ABSTRACT

This paper describes a digital, microprocessor controlled data acquisition system which optimizes man/machine communications. The processor provides digital feedback control, data collection over any number of channels (up to 8), 32 BIT floating point (7 significant digit) mathematics, and a variety of output formats. The main features of the device are the ability to work directly in any numerical unit desired by the user, mathematical noise filtering and automatic feedback control.

The particular application under consideration is automatic data collection and angle-of-attack control of a subsonic wind-tunnel. Data are presented to demonstrate the data logging capabilities of the system.

ACKNOWLEDGEMENT

The author takes the opportunity to express his most sincere thanks to Cdr. David Caswell, USN, thesis advisor, for his logistic support and patience; to Dr. Louis Schmidt, co-advisor for the physical design of the ADL system and wind tunnel interface; to Ted Dunton, chief technician for his tireless and cheerful troubleshooting.

Special thanks go to Charles Lembo, president of CYBERDATA Corporation, Monterey, California for his generous loan of equipment and facilities during a period of hardware malfunction.

Most of all, thanks to my family for their endless support and understanding.

I. INTRODUCTION

A. BACK GROUND

The use of microprocessors (U-P) to control various analog and digital devices has grown exponentially in the past two years. Applications range from TV tennis games and 'smart' traffic lights, to industrial plant monitors and high speed data handling. The state-of-the-art U-P at the time of this writing is the INTEL 8748. This single integrated circuit contains:

- 1. Central Processing Unit (CPU)
- 2. 1K bytes of erasable, programmable, read-only memory (EPRCM)
- 3. 64 bytes of random access memory (RAM)
- 4. 8-BIT interval timer/event counter
- clock driver

In addition, this device draws only 150 milliampere (mA) at 5 volts (V).

Microprocessors have greatly enhanced the important technological application called DISTRIBUTED INTELLIGENCE. For example, routine - but time consuming - chores such as parallel to serial data conversion, x-y plotting, equipment polling, etc. can be controlled on site. Engineering analysis of such large interconnected subsystems reduces to a 'black box' problem rather than the more complex problem

of centralized command and control.

B. DISCUSSION

This paper describes the development and construction of an automatic data logging system (ADL) which is configured via software to suit a particular application. The software modification is dynamic in nature, which means that the system operator needs only to type in a few simple commands to change the system input/output (I/O) to measure volts, feet, psi or any other quantity directly without external hardware modification or adjustment. The requirements for system and an overall description of the ADL hardware are given in chapter II. Chapter III discusses the command words available along with examples of actual output. Chapter IV presents a specific application of the system. Guidelines for interfacing the digital feedback control function with various types of equipment are also given. Chapter V contains the software assembly listing as well as flowcharts and explanations of the more important routines. Chapter VI discusses the use of U-P development systems and gives recommendations for software development. Appendix A is a glossary of U-P and data acquisition terminology which is used throughout the paper.

II. SYSTEM DESCRIPTION

A. REQUIREMENTS

The purposes of a data logging system are twofold. First, the system must be able to take readings from a variety of physical devices. Second, these readings must be converted into a form suitable for data reduction and human interpretation. The obvious use of such a system is taking data over extremely long or extremely short time periods, filtering out noise, controlling external events and providing tabular and/or graphical output. With the above in mind, the following requirements are defined:

- 1. 8 channels of analog input
- 1 channel for digital feedback control of some external device.
- 3. Plain language man/machine interface via serial data transmission.
- 4. Manual and automatic data acquisition functions.
- 5. Limited data manipulation.
- 6. Multiplexed digital voltmeter function.
- Limited text file storage and editing.

It should be pointed out that the above requirements were defined with the wind-tunnel control function in mind (ch. IV). Nevertheless, the concepts may be extended to other applications with minor software modifications.

B. DEVICE SELECTION

A strictly hardware-oriented implementation of the system requirements was not a valid alternative due to the inherent inflexibility of such designs. Large scale computer installation was prohibitive from cost and under-utilization considerations. It was therefore decided to use an available microprocessor - the INTEL 8008 - to implement all logic and data manipulation functions. This U-P device is the heart of the PROLOG Corporation 805 microprocessor system. Figure 1 is a schematic of the 805 system layout as modified for this project. Appendix B presents vendor specifications for same. Figure 2 shows the overall system layout including the command and communications links between the system components and the operator.

C. INPUT/OUTPUT DEVICES

The man/machine interface was the most difficult task to implement. The major difficulty was not in the physical interface, but the language used for two-way communications. A software driven ASR-33 Teletype was used for command entry, data presentation, and test functions. Although teletype driving wastes CPU time, the time delays involved are still much less than the mechanical time delays of the relays and driving motors which the U-P is controlling.

A group of eight HEWLETT PACKARD 5082-7302 display lights was used to implement the digital voltmeter function. This display is used to set amplifier gains, set nulls and to verify that data present on a particular input are being

processed by the system. The light display is controlled via software to display data in volts.

Up to eight channels of analog data may be multiplexed (DATEL MM-8) into the sample-and-hold unit (DATEL SHM-4), as shown in figure 3. The analog-to-digital (A/D) converter (DATEL ADC-149) has 14-BIT resolution over a 20-volt range. These three devices are also driven via software in order to provide various time delays between data samples. The time delays are utilized to mathematically filter out low level noise and A/D glitches from the system. Appendix B contains vendor data for the above mentioned devices.

D. FUNCTIONAL ARCHITECTURE

1. General

The primary advantage of a software configured system is that its processing functions and I/O can be modified wihout external hardware adjustment. This implies that the system possesses a 'general purpose' quality. However, a compromise must be made between a completely general system and one which can be easily implemented by an operator who has little knowledge of the operating system (OS) software or of the dynamics of the system from which this person is collecting data. In order for the logging system to be used effectively by students in a variety of engineering disciplines, the OS was set optimize man/machine interaction. Thus, the operator has no control over such parameters as relay and drive motor transportation lag. These particular system parameters are fixed (see chapter IV) but still provide wide applications such as probe placement and angle setting. Although obvious,

it is worth mentioning that the feedback controlled movement of an external device may not be coincident with data acquisition and reduction, as the U-P can perform only one function at a time. In general, the internal data handling of the microprocessor is transparent to the user.

2. Internal

Figure 4 is a flowchart of the basic numerical data conversion processes. Note that two levels of conversion take place. The first level converts data from the 14-BIT binary provided by the A/D converter into a numerical voltage between -10 and +10 volts. This interpolation routine is called before any raw data are processed. The next level of conversion is accomplished with a scaling routine which changes voltage units into any unit desired by the user. If the user does not specify a particular scaling factor, the system defaults to volts for all I/O presentations. Scaling factors can be changed at any time, on any of the input channels; different channels may have different scaling factors.

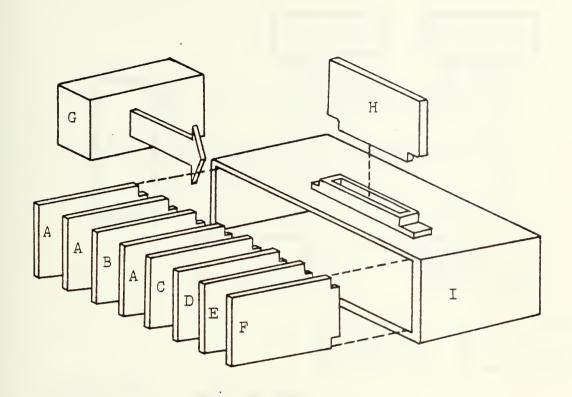

The mathematics package used is from the INTEL Users Library and is discussed in Appendix C. Although the math package performs all operations with 7 significant digits, numerical output is rounded to 4 significant digits (with choice of decimal or exponential notation). This was done to improve readability of tabulated output and to permit all eight channels to be printed in the limited space provided by the teletype. The only exception is the DUMP routine (ch. III), which always outputs 7 digits. This is because scaling factors of up to 7 digits can be entered by the operator (also fig. 4).

The decimal format presents data between 0.0001 and

9999. The exponential format presents 4 significant digits between $1.000\,E-28$ and $10.00\,E+27$. All numerical entries by the operator can be in either format , with the exception of channel numbers, which are only single digit integers.

