The circular further says that "the Senate of Hamburg, as well as the Prussian Minister of Agriculture and Forests, have kindly promised to give the exhibition their cordial support, and an executive committee has been formed for the carrying out of the Exhibition."

We shall keep our readers informed of the progress of affairs in connection with the proposed Exhibition, and will be glad to receive suggestions and opinions concerning the American display from breeders—all of whom are invited most cordially to correspond with us on the subject, either privately or through the columns of the Weekly BEE JOURNAL.

North American Bee-Keepers' Society.

We have received the following circular from Prof. Cook, which is worthy of careful perusal by the bee-keepers of America. As the time fixed for the assembling of the next Convention is rapidly approaching, its publication will not be considered premature, and may serve as a reminder to some who will require time for preparation:

State Agr'l College, Lansing, Michigan, May 11th, 1882. J

To the Vice Presidents of the National Bee-Keepers' Association, and the Bee-keepers of America:—I beg leave to call your attention through the several bee papers of the country, to the next meeting of our Association, to be held in the city of Cincinnati some time in October next.

All disinterested friends of apicultural progress will recognize the valuable work of the Association, and the greater good that may come, yes, and will come, when all our associations are harmoniously working together to build up our art. Those present at the last meeting at Lexington will recall the perfect harmony, and the perfect spirit of accord that prevailed during the entire meeting, and the feeling of real satisfaction that was manifested by those present from every section. Let us commence early to secure even greater fruits at the next meeting. With this end in view, I wish to offer some suggestions:

Let any one who wishes the character of the meetings changed in any particular, write to me at once, and their wishes shall receive earnest attention.

Let the delegates from each State come prepared to give accurate data as to the honey crop for the season of 1882, that we may be able to give the best advice as to the marketing of the crop.

Let it be remembered that committees were appointed to experiment in several lines, particularly in controlling fertilization, and let us hope that full and able reports will be rendered. Let others come prepared to add to the reports, and to discuss them.

In accordance with the general opinion, few and short essays will be read, that the discussions may be more full. With this in view, let every person come prepared to give quick and accurate accounts of what he has learned that will be helpful to the bee-keepers of the country.

Let us hope for a large attendance of the enthusiastic bee-keepers of the country, and that all may come full of the spirit of progress, good feeling and harmony, that the meeting may be great in the good that shall be accomplished, and entirely free from all harsh, uncharitable words, which, in no convention, tend to edification.

A. J. COOK, Pres.

Inventor of Broad Frames for Sections.

Mr. H. H. Flick writes us regarding our answer to Mr. Friedemann Greiner, on page 258, as follows:

Are you not mistaken in the issue of April 26, page 258, about sections and broad frames? I claim the honor of inventing the frame to hold sections. By referring to the Patent Office, you will find that my patent covers the broad frame holding sections, which was dated on Sept. 21, 1869, and ante-dated Sept. 8, 1869, and numbered 95,100.

We cannot see wherein we made any mistake. Mr. Greiner inquired if sections were in use in this country before the year 1875, and whether it was so published in the BEE JOURNAL of 1874 or 1875. Upon examining our back volumes we found several mentioned before that time, referring to them and reproducing the identical cuts used to illustrate the several inventions at the respective dates. We gave no one credit for originating anything except so far as indicated in the back numbers of the BEE JOURNAL, and if Mr. Flick's invention was noticed or advertised previous to 1875, we overlooked it. We did not say those parties, or any of them, were the inventors of the broad frame, nor that Mr. Flick was not. We merely cited the cases on record to prove that sections were used in America prior to the time that they were claimed to have been invented in Germany. We would not intentionally deprive any man of credit to which he is justly entitled, and especially regarding so important a matter as the section case or broad frame.

The Albino Bee Controversy.—Mr. S. Valentine, on page 199 of the BEE JOURNAL, gave the origin of the term "albino," as applied to that particular strain of bees, and claimed to have been their originator as a fixed type; to this Mr. D. A. Pike rejoined in an article published on page 250, claiming at least a share of the credit. We have received still another communication from Mr. Valentine on the subject, but as both gentlemen have already been heard, and each made out

a pretty strong case, we will have to let the matter rest where it is. It is not a question that interests the general reader, and no good will be accomplished by continuing it. We are more convinced than ever, that personal controversies relating to business matters, when carried to any length through the columns of a public print, are not only in bad taste but frequently give rise to damaging impressions. We shall endeavor to discourage this class of correspondence as much as possible hereafter.

Bee-Keepers' Associations.

It is exceedingly gratifying to observe the perfection of the bee-keepers' organizations in Utah, and many old States, with much greater pretensions in an apicultural point of view, could study and adopt their system with great profit. It will be seen there is a Territorial or head organization, with its President and general officers. Tributary to this are District or County Societies, each with its President and Bee Commissioner, and these make it a special business to inform themselves of the number of colonies in their respective districts, their condition, and the manner of treatment and care of bees, and success. They are also clothed with arbitrary power regarding foul-brood and other contagious diseases, and report all matters of general interest to the Territorial Association. By this system of thorough organization, all data bearing upon the production, condition, treatment, and prospects are easily arrived at, and the most practicable system of co-operation can be determined upon and effectively practiced.

The Irish Bee-Keepers' Association have adopted as its standard frame the same size as that of the British Association, and adopted a "resolution in favor of a journal exclusively for bee-keepers, and independent of trade influences, and promising to support such a journal if brought out under proper management." So says the *London Horticultural Journal*.

Our new location, 925 West Madison street, is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

MISCELLANEOUS.

Honey Shows.—The *Northwestern Farmer and Dairymen*, of Portland, Oregon, remarks as follows:

The Irish Bee-Keepers' Association is to have space at the Royal Dublin Spring Cattle Show. Lectures will be given and, if the weather is propitious, the actual manipulation of bees will be freely shown by skilled apiarists. It will be a brief session of an apiarian school. And the *Prairie Farmer* well says: "Why cannot American bee-keepers take a hint from this and increase the value and interest of the bee and honey exhibits at our annual fairs? The bee-keepers should have a tent or building to themselves, where they can show their hives and other devices to good advantage, and where they can lecture, talk and instruct each other and the people in general, in bee handling and care."

In thus conducting the bee exhibit a great interest would be created and bee-keeping materially extended. This interest is too greatly neglected in this northwest, though Oregon and Washington are eminently well provided for successful bee-keeping, and there is no good reason why nearly all our honey should come from California.

The Weather and Feeding.—The *Indiana Farmer* remarks as follows on the weather, fruit bloom, etc.:

The cool and unfavorable weather of the past few weeks has been quite detrimental to the bees. Very little honey was gathered from the fruit bloom. Many colonies will be short of stores, and must be fed to keep from starving, or if not so bad as that, they may entirely suspend brood rearing, losing weeks of valuable time. We are feeding our entire apiary of 150 colonies. It is not necessary to make syrup with which to feed, by boiling. Neither is it desirable that it be made thick. Sweetened water is all that is required at this season of the year. We simply fill a large extractor with water; scoop in sufficient sugar to make it sweet, stir until the sugar is dissolved and drawn off into the feeders.

The Crafty Bee and its Sting.—The *Boston Journal* tells the following story concerning the sagacity of a bee:

A certain restaurant in this city, apparently to proclaim the unlimited resources of its cuisine, has in its show-window a huge tank wherein glittering gold fish, sullen horned pouts, dignified bull-frogs and sprawling turtles dwell together in a greater or less degree of amity. The other day a bee fell into the water and was solemnly

gobbled by a goggled-eyed fish. Hardly had the bee been engulfed, however, when the fish was seen to be strangely excited. He leaped into the air, drew in great volumes of water and blew them out again, and acted so insanely that the turtles scuttled away in hot haste, and the frogs tumbled off the rocks to right and left in sheer consternation. Meanwhile the bee reappeared and crawled out of the tank in safety, evidently congratulating itself, as it dried its wings, upon its possession of a sting, and the presence of mind necessary to use it to advantage in an emergency.

Introduction of Italian Bees into England.—The *British Bee-Keepers' Guide Book* gives the following as a scrap of history:

ITALIAN BEES.—This variety, sometimes called Ligurian, was introduced into this country in 1859 by Mr. Woodbury, of Exeter, from a small district amid the Alps, including portions of Switzerland and Northern Italy, where it is indigenous. Much prejudice existed against them at first, but now their superiority over the common black bees is almost universally admitted. The Italian bee is similar in form and size to the black bee, but lighter in color, and has three distinct yellow rings about the body below the wings. It is more prolific than the black bee, more active, working earlier and later, increases much more rapidly, is ready for swarming earlier, and gathers honey from plants which are not frequented by the black bee. Pure Italians are also of a more amiable disposition, and less inclined to sting, therefore they are easier handled. The introduction of Italian bees has done much to improve our race of black bees, by introducing new blood and correcting to a great extent the mischief which had inevitably resulted from long in-and-in breeding.

The Honey Prospect.—Mr. L. R. Jackson gives his views on this subject in the *Indiana Farmer* in the following language:

The prospects for a good honey crop are unusually good in this section of the country. The cold weather during fruit bloom has prevented the bees from storing the usual amount of surplus honey, but at the same time it has kept the trees in bloom, twice the usual length of time and the bees have been able to gather plenty of the nectar, to keep brood rearing actively going on and I have never seen bees build up as much during fruit bloom as they have this spring. The white clover never looked better and it will be fully two weeks earlier than common. The mild winter with but little freezing and thaws has left the roots of clover and other flowers in a healthy condition. Basswood is almost sure to be good, and with us that is better for surplus honey than all other bloom, it being so plentiful and so sure to give a surplus.

Care of Comb Honey—No. 1.

G. M. DOOLITTLE.

As I intimated at the start when commencing these articles, that I would take up the text under the different heads: "Production, Care, and Sale," separately, so having spoken of production, my next or second part will be care. At the outset I wish to say that many seem to suppose that the producing part is about all there is to any branch of business, which supplies our markets with merchandise. How often we find butter, wool, maple sugar, etc., taken to market in such poor shape that it does not bring as much, within 20 per cent., as goods of no better quality are selling for, where the producer understands that the placing of his product upon the markets in attractive shape, has much to do with the value thereof. It is said that Mr. Durand, an extensive strawberry propagator in New Jersey, always finds a ready sale for his choice strawberries at a very high figure, while those of shiftless producers spoil on the markets without a purchaser. Thus, Mr. Durand obtains more money from his few rows of choice fruit put upon the market in attractive shape, than is obtained from as many acres grown in a slipshod manner, and sent to market by shiftless parties. Honey is no exception to this rule, unless it is that the difference is still greater than on most other productions.

Hence, to place our honey upon the market in the best possible shape should be the aim of every bee-keeper in the land. My aim has always been, not only to get the honey off the hives before it was soiled by the bees, as I stated in the production part of these articles, but also to keep the combs as nice and perfect till they were placed upon the market, as they were when first taken from the hive. This is no easy task, for from the first, honey is liable to accidents which, if they occur, soon reduces the price from $\frac{3}{4}$ to $\frac{1}{2}$.

I once hired a man to help me remove honey from the hive, as I was nearly sick and unable to keep even with my work as I desired to, but after his working with me half a day I so improved in health that his assistance was no longer necessary. He would manage to get his fingers against the honey so as to break the nice cappings to nearly every box, in spite of all I could do, and if he did not do that he would get the corner of one box into the face side of the comb in some of the other boxes, and I actually believe I paid him 75 cents for doing me \$10 damage. Where a person is naturally sensitive, such proceedings will cure slight sickness

quicker than a physician can. I only give this illustration to impress on the minds of the readers that the utmost care is necessary at all times in handling section boxes of honey.

The first requisite in caring for our honey after it is taken from the hives is a good room in which to store it. Years ago it used to be the custom to store honey in the cellar to keep it cool, but I believe all of our practical bee-keepers of to-day prefer a warm room to a cool one, on account of the honey sweating, or taking on dampness in a cool room, thus giving it a watery appearance. If left for a great length of time in such a place the honey will often become so damp and thin as to burst the sealing, and leak badly as well as to sour. While in New York, in 1877, I saw in a damp cellar several hundred pounds that had become thus damp and thin. It had run down the sides of the crates and over the floor, where it had soured, making it smell badly and look equally bad. To avoid an occurrence like this our honey should be stored in a dry, warm room, and be so piled up that the air can circulate freely all around it.

In visiting some of our extensive comb honey producers here in the east, I found them carrying their honey up a flight of stairs to the chamber of the house or workshop, that they might get the heat produced by the sun shining on the roof. Now, while this gave all that was necessary in the shape of a honey room, it also gave a large amount of extra work which I consider as unnecessary.

I use a room 7x10 feet, in the southwest corner of my shop, having the outside painted a dark color, so that the rays of the afternoon sun will make the room as warm as possible. As a body of honey, once thoroughly warmed, will hold the heat for a long time, the average temperature of this room will be pretty high, ranging from 80° to 100° most of the time, thus ripening the honey so that in a month's time it can be handled as you please and not a drop of honey will leak, even from the few uncapped cells the bees always leave around the edge of the box.

To secure a free circulation of air, as honey will take on dampness even in a warm room if the air is partially excluded from it, I build a platform of scantling a foot from the floor, and six inches out from the wall, upon which I pile the filled sections, keeping them in the same position they occupied while standing on the hive. On warm days raise the windows on each side of the room, so as to admit all the fresh, dry air possible, and as it comes toward evening close them again. To prevent robbers coming in, and also to let the few bees that may come in on the honey out, I cover the window (tacking it to the casing outside) with wire-cloth, letting it go above the casing nearly a foot at the top, and keeping it out from the building $\frac{1}{2}$ inch by means of strips of that thickness tacked to the outside of the shop, and running up and down the side. Thus, all bees from the inside crawl to the top above the win-

dow where they find an outlet, while the robbers are intent on getting through the wire-cloth where they can see and smell the honey, as their instinct is not equal to showing them that by going above the window a foot, and down behind the wire-cloth they could get the tempting sweet. So they are kept outside where you wish them by this simple device, while the climbing instinct of those inside enables them to get out, thus keeping your room clear of bees.

My next will be how to detect the work of the moth-worm when it first hatches, and how to head them off if troublesome.

Borodino, N. Y.

For the American Bee Journal.

Reply to Mr. Clarke.

JAMES HEDDON.

I wish to assure Mr. Clarke that I have no ill feeling toward him or any other bee-keeper; that I admire his terse and scholarly writings. In our views on practical apiculture we differ; that is best, perhaps. Of Mr. Clarke's practical knowledge of apiculture, I have never been able to learn much. I presume I was wrong in my use of the more belligerent term "attack," when I meant simply "criticism." I stand thankfully corrected. I ask to be excused for this literary mistake, having had far less chance to become proficient in this direction than the Rev. Mr. Clarke or Prof. Cook, having made honey producing a specialty since my youth, and have had to stick very closely thereto, to support my family and "get on in the world."

Mr. Clarke, do you not frequently read facts in the BEE JOURNAL, where experiments have been made especially to test the pollen theory, which indicate that pollen is one of, if not the chief trouble. I have many private letters upon the subject, all favoring that theory. Among them I call to mind Dr. A. B. Mason's, of Wagon Works, O., and Walter Harnes', of Manistee, Mich. There are many more, but I depend upon memory only. Referring to my religious views, and that, too, where it has no bearing upon the subject under consideration, I think myself is "questionable" in its "propriety." I mentioned it as I did to illustrate the point that Mr. D. and many others believed things implicitly, where there were no living "witnesses that he could cross-examine." I thank you, Mr. Clarke, for wishing that I believed a something, the same as you do, and I trust that you do not hold to the ancient custom of convincing me by a little screw applied to my thumbs.

But, really, has not the time gone by when you can satisfactorily answer a man's argument by pointing at what you think to be a hole in his coat? Perhaps I think more of science, and less of the supernatural than you do, because of our labors with and incomes derived from these sources. Whether "Thomas" doubted or not, honesty was always the best policy,

and always will be. The way "we" agree so nicely in our opinions in regard to apiculture here, is because "we," the family and 3 apprentices, are numerous enough to hold daily Bee Conventions, and when we differ, we just discuss the subject till we agree, if possible, and upon points that we do not agree, I do not say "we" think so. Now, you have not said any unkind things of me, that I know of. I do not consider sarcasm unkindness, any more than it is logic. I rather like "smart" hits, and would rather they would hit me than to never be shot. I smoke the pipe of peace with you, and if you will drop in upon me some time, I will convince you that my stomach is not sour—no not acid—not even bacterious.

Wintering Bees in Clamps.

W. Z. HUTCHINSON.

About a year ago an article appeared in the BEE JOURNAL upon the above subject, by Mr. C. J. Robinson. I was very much interested in the matter, and, after some correspondence with Mr. R., I decided to give this method of wintering a trial.

Learning that dampness was one great foe to success, I selected a dry, sandy knoll as a site for my clamps. I use the word in the plural, because I buried bees in two pits, in order that I might open one early and the other late, and note the difference in the condition of the bees.

In burying the bees, I first dug a trench two feet wide at the top, and two feet deep. This trench was filled with dry straw, then pieces of scantling were laid across the trench, and the hives set over the trench upon these pieces of scantling. With rails and pieces of rails a pen was built around the hives, and the space between hives and rails, which was about one foot, was filled with dry straw. The pen was built about a foot higher than the tops of the hives, the tops of the hives were covered with straw to the depth of one foot, and then the straw was covered with rails, the ends of the rails resting upon the outside pen. The sides of the pen were built slightly sloping, so that the top of the pen was smaller than the bottom. The pen was covered upon the outside with about a foot of straw, and then the whole was covered with earth to the depth of about 18 inches.

On Nov. 15, four colonies were buried in one clamp, and six in another. No openings were left for ventilation, and, during the past winter, I was obliged to "tell about those bees" until it really became tiresome. "What! don't you give them any air?" "No, only what was in there when they were buried, and what little finds its way through the earth." "Why! they'll smother won't they?" "No, I think not." "Well, I wouldn't give you much for them," etc.

I selected the lightest colonies, as Mr. Robinson said that he thought

that they wintered better in clamps than did strong colonies. The lightest colony did not cover three combs, while the heaviest covered six combs.

One clamp was opened April 1st, and the bees were found in fine condition. There were but few dead bees, scarcely any honey consumed, the bees very quiet with no signs of dysentery, no moldy combs, and the straw so dry and sweet that the cow ate it readily. The other clamp was opened April 17th, and the bees found in the same condition as in the other clamp, except that the lightest colony was dead, for which I can give no reason, unless it was because there were so few bees. With the exception of this one colony, the bees appeared to be in about the same condition as when placed in the clamps—as though they had slept only over night, instead of over five months, as some of them had.

This experiment helps to confirm my belief that, if properly managed, bees can be successfully wintered without carrying them out, in the winter, for a "fly."

I have been so successful in this attempt at wintering bees in clamps, that I shall try it again next winter upon a larger scale. If I remember rightly, Mr. Robinson has, for several years, wintered his light colonies in this manner, and wintered them successfully, too. I wish to thank Mr. Robinson and the BEE JOURNAL for information upon this subject.

Rogersville, Mich.

For the American Bee Journal.

Fastening Foundation in Sections.

L. JAMES.

On page 227 of the current volume of the BEE JOURNAL is an article by Dr. Miller upon the above subject, and its perusal as well as many others that have appeared at various times in the JOURNAL, leads me to believe that it is not known generally among the fraternity how easy a thing it is to fasten either foundation or combs in frames or boxes, that will remain just where you put them. And if the Doctor or Mr. Doolittle will give it a fair trial, I think the former will have no further "trouble in having it dropping out of sections just at the most annoying time when honey is coming in with a rush," and that the latter will lay aside his hot iron.

In practice it is simple, and the foundation can be inserted rapidly and securely. I will give to the fraternity my method of fastening starters of combs in surplus boxes, or whole sheets of bee combs in frames for the body of the hive for the past 15 or 20 years, with entire satisfaction, and I find it answers equally well in securing foundation in place. To hold the foundation in the frame (or section if that name is more expressive) conveniently for fastening it there, I make what I shall call a support, as follows: Take a piece of 3-16 inch board (a piece of cigar box I prefer) and cut it $\frac{1}{4}$ inch less on all sides than the inside of the section.

On one side of this piece and flush with the edge nail a strip $\frac{3}{4}$ or $\frac{1}{2}$ inch thick, and the same in length, and wide enough to project $\frac{1}{4}$ inch beyond the side of the top-bar of the frame, when the opposite side of the support is a trifle less than half way through the section (less the thickness of the foundation). To the lower outside edge of this $\frac{3}{4}$ inch strip nail a piece $\frac{1}{2}$ inch thick, $\frac{1}{4}$ inch wide and of the same length to gauge the exact distance the support will stand in the section so as to hold the foundation centrally in the section. Cut the top and one side of the foundation at right angles to each other so that it will come in close contact with the top-bar and one side of the section. Turn the section upside down and clap the support inside with the thumb placed on the $\frac{3}{4}$ inch strip and the fingers on the outside of the top-bar holding it securely in place, lay in the foundation carefully so as to have the straight edges fit nicely to the top-bar and side. This will prevent the melted cement from running under it. Tip the section a little to one side to prevent the foundation from falling out. To fasten it hold the frame in such a position as to have one of the straight edges at a suitable angle for the melted cement to run quickly down its edge to the corner of the section, if there is a surplus of it, by adroitly turning the section allow it to traverse on down the other straight edge of the foundation. It is not advisable to pour on too much at first, but after it has started down to keep dropping it from the spoon upon the descending current as it shows signs of stopping. Some practice and care is needed to keep the cement at a proper temperature; if too hot it will melt the foundation, and if too cool it will not flow fast enough to make a neat job. It requires but little cement to hold the foundation firmly in its place, and all beyond this is worse than useless. A little practice will enable the operator to hold the frame in a proper position to have the cement travel quickly along in its course so as not to have it spread too much on either the foundation or frame. If, however, too much has been used, or dropped on the frame, I find a table knife with the blade broken off so as to leave it an inch long on the back and half an inch longer on the cutting edge, giving it an acute angle (most conveniently done by grinding), a convenient tool to remove the superfluous cement. With the thumb placed on one side of the blade to act as a gauge it can quickly be removed if attended to before it becomes too cool.

The cement I use is made by melting together in my wax cup three parts of clean bees wax and one of clear, clean rosin, well incorporated by stirring after they are melted. The quantities are by bulk, and as near their proportions as I can guess, as it is added from time to time as I need it.

The best thing I have found for applying the cement with is a thin teaspoon with the point of the bowl drawn out to a narrow pitcher mouth shape, by hammering; I also find the

feather end of a goose quill, that is a little dished or spoon shaped, properly trimmed, quite useful on many occasions to touch up and finish any little imperfection that may have occurred in inserting the foundation, or in closing openings between the glass and box where the former happens to be too small to make a good fit.

While upon this subject I will give a description of my wax cup that may be of advantage to beginners—the old ones know all about it. It is a tin cup 5 inches in diameter, $2\frac{1}{2}$ inches deep, with a small lip soldered on one side, for the convenience of pouring the cement when wishing to clean out the cup. A strip of tin $1\frac{1}{2}$ inches wide crosses the cup and is riveted at either end to the sides of the cup, so as to stand $\frac{3}{4}$ of an inch above the top of the cup, with a circular piece cut out of the upper edge to correspond in a measure with the convexity of the bottom of the spoon, to readily clean off the drop of cement from the bottom of it as it is drawn through this depression, and conveyed back into the cup.

Atlanta, Ill., May 3, 1882.

Texas Agricultural Journal.

Bee Forage of Southern Texas.

THOS. D. LEONARD.

Honey is strictly a production of the vegetable kingdom, and in most cases is confined to flowers. All flowers do not produce honey. Some produce pollen (bee bread) only, while others produce both pollen and honey. Honey is secreted by minute glands, contained in small cups called nectaries at the base of the stamens, and also exudes from the leaves and stems of many plants. It consequently partakes more or less of the flavor of the flower that produces it. The God who created both bees and flowers made both in harmony with each other.

The sweet nectar is supplied by the flowers in a crude state, and consequently needs to be analyzed and refined. The bee is guided by its God-given instinct to select what she chooses and reject any and all impurities not consistent with her choice. Physically she is prepared for this work, and also possesses an extraordinary instinct, to guide her where and when and how to find honey or pollen when it exists even in the smallest quantities, and at its earliest appearance.

We have about fifteen varieties of trees that may be classed good and best honey producers, to wit: The peach is earliest to bloom; there are several varieties of haw which begin to bloom early in March and continue to April—it is valuable for brood-raising; red-bud is early and very good; hackberry, holly and prickly ash are good; wild peach may be classed first-best and blooms in April, and sweet bay may be classed with it but blooms later; youpon and huckleberry are very good and begin last of April and continue 3 or 4 weeks; dew berry is valuable and

blooms early; grape and ratan are the best vines, yet all the vines we have are good—nothing we have excels ratan and linden. The spring harvest closes with the linden. When it blooms, from the 15th of May to the 20th of June, we have our best flow of honey, so have your colonies in good condition for harvesting. The wild mulberry comes in bloom in June and lasts several weeks. The horsemint comes in bloom in May and continues four or five weeks. Golden-rod and boneset bloom in September and October—both are very good for winter honey. Corn and cotton afford some honey; melons afford honey; the white-flowered thistle is very good and lasts several weeks. There are several other trees and plants that produce honey. If you have bees, and will give attention, you will soon learn all they work on in your locality.

All the above named trees, vines and plants do not exist in any one locality; consequently, as they bloom at different periods, and none last more than 2 or 4 weeks, there may be gaps of 10 or 20 days in many localities, which would be detrimental to the bees. A 4 or 6 weeks drought at any time would seriously affect the honey crop. Too much rain is also disastrous. Any locality can be improved by selecting and planting such plants as will fill up the gaps that may exist. Such should be selected as might be planted on waste lands, old fields, road sides, banks of streams, hedges, etc. I do not think it will pay to plant anything that requires cultivation for honey alone. All the hedges that I have seen afford honey-producing flowers. Wild peach will pay planted for groves or shade. So will linden.

We have honey-dew some years in some localities. It is the product of an insect. It is not fine flavored but answers for brood-raising and winter honey. I have seen the insect in millions, and the honey dripping from the leaves of the trees.

Howth Station, Texas.

Home Science Gossip.

Shading for Bee Hives.

F. L. WRIGHT.

While all agree as to the propriety of shading hives from the hot sun of midsummer, all do not agree as to the method of shading. Without doubt the best shade for hives never has been thought of. Each has his pet method, such as grape vines, raspberries, hops, tomatoes trained on a trellis, evergreen trees closely sheared on one side, etc. By far the greater part prefer the first mentioned, viz: grape vines. This being our preference we will try to give you a short chapter on planting and caring for vines, and in our next will return to our subject.

A vine should be planted on the south side of every stand. Select some good salable variety, and one known to do well in your locality. For South I would recommend Martha, Ives, Concord and some of the best

Æstivatis class such as Herbemont, etc. For the West only such hardy sorts as Janesville, Clinton and Taylor of the *Ripirari* class, and the hardiest of the *Labruscas*. For the States east of Lake Michigan all of the best varieties of *Lab* and the hardiest hybrids will be found more satisfactory than the extra hardy varieties required for the West and Northwest.

Select good, strong one-year old vines, which can be had at a very low price.—cut back the tops to two or three buds, and the roots one-third. Dig a hole large enough to take in all the roots without having any two cross each other, and 18 inches or two feet deep. Fill up the hole to within 6 or 8 inches of the top with surface soil in which has been mixed some bones, wood ashes, charcoal, etc.; on this plant the vine, spreading out all the roots, and then fill up with fine surface soil packing closely and firmly.

As soon as the shoots have grown a few inches rub off all but the strongest one. A good stake should be driven firmly by the side of the vine and the vine should from time to time be tied to this, which will be all the support needed for the first two years. As soon as the young shoot has reached the top of the stake (which should be 4 feet high), the end should be pinched off which will cause it to throw out laterals, thus making all the more shade. At the end of the first season if the vine has made a good growth, you should cut it back to within 2 feet of the ground, and the next season allow but two of the strongest shoots to grow. These should be trained to the stake as before, only allow them to grow beyond its top and hang partially over the hive. At the end of the second season cut back to about the top of the stake. After this you will need a trellis of some kind. The one we give preference is known as the Caywood overhead vine trellis. It is constructed as follows: Set a good, sound oak or cedar post by the side of every vine, letting it extend out of the ground $6\frac{1}{2}$ feet. On the top of this spike 2x2 scantling 3 feet long, making a cross. On the top of this stretch 4 wires (No. 14) from one end to the other of the row of vines fastening them securely 12 inches apart on the scantling, thus making an arbor that, when covered with vines, will give good shade in the middle of the day, when most needed. The vines are also over head entirely out of the way, as the vines are simply taken up the post and allowed to extend along the wires, and if any grow off and hang down, simply throw them up over the wires. A very fair shade can be made with raspberries by simply allowing but 3 or 4 canes to grow, and, as soon as they reach the height of 4 feet, pinch off the ends which will cause them to throw out branches or laterals. These also should be pinched as soon as they grow a foot or so. If treated in this way they make a stocky growth and yield large quantities of extra fine fruit.

There are many other things used for shade with good results, but let me

caution you not to place them under large trees where they cannot receive the direct rays of the morning and evening sun. Hives in such localities are in damp times subject to fungoid growth, soon rot and combs often mold.

Plainfield, Mich.

Scientific News.

The Functions of the Queen Bee.

PROF. C. F. KROEH.

Some of the most surprising facts concerning the queen bee still remain to be mentioned. As there are three kinds of bees in the hive, we should naturally look for three kinds of eggs for them to hatch from; but the queen lays only two kinds. There can be no doubt as to the identity of the eggs from which queens and workers spring. We have waited until worker eggs hatched into tiny grubs, and then transferred these into cells which a queenless colony had enlarged to rear queens. Others have tried the same experiment, and the result uniformly has been that these larvae hatched out into queens.

It still remains for us, however, to account for the manner in which the queen lays two kinds of eggs after her fertilization. That a healthy queen knows what kind of an egg she is about to lay, and that she has the power of regulating its sex, is evident from the fact that she puts the egg in a cell of the proper dimensions, laying worker eggs in cells one-fifth of an inch, and drone eggs in cells one-fourth of an inch in diameter, without making any mistakes. The microscope has partly solved the mystery. The ovary of the queen consists of two lobes emptying into a common duct, just below the entrance of which there is a small vesicle, called the spermatheca, which Hunter, in 1792, proved to be filled with the seminal fluid of the drone when copulation takes place, and Leukardt estimates that this fluid contains about twenty-five millions of spermatozoa. Now, when the queen lays an egg, she may or may not compress the spermatheca at the moment the egg passes it; if she does, two or three spermatozoa find their way into it, and the result is a worker egg; if she does not, the egg remains unimpregnated and hatches out a drone. Siebold found from one to three spermatozoa in every worker egg, but none at all in drone eggs; and Donhoff reared a worker from a drone egg which he had artificially impregnated as soon as it was laid.

It was stated above that the microscope solved the mystery but partially; for it is contrary to our common experience that unimpregnated eggs should hatch at all. If hens, for example, are kept by themselves, they will continue to lay eggs; but these eggs will never hatch. Nevertheless, the evidence in the case of the queen bee does not admit of a reasonable doubt. In 1845, Dzierzon found the true interpretation of the observation so frequently made, that some queens

lay nothing but drone eggs. If a queen hatches out crippled, so as to be unable to fly, she will never be fertilized. If she is prevented by bad weather or other causes from flying out to meet a drone for a period of about three weeks after hatching, she is no longer capable of fertilization, probably by reason of a change in her organs of generation. In either case she will lay eggs that will hatch drones only. As queens grow older, their supply of spermatozoa, copious as it is, gradually dwindles down, and they will lay more and more drone eggs in proportion to the number of worker eggs. Indeed, the supply is liable at any time to become exhausted, and the brood will then consist solely of drones. Queens of the three kinds mentioned have been repeatedly dissected under the microscope, and in every case the spermatheca was found to be devoid of spermatozoa. As it is manifestly to the disadvantage of the bee-keeper to raise a large number of drones, which are consumers only and not producers, he remorselessly dispatches all drone-laying queens and replaces them by young fertile ones. As a rule it does not pay to keep a queen longer than three years.

So far as we know, a single fertilization lasts a queen for life. Instances have been reported now and then that a queen had left her hive for a second mating, but owing to the extreme difficulty of verifying observations of this kind, they cannot be accepted as facts until further evidence accumulates.

A healthy queen not only knows in advance the sex of the eggs she is going to lay, but she proportions their number to the wants of the colony. If the weather is cool, or the colony so weak that it cannot produce heat enough to hatch much brood, or if there is scarcity of honey, she will lay but few eggs. She deposits them, moreover, in contiguous cells, and after having laid a patch on one side of the comb, she crosses over on the other side and lays in the cells exactly opposite, so as to economize the heat of the cluster. In the height of the season, when an abundance of honey is brought into the hive, the development of eggs in her ovary is proportionally great. Then it often happens that she is pressed for room, all the cells being occupied by stores or brood. As she is obliged to lay the eggs as fast as they come to maturity, she sometimes lays two in one cell, one of them being then removed by the workers; or else she simply drops them. Langstroth states that the workers in that case often make a meal of them, and admires the self-control they must exercise upon other occasions in abstaining from dining upon eggs when they are not plenty.

The queen eats honey herself, but she is also fed by the workers, probably with partly digested honey and pollen. It is quite likely that the amount of the food thus offered her regulates the maturing of eggs in her ovary. When the workers collect an abundance of stores, they feed her

liberally, and she then lays a large number of eggs; but when stores are scant they do not stimulate her so much. Before dismissing this portion of the subject, it may be well to caution the reader not to allow his imagination to be captivated by the word queen to such an extent as to assign to her mentally the prerogatives of royalty. Some writers go so far as to picture her constantly surrounded by a respectful circle of subjects, waiting upon her majesty, and ready to carry her commands to every part of the colony. It appears, on the contrary, that the regulation of the affairs of the hive belongs not to her, but to the workers. They decide when to swarm, how much comb to build, and how much brood to rear. They determine when to raise new queens, probably transferring eggs into queen cells, and they protect them from the jealousy of the old queen. It seems as though the sole function of the queen is to lay eggs.

Stevens' Institute of Technology.

CLUBBING LIST.

We supply the Weekly American Bee Journal and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

	Publishers' Price.	Club.
The Weekly Bee Journal.....	\$2 00..	
and Gleanings in Bee-Culture (A. I. Root) 3 00..	2 75	
Bee-Keepers' Magazine (A. J. King) 3 00..	2 60	
Bee-Keepers' Instructor (W. Thomas) 2 50..	2 35	
The 4 above-named papers.....	4 50..	4 00
Bee-Keepers' Exchange (Honk & Peet) 3 00..	2 80	
Bee-Keepers' Guide (A. G. Hill).....	2 50..	2 35
Kansas Bee-Keeper.....	2 60..	2 40
The 7 above-named papers.....	6 30..	5 50
The Weekly Bee Journal one year and Prof. Cook's Manual (bound in cloth) 3 25..	3 00	
Bees and Honey, (T. G. Newman) " 2 75..	2 50	
Binder for Weekly, 1881.....	2 85..	2 75
Binder for Weekly for 1882.....	2 75..	2 50

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—a copy of "Bees and Honey."
" " 3,—an Emerson Binder for 1882.
" " 4,—Apriary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,—" " " cloth.
" " 6,—Weekly Bee Journal for 1 year, or Apriary Register for 200 Cols.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

“Pot-Bouille,” Emile Zola's new book, is creating a greater sensation in Paris than either “Nana,” or “L'Assommoir,” 30,000 copies of it having been sold in Paris on the first day of its publication, and the American edition is published this day by T. B. Peterson & Brothers, Philadelphia, in a large square duodecimo volume, uniform with “Nana” and “L'Assommoir,” and is for sale by all Booksellers, and at all News Stands, and on all Railroad Trains. “Pot-Bouille” is intensely interesting, and is a faithful picture of the manners and morals of the Parisian middle classes.

Local Convention Directory.

1882. *Time and Place of Meeting.*
 May 11—Champlain Valley, at Middlebury, Vt.
 T. Brookins, Sec., East Shoreham, Vt.
 16—N. W. Jll. and S. W. Wis., at Rock City, Ill.
 Jonathau Stewart, Sec., Rock City, Ill.
 25—Iowa Central, at Winterset, Iowa.
 Henry Wallace, Sec.
 June 3—Hart County, Ky., at Woodsonville, Ky.
 Oct. 5—Kentucky Union, at Shelbyville, Ky.
 G. W. Demaree, Sec., Christiansburg, Ky.
 Tuscarawas Valley, at Newcomerstown, O.
 J. A. Bucklow, Sec., Clarks, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

Salt Lake Herald.

Utah Bee-Keepers' Convention.

The Territorial Bee-Keepers' Association assembled at Salt Lake City, April 6, 1882, President A. M. Musser presiding.

Letters were read from various parts of the Territory. Mrs. Annie C. Woodberry, of St. George, writes that in the spring of 1881 she had 45 colonies, increased to 51, lost 5 during the summer, leaving 46 in good condition; had taken 2,200 lbs. of honey, mostly from top boxes.

Mr. John Price, of Washington, writes March 26, 1882: Six years ago I began bee-keeping with one colony, and now I have 88 colonies of bees in good condition; have lost 6 by bee moths; no foul brood in this place. There are 175 colonies of bees in Washington; no trouble wintering on summer stands, with shed roofs to shield them from our hot Dixie sun. We average 75 lbs. of honey to each colony, but I have taken 162½ lbs. from one.

Mr. Silas Richards, of Union, writes March 27, that they have 11 bee-keepers there, had 67 colonies, but have lost 12, leaving a balance of 55 this spring; winter on summer stands; generally practice natural swarming; do not use extractor, neither disturb the brood nest; use scarcely any bee veils or gloves.

Mr. Joseph E. Johnson, writes from St. George, March 31, 1882, that there are about 500 colonies in Washington, Kane and Iron Counties, yielding from 20 to 100 lbs. to the colony, honey varying from 15 to 25 cents per pound. The supply is equal to the demand. Not a single case of foul brood has been known in these parts. The best honey season there is during May and June. If there are late rains they have some fall bloom, and, as the winters are warm, bees fly nearly every day. Consequently, there is liability to about 25 per cent. loss by starvation, unless the bees are fed when the supplies are short.

President James Cullimore writes from Pleasant Grove, Utah County, that press of business prevents him

from giving a full report of the Association. He has 115 colonies, and has lost only one up to this time, wintered on summer stands. After so long a winter honey is scarce in the hives. Some in the neighborhood have lost but few, and others, none of their bees.

Mr. T. W. Lee says in Tooele City there are 16 bee-keepers, and 106 colonies of bees. They were put into winter quarters on summer stands. Losses 24, leaving 82 colonies in tolerably good condition. No foul brood. Bees are mostly hybrids.

Mr. Charles Connely says, as bee inspector, he had destroyed 21 colonies of foul brood in Box Elder County in one season; and on his return home expects to destroy others infected, and try to rid the county of this dreadful pest. He started with 2 colonies and now has 46. There are about 350 in the county. He wintered his bees on summer stands about 4 inches apart, filled with hay, chaff or straw. Gives upper ventilation, puts a cloth over the lower hive, keeps them dry and warm, and has no trouble in wintering. Honey sells there at 20 cents per pound.

Bee Inspector R. M. Birch, of Weber County, said he winters bees on summer stands in shed; puts cloth on lower hive and fills the upper box with hay. They winter well.

Bishop C. A. Madsen, of Gunnison, Sanpete County, said their bees, although but few in number, had wintered well, and as he learned more about bees his interest increased. Intended to progress in bee-culture in Gunnison.

Mr. N. T. Porter, of Davis County, said they had been sorely troubled with foul brood, and consequently heavy loss. He had lost his bees, but was starting again with better success. He had placed chopped feed near his hives and the bees worked wonderfully in it.

Vice President Samuel Mackey took pride in bee-keeping, and always had good success in wintering his bees, until this very hard winter when he had lost 56 out of 87 colonies. He thought the severe frosts had cracked some of the honey combs, and the damp of the hives had soured the honey, sickening and killing many of the bees; also, many of the bees had been lost in flight on warm days, thus weakening the colonies. Foul brood was imported into our country, and has spread fearfully in many places. It must be destroyed if we would be successful with bees. Most of his losses occurred in February. Thinks the loss in Salt Lake County will be over 50 per cent.

Mr. Wm. Egan said his experience had been quite different this winter from that of any previous year. He had only 5 colonies of bees left alive out of 40. For want of time he had neglected to pack his chaff hives last fall, hence his loss. Previously, when he had protected his bees, he lost scarcely any.

Edward Stevenson said we must provide better winter quarters for our bees in order to insure success, especially as our winters are so changeable

in this high altitude. He had placed some of his bees under shed roofs packed with chaff, with a movable front ten feet long and two feet wide, leaving four inches back and front, boxing the entrance, leaving a passage for the bees through the movable front. The hot rays of the sun will not so easily cause the bees to fly, until the air is sufficiently warm for them to return home again. This makes a cheap chaff hive, as six hives can be placed together in one packing, and be kept warm until late spring, thus inducing early brooding. They must have proper ventilation and chaff cushions in upper box. In Dixie scarcely any bees die because of the cold.

The meeting was well attended, and an increased desire to make Utah a success in bee-culture was manifested, that the land may flow with honey as it now does with milk.

Read before the Mahoning Valley Convention.

Pasturage or Forage for Bees.

LEONIDAS CARSON.

To every owner of an apiary, the most important question for consideration is a continuation of good pasturage or forage for bees, for on this rests all our profits. If we have not a succession of indigenous forage, we should plant to fill the vacancy. By indigenous, I mean those honey-producing plants and trees that are native, or produced natural in a country or climate.

If you have not the golden willow, procure it and plant, for it yields both pollen and honey in profusion, of a fine quality. For shade and timber plant the maple, which yields both pollen and honey. Next in season we have ground ivy, or Gill over the ground. Then the dandelion rears its golden head to gladden our little pets.

