from the copper put on the bottom pin on the plate; carry over bridges, and pin the same as before. Take care to take them off the wire in rotation, as they are not all the same size; of course, the last seven are single; these are thicker than the others, being double-covered with copper. Now you must run a piece of listing in and out of the strings below the bridges, and a piece of red cloth or braid over the top bridge. This is done to damp the sound in all parts except between the bridges. You can now stand the back on its bottom, leaning against the wall, and see that the coils are all nice and even round the pins; if not to your satisfaction, you can draw them close by slacking a little with your tuning-hammer, and drawing up with a button-hook. Now the maker, no doubt, would wish to hear the tone of his instrument, but of course he can only do this in a small measure until the hammers are in.

There is an operation which is called chipping up. This is really giving the piano its first rough tuning. You will want a C tuning-fork: this gives the note for pitch C. It is the third C from the treble end. Put your tuning-hammer on the treble pin of your note, strike the prongs of your fork, then place the end on your back. When it gives the note, pull up your string until it sounds the same as your fork; when you can hear the two sounding together as one note, that is right or in unison with the fork; but if it is not right, you will hear what are called beats, which I can only describe by saying they sound like "Woo, woo, woo;" the more it is out of tune the quicker will you hear the beats; you must tune until the beats cease, and sound like one note. Having got this right with the fork, you chip the other string of your note with a small piece of brass until it is in unison with the string you pulled up to the fork. Now you pull up your C below the pitch C; this is an octave below; when this is in tune and both C's are chipped, it will sound like one note, and very agreeable to the ear. Now pull up the G below; this is called a fourth; you can hear when the beats cease. Now pull up the D above; this is called a fifth, chipping the two notes together; then from D to A below, then A to E above, then E to B below, then B to F sharp; then get the octave F sharp below; then from F sharp to C sharp above, C sharp to G sharp below, G sharp to D sharp above, D sharp to A sharp below, then C to F below. Try the following chords G C E when you have tuned the E; G B D after tuning B; A D F sharp after tuning F sharp; and F A C after tuning F. If the reader has a musical ear and some perseverance, no doubt he will be able to master it. This is called the scale, being the basis from which the piano is tuned. There is a small instrument sold at music shops called the chromatic pitch-pipe; by moving a slide it gives all the notes in the chromatic scale. This would be found a great help to beginners in tuning. When you have chipped up the scale, you can go on with the octaves above; your irst note to pull up will be F below pitch C, to be pulled up an octave higher than the F below it, and so you can take each succeeding note until you have done the treble, then you tune the octaves below your scale, your first note to tune being E, going down to the bass. I need scarcely tell you that an octave would be from doh to doh, running up the scale or down. This having been done, you take a piece of hard wood with a slight groove in the end, and press all the steel strings singly, and pull out the copper strings. This is done to stretch the strings so that they stand in tune. Now you can chip it up again, repeating this operation several times at convenient opportunities, remembering that you are doing the instrument good (if you do not work the pin backwards so as to make it loose) and improving your ear. If you pull a note a shade too sharp, it is better to press it down. I may say you must keep the back in a dry place after it is strung to prevent rust. This completes the operation of stringing.

BRONZE AND BRONZING.

BY GEORGE EDWINSON BONNEY.

BRONZE—BRONZE PICKLES—BRONZING—BRONZING ELECTRO-BRASSED WORK—WARM BRONZE—BLACK BRONZE — STEEL BRONZE — GREEN BRONZE—GREEN ANTIQUE BRONZE.

Bronze.—Bronze is an alloy composed of copper, zinc, and tin in various proportions. When other metals are associated with copper to form a bronze-like alloy, a prefix is added to the word, and thus indicates the composition of the alloy. These alloys are found to possess characteristic properties quite distinct from those of ordinary bronze; not the least important differences to the electro-plater being those relating to their conductivity and resistance. Aluminium bronze, for instance (composed of copper 90 parts, and aluminium 10 parts), has a conductivity as compared with pure copper, represented by 12·6 to 100. Silicium bronze, composed of copper with a small percentage of silicon, as used for telegraph wires, has a relative conductivity of 98, whilst a larger percentage of silicon (in an alloy used for telephonic wires) pulls down the conductivity to 35. Phosphor bronze (as used for telephone wires) is composed of copper alloyed with a small quantity of phosphorus, and its relative conductivity is 29, whilst phosphor bronze, with 10 per cent. of tin, has only a relative conductivity of 6·5. An ordinary bronze, such as used in light castings, composed of copper 80 per cent. and tin 20 per cent., has a relative conductivity of 8·4. The following table will show at a glance the composition of some of the more common kinds of bronze.

TABLE OF BRONZE ALLOYS.

Name.	Copper.	Tin.	Zinc.
Coinage bronze	95·	4·	1
Pale bell metal..	96·	4·	0
Common bronze	94·3	5·7	0
Do. do.	91·5	8·5	0
Gun metal	90·	10·	0
Bell metal	79·	21·	0
Gong metal	78·	22·	0
Speculum metal	68·5	31·5	0

There are several other modifications of bronze used for particular purposes, but it is not desirable to examine them in these notes, nor to go thoroughly into the metallurgy of brass and bronze. Enough has been written to show the plater that both alloys differ very much in their composition when made for various purposes, and these differences may affect the deposition of metals upon them, on account of the varying resistances of the alloys themselves. These remarks apply particularly to the choice of a brass or a bronze to be used as an anode in the operations of brassing and bronzing.

Bronze Pickles.—Bronze may be pickled in any of the "acid dips" used for cleaning brass, but preference should be given to those which do not contain strong nitric acid in a large quantity, since the tin of the alloy does not form a soluble salt with this acid. The addition of some hydrochloric acid will assist the action of the pickle on bronze. (See *Brass Pickles*, page 597.)

Bronzing.—This term is generally applied to processes for giving a so-called bronze appearance to brass and copper. The electro deposition of bronze itself is rarely practised, since most brassing solutions can be made to yield a deposit resembling real bronze in tint, by merely increasing the quantity of copper in the deposit. Bronze solutions are made up in a similar manner and of similar ingredients to those used in brass solutions, the only difference being the substitution of chloride of tin for the sulphate of zinc used in those solutions. They are also worked in a similar manner, but the density of the current must be regulated to meet the higher electrical equivalent of tin—viz., 59, as against 32·6 of zinc; since 33·5 grains of tin will be deposited in an hour by the same current that will deposit only 18·5 grains of zinc. For further information, see note on *Brassing* and Mr. J. T. Sprague's remarks on the deposition of alloys.

Bronzing Electro-Brassed Work.—When it is intended to impart an ornamental effect to electro-brassed work by means of certain stains and varnishes, the process is termed "bronzing." The effects named below are produced as follows:—

Warm Bronze.—When a warm bronze or chocolate tint is desired on brass, it should be painted with a mixture composed of blacklead, 1 oz.; Sienna powder, 2 oz.; rouge, ½ oz.; made into a paste with a little water, to which has been added a few drops of sulphide of ammonium, or of chloride of platinum solution. The proportions of the various ingredients may be varied to suit the taste of the artist, just as he may desire to have a dark or a ruddy tone on the brass.

Black Bronze effects are produced by painting the brass with chloride of platinum dissolved in spirits of wine; or a mixture of blacklead with the chloride of platinum solution; or the same ingredient made into a paste with sulphide of ammonium solution. Mr. Watt prefers the platinum solution, because it produces a more brilliant and lasting effect.

Steel Bronze effects are produced by slightly heating the articles after being painted with the chloride of platinum solution used for black bronze.

Green Bronze.—A mixture for producing green bronze tints on electro-brassed work, is composed of chromate of lead (chrome yellow), 2 oz.; Prussian blue, 2 oz.; plumbago, ½ lb.; Sienna powder, ¼ lb.; lac carmine, ¼ lb.; made into a paste with water containing a small quantity of sulphide of ammonium, or of chloride of platinum.

Green Antique Bronze. — These effects may be produced by smearing the brassed articles with a mixture composed of acetate of copper, 10 parts; cream of tartar, 10 parts; common salt, 10 parts; carbonate of ammonia, or muriate of ammonia, 30 parts; dissolved in 100 parts of acetic acid, or in 200 parts of good vinegar. To this add a little water and mix well. The parts painted with this mixture must be allowed to dry at an ordinary temperature, and at the end of some twenty-four or forty-eight hours will be found to be covered with a green verdigris. This must be brushed with a soft brush previously rubbed on a lump of beeswax. A blue shade may be given to parts of the work by touching them with a little dilute ammonia liquor, and the green tints may be deepened by touching them with a solution of ammonia carbonate. As the dry powder brushed off from this dried bronzing mixture is poisonous, the workman should wear a piece of muslin over the mouth and nostrils whilst polishing work that has been coated with bronzing powders. The first four mixtures mentioned above should be polished with a soft long-haired brush when nearly dry. If it is desired to show the brass in parts, these may be touched up afterwards with a piece of chamois leather dipped in spirits of wine and rubbed on a lump of chalk or whiting. When finished, the work may be made moderately warm and varnished thinly with a quick-drying hard varnish.

PANELS IN GESSO WORK.

BY E. C.

PANELS may be put to so many uses that amateurs can hardly do better than decorate some for the sake of practice. Few persons, especially non-professionals, care to throw aside all their early attempts in any art-work. Unless, as students, they are resolved to go thoroughly in for any particular branch of art, when their work for a time consists of "studies" only, they prefer to utilise, as far as possible, all they do. And, indeed, the gesso worker who has a fair knowledge of drawing and painting already, will be unlikely to fail, even in his earliest productions.

Still, the panel is advisable to commence on. It is not heart-rending if it does not prove altogether presentable when finished; it is, or may be, small, and so takes little time to decorate; whilst the problem where to place it if the decoration is satisfactory is easily solved.

Here are a few positions which a panel decorated in gesso will fill with advantage: it will greatly improve the appearance of a door of a cabinet, and, if small borders are added about an inch or so beyond the outer edge of the panel, leaving a narrow band of plain wood between, the richness of effect will be enhanced. Naturally the design of the borders must be in keeping with the centre piece, and the separation will be increased or diminished according to the size of door. A bracket cupboard used for medicine or for books will be far more attractive if a well-executed "gessoed" panel is introduced in the door in place of the plain or commonly carved one often seen in these useful articles.

Some very inexpensive standing corner cupboards are to be bought now made of plain wood, and ready for staining or enamelling. The adaptation of an artistically designed panel would be the making of one of these, and turn it into an object worthy to figure in a handsomely furnished room. It will possess an interest through being the work of the owner that it could never have if merely purchased complete for use; but, then, the panel must be well done, or I, for one, would infinitely prefer that it should remain without ornamentation of any kind. Then there is the mahogany coal box with its sloping door, that might well be beautified by a good design in gesso; the fire-screen, with its one, two, or three panels; the flower-stand with panels in lieu of tiles; the fancy ebonised writing table, that might have a long narrow panel extending across the upright back, and the drawers enriched with delicate diaper patterns. And when a high standard is reached, the artist may execute panels bearing figure subjects that will be of sufficient interest to frame and hang on a wall. For there are pictorial effects to be secured of no mean worth by clever gesso workers.

I will now suggest two or three styles in which the accompanying illustrations can be carried out. Fig. 1 shows how gesso work can be employed with charming results for the decoration of a fire-screen. If we have a fancy for producing something uncommon, here is a fine opportunity. The framework of the screen is of white enamelled wood, and the carved mount of the gesso panels stained rosewood or mahogany. The combination of white enamel and mahogany will be found extremely pleasing; it is seldom seen, though now and again first-class decorators indulge in its use. Perhaps its rarity is in some respects a good thing, for unless due regard is taken of its surroundings, it may prove anything but attractive. As a foil to gesso work it is admirable.

Fig. 1.—Fire-Screen, Central Panel in Gesso Work, set in Carved Frame.

The whole of the panel should be laid with gesso, then the figure, birds, and foliage carefully modelled, the highest relief being reserved for the figure. The latter requires the greatest care, for by the manner in which it is rendered the skill of the artist will be judged. Colour may hide a multitude of sins, but cannot atone for inaccurate modelling. When the gesso is ready for tinting the figure may be treated first, though it is well not to finish it entirely until the foliage is somewhat advanced, as the tints react on one another, and we cannot produce a perfect harmony unless we work up all the subject gradually.

In a replica we can, of course, follow either plan. The first scheme of colour I propose is white, green, and gold, with touches of copper red. The drapery is white with soft reflections shown in th folds, the foliage a delicate gree veined with gold; in the frui and in the pot the touches o copper red are introduced; whils the plumage of the birds is give in tints of gold with copper re The ground is of gold, pure an simple, without a hint of coppe

It must be remembered tha gesso work is in its essence decorative art, and we must n attempt to portray naturalist effects; in the colouring w should fail utterly were we t try to follow Nature servilel A conventional decoration is wh we should aim at if we wish t be successful.

Now for the second suggestic for Fig. 1, which I must giv briefly: For the drapery use tl beautiful copper red tint; for tl foliage, emerald veined wit gold; repeat the copper red in modified tint in the pot, frui and birds, or let the foliage l rendered in copper and the p and birds in a bluish purp tint; and, lastly, gild the bac ground.

For Fig. 2 I should recommen that the dragons be wrought o in gold, the wings commenci with blue that is presently lo in purple, and continued in gol and copper; the ground in silve In modelling the wings of tl dragons cotton-wool will be foun to produce a delicate cobwebl texture that is wonderfully effe tive, and I cannot too strong advise the worker to try There probably will be a litt difficulty experienced in manipulating it at first, but the greater the cred when success is attained, and patient e deavour is never thrown away. We *mu* succeed if we resolve to do so.

Fig. 2.—Panel in Gesso Work: Dragons Guarding the Sacred Tree.

That the studen may acquire tl habit of working different styles, l should practise orn menting stained an polished wood. this decoration would have the reli lower than in the la mentioned, and tl painting principal relied on for attai ing an effective pie of gesso work. Tl amateur worker making his or h first essay in ges work may not l pleased with tl effect produce This, however, is tl natural outcome want of experien and lack of practic I am sure that little steady, pain taking, conscientio work will give bett and better result and eventually cau considerable pleasu in following up th branch of decorati art.

THE DULCIMER, AND HOW TO BUILD ONE.

BY R. F.

VENEERING, VARNISHING, STRINGING, AND TUNING.

HE back facing having been fitted, the ioulding has to be placed round the belly. he best kind of moulding to use for this urpose is a plain one, which can easily be iade by taking a piece of 1 in. stuff and iaking a half-round bead, which is then it off and divided down the centre (Fig. 5). When your moulding is ready, fit it irefully into its place, commencing with ie longest side, and glue and fasten it own with $\frac{7}{8}$ in. brads—of course, taking ire to bore the holes for the brads first.

Now we are ready for the veneering. 'rocure a piece of mahogany, walnut, or ny other veneer that suits your incy, and cut strips rather longer and ider than the facings of your intrument, and, having gone over he facings with a toothing plane (first noting that the screws are well below the surface), glue on with the best glue, and, squeezing and pressing out as much of the glue as possible, weight down, and allow to dry. When dry, the top edges may be veneered, and, after allowing another interval to elapse, may be cleaned off and gone over with a scraper. We have now a most important part of the work before us, viz., the "setting out" of the blocks for the "wrest" and "hitch-pins." Four lines, at distances of $\frac{1}{2}$ in. from each other, must be drawn from top to bottom of the centre of each block, and on the front, or inner, line of the right-hand block, at a distance of 2 in. from the front, make a dot, and another dot on the same line, at a distance of $1\frac{1}{2}$ in. from the back edge. Now divide the distance between these two into exactly nineteen spaces (twenty dots in all); $\frac{1}{8}$ in. higher on line No. 2 commence another series, and the same with Nos. 3 and 4. The hitch-pin block is marked in the same manner, but in the reverse order, the lowest dot coming on the *outside* line (Fig. 9).

The next operation is that of polishing or varnishing. I prefer polishing, as it stands better, and gives a brighter finish; but, if it is intended to varnish, first go over the belly carefully with Stephens' Ebony Stain, taking care not to come above the level of the blocks. Stain also inside the sound-holes as far as you can, and also the *back* of the blocks, and for about an inch round the outer edge of the back itself. When dry, if the colour is satisfactory, give a coat all over with size, made of glue one part, *warm* water six parts, and, when this is firmly set, varnish with good copal, which must be very lightly and evenly applied; and then the instrument may be set on one side for a few days for the varnish to get thoroughly set and hard.

While all these drying operations are going on, opportunities are afforded for getting out the wrest-pins, the hitch-pins, the bridges, the sound-hole frets or rings, the feet, and the stand; and here I may as well say that all these are better and cheaper bought ready-made, as they take some amount of time and patience in preparing. Messrs. Chilvers & Co., St. Stephen's, Norwich, supply every requisite at a very cheap rate. But we will suppose that you have both these indispensables at command; very well, commence then with the wrest-pins. Of these, eighty will be required. Get a piece of No. 6 B.W.G.—by-the-bye, this means Birmingham Wire Gauge—iron wire of the necessary length—that is, about 12 ft.—and cut it into $1\frac{3}{4}$ in. lengths, either with a hard chisel and hammer, with a hack-saw, or the sharp edge of a half-round file. Round up the top and bottom of these lengths, and file one end taper on both sides for about $\frac{1}{2}$ in. down. At the bottom of the taper thus formed, drill a small hole to receive the end of the string. Thread these pins on a piece of wire, and stretch it between two points, and black them for about half their length with Brunswick black, and the pin is complete (Fig. 8). The greatest difficulty will be in drilling the holes, and, if this is beyond you, a simpler plan can be adopted by using loops of thread, which method I will explain when we come to the stringing. The sound-hole frets are simply ornamental rings turned to fit the sound-holes, but are very often filled in with fretwork, carved work, inlaid stars, or other designs. The bridges (Fig. 11) are made of beech, turned as shown, and cut on the dotted lines with a chisel. Across the edge thus formed a V-shaped groove is made to take a piece of brass wire for the strings to pass over. These bridges may be either varnished in the natural colour, bronzed, or gilded. The feet are four flat balls of 1 in. diameter and $\frac{3}{4}$ in. thick, and are screwed on one at each corner of the back, after it has been covered with blue or other coloured paper. The stand is made of $\frac{3}{8}$ in. stuff, veneered on both sides *diagonally*, so that the grain of one side crosses that of the other, and both run in a different direction to that of the wood. The stand is 9 in. long and 5 in. high, and may be shaped to fancy; that usually adopted is shown at Fig. 10. This is screwed on to the back with a pair of 1 in. butts, at a distance of 2 in. from the back edge. Two pieces of brass wire, $\frac{1}{8}$ in. diameter, will be wanted for the grooves in the blocks, and about 2 ft. of No. 18 brass for the tops of the bridges. Also get a yard of velvet ribbon, about $\frac{1}{4}$ in. wide, for the block dampers. Cut off your brass wire to exactly the length of the grooves in the blocks, round up the ends, and polish them. *Outside* these fasten lightly with small tacks strips of your ribbon, one on each block. Cut off forty pieces of the No. 18 brass wire; file the ends level and to fit the tops of bridges. Fit and glue in your sound-hole frets or rings, and proceed to ornament the belly. This so obviously depends upon your own taste and style that I need hardly say a word about it, except that you must be sure that the varnish is *perfectly* dry and hard, not in the *slightest* degree tacky, or your gold leaf or bronze powder will assuredly stick where most you *don't* want it. But stop! I am

Fig. 8.—Wrest-Pin (full size). Fig. 9.—Method of "setting out" Blocks for Pinning. Fig. 10.—Stand. Fig. 11.—Bridge (full size). Fig. 12.—Diagram, showing Scale and Approximate Position of Bridge. Fig. 13.—Eye for String. Fig. 14.—Pin properly wound (A) and badly wound (B). Fig. 15.—Mode of making Moulding round Belly.

running on too fast—our blocks are not yet pinned. Well, then, just remove those pieces of ribbon again, and commence to bore the wrest-pin block. No. 6 wire measures $\frac{3}{16}$ in. diameter, consequently you must have holes considerably smaller than this for your pegs to work in, or in a very short time, what with the tuning and the pressure caused by the "draught" of the strings, they would soon work loose and the "pitch" run down. Take, therefore, a $\frac{5}{32}$ in. spoon bit, and on it fit a "stop" that leaves exactly 1 in. of the bit for boring. This stop may be made either by boring a hole lengthways through a piece of wood which is allowed to remain on the bit, and which leaves the necessary 1 in. protruding; or by binding three or four turns of copper wire round the bit in the place required. This stop is necessary to regulate the depth of the holes. Start by boring the lowest hole, and be very careful to hold the bit at right angles to the *face* of the block. When the first hole is bored, place in it a piece of wood like a small pencil, about $2\frac{1}{2}$ in. long, which just fits sufficiently tight to be easily shifted. This is to act as a guide for the boring of the succeeding holes, and should be shifted as each is bored, or you will have an irregular arrangement which will not add to the appearance of the instrument. When all are bored out, they must be *slightly* countersunk and the borings carefully removed; they are then ready to receive the pins, which must be *turned* not *hammered* in. This is done with the tuning key.

The hitch-pins are made of brass or iron wire, $\frac{3}{32}$ in. diameter, pointed at one end, and are $\frac{3}{4}$ in. long. A hole is bored with a small bradawl for about $\frac{1}{4}$ in. into the block, and the pin is then driven in till $\frac{1}{4}$ in. is left out. Then go over the tops with a large flat file, so as to get them all quite level, and the instrument is ready for stringing. The blocks may be bored and pinned at any time, but it is better to put it off till after the polishing is done, so as to avoid the possibility of any grease getting into the holes. Get 2 oz. of No. 9 brass wire and 1 oz. No. 8, 2 oz. No. 8 steel and 1 oz. No. 7. This is M.W.G. (music wire gauge). If your wrest-pins are drilled, well and good. If not, make a loop of black thread $1\frac{1}{2}$ in. long, and fasten on each pin at a distance of $\frac{1}{2}$ in. from the top, by passing the loop round the pin and threading the knotted end through it. When the pin is turned to the right this loop will tighten up and gather round. Now that ribbon may go on again, and the pressure bars be laid in their grooves.

Take the No. 9 brass wire, and, holding it in the left hand, unwind sufficient to make one string and twist an eye $\frac{1}{2}$ in. long; finish this eye off by turning the free end of the wire twice round the string, and cut off this free end, leaving $\frac{1}{4}$ in. of "tail" at right angles (Fig. 13). Put this eye on the hitch-pin, and cut off the string 4 in. beyond the corresponding wrest-pin. If the wrest-pin is drilled, insert the end in the hole so that it just peeps through; if not, make a small hook of the end of the wire and insert in the loop. Turn the pin to the right, and see that the string gathers regularly round (Fig. 14). Arrange so that each succeeding string lies on the "tail" of the previous one, and, when the note is complete, place a bridge under it (with one of the pieces of wire previously prepared on top), at a distance of $2\frac{1}{2}$ in. from the right side. Use No. 9 brass wire for the first five notes, and finish the remaining five with No. 8. Get all the brass strings on first, and be careful not to put them on the pegs intended for the steel.

The steel strings are put on in precisely the same manner, and the first bridge is placed *about* 10 in. from the left-hand side. Its *true* position cannot be determined until the instrument is tuned. The row of bridges under the brass strings should stand in a line parallel with the block, but those under the steel strings follow a somewhat erratic course, owing to the intervals into which they divide the strings being unequal. The *scale* is shown at Fig. 12, and also the *approximate* places for the bridges. If when the instrument is raised to pitch the notes given do not exactly correspond with the notes shown in the scale, the bridges must be shifted to right or left till the correct place is found. All that is now required is a pair of sticks or beaters to play the instrument with. Take a piece of stoutish cane, about 15 in. long, and split it into four lengthwise; taper these gradually along their whole length till the thinnest end will easily curl round into an oval; fasten this with strong thread, and round the lower side for about 2 in. bind Berlin wool or yarn till the required degree of softness is obtained. Fasten off with thread, and cut the beater to a length of 11 in. from bow to butt. It is as well to have two pairs, one clothed more lightly than the other, as with these a different quality of tone can be obtained.

One word as to preserving the instrument. It is almost essential that a wood case be made for it, as not only does it keep damp and dust away, but it also makes an excellent resonator to stand the instrument upon when playing; and it is *quite* essential that it be kept as free from dust as possible, and never put it away after using without first wiping the strings with a soft rag to remove any damp that may have got on.

One more—keep it well up to pitch, and don't allow it to get out of tune.

HINTS TO YOUNG JOINERS ON SETTING OUT AND MORTISING.

BY B. A. BAXTER.

The readers of Work remember some hints on planing which appeared a short time ago. I should like to explain how the preceding hints may be made useful, and carry forward the instruction given into the region of practical joinery.

We have all read with interest and profit the explanation of plain, tongued, and dowelled joints, and it is unnecessary to repeat instructions given so recently; any of my fellow readers who have not read those articles, are recommended to do so at their earliest convenience.

The beginner, however, ought not to be discouraged if he cannot succeed at first in making a plain joint; when he can do so, he is considerably advanced towards being a practical workman.

The chief difference between preparing stuff for frames, etc., and joining boards, is in the use of the square. It matters nothing if the edges of a joined board were not square when glued together, if only the angle of one is complementary to the other; therefore, in shooting, the same ends of the boards are kept towards the same ends of the bench—the face sides of the boards are in *one* case towards the bench when in the screw, and in the *other* towards the workman.

If upon trial the boards are not in the same plane, the angle must be altered; if the boards appear to stand correctly on trial, care must be taken that the plane is set truly, or by the time the boards are in contact all along (which is of course to be secured) the angle will be incorrect, and the boards when glued will be very much as in Fig. 1.

Now in preparing wood for mortising, we must adopt a plan. First plane one of the largest surfaces truly, mark it, and "shoot" one edge squarely, using the square frequently to test the accuracy of the work. It is of the greatest importance to the beginner to commence rightly.

The reason why he is recommended to carefully surface one of the largest sides of his timber is because he needs to have a data, a starting-point, a standard to which to refer. In all the arts this is the same. The musician must have his standard of pitch and his key-note. The optician must determine on some standard that he may compare various refractive media to each other. The surveyor must have his bench marks, and the artist his horizontal line. The joiner's best plan is to get one surface as accurate as possible, in order that by the aid of squares and gauges he may get the other surfaces true also. Always put a mark on the tried surface.

We will suppose this done, and having set our marking gauges, one to the width and the other to the thickness, and that we have marked with a pencil the already prepared surfaces, mark with gauges and reduce to the stroke, principally or entirely, with jack plane. If there are any mouldings to be "stuck" or grooves to be "ploughed," be careful to select the shot edge and the face side with a view to smooth and satisfactory finish, which will be secured by noticing the direction of the grain; it makes an immense difference to the ease and the appearance of the work of moulding if this is always remembered.

To set out "styles," that is the upright members of a framing, place them *face to face*, the inner edges the same way, which secures the top ends being together; the places for the rails can then be marked on the edges of one pair, or several pairs at once, with a square and pencil or striking-out knife.

The rails do not always so absolutely require being face to face, but it is better to place them so, especially if there are muntings, sash bars, etc., to be inserted. In the case of work with moulded edges, the place for the mortise must be determined by the moulding: the square central portion on the edge of the frame must contain the mortise, unless indeed the whole of the moulding can be cut away where the joints occur. In such a case two parallel mortises can be made, but it is never necessary unless the work is over two inches in thickness.

If there are panels in the framing, then the size of the mortise ought to depend upon the thickness of the panel, or, more correctly, upon the groove into which the panel is inserted. May I repeat in other words? The distance of the first or nearest stroke of the mortise gauge from the face side depends on any moulding that be used; the distance of the second depends upon the size of the chisel used, which should be the same as the width of the plough-groove, if any is present.

In setting out the rails, if any moulding is present, the shoulders wherever the moulding intersects must be as much longer as the moulding reduces the "styles," and the net width of the styles subtracted from the finished width will be the guide to the actual dimensions required. The best plan to set out a framing is to draw on a strip of wood a section of the length, and on the reverse side a section of the width to a scale of 12 in. to the foot, being careful to put in all panels, grooves, mouldings, muntings, rebates, etc.: having done this, the dimensions of the shoulders can be seen at once.

Having determined the position and width of the mortise, we will examine the chisel and see if it is in good condition; if not a visit to the grindstone is advisable, for a mortise cannot be made well by a beginner, unless the whole of the conditions are favourable.

The chisel should be ground so that the ground surface is flat or hollow, the edge square and straight, and the angle produced by rubbing on the oilstone not very different from the ground portion.

The angle between the ground portion and the back of the chisel should have no burr or roughness, and the extreme edges may be rubbed enough to remove any roughness that may be left from the grindstone. Our first endeavour to make a mortise can now be made. A mortise is a rectangular chamber excavated in a piece of wood, generally for the insertion of a "tenon"; the chisel usually gives the width of the mortise, and the mortise may be of any length or depth.

In this, as in every mechanical operation, attitude is of importance. Every one knows that a circular disc does not appear to have a circular boundary unless every portion of the outline is equally drawn from the eye; we all know that a circle drawn on a piece of paper and viewed obliquely gives the appearance of an ellipse. We know too that any three points may be regarded as in one plane, or in other words a plane surface (of suitable dimensions) may be adjusted to touch any three points wherever they may be placed. Now apply these two pieces of knowledge to our humble operation of making a mortise.

Let the centre line of the tool be imagined, and the centre line of the mortise be also either drawn or imagined; these should cross each other at right angles. When the tool is in a correct position to cut, the eye of the workman should be in the same plane as the two imaginary lines we have supposed.

Have I made myself clear in this description? Let me try once more. Stretch a chalk line between two points; at any point on the line stretch another to a point above, or preferably, let a plumb-line cut the horizontal chalk line. You *can* stand so that these two lines range in one line; when it is your habit to do so, you have learnt the true attitude to assume with respect to a mortise.

I fear I have not made this important matter quite clear, but those who already grasp my meaning will, I hope, pardon my effort to make it more simple.

Let us try a simple experiment: Take a piece of wood, draw on it a straight line, on this line stick a straight wire—a mattress needle or a long knitting pin will do; let us now light a lamp or a candle; the needle will cast a shadow which by a little adjustment can be made to lie along the line; the flame of the candle is now in the plane of both the lines; if the learner stick the pin obliquely, he will find it is still possible to make the shadow range, but in that case the light is not *on* or *over* the central line we have supposed, as it ought to be. No beginner can *rely* on making a true mortise unless he can assume this position, in which he can see the direction of his chisel.

There is one other consideration which ought to be mentioned, that is, that if the edges of the wood are not square (and some workmen leave the outer edges to be planed to finished sizes after the work is glued up), the mortise may be made apparently true, perpendicular to the bench or mortise stool, and yet, because the work is not properly prepared, the mortise is not parallel to the face of the work, as it should be.

Fig. 1.

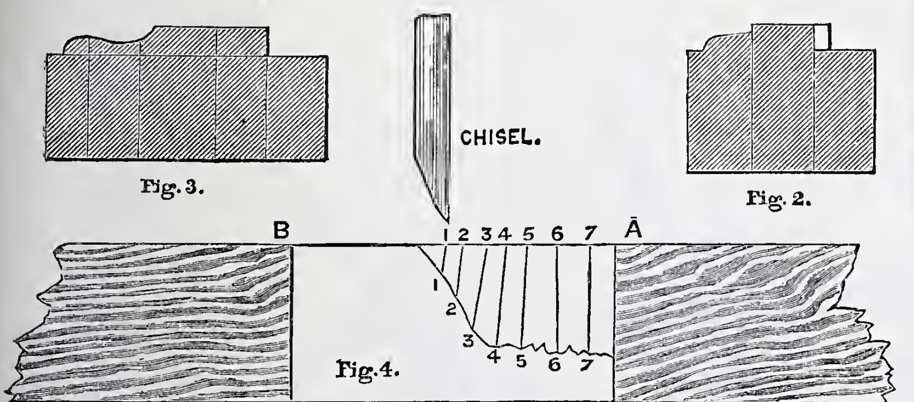

Fig. 3. Fig. 2. Fig. 4.

Fig. 1.—Section of Boards badly joined. Fig. 2.—Section of Sash Mortise situated between Moulding and Rebate. Fig. 3.—Section of Sash Style having Double Mortise. Fig. 4.—Diagram showing how to begin Mortise in Middle, cutting towards end A: reverse Chisel and cut from Centre to B.

Now a few words on the actual work, the manual part I mean. Beginners invariably make their mortises somewhat larger than they intend, because they scatter their energy over the whole mortise, and the core is an embarrassment to them. Let me advise a method. Begin the mortise in the middle, making the two first cuts remove a small piece of the core, then taking cuts towards one end about $\frac{1}{4}$ in. at each cut, and as soon as possible take each cut as deep as necessary; the flat side of the chisel is to be towards the end of the mortise to which you are proceeding. Having arrived at the line, turn the chisel; again begin in the middle, and advance in like manner to the other extremity.

Let the diagram given in Fig. 4 represent a section of the mortise, and the figures the results of each stroke.

I am supposing you can turn the style to finish from the other side. The cut marked 1 may be deepened from time to time; this will remove the core, so that when the mortise is finished, there will not be much left, and what there is will be in the middle, where it is most easily removed. If the mortise is right through, it is better to use a core-driver than to pick out the core with a chisel or other tool, but if it does not go right through, use a sharp chisel somewhat smaller than the mortise chisel.

Mortises that are intended for a tenon that passes through the style usually have the outer portion enlarged for wedging, not of course in width, but in the length; this enlargement for the wedges ought to be a very gentle taper, because taper wedges hold better than abrupt ones. An engineer's key in a cog wheel may serve as an excellent example, or the wedge of a plane is about a correct angle for wedge of tenon; these wedges, when glued and driven, convert the tenon into a dovetail, and also give a little opportunity of adjustment in putting together the work.

It is not always necessary that the tenon should go through; in such cases, care should be taken as to the direction of the mortise; neglect of this would, in case of narrow bars like sash bars, cause them to appear bent; in fact, would bend them.

Although I have said that the size of the mortise depends upon the size of the plough-groove (if present), and the position upon the size of any moulding that may be worked upon the styles, yet the cutting of the mortises is not to be left until these operations are accomplished. The mortises are best cut before either are done, although of course allowances are necessary to be made according to these. If our pupil will draw on the inner edge of styles a section of each rail in its right position, he will not be likely to make any mistake in the planning of his mortises. Every groove, rebate, moulding, etc., should be drawn, and it would be well if a section of styles, muntings, or bars were similarly drawn upon the rails—this would at once give the shoulders, and suggest where either mitring or scribing is necessary.

In all this, I have supposed that the beginner has ordinary woods to deal with, for many woodworkers, as coachbuilders, etc., do not make mortises in this manner. Among these a mortise is formed after marking out by boring away as much as possible of the timber from the centre of the mortise and paring the rest away with sharp chisels. This method is excellent for ash, oak, beech, or other hard woods, saving a large amount of work with the mallet, but a learner must exercise all his care or he will pare away too much in finishing.

About cutting tenons I shall say nothing at present, but our little experiment with the light, line, and needle may again be useful. The shoulders of the tenons in careful work ought to be marked with a knife or chisel, and the tenon saw kept the right side of the line, that is to leave the knife-cut line to form the actual joint, otherwise the saw kerf robs the length of the rail by an amount equal to its thickness.

If any question arises as to insufficient description or unintelligible explanation, it will be welcome, as many of these operations are more easily performed than explained.

In Figs. 2 and 3 are represented, in section, a single and double sash mortise. I have said that the shoulders of tenons should be marked with a knife or chisel. A chisel is, perhaps, the handiest tool by far for this kind of work for the skilled workman, but for amateurs of average capacity, an old dinner or dessert knife that has been broken across the blade, about the middle, leaving a square, or almost square, end to the blade, will be found excellent as a marker.

THE BROOCH: HOW TO MAKE IT.

BY H. S. GOLDSMITH.

BROOCH TONGUES.

THIS is the first of a series of papers on matters connected with the manufacture of jewellery and goldsmiths' work, and it is devoted to the consideration of the making of brooch tongues.

But before I enter on the subject I have chosen for my initial article, I think it will be desirable to put clearly before my readers the objects and aim that I have in view in writing these papers.

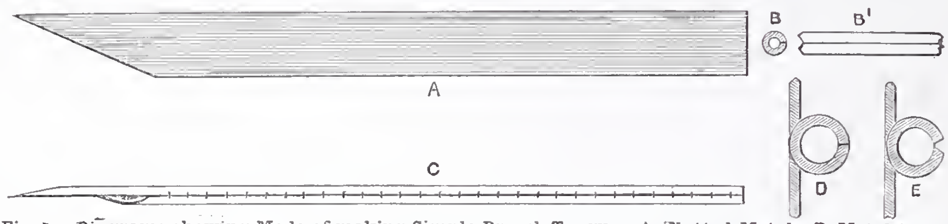

Fig. 1.—Diagrams showing Mode of making Simple Brooch Tongue—A, Flatted Metal; B, Metal turned up, transverse section; B', Ditto, Elevation showing Joint; C, Tongue complete; D, Joint rightly made; E, Joint badly made.

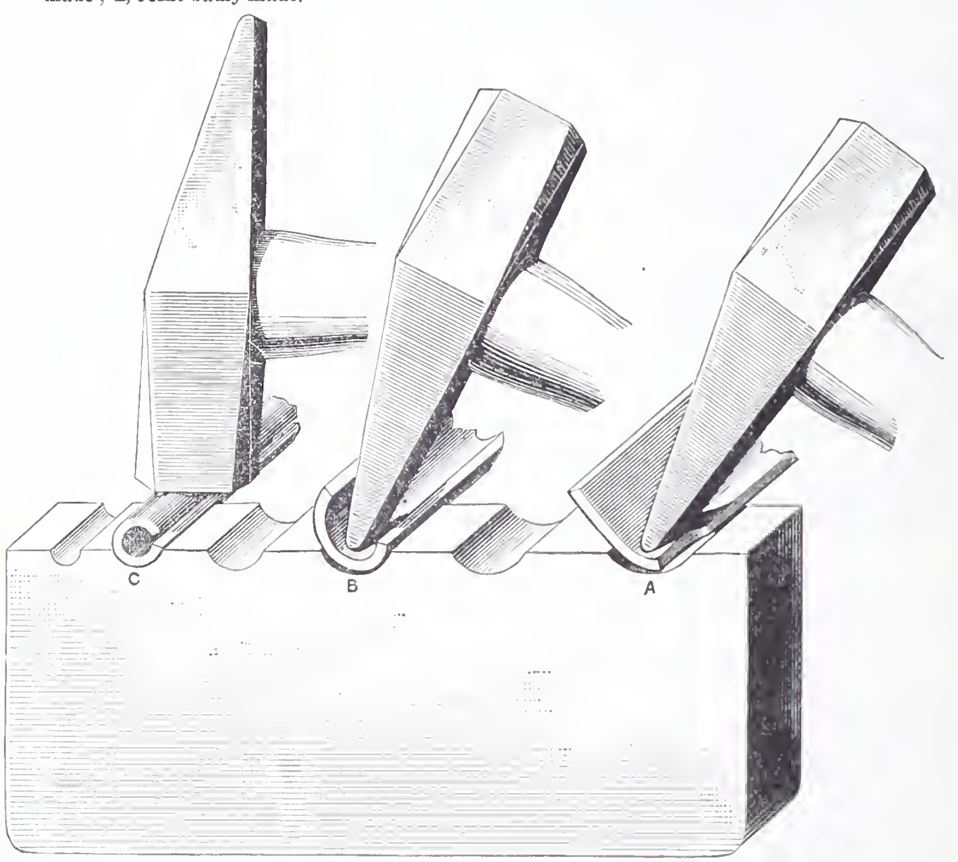

Fig. 2.—Hammering Plate on Bending Block in First Stage (A), Second Stage (B), and Third Stage (C).

In the first place, the objects are to help the younger members in the knowledge of their trade, and to give them some of the principles on which they should set about their work.

The method will be that of describing the manufacture of every-day articles, beginning with the simplest, and gradually advancing until we get to important pieces of work, such as, for example, bracelets and tiaras in gem work, and caskets, etc. etc., in all gold work.

My aim is to interest and, I hope, to instruct those who wish to improve themselves in the art of manufacturing jewellery and goldsmiths' work of every kind.

If I were to ask ten of my fellow-workmen what was the first article that they tried to make or were taught to make, I feel sure that nine would say in reply: a brooch tongue; and as we must make a beginning somewhere, I thought that would do as well as anything to start with.

Everybody knows what they are, and that they can be bought ready-made for very little money; but the fact of being able to *buy* things used in our trade will not carry much weight with the writer of these papers, for he holds that a workman should thoroughly know how to do things right out, from start to finish; not that we shall always have to do the things treated on, but that the knowledge *how* to do these things is useful knowledge, and, what is more important still, we shall be gaining experience in the materials in which we have to gain our living.

What sort of a living that will be depends on the things we have been taught *and learnt*, on the things we have picked up from fellow-workmen and from books, and the uses to which all these can be put. Therefore you apprentices, for whom these papers are principally written, not only get all the knowledge you can, but try and *think* about your work as well, for it is the lining of your head that will either bring you profit or the reverse—according to the way you have packed it yourself.

First of all, our materials to make the simplest brooch tongue are tubing, or chenier and wire.

The chenier will be made from flat plate of a thickness suitable to the size tube required—it is rarely as thin as size 3, Shakespear Gauge, and may be made size 10, or even size 15 for very large brooches, where a fancy shape such as a barley-corn joint is used.

Our piece of metal, either gold, silver, German silver, etc., will be first flattened to a suitable thickness. Secondly, cut to length and width required, as in A in Fig. 1. The width of plate is easily calculated by making our plate three times the width the tube is to be, or—to put it in another way—the plate is as wide as three diameters of the chenier. Cut the end off as in A in Fig. 1: make it perfectly flat, and with the borders quite parallel. While filing to regulate the borders, you can at the same time take a little more off the inner edge (Fig. 1, C), so that when the plate is turned up we shall get it to draw quite close, as shown in the same diagram (Fig. 1, D), and not like Fig. 1, E, as it will be sure to come if no provision is made for the different diameters, inside and outside of tube.

This direction is not of much importance in small chenier, but it is very necessary to have that allowance made in large chenier, in order to avoid that sign of bad workmanship. I mean filling up with solder. (I wonder how many of my readers have done that, not thinking it would be noticed by the master—but it was, wasn't it ?) Now that our plate is quite flat and true, and with this level properly made, we will proceed to make it into chenier by the aid of a hammer and bending block.

This bending block is usually of hard wood or horn for small work, while for larger and heavier sizes, bronze, brass, or iron is necessary. It is merely grooved out in varying sizes, as Figs. 2 and 3, and is held in the large vice, or else the bottom of a sparrow-hawk block is grooved out and used.

Fig. 2, A, B, and C, gives the position and successive stages of formation; the only remarks I have to make in addition are first, that the metal should have been annealed; second, that the edges are got up before the centre; third, that the pane of the hammer is of a nice rounding form, and not sharp at the ends, where it might cause some nasty dents.

Fig. 3, A and B, is the wrong way of making this chenier. It is easy to see that the outside edges will get reduced considerably before the draw-plate is able to get our tube round on the outside, and even then the hole, instead of being round, will retain some of the pear shape it originally had. No amount of clearing the hole out with a joint-brooch will correct it, and altogether we shall not be able to get a smooth working joint, as we should do, and such as we do get, when the tubing is properly made. Chenier drawn over a mandrel will be dealt with later on, when we come to consider joints of boxes, lockets, etc.

In order to finish our chenier ready for soldering on, it should now only require to be drawn through a few holes in a draw-plate to get it to our size.

Perhaps even during this process we may find that the point is too weak to stand the strain of drawing down. If that is the case, we shall have to strengthen it by soldering it up, or else by introducing a piece of wire.

ıd soldering that as well. 'ou must use your own ıdgment whether the latter ıethod is necessary; gene- ılly, neither is required for ıe common run of brooch ɔint.

It is then annealed in rder to clean it from any rease it may have picked p in its passage through ıe draw-plate, and put in ıe pickle (vitriol, 1 part; vater, about 30 parts). Varm is best, but cold will o if you are not waiting for our work. Take it out of pickle" when clean, rinse ; well in clean water, and ry it. If the metal we are vorking is rather hard, it vould be as well to tie everal pieces of iron bind- ng-wire round it in order o keep the seam closed up; r else, as we shall do later n, to wind iron binding- vire all round from one end o the other.

After drying it, score it ıcross the join or soldering eam with a saw or three- quare file, like Fig. 1, C, when t will be ready for use.

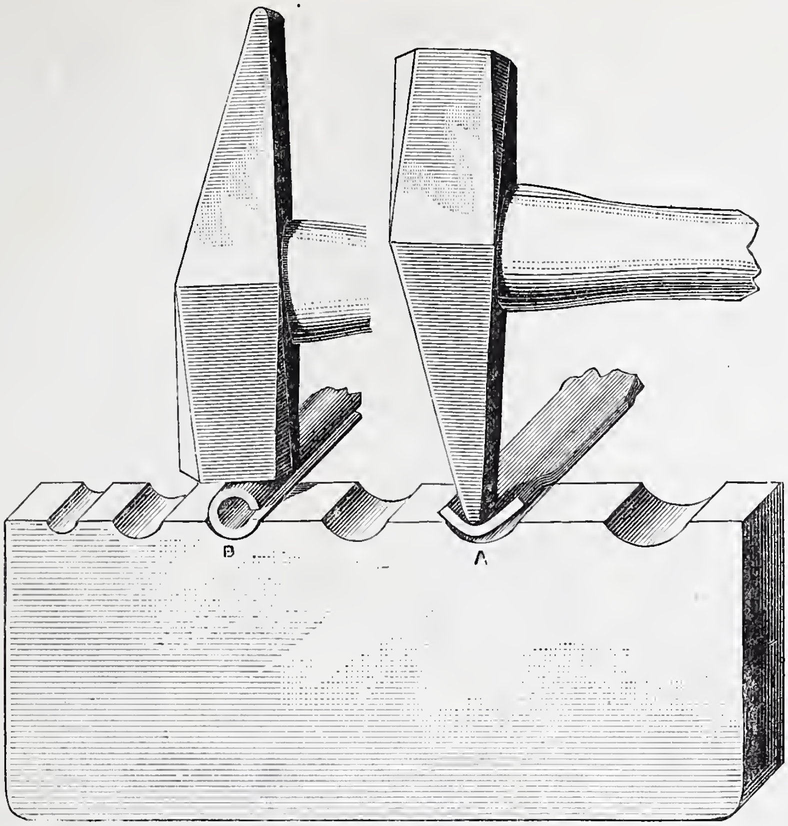

Fig. 3.—Diagram exemplifying at A and B the wrong way of making Chenier.

The wire out of which we ıre to fashion the tongue hould be drawn down to he proper size, and should ıot have been annealed for the last six to welve holes, so as to have it rather hard.

Now to make the tongue, which, after all, onsists merely of soldering a piece of wire ɔn a piece of tube. Cut a piece off the henier and place it on a piece of flat charcoal ɔr pumice-stone, in which a notch has been ut or filed to keep it from running away; ınd see that the seam is just where the wire vill cross it (Fig 4, B), and that this part is craped clean, else the solder will not hold.

The part of the wire that crosses the henier should be hammered just a little, so as to get a slight flat surface to rest on the chenier. Scrape the part that comes in contact perfectly clean, and then proceed to solder it, only don't make it red hot all along. Remember that we have drawn it down hard, for a reason that will appear presently.

Having soldered it, I hope you have done this without filling up the hole with solder. You can always prevent this by placing a single horse hair through the hole. It will not be necessary after a time, but new hands do the very things you do not want them to do whenever you give them the slightest opportunity to go wrong.

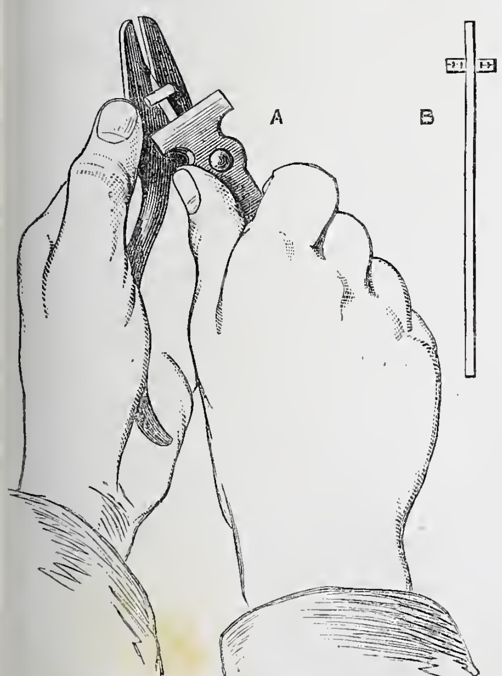

Fig. 4.—Twisting before Hammering (A); Metal before Twisting with Top attached (B).

Is it necessary to tell you that if your piece of joint is long, you must take care to solder the seam right to the ends; or should I leave such common-sense matters to you? I now and then see this left undone, therefore I here speak of it; but when I do meet with this, I can tell you I don't think much of the fellow that does it—or, rather, that does not do it—he is almost past praying for.

Now to finish the tongue. First it has to be boiled out, or "pickled," to remove the charred borax, etc. Then it has to be hardened, and, thirdly, fitted to the joint, filed up, and given the proper shape ready for the polisher.

The second stage only concerns us now. We have had to pickle the chenier, so you know what that means. And please remember, now and henceforth, that work from the boiling-out pan or pickle pan must always be rinsed in the clean water pan that should stand beside it under the soldering jets; or, if they are fixed to the board, then on the pickle shelf. A good deal of bother would be saved if this were always done.

If the tongue we are making be a 9-carat gold one, merely hammering it round and round on the flat iron, small anvil, sparrow-hawk, or beck iron, or whatever you use in your shop, will be sufficient; but if we are dealing with German silver or gold of a better quality, then it should be twisted (Fig 4, A) as well before we hammer it, else we shall find it is not hard enough. You see in Fig 4 that it is being twisted *only* near where it has been soldered; the other part that is held in the vice was drawn down hard purposely, as you will remember, in order to save trouble in doing work twice over.

The fitting into the joint is so simple that it wants no description; but it will need care and skill, too, to get it to fit well.

Now, as to filing up, it should be given a good shape in section; generally, it is either round or oval, although occasionally I have met with them triangular or bayonet shape.

The points should be filed the shape of Fig. 5, A, B, C, D, E, F, G; not the shape of Fig. 5, H, I, J.

I don't think any words are needed to point out the weakness of Fig. 5, H and I, or the clumsiness and ugliness of J. Just let me whisper that the end should be filed to a *point*, and not left partly done, as you do sometimes.

In reference to the shape or curve (if any) that a tongue should take, the illustrations are surely sufficient, particularly if you remember the work it has to do is like that of a bayonet or sword, not like a corkscrew.

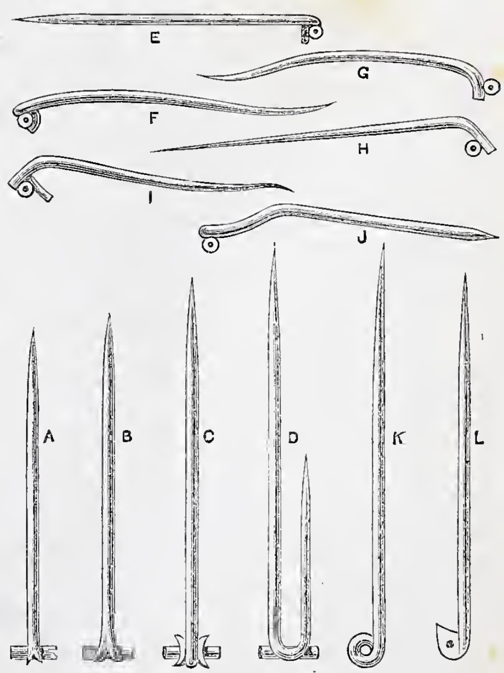

Fig. 5.—Right way of filing Point, A, B, C, D, E, F, G; wrong way of ditto, H, J, K; Wire turned round and soldered, K, L.

It has to pierce, not to wriggle, through cloth or other dress material.

The different ways there shown are all matters of every-day occurrence and explain themselves, with perhaps the exception of the double one shown in Fig. 5, D, which is intended to prevent a top-heavy brooch from tilting forward.

At K, L, in Fig. 5, two brooch pins are shown which are made differently from any of the others spoken of. K is simply the wire turned round and soldered, and this is used with a joint to be shown in the next paper. The illustration to be then given is one form of so-called Etruscan joint.

The pin at L is made with a flat plate, which is afterwards drilled and filed into shape. This also will be further noticed in the paper on joints.

Hardening the tongue should have much more attention given to it than it generally gets; for on the power of the tongue to act as a spring always pressing against the top of the catch the safety of the brooch depends to a very great extent. Perhaps if notice is here taken of this matter it may help us to get these tongues made properly. Surely they are simple enough to do, yet I find many workmen will file up and finish a tongue in great style as far as appearance goes, but the lady, on placing her brooch in her dress for the first time, finds the tongue bend just as though it were made of lead or copper. Such men cannot but know the proper way to make them, but they are not conscientious, and I am afraid set a very bad example to the juniors. Shall I be saying too much if I say that those who skulk their work in these small matters are a disgrace to their trade?

The very men who leave undone the part of the work on which safety so often depends, and which would not take them another five minutes to do, are those that growl and think themselves hardly done by when the foreman recommends the retention of a more conscientious, and may be younger, man in their stead, if it is necessary to choose—as it sometimes is. The one may have less experience, and may not have such an all-round knowledge of work, yet he will improve; while my daily experience as foreman teaches me that a tendency to skulk or shirk once shown will increase until it is almost impossible to suggest that they be given another trial, after they have once been "sacked." It causes trouble to everybody, and I much fear sends them down a few steps lower, and mostly, if my observation is not entirely in error, through their own fault.

On the other hand, I have the pleasure of knowing many members of metal-working or engineering professions whom it has been a real pleasure to work with in their classes for teaching technical matters: they take such an interest in their work. Has the lack of technical education in matters connected with this trade anything to do with the scarcity of really first-class workmen, and the miserable way many of them turn out work just a little different from the usual run? I believe it has, and if the ruling body of the Goldsmiths' Company will only consider the possibility of forming such classes, I feel sure that many who are willing to learn will avail themselves of them; and as for the others who do not want to learn—well, they can go about their own pleasures. All I dare hope for is that opportunities may be given to those wishing to advance themselves, as is done in nearly all other trades except this one. To any one who really takes an interest in his business, the gift of a large sum of money a few months ago for technical classes, which *do not include* ours, by the Goldsmiths' Company causes a great feeling of injustice; and this thought will arise: Are those in authority there in any way connected with the trade? It surely is open to great doubt when they help members of other trades to rise, and by their lack of interest in their own trade they deprive its members of gaining knowledge, which they admit is right in other cases, but not in ours. Surely the trade of goldsmith and jeweller is an artistic and scientific profession, and should be encouraged more than by the few prizes given by the Society of Arts, and others, which are for the highest class of work, and for which there is no opportunity of preparing oneself.

It is the improvement in general work and a knowledge of the principles on which it should be done that is wanted most at the present time, and I regret very much that more powerful pens than mine have not taken the matter up long before this.

Enough of that for the present, but I hope I may be allowed the privilege of writing a few words on other matters to which, I think, attention should be called.

OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

113.—DALE'S NEW CHIMNEY TOP "EJECTOR."

AT this season of the year the wintry winds, blowing in fitful gusts from every quarter, too frequently remind us that we have not yet arrived at anything like perfection in the methods at our command for warming our rooms and getting rid of the smoke that escapes upward from our fuel by reason of imperfect combustion. A composition has been produced with which we are to doctor our coals and render them smokeless at the cost of 1s. 3d. per ton—a most excellent thing in its way, if the results to be obtained from its use are in accordance with the promises made by its proprietors. I have not yet had an opportunity of testing this new substance, but it is my intention to do so, and tell my readers my experience of it, with as little delay as possible. Meanwhile, however, let us consider Dale's New Chimney Top "Ejector," a variety of "tall-boy" which, from its construction, seems likely to facilitate the escape of smoke into the open air without being driven back again by a downward draught to the place whence it has come, to make its way into the room itself, to soil with unburnt carbon and nauseate with its objectionable odour. The external appearance of the "Ejector" is shown in Fig. 1, and a sectional view in Fig. 2. From these its construction and action may be easily understood. The invention, as applied to chimneys or as a ventilator, has for its object improvements in its make for maintaining in either a continuous upward current of air, thereby preventing the down blow by the sudden or accidental cessation or reversal of such current of air. The chimney top itself is made in two parts—namely, the lower or central pipe, A, which is surrounded by an outer or external case, B, sustained by four triangular supports, C, which act as guides or channels to assist the upward current of air between A and B. It will be noticed that the lower end of the upper part, B, is so constructed as to form a cone-shaped projection, and round the central part of the lower portion, A, a piece of zinc is soldered on so as to form another conical projection, the counterpart of the projection above, and placed in a reversed position. The supports, C, are attached to the cones, D, D, and form the connections between the upper and lower portions of the chimney top. Thus between each pair of adjacent supports is a space to admit the ingress of air from whatever quarter the wind may happen to blow. The smoke ascending from below enters the lower portion, A, and makes its way into the upper part, B, in the direction shown by the central arrow, and having attained this point it is driven onwards, upwards and outwards, by the current of air which enters the spaces between the triangular supports, C, and proceeds upwards between the lower and upper parts of the chimney top, as shown by the arrows on each side. Thus the return of smoke down the chimney is prevented, for any downward action of the wind, or down draught, is prevented by the up-rush through the spaces between the supports shown at C, C. Of course, it is not possible to speak with absolute certainty of the performance of any contrivance of this kind without trial, but as far as theory goes it seems all right enough, and sufficiently good to warrant its trial by any one who is unfortunate enough to have a smoky chimney, which has been pronounced incurable. The Chimney Top "Ejector" is the invention of and is made and supplied by Mr. Walter Dale, 22, Malvern Road, Kilburn, London, N.W. It should be said that it can be made to fit any existing chimney pot, or with a square base, as shown in Fig. 1, for building in with brickwork—14 in. by 9 in.—in zinc, or galvanised iron, as the purchaser may prefer.