III. COMMAND WORDS

This chapter defines the commands which the operator may use to communicate with the ADL. A brief explanation of the word is presented; then the rules for it's usage and the ADL response is given. The commands are organized into three categories:

- 1. <u>DATA DEFINITION:</u> Used to set scaling and delay parameters, and to store the sequence of channels to be scanned.
- 2. <u>ACQUISITION:</u> These commands start various types of acquisition processing, including the voltmeter and feedback control routines.
- 3. <u>FILE MAINTENANCE:</u> These are convenience features which provide simple text editing and printing of repetitious table headings. They also provide abort capability and correction capability for misspelled words.

Note that command words are entered in upper case just as they appear in the following paragraphs. When the ADL is ready for a command, it prompts with the symbol >. The command word is then entered followed by pressing the RETURN key. In all examples given, the ADL-generated text is shown in parentheses for illustration purposes only. Section D of this chapter presents copies of actual printout from typical runs in order to further clarify the use of the commands.

A. DATA DEFINITION

1. UNIT

This command is normally the first used. It enables the user to specify a scaling factor so that all data I/O will be in any desired unit. A typical sequence of commands could appear as follows:

(>) UNIT
(CHANNEL =) 1
(UNIT/VOLT) 10.5
(CHANNEL =) 6
(UNIT/VOLT) .2
(CHANNEL =)

Thus the user has specified a scaling factor of 10.5 for channel 1 and .2 for channel 6. The abort command was then used to terminate the routine. The ADL responded with > when again ready to accept commands. The result of the above is that, for example, a 3-volt input on all channels will print out as 3.000 on channels 0,2,3,4,5,7; as 31.50 on channel 1 and as .6000 on channel 6.

2. WAIT

this command is used to set a known time delay between sets of data points. The ADL takes 128 data points from each channel and computes an average before a value is printed. Thus, the effects of noise and A/D glitches are

minimized. Because it takes 1 millisecond (ms) for the ADL to set up the multiplexer for a different channel, the WAIT delay must be used with caution in an environment which exhibits periodic noise. If only one channel is scanned, the time between data points will be as entered. However, if all 8 channels are scanned the time between data points on any channel will be the desired time plus 8 ms (1 ms for each channel).

3. SET SCAN

SET SCAN is a dual purpose routine. First of all, if a WAIT command has not been issued it will default to 15 ms and send a message to the operator; otherwise, it proceeds to the next step. The operator is then given the opportunity to specify the type of output format, namely, exponential or decimal. Second, the ADL asks the operator to input the channels to be scanned in the desired sequence. Section D presents some typical examples of SET SCAN usage.

B. ACQUISITION COMMANDS

1. READ

This is the command used to start the voltmeter function. A typical entry would look like:

(CHANNEL =) 3

When the RETURN key is pressed, the digital display will follow the data on channel 3 (in volts). The display is updated every 10 ms and takes the data through a 43 microsecond window. When the display is in operation, any

noise on the input will show up as a rapidly changing digit. This is unlike most digital voltmeters which integrate the input over a small time interval and present an average reading. This integration process may effectively mask any noise down to fairly low frequencies, depending on the voltmeter being used.

The main use of the above function is to set gain limits on the inputs. To transfer command back to the user, any key on the teletype can be pressed. The ADL responds with > and is then ready for another command.

2. SCAN

SCAN is used to manually control the tabulation of Upon command entry, the ADL checks to see if channel assignments have been made via the SET SCAN routine. If the check is negative, a message is sent to the operator and the routine is aborted. If the check is positive, headings are printed out with the proper spacing for the desired numerical format. The ADL then waits for a RETURN at which time a set of data is taken, averaged and printed out with the proper scaling factor applied. The printer carriage is then positioned at the end of the line of data so the user may enter any comments. The next set of data is taken when the RETURN key is pressed. Before each line of data printed, a three digit counter, called the coordination number, is incremented automatically. The SET SCAN is used to reset this counter to zero (also automatic). Thus, repeated calls to SCAN or RUN will keep the counter indexing properly. The SCAN routine is terminated by entering the abort command.

3. MOVE

Channel 0 was internally defined as the feedback channel for ADL control of some external device. The operator inputs the desired position (speed, angle, etc.) and the ADL will provide the logic necessary to drive the device to within 4 A/D counts; 1 A/D count is equal to 1.22 millivolt (mV). A sample is taken every 0.8 ms so the maximum slew rate at the input is limited to 6.1 mV/sec in order to guaranty convergence. This routine is used mainly to ensure slew rates are not excessive and that external device movement does not exceed acceptable limits. Chapter V presents a detailed flowchart of the feedback logic used in the ADL.

4. RUN

RUN internally calls the SCAN and MOVE routines in repetition in order to automate the tabulation of data at many different positions of an external device. A typical data entry sequence for RUN could be:

(START POSIT =) 10.0 (STOP POSIT =) 7.5 (INCREMENT =) .5

Note that the start position does not need to be less than the stop position. Also note that the incremental movement is in absolute value. Upon execution (the RETURN key) the ADL prints out column headings as defined by the SET SCAN routine, slews the external device to the start position and starts tabulating data at each of the positions between START and STOP. When the stop position data have been printed out, command is returned to the operator.

C. FILE MAINTENANCE

The following commands are used to input text information and comments.

1. EDIT

When the same heading information will appear as part of the documentation of each run, EDIT is used to enter this information for later use. After the desired text has been entered, the LINE FEED (L/F) key is pressed, followed by the RETURN key. The L/F is needed internally to mark the end of the file; this is the only routine that terminates with other than just the RETURN key. If the L/F key were not used, the entire buffer space (256 characters) would print out. At this time, if the END-OF-FILE symbol were not detected, an error message would be sent to the operator.

The EDIT mode can also be used to change or correct the text at any time. The routine is entered via the command word; the CONTROL and Z keys (cntrl-Z) are pressed simultaneously to step through the file. When the proper place in the text is reached, the RUBOUT key is pressed, then the new character is entered. Note that this entry is not inserted between two characters, but rather it overwrites; any number of characters can be reentered. In order to exit the routine without using the L/F key (which would truncate the text), the cntrl-A keys are used. Section D shows the construction and edit of a file.

2. FILE

The text entered with the EDIT command is printed out upon execution of FILE. Two lines are skipped automatically at the beginning and at the end of the file.

3. DUMP

Execution of DUMP will cause the contents of the conversion factor buffer to be printed on the teletype. This enables the user to verify the scaling factors which are being applied to each channel. Numbers are printed with 7 significant digits.

4. MIEST

This command is executed automatically upon system reset or when power is applied. All the ram area is tested by first writing 00H to each location, reading it back and comparing the result with 00H; the same process is repeated with FFH (Appendix C contains an explanation of hexadecimal notation). If an error were detected, the contents of the bad location would be printed out along with its address. This enables the operator to identify the particular circuit component which has malfunctioned. The routine can also be entered as a command, but use of this function resets all default values just as a system reset.

5. CNTRL-A

The abort command is used to terminate execution of all routines except RUN and READ. When the cntrl-A keys are used, command is transferred back to the operator and the system responds with a >. The RUN routine can only be

terminated with a system reset; the READ routine is terminated by pressing any of the teletype keys.

6. CNTRL-R

Pressing these two keys causes the phrase RUN NO. to be printed. The keyboard is then opened for the insertion of any desired alpha/numeric single line sequence.

7. CNTRL-C

This command causes **** to be printed in order to flag a comment. Note that this is a command routine and can only be entered after a > prompt by the ADL.

8. CNTRL-Z

Pressing these keys causes an internal counter to advance forward through the input buffer. In this manner, the contents of memory can be displayed (see EDIT).

9. RUBOUT

This key is used mainly to correct spelling errors or to correct data entries without aborting a routine. For example, assume the operator wants to enter SCAN but notices that SVAN has been typed by mistake. The RUBOUT key is pressed three times. Each time it is pressed, the previously entered character is printed and an internal counter counts backwards through the input buffer. The operator then retypes the correct letters (CAN) and the correction is complete. The teletype entries would then look like:

SVANNAVCAN

When executed, the ADL will only see SCAN.

Command word recognition is accomplished by summing the binary codes of each of the letters of the word. The result is then compared with a list of valid sums which are contained in memory (check-sum). Since the result of a summation does not depend on the order of the addends, the letters of the command word may be entered in any order (e.g., SCAN, NACS, etc.). Although this method could lead to ambiguity problems, the vocabulary of the ADL is small enough to prevent such an inconsistency. Any command , text or data entry can be edited with the RUBOUT key at any time.

D. EXAMPLES

The figures following this section are copies of actual ADL sessions. All ADL-generated messages are underlined the first time they appear for illustration purposes only.