The occupation of horticulture and bee-keeping go hand-in-hand. The first fruit tree to bloom is the peach, then the pear, apple and cherry follow each other in rapid succession, yielding pollen and honey in rich profusion. Near or about this time the strawberry begins to bloom. The wild cherry commences to bloom and fills the gap between fruit bloom and white clover. Next we come to our main or most general forage plant, which, if not found in natural profusion, may be grown in all localities, viz: Dutch or white clover. This rarely fails to yield honey of the finest quality. Those bee-keepers who have low wet fields with a damp, heavy soil, should sow Alsike or Swedish clover, it being a greater honey-producer than white clover, and is second to no clover grown for hay, and if not pastured too short, will never run out. At or about this time we find the raspberry in bloom, yielding plenty of fine honey of a quality surpassed by none. I have never known a season when it failed to secrete honey. Therefore, to the lovers of this fine fruit I say, plant the raspberry. Next comes linden or basswood. Standing, as it does, first in

rank as a honey-producing tree of rapid growth and luxuriant foliage, it is truly a beautiful tree for shade. To every bee-keeper I would say, plant many linden trees. It will pay to plant the tulip tree, known in this locality as poplar or white-wood. The tulip tree is a good honey-producer, the flowers expand in succession, thus affording more time to the bees in which to gather the rich harvest. The tulip tree blooms when 10 years old. Those who own rough, broken or waste land, should try sweet or melilot clover. Sow it in fence corners and along the roads. This plant yields a delicious honey. Do not forget to sow cleome or Rocky Mountain bee plant. It yields rich honey in profusion. In the driest seasons it has never failed to secrete honey. The bees visit it from dawn till dark. It will pay to plant the figwort, often known as the Simpson honey plant. The pretty little ball-shaped flowers, with a lip somewhat like the pitcher plant, is usually found filled with honey.

Sow buckwheat of the silver-hull variety from the 26th of June to the 4th or 5th of July. This cereal upon fair soil will yield all the way from 10 to 25 bushels of seed per acre, and if the season is favorable, a bountiful supply of honey.

If you have no golden rod in your locality, get a few roots and plant them, especially if you live close to some stream, where waste land is plenty. This, in some localities, furnishes the bulk of the great yield of fall honey. Last fall golden rod failed to secrete honey, on account of the dry weather. The aster is another fall-yielding honey plant. You may frequently find a half dozen varieties growing side by side.

There are many other plants and trees yielding honey, for instance, the box elder and catalpa. The last named would pay farmers to grow for timber, it being very lasting, and in its season is covered with honey yielding blossoms.

It will pay to plant the common locust both for timber and honey, and the honey locust for hedges and for the honey it produces. Plant catnip for honey.

I have only attempted to give a list of some of the most important honey-producing plants and trees. The most of which have a double value. Again I say, plant for a continual honey harvest.

Tuscarawas Valley, O., Convention.

The Tuscarawas Valley, O., Bee-Keepers' Association met at Coshocton, O., April 19, and was called to order by the President, who delivered his annual address.

No minutes were at hand, and a discussion ensued as to the propriety of striking out Guernsey and Muskingum Counties, these Counties having failed to be represented in the Convention. The motion was carried and the body will hereafter be known as the Tuscarawas Valley Bee-Keepers' Association, composed of Tuscarawas and Coshocton counties.

Moved and carried that all persons who are connected with this Convention and live in Muskingum and Guernsey Counties, can, if they wish, withdraw from the Convention and have their fees returned to them.

Election of officers: L. B. Wolfe, of Coshocton, was re-elected for President; J. B. Wolfe for Vice President; Joseph Love for Treasurer, and J. A. Bucklew for Secretary.

The following subjects were discussed: Which is the best mode of obtaining surplus honey, side or top storing? No conclusion.

Knowing that the bees will store more honey without the use of division boards, how can we prevent the queen from entering the surplus department? No conclusion.

What is best, natural or artificial swarming?

It is the opinion of this Convention, after hearing the experience of the members present and their modes of swarming, that artificial swarming is the best, "all things considered," if it is done intelligently.

Adjourned till 10 o'clock a. m. tomorrow.

The attendance in the morning being small, the morning was occupied in giving the experience of each other on different topics of interest to beekeepers, and a friendly and profitable chat was indulged in till noon.

AFTERNOON SESSION.

Which is the best, the black or Italian bee, and why?

J. A. Bucklew said his experience with Italians is, they are more docile to handle than the blacks. Lift a frame of them out of the hive and the bees tenaciously cling to their comb, the moving not disturbing them from their labors, but it is not so with the blacks: the moment you raise the frame they become greatly agitated, quit work and run off the frame thoroughly demoralized. An Italian queen is not the least disturbed by the removal of the frame, but continues to perform her duties. When a black queen is sought, she is not to be found, and seeks concealment in some nook or corner. The Italians are greater workers than the blacks, working later and earlier, going farther in search of honey, and guarding themselves better against robbers and the ravages of the bee moth.

How to make apiculture a success?

Mr. L. B. Wolfe said to be successful, the keeper must be interested in his business, must study it, read and be informed as to how and when to do the needed work. Have the best bees, and movable frame hives.

Best mode to increase your colonies, and how to defeat the moth worm?

Divide colonies instead of allowing natural swarming.

Mr. Wolfe said, never allow the bees any more frames than they can cover, and contract their hives with division boards to suit the number of frames left with them. Be sure that the colony has a healthy, prolific queen, then the bees will take care of the moth worm.

Best mode of obtaining surplus honey to realize the greatest profits?

Estimates made by J. A. Bucklew, T. Wolfe and others on the product of one hive as a test, was as follows: Number of pounds of comb honey, 100; value, \$20; expense, \$2.45. Number of pounds of extracted honey, 500; value, \$50; expense, \$26.75.

Is it advisable to plant for bee pasture?

Opinions prevailed that it was highly necessary to plant something to bridge over the time between apple bloom and white clover, and between basswood bloom and fall flowers.

The next meeting of the Association will be held at Newcomerstown, on Friday, Oct. 6, 1882.

L. B. WOLFE, Pres.

J. A. BUCKLEW, Sec.

SELECTIONS FROM OUR LETTER BOX

Drone Trap.—Since my inquiry regarding a drone trap, I have invented one, to be placed at the entrance of the hive. The worker bees can get in and out of the trap, but the drones cannot get out of the hive without getting in the trap, and when in they cannot get out. I have just come in from my apiary, and found the trap half full of drones. By this trap I can catch all of the drones that I do not want my albino queens to mate with, or catch all but the albino drones. My bees are in good condition, wintered without the loss of any. Now for *Apis Americana*. No more worthless drones. L. A. LOWMASTER.

Belle Vernon, O.

Promising.—The season continues very cold here; weak colonies are suffering, but those that have wintered well are very strong and promising.

J. ANDERSON.

Tiverton, Ont., May 6, 1882.

Bees Doing Well in Wisconsin.—Bees are doing well, with plenty of dandelions, and the fruit trees nearly in blossom.

JOHN CORSCOR.

Madison, Wis., May 9, 1882.

Wintered Well.—Bees wintered well—strong and weak alike survived. It is still freezing almost every night, although fruit trees are trying to put forth their bloom.

C. H. RUE.

Manalapan, N. J., May 4, 1882.

Free Advertising.—I have a few words to say in reply to that correction in the BEE JOURNAL for Feb. 15, page 98. I think it was hardly fair to attribute all my complaints to that one mistake. The two words "lose" and "have" might be written to look alike, and I thought that was a mistake, but the omission of words, parts of sentences, and the name of the manufacturer of the winter hive (which did not change ideas, but made my preference for those hives much less conspicuous), made it apparent to me that there was a reason

for it not explained in the correction. If it is out of place to express one's preference for hives or anything else used in the apiary, giving the name of the inventor or manufacturer, then I will be more careful in the future in making out my reports.

MRS. A. M. SANDERS.
Sheridan, Mich., March 13, 1882.

[Inasmuch as it is admitted in the above letter that the words omitted "did not change the ideas," of course the only thing to complain of was the omission of advertising in the reading columns—a thing we aim to do at all times—but once in a while such advertising is so woven into the letter that it escapes our notice. So long as the hive was mentioned, for which the writer had preference, it was wholly unnecessary to give the name and address of the manufacturer; that would be simply an advertisement for which our columns are open at 20 cents per line, and against which our reading columns are closed, at any price. So there is nothing to complain of, and no excuse for writing to the manufacturers of the hive that we had made the omissions to injure it, etc. Had we inserted the free advertisement in our reading columns, our advertisers, who pay for such notices, would have had cause to complain. But now, no injustice has been done, and no one has any just grievance.—ED.]

Waters Reeded.—The water has fallen 5 feet; $\frac{1}{4}$ of the lands overflowed are planted; $\frac{1}{4}$ will be planted this week; $\frac{1}{4}$ will be planted before June, and the remaining $\frac{1}{4}$ will not be planted this year. Weather 60° to 80°, and cloudy; rain last night. Bees are doing but little this month; no swarming so far. We fertilize from a nucleus of drones, made with two frames of hatching drone brood and one frame of honey.

J. W. K. SHAW.
Loreauville, La., May 8, 1882.

Bees Doing Well.—I started with 50 colonies—have 120 now, all vigorous; have had no spring dwindling or any disease here. I have on a large lot of sections that are being filled rapidly. Those I offer for sale here are all nicely capped and white as snow, and are looked upon with great wonder. An old fogy said: "See what this country can do besides raising cotton, if we only had the sense to develop it." I have repressed swarming as much as possible, and shall always hereafter clip a wing of every queen, to prevent swarming as far as I can. I am hopeful of Southern bee-culture. Success to the BEE JOURNAL and Northern bee-keepers the present season.

OSCAR F. BLEDSOE.
Grenada, Miss., May 10, 1882.

Rubber for Bellows Smokers.—Seeing in the *Bee-Keepers' Exchange* an article giving experiments with rubber bellows, I thought you would be pleased to place before your readers further experiments with that article. To do this and to avoid the implication of interest in the matter (except for the benefit of bee-keepers), I mail to the BEE JOURNAL, this mail, two Bingham rubber bellows, which have been in steady use since May, 1880, for inspection. The thinner rubber has stood the test much the best, and has worked quick and easy all the time. The heavy rubber has cracked much the worse of the two, and worked slow and hard. They both began to crack the second season, and have grown worse all the time since. When I began the experiment, I saw that rubber had two good points for smoker material, viz: Careless beekeepers would find that mice would not gnaw them, and that they would cost the manufacturer about two cents less apiece. To balance this, they would weigh more and perhaps have other fatal qualities. I was so well pleased with the thin rubber experiment the first season, that I contemplated putting rubber smokers on the market, and bought considerable material for that purpose, but lo! when cool spring management began, my much hoped-for rubber began to crack as you see, and no rubber smokers were offered for sale by me.

T. F. BINGHAM.
Abronja, Mich., May 8, 1882.

[The rubber bellows above referred to have come to hand, and both show evidence of much use. One only exhibits signs of cracking to any considerable extent, and even that is but little, if any, impaired for use. We do not believe, however, that they are at all superior to good leather, either in point of durability or effective work.—ED.]

Wintering Bees.—I commenced last season with 2 colonies of bees—one black, the other Italian; reared 40 Italian queens, and increased to 9 colonies; bought 4 colonies of blacks in August, and Italianized them. In September we united the nuclei and commenced to feed coffee A sugar, and just before winter set in we cut two $\frac{3}{4}$ inch holes through each comb about two inches below top-bar of each frame, and then they had large quantities of pollen stored, about one-half of the cells being partly filled with pollen and finished with honey, and we estimated that each colony had about 15 pounds of honey and sugar syrup, and the cold weather came on before they had capped all of it. This has been a very hard winter for bees in this section, the losses being larger than a year ago, averaging about 50 per cent. We enclosed each hive in a separate house, with 5 inches space between the house and hive on the sides, and 3 inches on the bottom, made high enough to contain the hive with the sections on, and

covered with a good, tight roof. We next put new, clean burlaps on top of the frames, then had a frame 7 inches wide halved on the lower edge so that it will shut down over the top of the hive one-half of an inch with two pieces of burlaps between them; then we tacked a piece of clean burlaps on the bottom of this frame, leaving it slack enough so that the halving will go down over the hive, we then filled this with chaff and placed it on the hive; next we filled all the space between the hive and house with dry sawdust 3 inches above the bottom of the chaff box, put the roof on the house, and leave the entrance wide open all winter and see that it is kept clear, and let them remain on their summer stands, which is about 4 inches from the ground. By so doing we now rejoice with 13 colonies, all strong and healthy, and, strange to say, they had consumed nearly all of their large supply of pollen before they commenced to rear brood, with no injurious results. I think that a properly ventilated and protected hive is the most essential thing in safe wintering. Our houses cost about three dollars each, and they are ornamental as well as useful.

ISAAC HUTCHINS.
Wellington, Me., May 5, 1882.

Still Cold and Cheerless.—Our cold weather continues, and snow and frost is the order of the day here in what is called "cold Spofford," as that is the name of our town. The morning of the 2d of May found us with 2 inches of snow on the ground and a freezing wind from the northwest, while on the hills it was fair sleighing. The 30th of April (Sunday) was quite a warm day, and some pollen was brought in for the first, but the cold of the 2d killed the blossoms of the elms and soft maples which were opening. With the exception of April 30th, it has not been warm enough to open bee hives in a month. My best colonies have brood only in 3 frames, while the poorest have none at all. I am hoping for warm weather soon. If it does not come, the mild winter will have been of little benefit, for our bees might as well die from a cold winter as from a cold spring.

G. M. DOOLITTLE.
Borodino, N. Y., May 8, 1882.

Honey Harvest in Texas.—Bees are gathering honey rapidly from ratan. This harvest will connect with horse-mint, and if seasonable, will give us a constant flow of 60 days.

WM. R. HOWARD.
Kingston, Texas, May 3, 1882.

Wintered Successfully Again.—Bees have again come through all in excellent condition. This is now 9 winters in succession without loss by my system of chaff packing, of which I am the originator. Wintering successfully is settled with me; but how to prevent swarming is the great problem with me, if I run for box honey.

H. H. FLICK.
Lavansville, Pa.

Unusually Early.—The interest in bee-keeping is increasing fast and greatly. I had a very fine Italian swarm come out to-day. This is unusually soon for us. Please answer: 1. I have a large number of sections partly filled with honey, and others with thick and thin dry comb; is it advisable to put them on the hives to be filled? My bees do not fill thick combs satisfactorily.

E. C. JORDAN.
Stephenson's Depot, Va., May 5.

[Use the sections. Many make a point of having their section combs built out the previous season, for early use. Unless very bright and clear, first extract the honey from the partly filled sections. We have observed that bees rarely fill extra-thick combs as satisfactorily as the medium or thin ones. You can probably remedy this by shaving down the surface of the combs with a thin, very sharp knife.—ED.]

Excessive Swarming.—I am having a lively time with my bees now; they are swarming very fast. I had 30 colonies to start with, and they have increased by natural swarming to 56, and not half of them have swarmed yet. I have had as many as 6 swarms from one hive. Two escaped to the woods, because I could not attend to them in time, being so many out at one time. They are storing honey pretty fast, and I am in hopes they will stop swarming. I have been a constant reader of the BEE JOURNAL for several years and have noticed the views of some men as to pure Italians, hybrids, etc., and so far as I have experimented with bees, I find the cross of the Italians and blacks to be as good as any pure Italian for honey, and better for increase, though increase is not the thing for me now, for I cannot sell pure Italian bees, in a painted, movable frame hive, for \$5. They do not know how to keep bees unless they can go to the swamp and cut a hollow black-gum, and cut it off with an axe, and set it by the meat house, and let it stand till June, then take a lot of rags and a hammer and go for some honey, bee-bread, young bees, etc. They say to me, how do you have such luck with your bees? I tell them there is no such thing as luck, it is in management. I do wish I could induce the people here to get to paying some attention to them. I have done all I can to get some of them to take the BEE JOURNAL one year; but no, they say they are too poor. I am satisfied if I had time to give the proper attention to my bees, I could make more from them than any one man can in cotton. I want to ask a question or two to be answered in the next issue of the BEE JOURNAL: 1. Will a non-fertilized queen's drones mate with a virgin queen the same as any drone? 2. Will a drone from a half-breed queen be pure, that is, will a pure Italian queen mated with a black drone, produce pure Italian drones; if not, how can

the Dzierzon theory be true. Please answer the above as I am a seeker of knowledge in the bee line.

H. M. WILLIAMS.
Bowden, Ga., May 7, 1882.

[1. It is generally conceded they will.

2. The best authorities heretofore have been nearly unanimous in the opinion that if the queen herself is pure, the drones will also be pure. There are, however, some very intelligent dissenters from this view. Our observations and experiments on the two questions have not been satisfactory.—ED.]

Sweet Clover.—My pets are doing well. I had queens and drones flying the first day of May. They are very busy on the maples, which are in full bloom. I have two colonies that they are trying to rob, and there is some hard fighting on both sides. 1. Please tell me what to do to prevent their fighting, as I have tried everything I know of. Enclosed you will find a specimen of a very good bee plant. It blooms from the middle of June till late in the fall, has a small white blossom, is very fragrant, and grows by the roadside. 2. What is it?

F. A. GIBSON.
Racine, Wis., May 9, 1882.

[1. Close the entrance to the hive being robbed so but one bee can pass in or out at a time.

2. You have sent us a specimen of our favorite honey plant—sweet clover (*Melilotus alba*). All will recognize its value when they have become familiar with it.—ED.]

A Prolific Queen.—As I gave in my report last fall, perhaps I had better tell you what I am doing now—busy hiving bees, 1 to 5 swarms per day. I put up my 33d swarm to-day. My first swarm came out on the 25th of March, and now has 10 frames of brood and is ready to swarm. I have a colony of bees in my apiary that are rather a curiosity. The queen is a fine Cyprian mated with a German-Italian drone, that is a hybrid drone. She was raised November, 1880, and mated on the 6th of December, and began laying a few eggs on the 10th of the same month; was wintered in a three-frame nucleus, built up rapidly last year, and gave a nice surplus and a few frames of brood. They went into winter quarters in 1881 on 8 frames, with space left for two more frames, which they filled with comb, and on the first of March the 10 combs were full of brood, and I gave them a full story with 10 frames of foundation. By the first of April these were full of brood, and I added a third story with 5 frames of comb and 5 of foundation, and 4 of these are to day full of brood, and eggs in three others—24 frames (standard Langstroth) almost solid brood. I extracted 12 lbs. of nice honey from the third story last week, and as long as the queen con-

tinues to lay as she has I will give her room; but I see our great honey plant, horsemint, is now beginning to bloom, and this army of bees will need more room soon. I never saw such demons; the smoke from a steam engine would hardly quiet the rascals; the moment the hive is opened at you they come. I prepare for them with gloves and veil, and work on as if they were my favorite Cyprians that behave so nicely. I have about 30 colonies of Cyprian bees in their purity, and a better bee never landed on the shores of America. I have had them in my apiary since August, 1880, and I know they are good. I started to tell you, I commenced operations this spring with 40 colonies; sold 32 colonies for \$231.60, and I now have 45 colonies, which I think will go up to 50 by natural swarming. I am now harvesting my early wheat, and will soon have cake and honey raised in 1882. B. F. CARROLL.

Dresden, Tex., May 1, 1882.

Bees in Utah.—I am well pleased with the BEE JOURNAL, and as an amateur in the bee business. I have received many valuable hints that would have been to my benefit last year. I had 3 colonies of bees last winter, but the winter has been the hardest we have had since this was a settlement, and many have lost heavily in bees. I lost all of mine; dysentery was the cause. This spring, seeing the advertisement in the JOURNAL of Paul Dunken, of Freeman, Mo., I sent for 2 colonies of Italian bees, which I received in first rate condition on the 17th of April, and it was 2 days after before I could let them out, owing to the snow storm then raging in this place. Since that time the bees have done well. Now we have the peach, apple, apricot, plums, cottonwood, and May flowers all in bloom. Bees are streaming in with pollen and honey. I find in one hive a queen cell started, and plenty of young brood and drones hatched out, and by all appearance will have to divide in a few days. Some of the hives are rather weak, but in general the bees of this settlement are doing nicely, with plenty of bloom—clover and lucerne. We have in the past attended to the milk, but now we are beginning to attend to the honey, and it will soon be as the Prophet has said, a land flowing with "milk and honey." JOHN DUNN.

Tooele City, Utah, May 6, 1882.

Well for Philadelphia.—A rousing big swarm to-day. How is that for latitude 40°? This swarm issued on the 4th, but as they were clustering it threatened to rain, and they returned to the hive.

F. HAHMAN, JR.
Philadelphia, Pa., May 8, 1882.

An Abundance of Bloom.—Bees are doing well in this locality so far this year. I had two fine colonies on the 5th inst. White clover is beginning to bloom and there is an abundance of it. ELVIN ARMSTRONG.
Jerseyville, Ill., May 8, 1882.

Rearing Queens.—In your advice to Mr. A. L. Conger, Earlville, Iowa, in regard to rearing queens, you say: "Now take out the frames one at a time from the hive removed, and shake and brush all the bees from the combs in front of the new hive, then replace the combs in the black colony and release the queen." Now, I want to know what the black colony is going to do for bees. I cannot understand that part of the instructions; the balance before is plain and simple. Please explain, so that a beginner like myself will know what to do. White clover and poplar are in their prime here now; about half my bees appear to be working on poplar, the other half on white clover. Mercury stands at 81° in the shade at 12 m. Bees are crowding out queens with honey. I am trying to get my neighbors to use frame hives and Italianize, which some are making preparations to do.

J. A. P. FANCHER.

Fancher's Mills, Tenn., May 4, 1882.

[In the confusion incident upon removing the black hive and lifting out the frames one at a time, you will find enough bees, young and old, will run down from the combs and remain in the old hive to perform maternal duties, and to these young bees will be added hourly as they emerge from the cells, which will each require but a few days to be duly qualified as nurses. One principal object in brushing the combs in front of the new hive, is to get a fair proportion of the younger bees, which have not done field work, in with the older bees, to do certain drudge-work which they can best perform.—Ed.]

Bees Light.—I have concluded to report this morning, as I have just finished overhauling my bees, doubling up, feeding, etc. So far, the spring has been the most discouraging (except that of 1879) I have experienced in my bee-keeping—6 years last April. We have had an abundance of fruit bloom, but the weather has been so very unfavorable that our best colonies have consumed more than they gathered. To-day it is so cold and damp that the bees are not flying, except where they are aroused by feeding. Owing to the exceptionally poor fall of 1881, and our present weather, bees are in a miserable condition to make a good showing for the season. I am compelled to feed my 33 colonies until something "breaks loose" for them to work upon. Many of them have only about half the amount of brood they should have at this time, and it will take close care to have them all ready for white clover, which promises much better than last season. We hope to get a good yield from basswood, as it was almost a failure last year. If it were not for the weekly visits of the BEE JOURNAL, which gives fresh courage, I should feel rather blue at times.

S. A. SHUCK.

Bryant, Ill., May 6, 1882.

Bee-Keeping in Colorado.—Every one knows how important is consultation where there are common interests to carry out. We have agricultural and horticultural societies to further the interests of those branches of industry, but there is no industry that calls louder for intelligent management and consultation than bee culture. When we consider that many bee owners are ignorant of the simplest operations of the apiary, it behooves us to do all in our power to impart that knowledge by which we can prosecute the science of bee-culture successfully. The exposition managers have offered their entire space to exhibitors free of charge. The enterprise is National in scope, and every industry will be represented. Any one wishing to exhibit, should communicate with the National Mining and Industrial Exposition Co., at Denver.

WOMAN'S' INDUS. ASS'N.
Denver, Col.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 " (3 months).....	20 " "
" 12 " (6 months).....	30 " "
" 16 " (9 months).....	40 " "
" 20 " (1 year).....	50 " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN.

625 West Madison Street, Chicago, Ill.

Special Notices.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

From Dr. L. James, Atlanta, Ill., we have received a section filled with thin foundation, as described on page 309. The section presents not only a very neat appearance, but the foundation is fastened substantially, it having withstood transportation and considerable rough handling.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

When changing a postoffice address, mention the *old* as well as the new address.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., May 15, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.
CHICAGO.

HONEY—As the season is well advanced, sales of extracted honey are slow and prices remain unchanged. I am paying 8c. for dark and 10c. for light, cash on arrival. Good comb honey is scarce and rules high.
BEESWAX—I am paying 24c. for good yellow wax, on arrival; 18@22c. for medium grade, and 15@17c. for dark.
AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for comb honey is slow, and prices nominal at 16@20c. on arrival. Extracted honey is in fair demand. Our jobbing prices for 1 lb. jars of clover honey are, per gross, \$25; for 2 lb. do., per gross, \$42. The demand for manufacturing purposes is very good. We pay 8@10c. on arrival.
BEESWAX—Brings 18@22c. The demand exceeds the offerings.
C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for honey is light, most of the trade finding fault with the best offered, as it is more or less candied. Values are not steady, prices being made to meet the views of the purchaser.
BEESWAX—Scarce, and in demand at 23@25c.
R. A. BURNETT, 165 South Water St.

CLEVELAND.

HONEY—Our honey market would be good, as there is considerable inquiry for white honey in sections, with none to satisfy the demand. It would bring 22c. readily for choice. Buckwheat honey, no sale. Extracted, 11@12c. per lb.
BEESWAX—25@30c.
A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—There is no white comb honey in the market. We quote; Comb honey 11@16c.; extracted 7@11c.
BEESWAX—Scarce; 26@27c.
THURBER & Co.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
BEESWAX—P. ime quality, 25c.
CROCKER & BLAKE, 57 Chatham Street.

ST. LOUIS.

HONEY—In fair demand. Strained selling at 8@10c.; comb scarce—nominal at 18@22c.
BEESWAX—Stiff at 21@22c. for prime.
R. C. GREER & Co., 417 N. Main Street.

SAN FRANCISCO.

HONEY—A little better tone is noted, owing to less favorable reports from some of the honey-producing districts. In Los Angeles county it is believed the yield will be light, but a good crop is expected in San Diego.
We quote white comb, 12@14c.; dark to good, 6@10c. Extracted, choice to extra white, 7@7½c.; dark and candied, 6@8c. **BEESWAX**—23@25c.
STEARNS & SMITH, 423 Front Street.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Bingham's Smoker Corner.

Bayou Goula, La., May 2, 1882.
Messrs. BINGHAM & HETHERINGTON, Abrovia, Mich.
Dear Sirs: The Conqueror conquers everything in the upland. It is almost a fight between my three assistants, as to who will get it first in the morning. A single puff from it will fill a double story with smoke. I will use no other after this.
Yours truly,
P. L. VIALLO.

ONE-PIECE SECTIONS a specialty. Pound size, \$4.50 per 1,000. L. Hives 50c. Also, Italian bees for \$5 per colony. Circular free.

EARS FOR THE MILLION!
Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow sea, known as *Carcharodon Rondeletti*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I hear no unearthy noises in my head, and hear much better.
I have been greatly benefited.
My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE, AS THE CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

To avoid loss in the mails, please send money by REGISTERED LETTER.

Only Imported by **HAYLOCK & JENNEY,**
(Late HAYLOCK & CO.)

Sole Agents for America. 7 Dey St., New York. 20wt1y

Twenty-five Colonies of Italian Bees

At Nine Dollars each; Ten colonies to one address, Eight Dollars each. Twenty Colonies of Hybrids at Seven Dollars each. These bees are in good, new, story-and-a-half hives, Gallup frames, 12 frames in a hive. In all respects in the best condition.
O. CLUTE, Iowa City, Iowa.
19wt2

PRIZE QUEENS for 1882,
From the Evergreen Apiary.

REV. E. L. BRIGGS, of Wilton Junction, Iowa, will furnish Italian Queens from either of his Prize Mothers, as early in the coming season as they can be bred, at the following rates: Tested Queens, \$3; Warranted Queens, \$2; Queens without guarantee, \$1; Two comb Nucleus, with Tested Queen, \$4. Orders filled in rotation, as received, if accompanied with the cash. 3wt2t

FOR SALE—ITALIAN BEES.

Six or eight Colonies, in Langstroth hives. Address, **J. C. OLDFHAM,** 9 East Main Street, 20wt1tp Springfield, Ohio.

THE BRITISH BEE JOURNAL

AND BEE-KEEPER'S ADVISER.

THE BRITISH BEE JOURNAL is published monthly, and contains the best practical information for the time being, showing what to do, and when and how to do it. It is edited and published by **W. N. ABBOTT, Bee-Master,** School of Apiculture, Park Row, Southwark, London.
1 We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.50 per annum.

Be SURE

To send a postal card for our Illustrated Catalogue of Apian Supplies before purchasing elsewhere. It contains illustrations and descriptions of everything new and valuable needed in an apiary, at the lowest prices. Italian, Cyprian and Holy Land Queens and Bees.
J. C. & H. P. SAYLES,
4sm15t Hartford, Wis.

ANOTHER NEW IDEA.

Foundation all ready for business. Every sheet wired and bound around with a light wooden rim, ready to adjust instantly in your frame. No advance in price. Small sample for 6 cents. I shall also breed choice Italian and Holy Land Queens, practicing a new stimulative process. Write now for prices and particulars. Address, 9sm1y **JOHN B. MARTIN,** Hartford, N. Y.

Cyprian Bees FOR SALE.

35 COLONIES OF BEES, having queens of last year's batch, bred from a queen of the D. A. J. new importation. They are in J. E. Moore's improved double-walled hive of seven frames, with side and top storage.

They will be securely packed and delivered on cars from the 15th to 31st of May, at the following rates: 1 to 10 colonies, \$8 each; 11 or more, \$7.50 each.

Also, **50 New Swarms,** hived on finished combs, delivered on cars from 10th of June to 5th of July for, 1 to 10 colonies, \$6.50 each; 11 or more do., \$6 each. Reason for selling: The increase of our mercantile business prevents our giving the apiary the care and attention it should have. Remit by Registered Letter to 19w3t **J. E. MOORE,** Byron, Gen. Co., N. Y.

BEESWAX.

I wish to buy a quantity of good yellow Beeswax. I am paying 24c. per pound, delivered here. Cash on arrival. Shipments solicited.

AGENTS WANTED to sell Dr. Chase's 2,000 Recipe Book. Sells at Sight. Double your money Address Dr. Chase's Printing House, Ann Arbor, Mich 36mlyp

Complete Apiary for Sale.

An Apiary of **90 COLONIES OF ITALIAN BEES,** with buildings and all modern appliances for running the same; are within 23 miles of Chicago, in a splendid location for wild pasturage. These bees show a good record for last season—**2,064 lbs. comb honey from 43 colonies,** and increased to **100 colonies.** They are in prime condition now, with **PROSPECTS OF A GOOD SEASON.**

I want to go into other business this fall, and would sell now, giving the purchaser the benefit of this season's work (and my services, if wanted), as an inducement to buy. Terms will be reasonable, and partly on time if necessary. Correspondence solicited.

H. W. ANDERSON,
17wtf Gibson's Station, Ind.

Given's Foundation Press.

The latest improvement in Foundation. Our thin and common Foundation is not surpassed. The only invention to make Foundation in the wired frame. All Presses warranted to give satisfaction. Send for Catalogue and Samples.

A NEW BEE BOOK!

Bees & Honey

OR THE
Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,
Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper cover, 50 cents, postpaid.

Appreciative Notices.

- Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.
- A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.
- We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.
- Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.
- Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.
- New and valuable, and embellished with 169 beautiful engravings.—Democrat, Salem, Ind.
- Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.
- Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.
- Just such a work as should be in the hands of every beginner in bee-culture.—News, Keithsburg, Ill.
- A valuable work for all who are interested in the care and management of bees.—Democrat, Allegao, Mich.
- The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.
- The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.
- It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.
- A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.
- Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.
- Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.
- Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.
- Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.
- Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

BINGHAM SMOKERS.

I can sell the above Smokers at MANUFACTURERS' PRICES, by mail or express, at wholesale or retail. All the latest improvements, including the CONQUEROR.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Lamestroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame. Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets.

For 2 American frames, 13x13 inches.....	\$8.00
For 2 Lang-troth " 10x18 "	8.00
For 3 " " 10x18 "	10.00
For 4 " " 10x18 "	14.00
For 2 frames of any size, 13x20 "	12.00
For 3 " " 12x20 "	12.00
For 4 " " 13x20 "	16.00

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.--Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the

State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees, full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY.**

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. P. WEST.**

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**E. H. WYNKOOP.**

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL.**

My success has been so great as to almost astonish myself, and a much of it is due to the clear, disinterested information contained in Cook's Manual.—**WM. VAN ANTWERP, M. D.**

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—**L'ABBE DU BOIS**, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *vade mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

Condemnation of Cheap Queens.

Several of our most prominent and successful apiarists have requested us to publish Prof. Cook's able and exhaustive article which recently appeared in the *Rural New Yorker*. We give the article entire, not because it is a reply to Mr. Hutchinson, but for its real worth from a scientific standpoint, and the much good it will accomplish by encouraging a pride in seeking for and breeding the best only. We view it as a virtual indorsement of the position we have taken on the cheap queen traffic, and the response it meets from the great mass of progressive bee-keepers is quite encouraging. The article was entitled "Dollar Queens," and is as follows:

I have been much interested in the discussions in the bee journals as to the policy of rearing and selling "dollar queens;" and no less so in the very candid article from my friend W. Z. Hutchinson, which appeared in a late *Rural*. Mr. H. need have no fear of giving offense. His very evident candor, truthfulness and honesty, must ever win admiration and esteem, and would leave no shadow of an excuse for any hard feeling on the part of an opponent. It is not argument and candor that hurt, it is invidious and crimination. I am glad to know that Mr. H. is a gentleman, and so has no use for these latter weapons.

As to the effect of the "dollar queen business," I think that Mr. H. does not understand my position. I believe he has only to understand me to agree with me. I have no doubt, nay, I am sure that he makes the business pay. I am further certain that he does just as he says he will do—that he rears his dollar queens with as much care as he does any, that he

breeds, only from his best queens, and that in all respects his dollar queens are just as good as the tested ones, bating their chance for impure mating—which with the care given to the matter by Mr. H. is slight. Nor am I at all certain that his tested are superior at all to the untested ones. In fact, I think, if I understand Mr. Hutchinson, I agree with him in nearly every point he makes. Yet, I believe that the "dollar queen traffic" had done more than any one thing to retard the progress of American apiculture. I believe it stands directly in the way of the best achievements, and accordingly anything that tends to throttle its existence is a blessing.

The breeding of bees, like the rearing of any other stock, is a matter that must not be hurried if we would secure the best results. Long watching, the most careful study, and the most rigorous weeding out are just as requisite here as in breeding the best short-horns. Does Mr. H. think that our short-horn cattle would possess their present excellence, had there been no greater inducement to hard and persistent effort than that held out to the bee breeder of to-day. It seems to me very patent that the "dollar queen traffic" has so cheapened queens that no person can possibly afford to take the pains that we ought to have taken, unless, forsooth, his bread-and-butter is secured by some other means. I wish we had breeders that could study their bees as did Hammond his sheep, and as hundreds of Hammonds are studying their sheep, cattle and horses all over the country to-day, and could select, mate and breed, not with rings solely in view, but with a far higher ideal in which mere coloration should form but a slight element; then we might look for real progress. I cannot find time with my numerous duties, to do this as I think that it ought to be done. Neither Mr. H. nor any other breeder can afford to do it. They would starve, far short of success; as, however well they might do, they could hope for no adequate remuneration, so powerfully has the late queen business tended to weaken the spirit of improvement. Our present system calls for economy of time, money and thought. But the maximum, not the minimum of care, is what will give us superior bees.

The point I make is just this: The energy and push put into the queen business of late—which energy was absolutely requisite to success, and then only the shrewdest business men could, if honest, make a living by rearing these cheap queens—have so cheapened the price of queens that there is no general demand for any other. But decided improvement can only come by the utmost pains in selecting breeding stock, both drones and queens, which in case of drones is very difficult, and requires the greatest tact, patience, and persistence. Now this very difficulty makes it necessary to have every inducement thrown in the way to incite any bee-keeper to undertake it. The prospect of a dollar or a little more for queens thus bred, would not only offer no such inducement, but would be the best possible extinguisher of all enthusiasm. More than this, to breed the ideal queen, will require such a rigorous weeding out that only a small proportion of the queens reared will be suffered to live. To support a family, the breeder of cheap queens must sell every one, and will then have great reason to rejoice if his ledger account shows a credit balance. In testing, Mr. H. only waits to see if the requisite number of bands are present. I would have him wait to see if the requisite number of eggs, bees and pounds of honey were forthcoming, and then when such assurance was gained, I would pay him \$10 for the queen and make money, while I would lose in the majority of cases to pay \$1 for the present queens. In buying several to test the matter, not however of Mr. H., I have won a blank at each venture.

Why did Avery & Murphy produce such a magnificent herd of cattle? Only because they took the greatest pains to secure the best material to breed from, and then used the best judgment and most consummate skill in crossing. Why did 25 cattle bring \$50,000 at the recent sale at Chicago? For the same reason. Why the exercise of the skill and caution? Only because of the prospective thousands at future sales.

Unless there is some money-influence to induce to more time, caution, and painstaking in breeding bees, then truly the bee of the future, which should and will be as great an advance on the bees of to-day as are our improved cattle, hogs, etc., upon those of the last generation, will not find its advent in this generation. The only chance to escape this conclusion is for some bee-keeper to set to work—as I would do could I give time to it, and had I capital to warrant the undertaking—and work to advance his bees, with no thought of present profit, to spare no time, no pains, no study, no money to secure the ideal bee, and then create his own market by distributing his bees to the enterprising bee-keepers of the country, asking them to test them and then pay according to the worth of the bees. In this way he could hope in time to get pay for his time and labor, and would have the satisfaction of being classed with Bates and the

Booths. Have we any, D. A. Jones, that can afford to undertake this work?

Ag'l College, Lansing, Mich.

History and Composition of Glucose.

The following is an interesting article by Jas. R. Nichols, M. D., editor of the *Boston Journal of Chemistry*, to which we would call particular attention:

It cannot be a mere matter of chance that substances used as food by men and animals are some of them sweet and others acid, or that some are sweetened with sucrose (cane sugar), others with glucose (grape sugar), and still others with levulose (fruit sugar). There is a wonderful adaptation of means to ends throughout nature. The sweet sensation is generally agreeable, as has been before stated, but it must be modified and adjusted, else it would become repulsive. If our fruits were all sweetened with pure cane sugar in differing proportions, they would lack a certain zest, due to a peculiar sweetness which they now possess; or, if our grapes did not form an exception to other fruits in the method of sweetening, they would not be the delicious fruit so universally esteemed. Apples, pears, peaches, and most other fruits are sweetened with levulose, or what may be regarded as a mixture of sucrose and glucose; and differing varieties hold unlike proportions, giving in conjunction with malic acid and certain essences the nice shades of flavor observed. The manufacture of sugar is not set up in fruits until the period of maturity is nearly or quite reached, and then the process is usually a gradual one.

The grape vine and fruit do not possess the power of grouping the atoms of hydrogen, carbon, and oxygen so as to form molecules of sucrose; the result of their work is confined to glucose. Hence a grape is never excessively sweet, or it does not reach a degree of sweetness beyond what glucose can furnish. If a grape were a solid mass of sugar it would not be very sweet, as the sugar is incapable of conveying to the taste any intense sensation. Every one who has tasted old or well-dried raisins has observed the hard lumps of sugar which frequently form, of considerable size, under the skin covering. These are lumps of glucose which result from the evaporation of the moisture in which it was held in solution in the grape. These lumps are deficient in sweetness, as has been observed from the earliest times. If this substance was supplied in large quantities from grapes or raisins, it would sell at a low price in the market. If a grocer sold it for pure sugar (cane sugar), it would probably come back to him again, and he would rightfully be charged with fraud. No shrewd dealer or manufacturer would sell it by itself as sugar, but those dishonest in the trade would mix it with cane sugar, and thus dispose of it

with less risk of exciting suspicion. This is now a form of fraud of enormous magnitude, as will be presently shown.

During the wars of Napoleon I., early in the present century, he established the famous Continental blockade, by which all products of England and her colonies were excluded from the markets. This of course made sugar scarce and dear in France, and stimulated search for products which might be substituted. The grape crop of France was enormous, and as commerce was destroyed it was useless to make wine; so attention was turned to extracting the sweet principle of grapes. Syrups and sugars were made from grape juice in large quantities, and Napoleon ordered it to be used in the palace as an encouragement to its production. He issued several decrees in regard to its manufacture, and the celebrated chemists of the time, Proust, Berthollet, Parmentier, and others, were kept busy striving to perfect the products. Montalivet, the great minister of the interior in Napoleon's cabinet, in one of his reports, states that it has been ascertained that the grape sugar equivalent of cane is a little over two and one half to one. This is not far from correct.

Thus it is shown that the chemists of France were making glucose more than seventy years ago from grapes, and if they had known that it could be made as well from potatoes, corn, or any other cheap substance holding starch, the discovery might have retarded the great progress that soon followed in producing cane sugar from beet juice.

It was as early as 1747 that Margraff made his experiments showing that beets contained sugar, but it was not until Achard, the son of a French refugee in Prussia, took up the subject, and published the astonishing results of his researches, that it excited public attention. The difference between the two forms of sugar, that from grapes and that from beets, was easily seen, and Napoleon's attention was called to it by his corps of illustrious chemists. He immediately gave himself to the work of creating and perfecting this new industry, and in 1812 he had the satisfaction of learning from the reports of his minister of the interior that 334 factories in the empire were producing annually 7,700,000 pounds of beautiful cane sugar from beets. This seems almost like the work of magic, and illustrates the greatness of the man whose power was felt in every part of the civilized world.

The early attempts to extract sugar from beets in Napoleon's time were made subjects for fun and ridicule. The Emperor himself did not escape the lampoons of the wits of the age. A caricature was exhibited in Paris, in which the Emperor and the baby King of Rome were the prominent characters. The Emperor was represented as sitting in the nursery with a cup of coffee before him, into which he was squeezing a beet root. Near him was seated the King of Rome voraciously sucking a beet root, while

the nurse, standing near and steadfastly observing, is made to say to the youthful monarch, "Suck, dear, suck; your father says it is sugar."

In manufacturing glucose from corn, the process is, first, to separate the starch from the other constituents of the grain, by simple mechanical means; and then, secondly, to act upon the starch with dilute sulphuric acid (oil of vitriol). When thick gelatinous starch is boiled for a couple of hours with this acid, a curious transformation takes place; the milky paste first changes to a fluid as limpid as water, and as the change advances this acquires a sweet taste, which is masked by the presence of the acid. If we now saturate the solution with some earthy carbonate, marble dust for instance (carbonate of lime), the acid is removed, and a sweet solution remains, which, after purification, may be evaporated to a syrupy liquid, or by still further manipulation converted into a white solid, which is *grape sugar*. This is the whole process for making "sugar out of corn," and it is simple enough. In this chemical transformation nothing is absorbed from the air, and no other substances but dextrine and grape sugar are generated, and the weight of the sugar exceeds that of the starch employed. What is still more wonderful, the acid used undergoes neither change nor diminution; it is all withdrawn in its original amount after the boiling is completed. If it could be withdrawn in its clear, uncombined state, one carboy of oil of vitriol would serve to change all the corn grown in the United States into grape sugar. Theoretically, one pound of corn ought to make a pound of solid glucose, but in practice it does not quite do this. The cost of *solid glucose* to large manufacturers cannot exceed three cents a pound, and it may fall considerably below this.