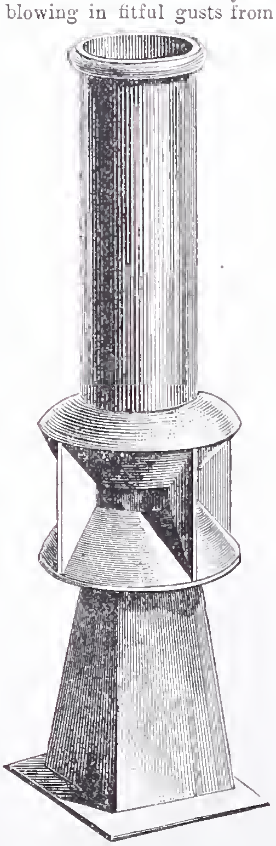

Fig. 1.—Dale's New Chimney Top "Ejector": external view.

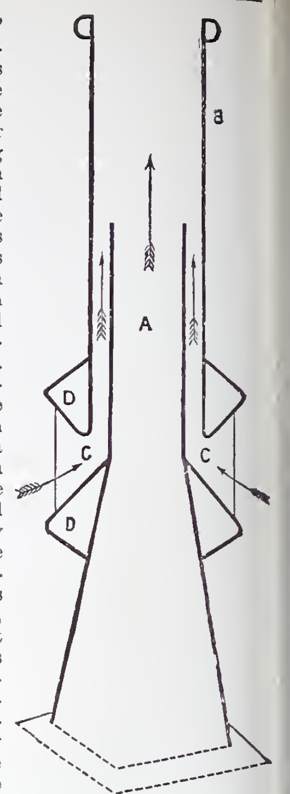

Fig. 2.—Dale's New Chimney Top "Ejector": section.

If any reader has tried the chimney top here described I shall be glad to hear the result of his experience, and to learn if its performance is equal in every respect to its promise.

⁂ Notice to Correspondents.—*In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of* Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

I.—Letters from Correspondents.

Bookbinding and Book Boxes.—R. W. S. (*Leeds*) writes:—"I hope you will soon be able to give us the articles on bookbinding, promised so long ago as May (in No. 7). The year is drawing to a close, and I daresay many of your readers, like myself, would like to bind their loose pamphlets and parts, etc.—the accumulations of the year—and place them upon their bookshelves. I have already tried my hands upon making book boxes, for keeping small papers, catalogues, etc., in a handy way for easy reference, and find them most useful. A friend procured me a number of cast-off cloth backs, removed from the books by the binder for enclosing them in more expensive bindings. These, with cardboard sides covered and lined with marbled and glazed papers, quite ornament the shelves, and cannot be detected from the genuine books. A loose index placed in the bookcase gets over the difficulty of the lettering not indicating the right contents. If you think that a description of how the boxes were made would interest the readers, I would be willing to forward an illustrated paper on the subject. I trust, when we do get the article on bookbinding, that we shall have the cheaper forms of bindings treated of at length, as I daresay the majority of amateurs would hardly care to tackle the expensive leather covers."—[The bookbinding papers will be given at the earliest possible date. Meanwhile cannot R. W. S. gather any useful hints from the articles "Binding Made Easy," in Nos. 6 and 9 of Work? I should be glad to see the paper to which you refer, if you will send it me on approval.—Ed.]

Printers' Rollers.—J. O. W. (*Bridgwater*) writes:—"I see a correspondent in No. 34 (see page 541) gives instructions for making printers' rollers, but he is certainly wrong. '1 lb. of glue to a gallon of treacle' would make a mess, but not a roller. Take 1 lb. of good glue, crack it up, soak in water a couple of hours, then put it on the fire to melt on the same principle as a carpenter's glue pot—vessel in a vessel. When melted, add 2 lb. of treacle, stirring it occasionally and letting it simmer together until well incorporated—about a couple of hours—when it will be ready (after scum is taken off) to pour into warm, oiled mould. Don't stir for a quarter of an hour or so before pouring, or you will get air-holes in roller. Let it stand till thoroughly cold (next day is best), when you may pull out. An amateur with a little ingenuity may easily make a small mould from tin, or a tin canister may be utilised. The quantities given are what I have used in practice, but rollers may be made harder or softer by adding more glue or treacle as the case may be. Printers' rollers are now extensively made from a different composition made of glycerine and gums, which composition may be bought ready for casting of any of the printers' brokers at from 1s. to 1s. 6d. per lb."

Working Drawing of Tramcar.—W. M. C. (*Glasgow*) writes:—"Would F. C. (*Leytonstone*) oblige me with tracing of above with measurements? I will gladly pay for it. Also drawing with measurements of the common cab."

Lacquer for Iron and Steel, etc.—A. J. L. (*London, N.W.*) writes:—"What Steel (see page 526) requires is, I think, either the 'Karnwood steel enamel,' or Koch & Co.'s 'varnish for metal and wood.' These are both of them blue and used cold. I cannot give the preparations, as I believe them to be secret."

A Simple Incubator.—W. H. J. (*Belper*) writes: "In No. 35, page 557, W. L. (*Kingsland*) writes how to make a simple incubator. Will W. L. please say, through 'Shop,' what size lamp is wanted, and what heat the sand should be kept? I hope to hear from W. L. soon."

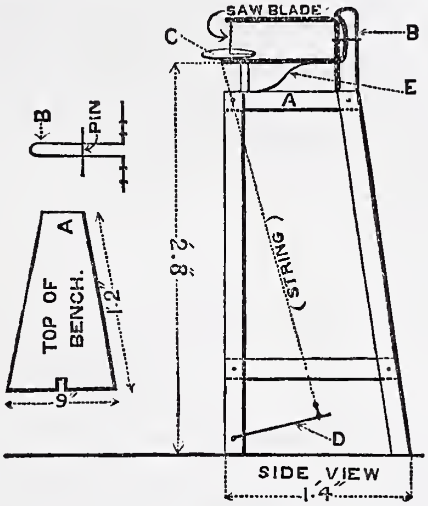
Wheeling.—G. W. (*Bournemouth*) writes:—"The mild effusion of Wheelwright's Clerk (see page 587) was partly caused by punctuation, or want of it. My meaning was for amateurs liking to try wheeling, to take the Editor's tip to Trench (page 237)—prepared wood, etc. It may be new to some (the fact, I admit, is not so old as the pit frame) that the major part of stamped forgings used in the trade comes from France. The average wheelers' trips to Glasgow, etc., are, or have been, on shanks' pony (see U. K. S. reports)."

Useful Scroll Saw.—Verdant writes:—"If Artist in Wood (see page 476) would kindly give a few more details concerning the above, I should feel greatly obliged. For instance, die of fly wheel, length of slide rods, how attached to saw? how is the saw strained or tightened? and how is the saw frame made?"

Small Foot-Power Bellows.—Medicus (*Hampstead*) writes:—"As many amateur mechanics like myself often have occasion to do some soldering or brazing, it would be a great assistance to us if you would give us a paper with sketches showing us how to make a small foot-power bellows with continuous blast to be used with the gas blowpipe. I have the latter, but I daresay a good many of your readers would be glad to know how to make this for themselves, if you would describe it in addition to the bellows."

Polishing Wheels—Tube Saws.—A Regular Subscriber (*Liverpool*) writes:—"I would like to ask Opifex through you which of the receipts for polishing wheels, given in No. 24 Work, page 371, he considers best suited for putting a fine edge on wood-turning tools. I would also like to ask S. M. (*Skelwith Bridge*) if he thinks the tube saws mentioned in his letter in 'Shop,' Work No. 27, page 428, would be suitable for cutting oak across the grain, say up to $2\frac{1}{2}$ in. diameter, in a 4-in. foot lathe."

Easily-Made Fret Machine.—A. J. P. (*London, S.W.*) writes:—"I send you sketch of one which I think much more simple than the one in No. 21, page 332. I made it myself; it is my own idea; I have had it in use for about four years, and



Fret Machine.

find it works well, and is very easily made. It consists of a small bench made of any pieces of wood of a suitable strength, and an ordinary hand frame of either 12 in., 15 in., or 18 in. from saw to back. First make a bench as shown at A, with three legs, a piece of hoop iron or wood, B, or small table, C, for working on treadle, D, and small steel spring, E. The cost of the whole is about 3s. If you do not quite understand the sketch I will send you a small model in cardboard."

Combined Bench and Tool Chest.—Tyro (*Hull*) writes:—"I notice in No. 33, page 524, of Work, a drawing of and instructions for making a Combined Bench and Tool Chest, by Mancuniam. I think it an excellent testimonial to the value of Work, as an assistant to the efforts of the amateur mechanic, that Mancuniam, from being—as he owns he was—only a tyro previous to the advent of Work, should, in the time that it has been before the public (33 weeks), be able by its aid to make such a useful article as the one he describes. Being somewhat of a 'wood-spoiler' myself, and having only a limited space in which to exercise my talent (?) in that line, and to stow away the tools I possess, I at once, on seeing Mancuniam's article, became fired with the ambition to construct such a one for myself. I should, therefore, esteem it a great favour if Mancuniam would, through your columns, state the quantity of wood required, and the probable cost, as hitherto my experience in wood-buying has been very limited."

Tool Wanted.—B. A. B. (*Hampstead*) writes in reply to Gauge Point (*Paris*) (see page 446):—"Two accurate 2-ft. rules will quickly and correctly measure any opening less than 4 ft. For wider ones Gauge Point might get one 3 ft. as well, or a pair of 5-ft. rods as used by surveyors. These will measure correctly and easily any dimensions between 5 ft. and 10 ft. I see nothing makeshift about it, and believe that if it were needed or if it were possible some simpler plan would soon be introduced. I do not see that any improved tool is called for. As to bevel for stair rail joints again, how can any tool be invented to fulfil conditions so varied, and which it is impossible to indicate beforehand! Gauge Point appears to want a universal template cheap and handy. A good plan to adopt for a square across hand rail if straight is a very thin steel straight edge made of clock spring steel. This, which must be wide to be correct, is very useful for squaring any rail that is straight and not tapering. As to a bench grip for veneer or a door, Gauge Point ought to consult the advertisement columns, looking for 'instantaneous grip vice.' There is now no difficulty about it. The only thing is to keep the thing in order when bought. Ordinary care will do this."

An Easily-Made Fret Machine.—H. S. R. (*Highbury*) writes:—"I notice in Work (see page 525) a reply to my inquiry of how the fret machine is to be worked, and must thank W. R. S. for his courteous reply, and shall be very pleased if you would give me his address so that I might be enabled to accept his invitation and see the machine at work. Since my letter to your most valuable paper, I have seen very many inquiries about this same machine, so that this shows that I was not the only one who could not see how it was to be worked. I am afraid I wrote a little prematurely about this machine, as I think I can see now what W. R. S. means, although there are a few little details for explanation which can only be explained by my seeing it at work. I should not have taken the trouble to write about this machine, only that I take a great interest in the paper and everything that is in it, and wait for its appearance with the same interest as I should the weekly part of a novel, as I consider it a most interesting and valuable paper, from which I have got many suggestions which have been of use to me. I might say that I have no intention of correcting the machine (could I do so), as I have little doubt that, from what W. R. S. says, it is perfectly feasible."

About Scrapers.—Scraper (*Cottingham*) writes:—"I have taken your paper from its commencement, and have gathered some very valuable information from it, which I should have taken an earlier opportunity to acknowledge, but I have seen so many letters of congratulation (and discontent) that I thought you would be tired of it. The article I more particularly wish to mention appeared in No. 24 of Work, entitled 'A Few Words about Scrapers,' by a Cabinet Maker. I had heard of this tool some time ago, and not knowing exactly what sort of thing it was, inquired at my tool shop, and bought one, but to my annoyance, when I tried to use it, I could make nothing of it. I scraped till the perspiration rolled off me, but not the slightest impression could I make, and at last threw it aside in disgust. I did not pay much attention to the article on scrapers when it appeared, as I think I had scarcely got over my previous annoyance; but having this week a little job on hand requiring a nice surface I thought of the article, and leaving my work, looked out the paper and read it carefully. I thought what a flat I must have been, for I knew that chisels and other cutting tools were not usually sold in working order, and I might have known that scrapers were the same, but I didn't. However, I went to work again, followed the instructions to the best of my ability, and to my great delight dressed up the wood to my entire satisfaction, and at once determined to write the first opportunity and thank the writer for his useful hints."

Index.—A. X. E. (*Nottingham*) writes:—"I think the suggestion of Barehead (see page 445) a very good one, although perhaps it might not be convenient on the first page, as he suggests. It might find a convenient corner somewhere, perhaps in place of the fly sheet I sometimes find snugly folded in my weekly copy."

Men Worth Knowing.—A. X. E. (*Nottingham*) writes:—"I can fully bear out Help Each Other's remarks on page 516, No 20, about Mr. Pool's tool warehouse being a good and cheap one. I have traded there several years, in fact, ever since he started in business on his own account. I was in his shop only last Saturday, and seeing a copy of Work on his counter, I remarked that I had seen his name mentioned in it, and he replied, 'Ah, you see what it is to have a good reputation!' And, being myself a native of Spalding, I can also bear him out in what he says about Mr. Massey. Perhaps cheap labour has something to do with cheap production thoro."

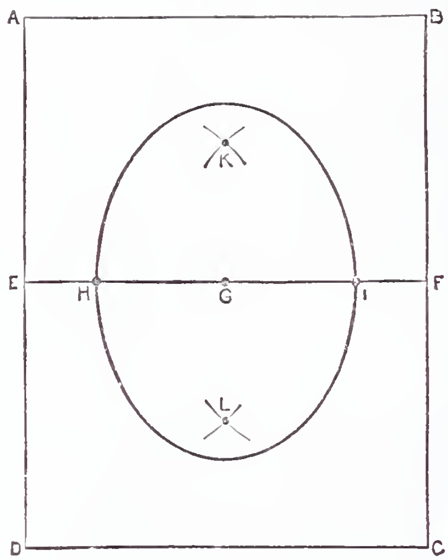
Plane Iron Bevel—An Amateur's Dodge.—R. H. (*Newcastle-on-Tyne*) writes:—"Finding a great difficulty in getting a straight, smooth, and even bevel on my plane iron, I found the following give a capital cutting edge, which worked very smoothly:—Take the iron out and unscrew the plate, set it $\frac{3}{4}$ to 1 in. from edge, and pass the whole through the sole of plane as far as it will go, depending on size of mouth. The iron will now project about $\frac{3}{4}$ in. Take sharpening stone in hand, and resting one end on back of plane work it over the projecting iron. The angle formed gives the cutting edge. I noticed some little time ago in Work instructions, etc., to sharpen a plane. It struck me at the time that perhaps my dodge would prove of service to many amateurs who have found a difficulty as I have in getting a straight and even bevel on the plane iron, so here it is."

Etching Mordant.—W. J. P. (*Tunbridge Wells*) writes:—"Having noticed the reply to Cupid (see page 541), wherein the informant says he never heard of such a compound as an etching mordant, I beg to offer the following information. The mordants used in etching vary much both in strength and materials. I have never used but one mordant, and that consists of about half nitrous acid and half water. This is rather a rapid bath, and I should say the biting in would be accomplished in about half an hour in all. The nitrous acid should be purchased in a stoppered bottle, and should be of a yellowish colour. I shall be pleased to furnish your correspondent with a further list of baths if required, and any other information in my power on the subject."

II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

Artificial Wood (Willesden Paper, etc.).—G. P. (*Openshaw*).—I imagine what you have in your mind is the welded Willesden paper, the manufacture of which depends on the following considerations:—It has long been known that a solution of cuprammonium hydroxide has the power of dissolving (or apparently dissolving) cellulose. I say apparently dissolving, for many chemists doubt whether a true solution takes place. At any rate, when paper, cotton-wool, and similar celluloidal substances are digested in such solution they disappear, and whether they are actually dissolved, or simply gelatinised and diffused through the liquid, is of little practical moment. In fact, the discovery itself, like so many others, was for a long time simply an interesting laboratory experiment. Scientific chemists were assailed with the usual, "Oh! very pretty, no doubt, but what is the use of it?" and had no reply till an ingenious chemist conceived the idea of taking canvas, paper, etc., through the solution at such a rate as to simply gelatinise the exterior of the fibres without disintegrating them, by which means, on subsequent drying, the film of gelatinised cellulose would be converted into an elastic varnish in which the copper would be taken up in the form of cupro-cellulose, thus rendering the article perfectly proof against water, rot, or mildew. The above process, with such modification as experience has suggested, has been for some time worked on a commercial scale by the Waterproof Paper Company, Willesden, and the verb to Willesdenise has found ready acceptance in this connection. The Willesden goods are broadly divisible into two general classes: (1) Round or made-up goods, such as cordage; and (2) flat goods turned out in the roll. Goods of the first class are simply dipped into a bath of the solution, the strength of which and the period of immersion varying according to the article. In addition to the water-resisting, etc., properties thus conferred, it is also found that the treatment adds to the strength of the material by more or less cementing the fibres together. Goods of the second class form by far the more important section, and are subdivided into canvas, screen, and paper. Of the two former little need be said, the treatment being but little different from that described above, except the goods are usually unwound from one roll, pass successively through the bath and a series of drying rolls, and are finally rewound on to another. Coming now to Willesden paper, this is either welded or unwelded, the former being simply a roll of paper, treated as above, and applicable to innumerable useful purposes, as waterproof packing paper, lining for damp walls, waterproof stationery, etc. Welded Willesden paper is formed by simply pressing one or more layers of the unwelded while still superficially gelatinised by the action of the solution into one compact solid sheet or panel of indefinite length. These sheets may be of any desired thickness, and are known as 2-ply, 4-ply, and 8-ply respectively, from the thicknesses most in use. For 2-ply, two rolls of materials, either alike or dissimilar (say two of paper, or one paper and one calico), are simultaneously passed through the bath, and then pressed and dried as a whole. Two rolls of 2-ply passed through the bath a second time, pressed together, and dried form 4-ply; while two rolls of 4-ply similarly treated produce the 8-ply. The 2-ply is mostly used as a floor covering, and it has been found to wear fully as well as kamptulicon, linoleum, and similar preparations while immensely cheaper. It is also found to serve a useful purpose for laying on or under floor boards as a damp and draught excluder, as also as a packing, for damp walls and leaky roofs, and for internal decoration; 4-ply has come into extensive use as a building material, especially in cases where a combination in the same material of strength, lightness, and flexibility is a prime consideration. Another strong point in its favour is that, being entirely weather-proof—neither damp, nor frost, nor tropical heat affecting it in the least—it requires no painting (though for decorative purposes it will take paint readily enough). It also possesses many advantages over galvanised iron. Being a comparatively poor conductor of heat, buildings thus constructed will be warmer in winter and cooler in summer than those constructed of iron, while being so much lighter, the cost of transit is correspondingly reduced; 8-ply is mostly used for panelling where extra strength is required, the entire absence of the slightest tendency to split or crack being not the least of the many advantages claimed for this material over ordinary panel boards. It is also strongly recommended as a material for boat and ship-building, as vessels thus constructed would be both light and very easy to repair. I should, therefore, imagine that this is just the material you require, and could readily be obtained with such further information and advice as might be necessary from the company named. Unless for the sake of the experience to be thus acquired, I do not think it would be worth your while to experiment personally, as so much nicety is required in adjusting the strength of solution, timing the duration of immersion, etc., to say nothing of the presumed absence of suitable appliances. The cuprammonium hydroxide solution is made by the action of strong ammonia on copper turnings in a current of air. It was early suggested that the corresponding zinc compound (zinc-ammonium hydroxide) might be substituted for the above, but its action was found to be both too slow and too feeble to make it capable of replacing the other with advantage. Inasmuch, however, as the presence of zinc in the finished product would, in some cases, be desirable, further experiments were made, and it was found that by combining the two solutions, or, better still, by making a compound solution (using brass turnings instead of copper), some advantages were gained, zinc-copper cellulose instead of simple copper cellulose being thus secured. Of course, there are other forms of artificial wood known and in use, and one of these I will now mention. This process, though invented fully twenty years ago, has only comparatively recently come into extensive use. It consists simply in mixing very fine sawdust with bullock's blood (whence its name "hæmosite"), and submitting the same to hydraulic pressure. A great variety of articles having all the appearance of the most beautiful ebony carvings can thus be pressed in strong suitable moulds. Quite recently I learn the process has been utilised in the manufacture of brushes. The hair is set into the paste while still soft. This is then covered with the perforated plate to permit the passage of the hair; pressure is now applied, whereby brushes of one piece are formed, which are more durable and cheaper than those produced by the old process. The composition is also largely used for the production of door knobs and smaller articles.—P. W. S.

Cutting Mounts.—R. H. (*Lancaster*).—In cutting mounts the professional man depends upon a steady hand and sharp eye for cutting ovals, domes, or any fancy shapes, and usually keeps an assortment of his old centres for marking out new ones. See answer in "Shop," August 10th, page 333, for cutting square mounts. The plan illustrated cost sixpence. To mark an oval, the following is always the way a professional mount cutter proceeds: Trim your board upon which the mount



Mode of Drawing Ovals for Mounts.

is to be cut square, as marked in accompanying diagram. Draw a line across the centre, from E to F, then take the dividing compasses at half the width of your oval required, and place pin leg in centre, and mark width, H and I. Then measure your compasses half the length, and place pin leg in point H, and draw half circle, and again pin leg at point I, and draw again. Knock pins or wire nails in points where lines cross K and L and H, tie a piece of cotton tight round the three nails, withdraw nail H, and place your lead pencil in its place. Keeping it perpendicular, draw the line at full stretch of the cotton, and the oval is struck. Withdraw pins or nails, and proceed to cut round pencil line.—G. R.

Generation of Electricity in Dynamos.—J. H. H. (*Rochdale*).—You know, of course, that the armature of a dynamo is whirled rapidly round in the field of two electro-magnets. The iron in those magnets have some residual magnetism—that is, permanent magnetism remaining in them. As the armature revolves, the coils of wire with which it is wound cut across the lines of magnetic force, which always extend from one pole of one magnet to the other pole of the other magnet. This action on the part of the armature in the field of magnetic force induces a current of electricity in the coil of wire wound on the armature, which is communicated by the brushes to the outer circuit of the machine. Space cannot be spared in "Shop" to fully describe and illustrate "the passage of the current through helix and magnets," but you will find it fully described and illustrated in Parts 4, 5, and 6 of "Electricity in the Service of Man," now being issued by the publishers of WORK. A volt is the unit measure of electromotive force given by the current from one standard Daniell cell. An ohm is the unit measure of resistance given to the passage of an electric current by a 10 feet length of ·01 inch copper wire of 95 per cent. conductivity, or any other piece of wire offering an equal resistance. An ampère is the unit measure of current volume. It is that volume of current which will liberate ·000159 grains of hydrogen per second, or the equivalent proportion of any other substance in the same time. For full information on this subject, see my "Notes for Electro-Platers," section on ampères, page 130. You will learn much by the study of Professor Thompson's book on "Dynamo-Electric Machinery," and also "Electricity in the Service of Man," just mentioned. Shall be pleased to help you with advice at any time.—G. E. B.

Bronzers' Manual.—J. W. V. T. (*Frome*).—I do not think such a work as you mention is published in this country. Paris being the seat of a vast industry of bronze and other fancy metal ornaments, would naturally furnish the demand for it, since, I take it, the work you know of would refer to the bronze metal and not the imitation work. Concerning the latter, I am pleased to be able to help you, having at one time expended much pains and time in collecting and bronzing a collection of uncommon plaster cameos, busts, etc. All colours of bronze can be purchased in powder form or in solution under various makers' names, of methylated spirits and shellac, or spirits of salts, etc. If bought in liquid form they are applied with a suitable brush. The effect of this kind of liquid bronze is but second rate, so I advise you to purchase the powder from a dealer in gilders' material, and one who has a large and varied assortment of dry bronzes for you to select from. As the subject of gilding and bronzing will be thoroughly treated in WORK, I will ask you to be content with a few brief instructions. Well dust your plaster castings, and then give two successive coats of strong patent size; when thoroughly dry and hard give a coat of hard-drying copal varnish, and when this again is hard another good coat. This last coat we rub the powder bronze on to, using a little piece of new wash leather. Apply the bronzes when there is a good amount of tack—that is, stickiness—upon the varnish, but the surface must be comparatively dry and not at all soft. Some fine effects of imitation copper and dark green bronzes can be made by bronzing the article all over with gold bronze. When hard give a thin coat of varnish, and after paint it with a mixture of varnish and bronze green or copper paint, wiping the paint off the raised parts with rag, which show the gold through the paint. Bronze powders are best protected by a last coat over of copal varnish. There are numberless methods of getting fine imitations by the use of gilding and transparent lacquers, but these must wait for the present. "Shop" is developing so rapidly that the space is becoming most valuable. Shall be pleased to help you later on if desired.—F. P.

Castings for Ornamental Slide Rest.—'ARRY.—Apply to E. Hines, Griffin Works, Norwich.—F. A. M.

Sand for Brass Casting.—'ARRY.—I believe the best sand for amateurs is obtainable from dealers in dentists' appliances.—F. A. M.

Boat Building.—BOAT.—I quite agree with you that papers on boat building will be generally acceptable. There is so much, however, in hand that they cannot be commenced in the present volume, though if any of the promised single papers on canoe building, etc., reach me, they shall appear.

Copy from Fretwork Pattern.—TO THE BITTER END.—If you want to avoid the trouble of tracing your copy from pattern, which, I presume, is printed, you cannot do better than adopt the cyanotype or blue printing process of photography. This you will find fully described in No. 13 of WORK. A still simpler plan is to sensitise the paper with a solution of bichromate of potash, instead of the chemicals used in the blue process, though the resulting prints (the copies which are brown) are not so distinct. In either case the copy will be got more quickly by oiling the pattern so as to render the paper less opaque. When you have a piece of fretwork to copy from, I suppose you are aware the simplest plan is to take a rubbing from it with heelball.—D. A.

Lawn Mowers, Sharpening of.—J. S. (*Spilsby*).—Lawn mowers on the Archimedean principle may be sharpened by reversing the direction of the blades and applying very fine emery powder and oil. There is a small iron handle, usually supplied with each machine, which screws into one of the driving wheels, and by which the reversed motion is imparted to the cutters. The spiral blades are set as closely as possible to the fixed horizontal blade, along which the emery and oil is smeared, and the blades are then made to revolve as quickly as possible. You ask how to "grind and set" a lawn mower "by hand?" This is, as you say, sometimes attempted by unskilled workmen with the invariable result, which you also point out, that "lots of lawn mowers are spoiled." The fact is that it is impossible to grind spiral cutters true without the aid of machinery.—OPIFEX.

Inlaying.—H. G. W. (*Bridgwater*).—The centre ovals for inlaying, of which you send sketch, are made of veneers. The coloured pieces are white wood dyed through their entire thickness, while the lighter pieces are of box or some other light wood, shaded with hot sand. Veneers ready dyed are to be had from such people as D. Witt & Palmer, Drummond Street, Euston Square, N.W., much better and at less cost than you can prepare them for yourself in small quantities. Each piece, whether plain, shaded, or dyed, must be accurately cut to fit the position it is to occupy, either by fret saw or other means, straight edges being shot true. To shade, take a pan or dish containing sand, which must be heated sufficiently to brown any wood put into it. Care must be taken not to make the sand so hot as to char or burn the wood. Put the edge of the piece to be shaded into the sand, carefully watching the effect produced, and continue doing so till the desired tint is obtained. Though not difficult to manage after a fashion, care is necessary to get the gradations equal. When all the pieces are ready, glue them either direct on the work they are to ornament, or adopt the usual course of gluing them down on a piece of paper along with the surrounding veneer. The whole can then be laid in one piece with the paper, which is afterwards to be removed, uppermost. Before laying the veneer, but after the glued paper has dried, go over it on the uncovered side with a toothed plane or file to remove inequalities in thickness, and to slightly roughen the surface. Lay with a caul. Any fret saw will do for cutting inlays. Marquetry cutters generally make their own saws, but you will probably find it more convenient to buy them ready made. You will find a No. 2 blade do very well, but you may use either much coarser or finer if you prefer for such work as the centres you refer to.—D. A.

Bevelled Ends of Wash-Tub.—J. G. (*Glasgow*).—To bevel the ends of a wash-tub without first bevelling the top and bottom edges, all that is necessary to be done is to bevel the edges of the blade of bevel as described on page 173, to the same angle as you have decided to splay your sides, and mark your joints on the square edges of same in that direction (Fig. 1), fixing the blade of the bevel blade square across the stock, as the butt joint would be square if the sides of the tub were upright and not splayed. A good way to thoroughly understand this would be to bevel an edge of a waste piece of stuff to the angle or splay determined, and mark on the face the splay, and on the edge the bevel of butt joint (given by above bevel). Then make a saw cut down about $\frac{3}{4}$ of an inch. If you now plane the bevelled edge down square again and apply the bevel, you will at once see what I mean. Should you find any difficulty in determining the splay of your sides you will find a simple method given on page 414, but I have generally found in practice that it is more important to work to a certain width of stuff without jointing. For example, let us suppose you want to make a washing-tub, and you have some pieces of stuff that will work, say, 14 in. wide and 1 in. thick when planed up; all that you have to do is make a mark across the width of stuff to any angle, bearing in mind that the nearer the angle is to 90° the deeper the tub will be when finished. If the depth is not of much consequence, this is the right line to cut to without any further trouble, whether the edges are square or bevelled (Fig. 3).

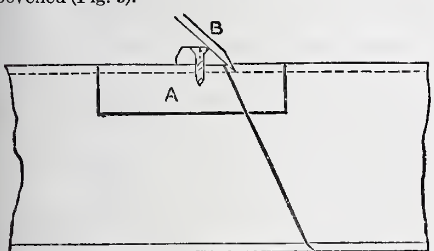


Fig. 1.

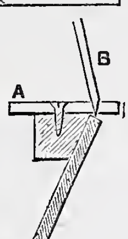

Fig. 2.

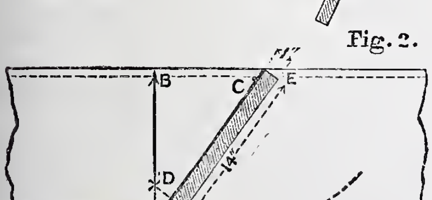

Fig. 3.

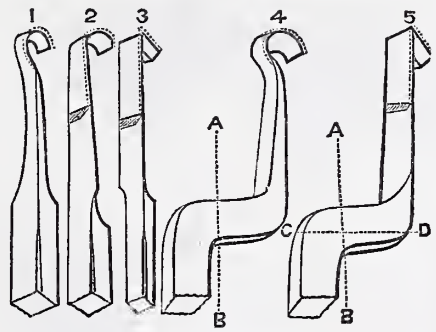
Bevelled Ends of Wash-Tub.

Should you wish to know how deep the tub would be if cut to this angle, you can easily find out by setting off the width and thickness of your stuff on this line (hatched on diagram), then mark off the two dotted lines, which will indicate the width the sides would be if the top and bottom were bevelled. Now square a line across the board from A to B, and from C, with width of board (which we will assume is bevelled) as radius, describe an arc, cutting A B in D; B D will then be the depth inside if the edges were bevelled. Should they not be bevelled it would be as much deeper as the stuff E E you do not plane off, and, if a line were drawn from D to C, that would give the bevel in elevation as explained by B. A. B., page 414; but I always endeavour, if possible, to keep away from elevations, etc., of oblique lines, as they are apt to be confusing, especially in connection with wash-tubs.—E. D.

Turning Inside Work in Soft Wood and Polishing Ivory.—Tyro (*Liverpool*).—You can, of course, turn your soft wood boxes inside with gouge and chisel, but if you want to make tooth-powder boxes by the score you will require hook tools, and must learn to use them. The chisel scrapes inside work, which answers perfectly for hard woods such as box-wood, but tears and leaves a rough surface in soft wood, requiring sand-paper to finish. The hook tools, Figs. 1, 2, 3, 4, 5, which are traced from the fourth volume of Holtzapffel's work on Turning, will cut and not scrape an inside surface, and the work is done with rapidity and smoothness. I have put dots round the cutting edge to distinguish it. Figs. 1, 2, and 4 act as gouges, Figs. 3 and 5 as chisels for flat surfaces, and these two last have an angle which is a little less than a right angle, and is very difficult to keep



Hook-Turning Tools.

quite sharp. Figs. 4 and 5 are called cranked tools; they can be used with the cranked part lying on the rest turned across the lathe-bed (as usual in inside work) along the line C D, which steadies and prevents their catching in; or they can be laid on the rest while it is still parallel with the bed along the lines A B, so that the hollowing can be done without even stopping to turn the top of the rest round. No. 1 costs 3s. 6d., and No. 3 costs 4s. 6d. from Holtzapffel. Ivory is scratched with sand-paper, and it may be turned extremely smooth with a sharp tool; if you must use sand-paper rub together two pieces of the finest grade before using them on the work, or you can use Dutch rush. To polish, make a cream of washed whiting, and apply it with a rubber of folded rag, moving it about to avoid marking the work with rings.—F. A. M.

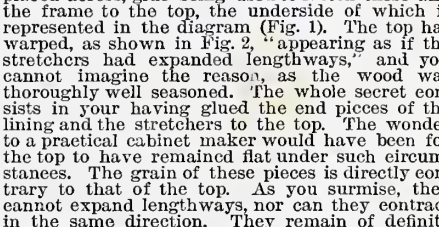
Polishing Fretwork.—N. M. (*Norwich*).—Do not be discouraged at your partial want of success in getting a fine bright polish on your fretwork, for the spiriting off is the most difficult part of the process. To manage it properly requires practice. You are probably correct in supposing that the cause of the polish being rubbed off is the use of too much spirit when "spiriting off." You should have the spirit rubber just moist enough to soften the surface of the shellac, and so remove the previous rubber marks. By having an excess of spirit in the rubber, you, of course, dissolve too much of the shellac, which is thus washed away. "Briskly" is hardly the way to apply the spirit rubber, as it rather implies that you have scrubbed too hard. Try an equable gentle movement, with what I may almost call a dainty touch, and by exercising your powers of observation, of which you are not deficient, you will soon note an improvement. Do you know that you should use a clean rubber for spiriting, and not the one you have bodied in with? Yes, you can move the rubber in any direction. Suppose you were to try glazing instead of spiriting. It is much quicker and simpler, and does well enough on fretwork, which, as a rule, is not subject to the wear and tear of ordinary furniture. As you are not an experienced polisher, you will probably get better results than by the superior method of legitimate French polishing. Now for the planing problem which you submit. With a fine set plane you should be able to smooth the edge of the board from whichever end you start, but it is almost impossible to say that this could always be done. A little "dodging" is sometimes necessary, and an experienced person would manipulate according to circumstances—in fact, it is just in cases of this sort that experience is most valuable, by showing when departure from a general rule is advisable, and may be practised with benefit. The jack is not the best plane for you to have used. The trying plane would have been better. If you have not got one of these, you might have managed with a smoothing plane, though, as this is short, very likely you would have experienced a difficulty in getting the edge perfectly straight. Don't think you are troubling. It is a pleasure to assist any one who evidently uses his brains along with his fingers and tools.—D. A.

Oak Stain for Pine Bookcase.—H. M. (*Glasgow*).—It is impossible to answer questions in the "first issue" after receipt, as the pages are made up some time in advance, that the enormous number of copies of Work may be printed and ready for publication by the date they bear. Hence the reason for answer to your query not having appeared ere now. You do not say whether you want a light or dark oak colour to your bookcase, but the following mixture allows of great latitude in shade as well as in actual colour, according to the quantity of water: Vandyke brown mixed with liquid ammonia, and then diluted with water, a little Bismarck brown being added to give the reddish tint required. Another good stain may be made by dissolving bichromate of potash in water, and adding some of Stephens' walnut stain to reduce the orange colour of the bichromate. If the putty which you have used to fill up (a bad plan) shows too prominently, paint it over with the stain till it corresponds with the wood.—D. A.

Ebonising and Polishing Picture Frames.—Chemicus (*Hammersmith*).—It will be better for you to buy a black stain ready prepared. You can get this from any oilshop where polish is sold, and it is not only more economical but more satisfactory to do so. If, however, you prefer to make your own stain, here is a recipe. Boil some log-wood chips in the proportion of, say, $\frac{1}{2}$ lb. to a pint of water, till all the colour is extracted. Apply the decoction to the wood, and when dry wash over with iron liquor made with steel filings, or scraps and vinegar. This turns the wood black, and when dry it is ready for French polishing in the usual way, which, I presume, you are acquainted with. Very likely the grain of the wood has been raised by the moisture of the stain. It should be rubbed down with very fine glass-paper till the surface is quite smooth again. As you do not say what wood your frames are of, I am unable to particularise on the details of polishing, but assuming this to have been done, and that a dull or dead black is wanted, the gloss is removed by emery or pumice powder dusted over with a brush or soft rag. For ebonising it is better, especially if the stain is not intensely black, to blacken the polish by mixing some gas black in it. This, however, is not always considered necessary, though it is a safe plan to adopt. The black polish should be strained before using.—D. A.

Warping of Table Top.—Somerset.—The cause of your table top having warped is very evident, and the lesson to be learned from it is so important that, for the benefit of other amateurs, I answer you as fully as the limits of "Shop" will allow. For the benefit of others the case is stated. A table top $\frac{5}{8}$ in. thick is lined up to 1 in. In addition to the framing, A, stretchers, B, were placed across, glue being used to fasten these and the frame to the top, the underside of which is represented in the diagram (Fig. 1). The top has warped, as shown in Fig. 2, "appearing as if the stretchers had expanded lengthways," and you cannot imagine the reason, as the wood was thoroughly well seasoned. The whole secret consists in your having glued the end pieces of the lining and the stretchers to the top. The wonder to a practical cabinet maker would have been for the top to have remained flat under such circumstances. The grain of these pieces is directly contrary to that of the top. As you surmise, they cannot expand lengthways, nor can they contract in the same direction. They remain of definite length. The table top, however, has contracted in width, and being bound across over its whole width, instead of splitting, as it would have done had it been merely fastened to ends of the pieces referred to, it has simply curved in the direction it has. I presume you have not read the articles on "Lining up," and "Lessons from an Old Bureau," which have appeared in our pages, and I should

Fig. 1.



Underside of Top.

Fig. 2.

FRAME

Warping of Table Top—A, Frame; B, Stretchers. All Glued on.

strongly advise you and other amateur cabinet makers to do so. Had you studied them before you made your table, you would have avoided the error, by no means a common one among amateurs, into which you have fallen. If you bind wood across the grain by transverse pieces, with the grain running in the contrary direction, one of two things is almost sure to happen. Either the wood will warp, as in your case, or split. If you had done as directed in the articles on lining up, screwed the ends of the frames and cross stretchers, leaving the screw necks loose, probably no such disaster would have happened. As the lining extends all round you should, even with screws, have cut the transverse pieces a trifle short—not much; $\frac{1}{16}$th would have been ample, for you can easily see that were they to fit tightly within the longer parts of the frame, the natural play of the top would be prevented almost as much as by glue, the chief difference being that it would probably have split instead of warping. If you preferred to use glue, you could have done so with safety by having the grain of the lining and stretchers in the same direction as that of the top. Look at the leaf of any good dining-table, and you will find the lining is glued on in this direction. You do not say the size of your table top, but as you say it is only small, I think you might safely dispense with the stretchers, B, unless the legs are fitted into them, in which case you can use screws to attach the top, as their grain will then naturally run across. The end linings will be better glued on, of course with grain coincident with that of the top. I trust I have made the cause of warping clear not only to yourself, but to others who may have met with similar mishaps, and I shall be glad to hear how you get on.—D. A.

III.—Questions Submitted to Correspondents.

Californian Red Wood.—Redwood asks:—"Having just fitted up a room with Californian red wood, which looks beautiful and neither requires paint nor varnish to improve it, I am anxious to know from any reader if anything can be done to preserve the colour, which I find since mine was finished has faded in the houses of others where it has been for some years."

Railway Carriage Building.—R. C. C. (*Plaistow*) writes:—"I shall be glad to hear of the best published book on railway carriage and waggon building, with price."

Fairy Bells.—Subscriber (*Bristol*).—Sorry I cannot answer your question as to the "Interior of a Fairy Bell." Possibly some reader may like to give you information.—W. F.

Bell Metronome.—Fiddler (*Glasgow*) writes:—"Would any kind reader please tell me how to make a metronome with bell?"

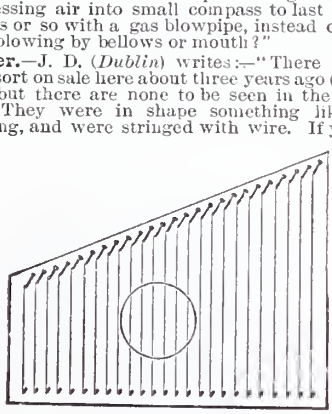
Chemistry Tests.—(*Cwmdn, Swansea*) writes:—"Please inform me through columns of 'Shop' if there is a book published 'Eggertz' Method Colour Tests for Chemistry'; where, and what price?"

Pitch of Roofs.—C. M. (*Hornsey Park Road*) writes:—"None of my building friends can really help me in this matter. When glassing the roof of a greenhouse or tiling a shed, I can only get an oracular 'That's too low,' or 'That's not high enough,' but none can give me any definite rule as to the necessary angle to be allowed. Will some of our Work friends kindly help me in the matter?"

Tarring Fence.—C. M. (*Hornsey Park Road*) writes:—"Will some obliging subscriber to Work tell me how to set to work on the above? What tar must I use, and how prepare it for use, and also how lay it on? Some of the tarring I see about remains wet for months, and gets half washed off by the rain."

Compressing Air.—Dealer (*Leeds*) writes:—"Would you or any of your staff be so kind as to give me dimensions of a simple arrangement for compressing air into small compass to last fifteen minutes or so with a gas blowpipe, instead of continual blowing by bellows or mouth?"

Zither.—J. D. (*Dublin*) writes:—"There was a cheap sort on sale here about three years ago (7s. 6d. each), but there are none to be seen in the shops now. They were in shape something like the following, and were stringed with wire. If you do



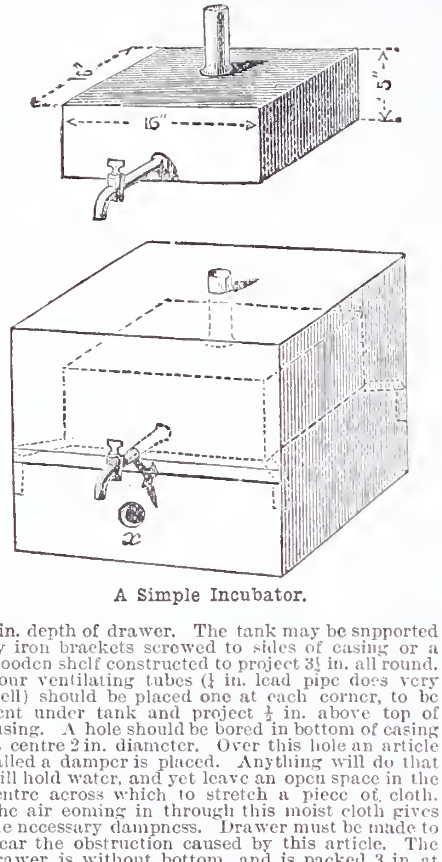
Zither.

not intend publishing a paper, perhaps you or some of your correspondents would let me know the proper angle at which to make frame with the length of strings, size of sound-holes, etc. By an early answer you will greatly oblige."

IV.—Questions Answered by Correspondents.

Tramcar Working Drawings.—X. Z. Y. writes:—"In reply to your correspondent J. W. F. (*Lancaster*), No. 33, page 526, working drawing of tramcar—Mr. J. J. Jones, 28, Overdale Road, King's Road, Chelsea, S.W., will give him what information he requires."

A Simple Incubator.—J. T. R. (*Walker, near Newcastle-on-Tyne*) writes in reply to B. F. (*Liverpool*) (see page 302):—"Regarding plan for incubator of a simple construction, I beg to offer him a few suggestions derived from a very successful experience in the matter of hatching out. I am only afraid that the space allowed by the Editor for reply to his question will hardly suffice to explain all that is desirable as to the proper management of this interesting 'tin hen.' If permitted, I shall be pleased to give the readers of Work the benefit of my experience at some future time, should the Editor deem the subject a suitable one for his all-round paper. First, the large tin box must be soldered tight. By this I mean there must not be any leak. If B. F. does not wish the incubator to cost him anything after he has it all made, he will adopt what may be termed the 'kettle of water' system, the heat being kept up by periodical fillings of hot water. Therefore the tank (tin box) will require a tube inserted on top, say, $1\frac{1}{2}$ in. diameter and about 4 in. high. A tap will also be required at front, about 1 in. above bottom of tank, to project, say, $4\frac{1}{2}$ in. Secondly, having proved the soundness of the tank, the outside casing may be made. This is a box built round tank, but 3 in. bigger at each side and top—viz., a 16 in. square tank will require casing to be 22 in. square. The height of the casing for tank of 5 in. depth would be 14 in., arrived at as follows:—3 in. for packing above tank, 5 in. depth of tank, and



A Simple Incubator.

6 in. depth of drawer. The tank may be supported by iron brackets screwed to sides of casing or a wooden shelf constructed to project $3\frac{1}{2}$ in. all round. Four ventilating tubes ($\frac{1}{2}$ in. lead pipe does very well) should be placed one at each corner, to be bent under tank and project $\frac{1}{2}$ in. above top of casing. A hole should be bored in bottom of casing at centre 2 in. diameter. Over this hole an article called a damper is placed. Anything will do that will hold water, and yet leave an open space in the centre across which to stretch a piece of cloth. The air coming in through this moist cloth gives the necessary dampness. Drawer must be made to clear the obstruction caused by this article. The drawer is without bottom, and is packed 3 in. at front with flocks. The best packing at the price is flocks, and the 3 in. space round tank and at top must be closely packed. There must also be 3 in. of packing at sides and back of drawer space, cased off. The front of drawer should be $\frac{1}{2}$ in. bigger each way (length and breadth), and felt placed round the projecting edge. A thermometer is required to project into drawer, and be able to be withdrawn without having to open drawer. My experience is that tin is of little use, the water quickly making its way to the outside. Black iron, and the tank galvanised after made, is best. I keep the heat up without aid of kettle, running a tube through tank, and using a small lamp, which is kept burning. Heat as near 104 degrees as possible for good results."

Varnish for Drawings.—M. T. C. C. (*Carrickfergus*) writes in reply to A. M. (*Glasgow*) (see page 508):—"I think the varnish A. M. wants is clear paper varnish; it is the only varnish that I know that is almost colourless; but he must first size his drawings, or when he puts the varnish on they will turn almost black. Let him give his drawings two coats of glue size, then varnish, and all will be well. Varnish can be had from any oil and paint merchants."

Cleaning Engravings.—M. T. C. C. (*Carrickfergus*) writes in reply to Ivor (*Bradford*) (see page 494):—"Ordinary paint will not stand the action of lime. But most enamels will. Brunswick black and black japan stand the lime pretty well too, if allowed to dry hard."

Trade Notes and Memoranda.

A Glasgow firm of manufacturers of engineering instruments—Messrs. McInnes and Cairns—have just arranged, in connection with their workshops, a testing department for engine-indicators and their springs, gauges, etc., which should prove of great utility and value to all engineering firms and others availing themselves of its use. Testing is effected by means of steam pressure, the steam being generated in a copper boiler having a safety valve loaded to blow off at 250lbs. pressure per square inch. On this boiler are fittings to which are coupled the indicators, gauges, &c., to be tested. The pressure, acting on the indicators, &c., is also admitted against a column of mercury 42 feet in height, extended from the basement to the top of the building. In the testing-room proper is a dial or graduated gauge 7 feet high, showing on a scale of 2 in. to the foot the whole range of the rise of mercury in the 42 feet column. By means of this plant Messrs. McInnes and Cairns are able to correctly test instruments sent to them under working conditions of steam pressure up to 250lbs. on the square inch.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

A WONDERFUL MEDICINE.

BEECHAM'S PILLS

Are universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, and all Nervous and Trembling Sensations, &c. &c. The first dose will give relief in twenty minutes. This is no fiction, for they have done it in countless cases. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

Worth a Guinea a Box.

FOR FEMALES THESE PILLS ARE

"A priceless boon, a treasure more than wealth; the banisher of pain, the key to health."

These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the nervous and debilitated is,

BEECHAM'S PILLS have the Largest Sale of any Patent Medicine in the World.

Prepared only by the Proprietor, T. BEECHAM, St. Helens, Lancashire, in Boxes 1s. 1½d. and 2s. 9d. each. Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

MELLIN'S FOOD

For Infants and Invalids.

TRADE MARK **NOT FARINACEOUS.** Rich in Flesh, Nerve, Brain, and Bone Formers.

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

No Food in the market can show such a vast collection of *bonâ-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

USED IN ALL CHILDREN'S HOSPITALS.

☞ *An Entirely New Work, entitled* The "Little Folks" Autograph Book, *is given away with*

"LITTLE FOLKS" for **January,** price **6d.,** forming the First Part of a New Volume, and containing the following amongst other interesting Stories and Papers:—

MASTER ROCKAFELLAR'S VOYAGE. *New Serial Story.* By W. CLARK RUSSELL, Author of "The Wreck of the *Grosvenor*."

Frontispiece in Colours—"The Pet of the Fold."
NOBODY'S HOUSE. *Serial Story.* By the Author of "Little Oddity."
Lost in Constantinople: The Adventures of Two Children.
Noble Deeds of Noble Children.
My Lord Rook's Judgment.
London and Some of its Wonders.
Saved by an Umbrella.
That Sulky Boy, Jack Frost. A Fairy Story.
A Learned Elephant.
The Dancing Crocodile. With Humorous Illustrations.
This Work-a-Day World. SUNDAY TALKS. By the Rev. FREDERICK LANGBRIDGE.
A Story of the Vestal Virgins.
A Living Rope. A True Story.
The Conjurer in Yellow.
"Music hath Charms." Illustrated.
"Black Bob," A True Story of an Old Cavalry Horse.
The New Special Prize Competitions for 1890.
Music for Children.
Pages for Very Little Folk.
Our Little Folks' Own Puzzles. Illustrated.
The Editor's Pocket-Book: Jottings and Pencillings, Here, There, and Everywhere. Illustrated.

The Part is fully illustrated by GORDON BROWNE, ALICE HAVERS, PERCY TARRANT, A. T. ELWES, etc.

CASSELL & COMPANY, LIMITED, *Ludgate Hill, London; and all Booksellers.*

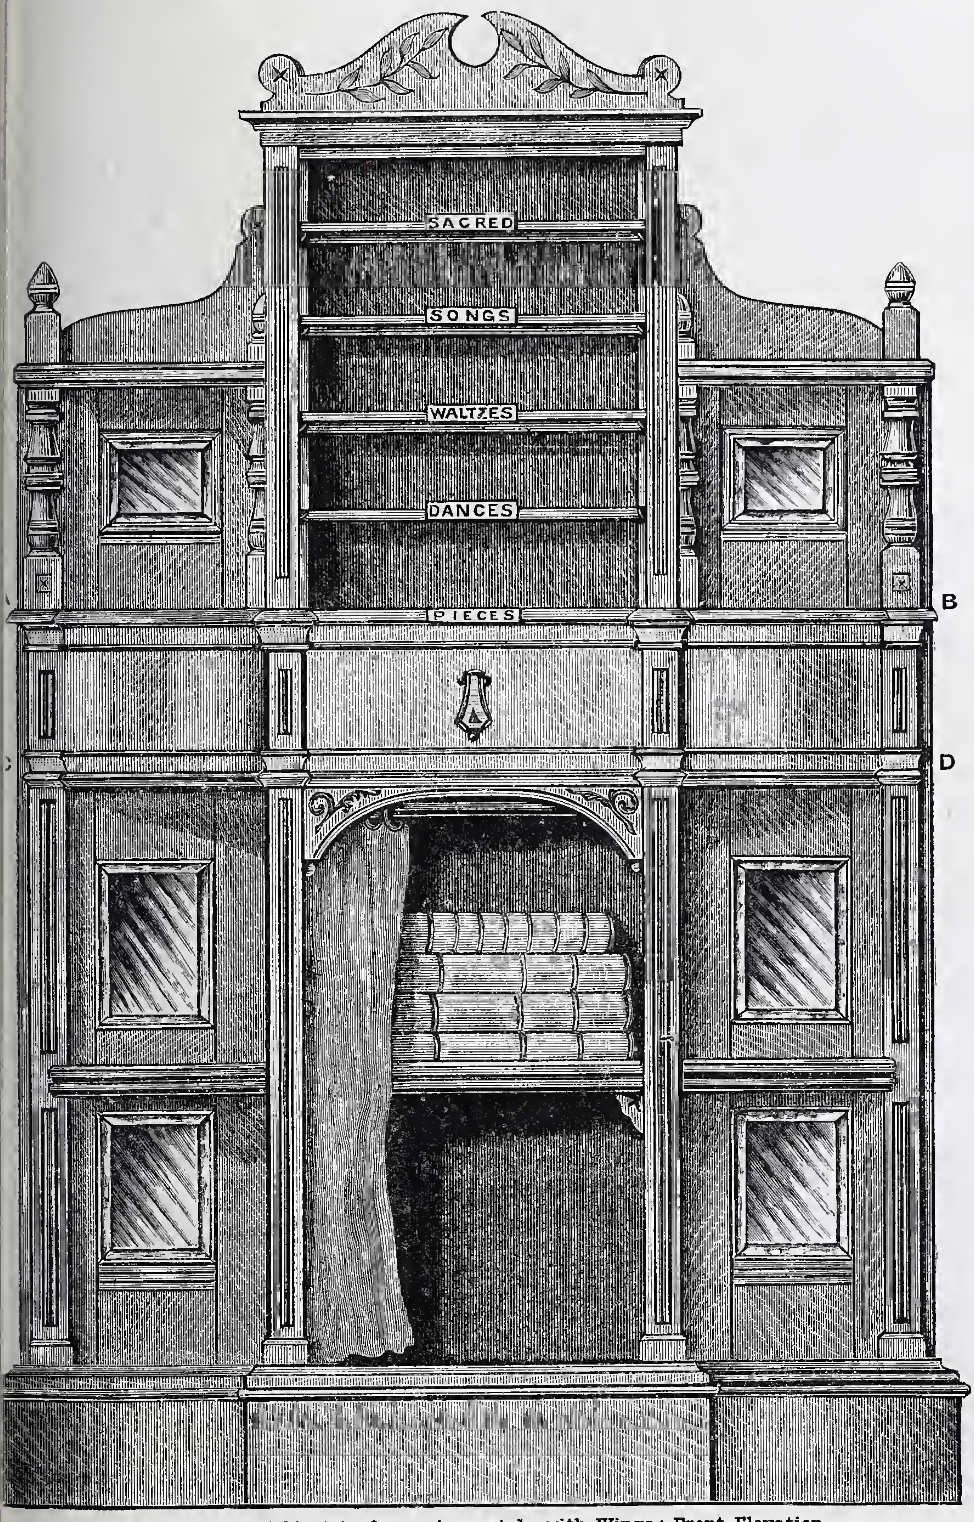

Fig. 1.—Music Cabinet in Queen Anne style with Wings: Front Elevation.

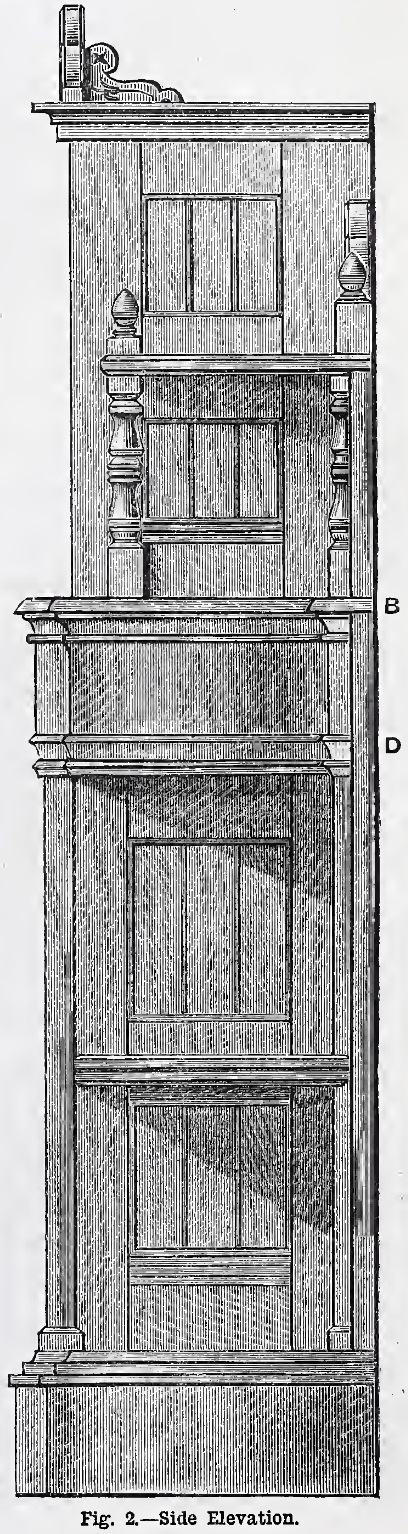

Fig. 2.—Side Elevation.

A MUSIC CABINET IN QUEEN ANNE STYLE.

AN ALTERNATIVE METHOD AND DESIGN.

BY JOHN W. HARLAND.

In continuation of my subject commenced in No. 39, I now give a design in the Queen Anne style, as more suitable for modern drawing rooms than the semi-Gothic, but simpler, cabinet shown and described in No. 39, which, as I then said, was more suitable to the school room and morning room than to the more expensively decorated rooms devoted to the reception of and entertainment of guests.

A reference to the drawings and a comparison with the first design, even if cursory, will show that, supplementing the same usefulness and the same actual proportions, a pair of wings are added for the display of the inevitable "bric-à-brac," the English translation of which, curiously enough, is found in the rhyming word "knick-nack," although derived as they are from distinct and wide-apart seats of language.

The height and narrowness of the former design are here dissipated by the means I have employed to give breadth and importance to the cabinet as a decorative piece of furniture, whilst its cost, so far as labour only goes, is augmented, the extra quantity of material being almost nominal.