Figure 5 shows a DATA DEFINITION sequence. The UNIT command was used to override the volt default on channels 0,1 and 2. The SET SCAN routine was used to select decimal format and to sequence channels 6,7,0,3,6. Note that the channels do not need to be in any particular sequence and that one channel may be used more than once. The use of a channel more than once enables the user to check the effectiveness of the noise filtering algorithm in a particular application. In this case, data taken on the first channel 6 scan will be 19 ms out of phase with the second channel 6 scan (15 ms for the delay parameter and a 1 ms intercycle delay for each channel). The operator then used the wait routine to change the wait parameter to 3 ms.

The subsequent call to the SET SCAN routine did not produce the default message (labeled A on the previous call).

Figure 6 shows a typical SCAN sequence which resulted from the commands entered from fig. 5. SCAN was used to take 5 sets of data, then RUN was used to take 5 sets. It is important to note that channel 0 must be included in the SET SCAN definition before RUN is executed. This is because channel 0 is the feedback path for the digital control functions.

Figure 7 shows the ADL response to improper inputs. After a reset, the operator tried to execute SCAN without first defining the channel sequence. The next example in this figure shows an invalid command followed by some examples of using the RUBOUT key to correct various entries.

In fig. 8 the operator did not use a LINE FEED/RETURN sequence to mark the end of the text. The resulting call to FILE is then shown.

Figures 9 and 10 present the data from a wind tunnel calibration session. Figure 11 is a graph of the lift data (channel 2) versus angle-of-attack (AOA, channel 0). Notice that the scaling factors for channels 0 and 2 were selected so that their respective output would be read in degrees and pounds directly. Figure 12 shows a run which utilized exponential format.

IV. WIND TUNNEL APPLICATION

The ADL system was constructed in order to facilitate data acquisition and documentation from the 3.5 x 5.0 foot subsonic wind-tunnel located in the Department of Aeronautics at the Naval Postgraduate School. Logging data by hand from the tunnel balance is time consuming, error inducing and produces somewhat biased and scattered results. Other related problems are:

- 1. Personnel communications in a noisy environment.
- Meter reading while the quantity to be measured is subjected to random perturbations.
- 3. Tunnel heating due to long run times.
- 4. Time consuming AOA setting.

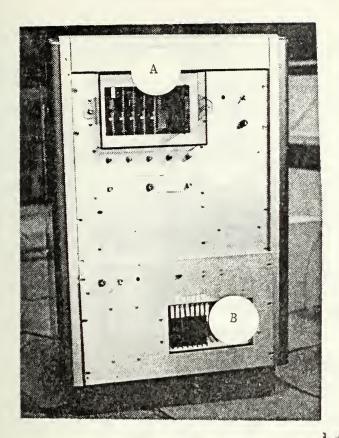

The ADL effectively eliminated all the above problems and in addition it proved to be versatile enough to be used as a data logger with other equipment. Figure 13 is a picture of the ADL installation. It fits compactly into a roll-around cabinet and requires only a standard 20 mA current loop, 110 baud I/O device (e.g., a teletype), and patch cords to connect it to the voltage sources it is to monitor. Five variable-gain, linear amplifier cards are included to provide low level signal buffering. Voltage sources can be connected to the ADL directly or patched through an amplifier, as long as the input excursions do not exceed -10V to +10V.

The feedback control function is implemented via two output lines - one labeled UP and the other labeled DOWN.

Each line carries an independent logic level voltage which is used to actuate a relay. The two relays in turn are used to control the direction of a motor. The desired feedback quantity (in this case position) is input to channel 0 which closes the digital control loop. Figure 14 is a detailed schematic of the AOA control as used in the wind tunnel system. To date, the ADL was used to calibrate the wind tunnel balance and the dynamic pressure transducer [1].

V. SOFTWARE DESIGN

The assembled program listing for the ADL is presented in this chapter along with flowcharts for the most important routines. Throughout the following paragraphs, frequent reference is made to the 'position' of an external device. 'Position' is used for illustration; speed, angle or many other attributes of the state of an external device can be used as a feedback parameter.

Figure 15 shows the averaging process used in the filter routine. A running sum is taken at 128 data points. This sum is then divided by 128, converted back to binary stored as a two byte quantity in registers D and E. The binary representation of the current desired position of the device is recalled from memory and stored in external registers B and C. Upon exit from the routine, the registers up to compare the actual and desired positions in order to determine in which direction to move the external device. The 'UP' driver is next shown. It makes use of the previous subroutine to determine when the desired position has been reached. The position correction routine in fig. 17 determines if the position arrived at by the UP or routines has met predefined error criteria. There are also routines for the DOWN direction that are identical to figs. and 17 (except for the direction of movement). routine is in fig 18; it provides the logic necessary to properly call the UP and DOWN routines. Figures 19 and 20 are flowcharts of the RUN routine. RUN provides automatic centrol function of the ADL by calling SCAN and MOVE at external device positions defined by the user.

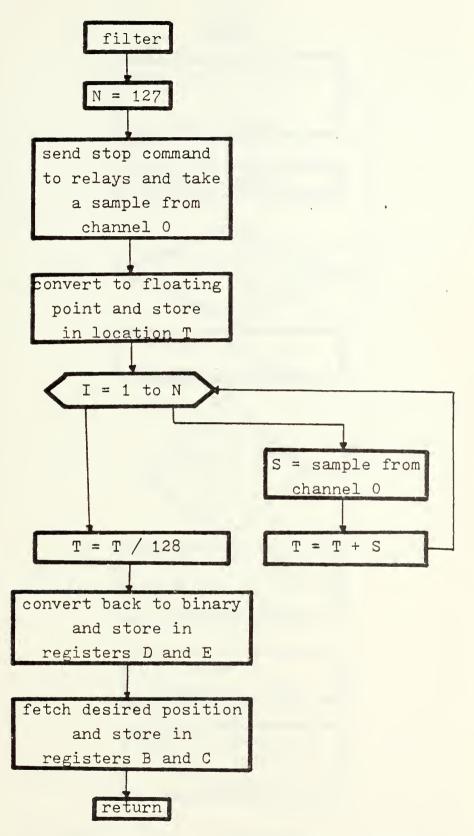

Figure 15 - NOISE AND GLITCH FILTER LOGIC

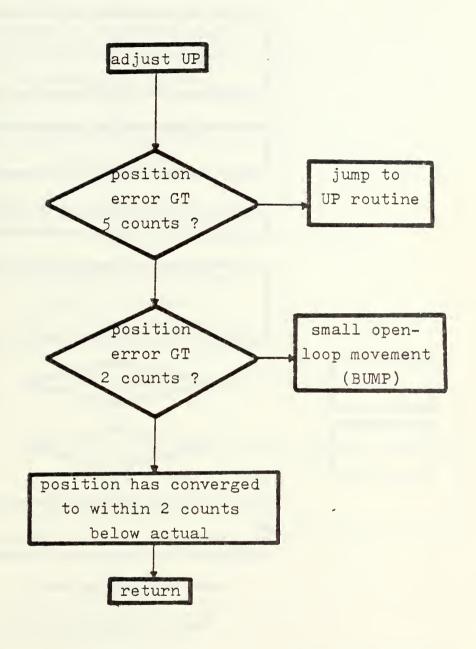

Figure 17 - OVERSHOOT/UNDERSHOOT CORRECTION LOGIC

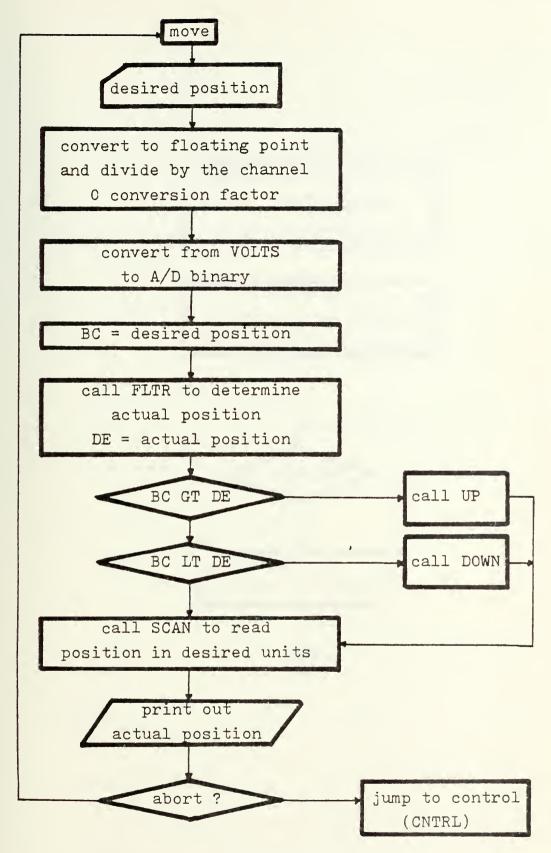

Figure 18 - EXTERNAL DEVICE CONTROL LOGIC

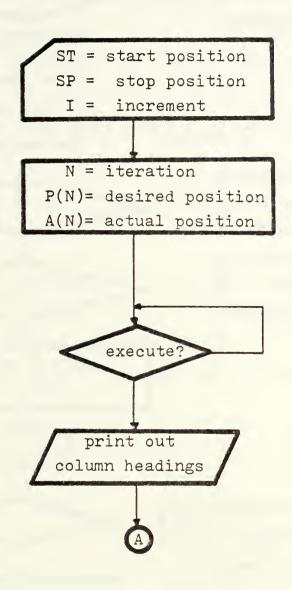

Figure 19 - RUN ROUTINE LOGIC (PART 1)