Nothing can be more paradoxical to the popular reader than the statement that sugar is produced by the use of one of the most powerful mineral acids known to chemists. To explain clearly and fully the chemistry of the reactions involved in the process would require more space than we have at command; and also, to understand the nature of the changes, more scientific knowledge would be required than is possessed by ordinary readers.

Glucose is a cheap, imperfect substitute for the genuine sugar of commerce. It is not a poison when well made, and, as regards its healthfulness, it may not be much more deleterious than ordinary cane sugar. Still, it does produce and aggravate dyspeptic symptoms, and by its proneness to set up fermentative processes its use causes flatulency and painful affections of the bowels.

What becomes of the millions of pounds of glucose manufactured in the Western States every month? It is used mostly as an adulterant in the manufacture of table syrups, and in adulterating the dark, moist sugars used largely by the poor. Its next largest use is in the manufacture of candies. All soft candies, waxes,

taffies, caramels, chocolates, etc., are made of glucose. Children are therefore large consumers of this substance; the *honey bees*, also, are fond of it, and will carry it away by the ton, if placed within their reach. The honey made from it is *no better than the pure glucose*, as it is stowed away in the comb without change.

A mixture of true "sugar-house" syrup with glucose syrup, in proportions of five or ten per cent. of the former, to ninety or ninety-five per cent. of the latter, constitutes the high-priced "maple drip" of the grocers. A Western chemist reports the results of recent analyses in which adulterations amounting to from five to fifteen per cent. of glucose were found in various popular brands of sugars.

In this brief consideration of the nature and uses of a comparatively new article of manufacture, the astonishing fact is disclosed that this year more than twelve million bushels of corn have been manipulated to produce an article employed almost exclusively as an adulterant to one of the most common and important constituents of food. It is a reprehensible form of fraud, and should be arrested by laws similar to those which govern the sale of "oleomargarine" compounds. Every package of this sugar should be stamped glucose, and sold as such; and every mixture made with it should be accompanied with a statement, stamped upon the vessels which hold it, giving the exact percentage of glucose contained in the adulterated sugar or syrup. A law similar to that which is found on our statute books regulating the sale of fertilizing compounds would be effective, if energetically enforced. The loss to purchasers in the glucose syrups is enormous as the quantity required to sweeten substances is at least twice as great as when cane sugar is employed, and the use of this quantity of the agent renders it *deleterious to health*. The attractive appearance of the syrups, which are white and clear, gives them a wide sale at high prices, and all consumers of sweets in the country are *victims to a form of fraud* which deserves the prompt attention of our law-makers.

Because of its scientific and historic character, the foregoing article will be read with interest, and although Dr. Nichols may disagree with the BEE JOURNAL in some points, still we do not differ as to the effects produced on the human stomach by its constant use. He states most positively that "it does produce and aggravate dyspeptic symptoms," and causes "flatulency and painful affections of the bowels;" that it is "deleterious to health," and that consumers of sweets are "victims to a form of fraud which deserves the prompt attention of our law-makers," and that it "should be arrested by law."

As to the difference between glu-

cose and grape sugar, Dr. Nichols says that glucose is a "syrupy liquid;" by "further manipulation" it may be "converted into a white solid, which is grape sugar;" the only distinction being that one is a "syrupy liquid" and the other a "white solid," both being made from the same material in precisely the same manner. It will be readily seen that the assertion made by Mr. A. L. Root in *Gleanings* for December, 1881, page 619, that "grape sugar and glucose are two distinctly different articles," is but a creation of his fancy, to evade the force of the argument against the use of glucose, when he was defending the use of grape sugar for feeding bees.

Should any of our patrons be suffering from disease and wish to obtain rest and quietude, as well as experience the remedial effects of mineral waters, they may be glad to know that "Jordan's White Sulphur Springs" is one of the most beneficial and pleasantly located of its class, but the attraction to bee-keepers would be the fact that the proprietor, Mr. E. C. Jordan, is an enthusiastic bee-culturist, and has an extensive apiary there, which supplies in abundance the tables of that institution. His new descriptive circular of 24 pages is on our desk, and a copy will be sent free to any one desiring it. Address E. C. Jordan, Stephenson's Depot, Frederick County, Va.

Last week a correspondent addressed a letter to us in this manner "A. B. J. Chicago, Ill." After wandering around, it finally came to us to know if it was intended for the BEE JOURNAL. It caused several days' delay and made much trouble to the postoffice employes—as there are *nine* postoffices in the city of Chicago. If any one wants to be brief address thus, "BEE JOURNAL, Chicago, Ill.,"—but please don't try to puzzle the postoffice clerks, and risk the safety of a letter by using what may be to them cabalistic signs or meaningless initials.

It is with much gratification we call attention to the resolution adopted by the N. W. Illinois and S. W. Wisconsin Convention, which will be found on page 330. If all Conventions would pursue a similar course, it would do much to strengthen the hands of those who are fighting the adulteration swindlers, and remove the prejudice against extracted honey.

Bees and Honey at Fairs.

Public manipulations with bees and magnificent honey exhibits will soon become the most attractive features of State, County, and District Fairs. There are many good reasons for introducing such, but the chief one, perhaps, is that those who produce honey for the market may be induced to present it in the most marketable shape; for the new methods and new ideas of practical management must take the place of the old and undesirable ones.

It is our aim to make honey a staple product. To this end we have endeavored to popularize the consumption of honey by the masses, as well as to raise the standard of production, by applying correct principles and progressive art to the management of the apiary.

Bees and honey are already the great attraction at such fairs as have given prominence to this industry—and this will become more apparent each successive year. The officers of the St. Joseph, Mo., Exposition were surprised at the result of their experiment in encouraging the apiarian department; they realize the fact that it formed the greatest attraction presented by the Exposition. The editor of the *Gazette* gave his views of the subject in the following article:

Few things last week brought us so many pleasant and profitable things combined—as the display of honey made at the fair, and the lecture of Mr. Newman, of Chicago, on “Bees and Honey.” The attention given to the subject this year marks a new era; the display attracted very great attention; good prizes were offered and awarded; the bee-keepers of the region were encouraged, and a more general interest was aroused in the subject. The lecture was very practical, and contained many hints that are invaluable. But practical as it was, the pleasure of the apiary as well as the profit was told; for Mr. Newman is an enthusiast, as, to use his own words, all bee-keepers are.

Mr. Musser, superintendent of the department, wrote as follows:

The exhibits of last year have worked up quite an interest in progressive apiculture in this vicinity. Many then, for the first time, saw the new apiarian improvements, single comb sections, comb foundation, etc., and had never heard of planting anything for their bees to get honey from. Not one cent in premiums was offered last year, but this year over \$120, besides diplomas are offered, and next year I know we can double the amount.

The managers of the St. Joseph

Fair, have, by their foresight, given a good example for others to follow, and we hope the time will speedily come when apiculture, so long neglected by the managers of fairs, will receive its due share of attention. Liberal premiums should be offered for the best exhibits, and these premiums should cover a large variety of special points in order to make the competition the more lively, as well as to enhance apiarian science in general.

The time has now come when arrangements for honey and bee shows must be completed. Vice Presidents of the Continental Society should at once see the Fair Committees throughout the country and have a liberal premium list announced. We suggest something like the following:

	First Prem.	Second Prem.
Best display of Italian Bees.....	\$25.00	\$15.00
“ “ Black or Native Bees....	20.00	10.00
“ “ Home-Bred Queens.....	25.00	15.00
“ “ Imported Queens.....	10.00	5.00
“ “ Comb Honey, not less than 50 lbs.....	25.00	15.00
“ “ Extracted Honey, not less than 50 lbs.....	25.00	15.00
Best Colony of Bees in Hive, including manipulation.....	25.00	15.00
Best display of Apiarian Implem'ts.....	25.00	15.00
“ “ Seeds for Honey Plants, with common and botanical names.....	25.00	15.00
“ “ Foundation for Brood Chamber.....	15.00	10.00
“ “ Foundation for Section Surplus Honey.....	15.00	10.00
Best Bee Hive for all purposes.....	15.00	10.00
“ Honey Extractor.....	5.00 diploma	
“ Wax Extractor.....	5.00	
Best display of Honey Pastry, etc.....	5.00	
“ “ Honey Wines and Beverages.....	5.00	
Best Sections or Boxes.....	5.00	
“ Packages for Extracted Honey, with Labels.....	5.00	
“ Bee Smoker.....		
“ Honey Knife.....		
“ Bee Feeder.....		
“ Blanket or quilt for bees.....		
“ Bee Veil or Face Protector.....		
“ Gloves or Gauntlets for handling bees.....		

Some of the above sums may seem slightly extravagant, to persons who have never seen bees and honey figure to any considerable extent in agricultural and mechanical exhibitions and fairs, but to any reflecting individual, who takes into consideration the magnitude of the bee-keeping interest at the present time, and the illimitable millions of pounds of honey now “wasting its sweetness on the desert air,” from want of the proper encouragement and development of the industry, the figures will seem modest indeed. Bee-keeping should rank one of the foremost, if not the foremost, feature at these great gatherings. We respectfully suggest to all who have the management of fairs, that a day be set apart during the season for public manipulations and explanations on this subject, and soon these *industrial days* will become as popular and attractive to the public as are now the “speed days” of

horses, or the “trial days” of reapers and plows.

The following is a convenient method of exhibiting bees at Fairs; One corner of a room on the second floor of a building on the Fair grounds is enclosed by mosquito bar—the lives of bees being inside, with a tube connecting with the entrances running through the sides of the building, allowing the bees free passage in and out of the hives. Manipulation or examination of the bees, may be accomplished by going inside the netting, and no one outside need be disturbed by the bees. This has been practiced with success at several Fairs in this county.

When in Great Britain, during the summer of 1879, we found that the most attractive features of the fairs were the public manipulations with

Corner of Building, inclosed with Netting, for exhibiting Bees.

bees, and the large display of honey of captivating beauty. There they had a large tent, the inner circle being enclosed by mosquito bar or netting around the sides and about 8 feet high, and 6 feet broad; in this inclosure the audience assemble to witness the manipulations with bees.

We gave eight half-hour lectures in this tent; each time the inclosure was full of eager listeners. Two of these were delivered at the Scotch Bee and Honey Show, at Perth, concerning which the *Dundee Advertiser* remarks:

The manipulating tent was a scene of great interest during the show. It is of octagon shape, the operator standing in the middle, while the public feel secure under the protection of an intervening gauze screen. Driving bees from a straw skip and transferring their combs to a bar-frame hive, were hourly operations,

and never failed to strike with astonishment the spectators, who stood aghast at seeing a human being unprotected turning up a hive of bees, and handling them as if they were blue flies. Mr. Thos. G. Newman, editor of the AMERICAN BEE JOURNAL, was present, and gave lectures on American bee-keeping, which were very interesting. The Society presented to him a medal as a souvenir of his visit to this country, and for the valuable services he has rendered to the present session of the Society.

For exhibiting bees, observatory hives were used—those having glass sides, through which the bees may be seen at work—the hives being inside the exhibition building, with a tube covering the entrance, and running through the side of the building, giving free passage, in and out, for the bees. Sometimes, a glass box inclosing each frame, arranged like leaves of a book, with a common entrance to all of them, from the tube running through the side of the building, is made to exhibit bees. This gives an opportunity for thorough examination

Corner of Building showing Position of the Entrance Tubes to the Hives.

tion of the whole colony. A correspondent in the London *Horticultural Journal*, says:

I can state without fear of contradiction that never in the memory of man has there been such a desire to keep bees as at the present time. People here have been so encouraged in bee-keeping as taught in the bee tents, that I have almost daily applications for instructions concerning bees and hives.

In a private letter, a gentleman in England says:

The American honey introduced into this country in the "prize" boxes, has exercised a complicative influence upon the honey show this year. The season being more propitious than last—the large number of American surplus boxes imported into this country, have gone into use, and the ninety-eight different exhibits, displayed at least a variety never found at an American fair, while the highest prizes in any class, were awarded to the honey in American sections.

Concerning the Toronto Bee and Honey Show, Mr. Wm. F. Clarke says:

Under the stimulus of the liberal prize list, there was a magnificent

array of honey. The directors appropriated an entire building to the use of bee-keepers, and for the first time at a great exhibition on the American continent, "honey hall" advertised itself side by side with horticultural hall, dairy hall, etc. Honey was displayed in every form, calculated to make the mouths of spectators water. The tin packages and cans were gorgeously colored and labeled; the glass jars were in various beautiful shapes, and even the wooden boxes displayed a wonderful diversity of taste. In the center was a miniature church, ingeniously built of honey comb and wax, with pinnacles and spire. A smashing trade in honey was done at the exhibition. Thousands of people might be seen with gay-looking tin cans dangling from their fingers, or with pretty glass

English Bee Tent.

jars in their hands, or nice boxes under their arms. They bought and carried them home very much as is usually done with toys and trinkets on such occasions. The success of this show awakens great expectations as to the future of bee-keeping in this country.

Of the Honey Show in San Francisco, Cal., the *Semi-Tropic* said:

The attractive display of bees and honey formed a center around which apiarists literally swarmed. One hundred and two varieties of honey-producing flowers, formed a novel and interesting feature of this exhibition. The decorations of white sage were tasteful and appropriate, and the nectar itself, in jars arranged in pyramidal shape, clear as crystal, supported by frame after frame of comb honey, snowy and inviting, made a picture which cannot be photographed except by the artist memory. There were samples of excellent honey vinegar, almost colorless, and above average in acidity; several samples of fruit preserved in honey with undeniable success, and three kinds of honey cake, which elicited the warmest praise from those who were fortunate enough to secure a sample. Fruit cake made with honey is richer and retains moisture much longer than that made of sugar.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

MISCELLANEOUS.

Historic Scrap.—The Baltimore *Sunday Morning* gave a description of the "Sunny Side Apiary" in that city, and adds:

This apiary was, in the days of the late Richard Colvin, the experimental apiary of the firm that then existed, composed of the late Samuel Wagner, founder and former editor of the AMERICAN BEE JOURNAL; L. L. Langstroth, the inventor of the movable frame hive that bears his name, and Richard Colvin, of this city, to whom the bee-keepers of the present day owe their deepest gratitude for bringing out the many useful appliances, introducing new varieties of bees, and various implements connected with bee management of the present day. It was here the first Italian bees were received that ever came from Italy. Mr. Lake still has in his possession the original hive in which they were received, a great curiosity to visitors.

Work During May in Texas.—Dr. J. E. Lay writes to the *Texas Agricultural Journal* as follows:

Our main honey flow for this section of our state takes place during the month of May. It comes from the famous horsemint, a plant belonging to the mint family, the botanical name of which is, if I am not mistaken, *Monarda Punctata*. It begins to bloom generally about the 25th of April, and ends about the 10th of June, continuing in bloom about five or six weeks. It furnishes a clear, amber colored honey of pleasant aromatic taste, very rich and thick, and I presume will be par excellence our market honey for this vicinity.

Now as it is of primary importance to obtain as much of this choice honey as possible, it is absolutely necessary that our bees have all the aid that an intelligent master can give them. We will suppose that during the three months previous all swarming and dividing has been accomplished, all colonies equalized by building up the weak from the strong, or if needed in any case, a quantity of pure white sugar syrup was fed to meet any emergency; and now, that all are ready for business.

You will perceive that the bees seem to have but one thing in view during the continuation of this bloom, and that is to fill every possible space with honey. As a rule, about the 15th of April is the time to put on supers for surplus storing, but this spring my bees were working rapidly in the upper stories of frames as well as in the section boxes by the 1st of April. By close observation the master will know how and when to lay out work for his ever willing

servants, and he should avail himself of the earliest opportunity to obtain this beautiful spring crop. We should have no arbitrary rules to govern us, but each bee-keeper should take advantage of an early spring. He should also become acquainted with the honey-bearing flora of his immediate vicinity, and be ever ready to reap to the best advantage. It is well to keep a record of such plants, which will give us valuable aid for future reference. I keep a note each year of the beginning and ending of every bloom from which bees gather a noticeable amount of honey. We must be on the alert this month (May), and see that the queen of each hive has ample room to deposit eggs, that the colony may not become depleted and thus fall an easy prey to the moth. Use the extractor and replace the empty combs, or give them frames of foundation in the brood chamber, having raised the nearly filled frames to the upper story; and if section boxes are used, take them off as soon as sealed and supply them with empty ones containing nice thin foundation very near the full size of the box.

Bee Notes for June.—The *American Agriculturist* for June is received and contains the following as its "Bee Notes for June:"

In all the Northern States, June is the great honey month. The bees are already bringing in this delicious product from the raspberry, the white clover and alsike clover, and before the month ends, the basswood bloom will bring the bees to the great honey harvest of the year. Every bee-keeper should ask and answer for himself: Shall we work our apiaries for comb-honey, or plan to get all, or most of it, as extracted honey? This question was recently asked in a meeting of one of the most wide-awake societies of the country, and all but one answered: work wholly for extracted honey. The unanimous opinion was, that nearly double the weight of honey would be thus obtained, which readily sells at 12½ cents per lb., or more, while the nicest comb honey is only worth 20 cents, the general price being 18 cents. And this is not merely local opinion. Three-fourths of those at the National Convention last autumn, follow this method. The extracted honey is intrinsically as good as the comb honey, and is more nutritious. The wax of comb is neither easily digested nor nutritious. If there is not a present market for extracted honey, one can be readily created.

The honey extractor is coming into general use, and justly so. It is a German invention, is comparatively simple, and not very expensive, and by means of this the honey is thrown from the combs by centrifugal force, when they are returned to the hive to be filled again. If taken from the hive before they are capped over, it saves work and time to the bees. If not removed for extracting before they are capped, the caps are cut off

with a sharp knife run over the comb. There are various machines now made. They should be of metal, run with gearing, be light and strong, and so made that only the basket carrying the combs is revolved, leaving the can or reservoir stationary. They should be large enough to leave space below the basket for at least 100 lbs. of honey.

If we are to work simply for extracted honey, the hive may be very simple, and either one story, or two. I think better results are secured from a one-story hive, though a two-story one looks better. The late Mr. Quinby, who had no superior as a practical apiarist, once offered \$50 for a non-swarming hive. By a faithful use of the extractor, almost any hive becomes a non-swarmier—a point in favor of extracting.

When necessary to uncap some of the cells, uncapping knives, made with a beveled edge, are the best. In extracting during the honey season, it is never advisable to wait for the bees to cap the honey. If the honey is kept in a dry, warm room, and it should be kept in no other, there will be no danger from souring, even if the honey is extracted when quite thin. We have frequently extracted during the honey season as often as every other day, and with no bad results. We would not dare do this, if the honey must be kept in a cool room, especially a damp one. The best place to keep extracted honey is a room that is warmed up to 70 or 80 degrees Fahrenheit, each day, when the sun shines hot. Put the honey in open barrels or cans; cover with cloth that will keep out the dust, but not prevent evaporation. In extracting, care should be taken not to take away so much as to starve the bees the coming winter. The bees can be fed, but that may be neglected, and so honey enough should be reserved. Honey may be extracted from combs with brood, and not throw out the brood; this requires a very even motion. A sharp, sudden jerk will remove most of the bees from the comb; the remainder may be removed by using a bunch of asparagus, a pine twig, or a quill from the wing of a goose or turkey.

If the market makes it more desirable to work for comb honey, sections should be used. Those 4¼ inches square and holding one pound, are the most profitable as they find a ready sale. The sections may be placed in a crate above the brood chamber, or may be suspended in the body of the hive in a wide frame. Sometimes the bees are slow to go into the sections above the hive. In this case it is quite desirable to have the sections so arranged that they may be readily transferred from the body of the hive to the rack above. They are put into the body of the hive until the bees commence to work in them, and then are removed to the rack above where the bees will continue to work. Putting a small piece of uncapped drone-brood into the sections above, will sometimes induce the bees to commence work there. As the brood hatches out, the bees will

fill the cells with honey, and no harm is done.

To secure a good yield of comb honey, the colonies must be strong, and to have them thus, and not be bothered with swarming, requires skill and care. A much more skilful bee-keeper is needed to obtain the best results with comb honey, than to procure the best harvest of extracted honey.

A Standard Frame.—Mr. G. W. Demaree, in the *American Bee-Keeper*, remarks as follows:

While watching the drift and current of the bee literature of the past, I have noticed that the subject of bee hives and "frames" has periodically come up for discussion. There is about the Langstroth frame a history the most remarkable of anything connected with the inventions of the past, so far as they have come under my observation. The Langstroth frame ushered in the great modern system of bee-keeping, and has lived through the stormy period of the past 20 years defying the inventive genius of the American people. Thousands of efforts have been made to supersede it with something better,—with a better frame for all purposes. But not even a large minority of bee-keepers have at any time been induced to accept of anything as being superior to the old "L. frame." I do not say that the Langstroth frame will never be superseded by an improved one. I have much confidence in the inventive genius of the American people. I set no limit to what may be done. The chief objection urged against the Langstroth frame is that it is too shallow and too long to winter bees to the best advantage. There is perhaps some truth in this, but it is an argument similar to that used by Mr. A. J. Root in favor of his "simplicity bee hive," viz: that they stack or pile up so nicely, etc. Well, I have no use for a hive to pile or stack up, neither do I have any use for a frame that is good for nothing but to winter bees on. What we want is a frame that answers all purposes.

Fertile Workers.—The *American Bee-Keeper* gets off the following in its April issue on this subject:

"Fertile workers we believe to be a myth, as we have been keeping bees all our life and have never seen such a thing as a fertile worker."

From the above it would seem that the editor of the *Bee-Keeper* doesn't believe in anything except what he sees. Following out this course of reasoning, as he has never seen his brains, he would be compelled to confess that he has none. This may not be very reasonable, but nevertheless it is logical. Now, we know there is such a thing as a fertile worker, because we have seen more than one of them. Mr. Harrison believes there is no such thing, because he has never seen one. That is the difference.—*Bee-Keepers' Instructor*.

Read before the British Bee-Keepers' Ass'n.

A Bee-Keepers' Experience in the East.

T. B. BLOW.

The Cyprian and Syrian races of bees having of late years come prominently into notice, and there being a great difference of opinion as to their merits, I determined to make a visit to these lands and see them in their native state, and so be able to form an accurate and unbiassed judgment.

My original intention was to travel *via* Trieste, Corfu, and Rhodes, take observations, and bring colonies and queens of the various races of bees inhabiting the Eastern shores of the Adriatic. I found, however, that my engagements in England would not permit of such a long absence as this extended tour would require, and, therefore, I determined to go direct to Cyprus and thence on to Syria.

My starting-point was Liverpool, the vessel, on Sunday, 11th December, touching first at Algiers. Owing to my short stay there I was unable to pay any attention to the bees of North Africa. The next port was Malta, and I was interested to find the bees were black. This raised a suspicion in my mind that the bees of South Italy and Sicily were black, and this has been confirmed by Mr. Benton in last month's *British Bee Journal*. He states that black bees do occur in Italy. When we consider that the bees of the Eastern shores of the Adriatic are black, I think that there can be little doubt that the yellow Ligurians of North Italy were originally bees of the extreme East, brought there ages ago by the Romans, and that they have since become a distinct local variety.

Cyprus was reached in about 15 days, and I took up my abode at the English club, there being no hotels in Larnaca. I determined to remain at Larnaca a few days to get a little idea of the sort of people I had to deal with, and to make the necessary arrangements for the journey up into the interior. Happening to mention my business, I was told that an American bee merchant resided in Old Larnaca; and, as I knew this could only be Mr. Frank Benton, I resolved to at once make his acquaintance. I found that he was just about to leave Cyprus, and was, in fact, packing his bees for transit. As I was not going up country for three or four days, I paid him frequent visits, and assisted in packing up his hives. I thus had great opportunities of observing how the bees conducted themselves in their own land in modern hives. Mr. Benton, too, freely gave me much valuable and interesting information, which I shall touch upon later on. Landing in a strange country, it was indeed good fortune to meet with such pleasant people as Mr. and Mrs. Benton, and I have a vivid and grate-

ful recollection of the many kindnesses they showed me.

Not speaking modern Greek, my first search was for a guide and interpreter, and I found they were scarce enough in Cyprus. Some, who were otherwise suitable, did not speak English; others, who did, did not know the country well; and at last I had to fall back upon one, by name Spero, whose character, as given to me in Larnaca, was not the most favorable. To be forewarned is however to be forearmed, and I therefore felt able to contend with him. I found that he had many good points. He never allowed any one, besides himself, to rob or cheat me; he spoke fair English, knew the island well, and all the people therein; was a fair cook (though, in a testimonial he showed me, and which he seemed to value very highly, he was described as an 'indifferent cook'); was able to provide mules, and did not get intoxicated more than once or twice a week. I entered into a contract with him to supply his own services, three mules, one muleteer, and the best food and lodging that the villages could afford for any number of days that I might think fit; and I must say that he carried it out well.

A start was made on Monday morning, January 2. In the mule bags were placed 48 small hives which I had brought out with me. As I desired to get the bees from the hills rather than from the plains, where tropical heat prevails in the summer, we struck in the direction of the mountain called Stavro Vuni, or mountain of the holy cross. Inquiries were made at the various villages through which we passed, but the people were not willing to sell their bees; and Spero assured me that in some cases I was mistaken for an official, and they feared that some taxation of the bees was intended, and therefore they declined to have any dealings. The fact that all the people live in villages only, of course, made it very convenient, for we had not to run from house to house a mile or two apart, as would have had to be done in a country where the people dwell in scattered habitations.

The first village where bees seemed to be in great quantities was Hagia Anna, but the people would not sell at any price. We passed the village mill in leaving, and the miller hearing what was required informed us that a man who owned 100 colonies was deeply in his debt, and he would see whether he was willing to sell. However, we found that the man had gone to Larnaca, and nothing of course could be done. The miller very much pressed me to wait, evidently seeing a fair chance of getting his debt. We proceeded, however, and, passing through many villages with but few bees, we arrived in the evening at Lithrodonda, a large village wherein were many hives. There was no inn in the village, but as Spero knew the parish priest, we put up there, and were very courteously received, the best room being set apart for my use. We adjourned to the cafe, and told the assembled gossips our business,

and two or three persons set off to call the bee-keepers of the place. They evidently were not anxious to sell, and this seemed to be the case everywhere, and Spero explained it in this way. For two years the people had had good crops of corn, wine and oil, and were well off and out of debt, and therefore did not much need money. One, however, had 6 to sell, and after long haggling we got to within about 1s. per lot of each other, but as I declined to advance, and he was unwilling to retreat, the bargain was not struck.

We returned to our quarters at the priest's, and it was soon evident that he and Spero were old cronies together. They soon waxed merry over their wine and mastic, and the priest, being told of our difficulty in bargaining, announced his intention of going to see the people, who were his relations, and to try and complete the sale. He soon returned, and told me that the bees were mine. This being satisfactory I retired. The furniture of my room consisted of a kind of shutter against the wall at one end, and supported on two legs at the other. This, with a somewhat thin collection of clothes, formed the bed. Great care was necessary, or the whole affair would have come to grief. Washing appliances did not seem to be considered necessary, and the people evidently were not fond of the application of water. A beeswax taper stuck against the wall, and the list of furniture is complete. To levy a distress on the furniture of a village home in Cyprus would be somewhat of a farce.

I rose early to get the bees, but found the man had been persuaded by his wife to run back from his bargain, and though the priest came down and tried to persuade them, and Spero fetched two zaptiehs, or policemen, they would not let us have them. However, we heard that a man had been to the village mill that morning, and, hearing that we wanted bees, had offered to sell. His place was more than one hour distant, but I determined to go. Here, again, the man's wife was the impediment. She, hearing that we wanted the bees, positively declined to allow her husband to come out of the house to see us. She stood in the doorway and kept guard over him, and inside he had to remain, and we to go back to Lithrodonda without bees. She—sensible woman—said that if her husband got the money for the bees he would spend it in wine, and next year she should have no honey. Arriving back in Lithrodonda, we found that our old friends there had repented that they had not sold the bees, and I therefore got the 6 lots.

There not seeming much chance of getting more bees near, I decided to go back to Hagia Anna, and see whether the debtor of the miller had returned. He had, but during his visit to Larnaca he had got some money and paid the miller, so no bees were to be had. He, however, kindly offered to sell his bees at 100 piastres (over 10s.) a lot, not to pick them, but take them from the stack. I should

remark that the bees are kept in clay cylinders, about 3 feet long and in diameter 15 inches at one end tapering to 10 at the other. These clay pipes are stacked in large piles, sometimes as many as 50 to 100 in one stack.

The accommodation at Hagia Anna was wretched. I had a mattress spread on the stone floor, and my saddle-cloth.

Next morning began the third day, and only about 6 lots of bees collected. I began rather to suspect that Spero was not trying his best to get me bees, but prolonging the journey a bit, that of course being to his advantage. I intimated as much, and Spero assured me that at a village about 15 hours off there were only 7 houses and 500 lots of bees. This looked promising, and as there were many villages on the route I decided to go. The village was hard by the monastery of St. Chrysostomos, and, I believe, nearly 2,000 feet above sea-level. We journeyed all day, and at evening stayed at a village at the foot of the mountain range running along the north of Cyprus. Here we stayed with the parish priest, who was a bee-keeper. He said that he had 300 colonies last year, but a hot wind came and melted the combs and destroyed the bees. His present stock was 3 lots only. He was very kind, and offered, had it not been so near Christmas, to have procured bees. I did not care to have them from such a warm place however.

In the morning we proceeded towards Kutzo Venti, but the progress was both slow and dangerous, owing to the heavy rain that had fallen in the night. The path up the mountains ran along the tops of deep ravines, and in many places had been washed almost away, and rendered very unsafe. About noon we arrived at this wonderful apiary of 500 colonies. Truly, there were 7 houses, and perhaps 50 lots of bees. The people would not sell at first, but consented, just as we were starting off, to let me have 7 lots; but on these conditions,—the cylinders were not to be moved out of the stack, neither were both ends to be opened. Being anxious to get bees I accepted these terms, but before I had got the first lot out I found that I had made a bad bargain. The seven lots I purchased were distributed about a stack of about 40 to 50 cylinders, and, as it was a warm day, the bees were flying strongly. In removing the ends of the cylinder I had to jar the pile considerably, and the consequence was that I had the bees of the whole 50 hives around me, and did not they sting? At first their owner and Spero had offered to assist, but not many minutes had elapsed before they fled howling in all directions, and I was left alone to fight the battle. I saw I should get worsted, and retired to the house, where I found the others extracting the many stings.

I offered the man a sum to let me off the bargain, which he did, and I retired from Kutzo Venti somewhat crestfallen. I upbraided Spero for deceiving me, and announced that I would go to Kythraea. He assured

me that no bees were kept there, but I insisted on going. This was the fourth day—result, about 8 lots of bees, Spero said that we could do no business during the next two days, it being the Greek Christmas. I suggested that we should return to Larnaca in that case. He at once changed and said he would do his best if I would not return.

After a few hours' riding we reached Kythraea, and a more lovely valley I had rarely seen. Streams of spring water ran down each side turning innumerable mills. The orange and lemon groves were almost continuous; every moist wall was a carpet of maidenhair fern, and crocuses and anemones in places almost carpeted the ground. Bees, too, were everywhere, and I believe that the valley, though only about 2 or 3 miles in length, contained more than 1,000 colonies. In many cases the cylinders were built into the walls of the houses and the bees' entrances were in the streets, and these streets narrow ones too; I never, however, heard of the people getting stung. The roofs, too, were covered with hives. The people here seemed a more business-like race, and before night about 13 lots had been purchased. The news that bees were wanted quickly spread, and, though it was Christmas day, the people after they had been to church were not at all averse to business. The priest too, was a most amiable man, and did all in his power to get me the bees, and with the result that before noon more than 40 lots were mine.

The next difficulty was transit. Most of the hives were grand stocks, and I did not like to transfer them into my little boxes. I therefore determined to convey them to Larnaca on mules in the cylinders and there transfer into larger hives. The mule and donkey owners of the village were called and demanded double rates owing to Christmas time; but after a lot of bargaining they consented to take a fare and a half, and I hired in all about 27 animals. Packing up 40 cylinders to be ready the next morning at 7 was no light task. I worked like a slave, and it was far into the night when my labors were completed. Each mule had two cylinders to carry, and, as each was loaded, the former owners of the bees fumigated both bees and ourselves by burning sweet-smelling leaves on little charcoal dishes to ensure that both ourselves and bees should prosper. It was a long day's journey from Kythraea to Larnaca (over 30 miles). The valley contains a succession of villages with very narrow streets, and the cylinders had many narrow escapes from being broken against the corners of the walls. The journey across the Messorea, or great plain, was diversified by a mule occasionally falling down or lying down to roll, or jumping across some little stream to the great danger of the hives. The end of one came out and so did the bees; but the muleteer had presence of mind enough to cover the opening at once with his coat.

Larnaca was reached between 8 and 9 at night, and bees were found safe.

I had previously hired a house, which had a very large courtyard and verandah, formerly occupied by the Russian Consul; and here I transferred the bees and combs into bar-hives made by a native carpenter of much larger size than those I brought out. This, of course, was the work of some days, and when completed I proceeded on to Beyroot to get Syrian bees. On landing, my bees were at once seized by the customs authorities and declared contraband. For two days they kept them, and it was only when I had obtained the assistance of the English Consul and some other friends that they gave them up, and even then I had to pay 10 per cent. duty on them. This delay was fatal to getting bees at Beyroot, where my friends, Joseph Abdelnour Faker and Dr. Beshara I. Manasseh had kindly made inquiries (in the neighborhood and on Lebanon) among the native bee-keepers, and where I should have readily obtained any number of colonies, but, as the steamer that I was to return by came in on the third day, I had to go on board. Tripoli was the next port, and though I saw some bees, I could not deal.

At Scanderon I had no trouble at all. Mr. Christian, of the Ottoman Bank at Beyroot, had furnished me with a letter of introduction to the agent at Scanderon, and he very kindly sent me to a bee-keeper close by. The bees at Scanderon are kept in wooden boxes about four feet long and nine inches square. The colonies were very strong, and I determined to take them home in the original cases. I decided to drive the bees to one end of the box and saw it in half. Getting a saw of the ship's carpenter, I returned and commenced work. This proceeding attracted many, curious to know what was going to be done. Seeing one hive cut in half was enough. The sawing, of course, greatly irritated the bees, and the crowd retired, many of them having their curiosity more than satisfied.

I was stopped at the Custom House, but my offer to open one of the cases to allow them to judge of the contents was politely declined, and I went on board. Whilst lying at anchor off Scandaroon, I gave my bees a flight on board, and no one got stung. This I did also at Alexandria, where we were delayed 16 days. The commander of the *Ararat*, Captain Sandrey, took much interest in the bees, and all along showed me the greatest kindness, giving me the offer of any part of the vessel in which to put the bees on the homeward voyage. I tried below deck first, and there unfortunately got a number stifled, owing to the rough weather causing the hatches to be battened down, and at same time I was much too ill *mal de mer* to go to their rescue. A call was made at Valencia, where another delay occurred through quarantine. I went into the country to observe the Spanish bees, but, with the exception that they appeared very black, they differed little from our English bees. After leaving Valencia, the sheep-pen on deck was used to shelter the hives in, and in this they safely ar-

rived at Liverpool after a voyage of over 6 weeks, about 20 per cent., I believe, being lost on the voyage.

As I before remarked, the bees are kept in cylinders in Cyprus, in Syria in long boxes, also in water-jugs and baskets plastered with mud. The bee-keepers of the East are far more advanced than the old-fashioned English straw skeppists, for they never kill their bees. The lid at the large end of the cylinder is removed, the bees smoked to the other end, and about half the combs in the cylinder are cut away, the other half being left for the bees.

The cylinders are placed in huge piles, and the bees enter at small holes in the front, the entrances not being a foot apart. I think a point in favor of bee houses can be brought forward, or, rather, one of their supposed disadvantages rebutted. I bought between 50 and 60 lots, and in no case was a colony queenless. The great disadvantage of a bee house is supposed to arise from the queen mistaking the entrance. If the Eastern queens can find their entrances thus readily in a pile of fifty to a hundred hives, they must either have better discernment (a point in their favor) than English queens, or this objection to bee houses is unfounded. Such grand colonies of bees as those I got both in Cyprus and Syria I have rarely seen, and these, too, never having had attention in the way of feeding, but left just in a natural state. Though it was winter, almost all contained fine patches of brood.

The queens are very prolific, and the brood is raised in compact, solid masses, no patches of comb being left empty.

The bees are undoubtedly better workers, being much more active and stronger on the wing than our bees, though just a trifle smaller.

The small amount of drone-comb they build is another great point in their favor. (I believe that I can say that I have seen more drone-comb in 2 or 3 English hives than in the whole 50 or 60 I transferred). Their gnawing propensity, too, I imagine will be of value. The development of the jaws of the Eastern bees is curious, and has doubtless been brought about by the grape crops of the East. A bee-keeper at Scanderon told me that great damage is done to the grapes by the bees, and that they get great quantities of honey or rather grape-juice from this source.

The great point against them is their irritability, and it is certainly a great drawback, and may prevent them from coming into general use. This irritability is far greater in the Syrians than in the Cyprians. An experienced bee-keeper would, of course, have no difficulty when once he knows the precautions it is necessary to take. If the quilts are removed very slowly, so that a great flood of light does not rush into the hive at once, the bars moved gently without jarring, and the bees not breathed upon, then all will be well—they will require no smoke and will be quite harmless; but a careless manipulator, not attending to these precautions, would

probably irritate them, and their temper once roused is not easily soothed. Mr. Benton went through hive after hive in my presence without gloves or veil, and assured me that he did the same thing during the summer and did not get stung. I believe the evil reports have arisen through a lack of knowledge on the part of the owners of these bees, or on account of not getting the genuine article. When these bees are angry they appear to be cautious in stinging, but attempt to bite in preference.

Braula ceca is very abundant on the Eastern bees, but especially so on the Cyprians. Though I had but little experience with the bees of Palestine, I noticed a marked difference between this race and the Cyprians and Syrians. The Palestine bees are much more slender and downy, and deserve to be ranked as a distinct variety. The Cyprians and Syrians are, in my opinion, almost identical. They vary a little in color, the bees from the north of Cyprus being very dark.

Lime Packing for Winter.

J. C. OLDHAM.

Our Southern friends have quite the advantage of us, in that they need not bother much about the wintering of their bees; not so with us here in the North. I read the Weekly BEE JOURNAL with much edification, and am greatly interested in what all contributors have to say about wintering bees—what absorbents are used; but never liked the idea of using chaff, straw, dry leaves, sawdust, etc., that were and are still so much advocated. Such absorbents retain all moisture, and therefore are as a wet blanket which is worse than none at all.

I use or have used only a quilt or carpet over my bees, until I first saw the lime project suggested, about Jan. 1, 1881, by some Kentucky gentleman, I believe. I had in the fall of 1880, 10 colonies in Langstroth hives in very good condition, but not as well prepared for winter as I desired—that is, more frames in the hives than were necessary. The cold weather set in so early and did not warm up again until spring. I liked the lime idea so well I thought I would experiment a little, and so put lime, partially slacked, in three hives; one I over-heated and killed the bees, the other two came through in splendid condition.

I lost 5 of the 10 colonies I had in the fall; from those 5 during the summer of 1881, I took 400 lbs. of honey, mostly extracted, and increased to 12, the number I now have, except on the 5th inst., I had a swarm, making more than I really want or have time to attend, as I only keep bees for pleasure and recreation. Last winter I put lime in all my 12 colonies. They came through splendidly. No doubt they would at any rate, but I occasionally looked in the hives, and the combs were always nice and dry with not the

least sign of frost. Lime is the least trouble of all absorbents to put in and take out again, much more convenient than the so-called absorbents.

For the American Bee Journal.

An Open Letter to Mr. Doolittle.

DR. L. JAMES.

DEAR SIR:—I have read with much satisfaction your late articles in the BEE JOURNAL, giving your plan of securing such favorable results from your bees and the large yield of comb honey as reported in them. In addition to the information communicated in those articles, I should like to have one more, connected with them, that no doubt will interest many others as well as myself, and it is this: How do you manage to have so many hives open on each favorable day, so early in the season, interchanging the combs in the hives, and carrying others of brood around among your hives, to strengthen feeble colonies, without having a cloud of intruders from the other hives, ready to pitch into a hive as soon as it is opened, and thereby endangering its destruction, if it is a weak one?

I presume it is nothing uncommon with you, on opening a hive, to find it necessary to trim off some honey from certain combs to have them fit the place of those with which they are to be exchanged. And as the honey resources at this time are rather scant, the bees are upon the alert and will follow around, waiting to begin depredations on their neighbors as soon as the frames of comb are exposed.

I find my bees are so easily trained in this direction as to give me much trouble after a few hives have been attended to. If the hive is not too heavy, by carrying it into the bee house and attending to it there, this annoyance and risk can be avoided, but, as a general thing, my hives are too heavy for me to do so.

At your earliest convenience if you will give us your method by which you avoid this trouble you will much oblige many readers of the BEE JOURNAL.

The Standard Langstroth Hive.

G. M. ALVES.

Beginners frequently spend a good deal of their time in study as to the kind of hive they should use. As this is a matter of considerable importance, and one in which one's crude fancies often run into error, I propose here, for the sake of these beginners, to give what seems to me good and sufficient reasons why the standard Langstroth hive should be adopted. I wish to state here that I am not interested in the manufacture or sale of hives.

1. The Langstroth hive was the invention of a man who brought to his

task great interest, great experience, and a mind probably better fitted for his peculiar work than any of his successors. Hence, in using his hive, we trust to authority than which there is none better.

2. The Langstroth hive has steadily grown in popularity, and to-day is much more used than any other hive. We thus have the sanction of time and experience, which are of the greatest value in testing the usefulness of any invention.

3. The Langstroth hive and furniture being standard articles, may be more easily procured than any other. There are few supply dealers that do not keep in stock these hives.

4. The Langstroth hive and furniture being standard articles, may be procured at a less cost than any other.

5. Bees in Langstroth hives can be more readily sold, and at better prices, than if in odd frames.

Thus there are 5 good reasons that cover the whole ground why beginners would do best to adopt the Langstroth hive. The best authority, the test of time, the certainty of getting hives, etc., readily, the certainty of getting hives, etc., cheaply, and the certainty of having bees and brood in the most salable shape, should they afterwards wish to sell.

Henderson, Ky.

N. W. Ill. and S. W. Wisconsin.

A special meeting of this Association was held at the apiary of Jonathan Stewart, in the village of Rock City, May 16. President R. M. Miliken being absent, the meeting was presided over by Vice President Levi Kiester.

After receiving and acting upon the report of the Treasurer, the Association proceeded to discuss a number of very important questions relating to bee-culture. The meeting was unusually interesting, and all the members present exhibited a deep interest in their work, and joined in the discussion of the questions before them with much ability and enthusiasm, and clearly showed careful study and close attention to progressive bee-culture.