Preserving the previous dimensions and the same construction, which is the strongest possible so far, the centre portion of both cabinet and pedestal, and also of the drawer and lower plinth, I must first show how the new design can be made so as to lift off the upper part from the lower, for convenience in removing it from one place to another—a great desideratum in London. This can either be done at A, B, B, or at C, D, D (see drawings), according to individual choice; the latter is my own preference, and the following construction will refer to this mode; any change therefrom will have to be modified somewhat by the individual carrying it out. Let us premise that our drawings are $\frac{1}{8}$th full size, *i.e.*, $1\frac{1}{2}$ in. equal 1 foot, and that the first step in the attempt to make it is to enlarge these scale drawings to full size, either on paper or upon a working drawing board.

Here note that, for the sake of symmetry, any article of furniture brought into juxtaposition with a pianoforte, organ, or even the ordinary furniture of a drawing room, should reproduce proportionately the relative heights of other furniture in the sub-division as to stages. The keyboard of a piano, organ, or harmonium, the mantel-shelf or board, the brackets round the walls, or any other principal projections, should have some ratio to one another, or there will be a distinct, though perhaps an unconscious, impression conveyed of incongruity, scarcely accounted for, but undoubtedly present. This has governed us in the height of the top of our pedestal and the commencement of the superimposed cabinet, both in the present and in the former design. Hence, if placed side by side it will be seen that the levels A, B, B, and C, D, D, are the same identically in both.

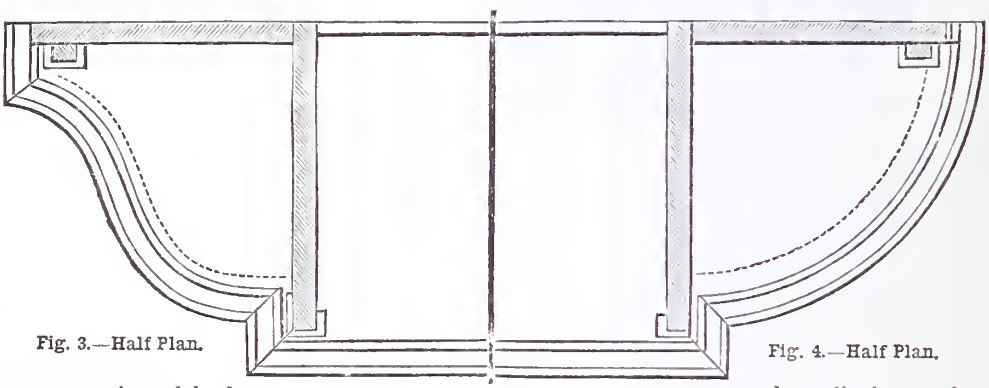

Fig. 3.—Half Plan. Fig. 4.—Half Plan.

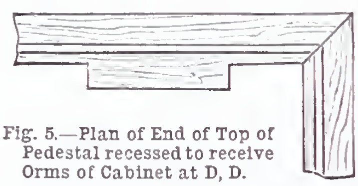

Fig. 5.—Plan of End of Top of Pedestal recessed to receive Orms of Cabinet at D, D.

Having framed together the two pairs of frames, with their panels made as shown, which constitute the sides of the centre portion of the design, in the same way as those described in my last—so far as the remarks then made can be adapted to the present design—proceed to frame a winged entablature with drawer in centre as shown, made to carry the wing-style next to be described.

On the extreme left and right of the back of the cabinet to support the ends of the entablature, to receive the ends of the plinth, and to carry the shelf for "bric-à-brac" above the entablature, at the same time affording a style for the panelling of the back boards of the wings, should be a corner post, $1\frac{1}{2}$ in. by $1\frac{1}{2}$ in., sawn into two at the level of D (so as to part there in lifting off the upper portion), but fitted with a dowel, to maintain its position, one end of which dowel should fit into a hole to correspond, but not of course glued, except where it is fitted into the lower part of this corner post, which should descend to the floor, and carry the end of the plinth, which should die into it, being tenoned and wedged into a mortise cut for its reception. These corner posts should be ploughed $\frac{1}{4}$ in. wide and $\frac{1}{4}$ in. deep on their interior sides, to receive the back panel frames, a similar and opposite groove being ploughed into the back styles of the bottom of cabinet proper, and the semi-table tops of the two wings must be made. This will consist of a rail the whole width of the back 6 in. deep, as shown, into which are mortised the two sub-plinths that form the sides of the receptacle for the drawer, and the curved wing rails also mortised into it at its extremities at one of their ends, their other ends being tenoned into mortises in the front ends of the drawer-rails or sub-plinths of the entablature, all these being of equal depth, viz.: 6 in. Similarly the plinth or base should be framed together, but instead of making this frame so deep as the former, it will suffice to make it 1 in. thick, left large enough to work it into the fillet and bead moulding shown in the drawings, the plinth itself fitting underneath it, and secured to the orms of the pedestal side frames, as before described (see Work, No. 39), in front and mitred and returned round them, again mitred inversely, and taking the curve of the entablature above, though larger than it, by the projection beyond it as shown in the drawings, the ends of this curved plinth will die into and be secured to the cabinet and pedestal side frames, to berth the other sides of the back panel-frames both above and below the entablature back rail. These back panels are shown in the drawings as bevelled glass in a frame of wood with a fancy beading to keep the glass in place; the glass may be either a mirror, a plain crystal, showing the wall through it, or backed by panels, faced with water-colour drawings with cut through mounts, with photographs, plaques, or other decorative designs; or instead of glass, china hand-painted plaques, or even wood panels, carved or plain, may be used as variations in all, or any of them. The curved rails of the entablature, and, of course, the under and upper shelves, may be either quadrants or circles or O G in form, according to which alternative half plan be chosen, as shown in Figs. 3 and 4. The table tops of both base and entablature should project as shown beyond the plinths in one case, and the entablature rails in the other, to be worked into one of the members of the mouldings, of which they form part, which should be mitred and returned round the square projections as shown, and the neck-beadings likewise. The top of the cabinet at front and the top of each wing at back should be finished as shown with shaped rails, whilst the sides of centre piece should finish with a rail, worked into a rather large bead on upper edge. The fronts of the corner posts and the fronts of the cabinet and pedestal styles should be fluted and stopped as drawn to match each other and small elongated panels carved in them where they traverse the entablature, above which the two corner posts may be turned with squares left on, rounded at their top and finished with turned knobs or "acorns," a third piece being turned to match, cut in halves, and planted each on each side-style of cabinet to carry shelf and correspond with the corner posts. The front edges of the styles being 1 in. thick only, should be thicknessed out by planting on them, outside, $\frac{1}{2}$ in. by $1\frac{1}{2}$ in. strips forming the return of the pilasters below the entablature and above it, to take the half of the turned counterpart of the corner posts.

A curved rail, as shown at top of pedestal forming an arch, conceals partially the curtain rod, which drops into its place at end in notches cut for it, before the top is put in place, which when in place keeps the rod from rising. At each end of book-shelf in pedestal is a small corner bracket shaped to form shown. The drawer is fitted with a brass or plated drop handle, with or without a keyhole and lock.

The cabinet contains trays of millboard covered with cloth or leather, with flaps as described before or wooden trays as shown with tablets for the different classes of music. In the design, both above and below the cabinet is left open; it may, however, be fitted top and bottom by single or double glass-panelled doors; if so, the side frames of both should be made $\frac{3}{4}$ in. wider for these to shut into; the top rail of the lower door or doors should be arched so as to carry out the idea of the design.

In this cabinet, as well as the former drawing, instead of a tray in the division j t above the drawer a space is left without a tray, but if preferred, one may be intro-duced.

[should have mentioned in my former per that various portions shown in draw-ings may be ebonised, the rest being ma-hogany, walnut, or other wood polished, the ebonised parts being of best pine or American whitewood for cheapness. In e manner, these parts might be en-amelled white, pale pink, or other tint picked out with gilding, the other parts being treated similarly, but paler, if tinted, in the rest, in which case all the wood ed might be whitewood or pine, which ain might be used for construction and neered, and inlaid even if wished.

Again, if required, a drawer might be fitted the front of the base plinth for MSS., usic, etc.

Such cabinets as these would contain when ll about 75 pieces in each tray, or 375 in , besides a dozen or more volumes of bound usic, and a quantity of MSS. and odd-ed sheets in the drawer; would keep it good order, and ensure any one or more eces being instantly found.

PLAIN AND DECORATIVE HOUSE PAINTING.

BY A LONDON DECORATOR.

ILS, VARNISHES, AND OTHER VEHICLES; SOLID AND LIQUID "DRIERS."

ERETOFORE we have considered the solids d pigments most useful to the house inter; we will now briefly occupy our-lves with oils and other fluids which, mpounded with those pigments, are in-spensable to the worker in mixing paint.

Oils are usually divided into two classes, d are termed *fixed oils* and *volatile oils.* xed oils are further distinguished, by eir nature and source, into *fat oils* and *ying oils.* Fat oils are those which con-in an excess of oleic acid, or stearine, as e animal and fish oils, and these are con-quently non-drying oils. Drying oils are ose which harden into a solid form, as, for stance, linseed, poppy, and nut oils.

With the first only of these latter—linseed need we here concern ourselves. Its source d appearance are matters familiar to all of ; but its qualities and properties, from e painter's point of view, is a matter it is cessary to dwell upon. Drying oils and iseed oil particularly, amongst that class, ve this characteristic of "drying" to their cess of resinous properties, and therefore, ien used under the influence of oxygen, they y or harden into a horny substance or film.

Good and reliable fluids, it will readily be iderstood, are as necessary in the mixing paint as are good pigments. Linseed oil cupies a premier position amongst its nd, similarly as genuine white lead takes at place amongst the solids; and further an this, just as white lead forms the basis nearly all light colour paints, so "linseed" the principal solvent in the preparation of rnishes and other vehicles.

The few imperfections common to good iseed oil are such as do not materially ect the work of the house painter. Least any, amongst all the articles used in the ide, should it be tampered with; the addi-on of fish oils especially, with which and pe it may occasionally be adulterated, ing inimical to its drying quality and rability. It should always be transparent, e from any rancid smell or taste, and of a ht yellow or amber colour.

With a well-stocked market of linseed to supply our wants at a very reasonable price, we have little occasion for using any of the other expressed oils; *boiled oil*—viz., boiled linseed oil—is, however, a very serviceable preparation we must notice.

As its name implies, boiled oil is the ultimate product of the raw linseed boiled with *litharge*—oxide of lead—or some simi-lar article. By this process the oxidising or drying qualities of the litharge are communi-cated to the oil, which latter furthermore gains body and brilliancy. Notwithstanding these considerable advantages, the boiling of linseed oil causes it to become much darker, and hence it is seldom used for light colours, and but rarely for interior painting. For preservative work boiled oil is almost indispensable, and especially with dark pig-ments; its colour is then no disadvantage, whilst its extra body and hardening qualities are a decided gain.

Gilders' Fat Oil is another condition of linseed oil, and is the chief factor used in making gilders' and decorators' *oil gold size.* It may be prepared by keeping raw oil in a closed vessel for a considerable length of time, by which it acquires a special bril-liancy and drying quality, when prepared as oil gold size with certain pigments. I have made good fat oil for gilding by keeping the accumulated skins and scrapings of gold size in a clay jar, and covering them with about a quart of best raw oil. After being exposed to the atmosphere, but protected from rain, etc., with occasional stirring, the oil, by the oxidising action of the old size skins and the exposure to air, has been converted into good fat oil after about a twelvemonth. Doubtless there are more expeditious ways of artificially preparing it, but the above gives a fairly quick and reliable result.

Oil of Turpentine, commonly, but incor-rectly, termed *spirit* of turpentine, ranks next to linseed for the painter's use. It is usually called, by an abbreviation, "turps," and its colourless appearance and strong pungent odour, as well as its inflammable nature, are items doubtless familiar to my readers. Although turpentine contains a slight proportion of resin and other matter which will not evaporate by exposure or heat, and which fact demonstrates the fallacy of calling it a spirit, its volatile nature makes it invaluable to the painter for thinning the drying oils and for making "flatting" paint. Since oil of turpentine contains but a small proportion of the resinous properties common to the expressed oils, it follows that its binding quality is very poor, and paint compounded with turps alone can be rubbed away by friction. Like linseed oil, that of turpentine is largely used in the manufacture of varnishes and other painters' vehicles The most important of such liquids we will now notice.

Varnishing is the last process of house painting, and consists in covering our pig-ments and paint with a film of a transparent resinous nature, which not only preserves the paint from the ill effects of the atmo-sphere and handling, but brings out the colour of the paint to its fullest extent. Where paint is prepared with an excess of raw linseed or boiled oil, varnishing is not necessary, since the oil itself encases and protects the particles of the pigment or solid used, and by its smoothness and body maintains a good gloss. For all better class work, however, and necessarily, for graining and marbling, a protective body of oil varnish is desirable, but experience and knowledge here are necessary to discriminate between the varied kinds that are made.

Varnishes may, for my present purpose, be considered in three classes, as *expressed oil varnishes, volatile oil varnishes*, and *spirit varnishes*, and from which nomencla-ture some notion of the solvents or liquids they are compounded from is gathered. It is customary in the trade to further distin-guish them by the substance or resin they contain, such as *copal* varnish and *mastic* varnish, and again to almost absurd ex-tremes by their probable use as *oak* varnish and *maple* varnish.

For whatever purpose varnish is required, it is most unwise for a novice to attempt to prepare it himself. Thirty years ago, when a painter's apprentice was necessarily initiated into the making of boiled oil, japanners' gold size, etc., the price of varnish was so high as to excuse the experiment, but nowadays, when varnish is about half the price it then was, the attempt can only be considered, under ordinary circum-stances, as a *dangerous* waste of time and material. Keen competition has now reduced varnish-making to a matter of fair profits, and my sole motive in briefly con-sidering here the articles they are com-pounded from is for the better and more intelligent use of the varnishes.

That there are to be purchased, otherwise useful, volumes containing receipts for making varnish, I am fully aware, but dis-cretion and experience alike teaches one to look lightly upon them. On the direct authority of one of our largest and most eminent varnish and colour-making firms—Messrs. Mander Bros., of Wolverhampton—I have it that "very little has been written upon the subject," and that the bulk of that little is "trash," and therefore, noticing several queries on the subject in "Shop" recently, I venture to commend this inform-ation to those would-be economists.

The best and most serviceable varnishes for use in connection with painting belong to the first of the three classes I have enumerated, namely, *oil varnishes;* and these are further usually known by the term "copal"—the name given to the gum principally used in their manufacture. This substance, which in appearance somewhat resembles amber, is imported from tropical parts, and is the product of certain trees. When a firm of varnish makers purchase what we may term a "parcel" of gums, it is very carefully assorted into various degrees of lightness and transparency. The whitest variety of the gum is usually the scarcest; and, as it follows that the colour of the copal must exercise a considerable influence over that of the ultimate product, white copal varnish is, consequently, a very expensive preparation.

In the manufacture of copal varnishes, the gum, generally, is first dissolved by heat, and then converted by turpentine into the liquid form, with the addition of linseed oil to give the copal elasticity; the colour of the oil used is, therefore, a further important factor. Colourless varnish, such as that known as *mastic*, can be simply made by dissolving the picked gum in oil of turpen-tine, but since the absence of linseed oil causes the liquid to set and harden very rapidly, such a preparation would be practically useless for the house painter, besides lacking in that elasticity and body which it is the special property of linseed oil to contribute.

The exigencies of space, etc., and the necessity for respecting these in every way, compel me to reserve the continua-tion of this part of my subject for another paper.

TINNING COPPER, BRASS, ETC., AND BRAZING.

BY R. ALEXANDER.

Articles made of copper and brass frequently have to be tinned, sometimes on one side only, sometimes on both sides. In some cases, such as stew-pans, tea-urns, and the like, they are tinned after they are made; but many things are made of sheet copper and brass tinned before working up. To do this proceed as follows:—

The sheets or pieces of the metal to be tinned must first be got clean; sheet copper or brass when procured from the makers or factors is generally fairly clean, and will not want a great deal of labour to get it ready for tinning. First of all, get the sheets flat and even by passing them through rollers, or by means of a mallet on a flat plate of iron, but do not hammer them. They must next be pickled. In shops where there is a lot of tinning done, they have pickling vats and tubs to immerse sheets and articles that require tinning. These are usually of wood or wood lined with lead; but for ordinary work in small shops it is not worth while to go to the expense of these, so proceed as follows. Take a piece of stick or iron rod about 18 in. long, and twist tow or hemp round it to make a kind of mop or swab; tie it to prevent it slipping off. Pour into a dish or basin some raw spirits of salts, and dipping the swab into it, rub the pieces of metal to be tinned on both sides; wash off with water, and well scour with "scale" from the blacksmith's shop, using a piece of sacking or similar material to rub with. When judged sufficiently clean, wash off the dirt, and stand to drain while you get ready for tinning. You will require for this some tin run out in strips like solder, some sal-ammoniac pounded up fine in a mortar, a pair of close tongs to hold the sheet metal whilst on the fire, a tinning rod, and some tow for wiping off. Assuming that a forge is to be used for tinning, a few remarks on the same will not be out of place. A fire for tinning should be in the centre of the hearth, as unless it is, there is not room to manipulate large pieces. If the forge is not so constructed, you must bring the fire out farther by fitting a piece of iron gaspipe (say about 10 in. long) into the tuyere, or tue iron as most workmen call it, though incorrectly, that is, the hole in the cast plate at the back of the forge through which the blast comes. Fig. 1 will show more clearly what I mean. It represents a portable forge; P is the pipe from tuyere to centre of hearth; H, a frame of stout hoop iron 3 in. deep and about 12 in. square, with hole half-way down for pipe to go through; this frame is to keep the fire from being scattered about. The pipe should dip a little towards the fire, so that if any molten tin should get in, it would not run back into the bellows.

Gas can also be made use of for tinning, and it is very clean and handy The home-made gas stove shown in Fig. 9 in the first of these papers (page 257) will answer very well for moderate-sized pieces; and by using a larger two-burner stove of similar pattern, such as Fletcher's No. 14 S (Fig. 2), it will be easy to do any kind of flat tinning. The tinning rod previously mentioned is made by bending a piece of ¼ iron rod to the shape shown in Fig. 3; file it bright before bending, and it will then tin itself whilst being used. This article is to rub the tin on to the surface of the metal to be tinned. To proceed, take the sheet or piece of metal that is to be tinned, and place it on the fire or gas stove; have close by the sal-ammoniac in a jar, so that it is handy to dip out with the end of the tinning rod. Scatter a little on the sheet, and blowing the fire gently (which said fire should be of charcoal), rub on a little tin, commencing at the end of the sheet farthest from you. As the tin flows, rub well with the tinning rod, adding more tin as required, and a little sal-ammoniac now and then. Pushing the sheet away from you as you proceed, and holding it with the tongs when it gets too hot to handle, be careful not to blow too hard or you will burn the tin. You will know when it is burning by seeing the metal turn blue. Should this happen, withdraw it from the fire at once, dash a little sal-ammoniac on it, and rub on some fresh tin, and proceed more carefully. When it is well covered all over, the superfluous tin must then be wiped off. This is done with a handful of tow wrapped up tightly. Commence with the end nearest you, which will be the hottest part of the sheet. Warm it till the tin is well melted, sprinkle a dust of sal-ammoniac on, and commence wiping away from you in straight strokes. Continue drawing the sheet toward you, and heating and wiping till it is all wiped smooth and bright. It should then be scoured with silver sand, dried in sawdust, and polished.

Stew-pans and other kitchen utensils are done in a similar manner, but as they are greasy and the acid or pickle will not act on grease, this must be removed before proceeding further. This is done by placing them on the fire and gently heating them till the grease or fat melts and flares off; the articles must be made well hot, but must not be allowed to get red hot. The scouring process is then the same as just described; this scouring must be thoroughly well done, or it will cause a lot of trouble in tinning. All repairs required should be done before tinning, such as the rivetting of loose handles, shaping, taking out bruises, and so on. As the handles get very hot during the process of tinning, it is usual to use a sheath on the handles of the stew-pans and covers. Fig. 4 shows one of these; they are about 12 or 14 in. long, and made a little tapering so as to slip easily on the handles and wedge tight, leaving 3 or 4 in. beyond the handle, that is, just enough to grasp it by; they are made of sheet iron; 20 gauge will do very well. When the article is well covered with tin, get well hot and rapidly and lightly wipe out with a bunch of tow; should any part get set before it has been wiped, heat it again; the outsides of the articles should be rubbed over before tinning with salt and whiting mixed to a paste with water; this prevents the copper from tarnishing with the action of the fire, and the goods are easier to scour.

A very good way to tin small articles of wrought iron, and which dispenses in a great measure with filing them up bright, is to boil them in "killed" spirits of salts in a pipkin or old iron saucepan; they will, if recently forged and not allowed to get rusty, be ready for tinning in a few minutes; taken straight from this pickle into a bath of tin they will tin at once, or if not, a second dip in the pickle will put them right. This method is of course known to some, but there are many who do not know it. And it is a great saving of time in a jobbing shop, when a few of such things as milk-pail fittings, iron rings, staples, etc., have to be tinned. The articles should be well washed and dried in sawdust, or they will rust. I cannot enlarge further on this subject, as I wish to get on as quickly as possible to the repairing and manufacturing part of this series o articles, but to any question that I ca answer I will reply in "Shop."

I will now turn my attention to a fe remarks on

Brazing.

Brazing is somewhat similar to solderin inasmuch as it is a process by which meta are united by means of heat; it is, howeve different to soldering in the fact that the un ting metal or spelter, as it is called, is muc harder, and requires a greater degree of heat t melt it than does solder, neither can it be a plied with a soldering iron. Brazing is use where greater strength is required than can b given by solder, or when an article has to stan a degree of heat that would cause solder t melt. In brazing, as a great heat is require it is necessary to have either a forge or powerful blowpipe; formerly there was onl the forge available, and many jobs were th rendered very difficult, especially in copp or brass, owing to the difficulty of getting top heat equally efficacious with the botto With iron or steel this objection does n apply with such force; I should advi all beginners to experiment a little with iro before trying the softer metals. Let u suppose, for an example, that you ha that very ordinary job in a country sh —to lengthen a key, say, for a large pla lock commonly known as a stock lock. W will suppose that you have an old key similar size of stem and bow; cut your ke that has to be lengthened (say 1 in.) at Fig. 5; cut your old key bow 1¼ in. long than the bow you cut off, and if cut off wi a chisel, file the ends true, but a hack saw the proper thing to cut with. The ne thing is to dovetail the two pieces togethe Fig. 6 shows how this is done, and explanation is needed; it is done with warding file, and the edges must be ke square and true; a small ½ round file w assist in this. Test the fitting as you go, a when they fit fairly tight give a light rap two on the side of the inner piece, that wi as it were, rivet them; the beginner will n get a good fit the first time, but he will g one thing—that is a lot of experience how go on next time. Fig. 6 A shows the k fitted ready for brazing. Now twist rou the joint about seven or eight turns of bra binding wire; this acts equally as well spelter, in fact, in this case better, as it ca not drop off. Now powder up a little bor wet the key at the joint, and sprinkle a litt of the borax on it. Now blow a fire eith of charcoal or small coke, or cinders coal, either will do; charcoal is a go fuel, but expensive to use; the others w do equally as well; in fact, nine workm out of ten first blow up their ordinary fire wi smiths' coal; in this case, however, it mu be blown perfectly clear, or the smoke w get in the joint and spoil it. A little to called a spatula is very useful and necessa in jobs of brazing to add a little spelter borax to the melting spelter, to rub off surpl metal, and to rub it into the joints as it flo It is illustrated at Fig. 7; it is made of round rod flattened one end to the sha shown, with an eye at the other end; two three of them in different lengths from 12 20 in. will be handy. Now to braze the ke Hold it by the bit with a pair of tongs, a placing it on a clear part of the fire commen to blow steadily; the borax will swell and ri up; you can press it down gently with t spatula; dip the spatula in cold water ea time you lay it on the hot metal, or the bora etc., will cling to it and be dragged off. Wh you see the wire or spelter begin to ru

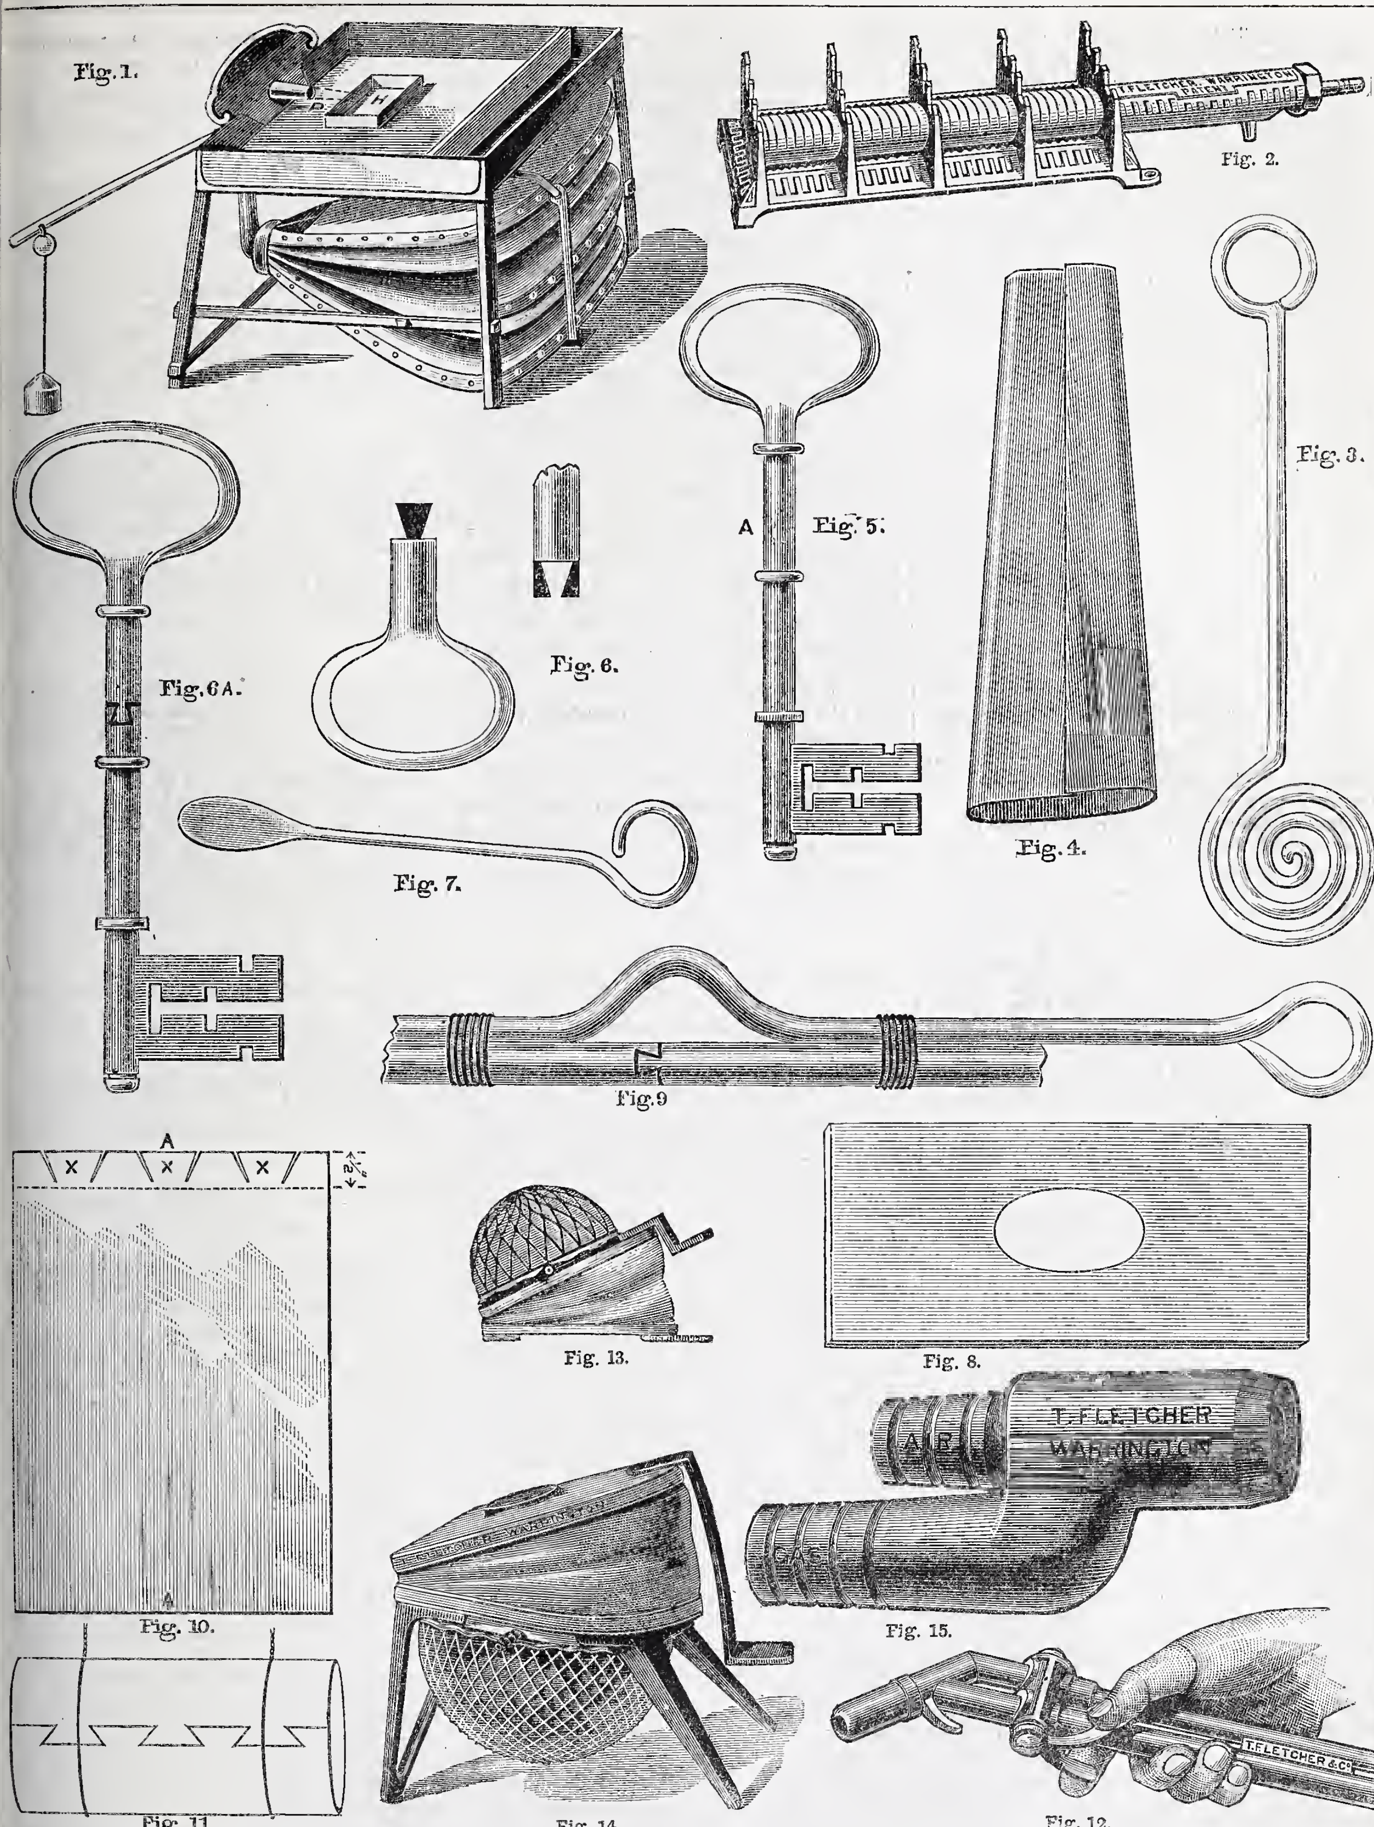

Fig. 1.—Portable Forge arranged for Tinning. Fig. 2.—Gas Stove for Tinning. Fig. 3.—Tinning Rod. Fig. 4.—Tinning Sheath. Fig. 5.—Plate Lock Key. Fig. 6.—Ditto, showing Dovetails. Fig. 6 A.—Ditto, prepared for Brazing. Fig. 7.—Spatula. Fig. 8.—Protection Plate. Fig. 9.—Mode of holding Two Pieces of Rod whilst Brazing. Fig. 10.—Piece of Copper Pipe cut out. Fig. 11.—Ditto, Tinned and prepared for Brazing. Fig. 12.—Automatic Blowpipe. Fig. 13.—Foot Blower. Fig. 14.—Larger Foot Blower. Fig. 15.—Fletcher's Injector Blowpipe.

sprinkle a little more powdered borax to help it flow, and when you see it all nicely running withdraw the key gently from the fire, rub off superfluous metal from the key (a little generally gathers underneath), and allow it to cool of itself; never cool a brazed joint suddenly, as the sudden contraction of metal is apt to injure the joint, though I know many who always dip a copper braze in the water directly it is taken off the fire. The key must now be filed up and cleaned so as to scarcely show, except by a thin mark of brass in the joint, where it has been joined. To lessen the trouble of cleaning a key or anything bright of a similar kind that has to be brazed, a guard (Fig. 8) is very useful.

It consists of a piece of stout plate iron about $1\frac{1}{16}$ in. thick, and of sufficient width and length to protect the article laid on it from the direct heat of the fire. A hole is cut in it about $1\frac{1}{2}$ in. long by 1 in. wide, and the key placed on the sheet iron in such a way that the joint comes over the hole as shown in the sketch. You can then blow away without fear of injuring the article by the fire. Some articles also require supporting and fixing, so that the joint will not shift while it is being brazed. Fig. 9 shows a way of holding a straight piece of rod or similar job. Many jobs will require a pin or rivet put through them as an additional security. Always get everything to fit as well as possible; it cannot be too good a fit; the spelter is sure to find its way in if the joint is clean.

How to braze a piece of copper pipe:—

Suppose for a trial job a piece of pipe 12 in. long and 4 in. diameter. Cut your stuff 12 by 13, thin down the edges, A A (Fig. 10), with a crosspane hammer about $\frac{3}{8}$ of an inch clear each side. Notch one side, as shown in sketch, turn it round, bend up the notched pieces X, and slip the other edge in as far as possible, and then knock the notches down and hammer together on a bick iron. Bind round at each end with iron wire as at Fig. 11. It is now ready for brazing. Mix equal parts of spelter and borax in a jar or tray with water, and with the spatula spread it on the joint (inside of course). Place on the fire and blow gently. Sprinkle a little powdered borax along the seam, and as the spelter melts rub along with the spatula, drawing out superfluous metal and putting more in if there should not happen to be enough at first. Be careful not to blow too fiercely, as copper will not stand near the heat that iron will, and brass less heat even than copper. It is sometimes very awkward to braze some articles with a forge, owing to the difficulty of directing the heat to the right place. But there is no need to despair of brazing the most difficult jobs, now that appliances for brazing by means of gas, etc., have been brought to such perfection, especially by Messrs. Fletcher & Co., of Warrington, and this article would not be complete if I did not mention some of them, as they are valuable alike to the professional workman and the amateur. Fig. 12 shows what they term their new automatic blowpipe, pattern C. It is a very simple and very efficient blowpipe for ordinary use. The medium size is C 40 for key brazing, small copper gaspipe, etc., and odd jobs not requiring much power. Where it is possible to do so, small articles should be placed on a piece of charcoal or pumice stone whilst brazing with the blowpipe, or carbon blocks made especially for the purpose by Messrs. Fletcher, in various sizes and shapes. These substances are used because they are fire-resisting, and do not rob the article of the heat imparted to it by the flame of the blowpipe. C 80 is a large blowpipe, same pattern; this will braze $\frac{1}{2}$-in. thick flanges on $1\frac{1}{2}$-in. wrought iron pipe and copper work up to about 2lb to the square foot. These blowpipes require a greater pressure of air than can be given by the mouth, so a means must be found of giving a supply of air under pressure, either by connecting them to a smith's bellows or using a foot blower (Fig. 13). The reason is that it is the pressure of air that rules the temperature of the flame, and, consequently, the power or heat thereby obtained. Thus, to get a sharp, concentrated heat, an air pressure of from 1 to $1\frac{1}{2}$ lbs. on the square inch is required. These blowers will give this with a steady pressure. The small sizes 3 and 5 (Fig. 13) can be worked by the foot or under the arm. Fig. 14, known as 9B, 3, and 5, are for foot use only, and are generally recommended for all purposes.

The same firm also supply very powerful blowpipes for heavy brazing, such as repairing copper pipes without removing, repairs to machinery, etc. No. 1, Fig. 15, requires a smith's bellows or a fan and $1\frac{1}{2}$-in. gas supply. It will burn up to 300 cubic feet of gas per hour, and will heat a 3-in. wrought iron pipe up to brazing heat in a few minutes. No. 2 is a similar blowpipe, but can be used with the foot blower, thus enabling it to be taken and used in positions where to use an ordinary smith's bellows would be a matter of difficulty. There are other useful blowpipes, but space will not allow me to describe them here, and I wish to get on as quickly as possible to the repairing and manufacture of tin goods, etc. My next article will illustrate and describe some further repairs, and the tools and material used for the same.

MEANS, MODES, AND METHODS.

Luminous Paint.

This is so recent an invention that it has not yet been taken into the category of applied science. It is as yet only a novelty; like the old phosphoric writing, visible in the dark, was a half a century ago. The Paris Exhibition has brought into prominence a variety of new ideas and useful inventions, which but for that display with fifty-three thousand exhibitors with a hundred times that number of varied exhibits might have been lurking unnoticed by the world in rooms and workshops; luminous paints amongst the number. Here it had a prominence, its display makes at once easy and manifest. Thousands of square cards were given away, showing the luminous paint on one side. They were thus in the hands of each recipient to test, and they fully established its title to luminosity in the dark so vivid that, by writing any word in Roman letters one-eighth of an inch thick on it, the word was visible. Dipping the card in water, so far from affecting the action of the paint injuriously, made it brighter; exposure to daylight does not deteriorate it.

Now for its practical value. If it is found to be enduring, the names of thoroughfares might be painted with it, and finger-posts at cross-roads, so useless to the benighted traveller who has to take out the lamp of his trap and throw its rays on to the direction; for stairways, and passages, and corridors; on walls of dark offices to add more light, to save the sight of the plodders of the pen. Its uses have to be found out by practical trials and more general knowledge of how it is best applied. It has already won sixteen medals of merit. W. C. Horne, 6, Dowgate Hill, London, E.C., is agent for it.—J. C. K.

To darken Common Mahogany to represent Old Spanish.

To 1 oz. of bichromate of potash dissolved in 1 pint of boiling water. Apply with a brush and allow to turn colour by action of the air.—H. T. N.

Brown Hard Spirit Varnish.

To 1 pint of spirits of wine (meth.), $2\frac{1}{2}$ ozs. best orange shellac, 1 oz. gum benzoin, $\frac{1}{2}$ oz. gum thust, $\frac{1}{4}$ oz. powdered resin, and size of a marble of gum sandarach.

Mode.—Let macerate for two days in a warm place, shaking often and strain.

Note.—Work should be warm but not hot to ensure a good polish with spirit varnish.—H. T. N.

Polish Reviver.

To $\frac{1}{2}$ pint cold-drawn linseed oil, $\frac{1}{2}$ pint spirits of wine (meth.), $\frac{1}{4}$ pint good vinegar and 2 pennyworth of butter of antimony.

Mode.—Mix the above and well shake. Should be used with a soft cloth, well rubbed in, and not a great deal used at the time; continue for one or two days, when a good polish will be obtained.—H. T. N.

Walnut Stain.

To 2 ozs. Vandyke brown, 2 ozs. American potash, 1 oz. bichromate of potash, size of walnut of soda, size of walnut of sulphate of copper, size of marble sulphate of iron, 2 ozs. nitric acid, and 1 gallon of water.

Mode.—Boil the water, brown, bichromate, soda, and sulphates until melted and well mixed. Then add the American potash, which must be melted first in a little water, otherwise it will effervesce over the sides of the pot. When lukewarm add the acid.—H. T. N.

Dark Oak Stain

To 4 ozs. American potash, 4 ozs. Vandyke brown.

Mode.—Proceed as above with the potash using 1 gallon of water.

The above are well tried, practical receipts, which I have used in the furniture trade (antique) for several years.—H. T. N.

SOME PHOTOGRAPHIC APPLIANCES

BY AN OLD HAND.

Backgrounds—Reflectors—Dark-Room Lantern—Small Folding Lantern—Dishes—Oscillating Developing Table.

Backgrounds are plain or scenic, made to roll up after the fashion of a blind, or stretched on a frame like a painter's canvas. Providing there is the necessary space at disposal, those of canvas on frames are decidedly the best, as by this means creases and markings produced by rolling and unrolling are avoided. They may be prepared either in oils or distemper. Although rather more trouble to prepare, those painted with oil paint, either flatted or bright, are the most serviceable, as in case of leakage from the roof or other accidental soil, it can be readily sponged off without damage, when a background in distemper would be irretrievably spoiled. Again, a distemper background is more easily made and less expensive, and the effect in the photograph is equally good to that of the oil-painted one. We will now proceed to make the foundation for one which will be the same whatever method may be selected for colouring it. Procure some battens the length and breadth the completed background is desired to be. We will suppose one of about 8 ft. high by 7 ft. wide, which is a moderate size, and sufficiently large for two or three figures. The wood should be ¾-in. deal, 3 in. wide, the corners cut to overlap, and strongly screwed together, as Fig. 1, additional strength being imparted by corner pieces (B, B, B, B), also screwed on. A bar across the centre—narrow way of the frame—mortised into each side, gives additional rigidity, and affords a convenient hand-hold in moving it, as it goes without saying the face of the background should be handled as little as possible. The frame will now appear as in Fig. 1. The reason for making the corners strong is that, when the canvas is stretched upon the frame, the least giving way would cause the material to pucker and crease, entirely spoiling the effect. Extra bars are sometimes put diagonally across the corners (Fig. 1, A, A, A, A) from the centre bar to outside. Of course, this adds to the weight, and is unnecessary with a background of the size given. The idea is to get a perfectly stiff framing. The lower bar of the frame may be provided with small wooden rollers let into the lower edge as W, W, in Fig. 2. The frame now being ready, it must be covered tightly with calico, which is sold under the name of sheeting, and may be had of various widths. If it can be procured sufficiently wide to do without a join, so much the better; but, if joining is imperative, the seam must be simply sewn and not felled, or an objectionable ridge would be made that no amount of colour would obliterate. Fig. 3 shows how the edges should be put together. The seams must always be vertical, and not across the background. The join being regularly and neatly made, and well rubbed down, spread the sheet on the floor and lay the frame on centrally; turn over one end of the sheet and tack it with tin tacks about 2 in. apart, taking great care to keep it level; do the same to one side, pulling slightly from the already tacked end. Now proceed to tack on the opposite side with a firm, steady pull and a diagonal direction. Keep the sheet as smooth as possible whilst it is being fastened. Lastly tack on the bottom, using a steady pull from the top during the time. Now raise the frame covered with the calico on end. It ought to be quite smooth and free from wrinkles; if not, make it so by altering the tacking, then, with a sponge or large brush, thoroughly wet it all over, and let it dry, when it will be found strained as tightly as a drumhead. Prepare some size—about 1 lb. of size to a gallon of water—and give it a good even coating, and let it dry, when it will be ready to paint. With a piece of charcoal draw two lines diagonally across, as in Fig. 4, to act as guides in the shading. Of course, if only a flat, even tint is required, this is unnecessary; but a shaded background is much better for all purposes than an absolutely flat one. Provide three pots of paint of different shades of grey by mixing lamp or ivory black with white lead. The depth of colour is decided in a great measure by the amount of light that will fall on it when set up for use. A light studio will require a darker set of tints than one in which the light is but moderate. Something also depends on personal taste, whether a light or dark background is required. With a brush well charged with colour of the lightest tint, begin at the left-hand top corner and paint down to the first charcoal line. Scrape the brush, and paint the middle division with the second tint, well softening the two together at the junction; then, with the darkest, fill up the lowest division, well amalgamating the tints where they meet. As soon as all the surface is painted over, work well over it with a softener until the background shows an even graduated tint from one corner to the other. In case of a flatted paint being used, it is almost necessary that the softening should proceed simultaneously with the painting, for, if it is left till the whole is covered, it becomes too dry to make a good job of it. Two persons may very well manage this, one to paint and the other to soften. The background, when dry, is finished, and ought not to show any definite lines of colour, but be one continuous tint, from light to dark. If distemper is used, the same precautions must be taken, the colour being thoroughly brushed into the material, which need not be sized first, the size being mixed with the colour. A little soap dissolved in it is also an advantage, keeping it more flexible. The distemper colour must look considerably darker a tint when wet, as it dries up very much lighter. There is plenty of opportunity for the exercise of individual taste in the preparation of backgrounds. The shading may be varied, or landscapes or interiors painted on it; but, whatever it may be, to be artistic, it must be rather suggestive than definite, and the central part free from any decided pattern or design which would interfere with the lines of the portrait. For genuine work, a design consisting of a panel surrounded with a slight moulding is as useful as any. Simplicity must be always aimed at, for elaborately patterned backgrounds are generally disappointing when partly hidden by the model—a matter more frequently overlooked than it ought to be.

Reflectors partake of something of the nature of backgrounds, being canvas covered with white paper on light frames, fixed on stands adjustable to any angle, for the purpose of reflecting light into the shadows. Fig. 5 represents a reflector ready for use; it consists of a light deal frame 4 ft. by 2½ ft. in size, to the central bar of which is fastened two semi-circular pieces of wood with holes through them (Fig. 6). The upright (Fig. 5, C) may very conveniently be made of an ordinary brush handle, 3 ft. 8 in. in length, cut flat at one end to work in the slot formed by the two semi-circular pieces of wood; a rivet with a screw thread on one end fastens them together, and the screw is kept in position by a winged nut on it. The foot is made of a circular piece of heavy wood 3 in. thick, turned somewhat ornamentally as Fig. 5, D; to the bottom a thick piece of stout lead is screwed to give additional weight and steadiness, three small knob feet are screwed in, and the reflector is finished; it, of course, may be stained, polished, or painted at the taste of the maker; different sizes may also be made, and attached by a ball and socket-joint instead of rivet and nut, or made in metal instead of wood; an old-fashioned iron head rest can easily be converted for this purpose.

The Dark-room Lantern is a very necessary piece of apparatus, and is of two species: one for a permanent fixture, and the other for travelling, or rather for occasional use and portability. The forms in which they are made are very varied, the object in all being to get a good safe light of convenient form, and to be used either with candle, paraffin, or gas. Within a reasonable degree, the greater the volume of light the more comfortable for the worker, providing the quality of the light is such as to have no action on the sensitive surface that will of necessity be exposed to it. Correctly speaking, no light is absolutely without action, and sufficiently long exposure to the most safe light we are acquainted with will produce decided photographic action. If a sensitive plate, exposed for a quarter of an hour to the full action of such light, and can then be developed without fog, the light may be considered safe in practice; this is a very much longer time than there is any necessity for submitting a plate to, but still the caution holds good—never to expose a sensitive film to any light longer than absolutely necessary. A very small subdued red light is very injurious to the eyesight if frequently used, and many workers under such conditions suffer considerable pain, besides permanent injury to the eyesight.

The disadvantages of working in such darkness, for it is little else, are numerous; upsets and breakages are of common occurrence, and development must be somewhat out of the control of the operator when he can, by the utmost straining of the eyesight, have but a faint glimmer of the developing image. All this points in one direction—to have as much light as can be safely used. Owing to the varying sensitiveness of different makes of plates, a light quite safe with one kind would not be so with another. Orthochromatic plates cannot be worked in any except a deep red light, without fogging, but for other kinds, two or three thicknesses of golden fabric will be quite safe for a candle or lamp, besides giving a comfortable flood of light all over the room. In order to obtain a large volume of safe light, a very much larger lantern may be used at home, where it would be more or less of a permanency than would be convenient for travelling. We will proceed to make one as follows: Cut out of oak 1 in. thick a piece the shape and size shown in Fig. 7; this will form the bottom of the lantern, and its weight help to prevent accidental overturning. Now get a sheet of tin plate, sufficient to bend round the curved side of the wood, and turn over half an inch in front on each side, and of the height of 18 in. Fig 8 shows the lantern in its complete state. Solder an L-shaped strip of tin down each side to form a groove, and from this strip, another one 1 in. wide across the curve at the top. A piece of glass, E, can now be slipped down in the grooves, and rest on the rebate of the wooden bottom. After ascertaining if the groove is of proper width in which the glass can slip easily, solder another slip of tin across the top from the outside edge of the groove before the other. Make a tin plate lid, F, with a hole 1½ in. in diameter in the centre, over which a tin cap, G, is fastened. The projecting pieces, H, H, H, are made to pass through the tin lid and act as supports, in case the solder should get melted by the heat of the lamp. The cap is intended as a light trap, and is therefore much larger than the aperture it covers; to the straight edge of the front of the lid is hinged a flap, J, made to fall over the opening through which the glass is inserted, and to prevent any unguarded light from the lantern getting into the room. The lower part of the body of the lantern is pierced with a number of small holes to permit access of air, over which on the inside of lantern is a strip of tin, K, soldered, sloping down towards the light to about ¼ of an inch from the bottom. The bottom itself may be covered with tin, which, if intended for a candle, may be provided with a shallow socket for it. Two pieces of glass, one deep ruby and the other orange, over which has been pasted two thicknesses of golden fabric, to slip into the grooves and either used as required, and if the groove is made of sufficient width both may be used together; a coat of black japan over the outside will complete it.

A Small Folding Lantern for travelling may be made of cardboard with a tin lid and base, as Fig. 9. Procure some short cardboard (other material can be used), and cut three pieces 6 in. by 12 in.; in one of them cut an opening 8 in. by 4 in.; lay them side by side on the table, and separated about $\frac{1}{16}$ of an inch; paste over them a is a very simple and useful lamp for travelling, and not likely to get broken. Cardboard is light, and perhaps as good a material as can be used; the fabric adheres better to it than to either wood or metal after it has been subjected to the heat of the light for a little time, from which it is liable to peel off. The projecting $\frac{3}{4}$ of an inch of fabric is to fold over the crack left; when the sides are set up, two strips are glued to the grooves with some ground white and re lead, and slide in a piece of stout glass; the fix on the end; when dry, go over the whol with one or two coats of shellac varnish.

The appliances that have been describe here, and, indeed, all that have been brougl under the reader's notice in previous paper can be easily made by any one who happe to be tolerably handy in the use of a fe of the most ordinary tools that are us

piece of ruby cloth; turn over, and cover the other side with golden fabric in the same manner, allowing both materials to project $\frac{3}{4}$ of an inch beyond the side of the card. Make two tin caps (Fig. 9, K^1, K^2), one of which has an aperture about $1\frac{1}{2}$ in. in diameter (capped over as in the other lantern), for the top and bottom. The cardboard sides can now be folded into a triangular form and put over the light, set on the lower lid in a socket (nothing is better than an ordinary night-light), and the top slipped on. This the outside at bottom to fall loosely over the air-holes, M.

Dishes useful for many purposes may be made of wood and glass, as Fig. 10. Suppose a dish is required that will conveniently hold a 15 by 12 plate. Prepare two pieces of $\frac{3}{4}$-in. pitch pine, $2\frac{1}{2}$ in. wide and 17 in. long, and two pieces 14 in. long; cut a groove $\frac{3}{8}$ of an inch deep and $\frac{3}{16}$ in. wide (Fig. 11); about $\frac{3}{4}$ of an inch from one side of each strip of wood mitre and glue two of the corners, partially fill in in carpentry, and the small amount o metal work, principally the tin-plate worl described above, will occasion no difficulty There are yet a few articles that the amateu or professional photographer may make fo his own use, but these must be reserved fo another paper. Abundant means of worl for the long evenings of winter have beer afforded any one who is desirous of supplyin himself with his own photographic appli ances in making those which have alread been brought under his notice.

THE BEE-HIVE TENT.

INVENTED BY CAPT. H. R. NEWBURGH-STEWART, R.N., WINDSOR.

BY JOHN CHARLES KING.

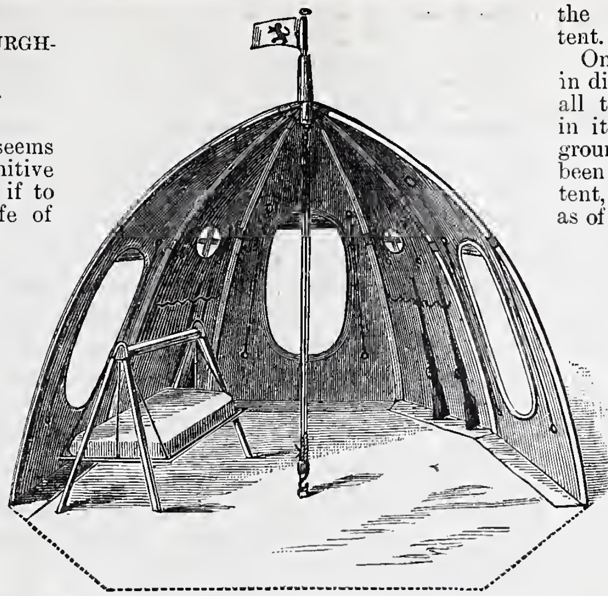

Fig. 1.—Section of Bee-Hive Tent exhibiting Interior.

The highest range of civilisation seems often to voluntarily revert to primitive methods of arrangement of life, as if to renew with pristine vigour the strife of man with the elements as in early ages of the world. Our Alpine clubs, exploring expeditions to unknown parts in the arctic and tropic zones; the chase of wild animals, with its hardships and perils; all seem to lend a charm to cultured existence, and give a healthy relief to the monotony of a life of ease and the plodding after gain of wealth that often debases existence. Even the exhilaration of a cross-country gallop to the ring of hounds' notes that enliven the chase, which is sure to bring falls, fractures, and sometimes death, to some of the best of the votaries of this manly recreation, yet which is followed with ever-increasing ardour. But the gaps in the ranks thus caused are filled by young men and women who keep life at high pressure enjoyment at the hazard of all risks. But in thus becoming nomads in travel and athletes at sports, there is mostly a stable reliance on a banker's balance, and the world's best resources it commands. The weapons, equipments, cattle, and human help, this balance commands, are a factor which must be estimated at its value here.

The canoe of bark, with its outer covering of skins of early ages, is for our modern tourist converted into a house-boat. For land-travel, tenting-out is popular just now. The tents of all peoples have been the homes and nurseries of nations. How picturesque is a tent, whether of leaves, skins, or canvas! Armies rest beneath them; but adventure and enterprise, as well as war, claim the use of the tent—the untaxed dwelling of the hunter, the tourist, and the emigrant.

Every one thinks he could pitch a tent. Doubtless many who tried would not be quite satisfied with the first attempt. Like everything else, it requires just that handy knowledge of ropes and canvas which few but seamen have. The only landsmen, not of the army, perhaps likely to do the work deftly would be the farm labourers, used to putting up rick-cloths over stacks. Even these men are falling off in their former general handiness, and nineteen out of twenty of them boggle over their rick-cloth raising. Machinery is making them more inert clods than ever, instead of raising their standard of technical excellence. There is an old saying, "He who knows nothing is readiest to learn," presumably because he has not to unlearn error or misteaching.

Tents vary in two essentials, shape and material. Skins form the covering in cold climates, grass and leaves in hot climates. Canvas, from its lightness and strength combined, is the main tent-covering of armies and most of the settlers and travellers who use tents. It is so well known as to need no description, the pole being the central support, and the lines and pegs, the stays to sustain it against the stress of weather.

The shape being conical, gives the least amount of convenient room for the occupant, if moving about in it upright. The middle has a post which may not be pressed against too violently by user or his luggage, or it may snap off, then down comes the fabric, and there it settles till a new post is upreared. This post is the ticklish part of the concern. Move it, and down flops your tent. "It's twelve feet across," says the tent man. He walks round it, and finds it is only about half that for upright range; a sort of no-man's-land is beyond the six feet head-room limit, which is only to be got at by crouching. It is valuable space wasted, where every foot counts for or against comfort. In a storm, beware of letting things touch the tent-cover and draw the rain through the canvas into the tent.

One who spent nine years under canvas in different parts of the world has changed all this. He does away with the post, and in its place puts a cord to a staple in the ground where the post-hole would have been; this cord reaches to the apex of the tent, which is furnished with a "rib-ring," as of an umbrella; this "rib-ring" has spurs with holes to take as many ends of "tent ribs" as may be used. A pin secures each top end of the "ribs," which for convenience are made in two pieces of American elm, or other flexible wood, joined by a simple square-edged oblong socket which retains the jointed ribs securely under any strain, and allows packing away in half lengths.

The tent, when first raised, is a true cone till the pull of the light tackle on the "rib-ring" and mid-staple in the ground brings down the apex to a dome shape, bracing the ribs securely on their bearing on the ground, the canvas preventing their out-spreading there, and the whole being as taut as if it were an expanded balloon.

The no-man's-land of the conical tent becomes exploited, as economists would say, and the bell tent converted to a bee-hive, that makes the user feel there is science in shape which yields the comfort of increased space, security from the elements, and less lumber weight to be carried about in tent moving. The door-openings are covered or opened by the canvas being raised or lowered blind fashion. Ventilators the same way; even the tent may be rolled up all round two feet from the ground for tropical use to gain more air.

To those who do not know anything of the weight of tent fittings, it will surprise them to learn that the conical tents for Indian service require each 100 iron pegs, weighing 300 lbs. The bee-hive tent requires only the iron hold-fasts, and four pegs for storm stays to be put on if wanted; 2,000 ft. of rope is saved. It is estimated that for a regiment with 100 tents, twenty tons' weight may be saved, and the more perfect form of tent for all purposes be secured with great economy of cost and durability. It is about to be brought before the notice of the Minister of War in France, when, if adopted in the French army, it may be noticed and adopted by other nations. But it is as a tourist's or emigrant's tent that we notice its merits.

The principle of the tent is as follows:—Fig. 1 exhibits a section showing the room gained, and manner of bracing the rib-ring to the staple in the ground, and Fig. 2 the tent set with two entrances left open. These openings afford convenient means for entering or quitting the tent. On the right of this illustration an entrance is shown closed up, and in each side means of ventilation can be seen which are entirely independent of the larger entrances, which are placed opposite each other in alternate sides of the tent.