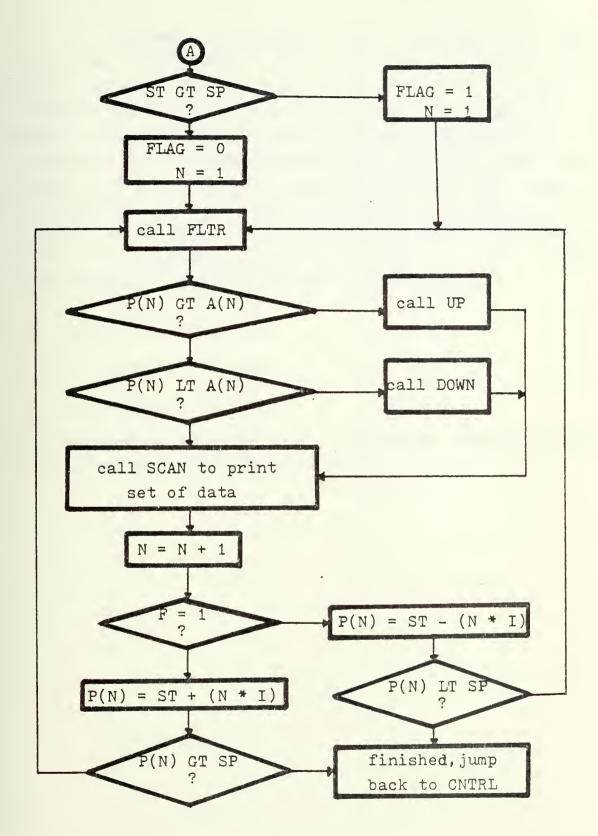

Figure 20 - RUN ROUTINE LOGIC (PART 2)

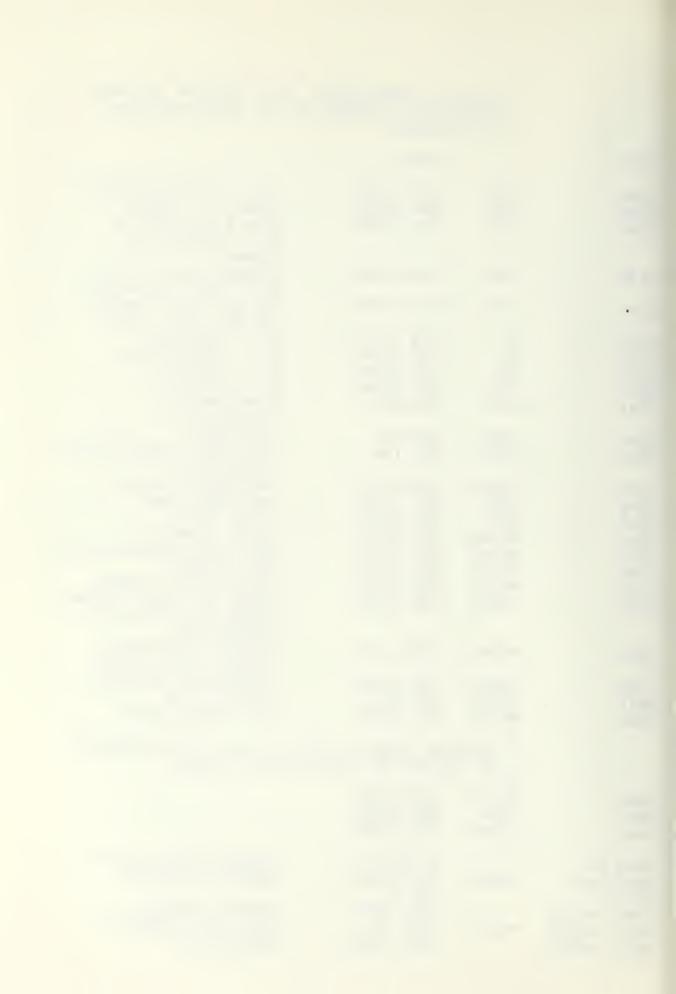

The following software was developed in small independent subroutines. This was done so that future revisions to logic could be accomplished with a minimum of redesign. For example, if a line printer is added to the system, all references to subroutine CO (console output) are changed so that the new routine can be called. The EQUATE tables at the start of each section of software are modified to reflect the address of the new routine, and the software is then reassembled. Similar procedures can be followed to alter I/O assignment, add new routines, etc. Memory requirements for the ADL software are as follows:

- 1. Pages 00H to OFH, ROM
- 2. Pages 20H to 27H, ROM
- 3. Pages 10H to 1FH, RAM

This program was compiled on the INTELLEC 8 microprocessor development system for the 8008 U-P.

VI. RECOMMENDATIONS

The ADL software was developed on an existing development system which used the following:

- 1. 110 baud teletype for program listing.
- 2. 110 baud paper tape punch for mass storage.
- 3. 1200 baud high speed paper tape reader.
- 4. 1200 baud CRT for program entry and editing.

While this system is a useful tool for writing and debugging small programs, it is not a viable system for large scale development. The percentages of time devoted to the creation of the ADL software package was 15% logic development, 5% manual entry, 15% debugging and 75% waiting for paper tape and teletype output. The last figure represents a significant and costly waste of manpower assets. The following system - while more expensive - could easily pay for itself in man-hour savings alone:

- 1. Floppy disk mass memory. this reduces an edit-assembly-reedit-reassembly cycle from up to eight hours (for the entire package) to less than five minutes (also for the entire package).
- 2. Line printer for producing source code and assembly listings.
- 3. Resident high level language such as BASIC or PL/M to enhance complex logic manipulations.

The Department of Aeronautics has recently acquired the

INTEL MDS 80 development system. This system contains the above components and is presently being used as a data acquisition system for an oscillating flow wind tunnel. In addition to data logging, this system can perform on-line fast fourier analysis of data taken in a highly turbulent and non-linear environment [2].

Microprocessor usage presents a unique problem; namely, better CPUs and more advanced peripherals appear on the market almost monthly. Therefore, a U-P oriented system rapidly becomes outdated. The software for the ADL was written using industry standard techniques. A change to the more advanced 8080 CPU can therefore be accomplished (with minor changes) by simply reassembling the program with an 8080 assembler. Such an update is recommended if the ADL is to be used to take higher frequency data.

APPENDIX A

GLOSSARY

- 1. A/D: analog to digital (adjective or noun)
- assembly: A listing which contains both source code and machine code.
- 3. BAUD: A data transmission rate expressed in BITs per second.
- 4. BIT: BInary digit. A single unit of information in a binary word.
- 5. buffer: A group of memory locations used to store specific data (input data, constants, output data, etc.).
- 6. buffering: A process by which electronic signals possessing different properties are made compatible.
- 7. byte: An eight-BIT word which is processed as a single quantity.
- 8. CPU: Central Processing Unit. The area of the microprocessor which computes and sequences all logic and arithmetic functions.
- 9. coordination number: A sequential, numerical label associated with a set of data points for a given run.
- 10. CRT: Cathod Ray Tube. Also used as the generic name for a television type display.
- 11. D/A: The inverse of the A/D process.