The attention of the Association was called to several species of fraudulent practices by some unscrupulous apiarists, whereby an inferior quality of honey is imposed upon the public, and the following condemnatory resolution was passed:

Resolved, That we strongly protest against, and severely condemn, the nefarious practice of feeding bees glucose or grape sugar, or the adulteration of honey in any manner, as dishonorable and dishonest; that we pledge ourselves individually and collectively to expose any person or persons who, to our knowledge, may en-

gage in such fraudulent practices; that no person so engaged shall be admitted to membership in this Association, and that it shall be deemed a sufficient cause for expulsion from membership.

The Association adjourned to meet again at Rockton, Winnebago Co., Ill., Sept 5, 1882.

JONATHAN STEWART, Sec.

The Northwestern Wisconsin Bee-Keepers' Society will meet in LaCrosse, Wis., June 9, 1882, in the City Hall. A good attendance is desired, as arrangements have been made for articles from practical apiarists.

SELECTIONS FROM OUR LETTER BOX

A Puzzle.—I have heard of persons running against a pozer, and it seems I have now encountered one, on which I want information. I introduced 6 queens last fall; of course they showed no progeny last fall. Two of the 6 showed their progeny in February, but none of the 4 have laid an egg yet. Of course they were dollar queens, but were well developed and as bright as a dollar. What is the matter?
COL. R. WALTON.

Industry, Ill.

[We could only guess at an answer, which would be as liable to be incorrect as otherwise.—Ed.]

The Journal a Necessity.—I cannot do without the BEE JOURNAL, and if I continue to keep bees, you can depend on me as a life subscriber, at least while you keep so far in advance of all other bee periodicals. My bees are doing well thus far. Some are working in sections, but I have three different kinds of hives, and have to use various sized sections. If the bees pay well this year I shall endeavor to get a uniformity of hives.
HIRAM J. WARD.

Farmington, Kan., May 14, 1882.

Bees in Western New York.—My bees have wintered well on their summer stands packed in chaff, 42 colonies. I have not lost any. The spring weather has been very unfavorable for the bees, and cold winds have prevailed most of the time. The elm and soft maple blossoms have been killed by frost. The early sweet cherry and peach blossoms are opening now, and the dandelion will, in a few days, be at the height of bloom. The orchards have never looked more promising than they do this year, and prospects are very good, if we only get suitable weather. The white clover prospects are not so good, for it has suffered with other grasses greatly from the many changes of weather last winter, with no snow on the ground. The reports from the surrounding country are that colonies have wintered well in cellars and on their summer stands, and are very strong in bees, and wherever there is any loss it is from starvation, and the bee-keeper is entirely to blame for it, for we had splendid weather in the latter part of February to look after the bees and feed them. By the way, I send you a little box with a plant in it. It grows here on the railroad track, and bees work freely on it. Can you give the name of it, and its value for the bees?
WM. BOLLING.

Dunkirk, N. Y., May 10, 1882.

[The plant is the corn growwell (*Lithespennum arvense*), naturalized from Europe, and widely disseminated in the Northern States, especially occurring on sandy banks and roadsides. Its flowers are very small, but contain a considerable amount of nectar, easily accessible to bees. I should not suppose the quality very good, but have no certain knowledge about this.—L. J. BURRILL, Illinois Industrial Institute.]

Gone to Florida.—I brought here last month from Gretna, La., 5 colonies of bees, and did not lose a half pint in the removal. They are doing splendidly on the saw palmetto at present.
A. T. WILLIAMS.

Tampa, Fla., May 11, 1882.

Unfortunate.—I can sympathize with Mr. R. L. Shoemaker, of Newcomerstown, O., as stated in the last BEE JOURNAL. On April 25, in preparing cages for shipping queens, in drawing a fine tack with the point of a knife, the tack flew into my left eye and destroyed the sight, which has had the effect of subduing my ardor in the bee business somewhat. Weather here is cold and wet. No honey from fruit bloom—too cold and windy. Bees are starving to death; am feeding every colony in my apiary. Outside of the feed, I have given them, I do not think there is one pound of honey in my entire apiary, consisting of 35 colonies. What the future will bring forth remains to be seen. Prospect is far from flattering.
M. H. SNYDER.

Elmwood, Ill., May 12, 1882.

Entomological.—I send by mail a small box containing some wasps and small bees; also, some cocoons of larvæ. The wasps I have noticed for the past 3 or 4 years. I have destroyed many of them—over 200—since yesterday morning. Do you think it necessary? They are easily destroyed while about the hives. The small bees first made their appearance this spring. They seem intent on taking the pollen from the legs of the bees, alighting on their backs. I have seen them carried into the hives in this way. I dug the cocoons of larvæ from the ground where I saw ground bees last summer.

SOLOMON VROOMAN.

Seward, N. Y.

[The wasps are very common everywhere in the Northern United States. They are indeed the most common of our paper-making species. What house-keeper has not been annoyed by them in the autumn and spring, and what child has not been stung by them during the pop-gun period of its existence? They are insect-eating wasps, and so are really our friends. I have never heard of their eating bees, nor do I think they do. I should never kill them. I have seen them destroy the common and very destructive currant slugs in the summer *in extenso*.

The little wild bees are sometimes annoying in the spring, and doubtless take some considerable honey. They do not try to enter the hives after the honey season commences, so far as I have observed. Those who have the Syrian bees will not be troubled much by these wild bees, or any other robbers. The Syrians seem to say practically, to all intruders, "We run this hive." There are two or three species of the bees, sent by Mr. V., all of which are common. They visit the bees and the hives for the honey and the pollen.—A. J. Cook.]

White Clover Prospect Good.—I wintered my 20 colonies on their summer stands as usual, in which manner I have never lost a colony. I commenced the bee business in 1877, have always used the movable frame hive, and have never lost a swarm yet. My bees are now in splendid condition, and only one has a faulty queen. The Syrian queen I wrote of in the BEE JOURNAL, page 374, 1881, and thought was lost, I found in February last when I examined my bees. She was in hive No. 13, about 60 feet distant. The former queen in No. 13 was a weak Italian, and worthless. I thought she might live till spring. I was glad to find her superseded. Bees have bred up very rapidly, the hives being full of brood, and drones flying when it is warm enough. To day the weather is 46°, and a drizzling rain. If it keeps on this kind of weather many

more days I fear the bees will run short of honey. The prospects for white clover is good.

R. M. OSBORN.

Kane, Ill., May 12, 1882.

A "Played-Out" Queen.—I send you by this mail a queen that I have had nearly two years. She has always been a good, fertile queen until about 3 weeks ago, when she commenced laying drone eggs. She would deposit but one egg in a place, in worker cells, but they all hatch out drones. I put on a feeder and fed them; also gave them brood from other colonies, but to no avail. I send her to you to dissect. How do you account for it? She has always been a good layer. My bees were never in better condition at this time of the year than at present, although we have had a very cold, backward spring. L. E. WELCH.

Linden, Mich.

[The queen is undoubtedly old and superannated, and has become a drone layer. Probably had you given another frame of brood, during a honey flow from fruit, the bees would have reared a young queen, and superseded this one. We have not the necessary time and facilities for scientifically dissecting queens or bees.—ED.]

Intruders.—Yesterday the bees flew out of one colony much excited, and settled back on the front of the hive. On examining them I found about 3 pints of dead bees, about half inside of the hive and the rest around in front of it. I could not see what caused it. There were a few moths enclosed in their cocoons, not much honey, and plenty of room and bees. When I opened the hive I saw a black bug in the super carrying a dead bee, but would have thought nothing of that under other circumstances, and do not think it caused the trouble. The bug was about as large as a queen bee; head half as large, abdomen a little larger and flat. Tell me what caused my bees to fight and kill each other? JOHN WATSON, JR.

Danville, Ill., May 15, 1882.

[We think a natural or abnormal swarm attempted to invade the hive, and was repelled by the bees belonging there. It may be, however, robbers caused the disturbance, but they would hardly have settled on the front.—ED.]

Extracted Honey.—We have had many excellent articles on running an apiary for comb honey, by Messrs. Doolittle, Heddon and others, in which all the details of the business have been very carefully and elaborately described. These chapters have been very useful and entertaining; but very little, comparatively, is written on the management of an apiary run exclusively for extracted honey. It would doubtless prove an interesting variety to the readers of the BEE

JOURNAL to have a few chapters on running an apiary exclusively for extracting, with all the minutiae that has been used in describing the best practices for securing comb honey. The best frame and hive to use where extracting is the leading feature of the apiary—in a word, all the *modus operandi*. A few papers on this branch of apiculture would prove a pleasant variety with the comb honey practices, and hair splitting theories, which the readers of bee literature have been so indulged with.

Highlands, N. C. E. E. EWING.

Various Matters.—I would like to ask a few questions: 1. How can I keep the queen out of the section? Mine are coming up in the sections—a few, at least, on nearly all the hives. I give them $\frac{1}{4}$ inch between the sections and brood frames. Found a few sections half full of drone brood. 2. How long can bees, after swarming, live without food? One week ago was nice, and I had several swarms come out; they were hived on foundation, and since then it has been cold, cloudy, and raining so they could not go in search of food. I got uneasy yesterday and went to feeding. 3. When two swarms are hived together, will they usually stay; 4. and would it be best to put on sections on such hives at once? I have two such that fill the lower story of the Langstroth hive altogether too full of bees. We have had a week of remarkable weather for May; people were wearing overcoats all the week.

D. W. BELLEMEY.

Vienna, Ill., May 14, 1882.

[1. Extract all the honey from the brood chamber, and use only worker foundation in the boxes.

2. They should be fed within 24 hours after swarming, if weather is unfavorable for gathering honey.

3. Yes, if one queen is removed.

4. No, not until the foundation is well drawn out below.—ED.]

Convention at Grand Rapids, Mich.—What became of the Bee Convention to be held at Grand Rapids April 26, 27? I was there but could not find any meeting of bee-keepers; neither have I seen any report of it published. B. DICKINSON.

[We do not know; perhaps the Secretary, Mr. W. M. S. Dodge, Coopersville, Mich., can give some satisfactory explanation. It was to have been held in Supervisors' Hall.—ED.]

Bad on the Pets.—We lost near all the apple and peach bloom by the blizzard; now we lose nearly all the locust and poplar or tulip by the continual rains of the past 10 or 12 days, bees hardly gathering enough for brood-rearing. To-night is almost cold enough for frost. If it was not for the cheering news brought by the BEE JOURNAL, I would feel very despondent; indeed, I have divided

several colonies which were making preparations for swarming, and had one large swarm from a box hive which I bought from a neighbor. A great many of my neighbors' swarms are leaving them this season. I live in hopes for the white clover.

G. W. ASHBY.
Valley Station, Ky., May 12, 1882.

Floating Apiaries.—Please state in the BEE JOURNAL whether there is any man or company of men who have steamboats loaded with colonies of bees, and advance up the river as the weather gets warmer; if so, please give particulars. Wm. SEARS.
Harrodsburg, Ind.

[Not that we are aware of; several have tried it, chief among whom was Mr. C. O. Perrine, of this city; but we believe the experiment has met with disappointment and loss in each instance.—ED.]

Milkweed.—I mail you a few bees that were handed me by a party who lives some 12 miles south of this. By examining, you will see the bees are in such condition they cannot use their feet, from the particles adhering to them; they cannot crawl in the gum. He says at the entrance of one old box hive there were about a quart of bees dead, all with these particles attached to their feet. I had a swarm of bees to-day that I obtained, to my certain knowledge, 4 queens from. I caught one as she came from the hive, which I caged, then moved the old hive and put a new one on the old stand laying the queen caged at the entrance, supposing they would come back. They went off 50 steps and settled. I took the caged queen and hive to where they settled; shook them off with the queen still caged. They commenced going in, when I discovered another queen; caught and caged her; took the first queen and put her in the hive she came out of, turned her loose in the old hive, and moved it back to its former place; went to the swarm, found them settling, where first settled; shook them off, and waited to see if they were going in, when I discovered queen No. 3. Caught and caged her, put No. 2 inside of the hive in the cage on a frame, and was watching to see if they were going in, when I discovered queen No. 4. Being out of cages, I gave her to my wife to hold, who, being timid, let her get away. She flew in the air. Whether I caught this one again I cannot say, but I got 4 queens that I know.

McKinney, Texas. SUBSCRIBER.

[In most of the United States there is a species of milkweed (*Aselepius*), the sap or juice of which adheres to the feet and legs of the bees, and not only causes them much trouble to walk, but is very distasteful to those in the hive. It is not an unusual occurrence for the hive bees to kill great numbers of them. Perhaps this

milkweed grows in your neighborhood, or some other plant of a like nature, the pollen or sap of which is the cause of the trouble.—ED.]

Snow and Frost.—This morning the mercury stood at freezing, and the ground was frozen. Yesterday we had a snow storm, and the snow has not all disappeared yet. Several days past have been quite cold, but to-day is pleasant. GEO. H. GOODWIN.
West Milton, N. H., May 17, 1882.

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10	per cent. discount.
" 8 ".....	20	" " "
" 13 " (3 months).....	30	" " "
" 26 " (6 months).....	40	" " "
" 39 " (9 months).....	50	" " "
" 52 " (1 year).....	60	" " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—a copy of "Bees and Honey."
" " 3,—an Emerson Binder for 1882.
" " 4,—Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,—" " " cloth.
" " 6,—Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
 Monday, 10 a. m., May 22, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—As the season is well advanced, sales of extracted honey are slow and prices remain unchanged. I am paying 7c. for dark and 9c. for light, cash on arrival. Good comb honey is scarce and rules high.

BEESSWAX—I am paying 24c. for good yellow wax on arrival; 18@22c. for medium grade, and 15@17c. for dark.

A. L. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for extracted honey, in the retail way, is fair, and our sales for manufacturing purposes were very good of late. We pay 7@9c. on arrival. Prices for comb honey nominal and demand slow.

BEESSWAX—Brings 18@22c. The demand exceeds the offerings. C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for honey is light, most of the trade finding fault with the best offered, as it is more or less candied. Values are not steady, prices being made to meet the views of the purchaser.

BEESSWAX—Scarce, and in demand at 23@25c. H. A. BURNETT, 165 South Water St.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.

BEESSWAX—Prime quality, 25c. CROCKER & BLAKE, 57 Chatham Street.

CLEVELAND.

HONEY—There are a good many small lots of very nice white section honey coming in now from time to time. White sells readily at 22c.; second quality 18@20c.; Buckwheat, no sale at any price. Extracted, none in market.

BEESSWAX—25@30c. A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—Little if anything doing in honey, and prices are entirely nominal. White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1@2 lb. bxs., 13@14c.; buckwheat, 2 lbs. per lb., 11@12c. Extracted and striped, white, 9@10c.; dark 7@8c.

BEESSWAX—There is only a moderate supply of beeswax, and with a fair inquiry prices are firmly sustained. Western, pure, 24@25c.; Southern pure, 23@24c. D. W. QUINBY, 105 Park Place

ST. LOUIS.

HONEY—In fair demand. Strained selling at 8@10c.; comb scarce—nominal at 18@22c.

BEESSWAX—Still at 21@22c. for prime. R. C. GREER & CO., 117 N. Main Street.

SAN FRANCISCO.

HONEY—Stocks are not heavy, but are larger than holders care to have them. Offerings are almost entirely second grade to inferior. There is a general desire to clean up prior to arrival of new crop.

We quote white comb, 13@14c.; dark to good, 8@11c. Extracted, choice to extra white, 7@7½c.; dark and candied, 6@6½c. **BEESSWAX**—23@25c. STEARNS & SMITH, 423 Front Street.

When changing a postoffice address, mention the old as well as the new address.

We learn, with much regret, that Mr. James Vick, of Rochester, N. Y., died of pneumonia on the 9th inst. Mr. Vick was a prominent and popular seedsman, and editor and publisher of a "Monthly" which was the admiration of every lover of the beautiful in nature. He was a thoroughly progressive and practical man, and one well-known throughout the World.

When changing a postoffice address, mention the old as well as the new address.

CLUBBING LIST.

We supply the Weekly American Bee Journal and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both All postage is prepaid by the publishers.

	Publishers' Price.	Club.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

We have on our desk Circulars and Price Lists of bees and apianian supplies from G. J. Pammel, La Crosse, Wis., L. E. Mercer, Lennox, Iowa, and W. G. Russell, Millbrook, Ontario, Canada.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Articles for publication must be written on a separate piece of paper from items of business.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

This one fact is being brought before the minds of the people of the United States: Kendall's Spavin Cure is not excelled as a liniment. 18w4t

Bingham's Smoker Corner.

Bayou Goula, La., May 2, 1882.
 Messrs. BINGHAM & HETHERINGTON, Abronia, Mich.
 Dear Sirs: The Conqueror conquers everything in the uplary. It is almost a light between my three assistants, us to who will get it first in the morning. A single puff from it will fill a double story with smoke. I will use no other after this.
 Yours truly, P. L. VIALLOIN.

A NEW BEE BOOK!

Bees & Honey

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,

Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, fully up with the times in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage & Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

025 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-keeping.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 108 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

A valuable work for all who are interested in the cure and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

A Liberal Discount to Dealers by the Dozen or Hundred.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and moving slides in the Comb baskets.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Lang-troth " 10x18 ".....	8 00
For 3 " " 10x18 ".....	10 00
For 4 " " 10x18 ".....	14 00
For 2 frames of any size, 13x20 ".....	12 00
For 3 " " 12 1/2 x20 ".....	12 00
For 4 " " 13x20 ".....	16 00

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber. It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,900. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY.

By A. J. COOK,

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that, no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book;

All agree that it is the work of a master and of real value.—*L'Apiculteur*, Paris.

I think Cook's Manual is the best of our American works.—LEWIS T. COLBY.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—J. P. WEST.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—E. H. WYNKOOP.

This book is just what everyone interested in bees ought to have, and which, no one who owns it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The reader will await its author.—A. B. WENZEL.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disseminated information contained in Cook's Manual.—WM. VAN ANTWERP, M. D.

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French, or foreign, which I like so much.—L'ABBE DU BOIS, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *vide mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small **White Shark**, caught in the Yellow Sea, known as **Carcharodon Hondaletti**. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthy noises in my head, and bear much better.

I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

To avoid loss in the mails, please send money by REGISTERED LETTER.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by
THOMAS G. NEWMAN,
925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide for Cook's Manual of the Apilary.—Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quincy's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces everything pertaining to the care of the honey-bee, and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.

Langstroth on the Hive and Honey Bee—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage as a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bterson Theory 1—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Pudding, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof. G. S. Essay, which is here given in full. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instruction in the raising of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how. Illustrated with 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous deleterious adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and deals all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gliders, Metal and Wood Workers of every kind. This work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Ornamentation of School Grounds.

We notice the evident tendency of the times to tastefully plant flowering plants and trees on the grounds of the school-houses. This has been too long neglected, but we hope it will now become the rule instead of the exception. This will, in a measure, educate the coming generation to beautify their surroundings, to plant trees for shade, flowers for beauty and shrubs for ornament. This will help the bees some, paying back cultivated bloom for the ruthless destruction of our forests, and the loss of the wild flora, which by civilization has been entirely destroyed. The *Farmers' Review* remarks as follows on the subject:

The ornamentation of school-house grounds by means of the tasteful planting of flowering plants and trees, is a long step towards the much wished for time when the rudiments of agriculture will be taught the children who are to become the intelligent agriculturists of the future. The practice also helps to develop a refined taste, a love of the order and beauty of nature, and gives a glimpse of what farm life may be. The Michigan Horticultural Society was the first to lead off in this good work, and its efforts were crowned with notable success. It is hoped that others will follow in the same direction, as the Western New York Horticultural Society has already done.

It is pleasant to note praiseworthy emulation and rivalry of the great seedsmen in works of public utility, even if their efforts are profitable advertisements, as they deserve to be. Messrs. D. M. Ferry & Co., for several years have been supplementing the work of the Michigan Horticultural Society, in ornamenting the

school grounds of that state. Now Mr. James Vick makes the liberal offer to send free, a collection of 12 varieties of seeds "to five districts in each county in every State that shall first apply for them," for cultivation in the school grounds. And Mr. Hiram Sibley has sent \$5,000 worth of seeds to the sufferers from the Mississippi floods. This is a way of "casting bread upon the waters," that is sure to return a many-fold recompense.

Scarcity of Beeswax.—The *Juvenile Gleanings*, which has doubled its size for May, says on the beeswax question: "There is now a prospect before us that the wax of the world will not nearly supply the demand for foundation... I should not be surprised if foundation should be up 10 cents per pound before the 1st of June. Of course no one can hold to present prices, unless they can get wax."

The Caledonian Apiarian Society will hold its "ninth grand show of bees, hives and honey," at Glasgow, Scotland, July 24-27, 1882. Cash Premiums, Silver and Bronze Medals and Diplomas will be awarded. We can send an entry blank to any one wishing to send apiarian exhibits. Foreign exhibits are entered free. Mr. R. J. Bennett, Glasgow, is the Secretary.

The late Mr. James Vick, of Rochester, N. Y., whose sudden death we noticed on page 333 of last week, was an Englishman and a playmate of Charles Dickens, and had also been a fellow typo of Horace Greeley, on the *Knickerbocker*. During the grasshopper troubles in Kansas he sent the sufferers \$20,000 worth of seed and \$10,000 to the Michigan sufferers.

The bee, although somewhat of a rover, thinks its first duty is to hum.

Another Case of "Glucose Meal."

From the Elgin, Ill., *Advocate* of May 6th, we clip this extract, giving another instance of injury and loss resulting from feeding the refuse of glucose factories to cows kept for dairying purposes:

This week Henry Waterman, who operates a creamery at Bartlett, and who is well known on the Board of Trade—informed us that he had recently sustained quite a loss on cheese, and was unable to account for it until he received the following letter from Charles D. Wells, of Chicago, who handled his cheese. Mr. Wells says: "Your cheese have arrived, and, on examination, I find they are such a poor lot as to be almost unsalable. They have the appearance of being finely made, but on inserting the tryer in the cheese, the plug comes out porous and gritty, and on holding them any length of time seem to rot and get bad. There is something in the milk, in my judgment, that causes these conditions. The cows are fed on something that is sweet, or foreign to their customary feed. The cheese seem precisely like a certain factory, the cheese of which I handled last year, which rotted down in thirty days, causing a loss to me after I had sold them. Some of my customers refused to pay at all. After investigation I found that the cows had been fed on glucose, which invariably produces this kind of cheese." Mr. Waterman, upon receipt of this letter, made investigation, and learned that a number of his patrons had been feeding glucose meal for the past few months. Factorymen of this section should stipulate with their patrons not to feed this meal, as it invariably results in a great loss. In Ohio, where glucose factories are quite numerous, the cheese factorymen receive the milk from cows fed on glucose meal, or refuse, and their example should be followed here. It is not fit for cows, and spoils the milk for food, butter or cheese.

"Rotted down in thirty days!" and yet the philanthropic manufacturers of glucose claim to be the especial benefactors of the farmers and dairymen, because they stimulate the market for corn, and afford a cheap feed for dairy cows; so, too, should they claim to be humanitarians, because of the employment they give the doctors, and for their premature contributions to the undertakers. Prof. Nichols, in his able article published by us last week, says glucose "is not a poison when well made, and, as regards its healthfulness, it may not be much more deleterious than ordinary cane sugar; still, it *does* produce and aggravate dyspeptic symptoms, and by its proneness to set up fermentative processes, its use causes flatu-

lency and painful affections of the bowels."

But with an unscrupulous class of manufacturers whose association holds its sessions with closed doors, and whose commodity is used mostly for fraudulent purposes, what likelihood exists that their wretched stuff is even "well made," or that they are any more honest than they expect their patrons to be? And even when well made, Professor Nichols says it produces the grievous complaints enumerated above. When cheese will "rot down in thirty days," caused by the infusion of the glucose poison into only a portion of the milk used in its manufacture, can it be wondered at that the horrid stuff soon rots the very timbers in the railway car which transports the meal, and that railroad managers issue orders to thoroughly scrub the car as soon as emptied?

If glucosed cheese will "rot down in thirty days," what must be the effect of glucose on the urinary organs and lacteal secretions of humanity? Can it be doubted that the effect is even more pernicious on the blood, lungs and heart, than on the bowels? One-half the evils resulting from the use of glucose have never been enumerated. As remarked by Dr. Kellogg, of Michigan, it enters into many complications which develop into well defined complaints, and are frequently attributed to other causes. We doubt not many chronic complaints, which have been fearfully on the increase of late, can be indirectly traced to glucose; and posterity will more largely pay the penalty. The *stuff* should be manufactured and sold under penalties and restrictions only, as is corn whisky and other poisons. The evils attending its manufacture and sale more than overbalance the good, and, therefore, it is a curse. The National Board of Health has a great work before it—but one which it must undertake, and the sooner they realize its magnitude, the easier will be the struggle. Meantime, let all honest producers, whether of honey, butter or cheese, or anything else of food, lend their influence against adulterations wherever found.

☞ During almost all of last week the weather was quite unfavorable in nearly all the Central and Northern States for building up weak colonies. Queen-breeders have also been much embarrassed, the weather being too variable for developing good queens.

Honey versus Glucose.

Mr. M. C. Stevens, Lafayette, Ind., sends the following semi-critical article. The expression to which he takes exception is an old aphorism, and was given as such. We do not know any who have been so foolish as to claim the same sweetening properties for honey that cane sugar possesses, though to the taste, honey is quite its equal, and glucose is not. That honey may have been considered a luxury in former times, there is no doubt; so, too, were butter, cheese, and, in remote times, wheat flour, but are they fairly so considered now? Honey is just as surely working its way into public favor, and it remains only for the combined wisdom of the bee-keepers to make it an equal necessity with consumers:

In your article in the *JOURNAL* for February 1, on "Methods for Granulating Glucose" you close with these words: "And finally, when our cane sweets shall have been exiled from our markets, the enterprising bee-keeper will have a market at his door for what (honey) he can spare from the neighborhood demand, because there will still be consumers in abundance for natural sweets—and what can be sweeter than honey?"

This question was propounded many years ago and ought to be a strong argument that honey is the sweetest substance known. It might have been so in Samson's day, but I think if you sweeten your cup of coffee with the same weight of honey as you do of cane sugar, you will discover a great difference in the taste. If I am not mistaken, there is not much more sweetening property to honey than there is in grape sugar or glucose. In fact, according to the most careful analysis, about 73 per cent. of honey is glucose, or, speaking more accurately, a mixture of levo-glucose and dextro-glucose, (36.45 per cent. of the former and 36.57 per cent. of the latter). Of the remaining 27 per cent. 18.5 per cent. is water. According to my information, it takes two and a half pounds of glucose to be equivalent to one pound of cane sugar in sweetening effect; and I am quite sure there is no more sweet, if as much, in honey as in glucose.

While I am a bee-keeper, and am a believer in honey, and have no patience with adulterations of any kind, and think they should be stamped out by appropriate legislation, still I think the consumers of it should understand that it is a luxury, and they should not be kept in ignorance of this fact. To sell a pound of honey to a man for twenty cents, and at the same time make him think he is getting the worth of his money in sweetening value as compared with cane sugar at ten cents a pound, is just as truly a swindle as to sell glucose for cane sugar. Let us not, in trying to steer clear of Scylla run upon Charybdis.

I will say in conclusion that I have never yet bought a pound of glucose, except I have done it in buying adulterated cane sugar, or in adulterated syrup, purporting to be pure sugar, home drip, or some such name. Let us continue to make every effort to have the bees put up their honey in an attractive form, seeing to it that they have ample pasturage of white and red clover to work upon as a main reliance, and that every thing about the apiary is kept neat and clean, and that the honey is taken off before the bees soil it by crawling over it with their dirty feet, and my word for it, there will be a demand for all the honey we can get at remunerative prices, although it is clearly understood that it is an article of luxury.

MISCELLANEOUS.

Bees Wintered in a Greenhouse.—Mr. A. Pettigrew, in the *London Horticultural Journal*, remarks as follows:

Can bees be wintered in a greenhouse with the doors of their hives open? Yes; we have kept weak colonies in a greenhouse during the winter and spring months. Many American apiarists winter their colonies in dark cellars, but there the bees have no light and never leave their hives to fly about. At Sale I placed colonies in a greenhouse with a span-roof, 60 feet long and 12 feet wide, and there let them fly as much as they liked. On the first day or two of their confinement, many of the bees flew against the glass and became bewildered, and some were lost. The bees that flew against the glass became fatigued and rested on the sill of the greenhouse. Many of the bees on the sills gathered together in clusters, when they were carefully picked or swept up and carried to their hives. In a few days the bees became accustomed to their confinement, and flew backwards and forwards in the greenhouse without attempting to fly against the glass. In placing bees under glass a little care and attention are necessary for a few days. By placing a dish of broken honeycomb near the doors of the hives the bees smelt the honey on coming out, and many of them commenced to carry it into their hives. By removing the honey to a greater distance the bees soon become acquainted with their new home and its immediate surroundings. When bees are in a greenhouse they seldom leave their hives till the thermometer rises to about 50°. When the mercury ranges between 50° and 60° the bees find every flower, and delight to work upon Chinese primroses. The gardener at Worsley Hall 10 or 15 years ago

placed a colony every season in his early peach house, and valued the services of the bees there very much, for they never failed to set a good crop of fruit.

Bees Resenting an Insult.—A correspondent of the *Courier*, Boulder, Colorado, remarks thus on the subject:

Bees by nature possess the acute temperament and sensitive nerve work of the higher order of creation. So susceptible are they that the presence of a stranger is at once understood by them, and don't you forget for a moment that there are thousands of tiny eyes watching for the first break of hostilities. The native or black bee is more aggressive than the Italian, but the latter, when the warwhoop is raised among them and fully aroused, are hard to subdue, and they never forget the intruder who has grossly insulted them. Instances are known where one member of a family where bees are kept has been a perpetual target for their darts on account of some misunderstanding, and the other members were allowed the freedom of the apiary unmolested. Bees think a great deal of their liberty, and cannot be forced. They must be handled with tact and average intelligence, so as not to interfere with their business, for, when angered, they are as persistent in revenge, as when distilling the rarest bloom.

Artificial Comb Honey.—Speaking of this foolish but oft-repeated story concerning artificial comb made of paraffine and filled with glucose, the *California Apiculturist* says:

"Never can human ingenuity fix up honey in such shape that it will closely or otherwise resemble the product of the honey bee. Why, the presumption is preposterous, and we shall dismiss the subject with all the contempt imaginable for the originator of the hoax, who has been seeking to injure the bee-keeping industry."

Oleomargarine.—The *Planters' Journal* makes the following observations:

The fight made in St. Louis by the regular butter dealers against the oleomargarine venders is waxing warm. A private detective of ex-Chief-of-Police McDonough's agency, has been investigating the manufacture of butter sold in that city, and, according to a report made by him, a good deal of the butter consumed in St. Louis is made from the carcasses of dead animals picked up off the streets by the dead animal contractor. According to his story, dead animals are bought in East St. Louis of the dead animal contractor; they are cut up, the fat separated, cleansed by a chemical process, the oleomargarine extracted, colored, packed, and sent to some point down the river. There it is marked "Goshen butter," and shipped

back to St. Louis dealers. The detective bought a firkin of this "Goshen butter" from the manufacturer, and under Governor Johnson's instruction carried it to a chemist, and the analysis shows conclusively that the alleged butter is made from animal fat. The sale or manufacture of oleomargarine is prohibited by the laws of this State but no arrests have been made.

Madeira Wine from Honey.—The following process is translated by *New Remedies from the Pharm. Handelsblatt*, and is given by a renovated authority on bee-culture, who pronounces the product as exactly similar to Madeira, and to be a royal beverage:

Mix 25 pounds of honey in a bright copper boiler, with 50 quarts of soft water, boil gently and skim. After half an hour add gradually 3 pounds of finely powdered chalk, under constant stirring. A tough mass will rise to the top, which is to be skimmed off, and when no more of it makes its appearance, the liquid is poured into a wooden vessel, where it is allowed to cool and settle. The liquid is then poured off from the sediment (chalk), transferred to the boiler, mixed with 6 pounds of finely-powdered, well-burnt charcoal, and boiled gently for 2 hours. It is then transferred again to the wooden vessel (which has been cleaned) allowed to cool, and filtered through a bag of felt or flannel. The liquid is again put into the boiler and heated to boiling. The white of 25 eggs having been beaten to a foam with water, is now gradually added. The coagulation of the albumen envelops the residuary fine particles of coal and other impurities which rise to the top, whence it is skimmed off. The chalk removes the acidity and the charcoal destroys the waxy taste. After the albumen has been removed, the liquid is kept gently boiling for a short time, then allowed to cool, and poured into a small cask, which must be filled so that a small empty space remains below the bung-hole. This is covered with a piece of clean linen and the cask left to itself until fermentation has set in. The liquid is then clarified in the cask in the usual manner, and filled in bottles. It keeps well for over 50 years. The cellar should be cool, having a temperature of 39 to 40 degrees F., and the bottles should be kept buried in moist sand. —*Scientific News*.

For Ornament and Honey.—The *Rural New Yorker* observes as follows:

There are some apiarists who, in setting out plants for bee pasturage, would like something ornamental as well as useful. This they will find in the Cordate *Bocconia* (*B. Cordata*) a hardy species from China, bearing large panicles of small, white or pale rose-colored flowers. Two other species, *B. Japonica* and *B. Phacelia*, are also good honey plants.

Winter Ventilation.—Herr Hilbert, at the Austro-German Congress, proposed to discuss the following question: "Is the normal wintering of bees viewed from the present standpoint of Apistic Science still worthy the name of a masterpiece on the part of the bee-culturist, and what points are necessary to successful wintering?" He gave his views in about the following language:

Thus far wintering has always been considered a sort of a masterpiece on the part of the bee-culturist. This very important question has already been sharply discussed and explained. The present treatment of it is to embrace only the strictly practical part of the question, and divide it into two portions: the preparation for wintering and the wintering itself. The preparation necessary to success in wintering must embrace attention to the following seven points: Construction of the hive; strength of the colony, with age of the bees; age and vigor of the queen; peculiarities of the race; quantity and quality of the stores for food; the proper completion of the preparation for winter at the right time, and, lastly, the location of the hives.

That a great deal depends upon the proper construction of the hive, every one will certainly admit. We have a great variety of quite suitable beehives, yet not every form is adapted to each locality and each climate. A hive is good to winter in when the brood chamber (the proper winter nest of the bees) retains the heat well, so that no frost can accumulate on the inner surface or on the combs. Second, the winter nest must be roomy enough so that it can accommodate sufficient winter stores and so constructed that the bees can easily reach these stores. How many colonies starve with full combs? I put little stress upon the position of the entrance; my preference, however, is for a hive which has an entrance at the bottom and also one above the middle of the brood room, that is, the winter nest. Suitable ventilation is an important consideration. In this direction Baron Berlepsch has caused much misfortune; he attached not the least importance to ventilation, indeed he even advised the careful filling up of every little crevice. Since I have arranged for proper ventilation I winter with scarcely any loss.

Only colonies with a large proportion of young bees are to be wintered. No race contracts its brood-space as early as does the Italian. We must therefore look to hybridizing. In order to obtain young bees, liberal speculative feeding is to be recommended for the autumn. Old queens always limit their laying earlier than young ones. The removal, then, of all old and failing queens must be attended to. Now we come to the quantity and quality of honey. If possible, no colony is to be put up for winter with less than 20 pounds of honey. A colony would indeed come through the winter with 15 pounds,

but since the spring weather cannot be foretold, it is always better to supply pounds. Unsealed honey is to be avoided as much as possible, likewise one should guard against old, crystallized honey; rape honey, especially, has a disposition to crystallize quickly. If such honey be found it is best to take it out, melt it up, and feed it back, yet this proceeding must take place early enough to give the bees time to seal over the honey.

As the last point to consider: the location of the hives. In order to keep the bees in their winter rest, all disturbing influences, as drafts of air, very warm sunshine, birds, mice, the rattle of wagons, and all other noises, should be kept from them. Besides, the bee-keeper must not disturb the bees for the purpose of finding out what his pets are doing. A light, continued buzzing betokens that everything is right, a sharp tone indicates a lack of warmth, discontent, too great warmth, need of air or water, while a moaning sound tells of queenlessness.

He who carefully observes all the stated points will winter his bees well. This much is settled; the whole of wintering is no master-piece.

Behind the Times.—The *Home and Science Gossip* says:

Keeping bees in the old box hive is entirely out of date, and the sooner it is abandoned the better. The difficulty with it is that you cannot regulate the internal economy of a colony, but must leave the bees to do pretty much as they please. Bees need management, the same as cattle, poultry, sheep, hogs, or any other kind of farm stock.

Bee Management.—The *Indiana Farmer* gives the following as its views on this subject:

While it is true, careful management will cure nearly all cross bees, it is also a fact that careless handling will make the most gentle colony vicious and cross. It is a part of the nature of bees to gorge themselves with honey when alarmed, and while in this condition they rarely sting without some great aggravation. During the honey harvest the bees are more or less filled with honey all the time, consequently they are less liable to sting at this season of the year. We seldom use smoke on the bees without first testing their temper, by raising one corner of the cloth covering the frames. We may go through the entire apiary examining every colony without having to resort to the use of smoke. Still, it is best to have the smoker going and setting handy, so as to have it, should the occasion occur for its use by the dropping of a frame or the mashing of bees by careless handling of them.

With the use of the many improvements in bee-keeping in both knowledge and implements, the success of the bee-keeper to-day depends alone on that over which he has no control, viz., atmospheric conditions. With

our knowledge of their wants and nature, assisted by the movable frames, we are able to build them up into strong colonies. With the use of foundation, we can give them material for combs, without taking the time, or stores gathered for its construction. With the use of the extractor we can empty their combs without damage, to be replaced and refilled. And we believe, by judicious planting, we will soon be able to produce a flora which will not entirely fail, let the weather, atmospheric conditions, be what they may.

Curious Statistics.—The *Boston Commercial Bulletin* gives the following:

There are few persons who have any idea of the immense agricultural and horticultural services rendered by bees; but a calculation just made by Rev. M. Sauppe, a great bee master, of Zuckendorf, Saxony, goes far to prove the utility and importance of bee-culture. His calculation is that, out of each of the 17,000 hives to be met in Saxony, 10,000 bees fly per day—equal to 170,000,000—each bee four times, equal to 680,000,000 of flights, or in 100 days equal to 68,000,000,000. Each bee before flying homewards visits 50 flowers, therefore the whole assemblage has visited no less than 3,400,000,000,000 of flowers. If out of ten only one flower has become fertilized, 340,000,000,000 of fertilized flowers would be the result. Supposing the value of the fertilization of 5,000 flowers to be only a German pfennig (one-tenth of a penny), the united bees of Saxony have earned, per annum, the sum of 68,000,000 pfennigs—680,000 marks, or about \$170,000. Thus each hive is calculated to do a national service to the value of \$10 per annum, and this they do while paying more than the expenses of their keeping by the honey they gather. Upon these figures M. Sauppe recommends that more bees should be reared and kept in Saxony, but his recommendation will do for this country as well.

☞ The Chinaman's version of "how doth the little busy bee improve each shining hour," is amusing. His teacher in the mission school gave him for his lesson that verse, repeated it to him, and he promised to remember it until the next Sabbath. When he came again, in response to her request, he rendered it in this wise:

"How see hlm beley [very] small sting bug
Go huntly sweet sting bug juice,
Sixty minutes all the day, all kinds places,
Lound [around] flowers just got bused."

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

CORRESPONDENCE

For the American Bee Journal

Rearing Good Queens.

E. A. THOMAS.

Probably there is no more important subject pertaining to bee-culture than this, as the prosperity and strength of a colony depends entirely upon its queen; if she be deficient in any respect, the colony must suffer in consequence; if she be strong, vigorous, and in every way desirable, the colony will prove valuable, withstanding our most severe winters and producing large crops of the sweet nectar. The queen, being the parent of the entire colony, must represent all the characteristics present in any strain; therefore we must realize the necessity of a scientific investigation of certain laws which regulate the propagation of the species, and the methods by which the finest and most perfect queens may be reared. A discussion of the laws which guide the scientific breeder in developing the most desirable qualities in a strain of bees will hardly be interesting to the large mass of bee-keepers and will be foreign to the intention of the present article. I will therefore pass on to the methods to be employed, and the conditions requisite to produce the most perfect queens possessing all the most desirable qualities.

But before proceeding further, I wish to impress upon the minds of all the fact that it requires hard labor, skill and perseverance to rear valuable queens, and those who do not appreciate this fact will have but poor success I am afraid. Queens reared in a shiftless manner without regard for, or knowledge of the laws and methods of correct breeding, are not worth the postage required to forward them to the purchaser. I give below a few ideas on queen-rearing, which may assist you in rearing your own or in selecting the best queen to purchase.

1. I have proved to my own satisfaction, at least, that queens reared from the egg are far superior in every way shape and manner to those reared from old larvæ. I have sufficiently demonstrated this to warrant me in setting it down as a fact and not as an affirmation or supposition. I have many times been called upon to investigate the condition of apiaries for the purpose of determining if possible why they proved unprofitable. In many instances I could find no defect in the management or pasturage, and seemingly no reason why there should be a short honey crop; but upon inquiring as to the method by which the queens were reared, I almost invariably found that they were reared, as far as known, from old larvæ, and in the absence of any other assignable cause, I fixed upon that as the reason, or one of the rea-

sons why the bees were deficient in those qualities which ensure a good honey crop and success to the apiarist. I could cite many cases which I am cognizant of, where the weakness of the bees was attributable, in part at least, to this cause. The bees, in a state of nature, rear their queens from the egg, a fact which proves in itself that this is the preferable way. I believe the closer we follow nature in such matters the less liable we shall be to err. I am so fully persuaded of the importance of this point that I shall take the necessary pains to rear all queens from the egg and will tolerate no other.

2. Plenty of honey in the hive I have found to be an essential condition. A half starved colony will not have ambition enough to properly develop the cells. It has been my experience that, in order to secure the best developed cells, it is necessary to stimulate the colony in every way possible. To satisfy myself in regard to this point, I deprived a colony of nearly all its honey and let it rear a batch of queen cells. Their appearance was so unsatisfactory that I destroyed every one at once. I then gave the stock an abundance of honey and fed them regularly, letting them rear another batch. The result was surprising, the cells were large and well formed and hatched out fine queens. I therefore feel justified in saying that, in order to procure the finest developed cells, the colony must contain plenty of honey and be stimulated by every means at the command of the apiarist.