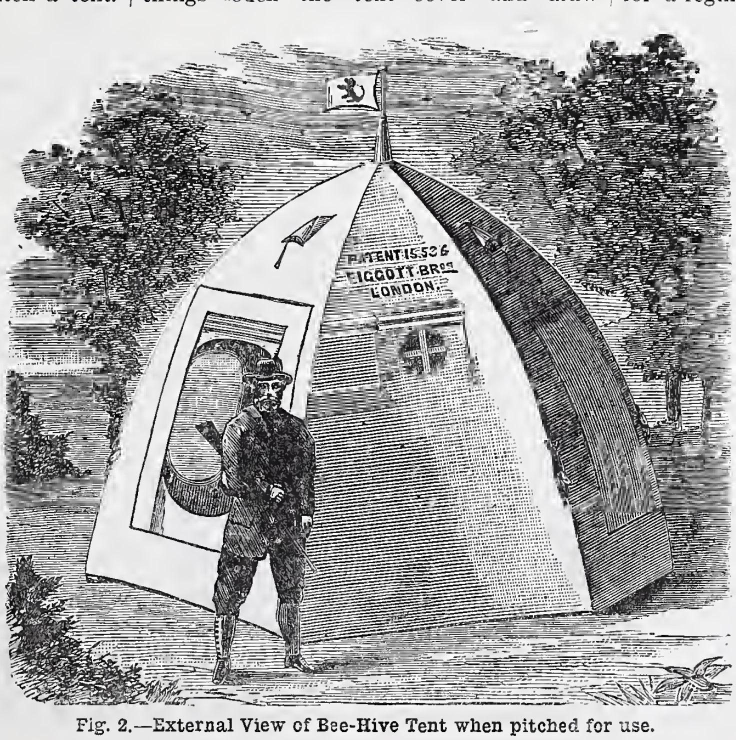

Fig. 2.—External View of Bee-Hive Tent when pitched for use.

BRITANNIA METAL, BRUSHES, BUFFS, ETC.

BY GEORGE EDWINSON BONNEY.

BRITANNIA METAL—BRIGHT PLATING—BRIGHTENING SOLUTIONS—BRUSHES—BUFFS—BUNSEN BATTERY—BUNSEN BURNER.

Britannia Metal.—This is an alloy composed of tin, 92; antimony, 6·2; and copper, 1·8 parts. This greyish-white alloy, nearly resembling pewter in colour and softness, is employed as the base for a large class of cheap, showy, electro-plated goods. These may be readily distinguished from best electro-plate by the softness of the metal, the thinness of the silver, the low price, and the sound given forth by the article when struck. Best plated goods are made of some hard alloy, such as German silver, and will give forth a sonorous sound when struck, whereas Britannia metal and pewter give out a dull sound. As such plated goods often come to the electro-plater to be replated, it is advisable to know how to treat the goods. After all the old silver has been stripped from the articles in the acid-stripping solution, rinse and scratch-brush them, then soak them in the potash dip for half an hour. Rinse them in a clean, diluted potash dip, transfer at once to a good plating solution rich in metal, and pass at first a strong current, so as to strike them at once with a coat of silver all over. As the deposit thickens, the density of the current should be reduced, or the silver will go on too fast at the finish. Great care must be taken in burnishing a coat of silver deposited on this alloy, or the coat will strip from too much pressure being applied to the burnisher. Whenever practicable, avoid burnishing this alloy, but finish off with soft scratch brushes and the "dolly."

Bright Plating.—It often happens that the silver plater has to electro-plate the insides of tea-pots, coffee-pots, and similar vessels, and he is expected to turn these out of hand in a bright and finished condition in every part. It is quite possible to reach the insides of ordinary sized and shaped vessels with suitably-designed scratch brushes, but there are always some interstices in ornamental and chased work that cannot be possibly reached by mechanical means, and it would never do to leave those parts with the dull white or "matt" coating left upon them when finished in an ordinary silver-plating solution. It is, therefore, usual to make up a special brightening solution to deposit a bright coat of silver on the finished article. The solution for bright plating is made up as follows:—

Brightening Solution.—Take 1 pint of old silver-plating (cyanide) solution, and add to it from 2 to 3 ounces of bisulphide of carbon. Put this in a glass-stoppered bottle capable of holding half a gallon of liquid, and add to it 3 pints more of the old plating solution; then shake the bottle well for a few minutes, and set aside to rest for twenty-four hours or more. Carefully decant the bright liquid into another similar bottle without disturbing the sediment, and add from 2 to 3 ounces of good cyanide of potassium dissolved in distilled water. Shake up the contents of the bottle to mix them, and when all is settled down again, the mixture will be fit for use. The daily dose of this liquid to the bright-plating solution must only be in the proportion of 2 fluid ounces to each 20 gallons of solution. This should be added at the close of each day's work, and well stirred into the plating solution. If too much brightening solution is added, the deposit will be brown, or streaked with black or brown streaks, and the solution spoiled. It should never be added to the ordinary plating solutions, since they are apt to be spoiled for other work by the addition of the brightening solution. The work bring brightened should be closely watched. The brightening effects will commence at the bottom of the article and spread upwards; when the article is covered, it should be removed at once, and quickly rinsed in warm water. *Caution.*—As bisulphide of carbon is a nasty, stinking, poisonous liquid, of a volatile nature, great care must be exercised in its use, so as not to breathe the fœtid vapour, the odour of which resembles that of rotting cabbage. This alone should warn amateurs against sniffing at the bottle containing it or the brightening solution.

Brushes.—In large plating establishments, a number of various kinds and shapes of brushes are employed in the process of scouring the goods preparatory to plating, and finishing them after they have been plated. The brushes employed in scouring the work are made of hog hair, containing one, two, three, four, or more rows of hair,

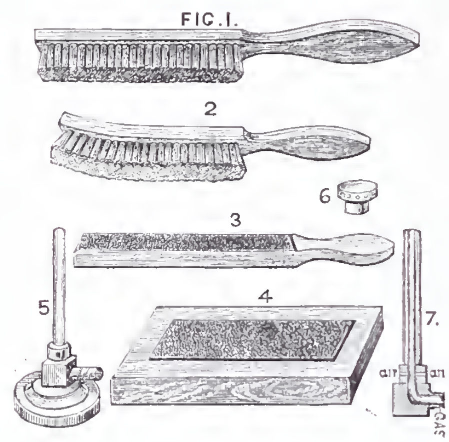

Fig. 1.—Scouring Brush. Fig. 2.—Curved Back Plate Brush. Fig. 3.—Buff Stick. Fig. 4.—Buff for Polishing Burnishers. Fig. 5.—Bunsen Burner. Fig. 6.—Rose Cap for Bunsen Burner. Fig. 7.—Section of Interior of Bunsen Burner Tube.

with solid wood backs (as shown at Fig. 1), in sizes suitable to the requirements of the plater. When first received from the maker, they should be dipped for a moment in the potash dip, to remove any grease there may be on the hair, well rinsed in clear water, and then kept exclusively for the purpose of scouring. Brushes made from cow hair are used to polish steel articles preparatory to being plated with nickel. Camel-hair brushes are used in ornamenting gilded and plated work with coloured varnishes and other colouring mixtures. Ordinary plate brushes with curved backs (as shown at Fig. 2) are very useful tools for brushing the insides of cylinders. Wire brushes are also used in scouring and cleaning iron and steel goods when these are coated with dirt and much corroded or pitted. It is sometimes necessary to use a steel-wire brush for cleaning iron castings before being brassed. The kind of wire brush, known as a scratch brush, will be noticed under the head of *Scratch Brushes* and *Scratch Brushing*.

Buffs.—These are sticks like hand brushes without hair, but with buff leather firmly glued to the wood (see Fig. 3). This buff leather is the tough, rough-grained leather used in soldiers' belts. Buff sticks, like scouring brushes, are made in various widths to suit the work in hand, the broad buffs being used for polishing broad plane surfaces; and the narrow, thin buff sticks for giving a polish to grooves and hollows. They are used with finely-powdered rottenstone and oil, or with finely-powdered crocus, to give a finishing polish by hand to articles about to be plated. Where polishing lathes are available, the buffs consist of discs of wood, faced with various qualities of leather to suit the several classes of work and the several stages of the polishing process. Buffs are also used to impart a perfectly smooth polish to steel and blood-stone burnishers. When used for this purpose, the strip of buff leather is first boiled in water and dried quickly, then glued to a flat piece of wood a little larger than itself, and weighted with heavy weights until quite firm. The buff then resembles a mounted hone or oilstone, such as is used in carpenters' shops (see Fig. 4). Its use will be explained in the notes on *Burnishers* and *Burnishing*.

Bunsen Battery.—The Bunsen battery as used in this country is made up of an outer containing cell of stoneware, containing a cylinder of amalgamated zinc, inside which is a cell of porous earthenware containing a square bar of carbon. The outer cell is charged with sulphuric acid diluted with from eight to fifteen parts of water, and the inner cell is charged with strong commercial nitric acid. The electro-motive force given by this arrangement is variously stated by authorities as 1·85 to 1·95 volts. The internal resistance of the cells varies with their size, the condition of the porous cell, and the condition of the acid charges; the resistance being variously given as 0·30, 0·08, and 0·06 ohms. These probably represent respectively the pint, quart, and half-gallon sizes of cells used by the persons testing them. The E.M.F. of the quart Bunsen when charged with sulphuric acid diluted with twelve parts of water in the outer cell, and strong nitric acid in the inner cell, may be put down at 1·86 volts, and its internal resistance at 0·08 ohm. This will give a current of about 23 ampères on a short circuit, or 1·72 ampères through an external resistance of 1 ohm. As gold is deposited from its solutions at the rate of 37·31 grains per ampère hour, this current will deposit 64·17 grains per hour. It will also deposit 105·50 grains of silver in the same time. As, however, silver is best deposited with a low E.M.F. of from 1·5 to 1·6 volts, and gold with an E.M.F. of 1·2 volts, the Bunsen has a tendency to deposit both of these metals in a rough condition, unsuited to work that must be burnished. It has been found in practice that the Bunsen cell is well suited to gilding and silvering small articles, such as chains and trinkets, slung to fine wires offering a high resistance; but, for spoon and fork work, and plating or gilding on large surfaces, the current from a large Daniell, Smee, or Wollaston is preferable, because it deposits a coat more amenable to the action of the burnisher. The Bunsen cell, however, has become a favourite with platers and gilders working in a small way on trinket work, because it is easy to set up and cleanly in working, thus causing very little labour in setting up and putting away. French platers charge the inner cell with strong sulphuric acid, and thus get a milder current with an entire absence of those nitrous fumes which render the presence of the Bunsen intolerable in close workshops. The current from the French Bunsen has an E.M.F. of 1·8 volts at starting, but it soon falls to 1·6 or 1·5 volts when the circuit is closed, because the sulphuric acid is inferior to nitric acid as a depolariser. Readers interested in the working of this battery are referred to the articles on this subject, in Nos. 1, 2, and 3 of this volume of WORK. In large plating establishments, dynamo machines are largely superseding the use of batteries. (See also note on *Batteries.*)

Bunsen Burner.—This useful gas burner (shown at Fig. 5) should be found in every work-shop. It is composed of a small short burner inside a piece of gas barrel some five or six inches in length, to which air is admitted at the lower end. The air mixes with the incoming gas in the barrel (see sectional sketch, Fig. 7), and the mixture burns together at the top with an intensely hot, smokeless, and non-luminous flame. This flame is well suited to the operations of soldering, brazing, and other blowpipe work, and also for heating and fusing small quantities of material. When the tube of the burner is surmounted with the cap shown at Fig. 6, the flame spurts out of the holes, and forms a "rose burner," to heat a sand bath or boil water.

OUR GUIDE TO GOOD THINGS.

*** *Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

114.—WATKINS' NEW PATENT SOLDERING FLUX.

THIS new flux, invented by Mr. J. H. Watkins, 29, Alma Street, Eccles, near Manchester, is intended to supersede resin, spirits of salts, etc., for soldering electric light, telegraph and telephone cable joints, as well as ordinary work in tinplate, brass, copper, zinc, and lead. The inventor represents it as being a solution of resin in a volatile solvent which has no corroding effects on metal, and which, on the application of heat, volatilises and leaves a coating of resin on each part of the work to which it has been applied, and being in a liquid form easily permeates any joint. Mr. Alexander, who tested the flux for me, says:—"It appears to be resin dissolved in either benzoline or methylated spirit. I find that it can be used for soldering tin, lead, copper, brass, zinc, etc., but as to its superseding spirits of salts for general work, I do not think it will. My experiments go to show that on lead, pewter, and other soft metals it acts very well indeed, but on copper, brass, tin, and zinc it is not to be compared with spirits of salts. The reason of this is plain. The patent flux is a flux and that only, but spirits of salts, either raw, as in the case of zinc, or 'killed' and diluted for the other metals, has a cleaning effect as well as being a flux. This difference was very marked in the experiments with copperplate, the spirits causing the solder to flow on and thoroughly join two pieces of uncleaned copper, just as it was cut from a sheet, better than the patent flux did on two pieces with cleaned surfaces. Experimenting with tinplate work, I find it acts well, and has an advantage over spirits in the fact that it is non-corrosive. But then we have always had a non-corrosive flux in the old-fashioned resin and oil, which has an advantage over the patent flux for tinware in the fact that it can be easily wiped off, which the patent flux cannot be, as the solvent evaporates and leaves the resin, etc., on the work. This, of course, in the case of electrical work, is a distinct advantage, and I am pleased to be able to say that I think very well of it for this class of work, being really convenient, effective, and economical." THE EDITOR.

SHOP:

A CORNER FOR THOSE WHO WANT TO TALK IT.

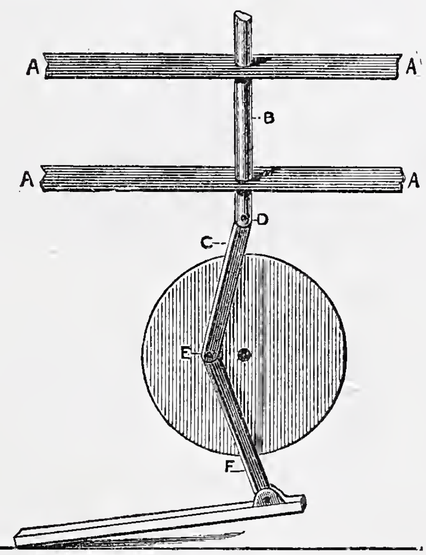
NOTICE TO CORRESPONDENTS.

*** *In consequence of the great pressure upon the "Shop" columns of WORK, contributors are requested to be brief and concise in all future questions and replies.*

In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of WORK in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.

I.—LETTERS FROM CORRESPONDENTS.

An Easily-Made Fret Machine and Wounds.—MEDICUS (*Hampstead*) writes:—"I thought perhaps it might be that I was extra stupid as I could not understand how the fret machine described by W. R. S. could possibly be made to work, but as I see, from the numerous inquiries with regard to this, that others are in the same position as myself, I begin to think I am perhaps not such a fool after all. The general idea of the machine sketched by W. R. S. is certainly good, and I am very much obliged to him. I intend to make one for myself, but I think in one or two details it may be considerably improved. He says his machine works well. If it does, the sketch he gives on page 332 of WORK must be at fault, for it is morally certain that if constructed as there depicted, the wheel could not possibly revolve. I imagine that the upper end of the piece marked C, which is hinged to the shaft, A, ought to have been placed on the inner side of the shaft, viz., between it and the wheel. With this arrangement the friction between the lower bearing and the shaft must be tremendous, as the latter must be bent out of the perpendicular at each revolution of the wheel. I enclose a rough sketch of the alterations I intend to make to obviate this. The wheel will be of wood, with



An Easily-made Fret Machine.

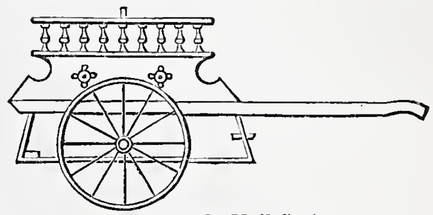
A, A, Guides; B, Shaft connected above with saw below hinged at D with C, a flat strip of iron, the lower end of which is fastened to the wheel and the treadle crank, F, by a pin at E, which passes through both and is bolted to the wheel.

strips of lead nailed round the circumference to give the requisite weight and driving power. Now to touch on another matter on which I do not write as an amateur. I refer to the bad advice given in your issue of September 14th with regard to treatment of cuts. If this advice is followed, I beg to point out that it will, in many instances, be productive of very serious results. To get a cut to heal, it should first be thoroughly cleansed with warm water, then the edges brought together if the wound is small by strips of sticking plaster, or strapping, if large, by as many stitches as may be necessary of silk or silver wire. The wound should then be bound up with a clean bandage, and the part be subsequently kept at rest if possible. Absolute cleanliness and rest are essential to insure rapid healing of a wound. The use of such remedies as French polish, glue, which is often in a state of decomposition, and common pins, is simply barbarous. They are only calculated to cause irritation, set up inflammation which spreads, and often renders it necessary to remove the affected limb in order to save the patient's life. This, I can assure you, from an experience of many years at one of the largest London hospitals, is no infrequent termination to a wound which, though slight at first, was neglected or improperly treated."

Noisy Fret Machine.—W. J. S. (*London, E.C.*) writes:—"I notice that G. W. J. (*Sheffield*) (see page 588) complains of his fret machine making a noise. If he will place rubber pads under the feet (as I do mine) they will materially deaden the sound, and thus remove some of the mischief."

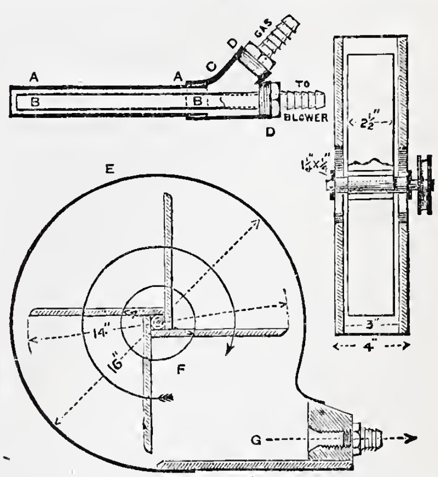
Lock Repairing and Key Fitting—Erratum.—MR. THOS. WILSON writes:—"I see your engraver has made a mistake in copying Fig. 5, which appeared in No. 24 of WORK. It should be as per figure in the margin. It is made out of a single piece of wire. The text is quite correct, but the inscription should be 'Lock Pin,' and not 'Mode of Repairing Pin.' They cannot be repaired. Inscription of Fig. 6 should be 'Desk,' and not 'Drop Lock Bolt.'"—[All contributors should be careful to write inscriptions under all figures sent. Not one in ten does so, and they have to be gathered from the text. In future all diagrams, etc., sent without inscriptions will be returned, that they may be filled in.—ED.]

Mail Carts.—R. H. (*Newcastle-on-Tyne*) writes:—"I notice in WORK No. 30 sketches of mail carts. I have just finished one, as below. There is one point that I think is of general importance. The steel spring is not necessary, but can be advantageously replaced by frame of pitch pine 1 in. square, to which axle is bolted."



Home-made Mail Cart.

Blowpipe and Fan.—ANIMO ET FIDE (*Loughboro', Leicestershire*) writes:—"I desire to thank A. S. P. very much for his lengthy and exhaustive answer to my query *re* bicycle repairs tools, which has been of great help to me, and taking advantage of his kind offer to give further help and information through 'Shop,' have enclosed tracings of blowpipe and fan I have constructed, and should be glad of his opinion as to their capabilities; and if they would be suitable for brazing up a bicycle, the fan driven from about a 16 in. diameter pulley; and as I have not seen any brazing done by blowpipe, I should be glad of a few hints regarding procedure. Also, can anything be soldered that has been hardened without softening it at all?"—[I can hardly speak with confidence regarding the capabilities of the blowpipe shown in drawing by ANIMO ET FIDE, as I braze only with charcoal furnace. A good blowpipe, however, is preferable, as it makes a cleaner job, and the work is much easier cleaned and filed up; besides, there is less danger of burning the thin tubes. I have not seen a blowpipe of the form shown by ANIMO ET FIDE. It would be an improvement to curve the nozzle to one side, so as to throw the flame down on the work



Blowpipe and Fan.

A, A, Ordinary ½ in. iron gaspipe; B, B, ordinary ⅜ in. (outside diameter) brass tube; C, Malleable iron T piece; D, D, Brass unions for indiarubber tube; E, Sheet iron casing; F, Air inlet; G, ½ in. gaspipe.

being brazed, while the tool is held conveniently in the hand. With regard to the fan, I should have the blades of a 16 in. fan not less than 3½ in. or 4 in. broad, and curved to a radius of about 12 in. The curved blades would be driven backwards, that is curving away from, not towards, the outlet, the backs of the blades thus driving or beating the air outwards towards the circumference. Such a fan and pipe ought to braze all the parts of bicycle frames. It should be used with a lump of charcoal under the work to be brazed. For some of the joints where solid stampings are inserted to be brazed into the tubes it may be necessary to make a clear charcoal fire in conjunction with the blowpipe, the charcoal being brought up to a good red glow under the work. The blowpipe, acting on the upper side, would bring up the necessary heat much quicker. To braze a hardened article would certainly soften it, but it would be hardened again considerably by plunging in cold water while yet red hot, but it would depend very much on the nature or use of the part thus treated whether or not it was not spoiled. For instance, a ball-bearing case would almost certainly be warped off the truth by such an operation.—A. S. P.]

II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

Dulcimer Dimensions. — WILL (*Norwich*). — You will find the subject most exhaustively treated in the articles on the Dulcimer commenced in WORK No. 31. The only allowance you will be obliged to make will be in the position of the inner and outer bridges, and the sound-holes. These will be 2 inches further from the sides than in the description, and your instrument would be tuned in the key of D. The proper dimensions of such an instrument would be, width at bottom 2 ft. 10 in., width at top 1 ft. 4 in., back to front 1 ft. 4 in., but if you desire to build one 3 ft. wide at bottom, then the top must be 1 ft. 6 in., and the depth 1 ft. 4 in., and strung with one size stouter wire.—R. F.

Pencils for Lettering, etc.—X.M.T.C.C. (*Belfast*).—Sable pencils, either for decorative painting or for sign writing, are named from the bird which the quill holding the hair is supposed to be taken from — thus lark, crow, duck, goose, and swan quills. The goose, or full-goose size, would be a medium quill, and its cost would be: goose, about ninepence, and large goose fifteen pence. These two sizes with a duck quill, costing about sixpence, would suit for almost anything up to six-inch work, using a flat long-hair fitch for filling in the letters. The best place to get them is of a large dealer; there are several in Belfast. Observe that the quill is well filled and the hair securely fastened. The brush should taper to a fine point, and should maintain the point unbroken when in use. When buying, wet the brush (they usually go into the mouth), and then whilst wet and the hair thus holding together, test the point by twisting it upon one's nail, making all sorts of imaginary circles and turns. If the point keeps firmly together and the brush works with spring and solidity it is a good article, but if the point splits up and the hair spreads about, try another one. Recently a good class of pencil for writing and so forth has been introduced which is made from brown ox hair, some call them "Taurus" pencils. They are not so fine as sable, but are considerably cheaper, and answer capitally for general use. Gilding and embossing on glass is almost a distinct art and craft, and would take much space and painstaking description to explain thoroughly. Doubtless it will appear in due time. For the embossing, acids and a thorough knowledge of the matter are necessary, whilst the gilding is done by weak isinglass medium, and then backed with black japan. You will surely now agree that, however sorry we are to refuse any inquirer, this time you have asked "too much at once."—F. P.

Smithing. — (*Birmingham*). — The articles on Smithing have already been resumed, and several branches of the art treated in an exhaustive manner. I think our papers will be far more useful to men of your trade than the book you name, and of which you say "the information you get out of it is not worth 2d." It requires a practical man, you know, and not a mere theorist, to write usefully and with effect on manual labour of any kind, and the way in which it is best done. There is no other cheap work on the subject that I can recommend to you and your friends except "Steel and Iron," by William Henry Greenwood, F.C.S., M.I.M.E., one of Cassell's excellent Manuals of Technology. It is sold at 5s. Possibly you might be able to get a look at it in the Free Library, if such exists, at Birmingham, or the library belonging to any workmen's institute there.

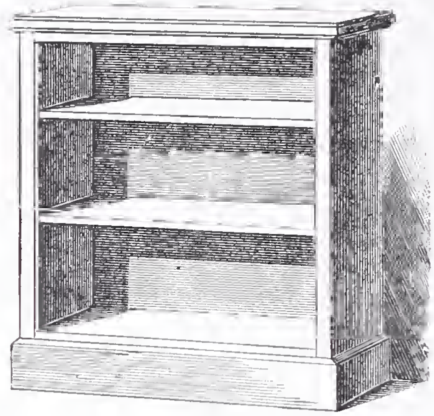
Prices of Batteries.—MANAGER ELECTRICAL CO. (*Crewkerne*).—I am obliged by your communication. Your company should advertise their goods in the sale column of WORK. MANAGER gives the following as a list of prices of Leclanché batteries supplied by the Electrical Company, Crewkerne :—

No.	Complete.	Zinc Rods.	Carbons Capped.	Porous Cells, Charged.	Glass Jars.
1.	1s. 6d.	2½d.	6d.	1s. 0d.	4d.
2.	2s. 0d.	3d.	7d.	1s. 5d.	5d.
3.	3s. 0d.	4d.	8d.	1s. 9d.	7d.

Sal-ammoniac is also supplied at 8d. per lb.

The prices quoted in the article were certainly the top prices from the price list of a London firm. Several country firms, including your own, supply the goods at lower prices, but all are not of equally good quality. I must repeat, do not hide your lights under the obscurity of your provincial towns, but advertise them through the world-wide circulation of WORK.—G. E. B.

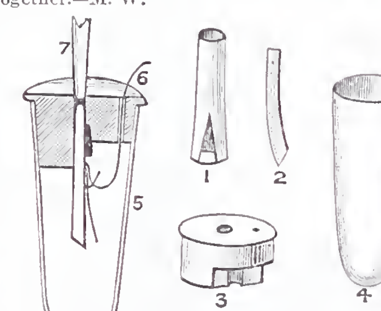
Dwarf Bookcase.—H. J. (*Bradford*).—I presume you mean a dwarf bookcase, though the sizes you give are very small even for one of these. Without going into full details, which cannot be given in "Shop," the following details may help you in making a plain one. Connect the ends together with a board of the same width at the bottom and at the top either with a couple of stays, one at the back, the other in front, or with a piece the same as the bottom. Use the lap dovetail form of joint. Below the bottom board fasten a plinth, for making which you will find directions in the articles on "Lessons from an Old Bureau." Fasten either a plain or lined-up top, using screws through the stays referred to. "Lining up" has been exhaustively treated, and if you do not understand this work, you should read the articles about it before proceeding. It is usual for dwarf bookcases



Dwarf Bookcase.

to have the front edges of the ends thickened up by adding a pilaster to them. This forms a rebate within which is the front rack, by means of which the shelves are made movable to any distance required from each other. It will, however, be simpler for you either to nail the shelves or to support them on slips of wood nailed to the ends. The back should be munted, but plain jointed stuff if dry would do very well for such a small job as you contemplate. Thickness of material throughout for ends, top, and shelves may very suitably be ¾ in., but there is no definite rule to go by, and even ½ in. stuff with judicious lining up might be used. The illustration shows the kind of bookcase. You will easily be able to add a door if you wish to have an "enclosed" job.—D. A.

Reed in Organ Pipe. — AMATEUR ORGAN BUILDER.—The reed in a reed pipe of an organ is the small metal tube in or against which the flat metal tongue vibrates. As it would appear that you have had no previous practice in this work, I think you would do well to buy the parts ready made, and even then you will have a very troublesome job before you succeed in getting the pipes to sound properly. The following sketches will explain how the various parts of a reed pipe are put together.—M. W.



Reed in Organ Pipe.

Fig. 1.—The Reed. Fig. 2.—The tongue. Fig. 3.—The block. Fig. 4.—The boot. Fig. 5.—Showing reed and tongue fixed in block by wedge. Fig. 6.—Tuning wire pressing against the tongue. Fig. 7.—Foot of pipe standing in hole over the reed.

Retinning of Stewpans, etc.—G. S. (*Langley, Bucks*).—To reply fully to your query would take up more space in "Shop" than could be spared for it, but I will endeavour to give you as much information in a small space as I possibly can. With regard to the tinning of copper stewpans and other kitchen utensils, you must proceed as follows:—First do all the needful repairs, such as taking out the bruises from the sides and bottoms by means of a hammer on the proper tools, viz., side stake and bottom stake; see that all the handles are tightly fixed, if not, rivet them up a bit; they must next be freed from grease. This process is called burning off, and is done by placing them on a forge over a good fire of charcoal, and gently blowing till the grease is all melted and burnt off. Care must be taken not to allow them to get red hot whilst doing this. Procure some strong spirits of salts and pour some into a dish or basin. Make a kind of swab by wrapping some cloth, sacking, or canvas round a stick; dip this in the spirits and rub the stewpan all over, inside and out. After this, well wash them with water, then take some blacksmith's "scale"—that is the iron that flakes off the red hot work as the smith hammers it on his anvil—and with a piece of old carpet well scour them all over. You must do this disagreeable job thoroughly, for on this your success or failure will depend; there must be no shirking it; scour handles as well; they will have to be done again, but it makes it easier to do them a bit at this period. Having finished scouring, rub the outsides all over with salt or salt and whiting mixed to a paste; this protects the copper, and prevents the fire tarnishing them so much. They are then ready for tinning. Several other things must be got ready. Some pieces of sheet iron must be turned to slip on the handles to take hold of while tinning. A tinning rod will also be wanted. This can be made by bending a piece of 3-16th or quarter rod in a series of rings, like a hair-spring of a watch. Leave the handle about 18 in. long with an eye at the end to hold by. Pound up some sal-ammoniac in a mortar, and get a wad of tan to wipe the tin off with. You will also have to rig up some arrangement to blow the fire with your feet; an old stump hung on the handle with a piece of chain is the usual thing. Have your tin run out in strips like solder; I find this the handiest form to have it in. Now place everything ready to hand, and commence to tin. Place a stewpan on the fire (sheath on handle); hold it in the left hand. Throw a little sal-ammoniac in and blow gently, and rub a stick of tin against the part that is over the fire. When a little has melted into the stewpan rub it about with the tinning rod, applying a little more sal-ammoniac and tin occasionally as required. The sal-ammoniac will turn black, but that will not hurt. Keep rubbing, and you will find it greatly helps to tin. Do not get the things too hot and burn the tin, but keep a nice heat so that the metal flows easily. Having gone all over it, and supposing it well covered, run it round once more, getting it well hot, then quickly take it off the fire, dust in a little sal-ammoniac, and then with a ball of tow wipe it round, drawing all the superfluous tin out. This will require some practice before you can hope to do it well. They are then well scoured all over again, inside and out, with silver sand, using tow as a rubber. Do not use the same piece for the inside as you do for the outside, or it will turn them black. Use plenty of water. Do one at a time; do the outside last, and dry off quickly in dry sawdust. Polish up the insides with flour, and the outside with crocus. With regard to retinning tin dishes I advise you not to attempt it. If they are small ones it would be a waste of time and stuff, as it would cost more than new ones, and if large dishes, such as milk coolers, etc., it would be best to send to a firm that does such things, as they could not be done over a fire, but would require a large bath of tin of several hundredweights, which I presume you have not got. Some more information on tinning that may be of service to you will appear in my next article. I know of no work on the subject of tinning, but trust the above instructions will afford you all the information required. If not quite clear on any part write again. My object is to help all those who are anxious to learn.—R. A.

Battlesden Cart.—H. P. (*Canterbury*).—I was glad to get your letter on the subject of Battlesden Cart, particularly as I see from it that you are a practical worker. You are quite right in your stricture on the hind step. It should undoubtedly have been represented rounded to match front. With regard to the wings, I think they present too much of a "paddlebox" appearance when carried down behind, as you suggest, and there is no danger of mud being splashed upon the occupants of the back seat. However, this is altogether a matter of taste. Many thanks for your kind words of appreciation of WORK. I hope you will be able to carry out your intention of getting a lathe. Get a good one when you go about it. I have just got a Britannia Company's No. 14, and am delighted with it.—OPIFEX.

Printing Ink.—E. C. M. (*Ipswich*).—You will find no book which will tell you how to make up various tints, as there are, up to the present, no standard colours; and you will find every maker's colours differ a little, and very often even the same maker will not be able to match exactly the shade of colour as previously supplied, therefore experience alone can teach you. You can buy all the dry colours ready for mixing nowadays from the very cheapest to the best.—J. F. W.

Crystoleum Outfit Cost.—CARP DIEM asks the cost of an outfit for crystoleum painting, and says Reeves' prices are high. I have not the slightest interest in recommending this particular house, further than this, that I have purchased material there, and have found them as cheap and good as any other house offers. I think that perhaps C. D. asked the price of an outfit which would include everything that an expert would require. The fact is a beginner does not require such a full set as would be comprised in an outfit. The ten colours I have mentioned will not cost more than about 3s., and can be obtained at any good stationer's or art dealer's. And really there is no need to purchase all those I have mentioned for a beginning. I should say 5s. would purchase all that would be required to begin with, which is not a very large sum. C. D. says he thinks he can get them cheaper. Perhaps he will try and let others know if he succeeds. I would recommend C. D. to procure a catalogue from Reeves, Newton & Wiltons, or some other dealer in artists' material; then he will see price of what he requires.—O. B.

Paraffin Wax. — GLU (*Manchester*). — I think you will find no difficulty in incorporating either your pigments or tube colours in the wax, if you will proceed as follows: Melt the wax in a water bath, then introduce your colour; stir till amalgamated, remove from fire, and continue stirring till nearly set. This is the plan druggists use to colour their ointments, etc.—P. W. S.

Sale of Fretwork.—George L.—You say, "I have taken very kindly to fretwork, and have bought a fret machine. I now want to recover what I paid for it, by selling the work I do with it. Can you put me in the way of disposing of it?" You do not say where you live. If you reside in a small town there is not much chance for you, but if your tent is pitched in a large one you might try the dealers in fancy goods, or start a window somewhere on your own account, giving the proprietor of said window a commission on everything sold, as remuneration, or as hire of window and for services rendered. Again, you might try to get orders for fret cutting from upholsterers and others in the town.

Tempering Chisels.—Chiseller.—No, my friend, your query has not been overlooked; but as, owing to the pressure of correspondence and the impossibility of putting more into the space allotted to "Shop" than "Shop" will contain, coupled with the fact that "Shop" was full up to No. 30, and there was yet more to be used before your letter arrived, it is manifest that in the common course of nature your want could not be met by the date of your second letter. Tell your friend to read reply below to E. L. (*Reading*) *re* Steam Launch. I cannot deal with "what are known as examination catch questions in Applied and Theoretical Mechanics, Steam and Steam Engine, etc.," except through "Shop." If you are in any difficulty, and want a leg over the stile with regard to any question, send the question, and, if possible, you shall have help.

Steam Launch.—E. L. (*Reading*).—The contributor who was to write on the construction of a steam launch has had his hands full ever since Work was commenced, but he assures me that if he cannot manage to tackle the job himself during the coming winter, somebody who is competent to do it shall be found to take his place. From this you will see that it is not in my power to say with any exactness when the papers will appear, nor can I attempt to say what may be the "dimensions, speed, number of passengers, and probable cost" of the launch to be described. One word more both to yourself and others who send *noms de plume* to be prefixed to replies to their queries—choose short ones. Such lengthy affairs as "One who is anxious to know" take up more room than is necessary. Anxiety for knowledge is most praiseworthy, but this is implied by the fact of your writing. For this reason I have replied to you under your initials, and name of town in which you live.

Silk Winder.—D. B. S.—Unless you understand the work of unwinding the cocoons, which you presumably do not, it would be useless to give such a description of a winder as would be of any service to you. However, it may be said that you do not require to accelerate the speed, and that a simple drum or reel, which can be turned, is all that is indispensable, and that it must not be turned too quickly. A rough outline of the process may assist you, and after reading it you will be able to judge for yourself whether it is worth while pursuing the subject further. The cocoons must be soaked in warm water to dissolve the gummy substance in them. The loose ends are then to be caught and passed through small eyes of some polished smooth material such as glass. During their passage through these, of which there are a series, they are gradually united till they form one thread which is then wound round the drum. This must be at such a distance from the vessel containing the cocoons that the silk is dry before reaching it. The operation altogether is a very troublesome and tedious one, and the result—with a small quantity—not commensurate with the labour.—D. A.

Plush Frames.—Plush.—A paper describing the construction of easily-made plush-covered frames is under consideration, meanwhile I may refer you to the various hints already given in Work *re* frame making generally.—D. A.

Boy's Barrow, Cage, and Secretaire.—Round O.—I am afraid the first subject is hardly within the scope of Work, but the others are, and papers on them will be given. With regard to the latter, let me tell you that secretaire is a generic term for writing tables of various kinds, and that by itself it conveys no meaning of the special shape or arrangement desired, so that I am unable to say whether any of those which are contemplated for early consideration will be exactly the thing you want. I may, however, tell you that the plain pedestal table will be among the first, but as you say you are only a "third-rate amateur" it will be a difficult job for you to tackle. I am afraid though that with characteristic Scottish modesty you have mistaken your capacity, which is, no doubt, equal to making—well, say lots of things. It grieved me sair when I read that Work does not reach your ideal, which is doubtless high, but on proceeding I was, in some degree, consoled by seeing that you consider it of much value. It undoubtedly is, and the intention expressed is a laudable one, which, if carried out, will soon cause you to rank as an A 1 amateur. You are by no means too old to make progress in mechanical arts. Really, no, we do not give "snubs to those who dare to ask too much." It is a pleasure to help them in any way we can through "Shop," and no one need be afraid of asking questions when it comes within the scope of this magazine to answer. You must kindly make allowance, and remember that we cannot always evince the grace and general *suaviter in modo* peculiar to your countrymen. Glad to hear you preserve Work. Please keep general business matters separate from remarks for "Shop."—D. A.

Xylophone.—Musicus.—The straw ropes are fixed on the top of the pieces of wood you saw, and are for the purpose of insulating the pieces of wood; they are generally on a sort of table, which may increase the tone. Fig. 1 is a plan view, and Fig. 2 a section, which I hope you will be able to make

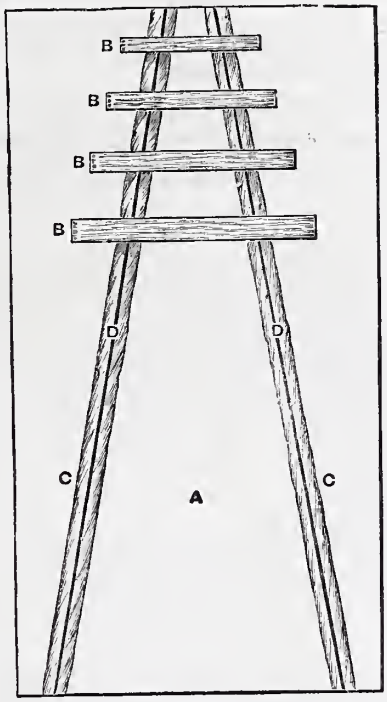


Fig. 1.

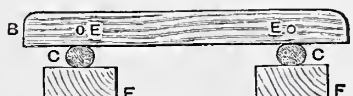

Fig. 2.

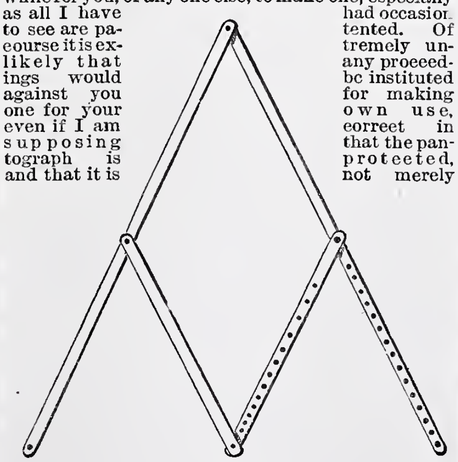
Fig. 1.—Plan of Xylophone. Fig. 2.—Section of Xylophone.

A, Table; B, Pieces of Wood; C, Straw Rope; D, Cord through bars; E, Hole for cord; F, Strips of wood on which straw rope is sometimes placed.

out; you had better try to see one, when you could take any measurements. I have seen one of pitch pine hung by the cords alone, and played, but I think the tone is better when on the straw ropes. You can tune them by cutting the pieces shorter. Rosewood is said to be the best wood.—J. T.

Pantograph.—W. M. G. (*Hull*).—As a pantograph can be had for 6d., it hardly seems worth while for you, or any one else, to make one, especially as all I have had occasion to see are patented. Of course it is extremely unlikely that any proceedings would be instituted against you for making one for your own use, even if I am correct in supposing that the pantograph is protected, and that it is not merely



Pantograph.

improvements which are covered, but it is just as well in case of doubt that you should be warned of the existence of a possible infringement. In construction the pantograph is simplicity itself, or rather may be, for expensive fittings are by no means necessary, though often employed on the more costly forms. To go into the whole subject of panta- or panto-graphs here is out of the question, but having made one on the lines indicated here, you will have no difficulty in finding out how to apply it. I believe this form of it is not patented. Size must depend on kind of work intended, but my advice to you is to get a small one first. Four pieces of wood, two of which are, say, 1 foot long each, and two of half that length, will be required (see figure herewith). The stuff need not be thicker than $\frac{1}{8}$ in., or wider than about $\frac{1}{2}$ in. Fasten them, or rather, hinge them together, as shown in the diagram. Small screws, or even pieces of wire, will do for the purpose. At the ends you will require hole for pencil, fastening pin, and guiding point. For the pin you can use an ordinary carpet or drugget stud, and for the guiding point a small French nail. What you have to remember is to make the parts work freely and yet not shakily. By altering the position of the joint on one side you can alter the proportion of your copy. If you want exact work you will, however, do better by buying one ready made.—D. D.

Parlour Floor: How to Polish.—Magister.—A paper on this subject will be given ere long, and if you will kindly wait till it appears you will gather more information from it than from any details which could be given within the limited space of these columns. With regard to articles of a more simple character being given in Work, I need only remind you that experienced men must be catered for as well as beginners. No doubt these latter experience difficulties in making things, however plain and simple, but members of the staff are always pleased to assist through "Shop." If you look through the numbers which have appeared, you will see that a very large proportion of articles suitable for beginners have been given, the desire being to encourage novices and others to undertake healthy, wholesome recreation in mechanical pursuits, as well as to advance the skilled professional worker. Thanks for the interest you have taken by bringing Work under the notice of your friends, and if those who find some of the articles "too technical" will just send along a note saying what they want to know, they will soon find what now seems too technical the natural language to express the work of the various handicrafts.—D. A.

Drawing.—A. J. T. (*Holborn*).—Apply to the secretary of any one of the following institutions:—The Birkbeck Institute, Chancery Lane, E.C.; the Polytechnic Institution, Regent Street, W.; West London School of Art, Great Portland Street, W.; Working Men's College, Great Ormond Street, W.C.—F. J. C.

Redressing Sandpapering Bands.—No Name.—Make a weak solution of glue, and spread upon your bands, then cover thickly with powdered glass. You will require two different sorts, one fine and the other coarse, although the coarse will work itself fine soon enough. You will be able to buy your powdered glass off any sandpaper manufacturer, whose name and address you will find at the back of one of their sheets. If, however, you wish to make it yourself, procure some thin broken window glass, and pound up with a piece of hard gritty stone, then sift through a fine wire sieve, and dust upon the wet glue before it sets as above mentioned. If the above is too much trouble I should advise you to cut sandpaper up in strips the required width, and glue on the bands, touch up the jointings with glue, and dust a little powdered glass over; use when thoroughly dry.—W. P.

Tube of Refracting Telescope — Driving Clock.—J. A. Sinclair (*Hammersmith*).—I have read your letter very carefully, and I do not quite see what telescope you are trying to make. But I can see that your acquaintance with the subject is very slight, and that you have a great deal of the simplest to learn before you can hope to understand "driving clocks." You must discard all idea of private inventions in the way of some apparatus on the object glass end of the telescope until you have succeeded in neatly mounting your telescope in the plainest possible manner. In trying to devise paper and tin tubes you will waste as much money and labour as would buy for you the necessary length of mandrel-drawn brass tubing, which is the proper thing to use. I can direct you how to mount your lens therein with no other aid than a file, a drill, a few brass screws, and a set square, so that your scarcity of tools need not make you despair. But there is not the least necessity for your main telescope tube to be cylindrical, though this fact seems always to escape the detection of folk unused to telescopes. You may employ your wood-spoiling capacities in the making of a neat piece of joinery in the form of a square-sectioned wooden tube of the required length of mahogany, which might be afterwards polished, or of plain deal. The term a "wood-spoiler" I use because you have used it, and not at all because I agree with you that it is synonymous with amateur. In this one private matter of astronomical telescope making, the art has ever been in the hands of amateurs. By-and-by, being amateurs in the truest sense—see the English Dictionary—they made their hobby and art their life-work, but that does not affect the question. Tell me whether you intend mounting your lens in metal or in wood, and then I will tell you how to proceed. Whatever merit for neatness your mechanical drawing may possess, your idea of a driving clock is so very crude that I cannot even undertake to tell you where it is wrong—it is wrong everywhere. The American clock you speak of would not do for you what you are presuming that it would do. Moreover, assuming for the moment that it had the necessary force, you have applied it to the wrong axis of the telescope. The very carelessness of you is shown by your question, "What do you think of the clock-work motion for the telescope? *not as anything at all accurate*" (the italics are mine). If the clock-work be not accurate it is absolutely, utterly, and entirely useless and absurd. That is what I think of it! Set to and learn somewhere the simplest theory of the refracting telescope, and then mount your lens humbly, and plainly, and neatly, and well. You will learn more of real art in one month by so doing, than you would be likely to learn in a year by trying to construct intricate apparatus. When you have made your telescope simply, and have used it awhile, you will discover that all intricate apparatus used in practical astronomy is used only in exceptional circumstances for exceptional purposes, and is never used when it can be dispensed with. WORK is always here to help and guide you, but as a true teacher and guide, it must ask you to do the simple work well before it may teach you the difficult work.—E. A. F.

Damaged Frames, How to Repair.—F. M. G. (*Stanningley*).—I am afraid you would find it laborious and expensive. What I should advise is to take your pictures out of the frames, and send frames to a maker to have them repaired and corner set on, or, if they are old-fashioned, chip off level and buy a set of compo corners. All that is necessary is to clean the corners, and place your new ones over steam for a few seconds—a cloth over a jug of boiling water—lay your corners on, take off, and place in position on frame. It does no harm to glue the part of frame first. Do not press corner too much, as you lose sharpness of pattern. Secondly, when corners are dry and hard, evenly spread with a camel-hair brush oil of gold size, let dry to tacky, then with a tip apply gold, using a cotton-wool dabber to press it on; then thoroughly dry off with clean cotton wool.—G. R.

Combination Couch and Bedstead.—COUCH BEDSTEAD.—Full particulars cannot be given in the limited space of "Shop," and this piece of furniture is hardly one that many readers would care to make, so that as there are so many subjects which are more popular, I fear a paper cannot be given, at any rate for some time. Of course, you can use any couch as a bedstead by making up the bed on it, but, I suppose, you want a thing which, in the day-time, will look like a couch, and when required as a bedstead can be increased in width. There have been several patent contrivances of this kind, but so far as I am aware none of them have met with anything like general acceptance. Such an article is less frequently met with than even the combination of cupboard and bedstead, a description of which is in the Editor's hands, and will appear shortly. My advice to you is not to waste time with a couch bedstead of the kind I suppose you want, but if you wish to try and make one, the hint that the seat frame, or rather an extra frame, is made to extend may be useful to you. Another way is to make the back so that it may be laid level with the seat when required.—D. A.

III.—QUESTIONS SUBMITTED TO CORRESPONDENTS.

Simple Incubator.—J. M. (*Glasgow*) writes:—"Would W. L. (*Kingsland*) (see page 557) kindly say at about what temperature the heat should be kept at in the box; and what kind of lamp may be used?"

Rivetting China.—A. JONES has not sent his address with his MS. and diagrams. Will he please do so?—ED.

Machinery for Making Surgical Plasters.—G. H. S. (*Manchester*) writes:—"Would any reader be kind enough to name a firm who makes a speciality of these machines, notably for producing the ordinary surgical sticking plaster—not court plaster?"

Flux for Welding Steel Spindles.—G. H. S. (*Manchester*) writes:—"Will any reader be kind enough to furnish a good flux, specially adapted for welding steel spindles of flax spinning machines? I have tried borax and sand, but they do not answer well."

Horse-shoeing.—A. R. (*Scorrier*) would like a practical paper or two on this subject.—[Will any competent writer volunteer to take the matter in hand?—ED.]

Waggon Brace Bits.—A. B. (*Northwich, Cheshire*) writes:—"Will you do me the kindness, in the way of letting me know the address of Mr. Leadbeater? He used to live in Spring Street, Birmingham, but he has a partner now. He is the maker of waggon brace bits. At present I have to walk about twelve miles to get the above bits, and when I get there sometimes the tradesman has none in."

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Complaint.—C. H. (*Bloomsbury*).—I do not insert your letter. J. H. knows perfectly well what he is about, and you are, or ought to be, aware of this.

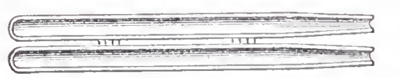
Tin Ovals.—H. S. W. (*Wakefield*) writes in reply to A. N. (*Airdrie*) (see page 540):—"I purchased one of your papers called WORK, and while looking over the same found a reader asking for particulars regarding tin ovals, etc. If A. N. would write, giving particulars of tin ovals, etc., wanted to J. Rhodes and Sons, Grove Works, Wakefield, England, no doubt he would obtain the price and particulars wanted either to work by hand or by power."

Barnes' Foot-Power Saw.—A. M. (*Bethnal Green Road*) writes in reply to REMINGTON (see page 558):—"These are very good tools, and cut up to 2 in. I would suggest that you see one of the patent saws made by Britannia Company, 100, Houndsditch, and compare. These cut up to 4½ in."

Parchment.—W. H. (*London, E.C.*) writes in reply to DRENNAN (*Kilmarnock*):—"Vegetable parchment can be obtained of Henry Hymans, St. Bride Street, Ludgate Circus."

Small Pump.—H. A. B. (*Ashton-under-Lyne*) writes in reply to W. R. S. (*Brixton*) (see page 558):—"You will be able to get a set of pump castings from Theo. Tomlin, Model Engineer, Breeze Hill Terrace, Oldham. Having fitted up several model engines (both for pleasure and profit), I can recommend his castings as the best I can meet with, as regards the price and quality."

Machine for Making Cigarettes.—THOMASO writes in reply to S. B. R. (*Blackheath*) (see page 494):—"As I understand your question, you want a cigarette machine, something after the style of a coffee mill, one into which you can put tobacco and cigarette papers by the bucketful, turn a handle, and cigarettes fall out on the floor. That machine may be looked for about the time when that famous American sausage machine comes into the market, into one side of which live pigs were driven, reappearing on the other as pork sausages! The best way I know, and in fact one method adopted by manufacturers, where perfect uniformity in size is desired, is the following:—Roll the paper round a blacklead pencil, or anything of the desired size; gum down the edge and slide it off. You now want a piece of brass



Machine for Making Cigarettes.

tube about 6 inches long, made to open lengthwise on small hinges as in the figure. One end of this is to be tapered off gradually, and made small enough to just slip a little way into the end of the paper tube you have rolled. You open the brass tube, lay about twice as much tobacco in it as will be wanted (putting the fine in the middle); close it, insert small end into the paper; hold the paper on, and keep the tube shut with one hand, while with the other you push the tobacco out of the tube into the paper with a small stick. When you see the tobacco emerge from the end of the paper, cease holding it on the tube; continue to push with the stick, and the paper with the tobacco in it will drop off, only needing the application of the scissors at each end to leave it a perfectly formed cigarette. The tube is best made of sheet brass, and must be perfectly smooth inside; the two halves should fit well together. The small hinges sold for fretwork purposes will do, soldered on. The end of the tube can be tapered with the mallet on a piece of iron rod previously filed taper."

Gas Stove.—D. M. J. (*Portsmouth*) writes:—"If your correspondent, S. P. (*West Bromwich*) (see page 526) will communicate his address to me, I shall be pleased to send him sketches of stoves that might suit him, if he will kindly state if he has any chimney flue from his lecture room, as in any case it is advisable to carry the fumes of the gas out of the room. The local gas company may be pleased to give him all information."

Insurance of Tools.—A. N. E. (*Nottingham*) writes:—"In answer to J. K., page 366, No. 23 of WORK, and also T. T., page 429, No. 27, I may say that I insured my tools some few years ago with a most unsatisfactory result. I first insured with a company for £10 at a premium (annual) of 5s. In eighteen months the company wound up, or burst up, and transferred all business to company No. 2, annual premium 4s. 6d. In about eighteen months after, company No. 2 handed business over to company No. 3. I received a form to fill up signifying my consent to the transfer, or if on the contrary, I was to receive the amount of premium applicable to the unexpired portion of that year. However, I signed the form filled up duly and truly, and sent it to Mr. Secretary somewhere in London—I have forgot the address, and destroyed the papers as rubbish by now—but I never received a policy or anything else from that day to this. I once wrote asking for one, but received no reply, so now I invest my penny a week in WORK, and get my penn'orth, and a good one too! So, if J. K. and T. T. will take my advice about insurance, I say—Don't. Possibly something of the kind on the lines you suggest, in answer to T. T., page 429, might answer, but such is my experience of the companies I have dealt with."—[You may insure, I think, with perfect confidence in the "Hearts of Oak," which appears to be an old and well-established benefit society.—ED.]

Trade Notes and Memoranda.

A VERY good idea of the perfection to which the making of ships' chronometers has attained is gained by noting the performance of a chronometer which accompanied the ill-fated Polaris expedition which set out in 1871 on an Arctic expedition. When Captain Hall perished—some time in 1872—the chronometer was abandoned, and lay buried in the snow for four winters, when it was found by some members of an English expedition, dug out and wound up, when it started up as usual, losing at a uniform rate of about one second per day. It had been subjected to temperatures ranging as low as 100° below zero. The chronometer was made in America, and has been sent from the British Admiralty Office as a present to this country, being now in possession of the Navy Department.—*American Machinist.*

A CURIOUS and noteworthy specimen of expert foundry work has been recently executed. It consists of three plates of cast iron about one-fourth of an inch thick, and seven by five inches in surface, covered with writing indented in the iron. This specimen of skilled workmanship was done by John Farrar, foreman at an American foundry, a life-long workman in an iron foundry. The impression on the iron is made by writing backwards on thin paper, pinning the paper in a mould, and then pouring on the iron. The writing thus transferred to the plates, when the iron is cooled, is wonderfully clear and distinct, and is so deeply imprinted as to defy any attempt at erasure.

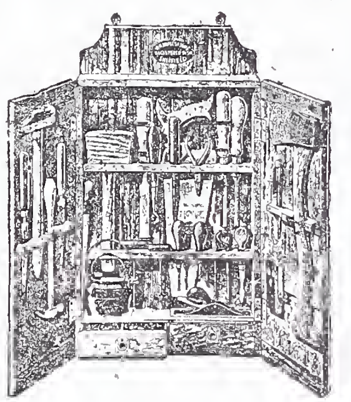
GENTLEMAN'S *Registered* TOOL CABINET,

PRICE £2 2s. each.

Size, 21 in. high by 14 in. wide, made of Polished Oak, with Two Drawers, and with Lock and Key, and with two Loops to fasten it to a wall.



The above is a strong, well-made Cabinet of polished Oak, and every tool is full size, serviceable, and warranted. The contents comprise such tools as are usually required for repairs, &c., in a household, and the investment of its small cost will soon be saved by the work done with them.

IT CONTAINS TOOLS AS FOLLOWS:—

Mallet,
Chisel,
Gouge,
Axe,
Two Hammers,
Saw,
Three Files,
Two Turnscrews
Square,
Claw Wrench,
Pliers,
Two Gimlets,
Two Bradawls,
Pincers,
Glue Pot and Brush,
Plane,
Compasses,

WORK

An Illustrated Magazine of Practice and Theory

FOR ALL WORKMEN, PROFESSIONAL AND AMATEUR.

VOL. I.—No. 43.] SATURDAY, JANUARY 11, 1890. [PRICE ONE PENNY.

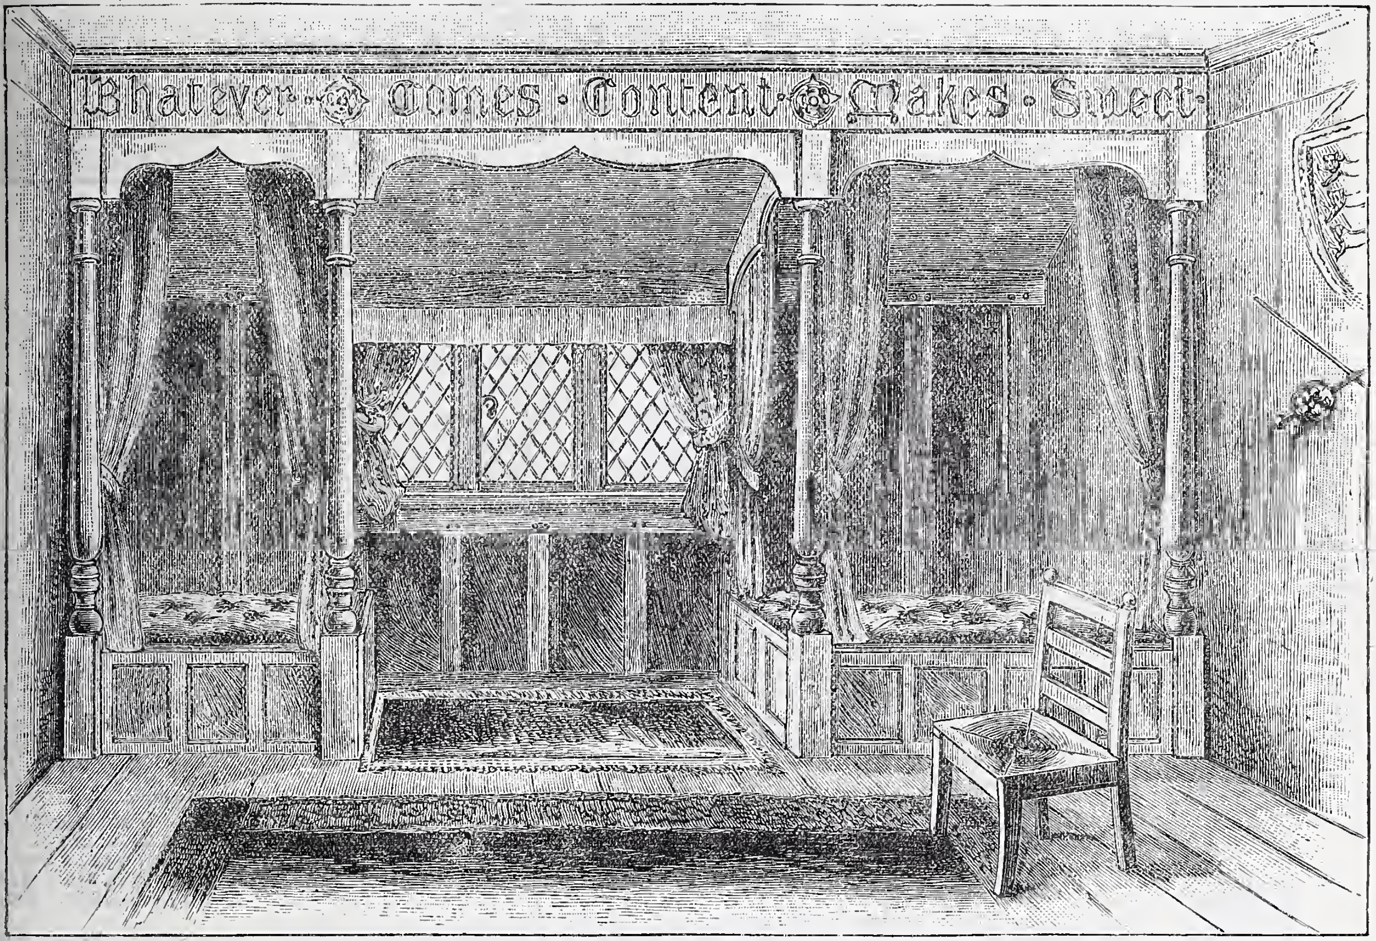

Fig. 1.—Perspective Sketch, showing Treatment of Room with Sloping Ceiling.