- 12. data logging: The acquisition and tabulation of data.
- 13. EPROM: erasable/programmable read only memory
- 14. driver: In a software context this term refers to a program used to control the actions of an external device.
- 15. external device: A physical device which is not an integral part of the microprocessor.
- 16. glitch: A missing BIT in a byte of data which can occur during data transmission or conversion.
- 17. H: A suffix which indicates a hexadecimal number (Appendix C).
- 18. I/O: input/output
- 19. K: A suffix which indicates a group of 1024 (2) items as in '4K of memory' meaning 4096 memory locations.
- 20. machine code: The BIT patterns actually used by the U-P in order to carry out its assigned logic functions.
- 21. MUX: a multiplexing device
- 22. nibble: The upper or lower four BITs in one byte.
- 23. OS: Operating System. Another term for Software Package.
- 24. page: a 256 byte segment of memory
- 25. RAM: Random access memory. Volatile memory used for variable storage and data manipulation.
- 26. register: A storage location located in the CPU.
- 27. ROM: read only memory, non-volatile
- 28. software: The program which resides in the U-P's memory.

- 29. source code: The program written by the user.
- 30. U-P: microprocessor
- 31. 8008: An 8-BIT U-P device.
- 32. 8080: The next generation U-P from the 8008.

APPENDIX B

VENDOR DATA

The following specification sheets give the major properties of the hardware used in the ADL system. Also presented are the I/O pin assignments for the 805 processor as well as the pin-outs for the other connecters used throughout the system.

MPS 805 MICROPROCESSOR SYSTEM SPECIFICATIONS

Physical

Three 4 5" by 6 5" printed circuit cards One 8111 CPU card One 8114 Input card - One 8115 Output card

One 8116 ROM card

One 8117 RAM card

Connector Requirement for each card

56 pin, 28 position dual read-out on 0 125 enters

CPU Card includes

8008 CPU Crystal clock

Address latches, data butters, and control decode circuits

Power-on and external restart.

DMA buffers

ROM Card includes

One 1702A PROM (256 bytes) and eight PROM sockets

Socket for card expansion circuit (up to 8 cards)

Eath 21.32 RAM (1024 bytes) and thirty-two RAM sockets

Solver or Lord expansion circuit (up to 4 cards)

TT inpu selector circuits addressable in groups of 8

- cket for a d'expansion circuit (up to 2 cards)

Outou: Card includes

. TTL output latch circuits addressable in groups of 8

Socker for card expansion circuit (up to 6 cards).

Operational

CPU

Executes all of the 8008 instructions

4 microsecond time state cycle using 8008 (MPS 1805).

2.8 microsecond time state cycle using 8008-1 (MPS 805-1).

Memory for data or program storage card expandable to any combination of ROM and RAM to 16384 words

ROM, 2048 word capacity per card.

RAM, 4096 word capacity per card

Input gates implement the INP instructions.

Output latches implement the OUT instructions.

ringle line, synchronized interrupt on CPU card can be optionally wired for multi-level interrupt or Power-on external restart

Multi-level Interrupt. Control lines available for external interrupt such as 8118 priority interrupt card.

Power-on and external estart option. CPU starts at instruction location 0000 by wiring restart output from CPU card to Interrupt Request input

"MA (Direct Memory Access)

Data, address, and control lines are 3-state disconnected by the CPU following a HLT instruction allowing

MA by peripherals. The CPU musi be interrupted to continue following a HALT

Refer to individual data sneets and schematics on the 8111, 8114, 8115, 8116, and 8117 for interface and wiring

Power Requirements for the five card set fully loaded

+VCC = t5%@3.3 Amp niaximum (35mA per ROM, 50mA per RAM)

GND 0 volts

VDD = 9 volis ±5% & 900 mA niaximum (35 mA per ROM)

Hardware

Compatible with Series 8400 interface cards.

Fits CR5, CR10 or CR19 card racks

Use M273 power supply

PROM's programmable on Series 81 programmers

MPS 800 hardware is fully compatible with any 8008 software assuming I/O and interrupt can be assigned compatibly. Teletype operating system and system monitor available. Assemblers, compilers and simulators, available through computer time sharing services

8 CHANNEL ANALOG MULTIPLEXER MODEL MM-8

FOR ANALOG TIME SHARING - \$69 each

FEATURES

☐ Low power consumption 300 milliwatts

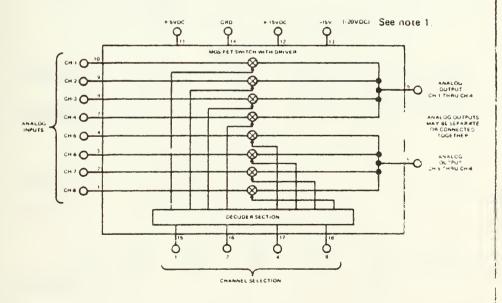

☐ High transfer accuracy ±0.01%

 \square Fast settling output 1 microsecond to $\pm 0.01\%$ of FS.

☐ Choice of input type Single ended or differential

☐ Completely self contained ... Includes 8 MOS-FET switches, drivers and decoding logic for channel selection

BLOCK DIAGRAM

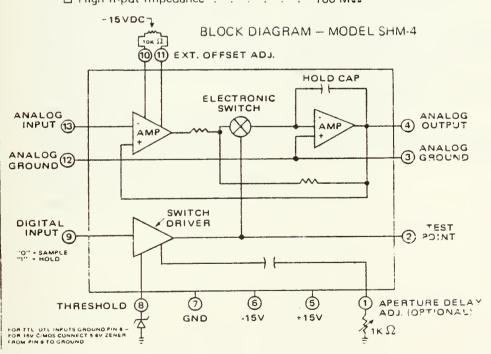

SAMPLE AND HOLD

MODEL SHM-4

FOR SIMULTANEOUS SAMPLE AND HOLD APPLICATIONS

FEATURES

- □ Fast Acquisition Time 6 µsec
- ☐ Adjustable Aperture Delay To zero between units
- \square High Input Impedance 100 M Ω

DESCRIPTION

The SHM-4 is ideally suited to simultaneous sample and hold applications, where the gain and aperture delay between units must be matched, and where the output droop of the sampled signal is minimized for time shared A/D conversion.

A double inversion circuit in the SHM-4 places the FET sampling switch near ground, which means that all variations of hold step and of aperture delay with input voltage are eliminated.

A unique closed loop design gives high accuracy and allows the rate error to be factory nulled. Rate error is the delay by which the output lags an input ramp and may be expressed in usec or in mV/V/µsec. For conventional sample and hold applications rate error is not serious because it merely causes an advance in the effective time of hold and tends to cancel out part of the aperture delay. However, for simultaneous applications the aperture delay minus the rate error must be matched between units so that the effective time of hold is the same for all. The SHM-4 accomplishes this by nulling the rate error to less than I nanosecond and for critical applications, by providing an external 5 nanosecond adjustment of aperture delay. Also, the high accuracy and low droop of the SHM-4 make it useful in conventional sample and hold applications.

Careful attention to circuit detail in eliminating leakage currents has decreased the output droop to less than 20 microvolts per millisecond allowing several SHM-4 modules to be time shared between one A/D converter.

Datel's Model MM-8 is a complete eight channel solid state analog multiplexer designed for applications which require fast output settling and high transfer accuracy.

The entire multiplexer is self contained in a plastic module measuring 0.8 cubic inches. It contains eight MOS-FET switches with associated driver circuits, each having a current limiter pull-up FET to provide minimum propagation delay, also included is all the necessary decoding logic to enable random channel addressing with a lour bit parallel binary input. Two MM-8 multiplexers can be cascaded to provide up to sixteen channels under command from one 4-BIT address. The addressing logic inputs are compatible with DTL/TTL logic levels.

Full scale inputs can be either ±5V or ±10V with a transfer accuracy (input to output) of ±0.01%, provided the output load is a minimum of 10 megohms. The high impedance amplifier provided with Datel's ADC-E, ADC-L and ADC-M series analog/digital converters and SHM Series sample/hold's are quite suitable for this application.

Output settling time for each channel is one microsecond to $\pm 0.01\%$ of full scale and each channel can sequentially switch at a 500 KHz rate. The output of the eight channels is divided into two parallel groups of four.