3. Queens reared in full colonies are, without doubt, the finest and most perfect. This would seem to be a self evident truth, as only in a full colony are all the conditions most favorable for the proper development of a valuable queen. Such queens are expensive to raise, and must be sold for a high price to make the breeder good, but I am inclined to believe that they are the cheapest for the buyer in the end.

As it is impossible to rear them all in full colonies, the breeder is obliged to resort to the nucleus system. It should be his aim to make all the conditions as favorable as possible; in other words he should endeavor to come as near "full colonies" as he can. To do this the nuclei should be kept as strong as possible, the stronger the better; the cells should be reared in full, strong colonies, and only transferred to the nuclei a few hours before the queens are ready to emerge. This requires watchfulness and care on the part of the breeder, and a considerable experience to tell just when the cells are ready to hatch.

In summing up I would say that too much care and skill cannot be exercised; too much time and money cannot be expended in the rearing of good queens, and, whatever the price they may be sold for, no breeder should allow a queen to drop into Uncle Sam's mail bag that he would not be willing to use himself.

It is only when customers demand the very best stock, be the price what it may, and breeders conscientiously

supply such demand, that we may hope for a permanent improvement of the American bees. We can all readily understand how a few queens purchased and introduced into an apiary may either improve or deteriorate the whole, as they may be good or poor. I cannot but believe that all who appreciate this fact will give this subject their careful consideration and only purchase the best stock, which is as essential for the production of good honey crops as improved hives or methods of manipulation.

Colerain, Mass.

New York Tribune.

The Glucose-Honey Question.

PROF. A. J. COOK.

There is much significance in the fact that the glucose makers in convention in Chicago sat with closed doors. Secret sessions and consultations held in darkness comport well with this whole glucose business. It well becomes men to hide their counsels when their very business can only succeed as it is nourished by fraud and deception. As the glucose industries of the country only thrive as the result of the most dishonest practices, it seems a pity that they cannot be throttled, and the manufacture of glucose counted among the lost arts. It is said that all our sugars, with the exception of the granulated, are largely composed of this artificial glucose. Reputable authority asserts the same to be true of nearly all of our table syrups; and much of the so-called honey on the markets is largely composed of this same grape sugar. Yet no sign of these wicked frauds is to be seen on the labels. If not pronounced pure, the purchaser is left to infer that such is the case. This state of things is a disgrace to our civilization, and should be denounced as base and corrupting by every honest man. Laws, State and National, should be enacted and enforced, so that all who practice these adulterations and thus sell articles under a false trade mark, should receive condign punishment. All intelligent and right thinking bee-keepers see in honey adulterations a serious foe to the success of their business. They all feel and know that such men as Perrine and the Thurbers have done more to injure bee-keeping by their wholesale adulteration of honey a thousand times over than they have done to benefit it by their energy and effort to push our honey upon the markets of the world. True, they have taken our product, but they have done their best to blast its good name.

Without doubt nearly, if not all of this honey adulteration is the work of the middle men. It requires skill, and is much more easy and profitable to the extensive dealer. In the great houses of our large cities is where the villainous work is done. I do not believe that bee-keepers have engaged in it at all. If they have done so, it surely has been exceptional. Even

to feed the bees glucose for exclusive brood-rearing is of slight advantage and doubtful propriety, and can in no way make up for the suspicion that will surely rest on bee-keepers if they deal in this weapon of the evil one for whatsoever purpose, even though the special use might be entirely right and proper. It is a matter for congratulation that all our bee journals are now united in opposition to all use of glucose in the apiary or by apiarists. This is most wise and politic. Our National and State societies of bee-keepers have worked most earnestly not only to create a right public sentiment, but to secure legislation to aid in putting down this dishonest and corrupt practice of adulteration. The Michigan Association took the initiative and exerted all possible influence to secure the excellent law passed by the last Legislature, looking to the suppression of this adulteration, and the traffic in adulterated articles. Many of our bee-keepers have written, spoken and circulated petitions for years at no small expense of time and money, to the end that this nefarious work might be put down. Bee-keepers everywhere in our country are tremendously in earnest in this matter, and are urging upon the press and the people to cry out against adulteration, not only on moral grounds but from a practical standpoint, and it might be added from a sanitary consideration as well. It is greatly to be hoped that they will be aided by others, that public opinion may become so enlightened that the entire public shall become incensed at these monstrous frauds and shall arise in their might to stay the evil.

It is a well known fact that most kinds of honey will granulate or crystallize whenever the temperature is reduced below freezing, or even a higher degree than 32° F. A few kinds of honey, like that from the famous white sage of California, will not granulate, but this is so exceptional that the candying test, as so often urged by Mr. Dadant, is a pretty sure one, and is by far the most practical one that has been suggested. Honey that as winter approaches becomes solid, may be considered as pure.

If it remains fluid it may well be regarded as suspicious. It is stated that the Thurburs first used glucose to preserve the fluid condition of the honey, as granulated honey was objected to by their customers. Of course they were not slow to appreciate the further gain of selling glucose at double its market value. Dr. Dadant then is right in urging people to purchase only granulated honey, unless they purchase comb. Extracted honey if granulated may be easily reliquefied by setting the vessel containing it into hot water, that is not more than 180° F. for an hour or more. Caution is required that the vessel containing the honey shall be entirely surrounded by water, so that the honey shall not be over heated at the bottom of the vessel. In this way candied honey is reliquefied without loss of flavor or quality. If after re-

ducing it it is kept in a warm place, it will not solidify again.

As already stated, the adulteration is done by the dealers. Once started, as suggested above, the excessive gains to the wholesale dealer secured its continuance until the sharp detectives over the sea brought the iniquitous practice to light. Yet the evil is by no means abated by the dealers. Hence another way to detect the pure from the spurious. If honey is offered for sale in a neat glass jar, with the trade mark of a New York or Chicago dealer, it may well be tested, especially if it shows no tendency to granulate upon exposure to the cold. On the other hand, if in tin pails or common fruit cans or jelly cups, with the name of a producer on the vessel, it may be regarded safely as honey. This will readily granulate, and very likely will be solid when purchased. This should be considered as a recommendation and not as an objection. It has been asserted of late that certain firms in Boston and New Jersey manufacture comb honey; that by use of delicate machinery the comb is made and afterward filled with glucose. It occurs to me that a person to give credence to such tales must know little of the wonderful delicacy of comb, and the exceeding attenuation of the walls to the cells, or else must be possessed of an amazing degree of credulity. To be sure, in these days of telephones we may believe almost anything possible; but I do not hesitate to say that the day of the manufacture of comb honey is not yet.

Bee Stings—Blacks vs. Italians.

T. C. G.

I am but a novice in bee-culture, and do not pretend competency to instruct my brethren of the craft. Like all others, I was once a beginner, and have gone on until by some experience and many blunders, I am beginning to know enough of bee management to make it a matter of interest and much pleasure to me.

I see occasionally an article about bee stings, that great terror of the uninitiated; I see, also, that occasionally some old bee men manifest a little dread of these daggers given our little pets for defense of "vested rights." Having discovered a prompt and efficient remedy, I present it for trial. If applied immediately, the pain quickly subsides and no swelling follows. I have never known it to fail. It is also a remedy for the poison of all insects, and even of serpents. It is simply saltpetre. Make a strong solution, upon being stung wet the place well with it immediately, and keep it so a moment or two and the work is done.

I have only 35 colonies, mostly blacks, which at this time are doing well. The honey flow at this time is grand indeed, if it will just last long enough. From a colony of blacks,

transferred from a box gum in March last, and which built out upon foundation all the combs for the upper story of an eight-frame Langstroth hive, I have extracted to date a fraction over 78 pounds of first-class honey, from the upper story alone. I do not know that this is at all extraordinary, except with beginners.

I notice an old complaint among bee men, that all colonies do not prosper alike. Some are flush with bees and honey, and others far behind them. Some time since I noticed one of my colonies in this condition. I could see no good cause for this. Wishing to Italianize a certain colony of blacks, I deprived them of their queen, and put her in this lazy colony. In a very short time the bees seemed to wake up and go to work all right, and it soon became one of the best I have. Hence, I have concluded from this and other experiments in the same direction, that when we have a backward colony and no cause being visible, clip their queen's head, and give them a good one. A change will soon be apparent.

I am using section boxes for the first time. I placed, about 10 days since, a set of sections in a hive and looked for several days anxiously, for a beginning of work in them. The bees, however, "could not see it." They did not seem inclined to go up into the sections at all, even for a promenade. I removed the sections to another hive; here the result was the same. I was puzzled; thought I had fixed things wrong. At last I concluded to have my own way just a little; so applied the smoker freely and drove the whole pack up among the sections and left them. The next day they were busy up there and have worked right ahead ever since. Since then I have placed sections on a number of other hives and smoked each colony up right off, and in every instance they have gone immediately at work in the sections. This is perhaps nothing new to old bee men, but novices like me may appreciate the fact.

I have a few colonies of Italians—gentle fellows, easy to handle, and very pretty; but so far they have not surpassed my blacks in storing honey during the present honey flow; in fact, the blacks are much in the lead. I have noticed, however, that when honey is scarce, the Italians gather more than the blacks. My curiosity was excited to look into this matter and see what caused the difference. I at once observed in scarce times that the Italians were social and friendly neighbors to my blacks. All around the apiary Madame Italian paid her respects, peeping in here and there, and occasionally effecting an entrance, and after a while coming out, with her honey sac replenished from the labor of her neighbors. As Messrs. Heddon and Archimides would say,—"Eureka." In times of scarcity, Italians rob most, at least mine do. Now if this is not peculiar to all Italians, then I have the real *Apis Americana*, and no mistake.

Planter's Journal.

The Song of the Bee.

ALBERT F. KERCHIVAL.

With dreary hum, I go and come,
Like flitting, fairy maiden;
And come and go where zephyrs blow
With flowery incense laden.

In hermit glen, from haunts of men
Afar, I seek my measure,
And revel long with beauties throng
To list my tender measure.

By fount and spring, on wayward wing,
Each flower bright pursuing,
Amid their bowers I see the flowers,
And trace them with their wooing.

With thrill of bliss bright lips I kiss,
Nor dream of faithless wronging,
And hour by hour from flower to flower,
I tell my tale of longing.

O'er hill and lawn, from rosey dawn,
Till sunset's lances quiver,
I flit and sing and sip and eling
Live lover fond forever.

And all day long with careless song
I drift o'er flowery meadows,
And sing and dream, and dash and gleam,
Till fall the twilight shadows.

For the American Bee Journal.

Mr. Heddon's Reply.

WM. F. CLARKE.

I am at a loss for language sufficiently expressive of the entire satisfaction, high admiration, and sincere pleasure with which I read Mr. Heddon's "Reply to Mr. Clarke" in the BEE JOURNAL, of May 17th. He has fairly "won the cake" by the manly, and may I add, Christian way in which he has answered me. His article leaves nothing to be desired on my part, except the visit he so kindly invites me to pay him, and, believing that it is not a mere formal invitation, I promise him that I shall certainly "drop in" upon him, so soon as time and money can be spared for the trip. Still somewhat critical and sceptical on points not fully demonstrated to my obtuse mind, I have a lingering doubt whether he will be able to convince me that his stomach is "not even bacterious." For, do not physiologists maintain that there are bacteria in every human stomach? I "speaks" there are some both in his and mine.

A duty of explanation is thrown upon me in regard to some points touched upon in Mr. Heddon's courteous rejoinder. First, as to the pollen theory. Yes, I have read statements in the BEE JOURNAL, and other apicultural periodicals, indicating that pollen is a source of trouble in wintering bees. The private letters referred to I have not seen, of course I freely admit that, under certain circumstances, bees may eat too much of it, just as human beings may eat too much of so wholesome a food as bread. If I partake too freely of fine flour bread and hot biscuit, of both which I am very fond, the result is a disordered stomach. But am I, on this account, to be wholly deprived of these articles of food? Must I have the staff of life taken away altogether because I sometimes lean on it too much? In like manner, I do not think we should clear our hives of pollen, but rather surround our bees

with such conditions, that they will follow their natural instinct and take pollen, only in such proportion as will be healthful. For, I cannot but think that in a thoroughly normal state of things, even adult bees consume some pollen. "Who shall decide when doctors disagree?" While Mr. Heddon and other high authorities, whose opinions I respect, take the anti-pollen ground, there are those, equally deserving of deference, who hold an opposite view. For example, Mr. Gallup, than whom, perhaps, there is not a more experienced bee-keeper on this continent, has this "touch on pollen" in the last number of *Gleanings*: "Your old colony, with 'lots and slathers' of pollen, would winter the best; your new colony, with new comb and but very little pollen, are the worst to winter every time." In transferring colonies from old box hives I never found one that was in prime condition in all respects, but it had "lots and slathers" of pollen in it. Mr. Heddon has had more experience in this line than I have, and will, I am sure, bear the same testimony. He will say, perhaps, that the bees being in first class condition, let the pollen alone, hence the quantity found in these hives. I, on my part would say, if the bees are all right in other respects, there is no need to deprive them of their stores of pollen, lest they indulge in it too freely. Bees, like human beings, are sometimes led or compelled by circumstances over which they have no control, to do what they would not do were the circumstances different and more favorable. All the trouble in bee-keeping grows out of our imperfect knowledge of what is the best environment of circumstances. When we discover that, and conform to it, I fancy bee-instinct may be safely trusted to do the rest.

Let me explain very briefly on another point, that I do not "hold to the ancient custom" of convincing people "by a little screw applied to their thumbs," nor to the modern custom of making them swear by a creed of any kind. I believe in free thought, and—free speech. In the old thumb-screw days, men could think as they pleased; it was the utterance of their thought that made them obnoxious to bigots. It is so now. The thumb-screw is obsolete, but there are still modes of persecution and torture in vogue for the punishment of men who have the courage of their opinions, which are a disgrace to the age we live in. I take no stock in bigotry of any kind, whether ancient or modern. "I love, oh! how I love, THE FREE!"

Mr. Heddon rather misunderstands my meaning when he asks whether "the time has not gone by when you can satisfactorily answer a man's argument by pointing at what you think to be a hole in his coat?" I did not consider there was a hole in his coat at that spot. In fact, I thought it was a particularly sound part of the garment. He declined to believe in the absence of meridian evidence. That's right. Honesty is, and always will be, the best policy. It is better

than a mere policy, for it is grand in principle. This first, and last.

"To thy own self be true,
Thou canst not then be false to any man."

Fortunately, as I think, for me, my "labors and incomes" have been connected with both science and the supernatural. This supernatural is the key that unlocks the mysteries of science. I never expect by searching to find out God. I see the traces of his wisdom and power. He is "wonderful in counsel, excellent in working," and nowhere more so than in that marvellous microcosm, the beehive.

I am just aching to attend one or two of those family bee conventions which are daily held in the Heddon house, and hope I may have that pleasure before very long.

Listowel, Ont., May 19, 1882.

For the American Bee Journal.

Mating of Queens.

J. M. SHUCK.

The statements of Prof. Kroeh, on page 311, 1882, of the BEE JOURNAL, will appear to many like a new necklace of old beads, and it is not often that anything seen in print is at variance with this old statement of facts, so called.

In 1879 I had two wingless queens that produced workers, and drone progeny in satisfactory proportions and numbers. In 1880 I clipped four queens just as they emerged from the cells, and confined the nuclei fifteen days; two produced workers and drones, and two were lost. In 1881 I clipped six queens, as in 1880, four of which matured into satisfactory queens and two were found dead.

I have witnessed laying queens leaving the hive for a flight unattended by a swarm, many times, and think it natural and proper that they should do so, for if the flight of queens be entirely restrained for generations, may it not occur that while the beauty, size, and length of tongue be increased, that the power of wing be greatly diminished. Our bees must be equipped with strong, tireless wings, the queens must possess them, and in order to produce the best results, must occasionally use them, in a long, airy, rapid flight.

Des Moines, Iowa.

For the American Bee Journal.

About "Dollar" Queens.

JAMES HEDDON.

Mr. Hutchinson, the BEE JOURNAL and myself, all agree in regard to what I believe to be a fundamental principal in progressive breeding, viz: That the "best bees will have just the requisite number of stripes, whether it be one or a dozen." Mr. Hutchinson asks me if these "hybrids can be bred in-and-in, or if the strains must be kept up by continual crossings with pure races?" I answer emphatically, by breeding in-and-in.

There is in your apiary for what I know, and perhaps in some colony, the better traits which can be bred in-and-in, but if only in-and-in the United States, or the world, breed in-and-in the good traits of character, and out-and-out the converse, and success is yours.

I think it has been proven that while we are breeding in good qualities with bees, there is no danger of any sort of physical, mental, or moral degeneration, by mixing the same blood, as is sometimes markedly the case in the human family and domestic animals.

If all the meritorious traits of character were possessed by either the black or yellow race, then purity would be the word, but as such is far from the case, we must unite the two races, and breed in the good and out the bad qualities of both. That, in my judgment after experimenting on no very limited scale, is the quickest and surest road to success in procuring the "coming bee."

I do not want to get into any extended controversy on the cheap queen subject, but I do wish to give clearly my ideas and opinions in regard to it, however open to criticism they may be. It seems to me we should all agree upon this subject. I have been opposed to the cheap queen traffic; Why? Because the price is down to such a low point that it not only tempts, but almost forces the breeder to cut too many corners to produce the best stock.

I have advertised a little, and sold a few queens of all three classes: Tested, warranted, and dollar. Now, honestly, I believe I have been the only sufferer in what dollar queen business I have done. I have not obtained a price for them that paid me for time, compared with the same time and capital put into honey producing.

With tested queens at \$2 or \$3 the case is different. The present condition of my apiary is such that the main difference between dollar and tested queens is, that I have to hold all queens till I become acquainted with the qualities of their workers and themselves, and I lose about 1 in 4 or 5 of them, that fall below my standard of excellence. Well, how do I dispose of those that are shut out—are below the test? Keep them to run down my stock? No. Sell them for dollar queens? No. What then? I destroy them, to help along the "survival of the fittest" to fill my honey barrels. Here is, you see, another tempting place in the system of general queen rearing. But I make tested queens a specialty. I rear no dollar queens. If I did, I should do as I used to, rear them just as I do any and all queens, the best I know how, sticking close to nature's laws, and ship them before tested, and make less money on them than I do now. But how about the purchaser? If he buys these cheap queens to breed from, he makes a mistake, unless he buys more than one, and then tests them himself. If he is hiring me to do his breeding for him, he is buying just what I should buy every time, if I know that the parties of whom I

purchase are competent, and conscientious.

Several years ago I had 40 colonies, and wished to Italianize them. I bought 40 warranted queens at \$2 each. I did better than to have bought an imported queen, and reared queens for myself. These queens were fertilized under far more favorable circumstances than I could command. Yes, more than 80 per cent. more favorable. I have had one colony gather more than \$80 worth of honey in one season. But as not one of these warranted queens proved impure, I was a loser in not buying dollar queens from that honest man that I dealt with. Well, he did not sell any under that name, and I had to pay out the \$80 or do worse.

But you may say you "advertise dollar queens." Yes, but my circular tells you that they are reared by another party, the gentleman who bought my Glenwood apiary one year ago; one who thinks, like Mr. Hutchinson, that he has the genius to rear them as good as they can be reared, and find a profit on them at one dollar.

The use of comb foundation, in securing all worker combs, placing the rearing of drones just where you choose in a location clear of other bees, has much to do with success in queen rearing and breeding.

Dowagiac, Mich.

Farmers' Home Journal.

A Review of the Past.

G. W. DEMAREE.

Sometimes it is not only profitable to us, but a real pleasure to look back over the rugged pathway by which we have reached the position we occupy, whatever that position may be.

These thoughts were suggested to me while making a sort of inventory of the discarded bee "fixens," that were to be seen lying around my shop and apiary the other day. There is to be seen a "bee gum" now doing service as a kind of a stand to set things on, that is a real wonder to the progressive apiarist. It was invented by your humble servant 20 years ago, and had the honor of accommodating a colony of native bees. It is a kind of a nondescript, neither a movable frame hive nor a common bee hive. It has some awful fixings on the inside, squinting considerably toward a frame hive, but it ain't. I sometimes smile when I pass by it, and ask myself why I could not have seen a little further at that time, and solved the mystery that Mr. Langstroth made so plain and simple, *i. e.*, a movable frame hive. Next comes my big clumsy honey boxes with glass sides and ends, as though I wanted iron bars between the bees, and my awkward self.

This reminds me of 20 years ago this blessed winter. At that time I wanted to purchase a few colonies of bees, and I had heard of a great bee man living on the Kentucky river. He was known far and near as a great

bee man. I fixed up my two-horse sleigh—there being plenty of snow—in which to bring home my purchase, if I succeeded in buying some bees. I reached his house late in the evening and stayed with him over night. The next morning we walked out into the back yard to see the bees, and such an array of gums and old boxes one rarely ever sees in one place. There they stood, some looking like the famous "leaning towers," and others perpendicular, but all the picture of squalid poverty and woe. The sun was coming up and casting his light over the snow-mantled hills, and I took a survey of the surroundings, and it was easy to see the key to the position. The hills and cliffs were covered with basswood (linden trees), while willow and soft maple were everywhere to be seen. The old fields furnished white clover, and the river bottoms gave a perpetual bloom. All this was what supported these bees, in spite of utter dilapidation. While I stood there, my friend discovered that I was interested in an old, old beech log, "gum," about 3 feet high, which was split open on both sides from top to bottom, and bound together with a rusty chain. Coming to my relief, he said: "That gum of bees is 30 years old." I attempted to explain by saying, "you mean that you have had bees in that log for that length of time." "I say that them bees are 30 years old!" I gave it up; he ought to know.

By the way, the other day while at the Capital, a gentleman heard me inquire of a lumber dealer for some material to make bee hives, and he at once proceeded to tell me of one of his neighbors who was a prodigy of a bee man. He keeps his bees in "gums" made so that you can see the bees through glass, and the gums have "drawers" to them, etc. Of course I could not just then take the time to explain to him that his bee friend, like the veritable "Rip Van Winkle," had been sleeping these 20 years, and if I had him in my apiary one of these warm days I could open a hive and lift out the frames, one at a time, and and point out to him the "king" (queen) as she moved gently among the bright Italians as they calmly and gently hang on to the frame, and hear him exclaim that I had turned "young America," and was going contrary to "nature."

Just think of a "king" honey bee reigning 30 years over subjects 30 years old, all the while in an old split beech log! Had I presumed to inform him that not a single worker bee that sipped the nectar from the white clover the previous season, would live to see another white clover blossom, he would have called me a "yearling," and looked upon me with pity and commiseration. I bought some bees, and left somewhat wiser in the ways of the world. If this old log, which doubtless had had the top pried off once a year, and the honey gouged out, gave 20 lbs. annually, the aggregate production of 30 years would be 600 lbs. Mr. L. C. Root, of New York, whose location could hardly be better than the one I have de-

scribed, reports that his best colony the past season gave him 483 lbs. of surplus honey. Do you see?

Christiansburg, Ky.

Bee-Keepers' Instructor.

Poor Queen, No Colony.

L. C. ROOT.

A noted horseman of the past has said, "poor foot, no horse." So may we say of bees, "poor queen, no colony." I think that all who have had experience will agree upon this point.

That we want the very best queens that can be reared will not be disputed; but many writers of the present day are proving that they do not understand the requirements for rearing such queens. I shall take strong grounds against the practice of rearing what are known as "dollar queens," not that I object to any person rearing No. 1 queens for \$1.00, but because I do not believe they can do so, and keep their stock up to the proper standard.

Keeping bees for profit is our main business, and I am arguing this question with the same interest that every bee-keeper has, who wants such bees as will gather most honey, winter best, and in fact are best for all purposes. I cannot here give my views as to the best methods of rearing queens, for lack of space, but will only say that the best methods must be continually followed up, which means more money, time and care, than the sale of dollar queens will warrant. Let me give some parallel illustrations:

We recently secured some oats of superior quality of one of the best farmers of our county. They were really fine, and much over weight. We examined them closely and found they contained a quantity of mustard seed and a portion of inferior oats. We sifted them, and from the 10 bushels saved about 6 bushels of the best. Again: Becoming interested in high-class poultry, we purchased the very best fowls we could secure, yet we find we can only hold them up to their present standard by selecting the very best birds each season.

Now, my point is, that even when we buy the very best queens we can without regard to price, this sifting process is necessary. I should not be quite so positive in this matter had I not tested it for myself, and know whereof I speak. When G. M. Doolittle proved the value of his strain of Italians by securing his large yield of honey, we should have felt ourselves to be short-sighted had we not at once procured the best queen he would sell, without regard to price. So, when P. H. Elwood obtained 586 lbs. of honey from one hive, it was proof that he had stock which we wanted. And so with W. J. Davis, Dadant & Son, Julius Hoffman and many others. We consider the introduction of such improved stock indispensable, and yet, the sifting process must be continued. We must not for a moment entertain the thought that we have yet reached the desired de-

gree of perfection, for we are a long, long way from it.

The substantial question to be asked is, how is this standard to be reached? Will the policy of rearing dollars tend in this direction? I am persuaded that it will not, no more than I think that the ruinously low prices for many of our apianian supplies—such as comb foundation, etc., are tending to purity and superiority in their line.

Thomas G. Newman strikes solid blows at this cheap queen traffic in his JOURNAL of March 8, page 125, when he says: "What the bee-keepers of America want is better stock, not cheaper queens; more honey, not lighter yields: longer-lived bees, not greater disaster; certain profits, not doubtful results." Will dollar queens lead to this end?

The April number of the *California Apiculturist* contains an article from the pen of Mr. Gallup. This is from a man of experience, and is of particular value to those living in warm climates. He says: "The genuine Italians are no humbug; neither can the moth miller humbug them." His point made is, do not breed for color unless with the light color you gain the extra qualities needed.

I am not urging these views especially to influence the experienced bee-keepers of the present time. They are capable of judging for themselves. But the mass of bee-keepers who purchase Italian queens are such as have had no experience with them, and they are looking to our journals for information in regard to the best and cheapest methods of securing them. Are they to be led to believe that they may purchase queens for \$1.00 each, expecting to begin under the most favorable conditions?

After an experience of 13 years, during the first 5 years of which I had the benefit of one of the longest and ripest experiences in America, I say emphatically that I consider the cheap queen traffic a hindrance to the best interests of profitable bee-keeping.

Mohawk, N. Y.

For the American Bee Journal.

Those Unkind Things.

HENRY ALLEY.

I was not aware that any very unkind things had been said about those who rear cheap queens. In giving a few facts about the cheap queen traffic, I did not intend to reflect on any man's reputation or business standing. In what I said I desired to be understood by all that good queens cannot be reared and sold at a paying profit for \$1 apiece. Those who rear queens and send them out in 2 or 3 days after they commence to lay, can know nothing about the worth and quality of such queens. The time to judge of the quality in respect to their prolificness is when the bees commence to seal or cap over the worker brood. If there are eggs and brood in every cell not otherwise used by the bees, or, in other words, if the combs are solid with worker brood,

put this queen down for a good one and worth \$2 to any man. If the brood is scattering, some cells with eggs, other cells with capped brood, put her down as a worthless one. Now, how can these facts be known unless queens are kept at least 14 days after they commence to lay?

I know from my long experience in rearing queens, that all queens are not good ones, and, as they are sometimes reared, a large number are worthless. I base my opinion on reports I have read in the BEE JOURNAL from time to time. I know that good queens cannot be reared in the way some of your correspondents say they rear them.

But the greatest mistake is made in making a selection for a queen to breed from. To illustrate what I mean, I will give a bit of my own experience in this matter. I usually select for a "breeder" the largest, handsomest and most prolific queen I can find, selecting one, of course, that would give me fine queens as judged by her worker progeny. One year I selected a queen that would answer the above description. Not one of the queen cells from her eggs would hatch, though they were made in full hives, and were quite large, and apparently perfect. Well, here is another case: I selected one of my most profitable queens for a queen-mother. Her daughters were very fine. They were all fertilized in due time, and all commenced to lay promptly. Those queens were sent out after laying a few days. Reports came back that they did not lay, and others reported that the eggs would not hatch. The loss to me was \$150. That is what it cost me to test that one queen. Now, you see the importance of testing queens for their laying qualities, if not for purity. Have both if we can, provided the cost is not above the reach of most bee-keepers. Sometimes I have complaints that queens sent out lay drone eggs only. About one queen in 500 will turn out just so. But this fact cannot be determined by keeping a queen 2 or 3 days. When the brood is capped over, then the fact is plainly seen. If people want cheap queens, rear them and supply them with all they want.

I will guarantee to sell queens for 50 cents each, provided the purchaser will never say one word about them to any one. How can I do that? Well, I will tell you how I can do it. I can compel a good strong colony of bees to build from 100 to 500 queen cells at one time. About 2 of the whole lot might be worth keeping, but the balance would not be worth as much as worker bees. I have often told you that the more queen cells one colony made, the poorer the queens would be, and that is just so. Unless I am more successful in the queen-rearing business this year than I have been for the last seven, I will retire from the field, and make room for those who have more money to lose than I have. If I do retire, I shall feel at liberty to say something about the secrets of queen-rearing, that is, I will tell how I can rear from one to 500 queen cells in a

full colony of bees. Now, to those who are rearing cheap queens, I wish to say that what I have said in the BEE JOURNAL was not intended to reflect on your honesty, not in the least. When I am talking about queen-rearing, I think I know what I am about. If a man can make money rearing queens for \$1, keep on rearing them. I cannot, and if I sell for that price or for a less sum, by-and-bye you can make up your minds that it is for self amusement.

137 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Western Michigan.

The Western Michigan Bee-Keepers' Association convened according to appointment in the city of Grand Rapids, April 26th and 27th, 1882. The attendance was good, considering the unfavorable time of the year. Much interest and good feeling was manifested, and the discussion as follows:

T. M. Cobb was asked to give his experience the past winter. Said, being anxious for increase the past summer, he had divided artificially, and the season being poor, they had failed to build up as he expected them to; consequently, had dwindled, and he had lost many. He would warn all to be cautious in this. Having no cellar suitable for the purpose of wintering, he had practiced packing with straw, setting the hives in rows. Had some colonies in chaff hives last winter, and should use them exclusively in the future.

The President wintered in a dry, well ventilated cellar 9 feet deep. Removed the caps from the hives (Langstroth), and slid back the board cover to leave a crack of an inch for ventilation. The winter before last, out of 60 colonies he had lost 7; 6 of these had starved. Last winter, no loss. Temperature of cellar never below 40°. Where he had found too much honey, he had extracted in August.

J. H. Robertson: Wintered in a cellar in which there was a spring of the temperature of 52°. The presence of water had a purifying effect on the atmosphere, and helped to maintain

an evenness of temperature. Used burlaps over the frames to allow moisture to pass off. Winter before last, through carelessness, had lost 8 out of 408 colonies. The past winter out of 511 had lost 2. Temperature 50° to 55°. Preferred 50° to 40°. Objected to the cost of chaff hive.

Mr. Cobb, with others, objected to the trouble of carrying out and in a cellar. He thought chaff hives better for summer as well as winter, and little more expensive, taking cellar into the account. He objected to oil cloth or board cover for winter use.

The President thought the extra expense would more than pay for a good cellar. The one he used, which would hold 350 colonies, had cost him \$50.

Mr. Robertson had built a cellar 4 feet in the ground, with earth walls 2 feet thick, rising 4 feet above the surface, to hold 390 colonies, for \$25. In answer to a question, he said he preferred well-ripened clover honey to winter bees on. Buckwheat honey, some seasons, was very nice, but he put no dependence on it. Buckwheat grown on clay produced honey inferior to that grown on sandy soil. Successful wintering depended much on the management through the season.

Mr. R. E. Kilburn addressed the Convention as follows, on

Planting for Honey.

Much has been done within the past few years toward making bee-keeping a grand success, so far as improved implements, and the careful breeding of the best strains of bees are concerned. We now have in place of the log gums "in which the working of the busy bee was a mystery not to be solved," the movable comb hive, by the use of which we are enabled to admire and profit by those very laws of nature which, before, were so mysterious, and are prompted to exclaim with the poet: "Little creatures, that by a rule in nature teach the law of order to a peopled kingdom."

And as regards the improvements of bees, we now have the beautiful Italian, Cyprian and Syrian bees, bred to such a high state of excellency that our Italian bees are declared to be fully equal, if not superior, to the native bees of Italy, so much so, that the propriety of further importing is questioned. But still, a great many of us are not satisfied, and we say bee-keeping does not pay! Now let us pause a moment and ask, why? We certainly have all we can desire in the shape of improved implements and highly bred strains of bees, and if so, there can be only one other cause of failure provided we manage properly—it is a scarcity of honey-producing plants or natural flora. And if this is the cause, what is to be done? Our forests are melting away with wonderful rapidity, and within a few years our honey harvest from forest trees, such as basswood, sugar maple, whitewood or tulip tree, will be a thing of the past; while on our prairies and river bottoms, every tract of land that is brought under cultivation, and every swamp that is

drained and made tillable, will take from the bees another portion of nature's flora, and from the apiarist a portion of his expected honey crop.

There seems to be only one great honey plant of all the natural flora, which is not injured by cultivation, but on the contrary is benefited by it, this is white clover (*Trifolium repens*). That modest little flower, from which bees usually obtain the richest and best harvest of the season. But it will not do to depend entirely on white clover, for it sometimes, by reason of unpropitious weather, refuses to surrender to the bees the rich gift of nectar expected, and as a consequence, the bees are threatened with starvation, and the bee-keeper gets discouraged and exclaims: "It don't pay," and he is probably right.

There is only one thing left for us to do, we must plant for honey. Several of our leading apiarists have recognized this fact. Mr. D. A. Jones, of Beeton, Canada, a practical apiarist, and the first importer of Syrian and Cyprian bees to America, is reported to have 20 acres of land sown entirely to sweet clover, for the benefit of his bees. Sweet clover (*Melilotus alba*), is one of the very best honey-producing plants known. The honey which it produces is considered superior to white clover. It is very hardy, will grow anywhere, and on all kinds of soil. A correspondent of the BEE JOURNAL writes that if sweet clover be sown in a bed of Canada thistles, it will ultimately destroy them.

Bee-keepers should see to it that all waste land in their vicinity, such as thistle patches, fence corners, swamps, etc., be well stocked with sweet clover or some other honey-producing plants. Borage, catnip, motherwort, mustard, etc., for instance, and they will be greatly rewarded in the extra amount of honey they will procure, and will exclaim: "Bee-keeping does pay!" Besides, there will be a great improvement in the looks of the ground where the thistles used to be. An estimate has been made that an acre of ground sown to sweet clover will support 20 colonies of bees, and afford from 500 to 1,000 lbs. of honey. "Such estimates are evidently a little large," but, nevertheless, let us all plant for honey, and see if it does not pay.

Mr. Robertson: A. I. Root was of the opinion that cultivating plants exclusively for honey would not pay. He (Robertson) was satisfied it would pay to plant the Alsike clover. The honey was the same as that from white clover. Stock preferred Alsike to red clover. In seeding, use only 2 to 4 lbs. to an acre. It did best on low ground. He found bees swarming on sweet clover last summer for the first time. Bokhara clover was the same as sweet clover or melilot, the difference being in the seed; the former being imported, and more perfectly cleaned. He was inclined to think the best plant for honey was the Simpson honey plant or figwort. It would grow on any soil.

Mr. Kilburn said Mr. Dadant had found it difficult to grow in Illinois.

Sweet clover was a favorite of his. By cutting back, its blooming could be prolonged until snow.

J. J. Robinson said last year had shown him the need of planting for honey. His fall pasture was poor. He recommended the planting of mustard. It was profitable for its seed, and cattle would eat it.

Mr. Cobb had been benefitted by the yield from bonaset last fall.

All agreed that while it does not pay to cultivate plants exclusively for honey, it would be found profitable to scatter seed by the roadsides and in waste places.

WM. M. S. DODGE, Sec.

SELECTIONS FROM OUR LETTER BOX

Wintered Well.—The BEE JOURNAL comes to hand regularly, and I like to see the able manner in which it is conducted. Long may it continue to condemn the adulteration of honey and food in any form. I see reports from all parts, some from near here; the weather has been cold nearly all the spring, with an occasional fine day to enliven up nature a little. Since the 10th the weather has been fine, with little or no frost. Last fall I told you of placing my 24 colonies in a cellar. This spring they all came out alive; 20 of them were in good condition, so I think with my little experience. They have from 6 to 9 frames filled with brood and eggs; frames 11x12 inches inside measure. Three of the others are weak in bees, brood and stores, having only from 1 to 3 frames filled with brood; the others are Italians; the queen died about 2 weeks after setting out, laying only a few eggs. The colony built two queen cells and they hatched only worker brood. 1. What was the reason? 2. Will sweet clover thrive as far north as 44° N latitude? There is a bird here that seems to eat nothing but bees. The throat and belly are all white; the top of the head and back, to look at, are black, but on opening the feathers on the head, the under feathers are a pretty orange. Some of the feathers I send with this. The bird is not so large as the robin. 3. What is it?

SAMUEL SANDERSON.

Glenallen, Ont., May 19, 1882.

[1. The larvæ was too far advanced before the cells were built and feeding of royal jelly commenced.

2. We think there is no doubt of it. It does excellently in other portions of Ontario.

3. There are two or three of our wild birds which might nearly answer your description, except that they do not eat bees that we are aware of. The better way will be to shoot one with line shot and send to some ornithologist for name and habits.—ED.]

Early Queen-Rearing.—Please name the enclosed plant for me. It is covered with bees now, but it is the first season I have ever known them to pay any attention to it; but that is probably owing to the fact that there is nothing else for them. Our apple bloom was all killed after two days' work upon it, and the locust was far enough advanced when the freeze of the 12th of April came for it to be killed. So far it has been the worst spring for bees that I have known. My bees are in fine condition owing to constant attention and feeding. If we have a good red and white clover bloom I hope yet to get a good yield, as my bees work on red clover splendidly. I sowed several acres of sweet clover last fall, but it has not come up to my satisfaction. I do not know what is the cause of it, unless it sprouted last fall (it being so mild) and the winter killed it. I gave a queenless colony eggs on the 20th of March to rear a queen from, and on the 23d of April she was laying, which I consider very early queen-rearing for this section.

R. W. KEENE, M. D.

Versailles, Ky., May 4, 1882.

[The plant is *Phacelia Purshii*, for which there is no common name. Like its relatives in the Waterleaf family, it usually grows in moist, shady places. It flowers from April to June, and secretes a considerable amount of very limpid nectar. The flower is beautiful and interesting.—T. J. BURRILL, Ill. Ind. University.]

Parthenogenesis.—Will you allow me to express my gratification that you thought well enough of my articles to insert them in your excellent BEE JOURNAL, and at the same time to define my position? At the time that I wrote the paper you have headed "The Functions of the Queen bee," I believed that the evidence adduced by Dzierzon was conclusive. The experiments of the Abbe Ulivi indicate, however, to my mind, the possibility that former observers have misinterpreted some of the facts, and I now entertain some doubts which nothing but experiment can settle. This explanation is deemed necessary, because the last article you published was written some time before the one entitled "Parthenogenesis in Bees." Hoboken, N. J. C. F. KROEHL.

Pollen not Detrimental.—Bees wintered well in this section, and are now doing well. I have already received enough benefit from reading the BEE JOURNAL to pay for it a good while. What was said about starving caused me to look mine over, and I found my best colony without honey. I wintered 8 colonies. Two of them I took out of trees in the middle of August; 1 of them I gave a little honey, and the other none. I fed both all the syrup (made from the best white sugar) they would take; both wintered without the loss of a hundred bees that I could find, but one of them lost its queen about a

month ago, and there was no brood or eggs in the hive. What I am getting at is this, I had a colony in the same kind of a hive that out-numbered either of the two I have mentioned at least four to one, and had more than 20 pounds of nice capped honey. It dwindled until two weeks ago, when there was only about 200 bees and the queen left. I put her with the swarm that had lost their queen, and she has done finely, so the trouble was not with the queen, and there was plenty of nice honey which was where the bees could get it. I think it would trouble some of the bee-keepers to tell what ailed that colony. A number of years ago I asked a man who had lost 80 colonies one winter, why he thought they died; he said he thought it was the want of bee-bread, as there was none in any of the hives, and there was plenty of honey. I don't take any stock in the pollen theory. I do not think it has anything to do with the bees dying, and I could give good reasons. T. ELLICOTT.
Fentonville, Mich., May 22, 1882.

Fastening Foundation in Sections.—Not knowing how others fastened their foundation into the section boxes I was obliged to find a way, and think I can put them in faster the way I shall describe than any way I have so far heard of. My sections were 4½x4½ and the sheets run almost 4½ inches in width, so after dividing the sheet in pieces large enough for the section, I trimmed off ¼ inch from the width; I then set my section up-side-down, and laid my foundation in far enough for it to extend ⅛ of an inch over the slot; in the meantime I had ready a lamp, with a box by its side of the same height; I had a very small table knife (such as the children use) laid on top, and when my section was ready my knife was hot (if any preferred they could use a charcoal fire, if they did not wish to use oil). I then passed the knife over the foundation about twice, which caused it to melt and go into the slot; I then laid on the ⅛ inch of foundation that I cut off, and with about 2 or 3 strokes of the knife, at the same time reaching behind and raising the foundation to a perpendicular, when it is complete. I have not yet tried it, but it might be an advantage to use a frame as described on page 309, by Mr. L. James, in the BEE JOURNAL, but I can, in the manner described, put in or fill 3 sections per minute, when the foundation is cut, and think, by a little practice, I could yet put them in much faster.

Ridgeland, Ill. W. H. BUSSEX.

Cold in Georgia.—For nearly a week we have had a "snap" of unprecedentedly cold weather for this season of the year. For several days fires were required in order to be comfortable. Such weather is very bad for queen-rearing. The season thus far has been fine and the flow abundant; the quality being much better than usual, of lighter color and better flavor. J. P. H. BROWN.

Augusta, Ga., May 18, 1882.

The Worst has Come.—We had a freezing wind the past 48 hours, and last night it went down and cleared off. This morning, at 3 o'clock the mercury marked 14° below the freezing point. The ground is frozen solid 2 inches deep. You can imagine the effect. Fruit is in full bloom; corn, peas, and beans 6 inches high; every green thing is cut down. Scores of small birds are lying dead in my orchard; several still remain on the roost cold and stiff; bees are dying fearfully, and are now worse off than on April 1st. All drones are killed, and since the 15th, full colonies have dwindled one-half. Clover has a good stand, but I do not know whether it will kill out or not. It is fully one month later than usual. I fear that nothing will be realized from bees this year. E. A. MORGAN.
Arcadia, Wis., May 22, 1882.

Various Methods.—Out of 33 packed in chaff, 5 were lost in wintering; out of 58 buried in the ground, 26 were lost; those that were lost, however, were very weak last fall. The 2 that I put in the cellar came out very strong. All my colonies now are in good condition. G. H. ADAMS.
North Nassau, N. Y., May 18, 1882.