HOW TO TREAT A SLOPING CEILING.

A SIMPLE METHOD OF UTILISING BED-POSTS.

BY F. W. KINNEIR TARTE, M.S.A.

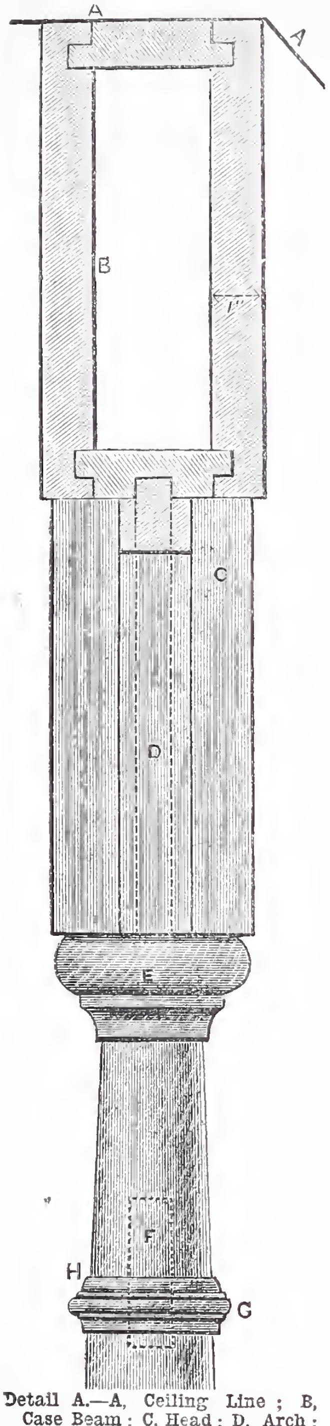
'CAN you suggest a way of improving this ıseful but ugly room?" said a friend to ne not so very long ago. The room he re-ferred to was about 12 ft. wide by, perhaps, 15 ft. long, and about 7 ft. high, with a slop-ng ceiling along the window end. The slope extends 2 ft. back from the face of the plaster.

The home we were in was a snug and uxuriously furnished cottage, with massive imbers showing on the inside of the rooms. The shape of the room was certainly incon-venient, but at the same time it was wished that it should be made into a snug and com-fortable sitting- and smoking-room. My friend being an enthusiastic collector of old oak work, he had amongst other things a num-ber of exceedingly handsome *oak* bedposts; accordingly, it occurred to me that these could in some way be utilised in making a picturesque gallery at the sloping end of this room. Fig. 1 is a perspective sketch of the way in which the room was eventually treated. Should the reader not consider himself capable of carrying out this himself —which I certainly hope will not be the case—he will find the cost very trifling in comparison with the effect gained by the addition of the "gallery." The whole of the work has in this case been executed in old oak as the posts were of this wood, but I see no reason for oak, and should not my-self hesitate to have the work carried out in the softer woods, and painted afterwards. I am inclined to favour a rich brown colour for painted work in most reception rooms; excepting, of course, drawing-rooms, and it is not likely that a room with a sloping ceiling would be set apart for this pur-pose. When the right tint is obtained, brown is a colour of which it takes a con-siderable time to grow weary.

I shall, therefore, consider that my reader intends to paint the work at completion. Fig. 2 is an elevation of the "gallery." Fig. 3 is a plan, and Fig. 4 a section of the same. Detail A is a section through the beam and arch, showing a side elevation of the addition to the bedposts. Detail B is a section through the seat. All of these drawings are drawn to scale.

In describing the way to carry out this work, I will commence with the beam across the room. This need not necessarily be solid, a case will serve the purpose equally well, and should be constructed with two 1 in. deal boards 10 in. wide, and as long as the width of the room. These will be the front and the back of the beam. The top and bottom pieces will be the same length and 2 in. less than the required total width of the beam. These should be tongued and grooved together as shown in Detail A, and the bottom piece, or underside, of the beam should also be grooved to receive the heads of the posts and the tongues of the arches.

When the beam has been constructed, it should be fixed to the wall at either end by holdfasts driven into the walls from the underside of the beam, and, if possible, made additionally secure by being screwed into the ceiling joists; these screws will be eventually concealed by the cornice moulding which will afterwards be described. The back edge of the beam should be in the angle formed by the flat and sloping portion of the ceiling.



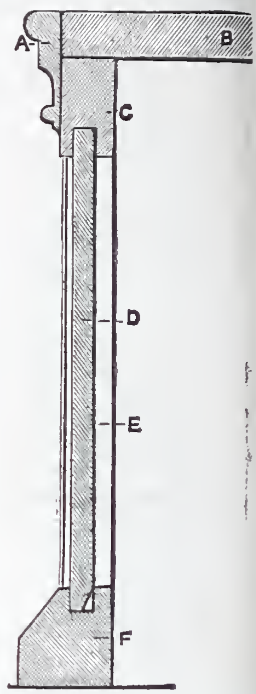
Detail A.—A, Ceiling Line; B, Case Beam; C, Head; D, Arch; E, Capital; F, Oak Dowel; G, Necking; H, Joint.

Next, the posts must be considered. It will be found that bedposts are not more than 5 ft. 6 in. long. This is the length of the posts I am writing about; and it was found necessary to increase them 6 ft. 6 in. This was done by fixing a short portion of shaft, a small turned capital and head dowelled and glued to the old posts with 1 in. by 3 in. long circular oak dowels immediately above the neckings (see Detail A). The joint thus is practically concealed. In lengthening the posts, of course, the total length when finished must be equal to the height between the floor and the underside of the beam, and the head 9 in. long, or equal to the depth of the arches. In addition to this there should be a tongue on the top of the head, to fit into the groove on the underside of the beam. The head should be grooved to receive the arches on either side; and the central heads should be grooved on three faces, so as to receive, in addition, the arches shown in Fig. 4. A post should be placed at the extremities of the beam, and the intermediate posts should be equidistant, or, as in this instance, opposite the window frames. Should the window not be in the centre of the room, as in the case in the accompanying drawings, the arches will be of different lengths; but this need not be considered, as it will add to the picturesque effect of the whole when completed. The head should be screwed into the beam from the sides. The feet should either be screwed to the floor, or inserted into square compartments formed with half round deal, mitred, and then screwed to the floor, by this means forming sockets for the reception of the posts.

The position of the posts having been arranged, it will be necessary to set out the arches. These should be of a length equal to the distance between the posts. The arches should have a tongue along the top and sides to fit into the grooves already described along the underside of the beam and the sides of the heads. In cutting out the arches the wood should be $9\frac{1}{2}$ in. wide, the half inch being the tongue. Care should be taken to keep the shape of the arch flat. Do not get a "*fat*" curve on any account. Three different widths of arches are given in the elevation, and the reader cannot do better than follow these lines. The arch shown in the section (Fig. 4) will depend entirely on the length of the slope of the ceiling. And should the room be as shown in the drawings, it should be cut from 12-in. stuff, with a tongue on the edge next the post head. This tongue should be inserted into the groove already described, and screwed to the upright post forming part of the window framing. Should the ceiling be uneven, as is very often the case in old houses, a moulding should be fixed to the arch along the ceiling line both back and front. The seat should next be formed. This is shown 14 in. in height and formed with panelling, the styles being moulded and 3 in. wide, pegged to sill and top rail, and grooved to receive the panelling. The moulding along the top of the seat is $2\frac{1}{2}$ in. deep; this should be secured with screws to the top rail, which should be made out of stuff $2\frac{1}{2}$ in. by 3 in. deep, grooved on the underside for styles and panelling, and rebated along the back edge, for the frame of the seat. The sill should be out of 2-in. by $2\frac{1}{2}$-in. stuff, grooved on the top to receive the panelling and styles and a splay should be worked along the front top edge. The Detail B shows the splay and the way to frame the fronts of the seats. The sill should be screwed at the back both to the floor and to the top rail, and mortised into the posts at either end. If it is thought necessary to simplify the front, a good way of doing this would be to have a $1\frac{1}{2}$ in. board 13 in. wide, and the length of the space between the posts, the 3 in. moulding being carried up 1 in. above the board to form a rebate for the seat-boards, with a small moulding nailed along the floor and front, to form a low skirting. This board could then have small panels formed by mitred mouldings, nailed on the face. This was frequently done in the 17th century, and the panels thus formed are rendered exceedingly fantastic by the methods of mitring.

Bearers must be secured to the walls along the sides and back, and 1-in. boards laid across from the rebate on the top rail to the bearer at the back. A cornice moulding $2\frac{1}{2}$ in. deep should be nailed along the ceiling line of the beams; and, should there be no cornice in the room, it will be better to carry this all round. The seat may be made in a variety of ways, and I must leave the reader to determine upon what suits his fancy. I should say that a movable cushion, about 2 in. to 3 in. thick, is probably the best form of seat, as it can easily be removed and dusted.

And now for the painting. I always use, and shall continue to recommend, "patent paints." The trouble that one has so frequently to go through in mixing up the tint for workmen is thus avoided, and the material used in patent paints may generally be relied upon as being first-class quality. In my own professional work I mix the tints required at the paint manufacturer's own works, and then it can be ordered in any quantity. Whatever paint is used, let it be *egg-shell gloss;* this is far more satisfactory than a highly glazed or enamel paint. And the *bastard or flatted* paints are rather too dull to be put on work in rooms for every-day use. If a patent paint is used, two coats will be found sufficient; if ordinary oil paint be preferred, it will be found necessary to have three coats. I have seen the process of painting described in back numbers of Work, and therefore consider it would be superfluous to again repeat a description of the operation.



Detail B.—A, Moulding, $2\frac{1}{2}$ in.; B, Boarding, 1 in.; C, Top Rail, 3 in. × $1\frac{1}{2}$ in.; D, Panels, $\frac{1}{2}$ in.; E, Styles, 3 in. × $1\frac{1}{2}$ in.; F, Splayed Sill, 2 in. × 2 in.

Mottoes are an old and excellent form of decoration, and more freely used as such in the 17th century, and, indeed, in the mediæval times. We never see a motto in a room but our gaze is arrested. Mottoes may be written in any language. But as we live in England, and there is no dearth of exceedingly appropriate lines, why depart from our own tongue? Probably the reason why mottoes are so rarely seen adorning the walls of our homes is because of the general want of knowledge of where they should be placed; and also, possibly, because of the abuse they receive in churches, where we see them written in plain block lettering, on sheets of tin, and nailed in the very places that would be better if left without them. But no mistake can be made if the motto is appropriate, the lettering good, and the frieze or beam of a room selected as its position. Shakespeare alone supplies a sufficient number of mottoes for the most fastidious to choose from. The one shown on the perspective view is from Herrick: "*Whatever comes, content makes sweet.*" And I have found that this line appeals to nearly every person who reads it. The lettering has been placed on the beam in gilded letters, the capitals 7 in. high, and the smaller letters $5\frac{1}{2}$ in. high, small gilded ornamental stops being placed between each of the words, and the whole well toned down with burnt sienna. The effect is that ts, room has been tnsformed from an ily and cheerless e into one where is delightful and reshing to sit.

The furniture has en purposely omitted in the perspecte, with the exception of one chair, in ler that as much the construction possible may be n. Perhaps I ght be allowed t say that the curtns shown are ng on rods at the ks of the arches. avy material is ter than light islin for curtains, it adds to the hness of the room a case of this sort, d is more inviting. r heavy material, ushette is the st expensive in the d, as it will wear a considerable

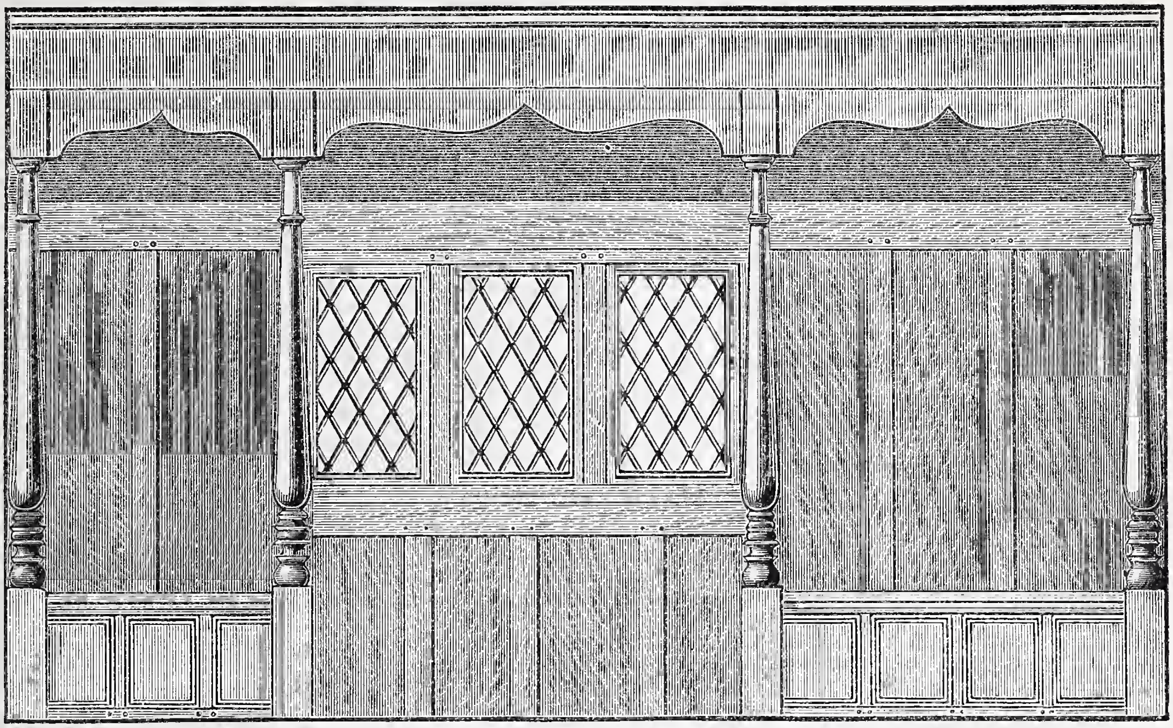


Fig. 2.—Elevation of Gallery.

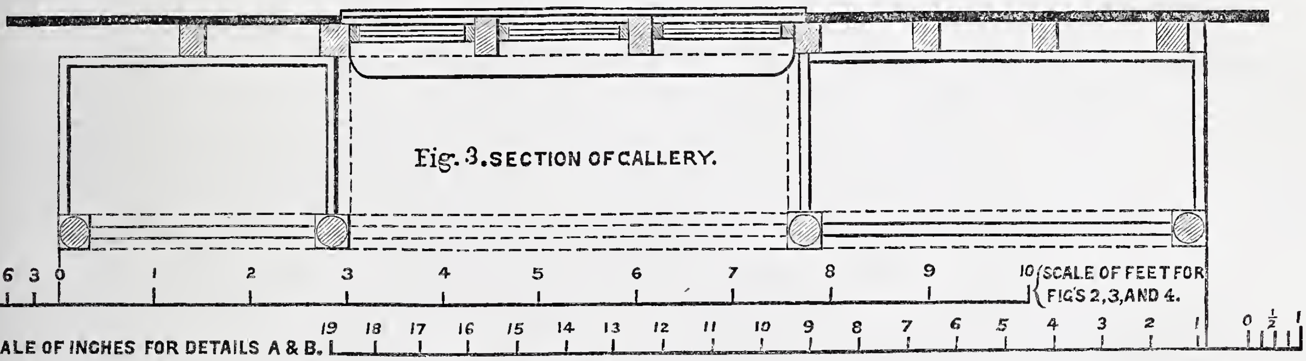

iod without fading or looking seedy, d, even when it does fade, the colour is still ceedingly pleasant to see; but if economy a consideration, I know of nothing better in art serge, which can be bought at Burtt's in King Street, Covent Garden, at 2s. a rd, 54 in. wide, in many different colours, of which are very beautiful. If serge rtains are used, let the cushions on the its be made of the same material. A ort valance should be placed across the ndow.

In conclusion, perhaps I may be allowed say a few words with regard to the ndows of rooms where snugness is a conleration. In the first place, plate glass ay be considered as an article calculated destroy all attempted artistic feeling. gain, large squares of sheet glass may be aced in the same category. For artistic d, so far as I am aware, for lighting purses, the diamond shaped, or small squares lead lights, are much to be preferred. obably the first thing a person does after ving entered a room is to look at the ndow, and the room will afterwards be dged by the scale taken from the squares glass. This may seem a comparatively inor consideration to the uninitiated; but is not so to the artist, who is careful ver to overlook such a point as this in s work. The ceiling is another matter of portance, and its treatment may either ake or mar the general effect. Do not der any circumstances have a pattern

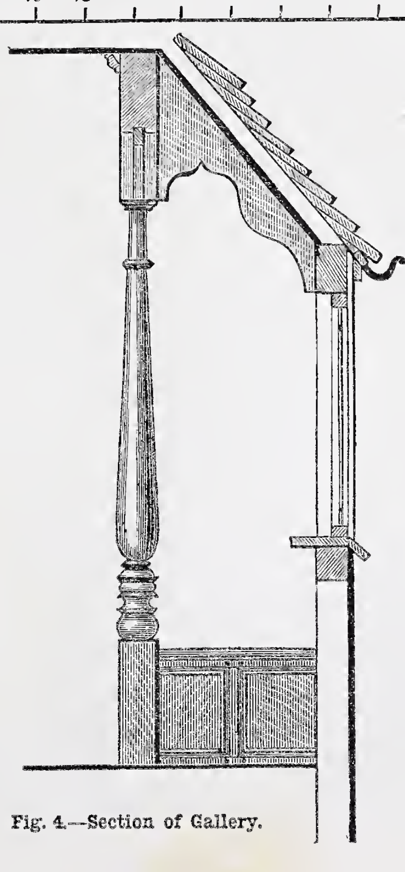

Fig. 4.—Section of Gallery.

paper on it. Plain white ceilings are usually preferable, but the whiteness may be toned down if wished to harmonise with the general scheme of colouring.

The floor should be stained with two coats of Jackson's walnut stain, wherever it is not covered by rugs or carpet. And to complete the whole, an Oriental rug may be laid on the floor below the window.

PLAIN AND DECORATIVE HOUSE PAINTING.

BY A LONDON DECORATOR.

Oils, Varnishes, and Other Vehicles: Solid and Liquid "Driers" (*continued*).

As a useful practical appendage to the remarks in No. 42 concerning the source and nature of painters' varnishes, the subjoined *résumé* of those particular varieties in general use will commend itself to the interested reader and worker.

For the finest interior work, *white oil varnish*, that is, a liquid which can be spread and worked upon broad surfaces, and such as will dry in about eight hours, is very requisite. Various eminent firms make such a varnish for decorators and painters, and sell it under such fanciful names as "Coburg," "Italian Oil," and "French Oil Varnish." The chief attributes aimed at are freedom from yellowness and the possession of good "hand-polishing" qualities—the latter process I will explain in the advanced part of the subject. The price of such a white interior varnish would be from 20s. to 30s. per gallon to the trade.

After this "polishing" varnish, a maker's list usually contains one or two varieties of what are termed *superfine copal* varnishes. These range in price from 16s. to 20s. per gallon, possessing different names and features, such as "polishing" and "extra hard-drying."

Lower down in the scale of costliness we find the best kinds of ordinary *copal varnish.* Many varieties are made of this quality, and for such purposes as the names *inside copal* and *outside copal* convey to the purchasers. The prices of these range from 12s. to 16s. per gallon.

The "cheap oaks," as they are usually termed in the trade, are generally a most serviceable class of varnish, and can be purchased, suitable for all kinds of interior and external surfaces, at from 8s. to 12s. per gallon.

If there is one article above the other "thousand and one" used by the house painter in which quality is *the* essential consideration, that article certainly is varnish. The prices given above are more for relative comparison than as any guide to purchasers, but they are well representative of the best makers' current prices.

Preparations of coarse oil and common resins are placed upon the market at much lower prices; such as these I would especially warn the worker against, and advise the inexperienced, especially, to purchase always an established maker's goods through—if necessary at all—a reliable retailer.

There are yet a few other varieties I must mention, and of these *hard drying* or *church oak* varnish is a "good friend" to us, although in copal oil varnish, quickness of hardening must generally be accompanied by a tendency to lose gloss and to crack from excess of resin. A preparation known under the above names is always to be had for seats of public buildings, stained floors, and common furniture, for which it is invaluable. This make of varnish, retailed at about 2s. per pint, is the "right stuff" for kitchen furniture and so forth; since, unlike many and even expensive painters' varnishes, it does not get soft and sticky by the warmth of the body, whilst its oily nature makes it very durable. The litharge or similar substance with which it is prepared, however, considerably darkens the oil, so that this would not do for light-coloured paint.

Maple varnish is but another name for a good quality of interior copal varnish, made from the lightest gums and refined oil, so that when coated over such delicate "figure" as the imitation of maple and satin wood, it shall not disadvantageously affect the colour of the grainer's work.

The varnishing of *wall papers* is a very important item of painters' work, and whilst the old paper-stainer's abominations, "sienna-marble" papers so-called, are being rapidly relegated to their proper—the *lowest*—sphere in the scale of æsthetic beauty and common sense, covering the walls of middle-class houses with pattern papers suitable for varnishing on staircase, bath-room, and kitchen walls especially, is a commendable and growing practice, consistent alike with sanitation, durability, and decorative effect. For all paper hangings on which the yellowness of copal varnish would not be detrimental to the colour of the design, a good quality of this variety is far preferable to the "paper" varnishes sold by the manufacturing houses. Whether used upon walls or woodwork, a moment's consideration will show that the colour of copal "oak" varnish would spoil such tints as French or green greys, delicate pinks or white; but for what we term "terra-cotta" shades, buffs, and "leather," or cinnamon colours, the yellowness would be no disadvantage.

Where *white* paper varnish is necessary, we use that which is termed *crystal paper* or *fine pale paper* varnish. The first is the whitest, and as it can contain but little linseed oil, it requires very expeditious and experienced working over large surfaces. *Crystal paper*, *copal cabinet*, and *quick furniture* varnishes come under the heading of volatile oil varnishes; so also does mastic varnish, used for varnishing paintings, maps, etc. Whilst genuine "mastic" costs about 50s. per gallon, the cheap substitutes given above range from 14s. to 20s., trade price.

Amongst the purely *spirit varnishes*, "white hard" and "brown hard spirit varnish" are the two most useful. They are similar in nature to French polish, all being prepared from various kinds of *lac*—shel-lac, etc.—and spirits of wine, or "methylated" spirit. The lustre they give is nearer to that of French polish and "softer" than that given by a "copal oil," hence "white" and "brown hard" are much used for furniture as a substitute for the more tedious process of French polishing, and also upon those portions where the "rubber" could not be used; they cost about 8s. per gallon.

Bath varnish is a very hard-drying, white liquid, similar in nature to the "enamels" now on the market, but is a more durable article, and resists the action of hot water to a greater extent than the other preparations. Its price is about 20s. per gallon.

Beyond all these herein enumerated, there is a further variety of "carriage," "boat," and "implement" varnishes. These are outside the scope of this paper, but any information concerning them will readily be given to any inquirer through the invaluable and entertaining columns of "Shop."

Before turning to the subject of "driers," there are a few *vehicles* and liquids used by the painter which scarcely come under the above heading of "oils and varnishes," but which are, nevertheless, indispensable to the trade. The word varnish is so identical with a glossy surface, that the name "flatting" or "lustreless" varnish, given to a preparation of oil of turpentine, copal, and wax, is somewhat a misnomer. It is not often called for, since it possesses very little body, but, upon timbered and ornamental wooden ceilings, can be used with decided advantage over ordinary copal, the small amount of wax gloss it gives out being far more restful and natural for such positions than a bright hard glitter. *Black japan* is a species of black copal varnish, made in various qualities, and the best for carriage painting. House painters seldom use it for other than blacking grates and ironwork, although there are many purposes it can be used for Thinned down with "turps," it makes a capital stain for wood of a rich brown colour. *Berlin black* is another preparation useful for various purposes, as it is a dense black, drying with only an egg-shell gloss; it is prepared, however, like Brunswick black, chiefly for ironwork. Cheaper black varnishes, similar in nature to "Brunswick," are also to be purchased at 4s. per gallon.

Patent knotting, or *knotting composition*, is a brown spirituous varnish, used chiefly for touching over the knots in woodwork previous to the "priming," or first coating, being spread. It is also useful for coating over stains and other effects of dampness on walls previous to their painting.

Varnish stains are liquids of similar nature and preparation to brown hard spirit varnish, but are coloured with permanent vegetable dyes to represent, when spread on clean white wood, the various colours of oak, walnut, mahogany, etc. When applied without any previous preparation, two coats are necessary to get a glossy effect upon new wood. As a varnish and stain combined, they are most useful and convenient for picture-frames, fret work, and other little matters.

Japan gold size, or "Japanners," is a liquid used for a great variety of purposes. Notwithstanding the name appears to connect it with processes of gilding, it is seldom used for that purpose, but rather as a liquid driers in combination with "turps" and "flatting" paint. Japan gold size is a preparation of linseed oil and litharge, and will usually dry in about half an hour. When nearly dry, it has to a slight degree that property of *tackiness* which is so characteristic of oil gold size, but with very little of the brilliancy of the latter. Only on out-door work, where it is advisable to complete the gilding forthwith, for temporary work, or for sign writing can it be recommended as a *gold size*.

In coach painting, engine work, and, to a minor extent, in house painting, "filling up" compositions, prepared with japan gold size for hardening it, are much used and in preparing "dead" black from *Ivory Black* ground in turpentine, this is also the best and safest binding liquid.

Having now reached the "binding" or drying agents, a few lines will suffice to complete my paper.

In noticing the properties of the expressed oils, the advisability, and generally the necessity, of adding some substance powerful in oxygen to our paints, in order to ensure their proper hardening, was briefly touched upon. Of these substances there is a considerable variety, which may be used to more or less advantage, according to their chemical nature and their effect upon the colour of our paint. *Red lead*, for instance is a good natural drier, but, of course, this would not do for assisting the *white* paint to oxidise. The subjoined articles, however represent the principal drying sources of all liquids and paints: viz., *sugar of lead sulphate of zinc*, *litharge* or *oxide of lead white copperas*, *white sulphate of manganese* and *white borate of manganese*, of which list the two last are the most expensive Nowadays, it is not necessary to "rub up" our own litharge or sugar of lead, for they are offered to us in the less pure, perhaps but far more convenient form of *liquid driers* and *patent driers* respectively.

Terebine, or liquid driers, is doubtless prepared in a manner similar to japan gold size, but with a greater proportion of the solvent oil of turpentine: in fact, almost substituted for the linseed used in the latter. Its price is about 10s. or 12s. per gallon, and it is most useful for the quick drying of all dark and outside paints Patent driers, in the paste form, is best for white lead paint. About one-tenth part weight or bulk, is enough for all ordinary work, and less under good drying conditions of the air, when one ounce to the pound is ample. Its price is a little above that of genuine white lead.

SIGN-WRITING AND LETTERING.

BY HENRY L. BENWELL.

PIGMENTS, GOOD AND BAD—TINT MIXING FOR SIGN-WRITING USES—TABLE OF THE PRINCIPAL TINTS, HUES, AND SHADES USED BY SIGN-WRITERS—"GROUND" AND "LETTER" COLOURS—EDGING LETTERS—COLOUR TABLE FOR BEGINNERS.

CONTINUING my remarks on colouring, we must now consider one or two practical subjects in connection therewith before leaving the subject. The general qualities of good pigments, technically called colours, are, according to the authority of Mr. George Field, as follows: (1) Beauty of colour, which includes pureness, brightness, and depth; (2) body; (3) transparency or opacity; (4) working well; (5) keeping their place; (6) drying well; and (7) durability. But few pigments possess all these qualities in equal perfection (I have already pointed this out in a previous chapter). Body, in opaque and white pigments, is the quality of efficient covering and hiding ground; but in transparent pigments it signifies richness of colour or tinting power; working well depends much on sufficient grinding, or fineness of quality; keeping their places and drying well depends greatly on the vehicles with which they are diluted or tempered. Durability also depends on the fine quality of both the pigments and the vehicles, and the varnish used as the finishing coat. Bad varnish, as every one knows, or ought to know, ruins a sign as quickly as bad oil and colours, and is the most general cause of premature deterioration of work in this direction. This being a subject which the student requires to have exceptional knowledge of, and space not permitting of its further extension here, I must ask him to continue his investigations by referring to Chapter IV. in "The Grammar of Colouring," and thereby well grounding himself in useful knowledge.

We now come to the mixing of tints, in which great care and caution are necessary, not only to be able to obtain a lasting colour, but also a bright and clear one; which, owing to insufficient knowledge and carelessness on the part of workmen, are generally those very qualities which are absent in home-made tinted colours. Now, as a rule, the ordinary house painter is a failure as a tint manipulator, mostly because he uses the wrong colours, or too many of them; is not sufficiently clean in his methods, and does not devote half the necessary time required for proper and thorough mixing. How often does one see a pure, bright, clean tint, and one which has not faded? But how can it be otherwise, when the one result of improper mixing, or, I should say, the insufficient amalgamation and blending of the colours used, is a muddy, impure, and uneven tint? Now this will not do for the high-class decorator and sign-writer; he must have bright, clean colours, or he will prove a failure. In compounding tints, one great consideration is to find out how to get the tint, shade, or hue required with the least number of colours; as, generally speaking, the less the number of colours used in making a tint, the purer it is. But it must be clearly understood that we must not depart from the proper colours necessary for the correct rendering of any tint and substitute others, for the simple reason that they are fewer in number than those given in the recognised formula. No; we should be as much wrong that way as the other; but there are often more ways than one for obtaining most tints, etc., and those which contain the least number of ingredients in the shape of colours often give the best results.

White is the basis of all tints, and here again it is upon the virgin purity of this basis which depends the success or failure of the resulting tint when the white is stained with colours. Of course, we must have the best and *palest* linseed oil for diluting and thinning, otherwise that fault alone would spoil our work. The theory and practice amongst workmen, in regard to compounding tints, is this. The very best white lead (or for indoor work, zinc white) is thinned down to a working consistency, or nearly so, and the requisite amount of driers added. The paint must here be well stirred, and left in this state long enough for the driers to incorporate with the oil, etc., say, for half an hour. Next, strain the paint carefully, and thin out the colours required for the tint; if these are to be added in certain proportions, which are given, such as three parts of one colour, two of another, and four of another, they should be measured, well mixed together, and gradually added to the white, which must be kept constantly and well stirred until the desired tint is obtained. The theory is, that there is a certain amount of white paint which we desire to transform into some delicate tint, and to do this we dye it, or, as it is technically called in the trade, "stain it." It will therefore be seen that this is a somewhat different proceeding to taking up certain portions of any two colours, such as red and yellow, and mixing together to obtain another colour—orange. Hence, certain transparent colours, such as Prussian blue, siennas, and lakes, are called "staining" colours because they are used to obtain certain tints, commonly called colours, by dyeing their basis white to the required tint.

The sign-writer seldom has occasion to mix tints but in very small quantities, and he often does this work on his palette by dipping his brush in first one colour and then the other, and rubbing them out on his palette and adding the white. This is a dirty, untidy method; it is much cleaner to take a little of each colour on the tip of a small palette knife, wiping it clean of one colour before introducing to it the next, and then mixing with the knife or brush. I now append a selection of tints specially used by sign-writers, taken from

THE SIGN-WRITER'S TABLE OF TINTS AND SHADES.

Buff.—This is a mixture of pale chrome yellow and white, tinged with a little Venetian red; carnation, lake, and white.

Chocolate.—Vegetable black and Venetian red; or white, Spanish brown, Venetian red, and vegetable black.

Claret.—Red, umber, and black.

Cream.—This is a mixture of chrome yellow, Venetian red, and much white.

Drab.—Raw or burnt umber and white, with a little Venetian red.

Common Flesh Colour.—Stain white lead with light red, and add a very little yellow ochre.

Fine Flesh Tint.—White, lake, vermilion, and Naples yellow, or yellow ochre.

Fawn.—White and burnt sienna, ground very fine; white, burnt umber, and Venetian red; white, stone ochre, and vermilion.

Grey Tints.—White and verditer, a blue hue; white and indigo, a blue hue; white, Indian red, and indigo, of a brown hue; white, light red, and Prussian blue, of a brown hue; white, burnt sienna, lake, and indigo, of a brown hue.

Green Tints. (These are somewhat important in fancy work.)—White, Italian pink, Prussian blue; Prussian blue, chrome yellow, and burnt umber (olive green); Prussian blue and yellow chrome (liable to fade); yellow ochre and indigo; raw umber and indigo; brown, pink, and indigo; raw umber and Prussian blue (sage green); white and Brunswick green (pea green).

Lead.—White, black, and indigo.

Peach.—Vermilion, Indian red, purple brown, and white; white lead tinged with orpiment; white, red, blue, and yellow.

Pink.—White, vermilion, and lake; white, crimson lake, or scarlet lake.

Pearl Grey.—Prussian blue and black, equal portions, and white.

Snuff.—Vandyke brown and yellow.

Sky.—Prussian blue and white.

Salmon.—White tinged with Venetian red; white tinged with vermilion; white tinged with yellow chrome, raw umber, and vermilion.

Silver.—Use white lead, indigo, and a little black, according to the shade that it is required to produce.

Straw.—White and pale chrome.

Violet.—Prussian blue, black, vermilion, and white; French ultramarine, white, and a little black.

Gold.—White, stone ochre, and red; pure light ochre; white, yellow chrome, and burnt sienna to desired shade.

Lilac, Lavender, and French Greys.—White, lake, and indigo; Indian red and Prussian blue; white, indigo, and rose pink; white, Prussian blue, and a little vermilion (French grey); white, with a little violet (lilac).

This list, which has been carefully compiled, will, I hope, be found of great service—to the young sign-writer just starting in business especially—to readers and workers alike. It must not, however, be taken as accurate throughout, and in some cases, even where it is perfectly so, the worker may fail for a long time in getting the desired tint, owing to the wrong proportions being added of the various colours composing the tint. These proportions can only be found out by repeated practical experiments, as of course the colours are not mixed in equal parts, but in such proportions as are necessary to give the tint or hue required. Mr. Field recommends the student to mix the various tints in different hues, giving in each experiment a predominance to one or other of the component parts. This is excellent advice, as I can prove from experience, as although I have only lately seen these remarks, it was a method I thought of, and practised when younger, and with good results. It will be found, when experimenting, that the smallest addition of any one colour gives the predominating tone of the tint, which also makes it warm or cold; by adding more white we produce a lighter tint, and by adding more of all the darker colours a deeper shade of the tint. But to thoroughly understand and grasp this subject, the student must study and understand the proper technical meanings of "tint," "shade," "hue," and "tone." The leading, or "key-colour," I may add, always gives the latter, which is the general effect of the colouring as influenced by what are called warm or cold colours. Warm colours, so called, are those in which red or yellow predominate; and cold colours those in which blue and green tints appear.

I have not yet spoken of neutral tints. Grey is termed, by way of eminence, the neutral tint, being the mean between black and white; but any two of the secondary colours will neutralise each other as well, also, as the primaries in due proportion. The neutralising or compensating power is the foundation of all agreement or harmony amongst colours. Another thing which requires much thought and study is *contrast*, which, fully explained, is the "opposition of any two things as to character, whether it be in lines, lights, shade, or colour," or to place figures, or colours, in such opposition or dissimilitude, that the one shall give greater visibility and effect to the other.

We have next to consider a few rules relating to the arrangement of the colours used for the letters, and their harmony and keeping with the ground colour upon which they are painted. In the first place, the ground colour should not be of a bright and glaring nature (except in special cases where a certain colour is used as a sort of trade mark or distinguishing sign); on the other hand, it must be of a subdued and quiet tone. A ground of some bright colour will not show up writing of a brilliant and showy description half so well as one of a quiet and neutral tone. Letters always stand out with greater prominence and distinctness on a quiet secondary or tertiary colour than on a primary colour, unmixed with white. Letters on a neutral subdued ground are brought or thrown forward; on a bright gaudy ground they are lost, the greatest prominence being given to the ground itself. Another thing to remember is that the style, arrangement, and colouring of a sign should be suitable and in taste with the trade, business, or profession which it represents; for instance, a sign with gold shaded letters on a lavender ground, surrounded with a black and gold moulding, although proving attractive enough for an undertaker's or a mourning warehouse, would look miserable and entirely out of place outside a gin palace, a confectioner's shop, or even a photographer's studio; although the latter is more or less associated with the "black art." The great point in colouring a sign is to make its colours, as far as possible, emblematic, and suggestive of the business indicated thereon. Of course, the style of lettering employed must also be chosen on the same lines, but with the alphabet we have, at present, nothing to do; suffice it to say that in every process it should be the earnest effort of the writer to emblematise in some way every sign he paints. The great thing to know is the exact effect a given combination of colours will produce as a finished whole. We frequently see a yellow and even a red letter on a black ground; now you must always pity the poor fellow who did that work, for he has not one atom of judgment or taste, and has in his own self his worst, bitterest enemy, as far as regards his advancement in his art. Such colouring always bears a common stamp, both of effect and workmanship. There is a given rule that one colour shall not ride over or overlap the other, so that it is necessary to divide the letter colour from the ground colour, with a thin line running round the edges of letters. Let us suppose we have painted some green letters on any dark ground with a reddish hue, such as, say, purple brown, and notice the harshness of the contrast; but outline the letters with white or gold colour, and see how all is softened down by this simple expedient. Again, put in an emerald green colour, and write your letters with vermilion or Chinese red: the result is worse than in the first case; but edge them with black or gold, and you are again safe. Mr. James Callingham, speaking on this subject in his work on "Glass Embossing and Writing,"* points out how important it is to bear in mind that coloured letters on a coloured ground should never be used unless they are at least invested with a white or gold edging; and if a gold thickness can be added, the effect will be heightened. A black cast-shade will throw the letters out, and help to give them a raised appearance. In some cases a coloured thickness may be rendered effective on a dark ground, so long as the indispensable gold or white line be not neglected; but it ought never to be allowed to impinge upon the colour of the letter itself, unless that colour be an imitation of, and a substitute for, gold; in which case it ought not really to be regarded as a colour at all, but as the thing for which it is substituted. This principle was exemplified by Mr. Owen Jones in the interior decoration of the Great Exhibition of 1851. Here, the primary colours were so arranged as to neutralise each other; and in order to avoid any harsh antagonism from their contact, or any undesired complementary secondaries arising from their immediate proximity, a line of white was interposed between them, which had the effect of softening and giving them their true value. I may add that the foregoing remarks do not apply to letters on a black ground, because black is not a colour, in the strict sense of the word. The edging round the letters must be boldly and neatly done, especially on gilded work, with the best sable pencils; it must show no sign of timidness or indecision, otherwise the line will have a rough, ragged appearance, and completely spoil the letters. Gold letters, in fact, show up an unequal line in an instant.

It will require some little time before the student finds out what coloured letters look best on the different grounds; but sign-writing is not by any means a hidden art, as we have only to perambulate the streets to find hundreds of practical examples. Mr. Callingham's book, just mentioned, also gives a host of information on this subject, and to which I must refer the more advanced student thirsting for further information on this subject. For immediate use I append a short table, each item being numbered for possible future reference.

A Table showing what Colours to Use for Lettering on Various Coloured Grounds.

	Ground Colour.	*Letter Colour.*	*Shadows.*
1	Stone colour	Black	White and dark stone colour
2	White	Any colour	Any colour
3	Black	White or gold	(Plain)
4	Light blue	Dark blue and vermilion	Light blue, dark shade, black, etc.
5	Bronze green	Gold, yellow, red	Vermilion, emerald green
6	Marble	White incised letters	—
7	Mahogany graining	Any light colour and gold	Various
8	Walnut	Any light colour and gold	Various
9	Oak graining, dark	Gold or red	Dark colour and black
10	Oak graining, light	White	Black
11	Chocolate	Pink, salmon, fawn, primrose	Letter colours and black
12	Dark blue	Gold, outline white	Plain
13	Medium blue	Gold	Orange and Vandyke
14	Vermilion	Gold or yellow	Green, white, and black
15	Sage green	White	Purple brown and black

* "Sign-writing and Glass Embossing" (Brodie & Middleton. 5s. 6d.)

The preceding is but a short list, inserted here for the special purpose of giving some slight assistance to the beginner having no knowledge on the subject, and refers mainly to simple plain lettering. The learner should now be able, from the directions given, to proceed with the practical application of his colours with some degree of success.

MEANS, MODES, AND METHODS.

A New Material for Bill-stickers' Paste.

Since Free Trade has cheapened the corn for the people, we hear less of adulteration of flour by salt, alum, ground bones, etc.; but, cheap as it is, it is a pity that tons of flour are used up for paste yearly by bill-stickers. It was said at the last School Board election for London, that the flour used for paste for the bills of the rival candidates would have supplied bread for many weeks for the famished children sent to the schools. Unfortunately, it is not the worthless flour that is used, but some of the best. Anything to prevent this scandalous waste of good food deserves a welcome from thoughtful persons.

A good substitute has been found by Messrs. Bull & Hofsten, natives of Norway. It is prepared from the whale's blubber. It is colourless, quick-drying, and very adhesive. Of its cost and continuity of supply, no statements are to hand. But from the seaweed that forms banks on our beaches an endless supply of gluten sufficient for bill-sticking could be made cheaply, and the by-products, by their utility and sale, would serve to make it cheaper even than flour.—J. C. K.

A Bright Red Varnish.

Procure some red sealing-wax, or any other colour, according to taste, and also some spirits of wine. Break the wax up into small pieces, about the size of peas; put these into the spirits, and put the bottle by in a warm place for a day or so. If, on examination, it is too thin, add more wax, and if too thick, a little more spirits. This is a capital varnish for iron or wicker-work, as it dries quickly, and with a good gloss. The varnish thus produced will be found useful for colouring or coating fishing floats, and a variety of like purposes.—E. A. P.

[Varnish of any colour, as it has been said, may be made in this way, by using sealing-wax of the colour required.—Ed.]

Imitation Coral.

Procure some acorns or gall-nuts; cut a little piece off each end, and bore a hole through them lengthways with a bradawl or short knitting-needle. Then take some of the red sealing-wax varnish, and dip the acorns or nuts well in it, rolling them about until they are evenly covered; then string them on wires until dry. They make very good imitation coral necklaces, and are useful for a great many decorative purposes. Small twigs can also be used, and are very like coral branches.—E. A. P.

[Smaller articles than acorns or gall-nuts should be used for imitating coral for a necklace.—Ed.]

Cheap Ink.

Take a 3d. packet of Judson's dye—any colour according to taste; dissolve in a small bottle with a little hot water, and when dissolved, fill the bottle with cold water. When required for use, pour a little into the ink-pot, and dilute with water to required weakness.—E. A. P.

PRACTICAL HINTS ON MOUNTING OBJECTS FOR THE MICROSCOPE.

BY A. T. SMITH.

GUM DAMMAR—PREPARATION—GLYCERINE JELLY—FARRANT—MOUNTING SECTIONS.

As the method of preparing objects for mounting in gum dammar, as well as the actual process of mounting, does not differ from that employed for mounting in Canada balsam, it is hardly necessary to recapitulate, and I will content myself with just giving a few hints as to the best way of preparing the medium itself for use. It should be prepared as follows :—

Choose a few clean and clear pieces of the gum and drop them into a little pure benzine. When the gum is dissolved, if the solution is not perfectly clear, strain through several thicknesses of fine dry muslin which has previously been washed quite clean by passing through it a strong stream of cold water.

The solution should now be perfectly clear, and like the solution of balsam, of about the consistency of olive oil, or perhaps slightly thinner. It should be kept in a similar bottle, which, indeed, will be found a very convenient form for keeping all kinds of mounting media in, as it is important that all dust be most carefully excluded. This is almost impossible in the case of an ordinary corked or stoppered bottle, for when the medium is in use the cork or stopper is bound to be placed on the table on its side, or with the bottom turned up, in either of which positions it is sure to pick up fragments of fibre and dust from the atmosphere or the table, and these subsequently find their way into the medium.

Glycerine, as I think I have already said, is, in my opinion, one of the most useful mounting media we have, it is capable of such universal application and gives such beautiful results.

There are, of course, some objects such as diatoms and some crystals which cannot be successfully mounted in glycerine, but these are exceptions, and, as a general rule, every class of object is better displayed, and is seen to greater advantage in glycerine than when mounted in any other medium ; and it is an undoubted fact that there are many objects which from their very nature it would be absolutely impossible to mount successfully in anything else. It is in glycerine, too, that those beautiful preparations of insects are preserved which have of late attracted so much attention. I refer to those mounted in cells so as to retain as nearly as possible their natural form and colour.

Glycerine as a mounting medium is capable of such endless modification that it is almost impossible in the short space at my disposal to do more than indicate briefly a few of the principal forms in which it is used for mounting specific classes of objects, and how these objects are best prepared.

I have already referred to the preparation of glycerine jelly and Farrant's solution, and the two other forms in which I have found it most useful are in its natural state with the addition of a little pure carbolic acid, or diluted with water and a trace of carbolic acid.

Glycerine jelly is useful for mounting sections of green wood either stained or unstained, roots, leaves, some of the coarser forms of algæ, and, generally speaking, objects which without deterioration will bear the slight amount of heat requisite for mounting in the medium, but will not stand the drastic course of treatment necessary for preparation and mounting in Canada balsam.

The objects referred to above require very little preparation except just carefully washing in water, and then soaking in pure glycerine for a few hours previous to mounting; and when the object is thoroughly saturated with glycerine (which should be the strongest and purest obtainable) it should be transferred direct from the glycerine to the centre of a glass slip, all superfluous glycerine carefully removed with the help of a piece of blotting paper or rag placed at the side, and then, after gently warming the slip, a drop of warm glycerine jelly should be placed on the top of the object with a pointed glass rod, and the cover glass applied in the usual way.

Some workers prefer to get the object into position on the cover glass first and then invert it on the slip. If this plan is pursued, you should after carefully cleaning both cover glass and slip, breathe on the end of the slip and then place the cover glass on the condensed moisture ; it will adhere quite firmly enough to remain in position whilst you are arranging the object, and when this is done, the cover glass should be gently pushed with the tweezers to detach it from the slip and deftly inverted in the centre of the slide.

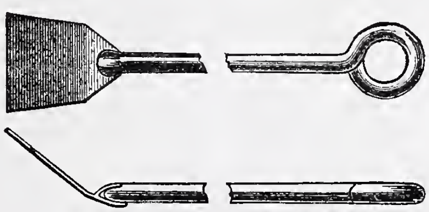

Fig. 3.—Spoon for Transferring Sections to Slide in—Front View (A) and Side View (B).

The glycerine jelly should now run out to the edge of the cover glass, but if it does not, another drop should be added at the edge, which will at once run in and fill up the vacant space. The slide should now be put aside to cool, and then it should be ringed with gold size, and finished off and labelled in the usual way. With a little practice, it is possible to make exceedingly neat mounts in this way, the great object being to get exactly the right amount of the medium on the cover glass, so as to avoid the necessity of cleaning away superfluous medium before ringing. I have some exceedingly pretty slides of fresh water algæ which I mounted in glycerine jelly fully ten years ago, and they look quite as well now as they did when newly mounted.

"Farrant" is an exceedingly useful medium for mounting the more delicate kinds of algæ in, and it is also used very largely for mounting delicate vegetable and animal sections. The latter will not stand much handling, and as a description of their preparation would take up more space than I have at my disposal at present, I will just defer giving it until a more convenient opportunity when treating of section cutting and staining, and give you here a few hints as to the methods I have found most successful in the mere process of mounting.

We will suppose that the sections are already cut and stained, and are now lying, either in spirit or in a solution of carbolic acid in water.

The chances are that the sections will be all curled up and mixed together in an almost indescribable mass. If this is the case, they should be emptied out into a basin of clean cold water, when they will gradually separate one from the other, and the most suitable ones for mounting can then be picked out with a dissecting needle.

As they are picked out, they should be dropped into clean spirit, and when they are thoroughly soaked in this, a watch glass or small porcelain tray should be filled with clean cold water. Having selected the section you wish to mount, it should be lifted out of the spirit on the point of a needle and placed upon the surface of this water. The result is almost marvellous ; no matter how much the section may be curled up in the spirit, as soon as it touches the surface of the water, it will lose all its folds instantaneously, and becoming *perfectly* flat, float upon the surface of the water.

This is exactly as it should be ; but now comes the question—"How am I going to transfer it to the slide without crumpling it up again ?" Fortunately, this difficulty is easily solved. Take a short piece of stout brass or copper wire and a piece of thin sheet brass or copper shaped as in Fig. 3, solder the two together as shown, and you will have a very convenient little instrument.

Now take this spoon, if I may so call it, and placing it gently underneath the section, lift it out of the water and slip it off on to the slip or cover glass prepared for it. A small camel's-hair brush will be of material assistance in making the transfer, and when the section is in position remove the superfluous water with blotting paper as before. Now place a drop or two of Farrant on the section and then apply the cover glass.

You will find that Farrant takes some few days to dry properly, and sometimes a mount which appeared to have no lack of medium when put aside will, a few days after, have some large vacant spaces at the edges. This can only be remedied by adding more Farrant in the usual way, and then when the edges are finally dry, the slide can be ringed with gold size and finished off as before.

It is necessary before ringing any glycerine mounts, to make quite sure that the surface of the cover glass and of the slip around the edges of the same are perfetly dry, otherwise the gold size will not adhere, and the result will be that after a certain time air bubbles will appear.

I have tried a great number of cements for the purpose of resisting the solvent power of glycerine, and my experience is that the ordinary gold size is, after all, the best, with, perhaps, the exception of an indiarubber cement made by dissolving pure rubber in wood naphtha. It is most important that the cement, whatever it is, should be very firm and adhesive, and not liable to crack when dry.

ENGRAVING ON METAL.

BY NORMAN MACLEAN.

ENGRAVING ON PEWTERS.

THIS branch of engraving is almost exclusively confined to London, as in no other place are pewter pots so extensively used. As a vigorous method is adopted in cleaning them by the use of silver or Calais sand, the engraving often wants renewing. Here, then, is an opening for some enterprising workman, who fails to find work in his own line of business, to qualify himself for re-engraving these pewters, and forming a connection at the various large inns and public-houses in and about the metropolis. As these articles are in constant use, the engraver would probably be required to do his work on the premises, and should fit up a small handbag with the few necessary tools for the purpose. I need hardly say that a respectable exterior in the applicant for work at such places goes a long way in his favour. If the workman can use the graver, but has not been used to lettering, he can easily drop into the style of work on pewter, which in most cases is simply Italian or ordinary writing (Fig. 31), which is easy enough. The inscription usually consists of the proprietor's name, with the name of the inn or hotel; sometimes it takes the form of a rather nice monogram (Fig. 29), engraved in ornamental cipher, which, with its sprigging or spraying, looks very pretty.* I have sometimes seen the legend, "Stolen from—" here follows the name of the innkeeper and name of the inn. I suppose his customers were rather doubtful characters. For this line of business a very few tools are required. A sandbag 6 in. in diameter, two or three gravers with corks on the points, a lead pencil, tracing point, oilstone, oilcan, small bottle of turpentine, paper, small pot of letterpress printing ink for taking black prints, pair of dividers, a short length of crinoline steel for ruling lines, and a few clean rags, are all that are likely to be required.

Fig. 29.—Initials for Pewter.

In renewing the engraving of a pewter, take the most legible and recut the lines as carefully as possible. Perhaps the engraving will be so far gone that it will require drawing afresh. Such being the case, draw a line down the pot opposite to the handle, and across this line rule with the flexible steel, parallel lines $\frac{3}{4}$ in. apart for the capital letters, and $\frac{1}{4}$ in. apart for the small letters. Rule these three lines in the centre, midway between top and bottom; the centre can be got by means of the dividers. Draw in the name carefully, balancing the inscription so that it will extend a given distance each side of the line opposite the handle. Now cut in carefully, making the curves graceful, and the turns of the letters oval, thickening the down strokes, not forgetting the dots to the "i's" or the stops at the proper places. See that every word is spelled correctly, and put in any small improvement your own taste may suggest. Having done the first one to your own satisfaction, the next thing is to take a "black print." Take on the end of your finger a small quantity of ink and rub it into every cut. Then take a piece of paper and wipe off the ink from the surface of the pot, leaving the ink in the cuts. Next damp a piece of paper—writing-paper will do—and lay it on the engraving; place another piece of paper on the top of the first, and a piece of parchment on top of the whole, and rub with the round end of the point (Fig. 23, page 596) on the parchment until the paper is forced into all the cuts, bringing away the ink in its course.

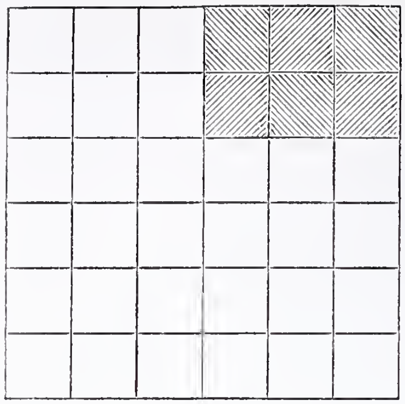

Fig. 23.—Example of "Colouring" Plate.

This is termed a "black print," and if properly taken will lay down a dozen or more impressions. As the impressions get faint, dust them over with the pounce bag, which will make them plainer. If the ink is very soft, mix a small quantity of finely powdered whiting with it; this will make it stiffer, and not so liable to smudge or smear. The print being taken, draw the line down the centre of all the pots to be engraved, mark with the dividers the height of the inscription, and proceed to "lay down" as many impressions as you can see from the print. From now, all "pointing in" is dispensed with, the inscription being *cut from the print.* This will no doubt be rather awkward at first, but with a little practice, and rather a longer graver than usual, soon becomes easy. The graver for this sort of work should be of an acute angle, and not "set off" more than five degrees, and should cut deep and narrow.

The other style of engraving on pewters—ornamental cipher—is the same Italian lettering embellished with sprays. It is usually entwined, which will be seen in Fig. 29. The work is done in a similar manner to that I have just described.

Pewter work is rather dirty, and owing to the presence of lead in the composition, care should be taken to wash the hands after work. It is also advisable to wear an apron with a "bib" or breastpiece, to avoid soiling the clothes, as the pewter, and most articles during the process of engraving, come in contact with the breast.

Having, I hope, successfully started the workmen in the brass plate, zinc, and pewter branches of engraving, I will now take up the young workman and endeavour to advance *him* a step. One side of the plate being engraved, it will be necessary to remount the plate on the block. Spring off the plate, and rub the dirty side over with a piece of tallow candle (this is the best thing I know of for removing cement), and warm the plate over the gas, holding one corner with a pair of pliers, and wipe clean with a piece of rag. Now warm the cement over the gas, and remount the plate as before. On the plate now rule parallel lines $\frac{1}{2}$ in. apart, again ruling cross lines to form $\frac{1}{2}$ in. squares, which may now be engraved. These lines being cut (noting, of course, from time to time the condition of the graver), fill in the squares with lines from corner to corner, the lines to be as nearly as possible $\frac{1}{32}$ in. apart, of the same depth. Each alternate square should be filled in with lines from corner to corner in the opposite direction (Fig. 28). This kind of "filling" is termed "colouring," and the style of ornament done in an irregular manner makes a good background for ecclesiastical lettering and ornament.

In making short cuts with the graver in line work, the graver is manipulated in a different manner to that used in cutting a long continuous line. This method or knack of springing the graver forward when within a short distance of the stopping line is peculiar and effective, and requires considerable practice to acquire it; but once acquired is used for finishing the cut on all kinds of work, whether colouring, veining, shading, or blacking out groundwork. The precision with which some engravers use this method is remarkable, never once slipping over the stopping line during a day's work.

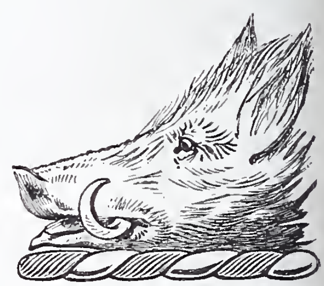

Fig. 30.—Crest for Pewter.