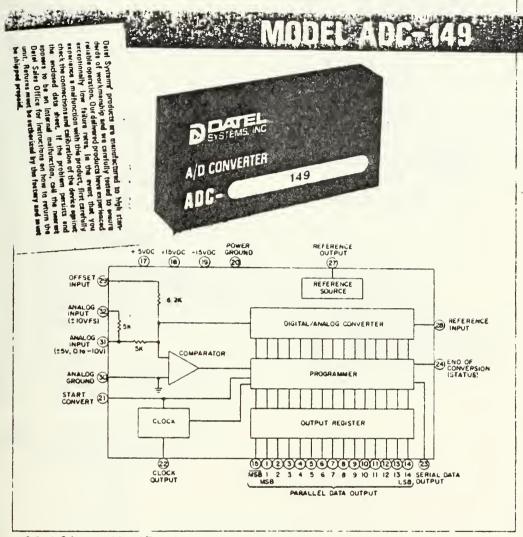

As stated before, MM-8 is complete and requires only +5VDC, +15VDC and -15VDC (-20VDC) for operation.

MM-8 modules are 2"L \times 1"W \times 0.375"H in size—come fully encapsulated, and feature dual in line pinning (0.100" grid pin spacing)

¹ Dynamic Accuracy of Sample and Hold Circuits, Datel Systems, Inc., Application Note V1-1.

HIGH RESOLUTION ANALOG-TO-DIGITAL CONVERTER

GENERAL DESCRIPTION

The ADC-149 is a 14 bit successive approximation type analog to digital converter for OEM use. It was specifically designed to give high resolution and accuracy at moderate cost for incorporation into precision instruments for process control systems and test and measurement systems.

The ADC-149 can resolve 1 part in 16,384 giving an operating dynamic range of 84.3dB. On the 10 volt full scale range it can detect an input change of less than 1 millivolt. Accuracy is adjustable to ±.005% of full scale ±%LSB. The temperature coefficient is held to a low ±15ppm/°C over the 0° to 70°C operating temperature range.

This converter accepts either unipolar or bipolar input voltages of 0 to -10V, 0 to -20V, ±5V, or ±10V full scale by external pin connection and performs a 14 bit conversion in 50 µsec. Several output codes are available including straight binary for unipolar inputs and either offset binary or two's complement for bipolar inputs. Two's complement is obtained by using the MSB output pin. Reverse coding sense is used with the most negative analog input corresponding to full scale digital output. A serial data output is also provided and has a nonreturn-to-zero (NRZ) format. Logic outputs ate DTL/TTL compatible and will drive 6 standard TTL loads

APPENDIX C

MATHEMATICS PACKAGE

Floating point (F.P.) binary numbers are used internally for most internal arithmetic functions. The method is fully explained in the following excerpts from the INTEL Users Library [3].

BOOR BINARY FLOATING POINT SYSTEM
ARITHMETIC AND UTILITY PACKAGE

THE ARITHMETIC AND UTILITY SUBROUTINE PACKAGE OF THE 8008 BINARY FLOATING POINT SYSTEM CONTAINS SUBPOUTINES FOR PERFORMING THE BASIC ARITHMETIC AND UTILITY OPERATIONS AVAILABLE IN THE SYSTEM.

THE ARITHMETIC AND UTILITY PACKAGE IS CONTAINED IN 768 CONSECUTIVE WORDS OF MEMORY (3 BANKS OF ROM) AND DOES NOT REQUIRE THAT ANY OTHER SOFTWARE BE PRESENT IN MEMORY. THIS PACKAGE USES THE FIRST 54 WORDS OF A BANK OF RAM AS SCRATCHPAD MEMORY.

THE INDIVIDUAL SUBROUTINES INCLUDED. IN THE ARITHMETIC AND UTILITY PACKAGE OF THE FLOATING POINT SYSTEM ARE DESCRIBED IN DETAIL BELOW.

THE 8008 BINARY FLOATING POINT SYSTEM CONSISTS OF A SET OF SURROUTINES DESIGNED TO PERFORM OPERATIONS ON NUMERIC QUANTITIES REPRESENTED IN A SPECIFIC NOTATION. SUBROUTINES APE PROVIDED TO PERFORM A VARIETY OF ARITHMETIC AND RELATED OPERATIONS.

THE SURROUTINES ARE DESIGNED TO BE STORED AND EXECUTED IN READ-ONLY-MEMORY (ROM) AND REQUIRE THE FIRST PORTION OF A BANK OF READ-WRITE-MEMORY (RAM) FOR SCRATCHPAD MEMORY. THE SUBROUTINES ARE SEPARATED INTO A NUMBER OF PACKAGES, EACH CONTAINING SUBROUTINES FOR A GROUP OF RELATED OPERATIONS. THE AMOUNT OF MEMORY (ROM AND RAM) REQUIRED FOR INSTALLATION OF THE SYSTEM IS DEPENDENT UPON THE COMBINATION OF PACKAGES TO BE USED. SCRATCHPAD MEMORY IS INITIALIZED BY A UTILITY SUBROUTINE WHICH MUST BE EXECUTED BEFORE OTHER SUBROUTINES ARE EXECUTED THE FIRST TIME.

IN GENERAL, THE SUBROUTINES HAVE SIMILIAR ENTRY AND EXIT CONDITIONS. UNLESS SPECIFIED DIFFERENTLY IN THE DESCRIPTION OF A SPECIFIC SUBROUTINE, THE SUBROUTINES HAVE THE FOLLOWING CHARACTERISTICS.

SUBROUTINES REQUIRING ONE OPERAND TAKE IT FROM AN INTERNAL FLOATING POINT ACCUMULATOR. SUBROUTINES PEQUIRING TWO OPERANDS TAKE ONE FROM THE ACCUMULATOR AND THE OTHER FROM THE MEMORY LOCATION INDICATED BY THE CONTENTS OF THE H AND L REGISTERS UPON ENTRY. THE NUMERIC RESULT OF EACH OPERATION IS STORED IN THE ACCUMULATOR AND IS RETURNED TO THE CALLER IN THE A. B. C. AND D REGISTERS.

UPON EXIT FROM THE ARITHMETIC SUBROUTINES. THE PROPERTIES OF THE RESULT ARE INDICATED BY THE SETTINGS OF THE CONTROL RITS.

CARRY BIT = 1 THE RESULT EXCEEDS THE CAPACITY OF THE ACCUMULATOR. THE OTHER CONTROL BITS. THE CONTENTS OF THE HARDWAPE REGISTERS. AND THE CONTENTS OF THE ACCUMULATOR ARE MEANINGLESS. THIS SITUATION IS ALSO INDICATED BY A NON-ZERO QUANTITY BEING STORED IN A FLAG WORD.

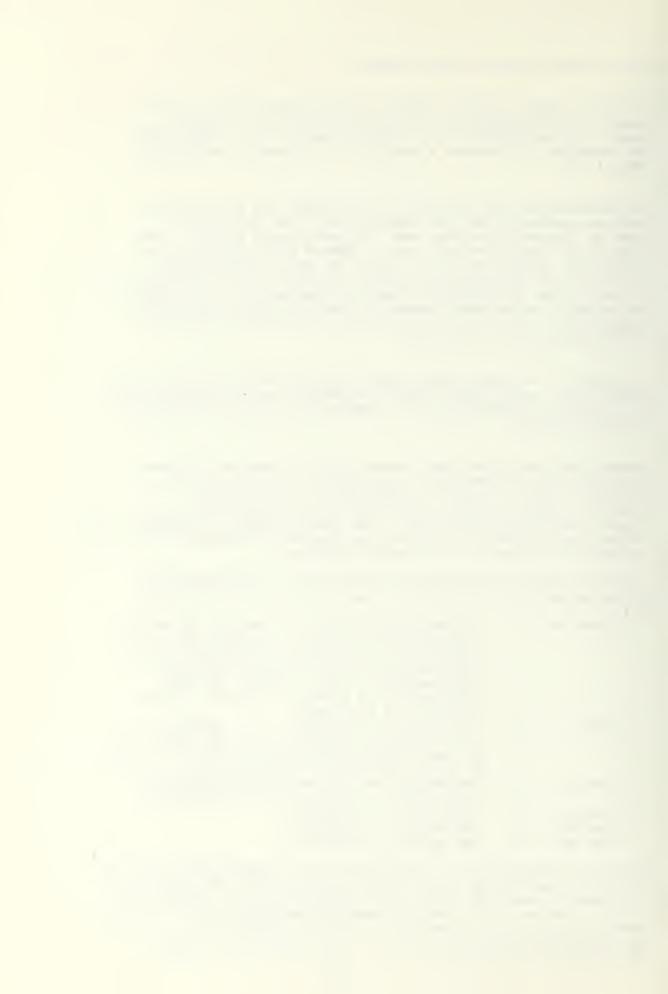

CAPRY BIT = 0 THE RESULT IS IN RANGE. THE ZERO AND SIGN BITS ARE PROPERLY SET. AND THE A. B.