Poorest for 30 Years.—For the benefit of our Southern friends, I will give them a little report from Minnesota. It froze last night $\frac{1}{4}$ inch; ground white with snow; bees doing poor—the worst I ever saw. Everything works wrong. From 105 I have only 60, and some of those so light I will have to unite. I have kept bees 30 years, and this is the poorest, as well as the coldest I ever saw for the time of year. M. S. SNOW.
Osakis, Minn., May 22, 1882.

Cold in New York.—Cold here all the while yet, with frost every morning. Night before last ice formed as thick as a window glass. We have not had one warm day this spring. Bees have but little brood and the show for 1882 as a good honey year is poor in this locality. G. M. DOOLITTLE.
Borodino, N. Y., May 18, 1882.

Bees in Alabama.—Bees are doing well, gathering honey from fruit bloom, tulip, etc.; they are richer in honey than at any time since 1877.

JOHN M. RYAN.

Apple Grove, Ala., May 16, 1882.

Tilia Americana in London.—I see Mr. Stathammar, of Sweden, notices a *Tilia* (page 263 of AMERICAN BEE JOURNAL), which flowers in September. I noticed some in England last year flowering in August. It was a larger leaf, and the stalk had a half bend below its junction with the leaf, which made the leaf turn its whitish under-side outwards. It had also a drooping habit, and the flowers were unusually fragrant and larger than the common lime (linden) which flowers in England in May and June. On inquiry at the Arboretum at Kew Gardens, I was told it was called *Tilia*

alba Americana. Another authority added *Pedulosa*. I planted 2 such trees last autumn, and hope this year to find I have been supplied with the right thing. H. JONAS.

London, Eng., May 12, 1882.

Death of M. Parse.—Our friend and brother, Melvin Parse, Pine Bluff, Ark., died on the 12th inst., after a very short illness, and unexpectedly. Mr. Parse was a good man and a good bee-keeper, and deserves a notice in your valuable paper.

CHAS. F. MUTH.

Cincinnati, O., May 24, 1882.

A Swarm in New Jersey.—I had a fine swarm from one of my strongest colonies to-day. It is the first swarm of the season. Bees are breeding finely now, and the weather has just now become warm and pleasant. Fruit blossoms are opening profusely. I have a number of colonies commencing in sections. JOS. H. M. COOK.

Caldwell, N. J., May 20, 1882.

The Weather in Scotland.—The weather has been very cold and changeable of late, so that our bees have had little chance of doing much yet. Throughout the country all seem to be in good order, and with some fine weather we expect a good season. Mr. Anderson, one of the Judges at the Perth Show, intends to take a tour through America this summer. He leaves here on Friday, June 2d, in the Ethiopia, for New York. I have sent you 3 copies of our prize schedule. I shall be very glad to take charge of any exhibits the American bee friends may be pleased to send, either for exhibition or competition.

JOHN D. HUTCHISON.

Glasgow, Scotland, May 13, 1882.

More Encouraged.—Warm weather appears to have set in now, and the growth of vegetation can be seen daily. We have some nice rain to-day. If the warm weather continues, the season may not be so far behind, and bees may be able to make up for lost time. EDWARD MOORE.

Barrie, Ont., May 23, 1882.

Destroying Drones.—My bees wintered well. Had drones in March, but the last month has been very hard on them, and they are killing off the drones. I am feeding to keep them alive until white clover bloom, as the heavy frosts destroyed the apple and all fruit bloom. White clover is coming on now, but the outlook for honey harvest is a little gloomy. W. H. GRAVES.

Duncan, Ill., May 23, 1882.

The Northwestern Wisconsin Bee-Keepers' Society will meet in La-Crosse, Wis., June 9, 1882, in the City Hall. A good attendance is desired, as arrangements have been made for articles from practical apiarists.

G. J. PAMMEL, Sec.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 ".....	20 " " "
" 13 " (3 months)....	30 " " "
" 26 " (6 months)....	40 " " "
" 39 " (9 months)....	50 " " "
" 52 " (1 year).....	60 " " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—	a copy of "Bees and Honey."
" " 3,—	an Emerson Binder for 1882.
" " 4,—	Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper, cloth.
" " 5,—	" " " " "
" " 6,—	Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

A Sample Copy of the Weekly BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Always Keep a Smile for Mother.—The above is the name of an elegant new song and chorus, by the popular writer, Charlie Baker, who has written some of the most popular songs in America. The words are elegant and music easy, so that every body will be able to play it. Price 35 cents per copy. Will be sent to any address in the United States, upon receipt of marked price, by addressing the publisher, F. W. Helmick, 136 West 4th St., Cincinnati, O. For sale by all music dealers.

When changing a postoffice address, mention the *old* as well as the new address.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, {
 Monday, 10 a. m., May 29, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—As the season is well advanced, sales of extracted honey are slow and prices remain unchanged. I am paying 7c. for dark and 9c. for light, cash on arrival. Good comb honey is scarce and rules high.
BEE SWAX—I am paying 24c. for good yellow wax on arrival; 18@22c. for medium grade, and 15@17c. for dark.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for extracted honey, in the retail way, is fair, and our sales for manufacturing purposes were very good of late. We pay 7@9c. on arrival. Prices for comb honey nominal and demand slow.

BEE SWAX—Brings 18@22c. The demand exceeds the offerings.

C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for honey is light, most of the trade finding fault with the best offered, as it is more or less candied. Values are not steady, prices being made to meet the views of the purchaser.

BEE SWAX—Scarce, and in demand at 23@25c.

R. A. BURNETT, 165 South Water St.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.

BEE SWAX—Prime quality, 25c.

CROCKER & BLAKE, 57 Chatham Street.

CLEVELAND.

HONEY—There are a good many small lots of very nice white section honey coming in now from time to time. White sells readily at 23c.; second quality 18@20c. Buckwheat, no sale at any price. Extracted, none in market.

BEE SWAX—25@30c.

A. C. KENDEL, 115 Ontario Street.

ST. LOUIS.

HONEY—In fair demand. Strained selling at 8@10c.; comb scarce—nominal at 18@22c.

BEE SWAX—Stiff at 21@23c. for prime.

R. C. GREER & CO., 117 N. Main Street.

NEW YORK.

HONEY—The market for honey is exceedingly dull, with not enough movement to establish prices, and quotations therefore are entirely nominal. White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.

BEE SWAX—There is a fair demand for prime lots of wax, and with the supply moderate prices are firmly sustained. Western, pure, 24@24½c.; Southern pure, 25@25½c.

D. W. QUINBY, 105 Park Place.

SAN FRANCISCO.

HONEY—A lot of 118 cases candied and crossed comb, light and dark mixed, arrived this week and was sold at 7¼c., 30 days time. A transfer of 54 cases extracted is noted, of which 27 cases light brought 8c., and the balance, dark, sold for 6¼c. We quote white comb, 13@14c.; dark to good, 7@11c. Extracted, choice to extra white, 7½@8c.; dark and candied, 6¼@6½c. **BEE SWAX**—23@25c.

STEARNS & SMITH, 423 Front Street.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$5 per 100.

Articles for publication must be written on a separate piece of paper from items of business.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

CLUBBING LIST.

We supply the Weekly *American Bee Journal* and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both All postage is prepaid by the publishers.

	Publishers' Price.	Club.

A NEW BEE BOOK! Bees & Honey

OR THE Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN, Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid. 925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.
A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.
We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.
Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.
A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.
New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.
Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.
Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.
Just such a work as should be in the hands of every beginner with bees.—News, Keittsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.
The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.
The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.
It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.
Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.
It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.
Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Loggmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.
It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.
Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.
It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

A Liberal Discount to Dealers by the Dozen or Hundred.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame. Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " 10x18 "	8 00
For 3 " " 10x18 "	10 00
For 4 " " 10x18 "	14 00
For 2 frames of any size, 13x20 "	12 00
For 3 " " 12½x20 "	12 00
For 4 " " 13x20 "	16 00

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, he conveyed to the undersigned for \$5,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,
925 West Madison Street, CHICAGO, ILL.

The Bee-Keeper's Guide;

OR,

MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the

State Agricultural College of Michigan.

—:0:—

320 Pages; 133 Fine Illustrations.

—:0:—

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

—:0:—

Read the following opinions of the Book;

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY.**

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. P. WEST.**

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**E. H. WYNKOOP.**

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL.**

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—**WM. VAN ANTWERP, N. D.**

It is the latest book on the bee, and treats of both the bee and hives, with their improvements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never met with a work either French or foreign, which I like so much.—**L'ABBE DU BOIS,** editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *trésor précieux* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as Carcharodon Roudelleii. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many successfully operation, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better. I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

To avoid loss in the mails, please send money by REGISTERED LETTER.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by THOMAS C. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide for Cook's Manual of the Apiary.—Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Dzierzon Theory;—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof. Cook's Essay, which is here given in full. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use.—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman.—Giving advanced views on this important subject, with suggestions what to plant, and when and how. Illustrated with 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees, Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered us food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Oas and Steam Fitters, Bronzers, Gliders, Metal and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Crops in General.—By correspondence from all parts of the country we learn that crops though backward, are generally in good condition. It is stated by an exchange "that the cool, wet weather has not been unfavorable for wheat, and has rendered it the conspicuous service of keeping back the fatal chinch-bug. If it has injured the corn it may have more than compensated for it by the opportunity it has afforded the young wheat of getting a good start before the chinch-bug was able to be out. But it is not yet certain that the corn has been seriously injured. It is backward; large tracts that should have been planted are not planted yet. In many localities the plant appears rather feeble. But, on the other hand, the planting can be finished very rapidly if a few warm days should be granted just at this time. Generally where the corn is up it is of good thickness, and promises, with warm, dry weather, to make ample amends for being behind time." Fruit promises well—the localities are but few where it has been injured—it has rarely promised better. As for Texas, everything there is in the finest possible condition; cereals, cotton, fruit, everything that grows out of the ground promises uncommonly well. White clover and pasture grasses are very thrifty everywhere, affording excellent grazing.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

Queen Trap.—Mr. F. Funk, Beverly, Ill., has sent us samples of his "Queen Bee Trap," which he claims to be a "sure and safe way to clip their wings without danger of injuring them." The trap consists of a small coil of turned wire, the coil being much larger at one end than the other. The large end of the cage is intended to be put down over the queen when on the comb, as she enters it the cage is to be lifted and both ends closed, then the wing can be clipped through the wire coil, without handling the queen or injuring her in any way.

The Weather in Colorado.—A letter from Denver informs us that the season there is very backward as it is in all the Northern States. The writer says:

"The weather is quite cool not being near so warm and pleasant as it was in February and March, and so much rain is unusual for Colorado; but although we in the city are generally displeased with it, the value it is to farmers can hardly be fully estimated. It will start vegetation everywhere, and make the flowers in the foothills, that yield so much pasture for bees, bloom in all their beauty and fragrance."

Col. Pearson, President of the Alsatian Bee-Keepers' Society, writes on April 6th to the *Bienen Zuechter*, published at Strassbourg, Germany, as follows: "My colonies of bees are in excellent condition. They have never been as populous as they are now. The season has not been favorable for apiculture; the few fruit trees in this vicinity are not sufficient to give the bees very much honey, at this season."

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Natural versus Forced Queens.

Mr. Edward Moore, Barrie, Ont., addresses the following pertinent letter regarding queen-rearing:

In "Cook's Manual" instructions are given for rearing queens. It appears necessary to drive the bees to the necessity of rearing queens for the purpose of increasing their numbers for traffic, for several reasons.

On page 6, of the specimen number of this year's volume sent last year, there are some apparent objections raised, which appear reasonable. Are queens reared in the way referred to as fine, large, healthy, strong, prolific, long-lived, and in every respect as good as queens reared in the natural order? Those who have had long practical experience in rearing queens should be able to tell, although it may be against the interest of some to do so. Will some one please answer for the information of the less experienced in apiculture?

There are many strong arguments adduced by the advocates of natural queen-rearing through the swarming impulse, some of which seem to us unanswerable, especially the fact that eggs are almost invariably selected by the bees from which to rear queens, when swarming is contemplated, and the further fact that the honey flow generally prevails, and the bees are most populous and prosperous when the *emette* takes place, and the most careful and deliberate provision is made for the future welfare of the parent colony. If, however, the colony be deprived of their queen, and eggs, larvæ and sealed brood prevail, the bees naturally force the maturity of a new queen by utilizing larvæ sometimes in various stages from which to rear her, as they well know that depletion must take place until a new mother is provided. In colonies of this kind, where queen-rearing is forced, it is not unusual to find queen cells, even after a week has elapsed, in various stages of development—some perhaps capped over, while others are but scarcely commenced, or with the larvæ just placed in, and the feeding of royal jelly not completed. The result is, that the larvæ 2, 3 or 4 days old from the time of hatching from the egg, are the first to emerge from the cells as queens—and the first out, although not more than two-thirds developed and wholly worthless, has vitality and vindictiveness enough to destroy the remainder. It is possible sometimes to rear good queens in this manner, but we believe they are the exception.

There is a serious objection, however, on the part of some queen-breed-

ers to the natural method of queen-rearing, as the number of cells built is not great enough to make their business profitable, and they have to await the pleasure of the bees and favorableness of the weather to procure any cells at all.

If, however, our favorite method of artificial swarming be practiced, the objectionable features of the forcing process will be overcome, and all the desirable ones of the natural swarming impulse will be obtained, while the number of cells will be limited only by the ambition and skill of the apiarist. The following is the simplest and most satisfactory manner: When the weather has become warm and settled, with honey coming in rapid enough to stimulate breeding to the fullest extent, remove a frame from the colony you wish to rear queens from, substituting therefor a frame of foundation in the center of the brood-nest; keep a close watch until it is well filled with eggs, then before any are hatched, remove from its stand, while the bees are working busiest, the strongest colony in the yard, and put an empty hive in its place; now put in the center of this the comb with fresh eggs, cutting away the lower one-third in a zig-zag shape, to afford an irregular edge on which to build the cells; if you can find a frame with all sealed brood place it alongside with all the young bees adhering to it, fill up the hive with its complement of empty combs or foundation, or at least enough to accommodate the bees, adding others as needed, cover well with blankets or cotton cloth, and put on the hive cover. By this method you will secure all the field-workers from the colony removed, and but little hinder it in general work; you will also get a liberal batch of queen-cells from your best queen mother, all maturing about the same time, and all can be left in the hive till nearly the last moment, and, we believe, all equally good as the best.

Twenty-four hours before removing the queen-cells, form your nuclei by placing a frame of brood (in any stage), a frame of honey, and an empty comb in a full-size hive, putting in a division board to contract the space and retain the heat; on the following day, cut a hole in the frame of brood comb and trim out a queen cell from the queen-breeding colony to fit it; now replace in the hive and cover well. Unless the weather be quite

warm, these queens should not emerge from the cells in less than fourteen to fifteen days, and we believe the longer they are left in the hive where built the more satisfactory they will prove. After the queen has hatched, another empty comb can be added to the nucleus if desirable, though it is not necessary unless very crowded with bees, and then, perhaps, it had better be delayed till the queen gets to laying. We have in this manner reared a full batch of queens, the last hatching within two hours of the first, all well developed, and equally as good in every respect as any swarm-reared queens we ever saw.

One thing should always be borne in mind, good queens are not liable to be produced, by any method, in cold, changeable weather, and we hardly think it matters much how many are reared from one queen, whether it be one or one hundred, if the weather and method are favorable, and eggs sufficient be given a large artificial swarm from which to make its selection. We know nothing of the methods practiced by queen-breeders generally or individually, and only give the foregoing as the result of our many experiments, and a desire to contribute the same to the benefit of those who wish to breed the best from the best.

Vennor's Prognostications.

Not because we have implicit confidence in Vennor's weather predictions, but because many of our readers have the curiosity to know what he has said concerning the coming summer, do we give the following as his forecast:

I desire to give a short, but comprehensive outline of what, in my humble opinion, are likely to be most remarkable features of the summer and autumn of the year 1882:

1. A season that will well merit the designation of cool to cold and wet generally. Not that there will not be terms of summer warmth and even intense heat for periods, but rather that these last will appear in the retrospect as of but comparative insignificance, or as the exception to the general rule.

2. The season will be marked by not only great precipitation, but by a mugginess of atmosphere generally, caused by the reeking condition of the earth and the long continuance of a cloudy sky. This will result in periods of extreme sultriness and heavy weather, during which the thunder and hail-storms will occur. In other words the summer will be the reverse of clear and dry.

3. There is a likelihood of June and

August frosts in northern, western and southern sections, and a general cold wave may occur toward midsummer.

4. The autumn months will continue moist. September will probably give rains and floods in western Canada and in western and southern sections of the United States. October will be much the same, with early cold and snow falls. November will begin the winter of 1882-83—a winter likely to be memorable on account of its exceptionally heavy snow falls and very cold weather over the whole Northern Hemisphere. That a "cold and wet summer is invariably followed by a cold and stormy winter," is a truth now so well proven and borne out by the testimony of past records that we cannot lightly put it aside; and if we have good and sufficient grounds for predicting the former—as we most assuredly have at this time—it is but right that we should warn the people of the latter in good season.

5th and last. The season will probably be the first of a couple of wet summers, and as 1882 so is 1883 likely to be. But here we must stop for the present.

HENRY G. VENNOR.

MISCELLANEOUS.

Adulterated Flour.—New cases of fraud are almost daily being brought to notice—not only in America but in Europe. We hope the day will soon come when we may have a congress of nations who will agree upon the main features of a law to be recommended to the law makers of each country to stop the nefarious business of adulteration, which has now become so universal. From a foreign exchange we extract the following on the adulteration of flour :

The usual mode of adulteration is to use oxide of zinc. German chemists have found 3 to 3.5 per cent. of oxide of zinc in bread, yet zinc and copper may be discovered to a certain degree in bread baked with old wood that has been covered with these metals, the wood readily impregnating itself with these mineral elements.

Flour is also adulterated with spar (baritza), plaster of Venice, chalk, pulverized stone, etc., thus increasing the weight. Exportations have been made from Netherlands of so-called imitation flour, made of crushed spar and plaster of Venice. These exportations were made to such an extent that the Prussian minister of commerce found it necessary to publish a warning against the production. It was observed that the mixture of plaster of Venice amounted to 30 per

cent., while the mixture of spar showed but 16 to 20 per cent. Imitation flour is used to increase the weight of genuine flour by mixture.

Humorous.—"Bill Arp" writes the following to the *Southern Cultivator*. It is a "good hit" on old-fashioned bee-keeping :

"When I hear the horn blowing, and the tin pans beating, and the bells a ringing, I know what is the matter, and so I drop everything and go to the house to hive the bees. It is a wonder that all this fuss don't drive them clean away, but it don't seem to effect 'em one way or another. If they have made up their minds to go they are going, and *vicy vooicy*. I've saved every swarm this spring with very little trouble. We don't run much science on bees at my house—haven't got time. These fancy hives are all right, I reckon, for educated bees with an educated manager to watch 'em and look after 'em every day, but they don't suit me nor my old-fashioned bees, and I don't want to be bothered with the little insects very much, nohow. Nevertheless, we are educated to some extent and don't use the old hollow gum like our fathers did. I make a plain box gum with an upstairs and a little door on a hinge to the second floor, and I put a little box with a glass front in there and it is no trouble to take it out when they fill it with honey. I make no movable frames. My hives are open at the bottom and set upon little bits of iron, or big nails, or even little rocks at the corners, so there is no crack or joint for the moth to lay in. In the winter I let the hive down on the plank to keep the cold out. I have had very good luck this way and not much trouble. Bees are very much like the human family. The queen is the head of the house and has power and authority, and fares sumptuously every day; but like all great potentates she lives shut up in her palace and has a guard to protect her, and hardly ever gets out to enjoy the sunshine or the flowers. Sorter like the King or the Queen, or the Czar, or even the President, for somebody is always on the lookout to shoot 'em for something or for nothing, and it don't matter which. Then there are the big, fat, lazy drones that lie around and eat and sleep and have to be supported and don't do a lick of work, and we can pick out just such folks in this subloary world who don't contribute a thing to the public good and never earn an honest dollar, but are always foraging on somebody, swindling, gambling or speculating, and when they get ready to die they can't recall a single benefit they have conferred upon mankind. Then there are working bees that gather all the honey and make all the comb, fill all the little cells and store it away for winter, and they are never idle, and what they work for they will defend and protect. Just so with the laboring classes who toil and sweat in the field and work-shop, and in the mines, whose constant labor supports and

sustains the world—who live hard and humble, and see their earnings go into the coffers of the drones and speculators, but still work on for more.

The working bees tolerate their drones for a time and support 'em, and put 'em out of the way for another set of the same sort. Folks don't do that, but I am not sure they ought to. The books tell us that the diligent labor of one man can decently support 8 people—provide 'em with good food and comfortable clothing, and its a fortunate thing that it is so, for they have it to do and more too, for those who actually work have to keep up the nabobs who don't, and supply 'em with finery and foolishness. My native bees don't seem to like these fancy hives, for some of 'em left 'em last spring and those that didn't, got eat up by the moths. Most all these new things have to be nursed up, and dandled up, and fondled up, and made fine and slick, and then they are put off on the fancy folks at fancy prices, and ever and anon a foolish poor man, like myself, gets taken in."

A German Apiary.—Mr. Alfred Neighbour, of London, England, attended the Austro-German Congress of Bee-Keepers at Cologne, and then visited Mr. A. Schlosser, at Ebnrenfeld, who was awarded a silver medal at the Congress for his large collection of honey and splendid colonies of bees. Mr. Neighbour thus describes his visit to Mr. Schlosser :

He is a fruit-grower on a large scale as well as an apiarist, and has a commodious house and garden. We were at once conducted to his beehouse, which is in the form of a cross, having 4 doors. Each one of the four wings projects nearly 11 feet, and is the same in breadth, which, adding the space of the interior, gives a diameter from door to door of about 33 feet. One-half the space of the interior is required for the necessary manipulations, the other half to the right and left is occupied by the hives. The first shelf is about 2 feet from the floor, the second tier is the same distance above, and the third is 2 feet higher. The hives are "Mehring's" twin-frame hives, and of much the same construction as Dzierzon's, except that the colonies are side by side, not end to end as is the case with the latter. Each shelf accommodates four twin colonies, so that the openings are cut in the boarding for eight entrances; thus there may be 24 colonies on each of the eight sides. This pavilion therefore holds when filled 192 colonies of bees. At the time I was there many colonies were away at the moors, consequently only a few were to be seen. The house is closely boarded and has a tiled roof. There is no admission of light except when the doors are thrown open. The hives open at the back, and are therefore easily manipulated without molestation by robber bees. Escape for

any bees that are outside the hives is found through the open door.

There is plenty of space to work the extractor in the center of the building. On inquiring if there was an apparent difference in the prosperity of the colonies facing the different aspects, Mr. Schlosser said that those exposed to the afternoon and evening sun, which induced the bees to fly out again, are placed in the most unfavorable position; but as long as the entrances are not exposed to the direct rays of the sun it makes no difference whether they face north, south, east or west, and the only drawback which he finds to his "pavilion" is, that when quite filled, the colonies are placed in too close proximity, which causes the loss of many queens in their return from their wedding flight.

Fairs and their Advantages.—The *Capital*, Topeka, Kansas, makes the following remarks on this subject:

The inception of an agricultural fair puts in motion the best elements of farm life. It stimulates a laudable ambition with reference to the locality interested. If it is a township fair, the township at once has a reputation at stake; if it is a county fair, then the county comes in to be sustained; if it is a state fair, the whole state is to be represented; and, in every case, all individuals interested in the good name of the township, county or state feel concerned about the success of the fair. It has the effect to organize the working powers of every community.

A fair is an advertisement for the community interested, and for every individual person who participates. If the general display is good, it gives a good reputation to the people represented; and in detail, every single exhibitor has opportunities for showing his own skill and success in his specialty if he have any. Every exhibitor meets hundreds of new acquaintances, and he learns to talk to them. He becomes a public man for the time being.

This association with his fellow men, and in connection with his own vocation, affords to the farmer many opportunities for improving himself socially, and for acquiring information that would never come if there were no fairs. Their educating advantages are seen on every hand. Not only the farmer himself, but his family and friends are benefited. They become partners in his gains, and share in his success.

Fairs operate to make men and women better, larger hearted, more liberal; they give men larger and better views of life and labor; and better than all, they educate farmers and their sons and daughters to regard farm life more favorably. Many farmers look upon their calling as common, and without attractions. This is a fatal error with some. Fairs correct this evil. They elevate the standard of labor, and help make farming appear to be what it really is, the most independent, manly and honorable of callings.

Bees Injuring Fruit.—A late number of the *Western Rural*, has an amusing burlesque on the subject of bees injuring fruit. Of course, there could have been no more conclusive evidence presented to the Dutchman's mind that bees did really injure his fruit, than to have a swarm attempt to cluster in his apple tree. So, too, with many who most positively assert that bees destroy their grapes; they have found the grapes punctured or the skins cracked open, and have discovered bees in large numbers sipping the juice, and this is sufficient ground with them upon which to base the assertion that bees do injure fruit, and to petition their condemnation* as a nuisance. Following is the squib:

We once told a Dutchman of our acquaintance that bees did not injure fruit in the least, when he said that he knew better and gave the following argument to prove that bees do injure fruit: "Vonce a long vile ago I vent into mine abble orchard to glime a bare dree to kit some beaches to make mine vrow a blum budding mit; und vent I kits away up on de toppermost limbs, a hole lot of pees, pees vat come for honey gitten, two, tree, five dousand hundred of em game, ven I vos on de highermost pranches, und tey selting me all over so pad as never vas, und right before mine vace too, und I not know vere I am, so I vall town so high up, mit one leg on both sides of de bicket vance, und like to stove my outsides in. Vas you say, hey! Peas no steal de fruit, ven I ketch 'em at it?"

Swarming and Dividing for Increase.

—The *Indiana Farmer* gives the following on the above subject:

There are no certain signs as to just when a colony will swarm, so far as outside indications will show, more than the clustering of bees on the outside of the hive, and the hanging of pollen gatherers with the cluster outside instead of entering their hive, but by examining the frame frequently, watching the progress, one can soon tell when they are about ready to cast a swarm, and as soon as the queen cells are about ready to cap over is the best time to divide. Probably the safest and easiest way to divide, is as soon as they are ready, lift out the frame, bees, brood and all on which the queen is found; place this frame in the new hive, filling out with frames of comb or foundation, or if you do not have either, fill out with empty frames. Now place the new hive, containing the old queen on the old stand, moving the old hive to a new location. By this plan you throw nearly all the working bees where the most work is to be done in the new hive, and they will proceed to work the same as though they had swarmed naturally. But if the old bees had made up their mind to swarm and you had left a queen cell on the

frames you had placed in the new hive, they will sometimes swarm anyhow, so you will notice to tear them down, if any exist before closing them up. The brood in the old hive hatching out very rapidly will soon make a good colony. The space in the old hive from where you removed the frame should be filled with comb, or foundation, for if an empty frame be placed there the bees will fill it with drone comb as they seldom make anything else while without a laying queen. In eight or nine days after dividing, all the queen cells except one should be taken out, so as not to cause after swarms.

CORRESPONDENCE

For the American Bee Journal.

Florida as a Bee Country.

W. S. HART.

On page 233 of the *BEE JOURNAL* Mr. T. S. Roys cruelly sweeps Florida clear out of the bee-keeping world with a few graceful turns of his pen. He also kindly shows the "great guns" the folly of their theories, and sets them right(?) "as to the cause of dysentery, diarrhea, etc." According to his statement and the date of his letter, he had been in this State nearly three winter months.

He says: "My observations have only extended to the peninsular portion of the State, and from what I know of that, would say, don't come here to go into the bee business. I am somewhat of a beeasticus myself, and know whereof I speak." If he has been to the peninsular portion of the State, he evidently has not been over it. He must have gone down a pine ridge and returned the way he came.

The writer did not feel competent to give a decided opinion of the honey resources of Florida until he had been here as many years as Mr. Roys had months and been clear around and pretty well over the "peninsular portion of the State." My opinion was then so well founded that I have as yet, after being here seven years, seen no cause to change it. However, I perfectly agree with Mr. R. in advising "all to look before they leap" into this or any new country for a permanent stay. Among the hundreds of letters that I have written in reply to enquiring bee-keepers, I do not think one can be found wherein I have advised selling a home in the North to come South, without first coming here to see how the country suits.

This is a peculiar country to the Northerner. It has more advantages and disadvantages than any State that I am acquainted with. Some people it will suit well, others it will not; but whoever comes here with a determination to stay, backed by

energy and reasonable judgment, is bound to do well and accumulate property. And one way of doing this is by keeping bees in the coast counties south of the 29th parallel, where the mangrove is plentiful. Whether or not Mr. R. has ever been where the mangrove is to be found he does not state, yet from his writings I should judge not. He writes from Jacksonville, has been in the State nearly three months, and assures us that the bees have been gathering honey about his house for the past three weeks. California is a large State, and only a small portion of it is good for bee-keeping, yet 600 people give their time wholly to the industry.

Florida is also a large State, as is shown by the fact that the Okechobee Land Co., propose to drain a tract of rich land in the southern portion of the peninsula, larger by 1,000 square miles than the combined area of the States of Rhode Island, Connecticut, New Jersey, and Delaware, said land being outside of the settled portions of the peninsula, and until within a very few years never had been visited by a white man.

Again, Florida has nearly as long a coast line as all the Atlantic States together. A large part of this coast line lies south of the 29th parallel, and there is the bee country that I recommend. I do not think Mr. R. has ever seen any of this country. There is certainly room for more bee-keepers, as in all that country I know of but one man who gives all his time to bee-keeping. He has been here over a year, and now wants to buy land and make a home for himself and bees. How he succeeds can be seen by turning to page 194 of *Gleanings*, and reading a short communication from Mr. C. F. Hopkins. I believe that Mr. Hopkins looked some further than Mr. Roys, saw more and speaks better of the prospects here. After reading his note turn over one leaf, and on page 196 see a few lines from Mr. E. M. Johnson, that speaks well for the bee interest here.

As a guarantee for my reliability, and indorsement of my statements, I will say that the Agent of the State Bureau of Immigration issued a pamphlet asking for information in regard to sheep raising and bee-keeping in this State, and sent copies to parties all over the State. One was sent to me with a letter inclosed, asking for something more elaborate than the circular called for. I wrote an article and sent it with the suggestion that all the bee-keeping returns be put together in pamphlet form for distribution. Hon. C. Drew writes me that he is acting upon my suggestion and will forward me 200 copies as soon as done. I will send a copy to the BEE JOURNAL, and also to any other parties that write for them inclosing stamp.

In conclusion, I will say that at present, railroads are few in the aforesaid country, although without doubt several will be built within the year, and most of the traveling is done by boats and slow teams; so, if Mr. Roys knows more of this portion of Florida

than the Puritans did of North America, he has traversed more of it than I think he has.

New Smyrna, Fla.

Farmers' Home Journal.

Rearing and Introducing Queens.

G. W. DEMAREE.

There is nothing connected with bee-culture that gives the apiarist so much satisfaction, as well as so many advantages, as the art of rearing and introducing queens. If he has a colony of bees that give poor results in the way of increase and production of honey, he can soon change the state of things by removing the unprofitable queen and introducing a better one in her place.

I have had queens that started in the spring with fair sized colonies that failed to get in working trim till after the main honey harvest was past, while other queens would fill their hives with bees and be ready and waiting for the harvest. To remedy these evils I commence to rear queens as soon in the spring as the weather will permit, in order that I may have good laying queens to take the place of such as do not give satisfactory results. If possible I would have a laying queen to introduce to the parent colony as soon as the first swarms issue. Managed in this way a colony will hardly miss the bees that are led off by the old queen, because they are furnished with a queen that goes right to laying and the hive is soon replenished with workers. This is made quite apparent when we take into consideration that the young generally hatches eight days after the old queen leads off the swarm and begins to lay at ten days old, which makes about eighteen days that the colony is without a laying queen. Really two or three more days should be added to this, because the young queens lay slowly for the first two or three days. These eighteen or twenty days sometimes make all the difference between a fair yield of honey and no surplus at all.

Doubtless some one will ask, "How do you rear queens?" Well, we older ones are apt to forget that our ranks are continually being filled up with candidates for bee knowledge, and therefore it is proper to go over what to us seems to be old grounds for the benefit of beginners, from time to time. Thus we "provide things new and old."

The methods employed by different bee-keepers vary somewhat, but the principle is the same. In order not to confuse the reader, I will simply give the plan I follow with satisfactory results. In this climate about the 15th of May is soon enough to commence to rear queens. Of course the state of the weather must govern these things.

I select a strong colony to rear the queen cells, and proceed as follows: I open the hive which contains the queen I wish to breed from, and from one of the center combs I cut a piece about 2x3 inches, containing eggs and

larvæ just hatched. This can be known by a small drop of white creamy looking substance at the bottom of the cell. I prefer to have some of the eggs just hatched, because I thereby save about three days' time, as it requires three days for the egg of the honey bee to hatch. I now move the colony, which I have selected to rear the queen cells, from their stand and place an empty hive in its place, provided with some empty combs or frames filled with foundation.

Now, cut a slot in one of the combs, near the corner and running parallel with the top bar, about a half inch wide and eight or ten inches long. As bees are decidedly pleased with an opening just below the cell, I usually cut notches in the lower edge of the slot like saw teeth; but this is not essential. I now cut the piece of comb containing the eggs, etc., as above described, into strips and fit them into the slot. If they do not fit close enough to stay in place, they can be secured by some slender wooden pins. I now open the hive that I have removed from its stand, and look up the queen and place the comb on which I find her in my comb box, or any other safe place. This I do to prevent a possibility of getting the queen into the new hive, which would certainly defeat the object of my labors.

I now take out one of the side combs containing honey, but no eggs or larvæ, and set it in one side of the new hive, and set the comb containing the eggs (I have supplied) next to it, and then finish out with empty combs or frames of foundation as above stated. I now shake the bees off of two or three combs from the old hive into the new one. This gives the new hive a division of the young bees, which is quite essential to cell building. The bees are now covered with a quilt, and the hive closed up. The queen is returned to the old hive, and the latter is given a new stand. The old bees will nearly all go back to their old location, and go to work like a natural swarm.

I keep an eye on the new colony to see how they progress in cell building. On the eighth day I examine the cells to see how many there are, and then proceed to form nuclei to suit the number of cells. This I do by taking two combs with bees adhering (be sure the queen is left at home) and setting them in an empty hive, at one side hanging in a division board to curtail the size of the hive. These nuclei are made from any strong colonies. In one or two days after the nuclei are made they will have realized their queenless condition, and will be ready to accept the cells.

We now open the queen rearing hive and cut out all the cells but one, or as many as we want, if there should chance to be a surplus. A bit of comb should be left adhering to each cell, and they must be handled carefully. Each nucleus is provided with a cell. This I do by taking out one of the combs and cut a hole in it, and fasten the cell to the edge of the comb (inside the hive) with a wooden pin inserted through the bit of comb ad-

hering to the cell, and into the edge of the comb. The bees will finish up the job. The young queens will hatch in two or three days, and will go out to meet the drones in five or six more days, and at about ten days old they will commence to lay eggs. You now have laying queens at your disposal.

Care of Comb Honey—No. 2.

G. M. DOOLITTLE.

Having our honey placed in a warm room, as recommended in my last, the next thing which will need our attention will likely be the larvæ of the wax moth, in order to keep them from damaging our honey, for I have yet to see the pile of 1,000 lbs. of comb honey which does not have more or less of these worms or larvæ upon it, after it has been stored in a warm room for 2 weeks. Some of our bee friends tell us they are never troubled in this way, but however strong my hopes may be, as I place my honey in the honey-room, that I shall, like them, be exempt from that nuisance "moth worms," still I have to eventually conclude with such hopes never realized, for the worms always put in an appearance. After the honey has been away from the bees about 10 days, if we inspect the cappings of the honey closely, we will detect little places of white dust resembling flour upon the surface of the comb, and usually most abundant near the bottom of the box. Now, although this place may not be larger than the eye of a fine needle, still it tells us for certain that a tiny worm of the wax moth is there, and that unless it is destroyed, it will destroy more or less of the nice white comb which encases our honey.

While in the city of Syracuse, N. Y., a number of years ago, I saw boxes of honey which had worms in them as large as a slate pencil, and an inch or more long, and although they had nearly denuded the honey of the nice white cappings to the cells, still I could not make the groceryman believe the worms lived upon the wax. Such a spectacle soon disgusts customers, and injures the sale of comb honey very much.

If, after several examinations, you fail to find such little white, flour-like places, you need be very thankful. If you should find these, the next thing is to sulphur your honey. To do this I get an old kettle and put some ashes in the bottom of it so there will be no danger of fire resulting from the heat from the coals, which are to be placed therein. When I have the kettle thus prepared, I take it to the honey room and pour sulphur, which has been previously weighed, on the coals to the amount of $\frac{1}{4}$ lb. to every 75 cubic feet contained in the room; when the kettle is quickly pushed under the pile of honey and the room closed, you will have to be spry, or you will get some of the fumes thereof yourself, which is not very pleasant, I assure you. I now go and look in at the

window, to which the few flies which chance to be in the room will come, hoping to escape their doom. As soon as I see the last fly is lifeless, I take out my watch, and, after the lapse of 5 minutes, I open the windows so as to carry out the smoke as soon as possible, for if allowed to settle on the combs it will turn them a greenish color, which damages the sale of honey very much.

If more honey is brought into the room this is also watched, and when the marks of the worms are seen on these the same operation is repeated again, and so on till I am sure the honey leaves my hands without danger of these pests making an appearance after it has been placed upon the market. After this is done, the next thing I do is to glass the sections, as most of our Eastern markets still demand their honey glassed. In order to have my glass cut accurate the narrow way, where it goes between the projections on the sections, I buy the glass cut in strips 6x30, and then place these strips in a box similar to a miter box, using the diamond to cut the glass in a similar way to which a saw is used in cutting lumber in such a box. Thus I have each glass just alike and exactly as I wish it. I once bought a lot of glass cut 5x6, because they told me at the factory that it should be cut accurate the 5 way, but upon getting it I found that accurate meant all the way from $4\frac{7}{8}$ to $5\frac{1}{8}$. As it was getting late, I was obliged to use it, but I had better have thrown it entirely away, for in crowding the larger glass between the projections to the sections, the combs were cracked loose from the sides of the box, causing it to leak and making it liable to break down in shipping. Thus I learned a lesson, which, though costly, has perhaps been a benefit to me. Since then I have cut my own glass the narrow way, and have learned by experience that to be just right the glass should be cut 1-32 of an inch narrower than the box, thereby letting it go between the projections without crowding. After the glass is cut, it is washed so clean that it fairly shines, when it is ready to be placed on the honey, which is done by bending up the tin points which were previously driven into the end pieces of the section at the time the sections were made. After bending up the tins, drop in the glass and bend them back over the glass, when the work is done.

Now scrape every bit of propolis and dirt off the outside of the box or section, so it will be as clean and nice as when first made, and it is ready to be crated. This point of scraping off the propolis is overlooked by some, for I have seen sections sent to market so daubed with propolis as to look untidy and injure the sale of it. If we wish to get a good price for our product and increase the demand for the same, all these little things should be looked after, for they go toward spoiling the sale of our crop, or enhancing the value thereof, as the case may be.

Either before the honey is glassed or afterward (generally before), I

grade it, making three grades of it. In the first grade I place all which is perfect or nearly so, and such as is termed A No. 1. In the second grade is placed all of my combs which have been soiled by having a few cells of brood or pollen in them, and also all which are light in weight or are not fully capped. In my third grade I put all which is off-color, such as buckwheat, or a mixture of light and dark honey together. The grading of all kinds of products pays well and that of honey especially. My next will be crates, crating, and hauling to market or the railroad.

Cultivation of Plants for Bees.

FRANK R. CHESHIRE.

That the place occupied in Nature by bees in general, and the honey bee in particular, is, as a rule, not understood even by the bee-keeper himself, is certain; and he in consequence is often led into expenditure which he would not otherwise have incurred, while he is not infrequently met by disappointment which a little greater knowledge would have prevented. Let me in order to make this clear explain that the business of the bee as a honey and pollen gatherer, although most interesting to us as bee-keepers, because upon this our profit rests, is after all but the least part of the work which the insect accomplishes in the great and wonderful scheme of Nature. The bloom secretes honey, but not for itself; it is a gift to the honey gatherer—nay, rather a payment, for the bee in its visits to secure food for itself and young unconsciously performs an act which completes the object of the flower's existence, and receives the honey as a compensation for its service. This subject is so full of marvels and is so various in its details, that anything beyond an illustration or two I cannot at the present attempt. Speaking broadly then, honey-bearing flowers have anthers which shed pollen, while at a certain period a central organ or organs of the bloom (stigma or stigmata) open and wait for pollen being placed upon their surfaces. When this occurs a pollen tube, as it is termed, grows down from the pollen granule to the ovary and enters the ovule, which henceforth passes into a new phase of its existence as a fertilized developing seed. Without this placing of the pollen granule upon the stigma the bloom remains expanded for an unusual time, but at length fades, leaving no seed behind. The placing of the pollen granule upon the stigma can hardly be accomplished without the intervention of insects, for almost all blooms present some curious correlation of parts which makes it difficult, or even impossible, for its seed to be fertilized by pollen it has itself produced. Cross-fertilization and not in-breeding is the law for a reason amazing by its beauty. This crossing is secured by means which are legion,

but amongst which two are the most common—viz., the anthers ripen first, and not till all their pollen is gone does the stigma become receptive (protandrous), or the stigma is first produced, the anthers not ripening till after an opportunity for fertilization by other pollen has been given (protogynous).

It is a general rule that honey continues to be secreted till fertilization takes place, when a diversion of nutrition occurs, and with the ceasing of the honey the petals, nature's colored flags hung out to attract the insect visitant, drop. The netting of the greenhouse or conservatory against insects is of course right, because here bloom and not seed is the object desired.

The scattering of Clover and borage seeds, and such like, in waste places on railway banks and disregarded corners, or in our grounds if extensive, is very useful, because here we conform to a natural instinct which we neglect if our blooms are made to nod their heads in the very face of the bees as they start from the alighting board. I have been told not a few times by disappointed purchasers of seed packets potentially containing whole supers of honey that the plants represented to be so suited to bees were quite unvisited. I hope I have now made the reason apparent. This year, in watching my cherry trees about 70 yards from my hives, I found but few yellow-banded bees amongst them in comparison with the number seen on those of a neighbor at four or five times the distance. It is thus by wide diffusion that the multitudes of bloom get in the main their needed attention, and that their honey is not provided in vain.

Canadian Farmer.

Management of Bees in Spring.