A few words about gravers. Sometimes we find in using a new graver that the point will persistently break off, or be rapidly rubbed away; in either case, the graver is of no use in its present state. When this occurs, do not think that the tool is a bad one, as it sometimes happens that the end has become overheated during the grinding or tempering. The best thing to do is to break off about $\frac{1}{2}$ in. and re-whet it. If the breaking of the point continues, let down the temper a shade or two, using for the purpose the end of a red-hot poker, and plunging into clean cold water immediately the colour has changed. For ordinary work I find a faint straw colour does best. In the case of the point of the graver rubbing away, it must be hardened and tempered again. Heat in a clear fire to a cherry red, plunge into cold water, rub one side of the graver with a piece of stone till bright, and temper as before directed. The breaking of a graver in the place required seems a simple matter, and there is a proper way of doing this. Place the graver intended to be shortened in a hand vice, with the end to be broken off above the jaws. Take a pair of pliers and nip the end firmly, and sharply twist the end of the graver off. The engraver having well practised the examples given for the practice plate, may now try something more ornamental in character, such as the outline of scroll work, etc. Excellent copies by Vere Foster, Esq., may be bought at any artists' material, etc., dealer's at twopence each, which includes ornament by

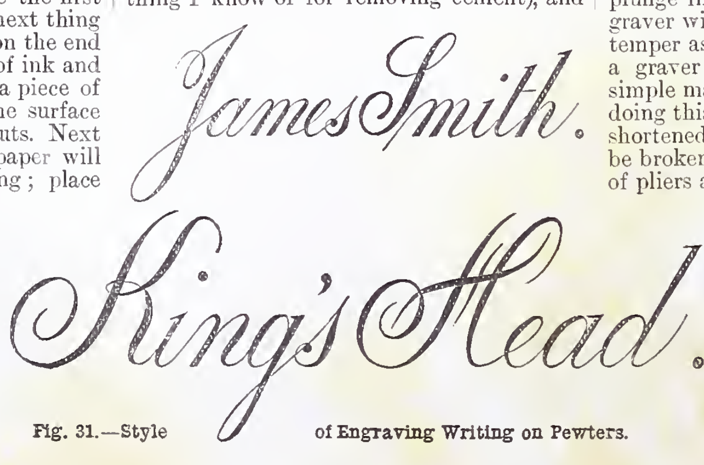

Fig. 31.—Style of Engraving Writing on Pewters.

* Occasionally, the engraving takes the form of a crest as in Fig. 30—the "Boar's Head."

. C. Hulme, Esq., I 1, 3, and 4; Flowers, 1 and 2; G 1 and 2; larine (for vignettes), [1, 2, 3, and 4; Ani- ials, 0 to 10. The vhole of the series may e had for nine shil- ngs, or ninepence per art, and will always be ound useful. The scroll vork may, if a change e desired, be put on ne side for a time, and etters and numerals be taken up. Vere Foster's A 2 drawing book will supply good opies. The workman at this point will do vell to consider which branch of engraving e likes best, as if he wishes to get his living y it he will require to devote all his time o perfect himself in the particular line he lesires to follow.

HOW TO MAKE A PIANO.

BY "NIL DESPERANDUM."

THE CASE: ITS CONSTRUCTION AND PREPARATION FOR POLISHING.

WE have now arrived at the construction of the case or exterior, or, as it is technically termed, fitting up; it is so called because the parts of the case are fitted on the back after it has been strung and chipped up. The parts of the case are made for the fitter-up by a part maker, which in most factories is a distinct branch of the trade. You have, no doubt, observed, in perusing the papers on piano making, that I have taken one branch in each paper, but in this I will deal with part making and fitting up together. As the reader is aware, there are a variety of designs of exteriors, and I must leave it to the individual taste of the reader how he shall embellish his case; there is no rule for fancy: it is unlimited. Perhaps he would desire to make it so that it is in keeping with the furniture of the room where it is to occupy a position; or he may wish to paint panels for it, or plant mouldings on it, or put tiles or crewel-work in the front of it; whichever way he decides to adopt in making the case, so long as he is satisfied, I don't see that it is my place to grumble. I shall here give the names of the parts of the case as they are known in the trade, so that when I speak of the way in which they are put together he can follow me. They are named as follows: the ends, cheeks, top door, bottom door, top, back hollow, fall, lock front, plinth, trusses or brackets, truss toes, pilasters, and key bottom.

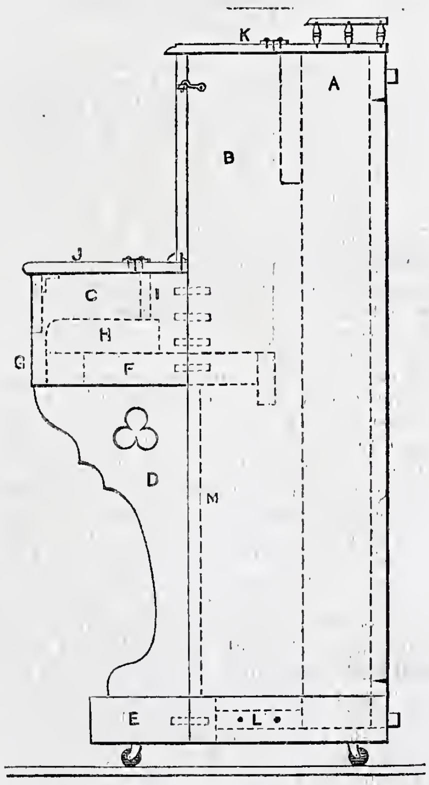

Fig. 2.—End Section of Case.

A, End of back; B, End of case to cheek; C, Cheek; D, Truss; E, Truss toe; F, End of key bottom; G, Lock front; H, Key block; I, Name board; J, Felted fall; K, Top with spindle rail; L, End of bottom board; M, End of pilaster.

The case I recommend the amateur to make is what is known as solid: that is, one that is not veneered. My reason for this is, that I think it would be difficult for him to manage the veneering of the parts of the case without appliances; of course I am aware that the veneer may be rubbed down with a veneering hammer. For a cabinet maker to do this it might be a simple matter, but to the amateur I am afraid it would be very difficult on so large a surface as a piano case, unless he has had experience in veneering. In a piano factory the flat parts are veneered by means of sheets of zinc one-eighth of an inch in thickness, made hot, and placed between each layer of veneer after being glued to the wood and pressed down with iron cramps; these press the glue out, and leave them perfectly flat and free from blisters. Now, the back hollow and fall of a veneered case are usually shaped; they are jointed up in ribs of pine, and worked to the shape with planes. Then there are what are named cauls; these are made of wood, and shaped one to fit outside of the fall and the other inside: these are lined with zinc, and the fall, with the veneer glued on inside and out, is pressed into the caul with iron cramps.

Having given a brief outline of the method of veneering, the reader will see that to be successful he would need appliances: that is my reason for recommending a solid case. I have sketched the simplest style of case from a mechanic's point of view, but when complete it is very effective, and leaves room for the amateur to display artistic taste in more than one direction. If you desire a black case, it would be as well to make it with American white wood and ebonise it, and have some gold lines incised on it to relieve it, but the case I introduce to your notice I intend to be made of English walnut, as it matches over-mantels and the prevailing style of light and artistic furniture; but, as I showed before, it is a matter for the maker's discretion.

Procure at a good timber merchant's some dry English walnut; you will require also a 10 ft. length of 2 in. square pine for your key bottom. If you will kindly refer to Fig. 1, you will see how this is made; it is 4 ft. 2 in. long and 14 in. wide. You plane one side of your pine over and square the edges, then cut off your muntings or cross rails 11 in. long: you will require five of these. Now cut your front rail off 4 ft. $2\frac{1}{2}$ in.; also you want a back rail the same length of 1 in. pine and 3 in. wide: these are dowelled together with round pegs of beech wood about $\frac{1}{2}$ in. diameter. I need hardly say that you use glue as well: when this is dry, you plane the top, side level across, and straight in its length. This key bottom is the portion of the case where the keyboard rests on. Now take the back of the piano, and plane each end of it straight and square, lay it on your trestles strings uppermost,

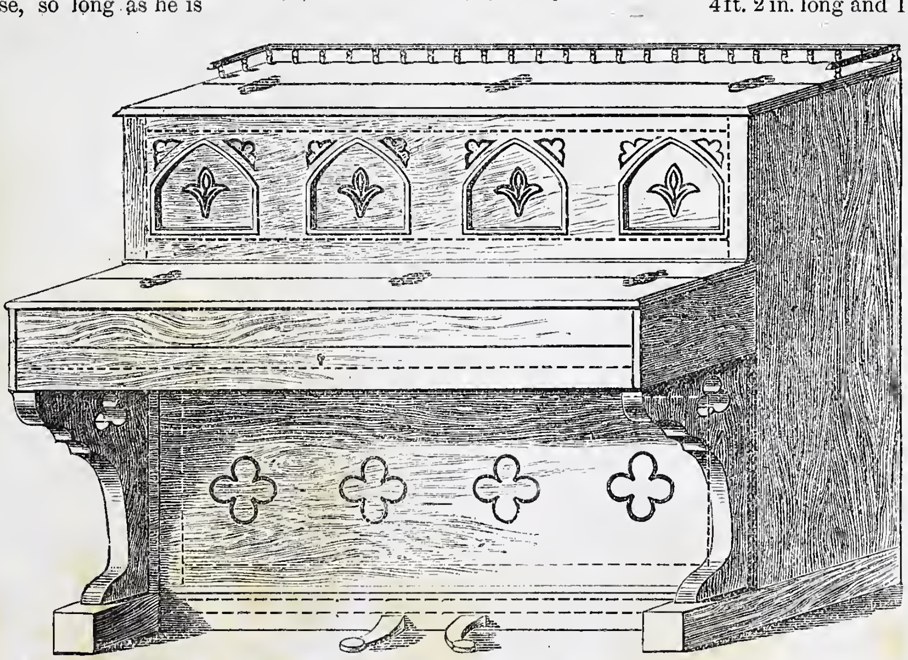

Fig. 3.—Case in Isometrical Perspective, Dotted Lines showing Top and Bottom Doors, Front of Key Bottom, and Bottom Board.

and cover it over with a sheet to keep the shavings and dust from it. Now you make the ends of the case; you will require two lengths of $\frac{3}{4}$-in. walnut 3 ft. 7 in. long × 12 in. wide: these are the finished measurements I will give you, so that you can allow a trifle over these for working. Plane the sides over nicely and shoot your front edges straight, and square the top ends. Now, if you look at the end section of the case, you will find that the end stands from the front edge of the end to the wrest plank 6 in.; select the best sides of your ends for the outsides, and put a small nail in 6 in. from the front at the top of each end, and one at the bottom of the treble end $7\frac{3}{8}$ in. from the front. These nails are only driven in temporarily, and allowed to stand out a little way for the ends to rest on the back; rest the treble end on the back, then take the bass end and rest the nail on the wrest plank. Stoop down and look across the top of the two edges of the ends, and either raise or lower the bottom end until it is level with the edges of the treble one; then make a mark and drive a nail in temporarily. Put some handscrews on, and see that they fit close to the back; if they do so, get your toothing plane and go over the parts to be glued. Now warm the ends and have your glue hot, so that it runs nicely from the brush, but not too thin; now glue one side and put your handscrews on as quickly as possible, then glue the other side in the same manner, keeping the square tops of your ends level with the top of the piano back. Having done this, you now prepare the cheeks, two pieces of walnut 10 in. long × 7 in. wide, and the same thickness as the ends; these are dowelled on the edges of the ends, at a distance of 1 ft. 9 in. from the top of the end to the bottom edge of the cheek. Put in four dowels $\frac{3}{8}$ in. diameter and 5 in. long; glue halfway in cheeks; you can mark for holes by making a template of a piece of thin wood the width of cheek; pierce four small holes in, and mark through on the ends of your cheeks and also on the edge of your ends to correspond, so that the dowels in your cheeks will enter the holes in your ends, and you will see by diagram that the cheeks are put on the end of the key bottom in the same way, with dowels. Having glued the dowels in your cheeks and holes in the ends, put them in their place temporarily; see that they are square with the ends; now take your key bottom and place the top side of it to the bottom edges of the cheeks, with the back rail resting on the ends; now having got the cheeks upright, make a mark inside the cheeks near the ends of the key bottom at each end, then square a line across from these marks, and plane the ends of your key bottom to these lines, so that it fits between the cheeks; keep the bottom level with the bottom edge of the cheeks, and 1 in. from the top end of the cheeks; put a handscrew on each side temporarily, and then you can mark across with a small square and pencil over the bottom edge of cheeks and key bottom the position for your dowels you will require, three in each; now if you take it out and gauge a line 1 in. from the bottom edges of key bottom and cheeks, and square across from lines previously made, it will give you the exact position for holes. Glue the dowels in the key bottom, leaving them to stand out $\frac{1}{2}$ an inch; try the cheeks on, and see that everything fits; now cut a piece out of each end of the key bottom $\frac{3}{4}$ in. wide, as per sketch, from the bottom of cheeks to the back: this is to give room for the pedals to work later on. Now make the ends of your key bottom warm and glue your cheeks on; put a couple of handscrews on; now glue the ends of your cheeks and the holes in your ends, and put the dowels in their respective places, and drive down with a mallet, having a piece of hard wood on the ends of the cheeks so that you do not bruise them; you will see that the cheeks and key bottom are put together at one operation. You now make a bottom board: this is fitted in between the ends, and level with the bottom of piano back, cutting a piece out to fit over the end of bent side and plate; it is glued on the bottom of the back and at the ends, and dowels are put through the ends into it: this is made of $1\frac{1}{4}$ in. pine, 4 ft. 2 in. long × 6 in. wide.

You now make the plinth: this runs along the edge of bottom board and runs through to outside of ends; you will have to cut a piece out of your ends to allow it to do so. This is 4 ft. $3\frac{1}{2}$ in. long, 3 in. wide, and $1\frac{1}{4}$ in. in thickness. You can glue a piece of $\frac{1}{4}$-in. walnut on 1-in. pine to make up the thickness. Now make the pilasters of walnut $2\frac{1}{2}$ in. wide; these are two in number, and are fitted one end under the cheeks at each side of the case, and the other end resting on the plinth, and the edge glued inside the end. Now, for the present, you may take your case off the trestles. To make the back flat and fall, you will require two pieces of walnut $\frac{3}{4}$ in. thick, and 4 ft. $4\frac{1}{2}$ in. long; the back flat to be 3 in. wide, and the fall 8 in. wide; the edges to be planed straight, and to fit on the top of the cheeks; the ends to stand over the cheeks at each end $\frac{1}{2}$ an inch and rounded; then you will want a name board of $\frac{3}{4}$-in. walnut: this is $2\frac{1}{2}$ in. wide, and is glued on the under side of the back flat, at the front edge: it lays behind the keyboard. Now make a front flap to fall: this is $3\frac{1}{2}$ in. wide, and fits between the cheeks under the front edge of the fall, and is hinged with small butt hinges to it. You can now fit the lock front: this is $3\frac{1}{2}$ in. wide, and also fits between the cheeks, and is glued to the front edge of the key bottom after being cleaned up with glass-paper. The top is now made: it is what is known as half-top; the back half is 7 in. wide and is glued to the top of the back; the front half is also 7 in. wide; allow it to stand over $\frac{1}{2}$ an inch at the ends and front, and bevel the edges. The two halves are joined together with fancy hinges to match hinges on the fall; in fitting these, it is only necessary to screw them on temporarily, as they will need to be taken apart to polish. You can now make the top and bottom doors. These are made in frames to fit the openings: the top door from the back flat to fit under the top, while the bottom door fits from the plinth to the key bottom, and between the two pilasters. The frames are to be made of $\frac{3}{4}$-in. walnut $1\frac{1}{2}$ in. wide. Plane the edges square and cut off to the length you require to fill the openings, the long rails to go between the short ones, and a couple of dowels put through each rail. When these are glued together and dry, plane the sides smooth, and then you can get some $\frac{1}{4}$-in. walnut: this is to make the panels to cover the frames above mentioned. The panels to be planed over smooth and cleaned up with glass-paper, and the openings may be cut out; the trefoils can be bored out with a centre-bit; then these panels are glued on the frames, with pressure from small handscrews along the edges. The edges of the openings are also to be cleaned up, either left square or bevelled. Behind these openings there are four smaller panels fitted: these are made square, to cover over the trefoils, and after being polished, a design can be incised and gilded, or painted on them, and screwed on from behind. The top door is screwed to the back flat from underneath, the back flat being placed on short dowels in the cheeks, the top door being fastened with small hooks inside the ends to eyes in the back of the door. The bottom door has short dowels in the bottom edge, which fit in a couple of holes in the plinth, while the top part is held in position by two small buttons. Now you can make the trusses or brackets; you can glue two pieces of $\frac{3}{4}$-in. walnut together to make up the thickness, or buy $1\frac{1}{2}$-in. walnut; these make 20 in. long. Now make the truss toes, 6 in. long and 3 in. thick; they are dowelled on to the plinth, and stand over the end $\frac{1}{4}$ of an inch. Then you make two end plinths, 3 in. wide, $\frac{3}{4}$ of an inch thick, to butt up to the truss toe, and glued to the bottom of the end. You now make a rail, $\frac{3}{4}$ in. wide and $\frac{1}{2}$ an inch thick, and procure from a wood turner $2\frac{1}{2}$ dozen spindles 3 in. long, with a $\frac{3}{8}$-in. pin at each end; then, after putting a $\frac{1}{4}$-in. bevel on each side of the rail, bore corresponding holes in the back edge of the top and rail, and mitre the corners for the short rails. Now you can fit in your lock. Mark the centre of your lock front, then set your gauge to the pin where the key fits on, from the top edge of lock; make a slight mark on the lock front to cross the other, gauging from the top edges; now you want an escutcheon of brass; bore with a small bit in the mark you have made, and fit your escutcheon in with a $\frac{1}{4}$-in. chisel. You now fit the lock in from the top edge by boring it out, and marking it so that the pin comes to where the escutcheon is let in; glue this in, and clean off level with a file; now, having fitted the lock, you will need to fit the link plate in the front flap of your fall. Take your key, and turn the bolt up as though you had locked it; now take some of the black oil from your oilstone and place on the bolt, turn the bolt down, and close your fall; now turn the key again, as though to lock it, and it will make the mark on the fall where you are to fit the link plates. You must now clean up the whole of your case, preparatory to polishing. Have your smoothing plane set fine and sharp; also you want a steel scraper and various sizes of glass-paper from Strong 2 down to No. 1, using the strong paper first, then using the other sizes until you finish with No. 1; you want a square piece of cork to wrap your glass-paper on: these are sold at most tool shops. Any small holes may be filled up with shellac, using a hot iron or old file to melt it in the holes; minute holes may be filled by rubbing over a piece of beeswax, and then papering level. Exercise great care in cleaning up the case, as it makes a better finish when it is polished.

OUR GUIDE TO GOOD THINGS.

⁂ Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.

115.—Bellars' Improved Burglar Alarum Contact.

When burglar alarum contacts are allowed to lie idle for many weeks or perhaps months hidden in a window frame or in a door post, the bearing parts are apt to become corroded and dusty. When the contact points are thus protected by a layer of dust or corrosion, the appliance fails to act until the protecting coat has been cleaned off. Many persons have experienced the annoyance of having to press a push button in hard several times before the bell can be got to ring, and this inconvenience is often caused by a dirty contact. We cannot expect the intending burglar to be so considerate as to take all this trouble in making an alarum bell ring, so must have the contact in working order when he calls. This condition cannot always be ensured with the old style pin and spot contacts, although tipped with platinum. Hence those appliances which are furnished with rubbing contacts are preferred before others. In the Improved Burglar Alarum Contact, invented by Mr. H. W. Bellars, a rubbing contact is ensured, and the working parts of the appliance are kept by this provision in working order. From Figs. 1 and 2 below, it will be seen that the rubbing motion is ensured by fixing one carved German silver spring to an insulated ebonite block on the base of the instrument, and causing the bent end of another German silver spring to rub against the other, when the door or window to which it is affixed is opened by the prowling thief. On comparing this with the contact shown at Fig. 53, page 485, a similarity in the mode of construction will be observed, but Mr. Bellars has given a longer rubbing contact to his springs. I prefer, however, a metal marble to a fixed lug of brass on the spring, because a ball or marble by its rolling motion causes less strain, wear, and tear on the spring and on the window sash. Mr. Bellars'

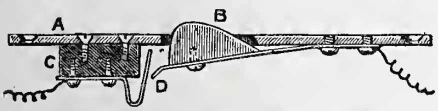

Fig. 1.—Bellars' Improved Burglar Contact in Section—A, Brass Plate; B, Brass Tongue; C, Ebonite or Hardwood Block; D, Rubbing Spring.

Fig. 2.—Ditto, in plan.

little appliance is strong and well made, and is very cheap at 12s. the dozen, the price at which they are now sold to the trade.

116.—Kristaline.

Under this name the firm of Messrs. J. & E. Hartley, Electro-platers, 13, St. Paul's Square, Birmingham, are importing and selling a colourless lacquer suitable as a protecting coat to electro-plated ornamental articles. The lacquer is made from a kind of celluloid or gun-cotton dissolved and held in some etherial solution which soon evaporates in a temperature of 90° Fahrenheit, and leaves an extremely thin but durable and almost invisible coat of protecting varnish on the article. The odour of the varnish resembles that of pine apple, or the well-known pear drops. It may be used for coating gilt or electro-brassed goods, or may be coloured if required for this purpose. The same firm also sell a cheaper article for lacquering brass. The price of kristaline is 16s. 6d. per gallon.

117.—Pool's Repoussé Worker's Album.

Repoussé workers will, I think, find a good shilling's-worth in Part 1 of the Repoussé Worker's Album, recently issued by Mr. Charles Pool, the Mechanics' Tool Depôt, 27, Hockley, Nottingham, and sent post free to any applicant for stamps to the value of 1s. 1d. The eight sheets contained in the part exhibit twenty good designs for door-plates, serviette rings, trays, crumb scoop, letter rack, pen tray, pipe rack, brush backs, photo frame, bellows plate, and stationery rack; affording an abundance of choice to those who are fond of this kind of work and may be on the look out for new patterns. Mr. Pool supplies in addition to general tools all tools and requisites for repoussé work, modelling, fretwork, wood carving, chip carving, engraving, and turning. The Editor.

SHOP:

A Corner for Those who Want to Talk It.

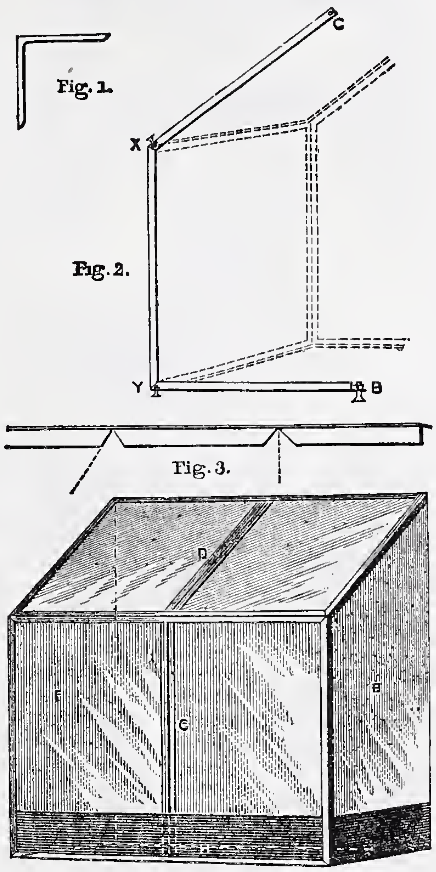
NOTICE TO CORRESPONDENTS.

*** *In consequence of the great pressure upon the "Shop" columns of* Work, *contributors are requested to be brief and concise in all future questions and replies.*

In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of Work *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

I.—Letters from Correspondents.

Window Conservatory. — Sancho (*Glasgow*) writes:—"In No. 12 of Work, instructions are given in detail how to construct portable or tenants' greenhouses, which are well adapted for houses such as villas and cottages in country and suburban districts. But what are we residents of cities to



Window Conservatory. Fig. 1. — Angle Iron. Fig. 2.—Mode of Making Framing. Fig. 3.—Mode of Cutting Angle Iron. Fig. 4.—Window Frame or Case complete.

do, should our fancy lead us to the training of plants and flowers, where every available yard of ground is built on, leaving as little space for offices, etc., as possible, for building thereon, and where the houses are built so compact internally, that little or no space for a single pot and plant, either in the way of household duties, or in a place where it would not thrive if left on the window-sill outside without any protection, to die the first sign of winter? In the sketch given, I presume every workman will understand its use as a window conservatory. My mode of construction differs from the usual way of fitting up window conservatories, which are generally framed complete and laid on brackets, or brackets fixed and built in place. When removing (as workmen in cities very often do, like birds of passage, only to suit their respective employment) — I quote my own experience — the whole framework has to be taken asunder, or lifted out bodily, and seldom without mishap, and then, perhaps, it will not suit new premises without a deal of trouble. Then it is laid aside and neglected, and our hobby for flowers has flown, and the taste for the beautiful gone. To make one portable and in seetions, procure two pieces of angle iron as in Fig. 1, $1\frac{1}{2}$ in. × $1\frac{1}{2}$ in. × $\frac{3}{16}$ in. Make two frames after the shape shown in Fig. 2, bent *vice versâ* for window sides, or instead of bending the angle iron cut inches out and bend the flat only, as in Fig. 3; after fitting exactly alike, have two pieces of angle iron to go across, as at X Y in Fig. 2. To fix frame outside window, the parts marked B must have a hole bored at end for a bolt run into stone with lead, and bound with nut on top. The parts marked C must have a hole bored at end to fix with iron rod screwed both ends, one screw longer than the other, to allow for slip into holes in stone side of window corresponding with holes in angle iron. The rod to slip through iron (angle) into stone brought back half and slipped through iron and stone opposite side, bound in place by jamb nuts or screws at ends of rods. The angle irons at X and Y must have holes in ends with holes corresponding, for fixing with small bolts and nuts. The frame complete is shown in Fig. 4. Next make the glass frames or cases. The top, D, neatly fitted in space; E and F, supporting top; G, additional support for top; H, sole, wood only, binding the three glass frames or cases on upright at bottom. For ventilation at any time when the lower sash of house window is closed, a small opening could be made in top or front glass frame to be opened and closed at will."

Spinning Wheel Mirror.—P. H. (*Allendale*) writes:—"I send a sketch, or rather photo, of a mirror which I made and have in possession for publication in Work, hoping it may be of use to some of its readers. The carvings are carved in wood $\frac{3}{8}$ in. thick, and the scrolls at the foot of pillars $\frac{1}{2}$ in. thick glued on to brown oak (the carved feet or claws are but 1 in. thick); the rim which runs round inside of wheel rim to form the rebate to hold the glass in is $\frac{1}{4}$ in. thick. The fretwork or carving on top of mirror is of stuff $\frac{1}{4}$ in. thick, and the front of stand is veneer. All the ornamental work is in black oak, or, to name it rightly, bog oak. The spinning wheel rim and rest of mirror are of old brown oak. The

Spinning Wheel Mirror.

whole in combination makes a splendid mirror, being, as I have said, of black and brown oak. I have made a variety of hanging mirrors with the rim only set with carvings, and some of a fretwork and carving pattern, of which I will enclose pattern, four of them to cover the rim. The pattern is of my own design. I think it is useless to attempt to describe it any plainer, as most people know, or at least can look at a swing mirror to see, how it is built. After you have purchased a little spinning wheel take the spokes out, and glue joints afresh if it needs it, and then commence to make your mirror, etc. The mirror stands 2 ft. 3 in. from table to top of carving, and bottom, 2 ft. to $1\frac{1}{4}$ in. from edge to edge of bottom mould."

Rubbing Down Oilstones.—C. H. M. (*Wylam*) writes:—"Under the heading of 'Means, Modes, and Methods,' in No. 31 of Work, I see W. G. shows how to prepare a board with emery to be used in rubbing down oilstones. His method seems unnecessarily long. I was taught in my apprenticeship days, twenty years ago, to use a sheet of coarse emery cloth tacked on to a board by the corners. It might be glued to the board, but, as the oilstone is always a little greasy owing to the oil sinking into the stone, the dust ground off is able to stick to the emery cloth. When the cloth is only tacked to the board, it can be taken off and be well beaten on the back. This gets rid of the dust so well that the sheet of emery cloth lasts a long time. A sheet of No. 2 or 3 is the best to use, and the hardest oilstone seems to rub off about as easily as chalk comes off on a piece of smooth wood. One would have supposed that so simple a plan would have long ago found its way among every one who used an oilstone, but as I have often come across workmen who still grind up their oilstones on a grindstone or flat sandstone, it may be worth publishing (probably for not the first time by a long way) the method of grinding by emery cloth."

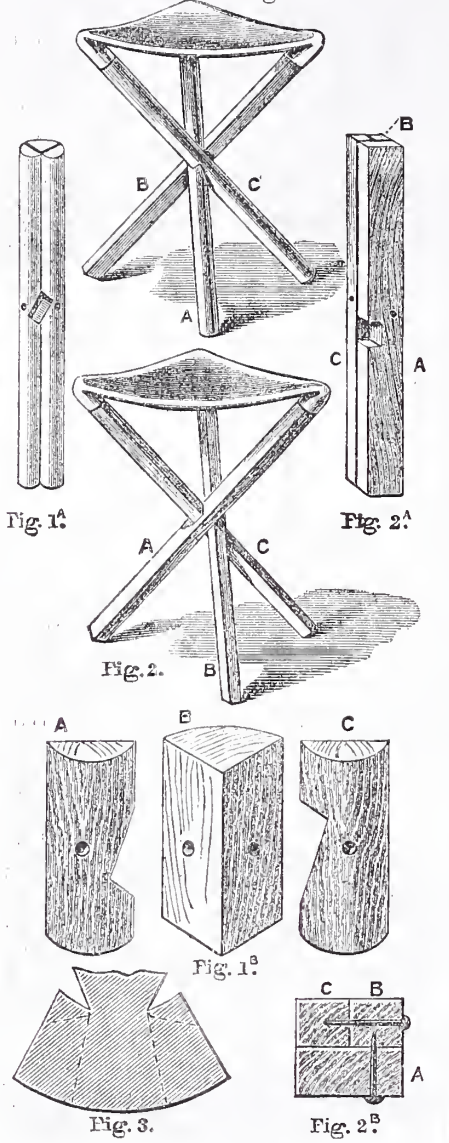
Simple Incubator.—T. T. (*Fulham*) writes in reply to W. L. (*Kingsland*) (see page 557):—"Could a thermometer be used in the incubator? If so, would it do to put it in the sand?"

Iron and Steel: Its Analysis.—A FOREMAN IN TIN WORKS writes:—"Owing to facilities afforded to the present generation for self-education, to the influence of Nonconformist ministers against drink being the one great object of life, and to the present rather high scale of wages at the Sydney Tin Works, a desire for scientific information has become established in classes where formerly the rule-of-thumb routine swamped all aspirations relating to the scientific processes in manufactures. Your above article is, it is to be hoped, only a prelude to a weekly series of similar information on such lines. May we ask for a percentage list or description of the slags resulting from modern iron and steel works, as we feel sure that if practical attention were directed to the subject that some commercial and profitable use could be brought about for the mountains of slag at present blocking up the works."

Combination Bedroom Suite.—F. C. writes:—"I am sure Mr. Scott will not be offended at T. B. R.'s suggestions—at least I hope not, as there is an old saying, 'two heads are better than one.' I, too, was so much pleased with the ingenuity of the suite that I took the first opportunity of my being in our nearest considerable provincial town to order the wood necessary for its construction, which, by the way, cost me in yellow pine £2 2s., which surprised me somewhat, as I had not thought it would take so much. As T. B. R. remarks (see page 555), I got 1¼ in. stuff for the frames, and here perhaps I may be permitted to remark that I am sure it would be a great convenience to the not very experienced amateur cabinet maker if a summary of the total amount of wood required were given at the end of the article. I would myself have done something by way of a start on this cabinet or wardrobe sooner, had I been able, without trouble, to say to the merchant what I exactly wanted. More experienced hands may be able to say at once what is needed for such a piece of work. Others who are beside the wood store can order it just as they want, but it is a different matter when you are at least sixty miles, as military men would say, from your basis. Though Mr. Scott expressly says he does not go into the construction, and his description of his excellent design is very full, there are undoubtedly several points which are not cleared up by the drawings, and, though I am by no means a tyro in such work, I fail to see how they are to be carried out. I have not the drawing before me now, so can from memory only speak of one point. The short drawer front on left in bottom compartment is drawn as a framed front. This for a drawer is, I think, a very unusual mode of construction, for unless the framing is mock—*i.e.*, merely slips pegged or glued on to front—the drawer sides cannot be dovetailed to the front, as they ought to be. What T. B. R. says of the looking-glass had struck me too. Also the risk, in case the spring catch for holding it up should at any time fail, of the glass falling down and being broken. I think the basin placed in a drawer, as suggested, would perhaps on the whole be the more convenient arrangement. Its jug might be placed sitting in it in the usual way, or else put in the central compartment right over the basin when closed in. Another point now occurs to me. I think Mr. Scott speaks of the drawer fronts as if they were to be flush with the case. In the drawing the edges seem as if bevelled off, so as to make the front project at least ⅛ in. or ¼ in. beyond the case. Is this so? I hope Mr. Scott will consider the suggestions given, and point out anything he may see against them before any of us commence work. I have often found that many would-be improvers, when they see anything they like, say, 'Oh, it would be a great deal better if it were so.' Whereas that very point with many another has been before the inventor's mind, and he has deliberately rejected it for some good reason. Now, while I do not see any objection to most of the suggestions of T. B. R., it may be the inventor does, and therefore we would be glad to have his views before us. Though I am struck with the ingenuity of the device for making the large panel serve as washhand table, I think it is attended with such disadvantages as make the drawer arrangement for basin much preferable—*e.g.*, unless you leave your clothes in the press open all day to dust. Whenever you wish to wash your hands, you have to open the door, let the panel down, arrange basin, etc., and then when done put all up again. This is a good deal to be done each time; besides, the panel is sure to be wet, and will shortly become discoloured and shabby if so used. If shut up wet or even damp, it is not good for whatever may be in the press. Instead of saying all stuff of ⅛ in. and styles of 1 in. or 1¼ in., would it not be well to say drawer fronts to be at least ⅞ in. or ⅝ in. in rough, division frames between large drawers to be 1 in? Half inch here would look skimpy. I question, too, whether ½ in. for vertical division of compartments will not look equally skimpy."

II.—QUESTIONS ANSWERED BY EDITOR AND STAFF.

Camp Stools.—A. S. S. (*Cheshire*).—In answer to your query, I have attempted to describe two forms of camp stools. In both diagrams you will observe that I have only given three-legged articles, as I see that the four-legged ones are patented. I do not think you would be infringing any patent rights by making one for your own use (although my knowledge concerning the patent law is not very extensive), but I consider that, by publishing sketches and description of making it here, I should be acting far from right towards the patentee. Your letter induced me to try to make a model of a four-legged stool, shutting up into one length, but having a different joint; and if you do not care for either of the two here shown, I would be willing, when it is finished, to send you a rough sketch of it, through the Editor, although I see no reason to



Camp Stools.

object against either of these two. The section of the three legs of Fig. 1 is shown in Fig. 1A. The sides of B have to be cut at the angle shown (Fig. 1B), and thus it will be seen that when A and C are turned on their pivots, if they are exactly cut, they will cross one another at their joint. The seat will help to strengthen them. You will find it rather difficult to cut the notches exactly in this stool, but with Fig. 2 you will experience less trouble, and I think a stronger job can be made after this pattern. Two of the legs in Fig. 2 will be square in thickness, the other one being the same width as these two together, and the same thickness (Fig. 2B). A is riveted to B, and B to C. In this stool each leg will be exactly at right angles to the leg it crosses. A piece is cut out of A to receive C. In opening this stool, A is turned from left to right, and C is turned forward at the top. The way to fasten these three legs will be to cross B and C, and run a pivot through them, and then place A across B, so that its thickness is under C; you will then see where you will have to cut the piece out, and fasten A to B. The top of A can have a piece cut off one side, so as not to make the corner of the seat any wider than the others. The rails may be rounded on the sides, and so make them collectively circular in section, but if this is done, it will be necessary to cut a different shaped notch in A. The corners of the material to form the seat might be cut after the manner I have shown in Fig. 3. The piece is bent round and sewn through the two long dotted lines, the two corners above the other dotted lines being sewn to the underpart of the material. The seat can be carried separately, but it will be best to tack it to the legs.—J. S.

Polishing Chairs.—J. F. (*Manchester*).—Pleased to hear you have found WORK so useful. You do not say what wood the chairs you wish to stain and varnish are made of, but I suppose they are light-coloured, and "in the white." By "stained varnish" I assume that you want a coloured varnish, by which you can darken the things to walnut colour at one operation. This may be done, but it is not so satisfactory as staining and varnishing separately, for the simple reason that if the coloured varnish chips off, the wood under it shows its original colour. When the wood is previously stained this does not happen. However, if you wish a combined stain and varnish, or rather to use a varnish which will colour your chairs in imitation of walnut, all you have to do is to colour the varnish accordingly. You may do so by mixing a little gas black and Bismarck brown with the varnish, and straining through muslin previous to use. By altering the proportions of the black and brown you may get any shade of walnut. Use spirit varnish.—D. A.

Tools.—W. H. R. (*St. Peter's Park*).—Without knowing something more than I do about the class of work you intend to undertake, I cannot give you a list of tools which would be certain to cover all your wants, but for general light joinery or cabinet making, you will find the following ample:—Some you might do without—for example, the jack plane could be dispensed with, if your wood is bought ready planed; but if you get all the following you will have a very good kit with which you can manage almost anything you are likely to want as a beginner. Of course if you want to go in for carving, turning and shaping, or fretting, you would have to extend the list greatly—Jack plane, trying plane, smoothing plane, rabbet plane, hand saw, tenon saw, dovetail saw, chisels from ⅛ in. to 1 in., brace and bits, gimlets, bradawls, screwdrivers, scraper, cork rubber for glasspaper, hand screws, oilstone, hammer, mallet, square, cutting and marking gauges, etc. Lots of other things will come in useful as your skill increases, but you can add them as required. I am afraid this may be too late to be of much service to you.—D. A.

Veneering.—C. T. C. (*Brockley*).—The remarks to which you take objection are quite correct, and no mistake has been made by the writer. The heart side is the proper one on which to lay the veneer. It is also the side which tends to become convex, although you say that it would "surely be the other side, and that the formation of the wood is against the heart side becoming convex." Well, facts are stubborn things, and, however you have arrived at the decision you have, it will not alter them. I am afraid you have never tried practically to see whether your assertion is correct, for if you had you would never have made such a rash statement. Suppose you were to try the experiment of veneering one piece of a board on the heart side, and another piece on the other, and watch the result. The way the board bends is not a matter of opinion, but of fact, so that a test as proposed would be more convincing and intelligible to your comprehension than anything else. I quite agree with you that it is an important matter, but you know theory can't stand against practical experience, and I always advise amateurs and novices to try for themselves, if they think practical men wrong in their methods. As a rule, the practical artisan knows more of his own trade than any other people, and in the absence of very strong proof to the contrary, the assumption fairly must be that he is not altogether wrong, as you would imply he is in this instance. It would serve no good purpose to explain at present how the board goes as it does.—D. D.

White Acid for Glass Embossing.—NARPY (*Sheffield*).—The "white acid" mentioned by you is probably hydrofluoric acid, composed of hydrogen and fluorine in their combining proportions—namely, 19 parts of fluorine to 1 part of hydrogen. It is obtained by dissolving fluorspar in sulphuric acid, and condensing the acid fumes in water. It may be got through any chemist and druggist, in gutta-percha bottles. The acid is dangerously corrosive, and will cause painful wounds if allowed to touch the skin. It will dissolve glass, or any other substance containing silicon, as china and earthenware, by the action of the fluorine on the silicon in the glass, hence it must be kept in gutta-percha bottles, on which it has no action.—G. E. B.

Future Subjects.—W. F. R. (*Plymouth*).—Thanks for suggested subjects. Effect shall be given to your suggestions in Vol. II. of WORK.—ED.

Restoring Writing Desk.—A. B. (*London*).—I suppose it is only the polish of your desk which has been scorched, and that the wood itself is uninjured. If this is the case, all you have to do is to scrape or clean up with glass paper, and repolish. If the wood is injured it will be a more serious matter, and I must have further particulars before I can help you. If you want further advice from us say, if you can tell it, the kind of wood, and especially say whether it is veneered or solid. Give any details you may think important, for in this, as in many other cases, the more particulars we have the better, if an answer is to help you as much as it might. Do not be afraid of giving too many particulars, thinking they will be of no use. Possibly they will not all be useful, but those that are not so will be skipped, so do not think you cause us any trouble by writing too explicitly.—D. A.

Picture Frame.—Wun Mare.—You ask how you can decorate the top of a picture frame, of which you send a paper cutting. Now, how can I possibly tell you anything that is likely to be of the slightest assistance to you without knowing more than I do about your capabilities? For instance, if you can carve I should suggest that by carving you might vastly improve the appearance of the top, although so far as I can judge from the paper it is hardly worth while wasting much time on a thing which is fundamentally poor. As this, however, is a good deal a matter of opinion you may be inclined to lavish work on it, and I should certainly recommend carving. If you are unable to do this you might put pieces of silk plush at the back of the holes—or even pieces of a different kind of wood You do not tell me what wood the top of your frame is made of, nor the thickness, nor whether it is simply as an overlaid veneer that you have availed yourself of the piece as per paper. I might go on conjecturing for ever what would do for your purpose, and still fail to hit the point. It is really a pity that so many inquirers frustrate efforts to help them by withholding details which might be easily supplied.—D. D.

Polishing Music Cabinet.—W. H. C. (*South Norwood*).—Your music cabinet must, indeed, be an elaborately carved and moulded affair if you cannot get it polished for less than a sovereign, and I am inclined to think there has been a mistake somewhere. The figure is a ridiculous one for such a piece of furniture as a music cabinet; but are you sure that this is what a cabinet maker would call your contrivance? Is it not rather what he would call a cabinet—without the music—and consequently a much larger affair than ordinarily known as a music cabinet? If you wish to try the finishing yourself in the way you suggest, you cannet do better than use a mixture of whiting and turpentine, with rose pink for colouring. For varnish which "you could put on with a brush that would look better than ordinary varnish," all I can say is that much depends on what you call ordinary varnish. A spirit varnish is what you should use, but this is the ordinary varnish for such work. Of course you must not expect the same degree of finish as if your cabinet were to be properly French polished.—D. A.

Loadstone. — A. B. D. (*Whitburn*). — Natural loadstone (more properly lodestone) consists of a combination of the protoxide and peroxide of iron. It is found in considerable masses in iron mines in Scandinavia, Germany, Italy, Spain, China, and elsewhere. To procure it A. B. D. will probably have to go to some dealer in mineralogical specimens. Mr. W. Cutters (naturalists' agent), 35, Great Russell Street, Bloomsbury, London, W.C., would be able to supply him. He will get a serviceable lump for about 3s. Unless we are mistaken magnets are more commonly made at the present day by subjecting soft iron to a strong current of electricity.—M. M.

Bichromate of Potash v. Chromic Salt.—T. F. (*Manchester Square*).—Chromic salt or chromic acid in a battery gives more lasting strength to the battery than bichrome of potash.—G. E. B.

Reclining Chair.—Cabinet Maker (*Rawtenstall*).—The copper rivets you inquire about can be had from Stanton Bros., 73, Shoe Lane, E.C., or Faithfull, Boro', S.E. The cost is about 10d. to 1s. per lb. Both these firms are in London. I do not know of any place nearer your home where you can purchase rivets, but why not use iron instead; you can then have them made cheaply by your local blacksmith, or, if at all handy with tools, can easily make them yourself from a piece of iron rod, purchasing the necessary washers at the ironmongers. This would save you trouble, and economise postage or carriage.—G. le B.

Practical Electricity.—S. G. (*Norwich*).—An authoritative book on this subject is Ayrton's "Practical Electricity," 7s. 6d., Cassell & Co.—F. J. C.

Copying Press Makers. — Pickwick. — The following are good makers:—Hughes & Kimber, West Harding Street, London; Mordan & Co., 7, Cheapside, London. A book on engines and boiler construction is Wilson's "Treatise on Steam Boilers" (6s.), Lockwood & Co.—F. J. C.

Small Sideboard with Drawers and Cupboards.—Peahen.— You send a proper string of questions to be answered. Several of them need scarcely have been asked, as they are answered in the text accompanying the designs. But you want apparently to thoroughly understand what you are going to make, and some doubts are troubling you which you want set at rest. This very laudable ambition on your part I shall endeavour to assist you in attaining. First then, I presume you find a difficulty in carrying the moulding shown on the raking part of the pediment along the ends. After clamping the moulding on the pediment, and finishing it as seen in the front view, you must place a piece of wood behind the pediment to work the moulding on till it reaches the backmost part of the cornice moulding. This piece of moulding that is put on behind the pediment need not follow the rake of the pediment—it may be quite flat on its top edge (see Fig. 1). (2) The upper part consists of one frame with 6 panels in it—3 below the shelf and 3 above—on the top of which rests the canopy, and against which the shelf is screwed. The cornice, therefore, and the shelf and brackets are all screwed to this back frame, and are held together by that means. The two side parts of this large frame are dowelled, or pinned to the centre glass frame. (3) The panel under centre glass has a planted moulding round it of same section as that round glass. (4) The upper portion is secured to the lower portion by means of screws from below the top entering the bottom rail of upper part, and by the pins turned on the lower ends of the pillars. These pins should fit tightly into the holes bored for them in the top. Dowels should also be put into bottom edge of brackets to fit into top in same manner. (5) If the fillet shown behind moulding under top (Fig. 11) be the one you refer to, it is required to make the drawer work properly, and it is screwed at front and back to the gable. (6) The division between two top drawers is the same width and thickness as the drawer fore edges, and

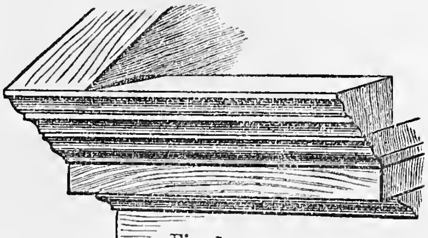


Fig. 1.

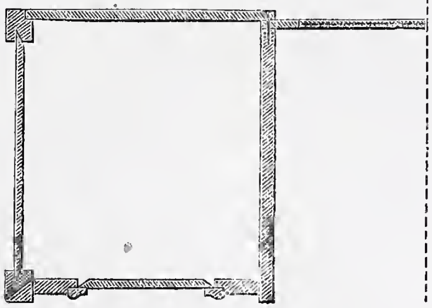

Fig. 2.

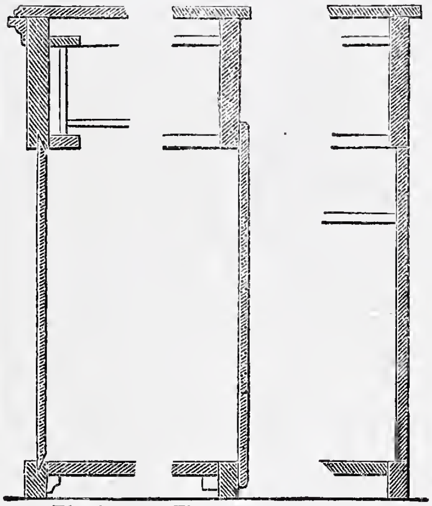

Fig. 3. Fig. 4. Fig. 5.

Small Sideboard with Drawers and Cupboards.

has two beads scratched on its face. It is mortised between the two fore edges. (7) The fore edge of centre drawer is mortised into the inner gables (8) which are ¾ in. thick. (9) The inner gables are fastened between bottom rail and fore edge by means of a pin or dowel. A fielded panel is one which has a broad shallow chamfer or bevel worked on its edges. Sometimes the fielded side is placed to the front and sometimes to the back. (10) The grain of bottom should run in the same direction as the top. It should be secured to end gable rails by means of dowels. There is not much fear of bottom splitting when it is blocked, if the wood is dry when you use it. (11) The shaded portion (in Fig. 12) under bottom rail refers, of course, to the little brackets underneath it. (12) The mouldings, shown in Fig. 2, in line with drawer fore edge consist of two beads scratched on top rail of gable, near its bottom edge. This top rail is broad enough to receive the drawer bearers on inside, so that it, therefore, appears in a line with the fore edge of drawer. A half-plan, showing horizontal sections of gables and carcase backs, etc., is given in Fig. 2, while an upright section of outer gable is given in Fig. 3, of carcase back behind cupboards in Fig. 4, and the same behind recess in Fig. 5. The inner gables being plain—not framed—an upright section is unnecessary.—A. M.

Silver Plating.—T. F. (*Manchester Square*).—When silver comes off from an article during the finishing process of scratch-brushing or burnishing, it shows either—(1) That the plating solution is not properly made up; (2) that the article was not properly prepared for plating; (3), or that the silver has been forced on too fast. The first fault you have certainly fallen into. You must not add the cyanide to the nitric acid solution of silver, as this will give you nitrate of potash in your plating solution, and thus cause the silver to go on in a loose condition. After dissolving the silver in nitric acid, diluted with one-fifth its bulk of distilled water, continue to heat the acid solution of silver until all the free acid has been driven off in the form of steam, and only a waxy paste remains. This paste will be nitrate of silver, and will form a solid lump when cool. Dissolve this in distilled water, and add to the nitrate of silver solution a solution of cyanide of potassium, a little at a time, stirring frequently with a glass rod, until the cyanide solution ceases to throw down white clots of silver cyanide. Allow it to rest for a few minutes, then pour away all the liquid from the silver cyanide precipitate, and pour in some clean water on the precipitate. Allow this to rest for a few minutes, then pour it off again. This is the way to wash the silver cyanide, and should be repeated two or three times to wash away all traces of nitrate of potash. When this is done, dissolve the silver cyanide in a solution of cyanide of potassium to form the plating solution. Note the weight of potassium cyanide used to completely dissolve the silver cyanide, and add one-fifth more to form free cyanide. Make up the solution with distilled water to contain at least 1 ounce of silver in each gallon of solution. The person whose instructions you followed, omitted those important details. Secondly, it is not enough to brush the article clean. By treating them thus, you have only made them mechanically clean, whereas they must be chemically clean to insure a perfect adherence of the silver coating. All mechanical cleaning still leaves on the article some particles of dust, or of loosened metal, and these must be dissolved off in a pickle before the article is placed in the bath. Dip them first in old nitric acid diluted with water, then in the cyanide dip, as you propose, before placing them in the plating bath. (See also my article on Brass for an account of pickles.) If they are to be burnished, they should also be quicked in a dilute solution of nitrate of mercury (½ oz. in 1 gallon of distilled water) before being put in the plating vat. Thirdly, if you use too much battery power and force on the silver too fast, it will strip off whilst being burnished. The current from one or two small Daniell cells, or Smee cells, in series, will be quite strong enough for your purpose. Let the silver anode exposed in the plating vat present the same surface as that of the article to be plated. I shall be pleased to advise you at any time.—G. E. B.

Acorn and Cone Work.—F. H. (*Darlington*).—For the work to which F. H. refers many objects which may be collected in country rambles will be found useful—all the many kinds of fir cones, acorns from the different species of oak, the beech-nut with its husk, grotesque and knotted twigs, etc. It is well to have plenty to select from before beginning work. These objects can be dried by putting them in an oven that is not too hot. Acorns will need to be taken from their cups and glued in again. For picture-frames, brackets, etc., the framework is best made of pine wood, which can be stained with umber to an oak colour. The smaller objects are merely glued on, the larger are secured either with small brass pins, the projecting ends of which are cut off with nippers, or with needle-points (which are sold by the pound for such purposes) the projecting ends of which are readily broken off. Another way is by breaking up large fir cones and gluing their scales over the entire surface of the wood so as to form a complete ground, and on this fixing the larger objects. In any case the whole, when finished, has to be varnished. Any good copal varnish will do, and by grinding burnt umber in it the work can be brought to the colour of old oak if desired. A camel-hair brush is used for putting on the varnish, and two thin coats are better than one thick one. While drying, the varnish must be kept from dust. Another method of utilising acorns is by piercing them from end to end, through cup and all, with a large needle (which must of course be done whilst they are yet soft), and threading them on wire. By a combination of such wires of acorns, baskets in which to suspend pots of ferns or flowers, and other half rustic matters, may be formed. These also need varnishing.—M. M.

Power of Daniell Battery.—Lineman.—If the cell in which the zinc element is placed is charged with a solution of zinc sulphate, and the cell in which the copper plate is placed is charged with a concentrated solution of copper sulphate maintained in this condition by a reservoir of copper sulphate crystals, the E.M.F. of each pair will be at starting about 1 volt, and this will probably work up to 1·07 volts, when the copper plate has been coated with electro-deposited copper. The E.M.F. of the 12-celled battery will, therefore, be 12 volts at starting, working up to 12·84 volts in the course of half an hour. The internal resistance of a Daniell battery varies considerably, and as the volume of current expressed in ampères depends upon the internal resistance of the cells, one cannot say exactly what the output of yours may be, apart from actual measurement. It is, probably, something between a quarter and a half ampère for the whole battery but not more. If copper is allowed to deposit on the porous partitions, the current will fail, not only on account of a higher internal resistance, but also because this short circuits the cells. To prevent this, keep the zinc, and also the zinc mud, from touching the porous partitions.—G. E. B.

Electro-deposition of Copper.—A. J. (*Manchester.*—(1) I do not know of a book devoted entirely to information respecting copper. "British Manufacturing Industries," Vol. IV., has an article devoted to Copper. In Bloxam's text book on metals, you will find an article on this subject. There are also some valuable lessons on copper working in Cassell's "Technical Educator." The electro-deposition of copper is fully treated in "Electro-deposition," by A. Watt, a book frequently mentioned in WORK. (2) It is possible to deposit a thin film of copper on both sides of a sheet of blotting-paper; but I do not know of any method apart from that of electro-deposition. Why do you object to this method? (3) There is no liquid which will soften a sheet of copper, either with or without dissolving it. A sheet of copper can be thoroughly softened by heating it to a dull red heat. (4) Copper will dissolve in sulphuric acid, and form copper sulphate; also in nitric acid, forming copper nitrate. (5) If you ask for annealed sheet copper you will get it soft; but if you want the softest copper obtainable, you will have to get pure sheet copper well annealed.—G. E. B.

Change Wheels.—E. G. (*Wolverhampton*).—Though your query was worded "chain" wheels, I perceive that you must have meant change wheels, and can picture your pleasure in coming upon the articles on page 438 of WORK, so clearly explaining how these are arranged. I hope you will thoroughly master that explanation. A very simple way to pick out the right wheels for the more ordinary threads is to put on the mandrel a wheel having ten times the number of teeth as there are threads per inch in the lead screw (in your case it would be twenty), then, on the lead screw, ten times the number of teeth as there are to be threads per inch in the screw you wish to cut. Thus, if you have two threads per inch in your lead screw, put twenty teeth on the mandrel; then if you want to cut six threads, put sixty on the lead screw; if ten, put 100 on the screw, etc.—F. A. M.

Screw-Cutting and Boring: Screw-Bore.—(*Warbleton*).—It weakens a screw such as the mandrel nose to cut a groove for the tool to run out into. You can avoid this either by drilling a little hole at the end of the thread, or by putting the left hand on the pulley of the mandrel to control its revolution at the end of the thread, and then gradually withdrawing the tool with the right hand by means of the feed screw. Of course this requires a little dexterity. The long hole in the casting of a poppet head must be very accurate indeed, and if you cannot use a bar to bore the heads in position on the bed, I should finish that hole with a parallel rhymer; a rose drill should do about as well if you leave very little for the last one to take off. I should use a ¾-in. boring bar in your case, turning up the cutter with the bar so as to ensure its cutting equally at each end.—F. A. M.

Picking Locks.—E. G. B. (*Rochester*).—Ordinary lever locks can be picked in the manner described in No. 26—*i.e.*, by raising the levers carefully one by one, and keeping sufficient pressure on the bolt to retain them in their position. This can be done with an instrument such as described, or with two small picks. It is, however, a tedious job, and it is usually much quicker to force the lock and repair it afterwards. Locks which have patented improvements, such as movable stumps, wedge, bolts, etc., etc., in addition to levers, are practically unpickable. The same may be said of a Bramah lock if it is in good condition, but the wards of this lock frequently get worn, and when this is the case they can generally be opened either with a blank or a goose quill. The ordinary letter padlocks are only made to open at one ward, so if you take down the letters off each drum, and put them on paper, you can see at a glance the different words the letters will make, and can try them in rotation. These can be bought for less than two shillings, so it does not pay to spend much time in trying to discover the ward, and the quickest way is to file the shackle off. The interchangeable ones, however, can only be opened by chance unless you know the combination. Letter locks are used extensively in America, but are not much in favour in this country, owing to the risk of forgetting the combination, being overlooked while setting the lock, or having it extorted by personal violence.—T. W.

IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Œolian Harp.—S. M. (*Gloucester*) writes in reply to G. L. G. (see page 476):—"I happen to have two recipes by me for the same, which I will submit for your perusal, and use if you think fit, though I can say nothing about the practical part of them. To construct an æolian harp, a box should be made of very thin cedar, pine, or other soft wood. It should be of a length exactly answering to the window in which it is intended to be placed, 4 or 5 inches in depth, and 5 or 6 inches in width. Glue on it, at the extremities of the top, two pieces of wainscot, about ½ an inch high and ¼ of an inch thick, to serve as bridges for the strings, and inside at each end glue two pieces of beech about an inch square, and of equal length to the width of the box, which is to hold the pegs. Into one of these bridges fix as many pegs (such as are used in a pianoforte, though not so large) as there are to be strings, and into the other fasten as many brass pins, to which attach one end of the strings. Then string the instrument with small catgut or first fiddle strings, fixing one end of them, and twisting the other round the opposite peg. These strings, which should not be drawn tight, must be tuned in unison. To procure the proper passage of the wind, a thin board, supported by four pegs, is placed over the strings at about 3 inches distance from the sounding-board. The instrument must be exposed to wind at a window partly open, and to increase the force of the current of air, either the door of the room, or any opposite window, should be opened. When the wind blows, the strings begin to sound in unison, but as the force of the current increases, the sound changes into a pleasing admixture of all the eight notes of the diatonic scale. An æolian harp is constructed after this manner: an oblong box of thin deal boards, about 5 or 6 inches deep, with a circle drawn in the middle of the upper side an inch and a half in diameter, around which are to be drilled small holes. Along the upper side of the box seven, ten, or more small strings of very fine gut are stretched over bridges near each end, like the bridges of a violin, and tightened or relaxed with screw pins. The strings must be tuned to one and the same note, and the instrument placed in some current of air where the wind can pass over its strings with freedom. A window which is exactly equal to the length of the harp, with the sash first raised to give the air admission, is a good situation. When the wind blows upon the strings, with various degrees of force different musical tones will be sounded. If G. L. G. adopts either of these methods, I should very much like to know the amount of success he meets with."