C. AND D REGISTERS CONTAIN A REPRESENTATION OF THE VALUE IN THE ACCUMULATOR.

ZERO BIT = 1 THE RESULT OF THE OPERATION IS ZERO OR A QUANTITY TOO SMALL TO BE REPRESENTED.

7ERO BIT = 0 THE RESULT IS NON-ZERO. SIGN BIT = 1 THE RESULT IS NEGATIVE. SIGN BIT = 0 THE RESULT IS POSITIVE.

DATA ARE REPRESENTED IN A NOTATION WHICH PECORDS EIGHT BITS OF EXPONENT. ONE BIT OF SIGN, AND TWENTY FOUR BITS OF FRACTION. THE LARGEST MAGNITUDE THAT CAN BE REPRESENTED IS APPROXIMATELY 3.6 * 10 ** 38. THE SMALLFST NON-ZERO MAGNITUDE IS APPROXIMATELY 2.7 * 10 ** -39. THE RESOLUTION OF THE NOTATION IS APPROXIMATELY 6.2 * 10 ** -8. I.E., BETTER THAN SEVEN DECIMAL DIGIT PRECISION.

DATA VALUES ARE REPRESENTED IN FOUR CONSECUTIVE MEMORY WORDS WHICH MUST BE IN THE SAME BANK OF MEMORY. THE INTERPRETATION OF THESE WORDS IS SHOWN BELOW.

WORD 1 IF NON-ZERO. THIS WORD CONTAINS THE EXPONENT PLUS A BIAS OF 200 OCTAL. THE EXPONENT INDICATES THE POWER OF 2 BY WHICH THE FRACTION IS MULTIPLIED TO OBTAIN THE REPRESENTED VALUE. IF THIS WORD IS ZERO THE REPRESENTED VALUE IS ZERO AND WORDS 2, 3, AND 4 ARE MEANINGLESS. WORD 2. BIT 7 THIS BIT INDICATES THE SIGN OF THE VALUE: O IF POSITIVE. 1 IF NEGATIVE. WORD 2. BITS 6-0 THESE BITS PLUS AN ASSUMED 1 IN BIT 7 ARE THE MOST SIGNIFICANT BITS OF THE FRACTION. THE FRACTION IS STORED IN ABSOLUTE FORM (UNSIGNED) WITH THE RADIX POINT POSITIONED TO THE LEFT OF BIT 7. THE VALUE OF THE FRACTION IS THUS LESS THAN 1.0 AND EQUAL TO OR GREATER THAN 0.5. WORD 3 THIS WOPD CONTAINS THE SECOND MOST SIGNIFICANT EIGHT BITS OF THE FRACTION. WORD 4 THIS WORD CONTAINS THE LEAST SIGNIFICANT EIGHT BITS OF THE FRACTION.

EXAM	PLES OF	DATA	NOTAT	ION.				
VALUE	WORD1	WORDS	WORD3	WORD4				
0.0	000	XXX	XXX	XXX	X	=	DONT	CARE
+1.0	201	000	000	000				
-1.0	201	200	000	000				
+0.1	175	114	314	314				
-100.1	207	310	063	063				

FLOATING POINT ACCUMULATOR.

THE FLOATING POINT ACCUMULATOR CONSISTS OF 5 SCRATCHPAD WORDS CONTAINING RESPECTIVELY THE ACCUMULATOR EXPONENT, THE ACCUMULATOR SIGN, AND THREE WORDS OF ACCUMULATOR FRACTION. THE EXPONENT IS RECORDED WITH A BIAS OF 200 OCTAL. AN EXPONENT WORD OF ZERO INDICATES THAT THE VALUE IN THE ACCUMULATOR IS ZERO AND THE REMAINING WORDS OF THE ACCUMULATOR ARE MEANINGLESS. THE SIGN WORD HOLDS 000 IF THE ACCUMULATOR IS NEGATIVE. 200 OCTAL IF POSITIVE. THE FRACTION IS RECORDED AS A NORMALIZED POSITIVE VALUE WITH THE RADIX POINT TO THE LEFT OF THE MOST SIGNIFICANT BIT OF THE FIRST FRACTION WORD.

OVERFLOW FLAG.

THE OVERFLOW FLAG WORD IS PROVIDED AS A CONVENIENCE TO THE USER OF THE FLOATING POINT SYSTEM. THE WORD IS INITIALLY SET TO ZERO AND MAY BE RESET TO ZERO BY THE USER AT ANY TIME. WHEN ANY OF THE SYSTEM SUBPOUTINES DETECT AN OVERFLOW CONDITION THE OVERFLOW FLAG IS SET NON-ZERO. THUS THE USER MAY CLEAR THE FLAG, PERFORM A SEQUENCE OF FLOATING POINT OPERATIONS. AND CHECK THE FLAG TO DETERMINE IF AN OVERFLOW OCCURRED ANYWHERE IN THE SEQUENCE.

8008 BINARY FLOATING POINT SYSTEM

THE 8008 BINARY FLOATING POINT SYSTEM CONSISTS OF A SET OF SUBPOUTINES DESIGNED TO PERFORM ARITHMETIC OPPRATIONS ON NUMERIC QUANTITIES REPRESENTED IN MEMORY.

FACH NUMERIC QUANTITY OCCUPIES FOUR CONSECUTIVE WORDS (32 BITS) OF MEMORY. THE LARGEST MAGNITUDE THAT CAN HE REPRESENTED IS APPROXIMATELY 3.6 TIMES TEN TO THE 39TH POWER. THE SMALLEST NON-ZERO MAGNITUDE THAT CAN BE REPRESENTED IS APPROXIMATELY 2.7 TIMES TEN TO THE MINUS 39TH POWER. EACH NUMERIC QUANTITY IS REPRESENTED WITH A PRECISION OF ONE PART IN APPROXIMATELY 16.000.000.

THE SOFTWAPE CONSTITUTING THE FLOATING POINT SYSTEM IS DIVIDED INTO TWO SECTIONS. EACH OF WHICH OCCUPIES 3 BANKS OF ROM OR RAM. SECTION I IS INDEPENDENT OF OTHER SOFTWARE. SECTION 2 IS OPEPABLE ONLY WHEN SECTION I IS AVAILABLE IN MEMORY. IN ADDITION TO MEMORY REQUIRED FOR PROGRAM. 63 WORDS OF RAM ARE USED AS SCRATCHPAD.

SOFTWARE SECTION 1 CONTAINS THE FOLLOWING SUBROUTINES:

- LOD LOAD SPECIFIED DATA INTO THE FLOATING POINT ACCUMULATOR.
- ADD ADD SPECIFIED DATA TO THE FLOATING POINT ACCUMULATOR.
- SUB SUBTRACT SPECIFIED DATA FROM THE FLOATING POINT ACCUMULATOR.
- MUL MULTIPLY SPECIFIED DATA TIMES THE FLOATING POINT ACCUMULATOR.
- DIV DIVIDE SPECIFIED DATA INTO THE FLOATING POINT ACCUMULATOR.
- TST SET CONTROL BITS TO INDICATE ATTRIBUTES
 OF THE FLOATING POINT ACCUMULATOR.
- CHS CHANGE THE SIGN OF THE FLOATING POINT ACCUMULATOR.
- ABS SET THE SIGN OF THE FLOATING POINT ACCUMULATOR POSITIVE.
- STR STORE IN SPECIFIED MEMORY THE VALUE IN THE REGISTERS AS RETURNED BY OTHER SURROUTINES.
- INIT MOVE CODE FROM ROM TO RAM IN PREPARATION FOR FXECUTION OF THE MUL AND DIV SUBROUTINES.

SOFTWAPE SECTION 2 CONTAINS SUBROUTINES WHICH ARE USED TO CONVERT DATA BETWEEN THE BINARY FLOATING POINT FORMAT AND A DECIMAL FORMAT SUITABLE FOR ENTRY OR DISPLAY ON INPUT/OUTPUT EQUIPMENT. THE DECIMAL FORMAT IS STORED IN MEMORY AS A SERIES OF CHARACTERS. RELATIVELY SIMPLE INPUT/OUTPUT POUTINES MAY BE USED TO INTERFACE THE MEMORY-RESIDENT CHARACTER STRINGS WITH ANY TYPE OF PHYSICAL I/O DEVICE.