S. T. PETTIT.

Allow me to say one word with regard to the management of bees in spring. Some few prominent bee-keepers with more zeal than wisdom, recommend feeding bees at this season of the year, large quantities of sugar syrup, so that when they begin to work on clover, the hives are already full of syrup, and consequently the first, and in fact all the clover honey must go to the surplus boxes. Now, all this sounds very nice, and possibly some beginners may follow such a course until a little more knowledge on the subject convinces them of the folly of that kind of practice. I will give my reason why not to do so.

When the surplus boxes are put on to make room for the queen, the bees will usually move a large part of the stores from the brood chamber to the surplus apartments, and thus you see you have an adulterated instead of a pure article for the market. But it has been said that a little sugar won't poison any body. Very true, it will not. But to do so, will poison your conscience; lower yourself in your own estimation, blast your reputation,

and injure the honey-producing interests of the country. The people want a pure article, and will buy it and use it liberally, when convinced of its purity. Every business man, or nearly so, to whom you offer honey, will ask you if it is pure. Now, if there is the least taint of sugar about it you must say so or lie. But if you begin to explain that there may be a little, etc., why, the game is up and you are out, for no respectable dealer will touch it, unless you can vouch for its purity. True, you could make a big report at the close of the honey season; but I am proud to believe that no Canadian bee-keeper would feel very happy over a crooked report, however large, consisting of sugar and honey.

Let us most religiously see to it that Ontario honey shall stand extra No. 1, in the markets of the world. Work hard and make your honey crop as large as possible; but never sacrifice quality for quantity.

Belmont, Ont., May 4, 1882.

From the Bienenzeitung.

A Peculiar Incident.

T. ZINCK.

I am always pleased to look at queen bees, but Tuesday, the 12th July last, formed an exception. On that day, between 5 and 6 o'clock in the afternoon, I discovered a queen in my garden about fifteen paces from the place where my hives are kept, resting on the ground and surrounded by a cluster of bees, to which my attention was directed by a number of workers hovering over the queen. The bees behaved exactly as they do when a swarm loses its queen, but I was quite certain that no swarm had issued from any of my colonies. I at once thought of a colony from which the queen had been removed twenty days previously. In this hive a young queen appeared on the 7th July, but the bees did not tear away the superfluous royal cells until the 10th July. On that day the weather was most unfavorable, nor did any drones venture out of their hive on the 11th, but I confidently expected the young queen of this colony to become impregnated on the 12th July, which was a lovely day. I picked up the poor queen, and finding that one of her wings was dislocated I put her into a queen cage, which I fixed inside the hive above the comb bars. The bees surrounded the cage joyfully; and as the queen did not try to get away from them, but evidently allowed herself to be fed, I liberated her a few minutes afterwards, and I soon saw her walking about among the bees.

It had to be ascertained now whether the queen was incapable of flying when she left the hive or whether she had met with an accident after the act of impregnation. Unfortunately the former turned out to be the case, for on the following day (Wednesday) I found her again in the garden at the same time running backwards and forwards alone, but some workers were hovering over her

again, which attracted my attention. I picked up the queen, who was now minus one of her wings, and allowed her to enter the hive by the entrance. She was again well received by the workers.

On the following day (Thursday) I noticed nothing unusual in the morning, and in the afternoon I was obliged to leave home. When I returned late in the evening I did not think it necessary to examine the interior of the hive, as the outside presented its customary appearance. I looked for the queen on the ground in the garden, but she was not to be found there. At half-past seven the next morning I paid a visit to my colony whose existence was in danger, and as soon as I opened the hive I knew at once that it was without a queen. I found the queen on the ground in the garden for the third time, surrounded again by a few workers. Of course she had not left the hive the same morning, but the previous afternoon, which accounted for the colony being in such an excited state. Knowing that it was impossible for the queen to become fertile on account of her being unable to keep on the wing, I placed her in a queen cage among the bees, and a few hours afterwards I introduced a fertile queen in her place.

Though this is a case of rare occurrence, nevertheless it will show that when a queen leaves the hive on her wedding trip she remains in communication with her colony by worker bees which accompany her. This was the interesting part of the affair, which inclines me to hope that queen bees do not so easily lose their way and perish, as is often stated.

It was the first time that I lost a young queen, and in this case it was, perhaps, through some fault of my own, as I performed some operations on the colony between the time of the queen leaving the cell and her wedding excursion. The exterior of the hive was, indeed, not interfered with, but I made some alterations in the interior, during which the wing of the queen may have become damaged by the workers or otherwise. The queen certainly appeared faultless to me when I saw her immediately after she was hatched.

"One misfortune seldom comes alone," and this saying seems to be true with regard to bees also. Last summer this same colony killed their own queen—the best one I possessed—after I had deprived them of all their honeycomb, which was replaced by empty combs, of which I had a sufficient number from previous bad times to enable me to make artificial swarms. When I gave them a new queen and liberated her after two days' confinement the bees immediately attacked her, and would have killed her if I had not rescued her from their fury in time. After this a royal cell was inserted, which was very late in hatching, and when at length the queen made her appearance she first laid drone eggs only, but afterwards she also produced workers. She did not prove very fertile, however, so that her population increased but slowly this spring. I therefore re-

moved the queen, leaving the colony to rear a new one. What happened to this queen has just been related. The new queen having been accepted I trust all its troubles will now be at an end.

Kleinheilbach, Germany.

Local Convention Directory.

1882. *Time and Place of Meeting.*

Aug. 10—Maine State, at Harmony, Maine.
Win. Hoyt, Sec.
Sept. 5—N. W. Ill. and S. W. Wis., at Rockton, Ill.
Jonathan Stewart, Sec.
Oct. 5—Kentucky Union, at Shelbyville, Ky.
G. W. Demaree, Sec., Christiansburg, Ky.
Tuscarawas Valley, at Newcomerstown, O.
J. A. Bucklew, Sec., Clerks, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Western Michigan.

[We give this week the remainder of the proceedings of the Western Michigan Convention, which had not arrived at the hour of going to press with our last issue:—ED.]

Italianizing an Apiary.

Mr. Robertson. I would start a nucleus for each colony, and save the time of the old queens until the young queens were ready to use. The cells should be grown in strong colonies, and only the best stock used. I use a lamp nursery, in which the cells are placed to hatch, and drop the virgin queens into the nuclei within a few hours after hatching. In introducing fertile queens, I generally use the caging process, though I have succeeded well with other methods.

Mr. Cobb. I use an introducing cage of my own, which I fasten to the side of the comb. After 48 hours I make a hole through the comb into the cage, and return it, leaving the bees to liberate the queen. Nuclei should be started 24 hours before putting queen cells in them.

Mr. Kilburn. It would endanger the life of the queen to disturb the bees within a week after introducing. I favor the mode of introducing used by Mr. Cobb.

Mr. Robertson thought one method infallible; that was to place the queen on combs of hatching brood. Remove the colony, placing the hive, containing the queen to be introduced on the old stand. The bees returning from the field would join the new queen, afterward the rest of the swarm could be given them, taking care, of course, to destroy the old queen.

Mr. Kilburn thought this would succeed only when honey was being gathered.

Artificial Swarming.

Mr. Robertson, in answer to a question, said he practiced artificial swarm-

ing entirely. He seldom divided, but preferred to make up a good swarm, from several, and give them a fertile queen.

This subject was further discussed on Thursday afternoon. All, or nearly all, favored the method, of making up swarms practiced by Mr. Robertson.

F. S. Covey dispensed with handling the queen cells, and obtained fine queens in this way; he made up strong swarms of young bees and brood, dividing into nuclei when queen cells were old enough, leaving one good cell in each hive. He then exchanged places with strong swarms. The majority were found to favor natural swarming in practice.

Cyprian Bees.

Mr. Cobb said he had tried the Cyprian bees one season. He considered his opinion rather premature as yet; had found them a little more inclined to sting than Italian bees, particularly so when no honey was being gathered. Felt like discarding them at first, but found some good points. He had found them more prolific and better honey gatherers than the Italians. His Cyprian colonies already had drone brood. He had an imported queen.

Mr. Robertson preferred the Italian to the Cyprian bees on account of their temper.

John Slabbekoorn. I have found them much crosser than Italian bees.

Mr. Kilburn. While they will breed a little faster, they have no other advantage over the Italian bees. As honey gatherers he has found them no better. They cannot be managed with smoke. They are more inclined to rob, and will defend their hives with more spirit than will Italian bees.

Mr. Cobb. I have found them manageable with smoke. I agree with Mr. Kilburn that they are more inclined to rob and will defend themselves better than Italian bees.

The President advocated the improvement of the Italian race, by careful selection and breeding from the most prolific.

The question was asked, "Is this extra prolificness desirable?"

Mr. Cobb thought that where white clover was the main dependence, extra prolificness was desirable.

Mr. Kilburn and others had found a cross between the Italian and Cyprian races produced very good bees.

The following paper was read by Mrs. Jennie Walcott.

"Thoughts on Bee Keeping."

That bee-keeping is a business or profession as much as agriculture, horticulture, architecture, or any of the various pursuits followed by mankind, none that have kept bees a few years will deny, and our success in this branch of industry depends entirely upon our natural and acquired ability. By acquired ability, I mean the amount of reading and careful study we have given this pursuit in its various bearings. It is unlike most trades where one serves an apprenticeship of several years before being considered capable of manag-

ing for himself. The bee-keeper must combine theory and practice in order to make the business pay. I have for 4 or 5 years been somewhat acquainted with the little busy workers, but for the last 2 years I have tried to study their natures and habits, and feel as yet I know but little about them.

In regard to wintering, I am satisfied upward ventilation is essential. Our bees were packed in chaff on the summer stands last November, all in good fair condition. In the cover of one hive a 1/2 inch hole was bored and a small tube inserted which came up through the chaff. Upon examining this hive in March, we found the colony strong, bees having that glossy look characteristic of health. The bottom board was nearly clear of dead bees and the hive presented the best appearance of any in the yard. My opinion of wintering is, first a strong colony; plenty of stores; a cool, dry atmosphere.

The problem with us is how shall we obtain the most honey? which I presume is the principal object with most bee-keepers (while each has his own particular way of managing his bees). Inventors and mechanics are constantly at work on improvements, thereby greatly facilitating the labor of the bees. I have to confess that our surplus account does not come within a long way of L. C. Root and some others. One man claims 600 lbs. per colony.

My opinion is the queen has much to do with the activity of the colony. Two colonies have stood side by side in our apiary; one colony produced more than as much again honey as the other. I think in obtaining queens this should be one of the ruling traits. We have tried various ways to make these lazy bees go to work, but without much success. I think the fault was with the mother.

Another thought concerning the sale of honey; ought we not, as bee-keepers, to obtain a uniform price? Competition is the life of business, is the tradesman's theory; yet may we not in justice to ourselves, and kindness to our brother bee-keepers, be conformed to a general price for our produce. In union there is strength. A really nice article will always sell more readily in the market than an inferior one, but if one dealer sells his honey 2 or 3 cents cheaper than the average price, it soon produces confusion in the market. Our home market is much better than the market East, West, or South, according to bee papers, and I hope it may still continue so. I think it will if we are careful to offer only a good article, and expect a good price for it. In regard to comb foundation, or natural comb, we say give us the natural comb. Not ignoring this noble invention of foundation (many times have we mentally thanked our brother across the ocean for this wonderful help in comb building), but we think its place is in the brood chamber. We save every small piece of natural comb, and fit them nicely together, and place them in the hive, the bees soon fix them solid and we have another comb for the extractor. One

more thought; may we not add to the general interest of the meeting if each one write a short account of this summer's experiments, both successes and failures, thereby being a mutual benefit to us all; lastly, may we not, as bee-keepers, greatly increase our facilities for honey producing, by planting small basswood trees by the road side and along line fences, and by sowing those seeds, and furnishing them gratis to our neighbors, which yield honey. Buckwheat, which is useful as a grain, and many other plants which amply repay us with the sweet nectar they furnish.

Mr. Robertson preferred foundation to natural comb. Used the Dunham—thick for brood combs and thin for sections. He preferred to fill the sections with it.

Mr. Kilburn preferred the Vandervort foundation on account of natural shape of base.

The President used foundation in sections only for starters. Had found the bees would sometimes prefer foundation, and sometimes natural comb, when placed alternately.

Mr. Cobb found comb honey sold best in 1 lb. sections, and the extracted best in glass jars; but thought buyers would learn to take well to candied honey in tin pails.

Mr. Kilburn recommended the tin cans for honey; the smaller sizes making a cheap and salable retail package, and the large cans more convenient and safe to ship in than barrels, as honey was hard to hold in barrels.

Mr. Robertson agreed with Mr. Kilburn, that honey was hard to hold. He used pine kegs uncoated, and considered them much better than oak. Spruce kegs were advertised; he liked the idea, but had not used them.

Mr. Covey thought bees were made more irritable by using too much smoke; he would give them a little, and proceed at once with his work.

The President said they should be given a little time to fill themselves with honey.

Mr. Covey. Time is money in the honey season. He thought they were more easily handled while engaged in filling themselves.

Mr. Robinson. Some bees could be handled well without smoke; others would be cross in spite of smoke.

Mr. Slabbekoorn thought the quality of the honey they were gathering made a difference. His bees were very cross while at work on seed onions.

The President thought that bees were aroused by the actions mostly. A colt of his could crop the grass close to the hives without getting a sting.

W. McCordan complained that the bees were much disturbed by loosening the frames in opening his hives.

Mr. Kilburn said the use of tin corners, with metal rabbets would prevent all sticking, but he preferred to use the common frame, with the metal rabbets.

The President carefully pried the frames loose with some instrument before handling, and had no trouble.

The secretary used a marline spike for that purpose.

Providing Water for Bees.

Mr. Robinson thought this was important. They would accept water many times very thankfully.

Mr. Covey. Many bees were chilled and lost in the spring while gathering water in cool weather; believed they should at such times be provided with water at home.

The President. Bees are supposed to prefer brackish or salt water.

Mr. Cobb gave them water made a little sweet, in feeders, to keep them at home. It was easier, but not as effective to feed water in the yard.

The President had fed bees water while in the cellar, with good results.

Mr. Covey had a swarm become very uneasy in the cellar and finally die. On examination he found they had considerable brood, and thought the want of water had made them uneasy.

Clipping Queens.

Mr. Cobb said, in his early experience he had a good deal of trouble with absconding swarms; he now clipped all his queens.

The meeting adjourned to meet in the same place at such time in October or November next as the officers should elect.

WM. M. S. DODGE, Sec.

Maine State Convention.

The Maine Bee-Keepers' Association met at Foxcroft, Thursday, May 11. As Mr. Torrey was not present with his essay upon wintering bees, we passed to the reports. Mr. French reported a loss of six colonies out of forty-one, during the winter, wintered partly in the cellar, and partly out of doors, packed in chaff. Mr. Silver lost four out of thirteen on their summer stands, without any protection.

Mr. Crockett wintered seven without any loss, he builds a house that will hold three or four hives, and uses chaff for packing. Mrs. Vaughan lost four out of twenty-six, always wintered in the cellar without any loss, until the present winter.

President Additon said his bees had wintered well, but some of the queens were found missing this spring. Mr. Brockway and others had wintered without any loss.

In the afternoon a paper on "Bee-Keeping in Maine," prepared by I. F. Plummer, was read, followed by discussion, and numerous questions were asked and answered. Voted to hold the next meeting at Harmony, Somerset Co., August 10, 1882.

WM. HOYT, Sec.

The Northwestern Wisconsin Bee-Keepers' Society will meet in La-Crosse, Wis., June 9, 1882, in the City Hall. A good attendance is desired, as arrangements have been made for articles from practical apiarists.

G. J. PAMMEL, Sec.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

SELECTIONS FROM OUR LETTER BOX

Hunting Wild Bees.—Please state the plan of hunting bees. There are several bee-trees in my neighborhood, if they could be found early enough to transfer. I have 1 colony of bees packed in chaff on summer stand. They are doing nicely. K. J. LEE.
Carpenter, Iowa.

[It will take more space than we can spare to explain the whole *modus operandi*. We can supply you with a copy of A B C, which gives a very instructive article on the subject.—Ed.]

All Swarmed in May.—Last fall I packed 5 colonies on the summer stand; all were strong and in a healthy condition this spring. One swarmed on the 3d of May, and the others have since, the last coming out on the 28th. I anticipate they will furnish 100 lbs. of section honey in June. I think they are doing well considering the weather. L. J. MCKINNEY.
Burlington, Iowa.

Barberry.—This morning finds the ground white with snow, and bees are housed; but they are in fine condition, considering the weather. We have hope yet, but it looks to-day like it would be all hope. Inclosed I send you a specimen of a shrub that the bees appear to like very much. It grows about 10 feet high; commences to bloom about the first of May, and blooms through June. Can you tell me its name? F. J. SAWIN.
Kirkwood, Ill., May 23, 1882.

[The shrub is the common barberry, often cultivated for its pleasant, acid fruit, but more often for ornament. It is a native of Europe, whence it was introduced at an early day, and is now found throughout our country. It, however, rarely escapes from cultivation to become distributed in a natural manner. Insects of many kinds visit its flowers for the honey, which is secreted in considerable quantity. Mr. Sawin is probably mistaken as to the length of time the bush continues in bloom, but a quantity of it would materially aid the bees during its season. No one should fail to observe the movement of the stamens of the flower when these are touched near the base, as by an insect's foot or the point of a pin. It was formerly taught that this wonderful property was for the purpose of putting the pollen on the pistil of the same flower. Now we know that its purpose is to secure the distribution of the pollen from flower to flower through the aid of the insects which the nectar attracts. Watch them.—T. J. BURRILL.]

Worker Bees in Queen Cells.—In overhauling a colony that had cast a swarm, I found about 15 queen cells capped over. I cut all of them out, as I wished to make use of part, and opened the rest to see how far they were advanced. In the first one I opened I found an old, dead worker bee; the next one—a very fine looking cell—found another worker bee, but fully alive, with its head all besmeared with the food in the base of cell; the rest of the cells all had queen larvae in different stages of development. How did the worker bees get in the cells, and what caused them to be capped over? Please give answer in Semi-Monthly. Bees in this section are strong, but have very little honey in the hives, and are killing off drones. Out of 16 colonies I have had only 2 swarms. During bloom of wild cherry and locust, bees were not able to fly, white clover is coming in slowly, and I think it will remain slow business, as there seems to be very little, only able to find it in patches here and there, and our only salvation seems to be fair weather during linden bloom.

T. MUEHL.

Rhineland, Mo., May 20, 1882.

[The capping of worker bees in queen cells is of such seldom occurrence that it would be difficult to account for it, though we might account for rearing a worker bee, or malformation, in a queen cell.—ED.]

The Honey Season in California.—Bees are now booming on blue sage and fruit bloom, and good help is very scarce. They are doing better than last year. I never had hives filled up so since I commenced bee-keeping, in 1877. I lay it to comb foundation and a choice race of working Italian bees. Some of my queens are so dark that they look almost like black bees, but they give me good workers, all three-banded and uniformly marked; but they do not take so well as the lighter ones. I manage to breed from them annually and select. I have a very good cross from different breeds, and have several queens that throw as fine drones as I ever saw, and the queens are prolific, while the workers are workers. One in particular filled a 10-frame Langstroth hive in 2 days so full that the queen could not find an empty cell. Since our last rain about a week ago, the weather has been fine and warm, and the bloom is profuse. The yard smells of it at a distance from the hives, and it seems like somebody's nice kitchen on cake-baking day. The honey comes clear and fast, and when I see a cluster commencing at the entrance I extract, and take at least 6 out of 10, and often 8, and sometimes the whole 10 frames to empty. I find the honey about 11 lbs. to the gallon. Of course not fully ripe, as I have to extract to make room in the brood apartment. Some hives have 20 frames, and some have two tiers of sections, on some the first being full of honey. The queen did go into the sections until this week, but they crowd her out of them now. I would like to have some one to ex-

plain if they possibly can, a point not in the books. Last season the weather was cool and bad for rearing queens. My queens quit laying Oct. 15; I found no eggs in the hives from then until Jan. 1, 1882. I examined, as I thought, thoroughly. Queens seemed to be all right; noticed in some hives young queens appearing where the old queens were superseded. They ceased laying; tried to rear queens in September and October, but had some drone layers which did not lay until January, and I killed them when I found what they were, except one very fine looking queen. In the fall my bees went to the neighboring wine-presses and got drowned by thousands, and were reduced accordingly. Some colonies were small through the winter, and mostly all old bees in the spring; I kept reducing the hive with division boards made expressly. The young queen (drone layer) quit and had to be replenished occasionally, to keep her along, but did not last. All my old queens had their wings clipped, so I knew when a queen was superseded. I dared not interfere with the young queens until they had laid, and had a good card of eggs and sealed brood, though I marked when the eggs first appeared. Now the strangest part appears—the brood appeared to be worker brood, and so proved, and pure Italians. Explain that if you can. My idea is, the queens remained dormant until spring, when a few stray drones appeared, and the queens got fertilized from them, as I aimed to rear drones early, but the bees were not so minded and were not early. She must have been fertilized late in the spring, or after January. You may be sure I was agreeably surprised, and now some of those queens have their hives full of bees and are as prolific as any as far as I can see, I saved over 100 combs of foundation all winter, besides a lot of full ones. The foundation was all built out. They were not touched by the moth and are all in use now. The full combs I uncapped and gave to the bees as they needed it, and am extracting now. The honey I gave was dark, from goldenrod, and the bees used it in breeding hives full of bees, and the extracted honey is clear and fine, all No. 1. The air is full of bees. So far I am ahead of swarming, though they have plenty of queen cells.

J. D. ENAS.

Napa., Cal., April 30, 1882.

Prevention of Swarming.—I am having trouble with many colonies which I, two weeks ago, prepared for storing honey in top boxes. After following the directions of Mr. Doolittle (whose articles I consider of more practical value than any others I have read), by adding bees and brood to a colony, and then putting on top boxes. The bees commence working beautifully in the top boxes, and then send forth a large swarm, thus depopulating the hive. All work in the top boxes ceases at once. Now, if I wait for the hive to fill up again in the natural way, the honey harvest will be over before the bees commence work again

in the top boxes. What is to be done? I have about 80 colonies, with a fine prospect of a good yield this year.

JOHN W. HINSDALE.

[Use the extractor very freely in the lower story and destroy queen cells, then clip a wing of the queen. In fact, we cannot too highly recommend clipping a wing of the queen when the boxes are put on, whether you find queen cells or not, and regardless of symptoms for swarming.—ED.]

Wild Honeysuckle.—I have had to feed my bees ever since fruit blossoms closed off. I send you a leaf and flower of what I call a wild honeysuckle; what is it? From the long sheath of its flower I supposed the bees would not be able to reach its honey, but I find they manage to split it down, or make an incision near the bottom, and work upon it from morning till night. I also find the spirea opulifolia a good honey plant.

WM. MAXWELL.

Edgerton, Kas., May 23, 1882.

[This is, as Mr. Maxwell calls it, a wild honeysuckle (*Lonicera parviflora*). It prominently differs from two other species, probably found native in the same locality, by its less rank growth and by the shorter tube of the flower. The common name suggests the quantity of nectar secreted and lodged in the bottom of the tubular corolla; but this nectar was evidently not intended to entice the honey bee to visit the flower, the tube being too small for entrance, and too long for this insect's tongue. The manner in which bees do obtain the sweet fluid, as related by Mr. Maxwell, and as often before observed, does show the surprising intelligence of the insect. It is scarcely possible that what is called "instinct" has anything to do with the cutting of the base of the tube from without. Simply crowding down the throat might teach them to split the corolla, and gaining access in this way at times might tempt them to try many other methods. Or we may not be wrong in attributing sense enough to the bee to know what it wanted and to devise at once a process of securing it. At any rate, the lesson is a good one and ought not to pass unheeded by any one who desires to understand the facts of nature, or to be mentally stimulated himself to thought and pleasurable inquiry. As the plant blossoms profusely for some weeks, and secretes an abundance of nectar, *educated* bees may considerably profit by its presence.—T. J. BURRILL, III. Industrial University.]

Use New Honey Packages.—In this part of Nebraska as elsewhere, spring is lagging behind very disagreeably for the bee interest. The greater portion of the weather so far has been cool and chilling, and the bees apparently being anxious to get out, venture forth when it is so unfavorable that they perish by hundreds, and some days even by thousands; but we are feeding a little to stimulate breeding, and thereby our colonies are gaining in strength, notwithstanding the unfavorable weather. Bees passed through the winter in good shape in this locality. The following are some of the reasons why Eastern Nebraska is a favorable place for bee-keepers: About April 1st cottonwoods are in bloom; April 10th to 30th wild and tame fruit, box elder, and, I believe, soft maple. During the fore part of May wild flowers begin to make their appearance, and keep coming more and more until frost; April 15th to 25th willows are in bloom. About this time, if we have attended to business, rape will begin to bloom, which will carry us into clover; then about July 1st. vervain, which grows quite extensively along the streams, gets up a terrible excitement among the little bees, and about July 10th heartsease begins to bloom, which sends everything booming until checked by late September frost. You will readily see that we have fully two months in which to build up our colonies and get ready for the honey harvest. Would you recommend putting extracted honey in old whisky barrels, or would one extreme flavor disagree with the other extreme?

M. L. TRESTER.

Lincoln, Neb., May 18, 1882.

[By no means use old whisky barrels, nor any other second-hand packages for putting nice honey in. If intended for market, you cannot be too careful, nor too tasteful, in the selection of kegs. Any flavor which is not that of pure honey will be found detrimental. We recently sampled some honey which had been sent to a dealer in this city, and put up in a keg that had contained maple syrup. The honey was badly tainted, and both the flavor of the honey and of the maple syrup were so badly neutralized, that several experts unhesitatingly expressed the opinion that it was more sorghum than honey, through some mistake of the shipper, who is one of the most conscientious men in the country.—ED.]

Warranted Queens.—Spring has seemed to come at last. Bees are now at work on apple blossom finely. I have lost several weak colonies from dwindling, owing to the cold weather, but hope that now we will have some good weather. It rained all last night, and is raining still. If it clears off warm I shall be glad, as we needed the rain. I ordered 4 warranted queens a year ago the last of last

April. They were promised to be sent me the first week in May. I received one of the four which was improperly mated. I could not get the rest until the middle of August, and, as 3 of them were put into hybrid colonies, I could not tell for certain how they were. I find this spring 2 of them produce about one-third black bees; one has bees pretty good. One I put into an Italian colony, and knew last fall that she was not pure or purely mated; but it had got to be too late in the season to replace her, so I said nothing, nor have I yet to the breeder. Should he make them good this summer? Or should I lose my money? Answer in BEE JOURNAL.

A. C. BALCH.

Kalamazoo, Mich., May 27, 1882.

[If ordered in reasonable season, and received too late to test last fall, they should be replaced this spring; but if you had ample time to determine their character last fall, you should have promptly reported the facts in the case to the breeder from whom you purchased them, who would undoubtedly have been glad to make the warrant good.—ED.]

Duplicating Eggs.—I have a queen bee which lays from 1 to 5 eggs in each cell. The colony does not seem to do well; is it on that account, or does that make any material difference with brood-rearing? Please answer through the BEE JOURNAL.

Eastville, Iowa. A. L. CONGER.

[If the brood chamber is honey-bound, a prolific queen would be obliged to cease laying or duplicate her eggs in the cells. If there is plenty of room, and she persists in the habit, better supersede her as soon as possible. It is this duplication, whether forced or otherwise, that retards the prosperity of the colony.—ED.]

In the Sweet By-and-By.—May 22—Amid the bursting buds and springing flowers, through the balmy spring days and under the laughing skies, how pleasing the sight and sound of the "blessed bees." Never did the music of their tireless wings seem sweeter, never did the apple blossoms teem with more fragrance, never did the prospect of an overflowing honey crop gladden more the heart of ye lover of liquid sweetness. A year ago I seeded about half an acre to alsike and white clover mixed. It is intended for lawn. I never saw such a luxuriant growth as it has made. If the reality is anything like the prospect, that patch ought to yield half a ton of honey this summer. I have seeded about twice as much this spring in the same manner, and for the same purpose. My object is to make a lawn, and I thought that by mowing twice during the summer I could keep the clover sufficiently short for so large a yard, and at the same

time get two crops of white clover honey. Whether any advantage will be gained by mixing the varieties remains to be seen. May 23—How vain are human hopes and anticipations! Last night there came a frost—"a biting frost"—and to-day the tender things look sick enough. The Manitoba wave struck Iowa, and struck her hard. It will take several days for nature to heal the sick flowers and tender vegetation. Yet I hardly think the apple blossoms are entirely killed. The bees brought in pollen from some source to-day. So we will continue to hope. It is better to hope against disappointment, than to despair when prosperity is possible.

EUGENE SECOR.

Forest City, Iowa, May, 1882.

Winter in May.—This morning found the ground covered with snow to the depth of two inches. So far this season my bees have been able to work only a very few days. Early forage, including fruit bloom, has been almost an entire failure, on account of the cold and wet weather. My bees are rapidly consuming their stores, notwithstanding I am feeding considerable. Bees have to be looked after very closely, as they consume feed very rapidly in rearing brood. White clover promises to be very abundant—saw it in bloom on the 21st. Should the weather turn dry and warm, I shall look for a bountiful harvest.

W. C. NUTT.

Otley, Iowa, May 23, 1882.

Disgusting.—The disgust of beekeepers in these parts was perhaps never greater than it has been with the weather regulations since the freeze-out early in April. Storms, followed by frosty mornings and windy days, kept the bees in or destroyed those that ventured out until many exhausted their stores and had to be fed, and the stimulus of our first honey flow was so great that the queens filled the hives with brood and young bees, so that swarming with some commenced very early, the bees taking advantage of our occasional short spells of good weather to swarm, only to be shut up in a starving condition by succeeding bad weather. After two days of rains, yesterday was a fine day, and the flow of honey for those in reach of the tulip tree the best it has been since the disaster to fruit bloom, in April—what little white clover is in bloom being abandoned for this more easily procured nectar. In looking over one of my colonies yesterday, I found something that so far exceeded anything I had ever seen in my 4 years experience, that I have thought it worth reporting. During our short flow of fruit honey, early in April, this colony was storing up rather better than the others; I put on the second story, with ten sheets of foundation in Langstroth frames. Upon examination, I found that the queen had gone up and taken possession of the upper story and filled eight frames, most of them from end to end and from top to bottom. Supposing that she had entirely

abandoned the lower story, I looked in it, and found six frames, not quite so full, but about as usually found at this time in the spring. If all my queens were capable of doing as well as this, I should consider that the "coming bee" was already here, and would not look any further. This queen is two years old. Most of her bees show only one band, and some not that. Last year this colony gave a surplus of 100 pounds with the extractor, while some colonies under the same conditions, gave little or none.

JOHN C. PEDEN.

Lawrenceburg, Ky., May 24, 1882.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., June 5, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour :

Quotations of Cash Buyers.

CHICAGO.

HONEY—As the season is well advanced, sales of extracted honey are slow and prices remain unchanged. I am paying 7c. for dark and 9c. for light, cash on arrival. Good comb honey is scarce and rules high.

BEESWAX—I am paying 24c. for good yellow wax, on arrival; 18@22c. for medium grade, and 15@17c. for dark.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for extracted honey, in the retail way, is fair, and our sales for manufacturing purposes were very good of late. We pay 7@9c. on arrival. Prices for comb honey nominal and demand slow.

BEESWAX—Brings 18@22c. The demand exceeds the offerings. C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for honey is light, most of the trade finding fault with the best offered, as it is more or less candied. Values are not steady, prices being made to meet the views of the purchaser.

BEESWAX—Scarce, and in demand at 23@25c. R. A. BURNETT, 165 South Water St.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.

BEESWAX—Prime quality, 25c. CROCKER & BLAKE, 57 Chatham Street.

CLEVELAND.

HONEY—There are a good many small lots of very nice white section honey coming in now from time to time. White sells readily at 22c.; second quality 18@20c. Buckwheat, no sale at any price. Extracted, none in market.

BEESWAX—25@30c. A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—Prospects for the coming yield were quite bright earlier in the season, but with no superabundance of moisture in some honey sections, drying winds and frosts have recently made the outlook less promising. However, it is still fair as compared with last year. We note this week a sale of 74 cases extra white extracted, one large can to the case, at 8 1/4c. cash.

We quote white comb, 13@14c.; dark to good, 7@11c. Extracted, choice to extra white, 7 1/4@8 1/2c.; dandelion, 6 1/4@6 3/4c. **BEESWAX**—23@25c. STEARNS & SMITH, 433 Front Street.

NEW YORK.

HONEY—Scarcely anything doing in honey, and prices are entirely nominal. White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.

BEESWAX—The market continues rather quiet, but the supply is light and prices firmly sustained. Western, pure, 24@24 1/2c.; Southern pure, 25@25 1/2c.

D. W. QUINBY, 105 Park Place.

ST. LOUIS.

HONEY—In fair demand. Strained selling at 8@10c.; comb scarce—nominal at 18@22c.

BEESWAX—Prime in demand at 22@23c. R. C. GREER & Co., 117 N. Main Street.

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance :

For 4 weeks.....	10	per cent. discount.
" 8 " (3 months).....	20	" "
" 13 " (6 months).....	30	" "
" 18 " (9 months).....	40	" "
" 23 " (1 year).....	50	" "
" 28 " (1 year).....	60	" "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club :

For a Club of 2,	a copy of " Bees and Honey."
" " 3,	an Emerson Binder for 1882.
" " 4,	Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,	" " cloth.
" " 6,	Weekly Bee Journal for 1 year, or Apiary Register for 200 Cols.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

When changing a postoffice address, mention the old as well as the new address.

The postal law makes the taking of a newspaper and the refusal to pay for the same, theft, and any person guilty of such action is liable to criminal proceedings the same as though he had stolen goods to the amount of the subscription.

THIS PAPER may be found on file at Geo. P. Rowell & Co.'s Newspaper Advertising Bureau (10 Spruce St.), where advertising contracts may be made for it in **NEW YORK.**

Advertisements.

Stanley's Vandervort Foundation.

We are now prepared to furnish our heavy and light foundation at the following prices: Heavy foundation, cut in any size frame, running about 5 feet per lb., with high side-wall, 43c. per lb. Thin foundation, made on the light or high-walled mill, 55c. per lb.; 10 per cent. discount on 100 lb. lots, if cut all one size. G. W. STANLEY & BRO., 23w4t Wyoming, N. Y.

CAGE AND TRAP for Containing the Queen while Clipping her Wing.—Any person that can open a hive and find the queen can, with this device, clip her wing without danger of killing or injuring her in the least. Price by mail, postpaid, 30 cents; 4 for \$1. Dealers send for price list by the quantity. **F. H. FUNK, Beverly, Adams Co., Ill.** 23w4t

FOR SALE,
One of the Largest Manufacturers
OF
Apiarian Supplies in the World.
35 Hands now Employed.

Here is an opportunity for one or two bee-keepers to obtain a good business. My reason for selling is that I am disabled. For information address "S," care of the Bee Journal, Chicago, Ill., who will forward the correspondence to me. 23w4t

NEW IDEAS.

Foundation ready for business, sheets bound with a light wooden rim, sample 6c; Bee's Tongue Register, sent by mail for \$2.25; Italian Queens improved by a new process; Italian or Black Bees for sale in a hive adapted to migratory bee-keeping—can be securely closed for moving in one minute. For particulars address, 9amly **JOHN H. MARTIN, Hartford, N. Y.**

Excelsior Dunham and Vandervort
FOUNDATION.

Owing to the large advance in the price of wax, I now quote prices thus: Dunham, 10 to 50 lbs., 42c., over 50 lbs., 41c., less than 10 lbs., 44c.; Vandervort, 10 sq. feet to the lb., 1 to 10 lbs., 57c., 10 to 50 lbs., 54c. No discounts. Circular free.

A NEW BEE BOOK!
Bees & Honey

OR THE
Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN,
Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasture a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—Newa, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Palaski, Teon.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

H. H. BROWN,
Light Street, Col. Co., Pa.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal stand for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 15x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Lang-troth " " 10x18 " ".....	8 00
For 3 " " " " 10x18 " ".....	10 00
For 4 " " " " 10x18 " ".....	14 00
For 2 frames of any size, 13x20 " ".....	12 00
For 3 " " " " 12x20 " ".....	12 00
For 4 " " " " 13x20 " ".....	16 00

ALFRED H. NEWMAN,
923 West Madison Street, Chicago, Ill.

I wish to buy a quantity of good yellow Beeswax. I am paying 24c. per pound, delivered here, Cash on arrival. Shipments solicited.

ALFRED H. NEWMAN.

HIVES AND SECTIONS.

We are in better shape than ever to furnish Bee Hives and Sections, having remodeled our machinery, and put everything in tip-top order for the coming season. We make a specialty of our

"BOSS" ONE-PIECE SECTION.

We have not sold any rights to manufacture, therefore we are the sole manufacturers in the United States. Send for Price List.

JAS. FORNCROOK & CO.

Watertown, Wis., Dec., 1881.

NOTICE—Some persons having infringed upon our Patent "One-Piece Section," we hereby give notice, that we shall prosecute all manufacturers. We shall not molest bee-keepers for USING those purchased before Dec. 1st, 1881, but hereby caution them against buying any except those bearing our stamp. It has been reported by some that it is our intention only to prosecute bee-keepers for using those One-Piece Sections heretofore purchased; this is wholly untrue and false.

Our experience dates back to the first experiments of Mr. Langstroth in the movable comb system. Send for our price list of bees, queens and supplies, before making your purchases for 1882. Address, WM. W. CARY & SON, 1m6t Coleraine, Franklin Co., Mass.

Friends, if you are in any way interested in BEES OR HONEY

We will with pleasure send you a sample copy of the Monthly *Gleanings in Bee-Culture*, with a descriptive price-list of the latest improvements in Hives, Honey Extractors, Comb Foundation, Section Honey Boxes, all books and journals, and everything pertaining to Bee-Culture. *Nothing Patented*. Simply send your address written plainly, to A. I. ROOT, Medina, O.

1882.--QUEENS--1882.

I am now booking orders.

Warranted Italian Queens \$1.00, six for \$5.00; Tested do., after June, \$1.50. Cyprians. Unwarranted, \$1.00, six for \$5.00. Send for circular giving description and recommendation from Postmaster and county officers. Money order office, Versailles, Ky. J. T. WILSON, Mortonsville, Woodford Co., Ky. 1mf

C. OLM's Comb Foundation Machine.

Send for Sample and Circular. 18mf C. OLM, Fond du Lac, Wis.

Italian Bees, Queens and Sections.

Untested Queens, in May, \$1.50 each; in June, \$1.25; July and after, \$1 per dozen, after July 1, \$1.0. Sent by mail, with directions for introducing. Italian bees by the half pound, same price as untested queens. One 3 comb nucleus, without queen (Gallop frames), in May \$3, June \$2.50, July and after \$2; 2-comb nuclei, with the standard Langstroth frames, 25 per cent. more. Sections—Planned dovetailed sections, 4x4x1 1/2, \$4.50 per 1,000; 5x5x1 1/2, \$5 per 1,000. Sections of this thickness do not need tins between them to insure straight combs, and the bees can ripen up and seal honey faster than in combs with deeper cells. See testimonials in March number of *Gleanings*. Please remit by P. O. money order, by registered letter, or by draft on New York or Chicago. Address, O. H. TOWNSEND, 19mf Kalamazoo, Kalamazoo Co., Mich.

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 30th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,
925 West Madison Street, CHICAGO, ILL.

The Bee-keeper's Guide;

OR,

MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book;

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—LEWIS T. COLBY.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—J. P. WEST.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—E. H. WYNKOOP.

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—A. E. WENZEL.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—W. VAN ANTWERP, M. D.

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—L'ABBE DU BOIS, editor of the *Bulletin D'apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *volume mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

EARS for the MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small **White Shark**, caught in the Yellow Sea, known as **Carcharodon Rondelati**. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years on Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better. I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Day Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by **THOMAS G. NEWMAN,** 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Aptary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quahy's New Bee-Keeping, by L. C. Root— This author treats the subject of bee-keeping as that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root— This embraces everything pertaining to the care of the honey-bee, and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.— This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee— This is a standard scientific work. Price, \$2.

Bleesed Bees, by John Allen.— A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.— Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Dzierzon Theory— presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.— This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.— This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof. C. C. A. Essay, which is here given in full. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use.— Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.— A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman.— Giving advanced views on this important subject, with suggestions what to plant, and when and how. Illustrated with 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a legislative act for consumer protection. It contains many health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.— No book could be more useful to horse owners. It has 35 engravings illustrating positions of the horse, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.— A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 industrial facts, calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., June 14, 1882.

No. 24.

ESTABLISHED IN 1861

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

Published every Wednesday by

THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR.

925 WEST MADISON ST., CHICAGO, ILL.

At \$2.00 a Year, in Advance.

WEEKLY—(52 numbers) \$2 a year, in advance.
Three or Six Months at the same rate.

Any person sending a club of six is entitled to an extra copy (like the club) sent to any address desired. Sample copies furnished free.

Free of postage in the United States or Canada.
Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

Prospects Brightening.

Cheerless and unpropitious as has been the weather, and despite the numerous complaints regarding the backwardness of spring many are beginning to realize that all has been for the best. Last Thursday (8th inst.) we observed an Italian bee working satisfactorily on the few white clover blossoms which have yet made their appearance in this locality; and it was the more gratifying, from the fact that the blossoms were quite fresh, and the nectar secretion had come to the surface almost simultaneously with the unfolding of the petals. While the rain and cold have in places disappointed many who anticipated a surplus from fruit bloom, they will prove to have been a blessing in massing and invigorating the white clover sward, and in strengthening the fibers for a greater honey secretion. Last spring our first observation of a bee upon white clover blossoms was June 10th; so, notwithstanding unfavorable weather, we are still two days in advance this year. But it will be fully a week or more before white clover will be in general bloom with us. We must credit Mr. C. H. Dibbern, with the first shout of joy, dated Milan, Ill., June 7, 1882, as follows:

We are now having some "glorious days" for the bees. White clover is just coming into full bloom. Bees are working in sections and swarming. Everything is now favorable for a good yield.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

The report of the Department of Agriculture for June announces a decrease of 17 per cent. in the acreage of spring wheat. Winter wheat averages 100 in condition, and there is now a strong probability that both varieties will give a very satisfactory yield, being exceeded only by the crop of 1880. Corn planting in many of the States was not completed by June 1st, but a large increase in acreage is reported. The prospect for oats is most excellent, and the acreage is increased 7 per cent.

H. A. Burch, we learn, is endeavoring to redeem his reputation by filling some of the orders received and not filled last year. We shall be glad to learn that all are filled, and hope all who get anything will report to us, not necessarily for publication, but that we may have the facts.