Battlesden Cart.—AN AMATEUR (*Paris*) writes in reply to W. W. W. (see page 414), who says "'he is astounded at some things said in reference to making a Battlesden Cart.' That feeling will subside as his intelligence expands. He says he is an improver. The few words I have to say will be of service to him, as he is obviously anxious for improvement, and desires it in a branch of his trade closely allied to the branches he is waiting to have explained in WORK. But first, to thank you for your courtesy in allowing adverse remarks to appear in your most useful columns, which, amongst other features of worth, enable workmen to express their views with unabridged freedom. This latitude will, I trust, teach the amenities of correspondence, and may be the starting-point of descriptive excellence, too often lacking in workmen's writing, which should make us bear and forbear, if some trivial mistakes in terms or omission of a word occurs to mar the completeness of good intentions in writing for others' guidance more than for their own gain. I know nothing of the writer of the article on 'Battlesden Cart Making,' so that I can say the few improving words to W. W. W. which, upon reflection, he will appreciate. First, as to it being written by a clerk—if so, it is to his credit. One of the leading writers on coachmaking, holder of prizes and certificates from the Coachmakers' Company and International and other Exhibitions for reports and improvements in carriages, was a workman like W. W. W., and was offered the position of clerk and manager at greatly increased wages. This did not detract from his competence to write on coachmaking, which is appreciated even in America, by the fact of seven different journals copying one of his articles as soon as it was seen in the States, and he is now supplying matter from the French Exposition for thirty journals, English and American, which are extensively copied into other journals. But to the part of my letter which I write specially for W. W. W.'s improvement. The writer on 'Battlesden Carts' spoke of shafts of American elm, which is different to the elm which seems to have come under his notice. It is extensively used for shafts in America, France, and, to a large extent, in England for cheap carts like those referred to. American elm is used for the sides, in alternate strips about four inches wide. Birch is used, but if the writer omitted that word, he would of course admit it, as W. W. W. must admit his quotation omitted the word 'American.' But it is to be of service in instructing the writer, and those who he said he asked about elm shafts, that I mainly write to inform him that there are about fifty-four varieties of elm, most of which grow in England, one extensively, which deserves the attention of W. W. W. It is the wych-elm, a straight-grained, tough, pale yellow wood, often with a small heart of dark brown colour. It bears the male and female blossoms on the same tree, and it is supposed the brown heart is due to the accidental impregnation of the female seed by the male seed of the brown or common elm. As this brown is not quite so tough as the yellow wood in some parts of England, the wych-elm is used for plough-beams, waggon and cart shafts, or parts where toughness or strength is essential. If cultivated with the same attention to pruning for straight growth as ash, it would be a useful wood for coachmakers, as it is now for wheelwrights in the country for waggon and cart work. It is a little dearer than the brown or common elm."

Simple Incubator.—NOVICE (*Johnstone*) writes in reply to W. L. (*Kingsland*) (see page 557):—"I find a very useful article under 'Simple Incubator,' which I mean to try. What kind of lamp would you advise, and how long will it burn? Is there nothing about regulating the heat, and has same to be kept constantly applied to it?"

Trade Notes and Memoranda.

THE following, as a flexible paint, is said to retain sufficient flexibility to enable a sheet coated with it to be rolled:—Soft soap, 2 oz.; boiling water, 12 oz. Dissolve and work well into usual oil paint.

COMMENTING on the cost of City improvements, the *City Press* says: "The widening of Ludgate Hill has covered a period of nearly twenty years, and is now almost completed. The houses set back are all on the southern side. The first lot, including the houses from 51 to 71, Ludgate-hill, cost the Commissioners of Sewers £85,405. A few years later another block was taken—19 to 35—at a cost of £43,825. The houses, 11 to 17, necessitated an outlay of £63,268, and the last operation, including 37 to 47, and 5, St. Martin's Court, cost £131,828. This makes a total expenditure up to the present time of £324,326; but there will be a considerable recoupment in connection with the last item.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

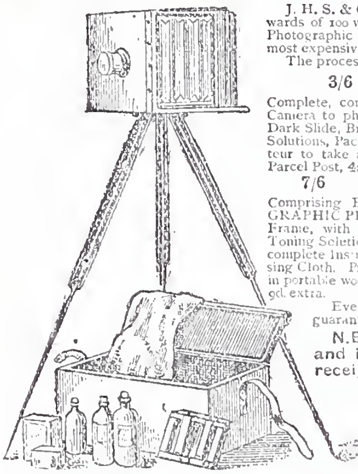
BRITANNIA CO.,

100, HOUNDSDITCH, LONDON.

ALL LETTERS—BRITANNIA CO., COLCHESTER.

J. H. SKINNER & CO., EAST DEREHAM, NORFOLK,

Manufacturers and Importers of Photographic Apparatus and Fretwork Materials.



J. H. S. & CO. have now a large Factory with accommodation for upwards of 100 workmen, which is used exclusively for the manufacture of Photographic Apparatus of every description, from the cheapest to the most expensive.

The process is simplicity itself. Full Instructions supplied with each set.

3/6 The Eclipse Camera Set. 3/6

Complete, consisting of a Polished Mahogany Sliding Bellows, ¼-plate Camera to photograph full-size carte-de-visites, with Focussing Screen, Dark Slide, Brass-mounted Lens, Brass Fittings, Developing and Fixing Solutions, Packet of Dry Plates, and full Instructions, enabling any amateur to take a good Photograph. Price 3s. 6d., or securely packed by Parcel Post, 4s.

7/6 Complete Photographic Outfit. 7/6

Comprising ECLIPSE CAMERA SET, as above; also PHOTOGRAPHIC PRINTING APPARATUS, consisting of Hardwood Printing Frame, with Brass Spring Back, Sensitised Albuminised Paper, Gold Toning Solution, Fixing Solution, Glass Rods, Cards for Mounting, with complete Instructions. Also Hardwood Folding Tripod Stand and Focussing Cloth. Price 7s. 6d. Securely packed, post free, 8s. 6d. If packed in portable wood case, with hinged lid and leather strap, as in illustration, 9d. extra.

Every Set is carefully examined before being sent out, and guaranteed to be in working order.

N.B.—If Apparatus does not give satisfaction, and is returned uninjured within three days of receipt, we guarantee to refund purchase money.

Better Sets, 10s. 6d., 21s., 42s., 100s., and upwards. Complete Catalogue of Photographic Apparatus, one stamp. J. H. SKINNER & CO., EAST DEREHAM, NORFOLK.

Wholesale Agent for London—J. MOTHERSILL, 60, Holloway Road, N., and 6, Southampton Row, where Samples may be seen.

Timber Yards, Sawing and Planing Mills covering about Two Acres near Railway Station.

J. H. S. & CO. keep regularly in stock about **120,000 FEET OF FRETWOOD,** solid and 3-ply, veneers, &c., besides a very large quantity of Logs, Planks, and Boards, Carving and Turning Wood, &c., and **200,000 FULL-SIZE DESIGNS for Fretwork, Wood Carving, &c.,** besides an immense Stock of Joiners' Tool Chests, Fretwork Outfits, Drills, Saw Frames, Hand and Treadle Machines, Saw Blades, &c. &c.

Specialities for 1888 & 1889.—Books of New Designs. FRETWORK No. 1, containing 12 Large Sheets, price 1s. No. 2, containing 20 Sheets of larger and more elaborate Patterns, 2s. 6d. Book of Wood Carving Designs, containing 14 Patterns, price 1s. ; these are all New Patterns, not sold in any other form, and would, if sold separately, cost three or four times the amount charged. Fretworker's Handbook and Workshop Guide, price 1s. New Designs. All Patterns greatly reduced in price.

Complete Fretwork Outfit, comprising 12-inch Steel Frame, 48 Saws, Awl, File, 4 Designs (with sufficient planed Wood, gratis), and 1s. Handbook on Fretwork, price 3s. 6d., carriage paid. 12 feet Assorted Planed Fretwood, 3s. 6d.

☞ Special Fretwork Design, in commemoration of Her Majesty's Jubilee, size, 36 in. by 26 in., price 2s. 6d.

Catalogue of Machines, Designs, Wood, Tools, &c., with several Hundred Illustrations, and full Instructions for Fret-cutting, Polishing, and Varnishing, price 4d., post free. Good Fret Saws, 1s. 6d. per gross; best ditto, 2s. per gross.

Eclipse Design, No. 102.

Wall Bracket. Price 5d.

"A great want is supplied in 'Science for All.'"—GRAPHIC. NEW SERIAL ISSUE in Monthly Parts, price 7d., of

Science for All. A Popular Treatise in which the Wonders of Science are made interesting and intelligible to all. With about *1,500 Illustrations* and *Diagrams.* PART 1 *ready* January 27, 1890, *price* 7d.

*** *With* PART 1 *will be issued as a Frontispiece a valuable* COLOURED PLATE, *showing the Order of Succession of the various Rocks that compose the Crust of the Earth.*

*** Prospectuses at all Booksellers', or post free from CASSELL & COMPANY, LIMITED, *Ludgate Hill, London.*

TOOLS.

WRITE FOR PRICES OF WHAT YOU WANT.

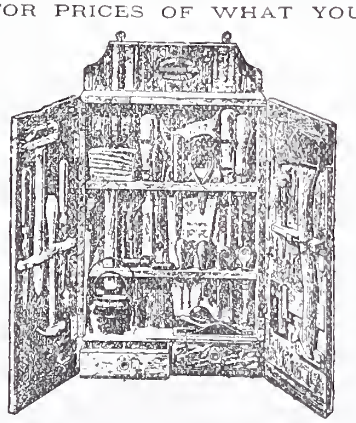
OBSERVE THE FOLLOWING

GENTLEMAN'S *Registered* TOOL CABINET,

PRICE

£2 2s. each.

Size, 21 in. high by 14 in. wide, made of Polished Oak, with Two Drawers, and with Lock and Key, and with two Loops to fasten it to a wall.



The above is a strong, well-made Cabinet of polished Oak, and every tool is full size, serviceable, and warranted. The contents comprise such tools as are usually required for repairs, &c., in a household, and the investment of its small cost will soon be saved by the work done with them.

IT CONTAINS TOOLS AS FOLLOWS:—

Mallet,
Chisel,
Gouge,
Axe,
Two Hammers,
Saw,
Three Files,
Two Turnscrews
Square,
Claw Wrench,
Pliers,

A COMBINED HAT AND UMBRELLA STAND AND HALL-SEAT.

BY JAMES SCOTT.

It is supposed by some that, with regard to the building and furnishing of houses, our ancestors were much better off than we at the present day are; and that the "hall" has slowly, but surely, degenerated into the "passage;" but this is not so—at least, if one depends upon historical reports and pictures. By "hall" I mean the large entrance apartment represented in drawings of old English mansions; and by "passage," the small narrow entrance to be seen in most modern dwellings. True it is that our forefathers built massive, grand, and commodious mansions, possessing spacious halls, compared to those that are generally raised nowadays; but they were occupied by the aristocracy; and the lower and middle classes were not, I believe, so well off in the matter of space and accommodation as the lower and middle classes of to-day are. The majority of houses, although being extremely picturesque when viewed from the exterior, were exceedingly far from comfortable to live in, and very few of them indeed possessed either a hall or passage, the entrance door generally opening immediately into the front apartment.

Although the nineteenth-century lower- and middle-class dwellings—of course, I am not speaking of the "slums," that caused so much public commotion a short time back—are not to be compared to those erected two or three hundred years ago so far as external appearances are concerned, we have a great deal to be thankful for in regard to internal arrangement; and as improvements are rapidly increasing with every year that overtakes us, I think the present "passage" will eventually develop into the more convenient "hall."

But as most dwellings possess merely the former of these two, we must remain content to bestow our care and attention upon it, and wait patiently for its final development. It is a noticeable fact that very few householders pay much attention to this part of their houses, one reason being, I presume, that they consider hall-stands are too large and bulky. This, to a certain extent, is true, but there is no reason why something smaller than the usual thing should not be used. Perhaps another reason is on account of the numerous petty thefts committed by idle and vagabond men who make a continual practice of abstracting hats and coats from their temporary resting-places, by opening the street-door by means of a key that the landlord of the house never gave to them. And as so many street-doors can be opened by the same key, thus certainly making the chances of losing apparel very great, perhaps Mr. Bonney, the gentleman who has been giving the readers of Work so much good and useful electrical information lately, will give us something that will sound the alarm when a coat or hat is being appropriated by any other than the rightful possessor.

The "stand" that I show in the present illustrations I have designed to be of more use than ornament. It is smaller than the average article, and can be put to more uses than even the larger patterns can. The outside dimensions are:—Height, 6 ft. 6 in.; width, 2 ft. 6 in.; distance from back to front, 13 in. And yet we have an umbrella-stand, hat and coat pegs, glove and boot cupboard, brush-box, looking-glass, and hall-seat!

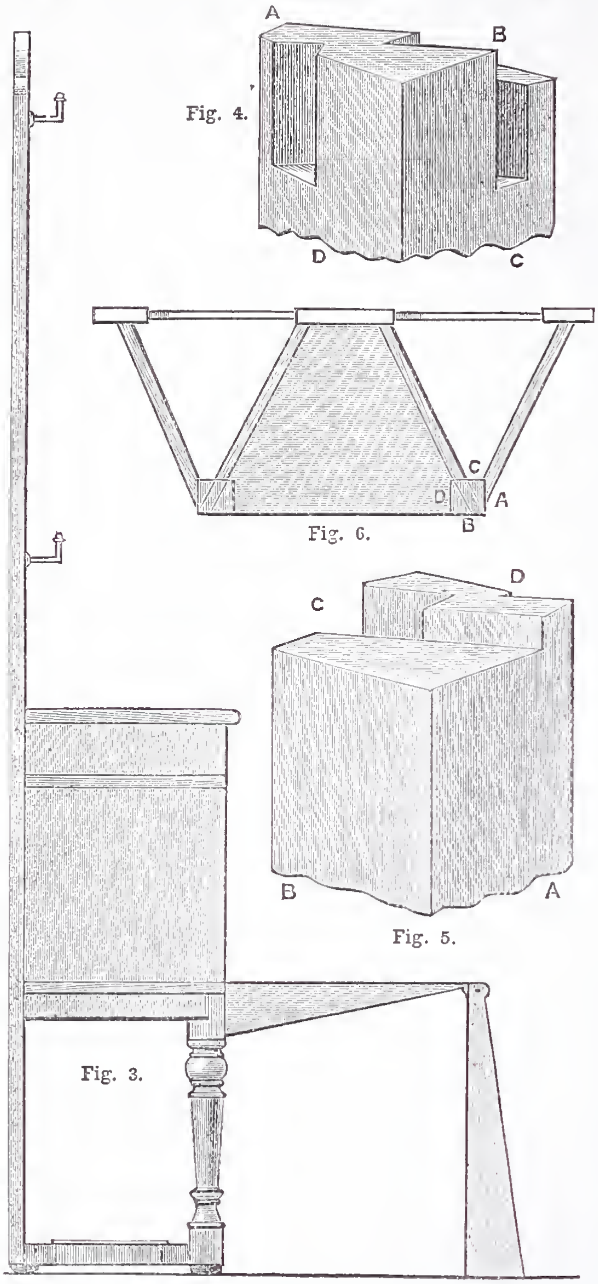

Fig. 3.—Sectional View of Stand (scale, 1 inch to 1 foot). Fig. 4.—Method of cutting Leg Blocks for Joining to Carcass: Back View. Fig. 5.—Ditto: Front View. Fig. 6.—Plan of Stand (1 in. scale). Letters in Figs. 4, 5, 6 show correspondence of Parts.

There are several wives who can testify to the exhaustion of their patience and good humour by the entrance into the parlour of their husbands with wet and muddy boots, after a day spent, perhaps, in travelling about the dirty streets in rainy weather. With a hall-stand after this style, there is little doubt that these petty but not unreasonable quarrels would arise, as, having a seat attached to it, the husband could take off his dirty boots and place them in the cupboard, and put on his slippers, which should be at hand in the same cupboard. "But," I fancy I hear one of the before-mentioned husbands murmuring, "I always like, and always have, my slippers nice and warm." That may be so; but still one cannot always combine comfort with convenience, and I trust that the present suggestions I have offered will not be discarded on that account.

It will, doubtless, be observed that the supports for the seat fall into position when the door is opened, so that no complaint can be lodged against the article of causing too much trouble.

The door is really a box having three sides and a lid. This will form a handy receptacle for a clothes brush or brushes, or any other small and necessary articles; and the lid need only have a small knob to facilitate opening it, as the inside shelf, or—if made without a shelf—the shape of the cupboard, will prevent it from falling down when the door is up, thus doing away with the need of a fastening. The bottom of this box projects a few inches, and, when it is down, adds a firmness to it as a seat, and with the supports will really be all that is required; but to prevent accidents that might sometimes arise from the supports slipping, I should advise some part of the back of the stand above the boxes to be fastened to the wall.

As the shape of the cupboard will prevent very much strength to be obtained by joining, I have inserted at each side of the stand, in addition to the necessary top rail, another rail, with fretwork between the two, and a shaped piece of wood beneath them, to add a solidity to it.

Of course, variations of the same suggestion could be utilised. For instance: the cupboard might be square, and have no box in front; and a straight piece at each side could be cut out and pivoted to the top in a similar manner to that shown in the present design, both pieces being connected at the bottom in precisely the same manner. But it is always advisable to give the whole of the conveniences, and leave it to the reader to modify them according to his taste and requirements. Having said thus much, I will proceed with the dimensions.

The back framing should be put together first. The centre board will be 6 ft. long and 6 in. wide; the two side rails, each 5 ft. 3 in. long and $2\frac{1}{2}$ in. wide; the bottom rail 2 ft. 1 in. long and $2\frac{1}{2}$ in. wide; and the two pieces fitting in between the centre part and side rails, each $9\frac{1}{2}$ in. long and 6 in. wide. The thickness of this framing should be about $\frac{3}{4}$ in. The centre part need not be cut for the glass, but a narrow frame with a rabbet on the inside cut for it, may be screwed on from the back of the centre piece. The glass might be 18 in. long and 4 in. wide. The shaped pediment need not consist of a moulding; a flat rail $2\frac{1}{2}$ in. wide, with a few lines along it, will answer the purpose. The length of it, measuring straight, will be about 1 ft. 9 in.

Coming to the front, the top of the cupboard will be 19 in. wide on the front, and 7 in. at the back, and $12\frac{1}{2}$ in. from back to front. The two sides will each be $13\frac{1}{2}$ in. wide, and 18 in. long; and if, as the cabinet makers say, "a good sound job" is required, the various boards should be either $\frac{5}{8}$ in. or $\frac{3}{4}$ in. thick. The length I have given for the sides of the cupboard allows for an inch or two to be joined into the pillar blocks. The shelf and the bottom of the cupboard will each be $16\frac{1}{2}$ in. wide on the front, and $4\frac{1}{2}$ in. wide at the back. The front of the brush-box will be $16\frac{1}{2}$ in. square, projecting to a distance of 3 in. or 4 in. at the bottom. Three narrow sides and a lid complete this box. This lid should not be hinged right at the back, but a few inches from it, to a narrow piece firmly joined there. The thicker the parts of this box, the better and stronger it will be when being used as a seat. At each side should be a triangular piece $\frac{3}{4}$ in. thick, with a small half-circular piece projecting at the narrow end and fastened to work on a pivot at the top. Both these rails should be united by another rail crossing them at the bottom.

One particular thing must be remembered concerning this movable part, and that is: the height to the top of the seat when down will be 18 in.; therefore the length of the supports will have to be the same, being a few inches longer than the front of the box.

Along the top of the outside of the door should be fixed a piece of wood, half-circular in section, to which the support is pivoted. When the door is opened, this support falls into position without any touching. The back of the brush-box will have to be very strongly hinged to the bottom of the cupboard; and the whole of the front will shut up *outside* the carcass. On the front the panel might be ornamented by having a little figuring incised or painted, which will add a finish to it.

The pillars should each be turned from $2\frac{1}{2}$ in. wood, and the length of each, including the blocks, will be 18 in.

The bottom board will be 2 ft. 6 in. long on the back, and 18 in. long on the front, and 12 in. wide. It should be $1\frac{1}{2}$ in. thick, and cut to admit a tin or zinc pan, which can be of any size and shape; therefore I leave it to the reader's option. Whatever shape he chooses, he will, doubtless, be able to obtain it at almost any tinsmith's; or, if not kept in stock, he will have no trouble in getting one made to order. But if he reads the instructions given lately on Soldering, etc., he will have no very great difficulty in making one himself. A rim should run round the top of each, and will be sufficient to support it in its place if made to fit accurately.

The side rails will each be $13\frac{1}{2}$ in. long and 1 in. thick. A piece of fretwork might be introduced between each pair, or even a few spindles would look well. The shaped pieces under these rails afford additional strength, and add to its appearance; and the shaped pieces at the back can claim the same advantages.

Four or six brass hat-hooks should be fastened on the front; and two smaller ones fastened one on each side to the thickness of the upright rails.

Being of a small size, I think it would be preferable if made in a dark wood or stained a dark colour.

Of course, the size of the entire article could be increased, but the sizes I have given for the seat should be carried out as nearly as possible. But it will be found that the shape of the cupboard and the position of the side rails allow for the introduction of a great number of umbrellas and walking-sticks; and that ample room for the purpose required will be found in the cupboard.

The side rails, too, instead of being quite straight, as I have shown them, could be curved; but unless the sides and top of the cupboard were curved in a similar manner, such a proceeding would spoil the symmetry of the article, upon which its appearance depends a great deal, and which I have been compelled to consider as secondary.

SIGN-WRITING AND LETTERING.

BY HENRY L. BENWELL.

PERSPECTIVE MODIFIED AND ADAPTED TO THE REQUIREMENTS OF THE SIGN-WRITER.

In the course of his every-day routine of business, the student will often have, not only to paint the various styles of perspective letters such as the examples given with this chapter, but he will also occasionally have to treat his whole subject from a perspective standpoint, and I am now going to show him how to practise for and execute this department of his work. In sign-writing we cannot, in many cases, carry out the strict rules of perspective, consequently a violation of those rules is the result; but, although we cannot follow the true laws of perspective as laid down by the writers in the various text-books on the subject, I would urge the sign-writer to make himself a complete master of the art, so that by having the various problems at his finger ends, he will readily be able to make them conform to sign-writing requirements.

Of course I am not going to attempt in these pages any instruction on the principles of perspective in general: that would require treatment as a separate subject; all I can do is to point out a few examples of sign-writers' perspective as they occur to my mind at the time of writing; but should the reader care to study the subject seriously, I can recommend a small handbook by the Rev. Henry Lewis, viz.: "The Principles of Perspective," explained and applied in a series of graduated exercises; and also the chapters on perspective for letter and sign-painters in Mr. Davidson's work, "House-Painting and Sign-writing." Those who followed my advice in the earlier chapters of this series, and made themselves a black-board—and I know there are many who have done so, from letters received—will be able to work out the various problems and practise the various letters with the greatest facility.

Most writers, I am bound to say, have but a very crude knowledge of perspective: just sufficient, in fact, to enable them to carry out their designs with a passable amount of truth; but occasionally we see a glaring slip, either through want of knowledge of or a wrong conception of the proper application of perspective lines to the purpose in view. Certainly, a little knowledge of this subject is better than none at all, but what little the student does learn he should take care to be perfect and correct in, and he then may get on fairly well. The best sign-writers use as few lines as possible in order to give themselves freedom of action and plenty of scope in carrying out their designs. The beginner should follow the same course, otherwise he will be considerably hampered in his movements, and an awkward stilted job the result. Both linear and aërial perspective may be applied to sign-writing, and with plenty of practice on the blackboard the student may become so proficient and expert as to be able to entirely dispense with the various complicated lines in putting letters in perspective on the sign, trusting to the educated eye alone. A difficult arrangement or design for a sign executed in perspective should always be drawn out in true perspective on paper, and to scale. This work is best done at home, where everything for use is at hand, including mathematical instruments, squares, and drawing board. When finished in this way, the workman may transfer his design in its enlarged form to the signboard, converting or adapting the perspective as the height and position of the signboard may require.

In sign-writing, as in picture-drawing, there is but one point of sight and one horizontal line for each line of letters. Now, only the other day I saw, in London above all places, a perspective sign which contained at least three points of sight, which is of course absurd, as the spectator can only be at one point at one and the same time, and cannot see the first row of letters from one point of view and the second row from another point all at once, yet the sign-writer in this instance must have thought so. In lettering of this description all the top and bottom lines must incline to one vanishing point, such point being situated on the horizontal line, which I will explain by the aid of a diagram (Fig. 61).

We will take an oblong piece of paper, and for simplicity draw the horizontal line right across the centre, from A to A. The vanishing point is next decided upon, and in this case it is at B, and in the case of raised or shaded letters there must necessarily be another vanishing point on the left, as the lines of the thicknesses run in an opposite direction. This point is at C. This second point has nothing to do with the actual body of the letters, and is only called into use for the shading, so it does not contradict the statement just made. The next thing is to decide upon the height of the first letter on the left, and having drawn this in, we strike two lines, D, D, from the top and bottom, respectively to the vanishing point, B, and between these two lines the letters must be kept. On referring to the diagram, it will be seen that the letters not only diminish in height but also in breadth as they recede towards the vanishing point, B. The outline of the thickness for each letter must retire towards the point C, as shown by the dotted lines. In Fig. 65 is given a specimen of work treated in the way just described: this is for an advertising sign over an office, but a much more effective way of treating a perspective subject of this class is by the method shown at Fig. 62. For some descriptions of work this way of treating a sign is superb, and it makes a most attractive and catching advertisement. In Fig. 64 we have an instance of the point of sight being in the centre of the board at A, and a vanishing point on either side at B, B. There being seven letters in the name *Higgins*, the second *g* is consequently the middle letter, and the size of this being determined upon, it is drawn exactly in the centre of the board, and the vanishing lines drawn on each side accordingly. A short sign, rendered necessary by cramped space, is a good subject upon which to apply this method, and it is made more showy and complete by the addition of an oval border. It is, I am aware, a very difficult proceeding to strike perspective lines on a signboard, when the vanishing points are situate some distance outside the margin of the sign—and in a great many cases it would be impossible to do so—but there is a method of transferring perspective lines from a scale drawing on to a larger surface, which is both easy and accurate. I have used this plan for some years in scene-painting, and although I have never done so, feel sure it could be put

to the same use in lettering, with a slight modification. It is with deep regret I cannot lay this plan before my readers, as I feel it would prove of immense use to all sign-writers, old and young; but as it would take much space to describe, and require two rather large diagrams, I can only say I may incorporate the subject in a separate article at some future date. Referring back to the point of sight, I should remind the student that in raised and shaded letters, this point is generally on the extreme right of the sign, and for this reason: By standing opposite the centre letter on a signboard, consisting of wooden projecting letters tacked on to the board, it will be noticed, on referring to Fig. 63, that we can only see the front surface of the centre letter, and not the sides; in the letters to the right we see only the front and left side of the letter, and in the letters to the left of the centre the front and right side of

Fig. 59.—Perspective Egyptian Alphabet: Capitals and Numerals.

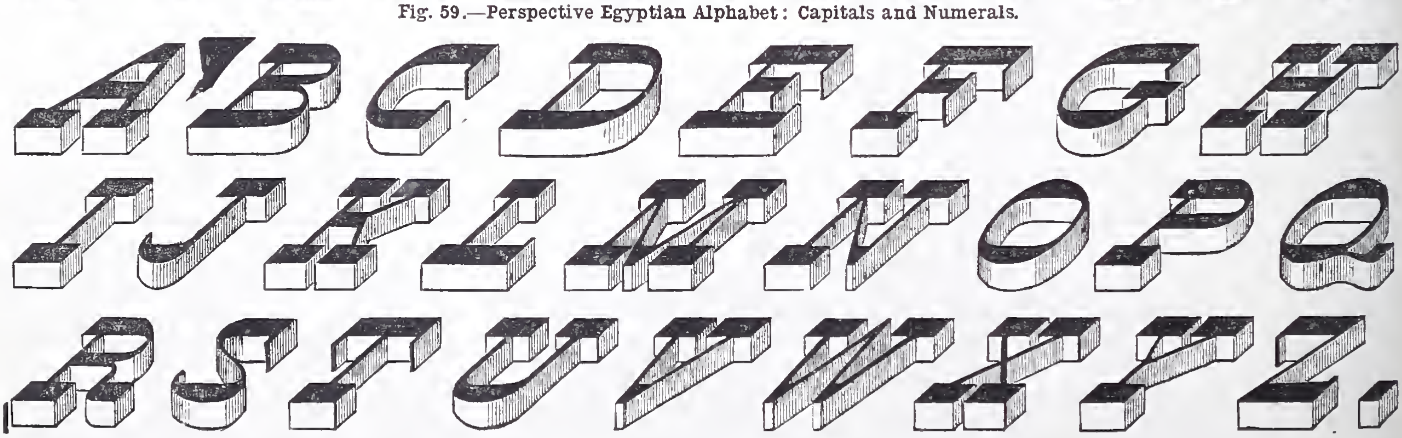

Fig. 60.—Perspective Italian Alphabet.

such letters. Now, this is of course perfectly true perspective, but we never see it, nor follow such a rule in lettering. If, however, we stand to the left of the sign, we at once catch all the left-hand edges, and if we go to the extreme right we see the right-hand thicknesses. This also is correct perspective, the point of sight being in the first case to the left and in the second to the right; we cannot have this point in the centre, but we may have it right or left, and the former is the one most general in use. But even here the sign-writer cannot follow the rules of true perspective in shading and raising his letters, for if, in this work—in contradistinction to the drawing of the body of letters in perspective, as described earlier in this chapter—he made use of one vanishing point only, which in this case would be the seat of the eye, situated much below the row of letters, and also in the first place arranged the thickness of the first or nearest letter, to slant off at an angle of 45°, arranging his vanishing point accordingly, and struck the perspective lines for the thickness of each letter, from this point, he would find each thickness, being a greater distance away than the preceding one, would have a greater angle, or become more oblique in each case; and moreover, if the letters were strictly drawn, the thicknesses or edges should be made narrower. It, therefore, follows that we cannot carry out this method on a signboard, as although perfectly correct for other art purposes, it would in this case entirely destroy the symmetrical appearance of the sign. The general practice, therefore, is to have a fresh vanishing point for each thickness, which in effect means that most sign-writers draw all their receding lines in shadows and thicknesses at an angle of 45°. A good practical man can do this with the eye alone, but I should advise the beginner to make use of a set-square for the purpose, as nothing looks worse or spoils a job quicker than badly shaded letters: nothing, in fact, puts a really perfect letter out of the perpendicular or gives it a tumble-down appearance more than a wrong raising or thickness, from a modified perspective standpoint. It should therefore be remembered that although each letter on the same line is blocked on perspective principles, these perspective lines are only applicable to each separate letter in the row.

Although blocked or raised letters must therefore of necessity be treated upon perspective lines, it may to a great extent be left to the writer's discretion as to what angle of perspective he uses for different sets of alphabets, but he must take care that all letters on the same line have the same angle or inclination. Most writers find the ordinary set-square with an angle of 45° to be the most useful for setting out the proper inclination of the thicknesses, and if the student will put the set-square on the top line of each row of letters with the slanting edge downwards, and just touch the top corner of the letters, he will get the best of perspective lines for his purpose, and if he then moves the set-square along so that it touches each corner in succession, he will get every part of the block on the same inclination of perspective. Mr. Wm. Sutherland recommends this plan as the best possible way for the student to educate both the eye and the hand, and upon this subject there can be no greater authority than this veteran in the decorative arts, who wrote upon sign-writing over forty years ago, and whose latest work, "The Art and Craft of Sign-writing," is now looked upon as the standard work upon the subject by the whole of the profession.

I have necessarily only touched upon a few simple questions in this chapter on perspective; to do so in a thorough and

complete manner would be impossible with the limited and valuable space at my command, but my readers can find more advanced matter in the book mentioned above. In my next chapter on light and shade, my readers shall have the benefit of some portion of this gentleman's ideas, as far as I am able to express them in writing. I give with this chapter Italic and Egyptian alphabets and two complete perspective alphabets (Figs. 56-60), in accordance with the wish of several correspondents, which will, no doubt, prove of value in actual practice.

SOMETHING MORE ABOUT TAKING OUT A PATENT.

BY A CONSULTING ENGINEER.

[*⁎* The following has been sent to us by a Consulting Engineer of high standing and wide experience, and will be valuable to all who are interested in this subject, as it deals with certain aspects of "Taking Out a Patent" which were left untouched or nearly so in the previous paper under this title.—THE EDITOR.]

POPULAR IGNORANCE IN REGARD TO PATENTS—GRANT OF A PATENT NO PROOF THAT IT IS A PROPERTY—WHERE THE VALIDITY OF A PATENT IS ASCERTAINED—A SOUND AND VALID PATENT A VALUABLE PROPERTY—INVALIDITY ONLY DISCOVERED AT A LATER PERIOD—LEGAL OPINION OF A LEGAL WRITER ON SPECIFICATION—ANY ONE MAY PREPARE AND LODGE HIS SPECIFICATION—IMPORTANT POINTS UNKNOWN TO OR NEGLECTED BY SUCH—"UNPROFESSIONAL" AGENTS—DANGERS OF SUCH—ABSOLUTE NECESSITY FOR A CAREFUL SEARCH AS TO NOVELTY, AFTER SPECIFICATION IS PREPARED BUT BEFORE LODGING THE SAME, AND WHY—ILLUSTRATION OF COSTLY RESULTS OF NEGLECT OF THIS COURSE—GREAT INJURY DONE TO PATENT PROPERTY BY NEGLECT OF PROPER PRECAUTIONS AND THE WORK BEING DONE BY UNQUALIFIED PERSONS—IMMENSE AMOUNT OF VALUABLE PROPERTY AND MONEY WASTED—COST OF PATENTS INCREASED UNDER NEW LAW—HOW AND WHY—A USELESS AND INSUFFICIENT PATENT DEAR AT ANY PRICE—KNOWLEDGE, EXPERIENCE, SKILL, AND ABILITY SHOULD BE PAID FOR IN PATENT AS IN OTHER WORK—"CHEAP AND NASTY."

AMONGST the many popular fallacies of the present day, and one that is too often the cause of injury to the practitioner, and a great nuisance to other people, is the prevalent idea that *when* an "inventor" has contrived to get his "invention" accepted at the Patent Office, and obtained the grant and seal, he has *therefore* got a valuable *property!* The article of "C. C. C." in WORK, of Nov. 16, 1889, will evidently tend to perpetuate this fallacy, inasmuch as it omits to notice the principal and most important points relating to a patent; and would, without the admission of the writer, show to any man of practical experience and knowledge of the subject, that it could only have emanated from an "unprofessional patent agent," or a mere amateur, and is a good illustration of the truth of the old saying, that "a little knowledge is a dangerous thing," more especially when he illustrates his peculiar and profound knowledge of patent matters by telling us, that "if we require protection for the Colonies, as well as Great Britain, it will be marked A1." If this *were* true, it would be A1 indeed! It would have been thought, and expected, that, in these days of general and gratuitous information, and extensive and general setting forth of individual abilities as competent instructors of an unenlightened public, it would have been known that *each* colony of Great Britain has *its own Patent Laws*, entirely *independent* of the Mother Country, and *each* requires its own special treatment. Truly it may be said that the class the poet speaks of as not hesitating to do what angels fear is not yet extinct.

Now, it should never be forgotten that, in granting a patent in Great Britain, the Government does *not* in *any way* assume *any responsibility*, or *guarantee* the *validity* of the patent; this it throws on the applicant, who is presumed *before* he makes his application to know *exactly what he wants or requires*, to have *ascertained exactly what he may apply for*, to have made *suitable investigation* to have *decided this point*, and found whether his idea or plan is *anticipated*, and *how*, and to *what extent* he must *modify* them so as to prevent his patent from being *valueless*, and enable him to shape his demands, and *properly* to describe, illustrate, and secure that which he is entitled to, and to have had his title, specification, description, drawings, and claims, so *properly* and *fully* prepared, with *all* necessary points *so clearly explained and defined*, that when he has got the patent, he has *then* acquired a property.

The value and validity of a patent can only be ascertained and proved at a *later* period, if it has not been clearly ascertained before, either by the discovery that some other person has a *prior* claim to the "invention," that it has been *already published*, or that the *incorrect* or *insufficient* preparation of the title, specification, drawings, or claims, prevents it standing the test at the Law Courts, or else that the specification, etc., of the patent have *not* been made to cover the *most important parts* in the "invention."

A sound and valid patent for a really useful and practicable invention, when *well* considered, described, and illustrated, is of the greatest value, and an inventor should spare neither *time, trouble*, nor *expense* to obtain such; and if he has any confidence in his plan will most certainly do so, seeing that they are the title-deeds of what may prove to be a most valuable property. If a man purchase an estate, a house, or other property, he is generally extremely careful to have all the papers and documents prepared and examined with the greatest skill and care; but in the case of Letters Patent, this does not seem to be thought of, although they are in reality the title-deeds to prove his right to the invention, which make it a property, define its limits, explain its powers, and enable him to resist successfully any encroachments on his property or his rights.

It should never be forgotten that the discovery of the advantages which would have resulted from doing things in a *proper manner at the first*, is only obtained when the patent is *lost*, or its utility so damaged that it becomes virtually useless, and that *no expenditure at a later period*, unless only *a portion* of his invention may be wrong, when a disclaimer may be entered, can compensate for this deficiency at the commencement.

To show that this is true, and also how carefully such matters require to be done, inventors, "unprofessional patent agents," amateurs, law writers, law stationers, copying clerks, and the motley host of such as consider themselves quite qualified to advise on inventions, and prepare the documents, drawings, etc., should carefully bear in mind what a writer on the law of patents (Mr. C. Drewry, barrister-at-law) has said on this subject. "The most difficult perhaps of all legal documents to prepare is a specification of a patent; and for this reason, that it fulfils a *double* function. It is an explanatory direction to *workmen*, which must be couched in *language intelligible to them*, and sufficient to teach them *how* to produce the patented thing. It is *also* a document supporting *legal title*, and *as such* is subject to the same rules of construction of the language as are applied to any legal instrument."

It is quite true, as "C. C. C." states, that "any inventor who can express himself intelligibly in pen and ink, and can make a mechanical drawing, or who has a friend who can help in either or both ways, may get his patent without the intervention of an 'acknowledged agent,' and *secure* (?) his rights without running into any unnecessary or unknown expenditure," and *if* an inventor *did* or *could* do so, then no one would do wrong in following this course; but before doing so, he should carefully bear in mind that in law a specification is held to be *bad*. 1. If its *terms* are *ambiguous*. 2. If *necessary* descriptions are *omitted*. 3. If *parts* claimed are *not original*. 4. If things are inserted to *mislead*. 5. If the drawings are *imperfect* or *incorrect*. 6. If *one* of *different* ways or of different *ingredients* named *fails*. 7. If the *things* and *mode* described are *not the best known to the patentee*. 8. If the *old* parts are not *properly distinguished* from the *new*. 9. If the claims are *too wide* and not sufficiently explicit.

All these points, it must be remembered, are *not* decided by the employés at the Patent Office, but are considered and settled by *lawyers* who have to regard things in the manner described by Mr. Drewry, and here, and here only, the rights of an inventor, the value of his property and what he is entitled to, are inexorably defined and decided. From this it will be seen how little the results of the labours of "C. C. C."—whilst acting "in the capacity of agent, none of his work as such has failed, and he believes he has been successful chiefly because in his specifications and drawings he has kept in view the primary and fundamental objects of the patent laws," in getting the papers through the Patent Office—can influence in any degree the results of the ordeal such have to pass through under the rigorous sifting of the Law Courts. *When* he can produce *one* patent of which he has prepared the specification, drawings, etc., that shall have passed unscathed through this, *then* he may boast of being "successful," and of his understanding of the "primary and fundamental objects of the patent laws."

It is an imperative necessity for any one desiring to obtain a sound and valid patent, and to obtain a property therein, *after*, in the words of "C. C. C.," he has "decided on the most fitting title," and whether we are to speak of it as an "invention" or an "improvement," to "sit quietly down with a sheet of paper before us, and as simply, straightforwardly, and clearly as we can, draw up a description of it. If it will admit of such aids to verbal description, we should make rough drawings as we go on, marking them and our manuscript with letters, so as to render reference easy. While thus engaged, we should bear in mind the rule already laid down—that the object of our description and descriptive drawings is to so explain our invention that, from them alone, any person may, at any future time, be able to make the article, or to perform the process which we are describing. If we do this, we do all that the Patent Office requires of us. The most experienced agent can do no more;" he should *at once*, as he will *then* be in the position to do so, institute a most *careful* and *analytical* search through all the specifications *relating to the subject*, in order to ascertain how far his invention or improvement is novel, and how far it is not novel, so that he may protect himself and define and obtain his rights by lodging *proper documents*. If he *fail in doing this*, all the acceptances at the Patent Office, all the grants of a patent, will *not* create a *property* if he fails in this respect, as it will, undoubtedly, do in ninety-nine cases out of a hundred—and more especially when manipulated in the manner, and on the lines, laid down by an "unprofessional" agent.

Some few years since, an attempt was made to float a company to purchase a French "invention" for propelling tram cars by means of compressed air passed through a vessel of hot water just before it entered the cylinders, so that it became heated and expanded thereby; but, though a fabulous sum was to be given to the Frenchman for his "invention," and all stamps were paid for the whole term of the patent, *no search as to novelty was made;* but an "eminent" engineer, who was, evidently, profoundly ignorant of what had been done before in this direction, was mightily struck by it, and reported it as being one of the greatest inventions of modern times!

A short time after, the company was brought out, and prospectuses issued, but, in a few days, it was satisfactorily proved that this so-called "invention" of the Frenchman had been patented by an Englishman so far back as 1797 and 1801, and also by others at later dates, but *all long before* the Frenchman; consequently, the whole thing fell through, leaving the promoters, financiers, and the "eminent" engineer on the *wrong side* of several thousand pounds, with the chance of becoming wiser men for the future; but, whether they have, or will, use the chance, has not been ascertained.

Few persons can know how seriously the value of patent property has been, and is being, injured through "intelligent inventors," sometimes aided by "unprofessional" agents, or law stationers, or law writers, and copying clerks, preparing their own specifications, etc. The host of individuals of the above description who are ready, and push themselves forward as prepared, for the smallest consideration, to act the part of scientific mentors to "intelligent" and other inventors, and aid "unprofessional" agents, evidently, as well as the rest, participate, in most cases, in the popular belief that "anybody" can prepare a specification, and so create a property, and "everybody" is capable of advising thereon; and that if, after a little trouble, the papers are accepted at the Patent Office, all is right, and a great success at once achieved.

Where capitalists were once only too glad to invest in patent property as a safe and profitable proceeding, but few now will look at one, most having a just and wholesome dread of such articles, especially since we are flooded with the mass of "home manufacture," or the outcome of the transcendental abilities of "intelligent inventors," "unprofessional" agents, law stationers, law writers, copying clerks, etc., knowing full well that getting the papers through the Patent Office is *not* the *slightest proof* of the value of the property, nor a guarantee that it will pass through a trial at law.

Intending patentees should be extremely careful not to fall into the hands of the extensive fraternity who profess to obtain a patent for a *fixed sum before even they have seen the subject, know the mode, or what is proposed or requires to be done*, and have no idea beforehand of anything relating to the matter! A moment's reflection should satisfy any one of ordinary intelligence that such offers are about on a par with the benefits to be derived from falling into the clutches of those amiable and philanthropic individuals who offer pecuniary accommodation *without any security!*

An inventor, if he *really* has a good thing that is worth anything at all, will rarely fail in being able to find a reputable and respectable practitioner who will arrange terms with him for carrying out his wishes in a proper manner, and at a fair remuneration for his services; but, as every labourer is worthy of his hire, and few men of ability and experience work for the advantage of other people and their benefit, simply for amusement, it is only right that they should receive a *fair* return for their skill, experience, and labour.

It would, no doubt, astonish "unprofessional" agents and "intelligent" inventors if they could see, at one view, the immense amounts of valuable property and money that have been *lost* and *wasted* entirely through the absurd proceedings in regard to taking patents that have existed and still exist, far too generally, in the mind of the average public, "intelligent" inventors not excepted.

That there are incompetent and unprincipled parties occupying themselves about taking patents is well known, and too many "intelligent" inventors have been victimised by such; but a better means of maintaining and increasing the breed cannot be devised than that of considering that the work of a mechanic should not receive higher pay than that of the labourer; hence it will be found that there will be only labourers to do the work, and the value of the work done will be nearly equal to the amount expended in obtaining it.

So far as the *cost* and *labour* required in obtaining a patent goes, under the new law, instead of being *reduced*, experience shows that they are really *increased*, inasmuch as the waste of time encountered in combating and removing the "objections"—too often absurd and frivolous; the "suggestions" far too often impracticable; and the "improvements" in nine cases out of ten of anything but this kind—proposed to be made by the employés in the office must be paid for, or else the person undertaking the work must be at the loss; whereas, under the old law, it was *not* the province of the law officers to occupy themselves with anything of the kind. In fact, except in the reduction of the stamps, inventors, patentees, and those engaged in preparing the documents, drawings, etc., were far better off, inasmuch as they knew *what* they had to do; *how* to do it, and *did* it; whereas, now, it is extremely difficult—if not impossible—to know or foresee anything, or to work to any established precedent; in fact, we have seen by experience that apparently the best qualification for employment in the Patent Office is the least possible acquaintance with, if not a total ignorance of, all matters relating to patents and the kind of work that has to be performed.

It has well been asked, "Of what good is a 'patent' which does not fulfil what should be the chief object to be secured by obtaining one, however 'cheaply' or at a 'low-priced' rate it may have been obtained, and the specification drawings, etc., have been got through?"

Do "inventors" and "intending patentees" ever give this point a moment's consideration, or ever remember the results of being one's own lawyer? "Cheap and nasty," most truly applies here.

"Cheap and nasty" is an old and true saying, but is a very expensive amusement when it is patent property that is played with. How much ought I to pay to secure the services of a proper person to create me a property in my invention? should be the ruling principle of an inventor; *not* where can I get my papers put through "cheapest," or at the *lowest* price. Practical knowledge, skill, and ability ought to be worth more than the labour of a copying clerk or law writer, which requires no brains, but merely aptitude in copying what is put before them.

OUR PRIZE BOOKCASES.

I.—A Hanging Bookcase.

For which the First Prize was Awarded.

Before giving a description of how to make the above, I think it would be advisable to say a few words about the kind of wood that is most suitable; and as the cost of wood in this particular case is not of so much importance as the labour, I take this early opportunity of impressing upon my readers the desirability of using only the *very* best of stuff. It will be found for this class of work that the best material is always the cheapest in the end. For, if only one piece of stuff has to be thrown out on account of some defect after the time and labour have been spent on marking, sawing, planing, and setting out, it would most likely be found that it would have been cheaper to have given a penny or so a foot more for the wood in the first place, to say nothing of the delay. Where is the joiner or cabinet maker who has not, at some time or another, persuaded himself that a dead knot or shake would be either worked out, or come at the back, or that a bad edge would be rebated out, etc., in the working? and, at the last moment, when he had hoped to get his work glued up before knocking off, found that the knot did not come in the tenon, but right across the shoulder; or that the shake was just in the mortise; or, for some unaccountable reason, the sap was on the edge that was most seen, or that the bad edge was *all but* worked out by the moulding. And what is the result? let a piece in, and if it is hard wood the chances are that although it is cut out of the same piece of wood as the defective piece, it will come out a different colour when polished. One then sees the artistic polisher—with some mysterious compound in a receptacle concocted out of a piece of old glasspaper—endeavouring to match it by painting, but it is very seldom that it is matched properly. And the alternative is to get out a fresh piece, which means that it must be set out quite separately, after which it is found that the mortise-gauge, plough, fillister, etc., as the case may be, has just been shifted. Take my advice, use good stuff.

Now for a few precautions, tips, etc.

If it is made in walnut, oak, mahogany, or any hard wood and polished, be sure to have the spindles, finials, brackets, gallery rails, mouldings, etc., in fact everything possible, at least bodied up by the polisher before gluing up: should it be made in walnut, it would be better if it were dull, or fine polished.

If made in pine or American whitewood, stained, polished, or varnished, do as much staining, polishing, or varnishing, as you possibly can before gluing up.

It is also very necessary to take great

care that there is no glue left on any of the joints, mitres, etc. It is better to put the glue on very carefully than to have to clean it off after it is dry, which is not only rather troublesome, but very often far from satisfactory, especially where there are many internal mitres. It will be found easier to wash any superfluous glue off before it is dry with a clean piece of sponge, dipped in hot water and wiped thoroughly dry, making sure to get rid of all signs of glue or glue water, or size; the act of washing off the thick glue with water very often causes a coating of size round the joint, and wherever there is a trace of this, the stain, etc., will not take properly. This washing may very likely raise the grain of the wood, but a few rubs with a piece of fine glasspaper will soon put it all right. In working reeds, mouldings, etc., with a scratch, or router, especially in soft wood, it is a very good plan to damp the reeds, etc., after first working, which will cause the grain to swell; and when it is dry they can be papered down. This to a great extent anticipates the action of the stain, and the rubbing down can be done much more readily and with better effect before the work is glued up. If it is decided to varnish it after staining, give the work two coats of patent size, rubbing down between each coat with a piece of soft rag or brown paper (it is better not to use glasspaper after the wood is stained if it can be possibly avoided), and varnish with flatting varnish, for stained work of this description looks common if finished with a glossy surface.

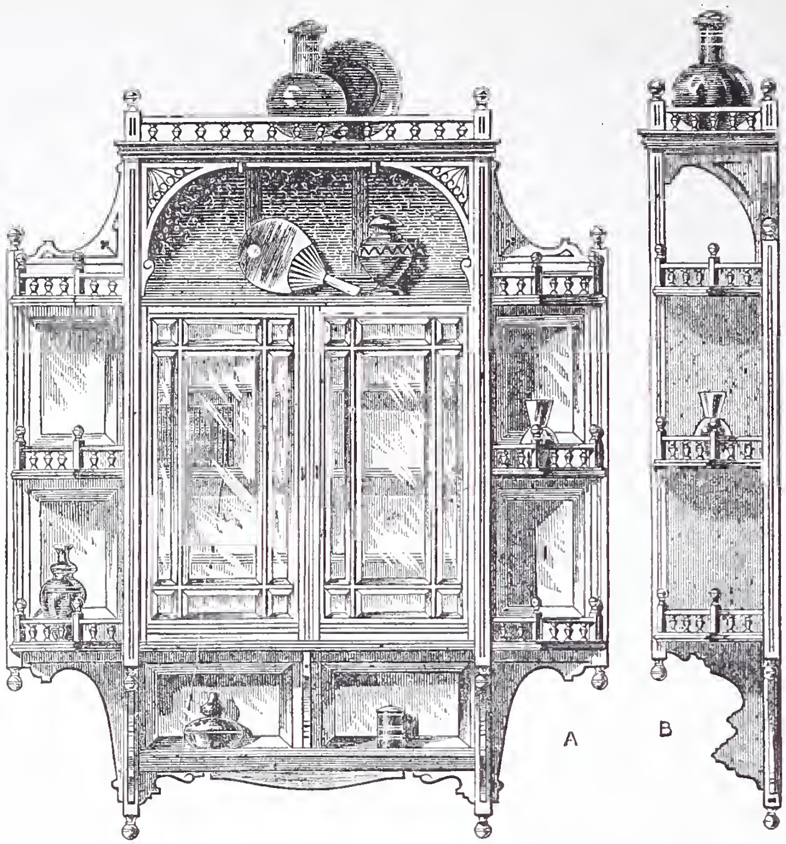

Fig. 1.—Prize Design for a Hanging Bookcase, to contain Two Hundred and Eight Volumes of "Cassell's National Library"—A, Front Elevation; B, Side Elevation ($\frac{3}{4}$ Scale).

On no account use sappy wood, for it is generally found to come out very bad when stained.

As American whitewood is very nearly the same price as best pine, it would be better to use it for stained work, being not only harder than pine, but more adapted for fine work; and it, moreover, takes any stain beautifully.

A cheaper way of finishing it would be to enamel or paint it in suitable colours, on account of the advantage of being able to use up any odd piece of stuff, either hard or soft, provided it is sound. But again let me say, do all you can before gluing up.

I hope the above precautions will not be considered out of place; for it is just these little things that go to make or mar a job.

Whichever wood was used, it should be cut off as soon as possible, and stood about to dry, even if it has been cut some time.

Let us now suppose it has been decided to make it in pine. The first and most important thing to do is to take two pieces of thin stuff, and plane up one side and one edge of each; chalk all over the planed sides, and glasspaper across the grain; and after dusting off any chalk, etc., that remains, set out on one the full-sized section marked height section on drawing, and the one marked width section on the other. These are called the rods.

To some, this may seem unnecessary labour, but I can assure you it is not, as will be seen as we go on.

Now, with the rods in front of you, mark off on a piece of paper every piece of stuff you require; clear the bench, keeping the rods ready for reference, and mark and cut out everything. If you take a shaving off all sides and edges before standing the pieces down, it will enable the air to get at the stuff better than if it were left rough; and the longer it stands about the better. This is the reason that I say, cut all the pieces out before doing anything else.

The next thing to do, is to properly plane and get out of winding one face of every piece, taking care that the edges or faces that have to have mouldings or rebates worked out of them are the best; and that the grain runs the way you wish to work the mouldings. Now square one edge, and put what is termed a tried-up mark on the face, as in Fig. 2.

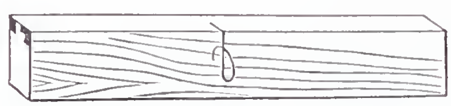

Fig. 2.—Wood for Moulding with "Tried-up" Mark on Face.

You cannot possibly get the grain always to work as you want it, but a great deal can be done with a little care.

Then again, if you get it to work right for moulding and rebating, the chances are very much against its being right for reeding. But, as it happens in this case that you can reed from either edge, seeing that the reeds are parallel to the edges and the stuff is gauged to a width, and not too wide to allow the scratch to work, it would be better to make provision for the moulding, as that can only be stuck one way. Great care should be taken that the above tried-up mark is put on every piece of stuff as it is tried up; for it not only indicates which side has been got straight and true, but shows on which edge you originally intended to work the moulding, and it is from this tried-up side that all squaring, gauging, moulding, etc., is done.

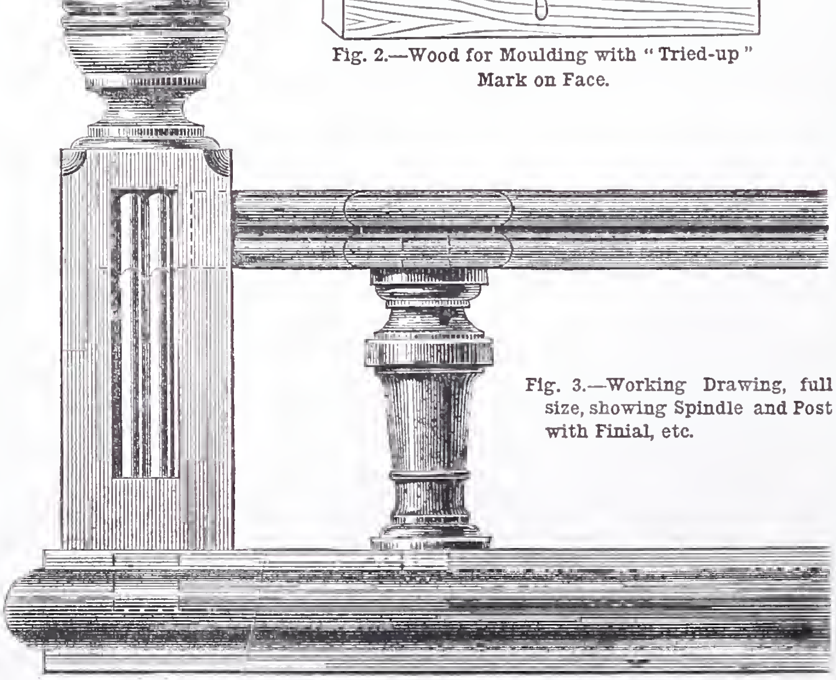

Fig. 3.—Working Drawing, full size, showing Spindle and Post with Finial, etc.

Now carefully examine the rods, and if they have been set out properly, they will at once show the exact section of nearly every piece. We now proceed to gauge the widths of the various pieces: let us take the width rod first; this will give the exact widths of all the uprights, styles, columns, posts, etc.; next follow with the height rod, and this gives the exact section of shelves, rails,

e. Each piece should be marked as it is g ıged, for instance, top rail of door—style o false back—f nt columns, e ,etc.; of course t se marks may b as brief as is c isistent with c ırness.

The front c umns, and the p ts marked A i Fig. 7, should n v be gauged to t exact thick-n ss; and, as they a square, they s ıuld be gauged v h the same g uge as the v lth before it is s fted. The small c ner posts can l got out in any l gths, and cut ı afterwards. 'is remark also a plies to the p ces for the s ndles, gallery ı ls, and termi-ı ls, or finials, at t top and bot-t n of columns. 'e shelves, up-ı hts, brackets, s les, rails, and l rs of doors, p nels, rails and ı llions, etc., of t se back should w be thick-ssed. The back umns and rails th the brackets, shown in Fig. need not be icknessed; for, they go against e wall, no pur-se would be rved.

We will now ke it for granted at every piece quisite has been auged and arked. The indles, termi-ıls, and corner sts, may now e set out and nt to the turner, e brackets sent the fret cutter d carver; for, though it is ery nice to do verything one's self, there appears to be such a great deal to do in a job of this kind, that have often noticed the interest seems to flag. This, of course, does not apply to every case. If one has a lathe and can use it, by all means do the turning at home; and again, if you possess a fret saw, the same remark holds good for the brackets. I should certainly not advise any one to cut them out with a bow saw, and spend a day in cleaning up, when the fret cutter would cut them beautifully for a few pence, and a rub or two here and there with a piece of glasspaper is all that is required.