THE CHARACTER STRINGS CONSIST OF BCD REPRESENTATIONS OF DECIMAL DIGITS AND ARBITRARY REPRESENTATIONS OF +, -, .. AN EXPONENTIAL SIGN(LETTER E), AND SPACE. CHARACTER STRINGS MAY NOT CROSS MEMORY BANK BOUNDARIES. AN INPUT STRING IS THEREFORE LIMITED TO 256 CHARACTERS. AN OUTPUT STRING CONSISTS OF 13 CHARACTERS.

THE OUT SUBPOUTINE GENERATES CHARACTER STRINGS IN 2 FORMATS: THE CHOICE OF FORMAT DEPENDS ON THE MAGNITUDE OF THE VALUE REPRESENTED.

MAGNITUDES BETWEEN .1000000 AND 999999. ARE REPRESENTED BY A SPACE OR MINUS SIGN, SEVEN DECIMAL DIGITS AND AN APPROPRIATELY POSITIONED DECIMAL POINT. AND FOUR SPACES.
MAGNITUDES OUTSIDE THE RANGE ARE REPRESENTED BY A SPACE OR MINUS SIGN. A VALUE BETWEEN 1.000000 AND 9.999999. AN EXPONENTIAL SIGN. AND A SIGNED TWO-DIGIT POWER OF TEN.

THE INP SUBROUTINE CONVERTS CHARACTER STRINGS IN EITHER OF THE ABOVE FORMATS. OR A MODIFIED VERSION OF THEM. THE LEADING SIGN MAY BE INCLUDED OR OMITTED. ANY NUMBER OF DIGITS MAY BE USED TO INDICATE THE VALUE. WITH OR WITHOUT AN INCLUDED DECIMAL POINT. IF A POWER-OF-TEN MULTIPLIER IS INDICATED IT MAY BE SIGNED OR UNSIGNED AND MAY CONTAIN ONE OR TWO DIGITS. AN INPUT STRING IS TERMINATED BY THE FIRST CHARACTER WHICH DEPARTS FROM THE FORMAT.

THE FOLLOWING ARE EXAMPLES OF INPUT AND CORRESPONDING OUTPUT CHARACTER STRINGS.

8008 BINARY FLOATING POINT SYSTEM

FORMAT CONVERSION PACKAGE

THE FORMAT CONVERSION PACKAGE OF THE 8008 BINARY FLOATING POINT SYSTEM CONTAINS SUBROUTINES FOR THE CONVERSION OF DATA BETWEEN THE FLOATING POINT SYSTEM NOTATION AND TWO OTHER FORMATS. THE NON-FLOATING-POINT FORMATS ARE FOUR WORD FIXED POINT FORMAT AND VARIABLE LENGTH CHARACTER STRING FORMAT.

THE FORMAT CONVERSION PACKAGE IS CONTAINED IN 512 CONSECUTIVE WORDS OF MEMORY (2 BANKS OF ROM) AND REQUIRES FOR ITS EXECUTION THAT THE ARITHMETIC AND UTILITY PACKAGE BE AVAILABLE IN MEMORY. THE COMBINATION OF THIS PACKAGE AND THE ARITHMETIC AND UTILITY PACKAGE USES THE FIRST 64 WORDS OF A BANK OF RAM AS SCRATCHPAD MEMORY.

THE FIXED POINT FORMAT DATA PROCESSED BY THIS PACKAGE CONSIST OF 32 BIT BINARY NUMBERS OCCUPYING FOUR WORDS. TWOS COMPLEMENT NOTATION IS USED TO REPRESENT NEGATIVE VALUES.

THE POSITION OF THE BINARY POINT RELATIVE TO THE BITS REPRESENTING THE VALUE IS DENOTED BY A BINARY SCALING FACTOR. THE RINARY SCALING FACTOR IS NOT NORMALLY RECORDED IN THE COMPUTER, BUT WHEN A FORMAT CONVERSION SUBROUTINE IS CALLED THE BINARY SCALING FACTOR MUST BE SPECIFIED (IN THE E REGISTER). A BINARY SCALING FACTOR OF ZERO INDICATES THE BINARY POINT IS IMMEDIATELY TO THE LEFT OF THE MOST SIGNIFICANT OF THE 32 BITS REPRESENTING THE VALUE. A BINARY SCALING FACTOR OF 32 INDICATES THE BINARY POINT IS IMMEDIATELY TO THE RIGHT OF THE LEAST SIGNIFICANT BIT. THE PERMISSIBLE RANGE OF THE BINARY SCALING FACTOR IS -128(200 OCTAL) TO +127(177 OCTAL).

THE CHARACTER STRING FORMAT DATA PROCESSED BY THIS PACKAGE CONSIST OF BINARY REPRESENTATIONS OF CHARACTERS OCCUPYING CONSECUTIVE WORDS OF MEMORY. A CHARACTER STRING MAY NOT CROSS A MEMORY BANK BOUNDARY. THE CHARACTERS WHICH MAY BE INCLUDED IN A CHARACTER STRING. AND THE CORRESPONDING OCTAL REPRESENTATIONS ARE LISTED BELOW.

DECIMAL DIGITS 0008-0118 BCD DIGITS
SPACE 3608

• 3738 PLUS • 3758 MINUS

376B DECIMAL POINT

EXPONENTIAL SIGN 0258 LETTER E
(THESE OCTAL REPRESENTATIONS CAN BE CONVERTED TO THE
CORRESPONDING ASCII CHARACTERS BY ADDING 0608 TO EACH)

THE OUT SURROUTINE GENERATES CHARACTER STRINGS IN TWO FORMATS. EACH CONSISTING OF 13 CHARACTERS. THE FORMAT USED IN A SPECIFIC-CASE IS DEPENDENT UPON THE MAGNITUDE OF THE VALUE REPRESENTED.

SIGNIFICANCE INDEX

THE FLOATING POINT ADD AND SUBTRACT SUBROUTINES RETURN A SIGNIFICANCE INDEX TO THE USER WHEN THE RESULT OF THE OPERATION IS NOT ZERO. THIS INDEX GIVES AN INDICATION OF THE CHANGE IN THE VALUE OF THE ACCUMULATOR EXPONENT AS A RESULT OF THE ARITHMETIC OPERATION PERFORMED. IT IS USED PRIMARILY FOR COMPARISON OF TWO VALUES WHICH ARE EXPECTED TO BE EQUAL. BUT WHICH MAY DIFFER BY A SMALL AMOUNT DUF TO MEASUREMENT OR ROUND-OFF ERRORS. AS AN EXAMPLE, A SIGNIFICANCE INDEX OF 354 OCTAL (-20 DECIMAL) INDICATES THAT THE RESULT OF THE OPERATION IS SMALLER THAN THE OPERANDS BY A FACTOR OF APPROXIMATELY ONE MILLION (2 ** 20). THE FLOATING POINT TEST. COMPLEMENT AND ARSOLUTE SUBROUTINES RETURN THE SIGNIFICANCE INDEX FROM AN IMMFDIATELY PRECEEDING ADD OR SUBTRACT OPERATION.

HEXADECIMAL NOTATION [4]

Hexadecimal Notation is a convenient way of representing all sixteen combinations of four bits of information with a single character. The most popular character set for displaying Hexadecimal data are the characters 0 thru 9 to represent the binary combinations 0 thru 9 and A B C D E and F to represent the binary combinations 10 thru 15.

Hexadecimal	Binary Bits	Decimal
Characters	8 4 2 1	Characters
0 1 2 3 4 5 6 7 8 9 A B C D E F	0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 1 0 0 0 0 1 0 0 0 0 1 0 0 0 0 1 1 1 1 1 1 1 0 0 0 1 1 1 1 1 1 0 0 0 1 1 1 1 1 1 0 0 1 1 1 1 1 1 0 0 1	0 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15

As an extension of this technique, all 256 combinations of 8 bits can be represented by two hexadecimal characters as shown in the following examples.

Hexadecimal	Binary	Decimal		
Characters	Bits	Characters		
00	0000 0000	0		
01	0000 0001	1		
3E	0011 1110	52		
42	0100 0010	66		
E1	1110 0001	225		
FF	1111 1111	255		

Going further, all 4096 combinations of 12 bits can be represented by three Hexadecimal characters. This technique can be extended indefinitely, adding a Hexadecimal character for each four bits of information.