Now set out the back, the half of which is shown in Fig. 5. This is done by laying the various pieces on the rods directly over their places, and marking the widths, etc., of the pieces that intersect them.

Next, with a mortise-gauge, gauge for tenoning and mortising the rails into the uprights, etc., but do not mortise right through the uprights. The tenons can be held in their places by screws put in from the back. The rails, C C, should run right through, having the pieces cut out as shown, and halved on to the uprights. This will greatly assist in strengthening the back until the front part is glued on. Before cutting the shoulders, work the mouldings and reeds, stopping the latter where shown. The moulding on the uprights marked D, Fig. 5, had better be planted on (that is got out separately, and glued and bradded in their place). Bore all the screw holes for screwing on the shelves, brackets, etc., likewise the tops and bottoms of uprights to take the pins of terminals. The shoulders can now be cut, and the whole thing fitted together. After comparing

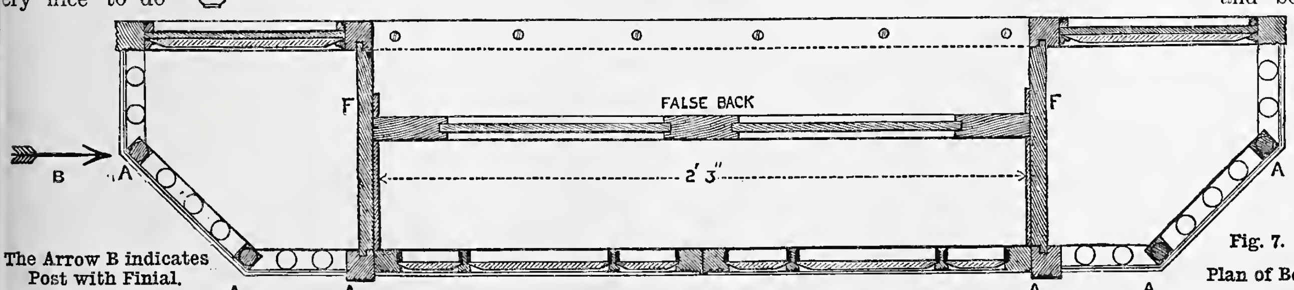
Fig. 4.—Height: Section—A, Cove covered with Stamped Plush or other approved Material. Fig. 5.—Diagram showing Method of preparing Back with Posts, Rails, etc., reeded, and Brackets fixed all ready to receive Case, Shelves, etc., dowelled and screwed on. Dotted Lines indicate Position of Shelves. (Scale, 1½ inches to 1 foot.)



The Arrow B indicates Post with Finial.

Fig. 7. Plan of Bookcase.

it with the rods, and trying a cramp across it to see if everything is all right, knock it to pieces, marking each piece as you take it apart, and stain and polish, etc., all the internal mouldings and edges that are seen. It can now be glued up and left to dry, care being taken that it is quite square and out of winding. The best way to square anything of this description is to try the length from corner to corner, and see if they are the same distance apart.

The directions taken by the rod for doing this are shown in Fig. 5.

The shelves directly above and below the doors marked E, and the uprights F in Figs. 4 and 5, should now be set out, letting the shelves, E, run by the uprights, taking notice that the shelves are wider than the uprights by the thickness of the back and front uprights. Groove the shelves to receive the uprights, and the underneath of bottom shelf to receive the brackets under uprights, also groove the uprights to receive the two outside middle shelves.

Now form the tongue on the front and back edges of the uprights to receive the front columns and to fix on to the back.

Although I show a tongue on these uprights, a cheaper and easier way would be to dowel them, especially at the back. Cut the corners off the shelves, set out and bore for the spindles, work the mouldings on the front edges, etc. (or plant them on). Prepare the two centre side shelves to match the overhanging part of shelves, E, bore for spindles and fit together, and it will then present the appearance shown in Fig. 6.

The lines of the mouldings are omitted, and the thickness of shelves and uprights exaggerated.

Now, clean off the face of the back, and fit these shelves, etc., in their places, screwing them on from the back, but do not glue them. All the rest of the work should now be got ready.

The doors and false back may now be framed up. Do not cut the bars of the doors through where they intersect, but halve them, giving the upright ones the appearance of running through. This may not at the first glance seem practical, but a little consideration will soon solve this difficulty. Bear in mind that the reeds should be worked before this is done or the shoulders cut. After fitting the doors together, take them to pieces, and stain and polish the edges, and let them stand till the last moment. The front columns should now be fitted on to the uprights, and the bottom and top shelves screwed on but not glued. Now fit in the cove. Although this is shown as if it were framed up, an easier method is to cut some rough brackets as at G in Fig. 4, and secure them to the under side of the top shelf and the back; now bend a thin board over them, and fasten it with screws, glued on and blocked from the back. Cut out and fasten and glue on false styles, rails, and mullions. Next, fit in the brackets at end of cove; these brackets should have a rough bracket fixed on the inside of them to carry the ends of cove. If the rest of the brackets are now fitted in, the whole may be taken to pieces and stained and polished on all visible faces. The cove brackets being only screwed to the rest of the work, but the thin board and the false styles, etc., being glued, will enable you to take the cove away entire, and the styles and rails can be stained and polished with the rest. For, as the panels are to be covered with plush, this will, to a certain extent, hide the inside edges where the polisher cannot get to polish.

The doors may now be glued up, and, whilst they are drying, get out the beads for the backs of the whole of the glass. Now clean up the doors; fit in the beads, which should be polished, etc., in the length before being cut (those behind the glass in the sides and bottom, of course, need not be polished). Next see that the moulding for the cornice (which, by the way, can be bought as well as the moulding round the edges of the shelves), gallery rails, spindles, corner-posts, terminals, etc., are all polished ready, and everything will be ready for fixing together. The more screwing and fitting you have done up to now, the easier you will get the whole together, for it is a great nuisance to have to bore holes or fit anything when you are gluing up.

In gluing the whole together, lay the back flat down, letting one part hang over the bench, to enable you to get a screw in here and there quickly when you put the front shelves, etc., on. Next cramp the two long shelves together, screwing the shelves up and down to the uprights. With a sharp chisel, scrape off any polish that may have run over the back edges, and also scrape the polish off the face of the back, or anywhere else where you wish to glue. Now screw the shelves and uprights on to the back, using but very little glue. Next follow with the cove, front columns, brackets, etc. The doors should now be fitted in and hung, taking care that the centres of the hinges project so that they are level with the face of the front columns, to allow the doors to open right back without straining. Next, fit in the shelves inside the bookcase, commencing from the bottom with the first piece of the linings marked H in Fig. 4, and build upwards.

As these linings also form the stops for the doors, close the doors from time to time, to see that they are all right. These side linings might run right up if desired, and not cut in between each shelf, thus saving a considerable amount of fitting where they meet in the centre and front of shelves. The shelves, in this case, could be supported on brass bookcase studs. Fit small flush bolts or any approved catch to the left-hand door, and a spring lock with fancy brass plate escutcheon to the right-hand door and drop handles, one on each door, for the sake of appearance. Hinge plates, screwed on the face of the doors, would be an improvement. Now unhang the doors, and stand them down ready for glazing, and fit and fix in the false back. The corner-posts and spindles should now be fitted in, and the gallery rails cut, bored, and fitted and glued on. It is hardly necessary to mortise and tenon or dowel these rails to the posts, etc., for, if they are fitted in tight and glued, a small pin driven in from the top will hold them. The bookcase is now ready for glazing. The plates of glass should be all blackened with a little size and lampblack on the edges along with the rebates, to hide the ragged edges. Two slips of baize glued on the front of backboards will prevent damage to the silvering. Next follow with the plush in panels of cove. One of the safest ways of fastening this to the panels is to glue the panels carefully with thin glue, and, just before it loses its stickiness, lay the plush on, patting it down with a soft brush. If the plush is put directly on to hot glue, the glue very often comes through and spoils the plush. Strong glass plates may now be screwed on to the back for fixing, and all that remains after glazing and rehanging the doors is to glue in the terminals to the front and back columns.

Although the above remarks are not written for the thoroughly practical mechanic, I have taken it for granted that any one who would commence to make a piece of furniture of this description at least understands a working drawing, and can use the ordinary bench tools.

PLAIN AND DECORATIVE HOUSE PAINTING.

BY A LONDON DECORATOR.

MIXING OIL PAINTS AND COMPOUNDING TINTS AND SHADES OF COLOURS FOR PRACTICAL USE.

THE chapters hitherto contributed to the pages of WORK upon this popular subject have necessarily been of that elementary nature which may not equally command the interest of professional and occasional workers in paint alike. It can scarcely be expected that the amateur—who is only desirous to know how, at the least cost, he may make wholesome or how embellish his own little "castle"—will consider it necessary to master such detail of "source and nature" to the fullest extent, and with the same painstaking effort, as it is most necessary the rising apprentice or improver to house painting should so do. The reader who may have "scamped" my previous explanatory papers, and yet desires to make practical use of the "working" ones, will, however, doubtless soon be turning up back numbers, since each forward movement we now make will prove the knowledge contained therein to be the only foundation the painter can with confidence and security work upon.

In preparing oil paint, for whatever purpose it may be required, the first question to be considered is the nature of the surface to be painted, whether of wood, stone, or metal, and to what degree it is absorbent. Second to this only, we must remember the conditions of circumstance and position of our work, such as refer to expense, durability, and drying qualities; and lastly, we have the all-important matter of appearance and colour to bear in mind, whether our paint is for the first or last coat. We will therefore proceed to an imaginary mixing of paint for these different substances, bringing in therewith a lesson on their application to the walls and woodwork of a building.

Let us suppose, for the purposes of this practical lesson, that you, my reader, are the fortunate possessor of a small modern (but not jerry) built villa-residence, and that the builder employed has just completed, according to his specification, an addition to your house in the shape of a billiard-room. Furthermore, let us suppose that the apartment is principally lighted by a ceiling light; that the remainder of ceiling and the walls have been plastered with the usual finishing coat of lime-putty and plaster; that the enriched plaster cornice which frames the ceiling is of fine plaster, and the skirting and reveals of recessed windows are of Keen's or Parian cement; that the side windows are glazed with combined English sheet and ornamental coloured glass; our doors are hung, and of well-seasoned wood; and that, finally, reader, I am going to paint it in a temporary but comfortable style for you, leaving for the future its permanent decoration, which, with the whole of your villa, we hope to undertake together later on.

"But how about the tools?" may be your first inquiry. As, however, you will, for the esent, but stand by and watch the worker, e can afford to have a special talk about em alone, confining our present remarks id attention to the mixing and suitability paint and colour, not only for this billiard-om, but for any other part of the house.

All our plaster work being thoroughly dry, e have decided to finish it in oil paint, ith the exception of the ceiling, which we iall distemper: that is, coat with water, or ze, colour. The plaster cornice, with its ist enrichment, is the most absorbent por-on; next to this comes the wall space, hich the trowelling to its surface has made ither less "thirsty." The skirting, etc., iade from Keen's or Parian—which are hite and "hard-faced" cements—if well nished off, will absorb but very little oil, nd therefore must be treated accordingly.

My first aim is now to stop the "suction" f cornice and walls before getting an in-rustation of lead paint upon its surface, nd to that end I break up genuine white ead and the best "patent driers," in pro-ortions of about fourteen to one respec-ively, with a small wooden spatula or flat-haped stick. Notice how, with a little raw nseed oil, I first get it to a thick batter, nd then, when well broken up, I make it o the very thin working consistency which ur first coating requires—of not more than our pounds of lead pigment to one pint of aw oil. As some of our cornice is rather laborately cast, I thin a part of this paint vith still more oil, and proceed to first coat he cornice only. In painting this portion, take every care not to break the delicate laster work, using light and suitable-sized aint tools to enable me to coat both re-essed and prominent parts.

Here, perhaps, you may remark, "Why iot use the same paint and cover the wall s far down as you can reach at the same ime as the cornice?" To which I reply, xplaining that "even then I could not each to such a height from the floor, whilst he plaster on your walls being well pre-ared and trowelled, I expect to use the aint slightly thicker—or 'rounder,' as it is alled in the trade—with advantage; and, urther than this, that a full-sized paint-rush will be necessary to spread it over a arge plain surface, whilst it will be advis-ible to strain my paint through a wire gauze aint strainer or piece of muslin before ising it on walls or woodwork."

I now carefully work the paint through he strainer into another vessel with an old aint tool, and, meanwhile, explain how it s nearly always necessary to previously xamine the walls and pick out the little listers which have formed on the face of he plaster, and then to well wet the lamaged place with water and make good vith plaster, but which is not necessary in his case.

Now, you having, like a good, sociable ellow, helped me to lower my plank a ouple of steps, so that I can reach half-vay down from cornice to skirting, I mount ny little scaffold, and once more start.

I first take a piece of partly-worn glass-aper, fine or middle 2, and lightly rub over he wall as far as my plank carries me; hen with a dusting-brush and downward novement, remove any dust which has ac-umulated thereon. With a full brush of olour I now make a start from the right-iand extremity, and, working towards the eft hand, cover about a yard in width at ach shift. Carefully note, my friend, how, fter taking a good dip of colour, I gently lraw the brush against the side of the paint-ot, and then carry the colour to the wall with an up-ended movement, and by which simple details I avoid wasting much in transit. See also how I spread each of these brushfuls of colour with a long up and down movement, about six inches apart, and then, when they extend about three or four feet in width, how I spread it evenly over with a repeated cross-brushing action. Now it is roughly distributed, but not sufficiently fine, since the marks of the brush-hairs show very distinctly; it there-fore has to be gone over again with the brush, but no more colour, first with the perpendicular, and then with horizontal brushing, and with a lighter hand each time, so that now, having finally drawn the tip of the brush down the work, starting each movement from the top and working across it still from right to left, we find the marks of the brush are not noticeable—in short, that the paint is properly "laid off." The pot is now shifted a little to the left. I again commence with laying on brushfuls, and spread and lay it off as before, until the top of one side of the wall is covered. I now descend and paint the lower half in a similar way, save that in the final laying off I finish with a light *upward* movement from skirt-ing to the join, whereby all sign of the latter is removed.

All house painters do not spread colour on this simple but regular plan, but for good and tradesmanlike work it cannot be excelled, and is far preferable to any hap-hazard system—or, rather, want of system —we often may see in vogue even with pro-fessed workers.

Our painted walls must now stand for at least a day, and, meanwhile, we turn our attention to the woodwork. This, by ar-rangement with the builder, has been left in the white, or plain wood, with the excep-tion of the sashes and window frames, which have to be primed before being glazed, and protected from the ill effects of wet weather before fixing.

Paint is something like charity in one re-spect—it covers a "multitude of sins;" and its absence on our principal woodwork has required good and well-finished doors from the contractor—which isn't always the case, even if paid for! The sooner, however, we get a coat of priming on new woodwork which is to be left in paint the better; so, after touching over any knots in the wood with one or two coats of quick-drying "patent knotting," and which article prevents the resin exuding and discolouring the work, I take some of my thin oil paint as used on the walls, and adding to it sufficient dry red lead to make it a full pink colour, prime the new woodwork. As with the wall, so with the woodwork—I first lightly rub it down with glasspaper, and carefully dust the work. Note that I paint first the edge of the door and panel mouldings, then the panels themselves from the top downwards, and finish off with the styles between panels, the top, lock, and bottom cross rails, all brushed in the direction of the grain, laying off, last of all, the outer rails, which reach from top to bottom of the entire door. Careful spreading and systematic working are just as necessary for woodwork as for wall, but whilst the latter is always laid off with the up-and-down movement, the former is finished with the grain of the wood.

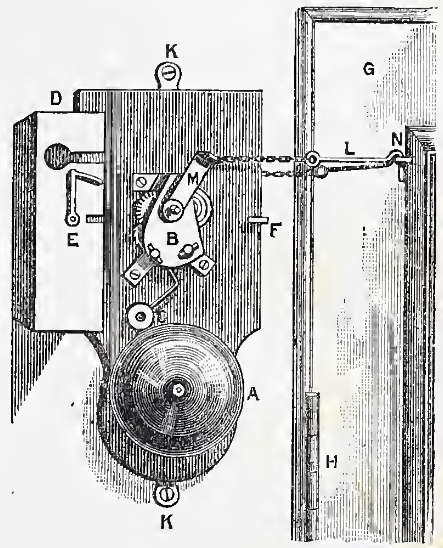
The first, or *priming*, coat being now completed to our satisfaction, we proceed to the second coating; but the consider-ation of this, through want of space to deal with it now, must be left for another chapter.

OUR GUIDE TO GOOD THINGS.

**** Patentees, manufacturers, and dealers generally are requested to send prospectuses, bills, etc., of their specialities in tools, machinery, and workshop appliances to the Editor of WORK for notice in "Our Guide to Good Things." It is desirable that specimens should be sent for examination and testing in all cases when this can be done without inconvenience. Specimens thus received will be returned at the earliest opportunity. It must be understood that everything which is noticed, is noticed on its merits only, and that, as it is in the power of any one who has a useful article for sale to obtain mention of it in this department of WORK without charge, the notices given partake in no way of the nature of advertisements.*

118.—Galley's Patent Detective Alarm Bell.

The simplicity of the Patent Detective Alarm Bell, invented and recently introduced by Mr. A. R. Galley, of Torquay, renders it a desirable means of protection for tills, and a safeguard against burglarious entrance by door or window, for all who may not care to be put to the trouble of managing and maintaining a battery suited for putting in action an electric alarm. The entire appliance is well made, and presents a neat appearance, being similar, as far as outward look is concerned, to the electric appliances just



mentioned. The bell, A, is fixed to the lower part of a baseboard, as shown in the illustration, and the mechanism, B, by which the hammer, c, is actuated, is placed above it. The works, so to speak, are covered in by a casing, D, which is attached to the baseboard by brass hooks, E, which fasten into eyes, F, one on each side. This case is shown turned on one side in the illustration in order to display the works. To make the way in which the alarm bell is to be fixed and used perfectly clear, when attached to doors it may be said that G is the upper corner of a door on the side on which it is hinged to the adjacent jamb, the top hinge being shown at H. The alarm bell is fixed to the casing of the jamb if wide enough by screws passing through glass plates, K K, screwed to the back of the base-board, or, if not wide enough, to the wall by brass-headed nails. The wire hook, L, and the chain intervening between it and the lever, M, the chain and wire working freely through the hole and slot shown in the casing, D, should then be drawn out quite tight, bringing the lever, M, into the position shown. The hook, L, is then inserted into an eye, N, put into the door at such a distance as will allow the chain and wire to be kept as tightly strained as possible when the door is closed. On any attempt to open the door, the tension on the wire is relaxed, and the backward motion of the lever, M, sets the bell ringing. For windows the bell must be fixed at the top, and a sufficient length of chain or wire added to allow of the insertion of the hook in the eye, which must be fixed in the bottom sash. On testing the alarm I have found its action to be very satisfactory. THE EDITOR.

SHOP:

A Corner for Those who Want to Talk It.

NOTICE TO CORRESPONDENTS.

*** *In consequence of the great pressure upon the "Shop" columns of* WORK, *contributors are requested to be brief and concise in all future questions and replies.*

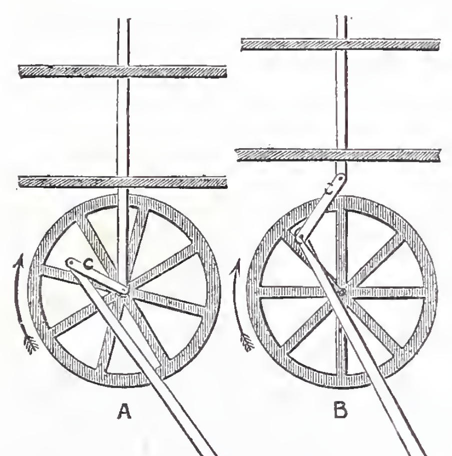
In answering any of the "Questions submitted to Correspondents," or in referring to anything that has appeared in "Shop," writers are requested to refer to the number and page of number of WORK *in which the subject under consideration appeared, and to give the heading of the paragraph to which reference is made, and the initials and place of residence, or the nom-de-plume, of the writer by whom the question has been asked or to whom a reply has been already given. Answers cannot be given to questions which do not bear on subjects that fairly come within the scope of the Magazine.*

I.—Letters from Correspondents.

Boot and Shoe Making.—W. S. (*Bury*) writes in sequence to LEATHER (see page 492):—"I am sorry you have decided not to say anything about shoe making. I have been a subscriber to WORK ever since it came out, and have derived great benefit from it. Though many would be inclined to mend their own boots, I don't think any would try their hand at tailoring or hatting. I am a married man with five children, and find it very expensive to keep all in clogs and shoes. I am able to sole my own every-day boots and clog my children's clogs, but am unable to tackle a Sunday pair to do them to look to my satisfaction, and I think if you could kindly undertake to give a paper in WORK on the subject you would confer a favour on me and a great many of your readers, because I know lots in the same predicament as myself. I sometimes hear you say 'get some tradesman to help you,' but that is rather difficult. Tradesmen don't care about you knobsticking and taking away their trade to their loss and your benefit. I have been trying several months to get some one to show me how to put a bristle on a wax end, and only managed the other day from some one not in the trade. I hope you will excuse this trespass on your time, and trust you will be able to give a few words on the subject, because there are lots of wrinkles it takes an amateur a long time to find out by himself."

Printers' Varnish.—J. W. H. (*Newington Butts*) writes:—"Messrs. Stanbury & Co., West Harding Street, London, E.C., inform me that they will supply small quantities of ink to amateurs in 2-oz. tins, and upwards, at their list prices, of any colour or shade, varnish also; and will send list free by post on application. They fully confirm our statement as to the danger of burning oil, and further inform us that any one attempting it within a certain distance of London is liable to imprisonment."

An Easily-Made Fret Machine.—H. W. (*Gateshead*) writes:—"In reference to an easily-made fret machine described in WORK by W. R. S. (see page 332), I notice that it is a bit of a puzzle to many readers as it was to myself. I found that the principle was right, but the drawing misleading, as to look at it you would think it would work like A in the enclosed drawing instead of like B, which, I think, W. R. S. means. I hope this will assist the puzzled ones, as with no disrespect to W. R. S., I might say that if this is not correct my machine will be wrong (not like his), for I have

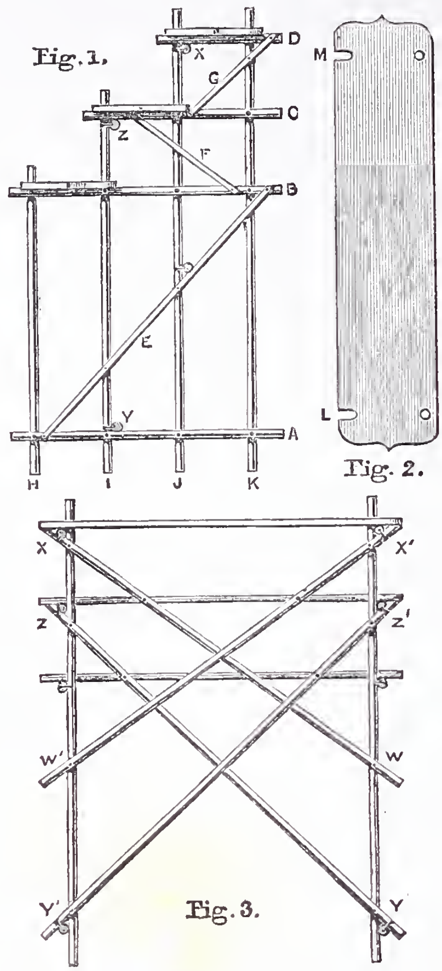


Easily-made Fret Machine.

made it like B, and find it works beautifully. I forgot to state that the throw of the machine is not measured from centre to centre of G, as W. R. S. says, but from centre of wheel to centre of crank, where it is connected with wheel."

Gas Meter Index.—E. L. F. (*Oxford*) writes:—"If you refer to WORK No. 34, November 9, page 541, second column of 'Shop,' I think you will find a slight mistake. In the letter to H. N. (*Chelsea*) 'How to Read the Index of a Gas Meter,' it is put in brackets 'bear in mind that it would have to go right round to be 1,090,' which should be 1,000. I think, instead of 1,090."—[Thank you for correcting the misprint.—ED.]

Bamboo Flower Stand for Window.—J. P. A. (*Walthamstow*) writes:—"Some time ago I, in a rash moment, offered to send a description of a flower stand I had made out of canes (garden canes I suppose they are called, as they are sold for the purpose of supporting flowers, etc., and can be



Bamboo Flower Stand for Window. Fig. 1.—End View. Fig. 2.—Shelf. Fig. 3.—Back View.

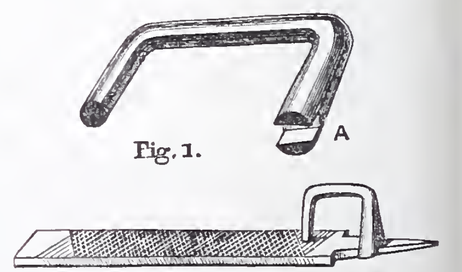
bought at seed shops, and I have seen them in oil shops). But since making that offer there have appeared several complaints about descriptions of various things not being clear enough to work from, and I have been on the side with those who have complained sometimes, though I have said nothing. Now, however, I see the difficulties of making everything quite clear when it has to be done in writing, and would suggest that you request those who cry out loudest to set to and give a description of something they have made or know well how to do. Those who now go in for a little bamboo work will not be in the same fix as I was, for I see the promised articles are commenced, and will certainly be a great help. I had decided to make some sort of a stand to put some flowers on in the window, but had not settled what it was to be, when coming across some canes I was surprised at their strength and lightness, and set about trying what could be done with them. I got a dozen about $\frac{3}{4}$ in. diameter for 9d., and a dozen $\frac{3}{8}$ in. diameter for $4\frac{1}{2}$d.; then sketched out the ends as shown in Fig. 1, and then decided on the sizes; the front shelf was put low enough for a 5-in. flower pot to be out of sight from the street; the others rise 6 in. The stoutest canes were used for uprights and horizontal pieces, and where they cross I filed notches in the uprights, and fastened them together with screws; the $\frac{3}{8}$-in. canes were used for diagonal pieces, and were let into the horizontal ones just through one side. I tried several plans to get the holes in at the proper angle, and thought I would have to give it up, for the cane split with drill or bit, and a knife or file seemed slow work. I then tried a piece of $\frac{5}{16}$-in. round iron, red hot, with a hole at the required angle, and just a fit (when the charred part was cleaned out), for the $\frac{3}{8}$ in. cane could be made. This tool is not mentioned by D. D.—perhaps he will give it a trial when a hole is wanted at an acute angle in a piece of bamboo—for though a rather primitive method of making holes in wood, I feel convinced that it is better than the ordinary boring tools, and much quicker than a knife or file for cane. Perhaps it will be best to give the lengths that suited my purpose, then others can suit their own. For the two ends four pieces were cut 22 in. long; they are for A and B; the two pieces for C are 16 in. long; and two, D, are 10 in. long. Then the four uprights, J and K, are 3 ft. long, and the two for I are 2 ft. 6 in. long; the two for H are 2 ft. long. These were then laid out as shown on Fig. 1, and the position of the holes for the diagonal stays marked and bored with the hot iron. The stays were then put in the holes, and all the lot fastened with screws. Having got the two ends made, the three shelves are next wanted; $\frac{1}{2}$ in. stuff $7\frac{1}{2}$ in. wide was used, and holes put in them a good fit for the cane; the top shelf can then be put on, but to get the other two on a piece must be cut out of the side, as shown at L, M. When the shelves are on, the stand will be pretty firm, but to make it more so, stays were put from W and W', to X and X', and from Y to Z; these pass the back of the shelves, and are screwed to them. The job is done, except the ornamenting of it, and the articles that are appearing will, I expect, give much better instructions than I can."

Linoleum Tiles for Roofing.—J. W. H. (*Newington Butts*) writes:—"In this connection Messrs. G. Glanvill & Co., Roupell Street, Blackfriars, S.E., write to me that they have a large accumulation of cuttings of well-seasoned, best quality linoleum, which they would dispose of very cheap, suitable for cutting up into tiles. They would also supply tiles ready cut, 13 in. by 6 in., 8s. 6d. per gross, or 9d. per dozen; 9 in. by 6 in., 6s. 6d. per gross, or 7d. per dozen; and 4 in. by 6 in. at 2s. 9d. per gross, or $3\frac{1}{2}$d. per dozen; or cut to other sizes to order at proportionate rates. Any readers at a distance should, of course, remit cash with order. With such material a roof with an occasional coating of oil would last many years."

Vulcanite.—RAPIER (*Edinburgh*) writes:—"In a recent number of WORK I noticed a paragraph on the casting or pressing of vulcanite in plaster moulds, which were then subjected to a heat of 310° Fahr., and continued from seventy-five to ninety minutes, being enclosed in metal cases during the process. Now this at once places it beyond the reach of any but the professional to mould in vulcanite, and I should like if some of our readers would inform me if this casting or moulding of vulcanite could not be done during the process of vulcanising, and also inform us if this making of vulcanite is a trade secret. I understand it is a mixture of india-rubber treated with sulphur. Will some one kindly explain the process, and tell me how to mould small articles in this material, or refer me to any work for the information? I have got a piece of black vulcanite, but I can make nothing of it, except by turning in the lathe, and this does not suit, as there is a great waste in turnings."

Mail Cart Wheels.—The Victor Cycle Company write:—"In your issue, No. 34, under 'Shop' heading (see page 540), you gave the addresses of firms in the North of England from whom mail cart wheels are obtainable. We beg to say that we supply a superior pair, $23\frac{1}{2}$ in. rubber tired wheels, brass caps, good axles, washers, pins complete, at 5s. 6d., and believe they are the best value in the market. Ours is a convenient town for people to obtain from who are near the east coast. We notice firms you mentioned are situated near the west coast."

Handy File Holder.—WORKER BEE (*Hertford*) writes:—"I have taken the war-path of criticism again, and wish first to deal with the handy file holder described by J. C. K. on page 554 of WORK. The illustration given by him does not coincide with the letterpress description, nor does it give a clear idea of the utility of this tool to many



Handy File Holder.

who have not seen it in use. I have given a rough sketch of mine, which I made fifteen years ago when I worked in a large erecting shop where there were scores of them in use. Fig. 1 will show that the slot at A should be cut the same taper as the tang of the file, and not as shown by J. C. K., or you create a difficulty when, having worn one side of your file, you wish to reverse it to use the other. Fig. 2 I have given to show that a file can be used on flat surfaces of metal by the aid of this handy file holder, much as a plane can be used on wood."

—QUESTIONS ANSWERED BY EDITOR AND STAFF.

Taking out a Patent.—M. T. (*Brighton*).—A per on the above subject appears in WORK, No. 35.

Aquarium.—J. F. (*Portnall Road*).—The best aterial for the bottom of your aquarium will be te cut to measure after glass is fitted in—the te should be not less than ½ in. in thickness. The ater of the aquarium, when quite full, will weigh near as may be, 190 lbs.; add the weight of your aterial to this, and the result will give the weight the whole. I know of no special appliance for ling, but for emptying use a siphon pipe, which u can make by bending up a piece of compo pipe, a piece of stiff rubber tube will answer equally ell.—C. M. W.

Small Fountain.—B. T. (*Netherton*).—If you ant to keep your fountain going for so long a me as eight or nine hours, I would recommend u not to use springs, weights, or pumps, as you ould find either of them clumsy and laborious. our better plan would be to connect your aquarium your water supply, and the overflow pipe to the rain; but if this course is inconvenient you could rect a tank at a higher level, connect with quarium, catch the overflow in a vessel, and re-urn it to the tank. But why not be content with e fountain playing, say, one hour at a time? You ould then rig up a small tank to hold, say, a couple f gallons, suspend it over pulley wheel to ceiling, nd with a cord run it up as often as required, aking the connection to aquarium with flexible ubing, catching the overflow in a can, and regu-ating the height of jet by the height of your sus-ended tank above aquarium.—C. M. W.

Plumbing: Making Joints.—P. B. (*Pendle-on*).—You say that you are "a plumber's appren-ice, and want to learn how to make joints." The peration is described in a paper "On Soldering oints in Metal Pipes," which you will find in page 03, *et seq.* in No. 32 of WORK.

Steel and Florentine Bronze.—J. L. (*Glas-ow*).—I regret that it is not in my power to give an ntelligible or satisfactory answer to the query especting Florentine bronze. In conversation with a gentleman, who had spent some considerable ime in a large works in Birmingham a few years go, where candelabra, figures supporting lamps, etc., were made in Florentine bronze, I have learnt that this class of work was cast in what he termed stannate metal, which is of a leaden colour, and cheaper than brass. The casting was first coated with copper by electro-deposition, a dynamo supply-ing the necessary current; after this it was brushed over with some kind of bronze solution, and pro-minent parts of the surface were rubbed or burnished to give the effect of light and shade, and relieve its uniformity as suited the taste of the worker, who was a Frenchman, and very particular as to those he admitted to his workshop, the whole process being treated as somewhat of a trade secret. Evidently it requires costly apparatus and special qualifications to carry out the process.—T. R.

Bending Angle Iron.—(*Birmingham*).—The best method of bending or cranking angle and tee irons—if there are a great number required—is by pressing them in dies under the hydraulic press, but for a small number it would not pay to make the dies, and in such case you have no alternative to drawing it over a block. Some of the Welsh smiths are very clever at this work, and bend the iron without losing any of its strength.—F. C.

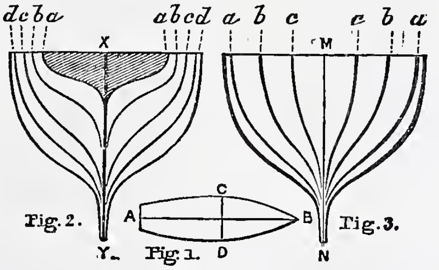
Printers' Varnish.—DURHAM.—The manufac-ture of varnish is not an operation that can be performed successfully without experience and without the necessary appliances. Messrs. Flem-ing, Caroline Park, Edinburgh; or, Mr. Horsell, 47, Meadow Road, Leeds, would, no doubt, supply a small quantity by parcels post, if applied to.—J. F. W.

Book on Loom Pattern Making.—J. P. H. (*Glasgow*).—A work on this subject is "A Practical Treatise on Pattern Making" (7s. 6d.), Lockwood and Co.—F. J. C.

Blackboards: How to Paint.—J. F. K. (*Car-diff*).—This question, or a very similar one, has been answered very recently; but as the subject appears to be one of more than individual interest, I append the best method for preparing and finish-ing new school blackboards. The board being quite smooth and well papered down, it must be painted with not less than three coats oil paint. The colour or shade is immaterial for the first two, but the last coating must be finished dark-lead colour, or with common black paint. You now procure ivory drop black, ground ready in turps, and mix with it some good oil varnish; best copal or carriage is as good as anything, and further dilute to working consistency with turps. The finishing black will dry hard in a few hours, and it should be without glass, otherwise the chalk will not bite on it. It would be best for a novice to try his black on the edge of a board and get it right for use, and aiming to get a good body of colour on, and for it to dry dead. The more varnish used the more gloss results, and, of course, *vice versâ.* Respecting your last item, I should say yellow pine before anything else. I might also note that an extra glue joint is better than using very wide stuff, and if you run a ¼ in. groove at each end, ¾ in. deep—across the grain of the wood this will be—and fill in with pieces of hoop iron of similar dimensions, you will get a good and lasting job I think.—W. P.

Working of Heating Apparatus.—THE BEADLE.—If the apparatus is made to work there must be two pipes from the boiler to the tank to secure circulation, one for the hot water to ascend, and the other for the cooler water to descend to the boiler, and be reheated. You regulate the heat by increasing the rapidity of the circulation, which depends upon the rate of firing. You need not be afraid of explosion, as your tank is open to the atmosphere; this tank, I presume, is self-feeding, with a ball-cock arrangement to prevent waste. The turncocks are for running out the apparatus to clean it, for otherwise the pipes and boiler would get choked up with sediment or scale according to the quality of water you use. A gauge would be of no use to you, but a thermometer in your tank would show the lowest temperature of your water, which should not fall below 100 degrees if you have to keep the church at 60 degrees, and then you must keep the doors shut. The supply of circulating pipes appears to me very scanty, and if the boiler is not tubular you will have great difficulty, unless it is a very large one, in keeping up the temperature to the point mentioned.—F. C.

Model Yacht.—MEDICAL (*Cambridge*).—Pre-suming that the sections which MEDICAL has are those of a cutter model, he should work from the following lines. Fig. 1 represents the deck plan, A, B being the centre line, and C, D the line amid-ships, which line should cross the beam or broadest part of the hull. Fig. 2 is a section amidships, with X, Y, sternpost, which, with the two sections *a* and *b*, are the only lines MEDICAL has to work from. There being no mathematical rule for arriving at the correct curves for the various pairs of ribs, the only way of proceeding is to decide on the shape of hull you intend working from, and to mould your



Model Yacht.

ribs to fit accordingly. The first pair for a cutter should be bent to the form of section *b*, Fig. 2, the second pair as section *c*, and the third as section *d*. If the lines are intended for a schooner model, the greater proportion of the length to the breadth of the hull will necessarily make the curves of the ribs less full than those of a cutter, but in all other respects the same lines will do for either. The above lines are the only ones for which MEDICAL asks, but I take it that he also requires the inter-mediate curves for the ribs between the beam and cutwater, which are shown in Fig. 3, M, N being the cutwater, and the thick curves section at beam. The ribs should be at intervals of ⅙ of the length of the hull, although if the model be a very large one, it will require the ribs to be placed closer, and of course a larger number of them, but this can easily be deduced from the above diagrams. I should warn MEDICAL, however, that he has chosen the most difficult way to build a model, and unless he is proficient in this kind of work, he will succeed better in one of the simpler methods.—G. J. E.

Bunsen Battery for Electric Light.—A. H. T. (*Padiham*).—As the voltage of 5-candle-power in-candescent lamps varies from 5 volts to 65 volts, it follows that I cannot answer your questions satis-factorily, since I do not know the voltage of your lamp. The number of Bunsen cells required to light a 5-c.p. lamp will depend upon the voltage of the lamp. If an 8-volt lamp, then 4 quart Bunsen cells will be enough if arranged in series. Find out the voltage of the lamp, and divide the figures by 1·86; the answer will give you the number of cells in series required to light the lamp.—G. E. B.

Magnetising Steel Articles.—ANXIOUS (*Liver-pool*).—See reply to V. R. (*Liverpool*) on Demag-netisation. Wind five layers of No. 18 cotton-covered copper wire in a hollow bobbin, having a thin papier-mâché tube for a body, and fill this with the steel articles to be magnetised. Send a current from 4-quart Bunsen cells through this coil, and proceed as advised to V. R. for mag-netising his bars.—G. E. B.

Steel Castings.—T. T. (*Newport*).—You will not get any information as to the making of steel castings from books, nor from any source except that of actual occupation in a steel foundry. This branch of trade is very exclusive. The making of good steel castings lies in the hands of a few firms only, who having achieved success through many failures, are jealous of giving others the benefit of their costly knowledge. Hence neither employers nor workmen will reveal their trade secrets, and those who, like the writer, have been permitted in the way of trade to observe the methods and processes followed in the steel foun-dries, feel bound in honour to say nothing. To understand steel moulding you must obtain work in a steel foundry, a difficult thing to do unless you know some one who might assist you in this respect. In reply to your other specific queries: The differences between moulding in iron, in steel, and in malleable iron are—steel has to be run at a much higher temperature than cast iron, and the moulds are, therefore, more refractory. Ganister is used, and ground crucibles, and they are faced with a tarry mixture, and dried so hard that you can stand upon them without breaking them, a thing impossible in green or dried sand moulds for iron. Then to prevent honeycombing, the castings are poured with large "heads;" and to prevent fracture due to the much higher percentage of shrinkage in iron than in steel, all sharp angles are avoided, curves, hollows, and brackets being inserted, whether required in the finished casting or no. The castings are annealed in malleable iron; the moulds are the same as in cast iron, but the castings are not poured from grey iron, but from white which contains no graphite, and the runners are not round, but flat and thin, to prevent shrinkage and fracture in their vicinity. After the castings are made they are decarbonised in pots, in contact with hematite iron ore. In malleable cast-ings the metal is melted in cupolas; steel is melted in pot furnaces, or if in large quantities, in the Bessemer converter, or more usually in the Siemens open hearth furnace. The composition of Sheffield ganister is as follows:—Silica, 89·01; alu-mina, 5·44; ferric oxide, 2·65; lime, 0·31; magnesia, 0·17.—J.

American Clock Cleaning.—A LOVER OF "WORK" (*London, E.C.*).—See that the balance swings perfectly clear of everything, that the pin working in the notch of lever when passing in or out of the notch is quite clear, that the scape teeth falls fair on the square, or dead part of the pallets, that it is quite in heat, and swings nearly a turn; if more it will strike the hanking, and so gain; if less it will vary; you will probably find that one or other of the above is wrong; see also that hair-spring is free between the pins or loop. I am rather afraid you have not got it in beat, and that it swings round and strikes the banking. Listen, and if it gives a kind of double tick, that is the cause. To put it in beat, take the power off scape wheel, and when the balance is at rest, the pivot of scape wheel, the balance pivot, and the pin in the notch should be exactly in line. See also that all pivots and scape teeth are oiled, but not the pin working the pallets. If no better, write again.—A. B. C.

Screen Escritoire.—F. A. F. (*Islington*).—With reference to your query for the screen escritoire, if the American white wood be the sort I know by that name, I think wood ⅝ in. thick would suffice for the sides. For the two long feet that keep the whole structure steady it is hard to give dimensions. I feel inclined to advise you to make them just as long as you can without giving an unsightly ap-pearance to the whole thing, or making the feet project so as to bring disaster upon unwary passers-by. In the original which gave the motive for the adaptation, the one weak part was this that you have noticed. I feel inclined to repeat the advice of a bookcase backing it, for if any one knows a heavier thing in nature than three or four shelves of ordinary literature, whether theology or fiction, they carefully guard the miserable secret.—G. W.

Overmantel, Dimensions of.—F. J. W. (*Wal-lington*).—The measurement given for the over-mantel, 4½ in. inclusive, is correct. If F. J. W. will try the width, he will see that 7 in. would be much too heavy. The design being in exaggerated perspective conveys a slightly untrue effect, for I have the structure in daily use, and can endorse the figures given. The shelf, marked K, is rounded on its under edge because it projects (which the others do not), and is a finish to the whole thing. Certainly add back to the cupboard. I rather object to doing so for the under portion as well, but it is of small moment. The effect of the whole is more pleasing than it appears in the engraving, where effect was sacrificed for clear explanatory diagrams. The bric-à-brac, which the engraver added, is also a wonder and a wild surprise to the designer, who certainly intended to suggest genuine native pottery—not the Lowther Arcadian horrors which somebody has substituted. But these groans only escape to show that even those who make the designs find the interpretation not quite clear, so can readily sympathise with outside queries.—J. G.-W.

Area of Ball.—FABER.—I suppose you require the surface of the ball: it is found by multiplying the square of the diameter by 3·1416; thus if the ball is 3½ in. diameter, its surface is $3·5 \times 3·5 \times 3·1416 = 38·4846$ square inches.—F. C.

Loose Spokes in Bicycle Wheels.—CARPEN-TER.—The four spokes are probably stripped in the screw. Repairers have a trick of hammering the screwed part of a spoke on an anvil, thereby flattening the end and broadening the screwed part, which often makes it take a hold in the hub, but it is a clumsy expedient and a lazy one. The proper way is to put in such spokes a size thicker, with the holes in the hub tapped afresh one size larger, or spokes the same thickness, but with the ends butted or thickened to screw a size or so larger than the old ones; or, if the screwing in the hub is uninjured, new spokes of the same thickness as the old ones will do. There is a small tool called a spoke grip sold by all the cycle dealers and makers for about 1s. 6d. This tool will screw or unscrew any size of spoke.—A. S.

Some Facts about Mahogany.—H. H. (*Liverpool*).—I am glad you liked Mr. Denning's paper on this subject. I daresay he will furnish similar articles on other woods used in cabinet making before long.

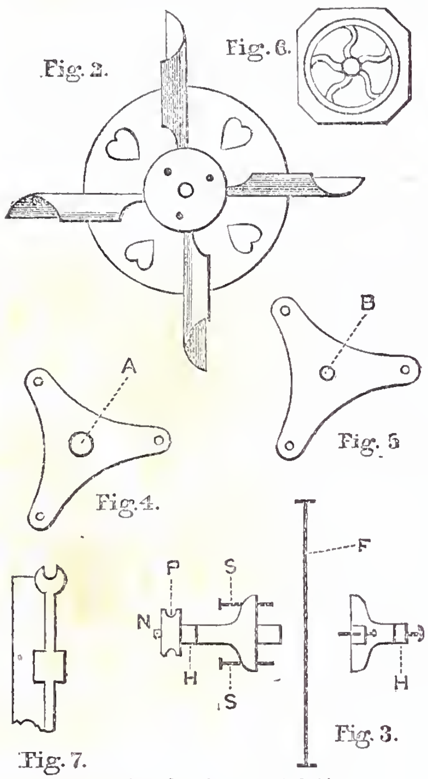
Numbers in Volume of WORK.—CARPE DIEM.—There will be fifty-two numbers in each volume of WORK.

Cheap Camera.—CARPE DIEM.—The camera you mention is good value for what is asked for it.

Honey Extractor.—J. J. BEE.—Your query relative to a honey extractor has been answered. There will be a paper on construction of apiarian appliances by-and-by.

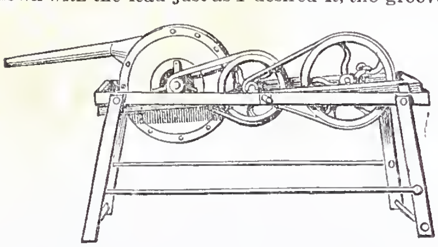
IV.—QUESTIONS ANSWERED BY CORRESPONDENTS.

Machine for Current of Air.—CABINET MAKER (*Allendale*) writes in reply to BELLOWS (*Gloucester*), (see page 109):—"I enclose sketch of machine of my own invention which BELLOWS may easily make, as I found little trouble with it. The machine complete, as shown in Fig. 1, is 2 ft. 4 in. long, 8 in. wide, and 17½ in. high. Fig. 2 is a tin fan or blower, Fig 3 is axle of blower made of wood with brass hoop on each end, H; P, pulley fixed with half round-headed screw nail, N; S, screws to screw wood axle together after fan is fixed between; F,



Machine for Current of Air.

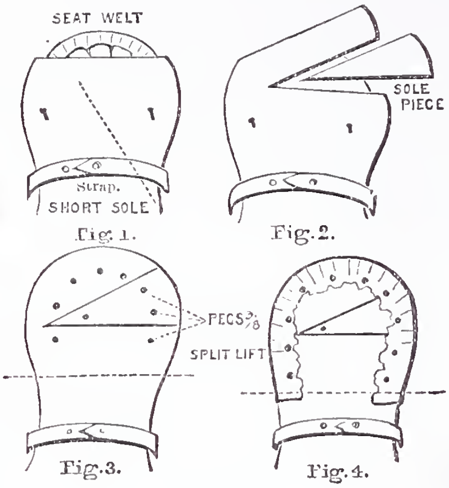
fan. Figs. 4 and 5 copper bearings for fan axle; hole, A, to receive hoop on fan axle on side next to the pulley; hole B, to receive half round-headed screw to screw in and answer as axle to run on. I made my wheels of lead and zinc, half and half, with brass centres cast in them. I made my moulds of wood, as in Fig. 6, so as to have only one side to dress, and the groove to turn out for belt. The moulds being of wood permitted me to turn wood down with the lead just as I desired it, the groove



Machine for Current of Air complete.

as shown in Fig. 7 being turned out last. It will be seen in Fig. 1 that the frame in which fan box and wheels are placed is working on two thumb screws, which pass through sides of the stand, to which fan box, etc., is fixed, so that the fan pipe can be lowered or raised to suit any height of fire as may be required, the thumb screws when screwed tight holding it firm to position required. The fan box is of sheet iron, 10 in. diameter inside by 2½ wide, fan or blower running at the rate of 2,560 revolutions per minute, the frame of 1 in. wood with stout ends to prevent warping; the stand of ¾ in. iron. The whole is painted in five colours, which makes it handsome enough to stand in any room. Should BELLOWS want more particulars I shall be glad to assist him in any way I can, or should he care to buy it I can sell it cheap, as it is perfectly new and of no use to myself. I only made it to keep my hand in."

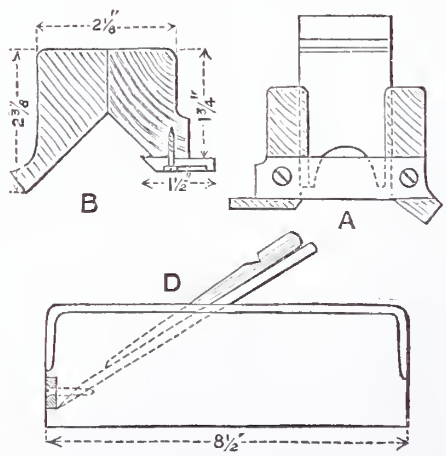
Cork Heel.—NITRAM writes in answer to J. R. (see page 526):—"I must confess that I am at a loss to grasp the whole meaning intended in some parts of his query. I presume you mean by a cork heel a particular shape of heel? If so, I am not cognisant of the term. To answer all your questions correctly would take up more space in 'Shop' than I could reasonably expect our Editor to grant. So with a few rough sketches I will attempt part this week and part later on, and so give all a



Cork Heel.

chance. Fig. 1, short sole. It is much better though to have the sole the proper length. The reason is obvious. Fig. 2, piece of same stuff let in. Fig. 3, pegged, rasped, and beat down with care all round. Fig. 4, with one splint left on, pegged with ⅜, taking care to use an American pegging, and sending your pegs in an oblique direction toward centre of seat of last. If your pegs be too long they will go into the last, so that you might have great difficulty in getting your lasts out when your boots are finished. Enough this week."

Chamfer Plane.—J. W. (*Burton-on-Trent*) writes in reply to APPRENTICE LAD (*Leicester*), No. 34, page 540:—"I have pleasure in forwarding sketch of chamfer plane. A is section of front end of plane, B, back end, D, side view. In making mine I found it very much handier by squaring up my piece, allowing about an eighth thicker, and then sawing it down; you can then face the insides, and cut out for the iron and wedge, and plane away the bevels to an angle of 45 degrees; it can then be glued together,



Chamfer Plane.

care being taken that they are exactly in place. The mouth is formed by a piece of iron or steel, about ⅜ in. by ¼ in. let in flush, and screwed on as shown. I used a broken 1½ in. chisel for an iron, which answers very well. The fence is secured by two screws, sunk in on slotted brass plates similar to a side fillister; the pitch of the iron should be more than 30 degrees."

Trade Notes and Memoranda.

IT was not said at the Institution of Electrical Engineers, but it is true, nevertheless, that nowhere is the application of electricity to the ordinary uses of life to be seen on a more interesting and extensive scale than at Hatfield House, the seat of Lord Salisbury. The electricity, generated by means of turbines in the River Lea, is transmitted to the house and over the estate for real work's sake. Pumps, ice-making machinery, and an air-propeller, fixed in the roof for ventilation, are all driven by the motors at the house. The motors are also used for elevating hay and corn sheaves to the top of the stacks at the farm, for threshing, grass-cutting, and for cutting chaff for ensilage. His lordship's corn is ground and his fodder made by electricity. He drives piles by electricity, dredges the river, and pumps the town sewage. And it is all his lordship's own scheming.

ACCORDING to the calculations of the Paris police, 5,000,000 provincials and 1,500,000 foreigners have visited the Exhibition. The foreigners include 380,000 English; 225,000 Swiss; 38,000 Italians; 32,000 Austrians; 7,000 Russians; 5,000 Greeks, Turks, and Roumanians; 3,500 Portuguese; 2,500 Scandinavians; 8,000 Asiatics; 12,000 Algerians and other Africans; 90,000 North Americans, and 25,000 South Americans.

WORK

is published at La Belle Sauvage, Ludgate Hill, London, at 9 o'clock every Wednesday morning, and should be obtainable everywhere throughout the United Kingdom on Friday at the latest.

MELLIN'S FOOD

For Infants and Invalids.

TRADE MARK

NOT FARINACEOUS. Rich in Flesh, Nerve, Brain, and Bone Formers.

IT is a fact that farinaceous foods cannot be digested by Infants. This is **the only food** in which the starch has been wholly changed into **soluble substances,** which can at once be converted in the body into **living blood.** This remarkable result is attained outside the body, by imitating exactly, in the process of manufacture, the natural conditions of healthy and perfect digestion.

MELLIN'S FOOD has been examined physiologically by the highest Medical Authorities, and tested chemically by the most distinguished Analysts, and has always been classed by them A 1. It has gained many awards of the highest merit at Public Exhibitions.

No Food in the market can show such a vast collection of *bonâ-fide* testimonials, and many of these allude in an emotional yet sincere manner to the fact that **"MELLIN'S FOOD has saved Baby from Death."**

USED IN ALL CHILDREN'S HOSPITALS.

ARE universally admitted to be worth a Guinea a Box for Bilious and Nervous Disorders, such as Wind and Pain in the Stomach, Sick Headache, Giddiness, Fulness and Swelling after Meals, Dizziness and Drowsiness, Cold Chills, Flushings of Heat, Loss of Appetite, Shortness of Breath, Costiveness, Scurvy and Blotches on the Skin, Disturbed Sleep, Frightful Dreams, and all Nervous and Trembling Sensations, &c. The first dose will give relief in twenty minutes. Every sufferer is earnestly invited to try one Box of these Pills, and they will be acknowledged to be

WORTH A GUINEA A BOX.

For Females of all ages these Pills are invaluable, as a few doses of them carry off all humours, and bring about all that is required. No female should be without them. There is no medicine to be found equal to Beecham's Pills for removing any obstruction or irregularity of the system. If taken according to the directions given with each box, they will soon restore females of all ages to sound and robust health. This has been proved by thousands who have tried them, and found the benefits which are ensured by their use.

For a Weak Stomach, Impaired Digestion, and all Disorders of the Liver, they act like magic, and a few doses will be found to work wonders on the most important organs in the human machine. They strengthen the whole muscular system, restore the long-lost complexion, bring back the keen edge of appetite, and arouse into action with the rosebud of health the whole physical energy of the human frame. These are FACTS testified continually by members of all classes of society, and one of the best guarantees to the Nervous and Debilitated is, BEECHAM'S PILLS *have the largest Sale of any Patent Medicine in the World.*

Beecham's Magic Cough Pills.

As a Remedy for Coughs in general, Asthma, Bronchial Affections, Hoarseness, Shortness of Breath, Tightness and Oppression of the Chest, Wheezing, &c., these Pills stand unrivalled. They are the best ever offered to the public, and will speedily remove that sense of oppression and difficulty of breathing which nightly deprive the patient of rest. Let any person give BEECHAM'S COUGH PILLS a trial, and the most violent Cough will in a short time be removed.

Prepared only, and sold Wholesale and Retail, by the Proprietor, THOMAS BEECHAM, ST. HELENS, LANCASHIRE, in Boxes, 1s. 1½d. and 2s. 9d. each.

Sold by all Druggists and Patent Medicine Dealers everywhere. *N.B.—Full Directions are given with each Box.*

TRAPS AND DRAIN SYPHONS.

BY W. R.

WHAT an exceedingly cautious man is the average British householder!

With what care he locks and bolts his doors at night, sets electric and all sorts of alarums, lets loose his dog, and takes every precaution to keep away that ingenious fellow, the enterprising burglar!

He sleeps in peace, and fancies he is safe, but how often do we find that an enemy worse than any burglar is stealing up from the underground regions through a pipe but a few inches in diameter, and finding its way into his very bedroom, robs him of that which is far more precious than his plate—his health!

He spends pounds freely to keep out the burglar, but if he has a plumber's bill of a few shillings for repairs to his water-closet or some such apparatus to keep off this enemy—sewer-gas—he storms and fumes under the conviction that he is being taken advantage of.

Every householder should know the state of all the sanitary arrangements in his house, so that he might understand the grave necessity for keeping them constantly cleansed and in good order, and also know what should be done when repairs are necessary. The most particular part of any sanitary fitting is its trap, which bears to it the same relation as the lock does to the door. As we ofttimes find a door guarded by a very poor lock, so do we very often discover a water-closet, a sink, a lavatory, or some such fitting, provided with a very ineffectual trap, and sometimes without one at all.

Now it should be laid down as a law of the "Medes and Persians," that every sanitary fitting should be disconnected from the drain by a proper and effectual trap.

The material of which a trap is made deserves important consideration. It should be either lead or earthenware; iron is sometimes used, but cannot be recommended even if coated as explained in a former paper or enamelled, for as it is holding water constantly and sometimes fæcal matter of a very corrosive nature, it is liable to rust and become rough and dirty.

For indoor work, lead traps are decidedly the best, but they need to be well ventilated, for I have seen a lead trap eaten in small holes like a sieve by the foul gases which had accumulated in the soil-pipe, in which no means of ventilation had been provided. For it must be remembered that effete organic matter begins to be decomposed immediately on passing into the drain, and gives off that foul and dangerous gas which we call sewer-gas.

For outdoor work, earthenware is best suited, as being fixed underground and of a non-corrosive nature, it is not liable to damage from a chance blow without, or from the foul air and matter within.

Sometimes, as explained in p. 516, we have to fix earthenware traps attached to w.c.'s within the house, and in such positions when fixed as explained therein, they give every satisfaction; but for traps immediately under housemaids' sinks, lavatory basins, baths, etc., lead should always be used.

One of the oldest traps now in use is the D trap, shown at Figs. 1, 1A. It was formerly extensively used for water-closets, and is very often found in combination with that abomination the pan-closet, though it is sometimes made in smaller sizes for sinks, lavatories, etc.

It consists of a lead body or box, A, with a dip or inlet-pipe, B, and an outlet C. The various parts are soldered together. As before stated, this trap is one of the oldest, and is at the same time one of the worst, traps in use, for despite the crusade against them, hundreds are still in use in various towns.

The body A soon becomes foul, for one flush from the closet never washes out all the excrement which has been deposited into it, and in a short time, if frequently used, it becomes a veritable cesspool.