In the last number of *Gleanings* the editor says: "Everybody now seems prospering in the bee business, and I hope this season to see nice honey offered at so low a price that it may come more into general use than it has ever done any season before." Many times have we expressed the conviction, that the consumption of honey was daily becoming more popular, and that its economic value as an article of food was being more generally appreciated, and for this reason we should greatly deplore an unusual shortness of product, or an exorbitant price; but we quite as sincerely hope the price will never become so depreciated as to make its production unremunerative. Better have a fair average crop, and good price for it, than a plethoric yield and a meager profit. But the market cannot be surfeited.

The price list of queens and bees of J. D. Enas, Napa, Cal., is received.

A "Scientific Plesantry."

On page 243 of the BEE JOURNAL we published, under the heading "Blunderers in High Places," an excerpt from the *Indiana Farmer*, attributing reckless language to Gov. Porter, of Ohio, and unscientific assertions to Prof. Riley. A recent number of the *Farmer* reprints our article with a criticism or rejoinder from a Mr. H. W. Wiley, which is certainly original in its style, if not very witty. Following are his remarks:

The above extract from a recent number of the BEE JOURNAL, is such a successful piece of humor that one not acquainted with its origin, should assign it to Mark Twain.

"Glucose" has the same effect on the BEE JOURNAL man that a red rag has on an infuriated bull, and it is decidedly amusing to see the awful anger which this innocent *taffy facient* can produce.

As I am probably the person meant by the "Prof. Riley" alluded to in their mellifluous effusion, I think it but just to the eminent entomologist of the agricultural department that I should relieve him of all responsibility for the "recklessness" which seems about to destroy his "posthumous reputation as a scientist."

I am perhaps also directly responsible for the "gross blunders" of Gov. Porter, and so I hasten in *propria persona*, and not as Prof. Riley, to take the whole burden of the BEE JOURNAL'S wrath on my own feeble shoulders. Perhaps it may be well enough to give here the origin of the "paraffine comb" story which has appeared, I believe, in almost every publication in the country. The original appeared in the *Popular Science Monthly* for June, 1881, in an article entitled "Glucose and Grape Sugar," which I contributed to that number, and on page 254, occur the following words: "Bees eat glucose with the greatest avidity; or rather, they act as funnels by which the glucose is poured into the comb. For it is quite true that honey made by bees which have free access to glucose differs scarcely at all from the glucose itself. But the quantity of honey which a bee will store away when fed on glucose is truly wonderful. This gluttony, however, rapidly undermines the apiarian constitution, and the bee rarely lives to enjoy the fruits of its apparent good fortune. In commercial honey, which is entirely free from bee mediation, the comb is made of paraffine, and filled with pure glucose by appropriate machinery."

This last clause which, when written, was meant for a scientific plesantry, came near throwing the whole bee world into epilepsy. It appears that persons who devote themselves to BEE JOURNALS undergo a certain cerebral inspiration which renders them incapable of seeing a joke. The only point which they can appreciate seems to be the sting of a bee. Governor Porter, in his able and inter-

esting address, said something similar to the above, and succeeded, as he intended, in raising a hearty laugh. I am appalled to think of the awful solemnity with which the Governor's remark would have been received had his audience been composed exclusively of editors of the BEE JOURNAL, instead of the intelligent yeomanry of Bartholomew county.

Governor Porter, however, did say that an eminent apiculturist told him that he could only tell genuine from artificial honey by the after taste of formic acid which the genuine honey left in his throat.

Perhaps in order to secure a "posthumous reputation," for which I care little, I might undertake here to show the BEE JOURNAL the great similarity between genuine honey and good glucose, but I fear it would be "love's labor lost." He is evidently suffering from an acute attack of gluco-phobia, and what I might say with the best intentions would only throw him into another spasm. When in "posthumous" times he shall send on those vast expanses of flowerful clover to which all good bee journal editors go, and live off of ethereal "milk and honey," let us hope that he may never find his milk chalk-water, nor his honey glucose.

H. W. WILEY.
Lafayette, Ind. (late Riley).

The rejoinder reminds us of an anecdote we heard many years ago, located in a rural district in Indiana. A well-to-do farmer lost a very fine filly from his pasture-lot, and after several days' search found it snugly tied in the log barn of a distant neighbor of doubtful repute. The neighbor was indicted, tried, and found guilty of larceny; when the Judge asked what he had to say, why sentence should not be passed, he put in a plea that the animal was only taken for a joke. The Judge inquired how far his barn was from the pasture lot, to which he replied, "about 5 miles." "Well," said the Judge, "that is carrying a joke too far; hard labor in the penitentiary for seven years." The writer above says he contributed to the *Popular Science Monthly* his "paraffine comb" story [lie] about a year ago, "which has appeared in almost every publication in the country." The latter part of the article, however, was only meant for a *scientific plesantry*.

Do scientific men indulge in plesantries which will cast a gloom over thousands of honest producers throughout the country, and depreciate the value of their product by creating a prejudice against it? For nearly a year this *scientific joker* saw his fabrication published in nearly all the papers in the country, and reiterated from across the ocean, and yet he

lacked the manhood to affirm it a joke until the "BEE JOURNAL man" counteracted its influence by showing the falsity and absurdity of the article. Whether it be true, as has been often intimated, that the story was instigated by parties interested in the glucose traffic, in retaliation for the hostility of the bee men to their frauds, we cannot affirm; but we do believe it originated with no honest intention. It is quite probable the article would never have attained the dignity of requiring a refutation, had it appeared in a less accredited authority than the *Popular Science Monthly*. And considering the author's *waggish* propensities, can it be possible he furnished the *Indiana Farmer* the item attributing to Prof. Riley the utterance of his own falsehoods? Evidently the *Farmer* placed too much confidence in the veracity of some one other than their own reporter. That paper, in its issue of the 10th inst., alludes to the article above, and evidently as deeply deplores Mr. Wiley's tergiversations as do all others honestly inclined. Quoting after the "street gamins" it says, "Shoot the 'scientific plesantry'."

Could any possible good result to society at large from such reckless assertions, there might be some palliation; but when the only justification which can be urged is that it was intended as a "scientific plesantry," it leaves the author but little to congratulate himself upon, even though he has succeeded in disgusting the world. H. W. Wiley (late Riley) has earned for himself a posthumous reputation, which will stand second only to that of his illustrious prototype, Ananias.

Mr. Peter Brickey, Salvisa, Ky., has sent us a portion of a frame exhibiting his method of fastening foundation for the brood chamber. He makes a V-shaped groove in the center of the top-bar, stands the foundation on edge in this groove, and fastens it by pouring melted wax along the sides, in the groove. The work is very neatly performed, and quite as substantial as comb itself. After the frames are prepared, we should think the work could be rapidly done.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Oleomargarine Before Congress.

The Associate Press dispatches from Washington, of the 8th inst., contain the following paragraph:

The house committee on commerce will hear representatives of the oleomargarine interest to-day against the bill to regulate the exportation of articles made in imitation of butter and cheese. The committee will either report this bill as it now stands or amend it so as to better insure the accomplishment of its purposes. The bill requires the word "oleomargarine," "sueine," "butterine," or some other word as may be proper to designate the article, to be branded on every tub, box, firkin, or package for shipment to a foreign country, containing any article or substance in the semblance of butter or cheese, not the actual product of the dairy and not made exclusively of milk and cream, but into which the oil or fat of animals not produced from milk enters as a component part, or into which melted butter or any oil thereof has been introduced to take the place of cream. The penalty for a failure to brand, mark or stamp such articles and filing in the custom-house a manifest thereof is \$1,000, one-half of which is to go to the informer. The bill provides that the secretary of the treasury shall appoint an inspector of dairy products for the port of New York and for any other port where he may deem it necessary. Under the bill the collector shall not grant any clearance for a vessel on which is found any of these unbranded articles until the same are properly marked and described in the manifest.

We sincerely hope the committee on commerce will report the bill back recommending its adoption. If the precedent is established regarding its exportation, as a commercial necessity, then it is subject to Congressional legislation as between the States, and it opens the way for restrictions upon the glucose traffic, and all poisonous adulterations, not only as a sanitary measure, but as a commercial necessity. We are still of good heart concerning the "good time coming," when commercial transactions will mostly be carried on honestly, many from conscientious dictation, but generally from compulsion—when it will be declared a punishable offense to sell bogus honey and butter.

The Chicago *Evening News* of June 8 has the following suggestive paragraph:

Owing to the depression in the glucose and grape-sugar trade, the national association, at a meeting in Chicago Wednesday, appointed a committee to devise plans for consolidating all the factories.

Whether the depression in the trade is owing to competition, or is indica-

tive of a growing disfavor we are not informed, but it is probably attributable to both causes; nor are we told what benefit they expect to derive from consolidation, unless it be to concentrate all their energies in the way of bribing legislation, and to resist the growing hostility which will ere long assume form and demand legislation from Congress to regulate the glucose traffic, and protect honest consumers from their poisonous adulterations.

Curiosities of Bees.

The London *Times* gives its readers the following as some of the "curiosities of bees," which were believed in ancient times. The modern bee-keeper will smile (and perhaps audibly, too) at many of the statements:

According to Virgil, Jupiter gave the bee its marvelous habits, because bees fed him with honey when, as an infant, he lay concealed in the Cretan cave from his father's search. The Curetes, a Cretan tribe, used to dance round the babe and drown his cries by rattling brazen cymbals, whence comes the origin of swarms of bees at the present day being pursued with much clanging of kevs against frying pans, the belief being universal that this noise is agreeable to them. Indeed, Pliny, with questionable logic, argues, because this clatter is always made when bees swarm, therefore they must be gifted with the sense of hearing.

Kirby, who wrote a most valuable monograph on bees, estimated that there are about two hundred and fifty species of them in England.

It is generally supposed that those bees which are peculiar to the New World are destitute of all offensive weapons. Humboldt, however, explains that they have stings, though comparatively feeble ones, and they use them very seldom—only, in short, when irritated and forced to defend themselves. While seated on the peak over Caracas, in South America, he tells us, "determining the dip of the needle, I found my hands covered with a species of hairy bee, a little smaller than the honey-bees of the north of Europe. These insects made their nests in the ground, they seldom fly and from the slowness of their movements I should have supposed they were benumbed by the cold of the mountain. The people call them *angelitos* (little angels), because they very seldom sting" (*Cosmos*, i. 435).

Among the numerous tribes of leaf-cutting and mason bees common in England, most possessors of gardens must have noticed the ravages of the *megachile centuncularis*, one of the former class. It is much smaller than the hive bee, and cuts little segments, as clear as if punched out by a machine, from the leaves of roses and peas. The operation is very speedily performed when the bee has once made

her choice; the strong mandibles go to work, and soon the bee flies off with her green load. If followed, it will be found that her nest is situated in some palisade or gate-post. The creature runs her tunnels into the wood by means of these same powerful jaws, and then lines them with the pieces of leaf. They are not fastened together, but the cells are honey tight, and as fast as they are lined with leaves, an egg is dropped into each. Perhaps Virgil, Pliny, and the other ancient writers who speak of bees carrying ballast to steady themselves in windy weather, had witnessed the doings of leaf-cutting bees, and confounded them with hive-bees.

The working bee never lives longer than nine months; they labor so incessantly it is supposed they never sleep. The daily consumption and waste of a large hive of bees in summer may be taken at two pounds of honey; it will show the industry of the working bees to bear in mind that, beyond this, such a hive in favorable weather will often accumulate honey to the amount of four and six pounds daily. Indeed it is upon record that a hive once gained twenty pounds weight of it in two days!

It is curious that even wild bees can soon be taught to recognize and refrain from attacking people who approach them. No wonder that the ancients esteemed them as divine; that their poet laureate, according to the Platonic philosophy, assigns them "a participation in the Supreme mind and in heavenly influences;" and that another speaks of their power of presaging wind and fine weather. Modern science points out that the fructifying of many flowers is due to the labors of bees in mingling the pollen; and most gardeners must have noticed the difficulty of preserving a pure strain of any plant when these active workmen have access to other varieties of it.

Mr. James A. Daniel, of Alexandria, La., has our thanks for a copy of the New Orleans *Times-Democrat*, detailing the mode of making glucose by a new process, as recently discovered by a couple of gentlemen of that city. As the names of the chemicals employed are purposely withheld, we draw the inference that it is no improvement on the vile stuff now in use, and has nothing to recommend it, except, perhaps, that it is a cheaper and quicker way of producing it.

Mr. Robert Corbett, Manhattan, Kans., has our thanks for a very fragrant bouquet, composed of roses, acacias, spirea, Indian currant, and other flowers. It is gratifying to observe the growing interest being manifested, by bee-keepers, in Nature's most pleasing work—the flowers.

MISCELLANEOUS.

Building Straight Combs.—The *Indiana Farmer* remarks thus on this subject:

All colonies which have been hived in empty frames should be examined frequently to see that they are building the combs straight in the frames. Hives should set perfectly level from side to side. A very good plan is to elevate the rear end of the hive three or four inches. The bees will commence at the highest point to build the combs. After they have built the combs about half way down the frames, turn each alternate frame end for end. This will throw the empty end of the frames between the pieces of comb built in the other frames, and will almost insure the balance of the combs to be built straight. Should you find they have built the combs a little crooked push them back in place, if too far gone for this cut them loose and tie in place as in transferring. Much care should be given to have all the combs built perfectly straight at the start, thereby saving much trouble and vexation in the future. The combs must be straight to secure the benefits pertaining to the movable frames. For unless the frames are really movable, exchangeable, they are of no more benefit than box hives.

Dzierzon Theory.—Mr. B. F. Carroll, Dresden, Texas, gives the following in the *Texas Agricultural Journal*:

I am skeptical about one feature in the Dzierzon theory. The ninth proposition is: "All eggs germinated in the ovary of the queen develop as males, unless impregnated by the male sperm while passing the mouth of the seminal sac or spermatheca when descending the oviduct. If they be thus impregnated in their downward passage (which impregnation the queen can effect or omit at pleasure), they develop as females." I claim that all the eggs are impregnated, male and female, or they would not hatch into a live insect capable of reproduction. What I deny is that "common or black queens fecundated by Italian drones, produce mixed or hybrid workers, indeed, but pure common or black drones exclusively." I claim, and with as much show of truth, that if the male progeny of a mammal, and especially our domestic fowls, is tainted by mismating, then we may expect the same of the honey-bee. I claim that the male bee is produced by the egg receiving a certain kind of very thin mucoid—which is enough to satisfy nature, and whenever a queen is mismated her drones as well as her worker progeny, will be hybrids.

Last spring I began operations with twenty colonies. Nearly all had

daughters of imported mothers—except four purely marked home-bred Italians, and one pure Cyprian mismated. Three of the queens were mismated, or in other words, were fecundated by black drones. I reared 20 young queens from a pure Cyprian, and some of these, I am satisfied met drones from the mismated queens, as one of the hives had nearly as many drones as the other nineteen, and their bees show plainly the black blood. All the the queens—four in number—that met the half-breeds, show that they are not pure, as many of their bees show only one and two yellow bands, and hardly any full black.

I claim the above as facts demonstrated in my yard in 1881, and it is no pet theory, but direct from the hive. If the Italian bee is only a "thoroughbred," as some assert, the facts are more easily proven. A cross between a pure Italian queen and a German drone, and a drone from this mismated queen crossed on a pure Cyprian queen, (which is a pure race) will produce a beautiful bee, but now and then the unmistakable signs of the original Dutch "granddad" will crop out, to prove to all who will believe the truth as I see it, that the theory of parthenogenesis in the production of the male bee is without foundation.

Canadians Beware of Glucose.—The *Rural Canadian* gives the following note of warning:

In view of the following advertisement which appears in the *Globe*, we must now keep a sharp look-out for adulterations of Canadian confectionery and honey:

"Glucose! Glucose! Glucose!—The Edwardsburg Starch Company now offer to the trade the finest quality of glucose, equal to any imported. Canada Grape Sugar Works, Cardinal, Ont. Office—Montreal."

Long before there was any need to do so, many of our people hesitated to buy extracted honey lest it might be mixed with glucose. The public should know that it is not at apiaries, but in city factories, that this adulteration is done. Our bee-keepers are alive to the mischief, and will brand their honey so as to guarantee it against vile admixture. Let honey buyers purchase only of known and responsible bee-keepers, and they will be all right.

Honey Crop in the South.—The *Planters' Journal of Vicksburg* says:

Bees throughout all portions of the Southwest are reported to be fine, healthy and in most excellent working condition. The amount of forage is large, and honey-making material abundant. There is a good prospect, and promise is that the crop of honey will be very largely in excess and superior in quality to that which has been produced in former years. A special reason, however, for this, is explained in the fact that the interest

in this industry is increasing in the South, and bees are being more extensively cultivated than formerly, all of which is gratifying to the *Planters' Journal*, which takes a lively interest in this specialty.

For the American Bee Journal.

Reply to Dr. L. James.

G. M. DOOLITTLE.

As Dr. James wishes to know how I manage to manipulate my bees in early spring (see page 329) without the intrusion of robbers, I will say: As a rule I do not find it necessary to open hives to any great extent till pollen becomes plenty. In most localities pollen is obtained from 6 to 8 weeks in advance of the main honey harvest, and as 6 or 8 weeks gives me time enough to stimulate the bees, thereby getting them ready for the harvest, I do not disturb them to any great extent till their disposition for robbing has become in a measure changed to that of pollen gathering. When busy gathering pollen, I find but little difficulty in opening hives as much as I please; still, by a little carelessness on my part, even with plenty of pollen, I am sometimes obliged to suspend operations during the heat of the day.

The point is just this: If we can so manage that no bee can get the first taste of honey, and maintain such a state of affairs all will go well; but if 2 or 3 bees get home with a load of stolen honey, we shall soon be obliged to suspend operations from the cloud of robbers which follow us. To illustrate: This spring I had been at work with the bees several days without trouble, when one day I set a comb down behind a hive for a moment, thinking to use it so soon that it would be useless to set it inside the box I always carry with me at this time of year to hold such combs and all scraps of honey which are trimmed off. When I wished to replace the frame in the hive, supposing I had set it in the box I opened the lid and took one out of there. As it was just about noon I was soon called to dinner, and, of course, left the comb where I had set it. When I came out from dinner the first thing I heard was the shrill noise of robber bees, and not knowing why I should see bees trying to get into many of the hives at the back side, I went into the bee yard to see what the trouble was. I was not long in finding my comb black with bees and quite angry at myself to think I had been so careless. Nearly a week elapsed before I could work with my bees again without a cloud of bees ready to pitch into every hive as soon as I opened it.

If I am obliged to open hives before pollen is plenty I do it after the bees

are mostly through flying, in the latter part of the day. Also 2 or 3 can be opened every two or three hours, even in the middle of the day; but as a rule, I open but few hives before pollen is plenty. At this time I provide myself with two boxes made for the purpose, one of which is to be used to convey combs from the shop to the bee yard and hold them secure from the bees while I am at work, and also hold all bits of comb which I have occasion to trim off. The other is used to set the combs in which are first removed from the hive in order to give room to manipulate the rest, thus keeping all secure from the outside bees; it is also used in carrying brood to strengthen feeble colonies, and for all purposes where bees, brood and honey are to be kept outside the hive.

By thus working I have no trouble, as a robber bee is sure to be caught as soon as he touches the top bars to the frames occupied by Italian bees. If a colony is weak in bees, the quilt is left to cover all the frames which do not have bees enough on them to protect them. Another point is, do not smoke the bees only just enough to keep them quiet, for if you smoke them enough to get them to running, they will "dive" for the honey, and also let the robbers "dive" for it, too. By thus using care, I get along nicely, while one careless move like the above keeps me away from the bees for nearly a week, only as I open a hive or two at a time, and work after the bees have mostly ceased to fly.

Borodino, N. Y.

London Journal of Horticulture.

The Heath Bee and the Caucasian Bee.

G. DATHE.

[The following paper was written for the Cologne bee meeting, but in consequence of the death of the author was not delivered, and has been published in the *Bienenzeitung*, from which this translation has been made.—ALFRED NEIGHBOUR.]

I have no intention of drawing a comparison between the Heath bee and the Caucasian bee; I only wish to give a short account of my experience as regards the two varieties of bees.

To begin with the Heath bee. The demand for Heath bees has been very much on the increase lately, though this is certainly not due to any special recommendation, and it no doubt proves that the good qualities of these bees are becoming more appreciated. It is a peculiarity of the Heath bees that they increase largely and give off many swarms, for which reason they are especially suitable for those beekeepers who are anxious to increase their colonies, and therefore rejoice to see their bees swarm frequently. But the Heath bees do not only give off many swarms, they also collect large quantities of honey, as may be seen in the Luneburg Heath district. In no part of Germany is the honey

harvest so large as it is there, for while in other parts of the country pots suffice to hold the honey which the bees collect, the Luneburg Heath bee-keepers are able to fill many casks. People are therefore disposed to look upon the Luneburg Heath as an "El Dorado" where honey is always flowing, but this is by no means the case. While in some districts a populous colony will collect 10 lbs. of honey in one day when pasture is plentiful, the outside maximum at Luneburg is 48 per day. Nor does the Heath yield honey uninterruptedly all the time it is flowering. We are satisfied with an average of 12 fine days for utilizing the Heath; if there should be any lightning while the Heath is flowering, it frequently puts an end to the visits of bees. In many a year the honey harvest from the Heath is next to nothing. The Heath bee-masters know how to alter their method according to circumstances, and this is the principal cause of their harvesting such large quantities of honey. This affords me an opportunity of giving a few hints as to the management of Heath bees in case of their introduction into other districts:

They are particularly suitable where the native bees do not swarm sufficiently. By simply intermixing the two races their hybrid offspring show somewhat more inclination to breed and to give off swarms. The bee-keepers' first and foremost endeavor should be to obtain swarms as early and as large in population as possible, and this he will be able to accomplish if those hives from which he intends the swarms to issue are fed simultaneously with a quarter to half pound of honey two to four times a week, commencing four to five weeks before the time of swarming, continuing the feeding until the first swarm has been given off. Should unfavorable weather set in about the time of swarming and continue, the first swarm might be driven off.

The first swarm will have sufficient population to form a separate colony, but the swarms that follow—and the size of which becomes smaller the greater the number that leave the parent hive—should be united so as to form colonies weighing at least 3 lbs. each. This is the more necessary in districts where there is no autumn pasture, but unfortunately this advice is very often not attended to. Every swarm, however small it may be, is frequently placed as a separate colony, and if it proves a failure people get dissatisfied and blame the Heath bees. When second swarms are put into wooden hives and can be assisted with a brood comb or two from other hives, they need not of course be made quite so large. When bees are found to make preparations for swarming, the drone comb both with and without brood and royal cells should be removed until the bees no longer show any inclination to swarm. If Heath bees are treated in this manner, it will be found not only that they increase largely in population, but also that they are able to collect large quantities of honey.

I will now proceed to make a few remarks on the Caucasian bees. I must frankly confess that I had lately become somewhat prejudiced against the introduction of new races of bees. I always found them highly recommended, but on close examination they generally did not come up to my expectation. For the same reason I was prejudiced against the Caucasian bees, and was doubtful whether I had better procure some. While in this state of uncertainty, I had a visit from Dr. Butlerow, Councillor of State of St. Petersburg, on his return from France, who requested me to give the Caucasian bee a trial, promising to send me two queens for this purpose from the Caucasus in the following spring. The two queens, each accompanied by a small colony and a supply of honey comb, arrived here in excellent condition last spring, and were placed at the head of two populous colonies of German bees, the Caucasian bees being allowed to unite with the German. My first experience with the Caucasian bees was that they unite with the German bees without exhibiting the least signs of hostility towards each other. The attempt made a few years ago to unite Cyprian and German bees in the same way resulted in the attack by the Cyprian on the German bees, which, in spite of all means of protecting the latter, continued for several weeks, until all the German population had been killed. My second experience was that they are very prolific and quite as fertile as the best colonies of Heath bees and the Italian bees.

The other qualities of the Caucasian bees could not be determined with accuracy until all the German bees had died off, leaving only Caucasians in the hive. With regard to their docility, which has been praised so much, I am able to state that they are very docile indeed. They do not sting when handled as bees generally are. I asked my son to irritate them, which he did, and I saw them buzzing about his face with the well-known angry sound, indicating that they were ready to sting, but they did not sting him. After several repetitions, one bee was at last induced to sting. We may therefore say, as a rule, the Caucasian bees do not sting, but if they are irritated they are capable of doing so. Because the Caucasian bees do not sting they have been supposed to be very phlegmatic bees, which would neither defend themselves against robbers nor collect much honey. But they are not phlegmatic; on the contrary, they are very quick and industrious. As soon as they make their appearance at the entrance of the hive, they at once fly off to the fields, and on their return are in as great a hurry to enter the hive. On the outside, the entrance is guarded by but few bees, but these are quite able to keep robbers away. Nor are the Caucasians, like other bees, to be seen in large numbers about the entrance of the hive in very hot weather; as they are very industrious, it is only natural that they should collect a large quantity of honey. As far as my own experience goes, I consider the Cauc-

sian a very good race of bees, which deserved to be introduced into Germany; but whether they will stand our winter well and prove satisfactory in every respect, the future alone can show.

Eystrup, Germany.

For the American Bee Journal.

The Dry Feces of Bees.

WM. F. CLARKE.

I wish to call attention to the fact that three eminent apicultural authorities have recently given their evidence to the effect that bees when thoroughly healthy, void their excrement in a dry, powder form.

The first is Mr. Abbott, the editor of the *British Bee Journal*. In *Gleanings* for May, he expresses himself as being "rather amused at the apparent uncertainty" which exists in America as to whether bees void dry excreta, and says, that a "swarm-box" in which bees can fly, will be found after their confinement therein for 24 hours without comb, with thousands of grains of bee excreta, about the size and color of coarse gunpowder, on its bottom. He adds that "when bees travel with combs the case is different. They appear too cleanly to foul them, and hence protracted confinement produces what, for want of a better term, we call 'dysenteric symptoms.'"

Mr. A. I. Root in some editorial comments on this communication, says, "it occurs to me that bees that have been sent to us almost invariably show something on the bottoms of the boxes that both sight and smell would have little difficulty in pronouncing excrement."

Mr. Gallup, in the same number, adverts to this matter when speaking of the manner in which bees would winter in old style hives, with a crack from top to bottom. Even "when the thermometer was 40° below zero, blow in the hive, or jar it, the bees would fly out as quickly and readily as bees do in the heat of summer, and you know, Mr. Editor, that when a bee flies out and is blinded with snow, he alights on his back, kicks up his heels, and just before he dies, discharges the contents of his abdomen. I have seen 'em do it in thousands of instances, and it was dry and powdery like, so much so, that it would not adhere to or smear anything." etc.

While I consider this third witness a highly credible one, I must confess that there is a dash of bigotry in his testimony which I do not admire. He goes on to say that "any bee-keeper in Maine, New Hampshire, Vermont, Northern New York, or Canada, who has not seen bees discharge dry, powdery excrement under the above conditions, is not and cannot be a very close observer." I am glad Michigan was omitted from this enumeration of localities, for do we not know that there are those in that State who not only can be but are very close observers, yet they have never seen what Mr. Gallup describes.

This matter is not one of curious

interest merely, but highly practical. When we have discovered the conditions under which bees discharge dry feces only, we shall have solved the problem of successful wintering. For I do not believe with Mr. Abbott, that "protracted confinement" produces "dysenteric symptoms" if the bees are in such a state that they can void dry excreta. These appear, I have little doubt, only when the digestive apparatus of the bee has become, from some cause or other, disordered and diseased.

Listowel, Ont., May 19, 1882.

Iowa Homestead.

A Few Hints to Beginners.

HENRY WALLACE.

In these days of adulteration one of the most essential requisites of the farmers' home is pure, unadulterated sweets. It is to be hoped that in the near future amber cane grown on Iowa soil will furnish the sugar and syrups—not only for home use but for export. In the meantime, the prudent and skillful farmer can partially supply the want from the bee hive. Unnumbered tons of honey go to waste year by year in Iowa, for the reason that farmers do not provide workers to gather in the harvest. One great obstacle to success in bee-keeping is the popular superstition that some persons have luck with bees, and others have not. In this, as in all other matters, "good luck" follows close on good management, whilst all kinds of bad luck accompany bad management. Another, and great difficulty, is the fact, that few farmers will take the time to study the subject of bee-keeping. The native bee in a common box hive or a bee gum is a foredoomed failure.

Two or three things are essential to success. First, some kind of hive must be provided with movable combs. It is just as important that the bee-keeper have access to the hive and any part of it at pleasure, as it is for the farmer to have access to his farm and any individual animal on it. The shape and size of the hive are small matters. Give patent hives of all kinds a wide berth. The hive may be a cube or a square or rectangle according to fancy or convenience, but the frames must be movable.

The bees must be Italians, either pure or hybrids, or more correctly grades, and as all other kinds of live stock, the purer the better.

The beginner should have no more than one hive at first and make that a matter of special study. In the bee business it is well to make haste slowly. If a farmer cannot make one hive a success it is useless to attempt more. A little observation will teach him more in a few weeks than all the books that have ever been written, without the observation. He will soon learn where to look for the queen, how to divide the hives and when, the time to put in honey boxes and how. The bee requires but little attention, but it must be given just in the nick of time. All she asks of us

is a house to live in for herself and a place to store our share of her labors. She boards herself, keeps her own house in addition, and presents her contribution to our table in a shape that no human wisdom can improve. She gathers in sweets that would else be wasted, and in so doing fertilizes flowers that would else be barren—in robbing flowers of sweets, she enriches them. Her home is the model of neatness and order. In industry and skill and cleanliness, and good government, and willing obedience there is nothing like it in all the earth. It is the ideal republic—excelling that of which Pluto dreamed. Its queen is not the ruler, but the servant, to be dethroned when her usefulness is past, but honored and served so long as she fulfills properly the duties of her station. To any farmer who has brains and will use them, we say, keep bees, keep them for your own sake; keep them to teach your children lessons of thrift, cleanliness, courage, order, and subjection; keep them to supply your table with one pure sweet, fresh from the hand of God—for bees do not make honey; God makes it and they gather it.

But we have not told our readers how to keep bees. When Joshua Reynolds was asked by one of his pupils how to mix paints, he answered "with brains, sir!" So it is with bee-keeping. Get a hive with movable frames and a good swarm of Italians. The rest is brains. If you have them and will use them, you don't need asking further. If you have not, give or sell them to your neighbor who has.

The Coming Market.

JAMES HEDDON.

The editorial in the BEE JOURNAL "Silver Lining of the Clouds," comes home to every bee-keeper of experience. Every good calculator is now doing just what is therein advised. But there is one vital point in this season's operations that it behooves us all to look well into. In last week's issue, I notice that Messrs Thurber & Co. quote "comb honey 11 to 16c." Here times are good. Labor is in good demand at advanced wages. All sorts of produce are very high; every time we turn around we are surprised at the advanced cost; comb foundation is 5c. higher; lumber is more than 20 per cent. higher; nearly all our supplies have advanced in price, and of those that have not, the material of which they are made has, though the vender stands the extra cost. The honey crop of last season was light and the markets are bare. I have received solicitations for honey from far and near, and I remember of no season coming in with clearer shelves than this one of 1882.

Now what is the meaning of "comb honey 11 and 16c.?" How many lbs. of this honey does it take to buy a bushel of potatoes, a ton of hay, a bushel of corn, or a pound of glucose? If honey gets much lower, and corn

much higher in New York, there will be no danger of glucose adulteration. Is this the way the "great importing firm" is aiding American apiculture? While it is true that supply and demand has more to do with the ups and downs of prices, it is also true that cornerers are still cornering the markets. Two years ago, the Chicago market was depressed to your and our injury, by one or two reckless uncalculating producers showing their honey on the market at prices that were not only damaging to all producers, but far below what they might have had, had they only known enough to have asked it.

The comb honey of 1882 should net the producer, in all the large markets of the world, not less than 20 to 25c. per lb., according to quality. The extracted not less than 10 to 15c. I have not sold one pound of honey in kegs and barrels, for the last three or four years, for less than 12 to 15c. per lb.; while my comb honey has netted me nearly the prices quoted above. Of course, the extracted was ripe, and the comb was in nice marketable shape. I refer to that style of goods, which is now mainly produced by all bee-keepers. Tub and pail honey is getting scarce, and there is no need for "scalping" our commodity any longer. Let every honey producer look about him and observe the prices he pays for every bit of produce he obtains, and let him realize the fact that under these conditions, it is the natural course of events that our commodity should also advance. Horace Greeley said "the way to resume" was to "resume," and I say the way to get what our honey is worth and costing us, is to ask it.

Look well to this feature of the season. Those who will not protect their own interests will soon be sold out, and their goods will just cultivate an appetite for ours, and the luxury-loving consumers are going to be willing to pay us a price in keeping with the cost of other produce. All of honey's competitors are going to be scarce. First is fruit—the late cold season has killed the bulk of the crop in most locations, as well as cutting away a portion of ours. Butter will remain higher this year than for several seasons past. Why "comb honey 11 to 16c.?"

[While we agree with Mr. Heddon, that the prospect for remunerative prices for honey were never better than this season, we certainly cannot indorse the implied strictures for giving correct reports of quotations in New York. We have no apology to make for Messrs. Thurber & Co., nor for any one else who may have been identified in doubtful transactions heretofore; but had they reported honey at a figure above its market value, we cannot see where any advantage would result to the producer. By reference to our market quotations for New York in this issue, it will be seen D. W. Quinby quotes honey at

the same figure the Thurbers did, and there is no one to impeach the correctness of Mr. Quinby. One fact must be taken into consideration in connection with this subject, viz., that where honey can easily be sold in November at 16@22c., the same honey would perhaps bring but 11@16c. if held over till May and June, when much would be candied and culled, and when, too, holders are forcing the market, in anticipation of the new crop. We hope our readers will never lose a good sale of comb honey in the fall or early winter, in anticipation of improved prices in the spring—they will meet nine failures where one success greets them.—ED.]

For the American Bee Journal.

Wintering Bees in Clamps.

THOMAS CHANTRY.

In number 20 of the BEE JOURNAL, I saw an article from W. Z. Hutchinson, who quotes my experience to some extent. I also saw the article from Mr. Robinson, but first I saw a description of a bee clamp in Langstroth's "Hive and Honey Bee," which I partly imitated in the winter of 1877-78 with perfect success. It was the first colony I ever had. I took it from a tree on the 15th of September, 1877. The bees eat but little honey. I constructed my clamp as did Messrs Robinson and Hutchinson, except I placed a tube 10 feet long, made from 4 inch boards on the scantling that I placed the hive on, and let it extend perpendicularly in the air, putting my covering all around it. If I had had ground that I thought was dry enough, I should not have placed this tube in, but as there was no side opening there could be no draught through, nor change of temperature.

I dug my trench last fall, near my apiary, 2 feet deep by 2 feet wide, and long enough for 6 colonies, and placed my scantling 6 inches below the surface in the trench, built my pen and filled it with dry oat straw, and set 6 of the weakest colonies (covering from 5 to 7 American frames), on the scantling, and covered the hives all over with the dry straw, taking care that it was not packed around but was as loose as I could make it, then placed the tube, made of 6 inch boards, on the scantling with a cap, and to prevent anything from falling down inside of it made airholes under the cap and covered it as described by Mr. H., except I only covered it with about 12 inches of dirt, and let that remain till frozen then covered with 2 feet of cane stalks and straw. When I dug the dirt off and opened them, the 1st of April, before I could set them on their summer stands they were flying, and the colonies seemed as heavy as when placed in 5 months before.

They seemed only to have slept

over night. The stronger were strong as ever; the weaker were as good as they were last fall; one had brood in all stages, and as soon as they were set out they all commenced breeding very fast, and are now as strong as any that wintered on the summer stands. I am pleased with my results of wintering in clamps. It is cheaper to me than a cellar, and I shall try it on a larger scale next winter. Those that have not a good cellar had better try it, and not be afraid of smothering the bees; but it must be dry.

Adair, Iowa.

For the American Bee Journal.

Work of the Overflow.

M. A. GARRETT.

Bees came through the winter without much loss. The winter being mild, my bees had a pleasant time of it. I had 87 colonies in the fall, and doubled them back to 70, so as to have them strong for winter. On the 10th of February I put on honey boxes, for the season was much earlier than usual. I gave M. A. Garrett, Jr., my son, half my bees, which he moved to my new home some half mile from where I am overseeing. I left mine at their old location. About the 20th of February the water began to rise from 2 to 8 inches in 24 hours. Having a large levee around our place we felt safe from any danger, as we had a large draining wheel to keep out seepage water. Unfortunately the water came to such a height that our levee gave way, and in 12 hours I had to put my 35 colonies on my gallery. It continued to rise till I had 3 feet of water in my house when I put my bees on a scaffold on the gallery, and in every window in the house. I then had to abandon my house to seek a dry place of safety for myself to stay. During my absence we had quite a storm, which washed the most of them off. My son had his in a new building elevated 6 feet from the ground. The waves turned it over and he lost his entire apiary. Together we lost 60 colonies; 59 were Italians; 25 empty hives and honey boxes, besides several hundred frames. We estimate our loss in bees, honey, etc., to amount to \$865; I lost, besides, my entire crop of cane and corn. Some of my brother bee-keepers thought I ought to have saved my bees in a boat. That would have been hard to do. They were in clusters as large as my head at the entrances, and you could not smoke them in; in fact I do not think they had room, as they were full of honey and strong with bees. It is very easy to stand off and see a fight going on, and after it is all over to say, "you ought to have done this and the other; you would have whipped," when, if they were in the same place, they would not have done so well. The bees were cross and kept up a continual motion, as if all were going to swarm at once. This, I suppose, was caused by moving them so often. I extracted a half barrel of honey from what I had left, and had plenty left in

the brood chambers. I think I may recover some of them this summer in the bee-trees. At this time the water is nearly out of our field, and we are busy planting cotton and corn, but I fear too late to do much good. It is a gloomy sight, to see our beautiful fields of cane and cotton left in such a horrible condition—fencing and houses taken off by the mighty power of the water.

New Iberia, La., May 25, 1882.

For the American Bee Journal.

Dollar Queens—The Place they Occupy.

W. Z. HUTCHINSON.

After all that I have written upon the subject of dollar queens, I fear that I am not exactly understood. Mr. Heddon says: "Yes, but my circular tells you that they are reared by another party, the gentleman who bought my Glenwood apiary one year ago; one who thinks, like Mr. Hutchinson, that he has the genius to rear them as good as they can be reared, and find a profit on them at one dollar." Now I have never intended to convey the idea that all of the dollar queens sent out by myself or by other breeders, are "as good as can be reared;" although I do think that many of them are as good as any queens that have been reared. The only point that I have tried to make, and the one to which I have clung so persistently, is that "dollar" queens are the equals of the so-called "tested" queens. When the BEE JOURNAL says that "the best is the cheapest," I agree with it in the main, and I presume that it will also agree with me, that "circumstances alter cases." If we can believe our leading queen-breeders, the only difference between dollar and tested queens is that the latter are known to be purely mated, while, with the care given to the matter by all reliable breeders, the chances for dollar queens to be impurely mated are very small. Mr. Geo. W. House, in the *Exchange* for April, says, and I agree with him, "that a properly tested queen (one that we would be willing to breed from), cannot be much short of two years old. We want to see the qualities of her daughters and grand daughters, before running her for queen-rearing, and for such a queen would expect to pay a good price." Prof. Cook says: "In testing, Mr. Hutchinson only waits to see if the requisite number of bands are present. I would have him wait to see if the requisite number of eggs, bees, and pounds of honey were forthcoming," and I agree with him. Choice queens, reared from the best stock, and selected with great care from a lot of queens that have been kept and thoroughly tested a year or two, cannot be sold for \$1.00 each, nor for \$2.00, or even \$3.00 each, and the breeder receive pay for his time and trouble; and I don't know as any one thinks, expects, or has asserted that they can, I know that I do not and shall not. The breeder who wishes choice queens to breed from, must buy a lot of dollar queens, or a lot of

the so-called tested queens, test them in regard to their best business qualities, select the best to breed from, and then select again from their progeny, and so on; or else he must buy choice queens of some reliable breeder, paying him for the trouble and time of testing them. The breeder of dollar queens, or of the so-called tested queens, can stock his own and his neighbors' apiaries with choice stock, he can rear his queens and drones in the best possible manner from the best stock that can be obtained, and then he must send out, as dollar queens, all queens that show no imperfections during the ten or twelve days that they remain in his yard, and, as tested queens, all queens that show no imperfections and prove to be purely mated. Some of the queens that he sends out will probably be as good queens as it is possible for him to rear, while it is quite likely that others will not be very valuable; the breeder does not know which queens will turn out prizes or which will prove blanks, that is something for his customers to find out. There is, however, no deception about the matter, as it is understood that the only guarantee in regard to dollar queens is that they are reared in a proper manner from good stock, and are laying queens. Tested queens are the same except that they are known to be purely mated.

If a bee-keeper secures an excellent breeding queen, paying a handsome price for her, and then rears queens from her, they are, virtually, dollar queens; they must be tested before it is known what they are. Now, then, what difference does it make whether a bee-keeper rears his untested queens or buys them?

When one has a large apiary as has Mr. Heddon, where queens can be kept doing duty in full colonies while they are being tested, the rearing and selling of tested queens for \$2.00 or \$3.00 each would probably be more profitable than the rearing and selling for \$1.00 of queens that had just commenced laying; but where one's apiary, with the exception of a few colonies for building queen cells, is divided up into nuclei, the case is different; as, after working two or three days, the queen has the combs of her nucleus filled with eggs, and then can do nothing but "loaf" until the first batch of eggs hatches out into young bees.

Rogersville, Mich.

For the American Bee Journal.

Light versus Dark Italians.

AARON BENEDICT.

I am aware that it is much easier for the careless breeder to rear dark than light-colored Italians, hence they are ready to praise the kind of bees they have, and if queen-breeders, they can send out all the hybrid queens they can rear, if dark. Now, I believe if these advocates of dark Italians had queens that were light yellow, and produced all light yellow bees, they would sing a different tune,

and their queens would give better satisfaction to purchasers. They would find that the yellow bees would gather quite as much honey as dark ones. It is the instinct of all honey bees to gather honey, if it is to be found.

I believe, and know, that bees can be bred as to size, color and docility; the larger the bee, the more docile. This holds good with the common black bees. Some are large, of a gray color; then there is a small, short, very black bee, which is very vindictive, and goes for horses, dogs, cats and chickens in a way that makes things lively. A cross between those small bees and Italians produces a bee that smoke, if once aroused, will not subdue, and whoever handles them will be obliged to have on double protection, and then if they do not find a way inside to a tender spot it will be a wonder. A cross between the larger gray bee makes a tolerable decent hybrid. I believe it should be the motto of every queen-breeder to breed from the very lightest queens that produce very light workers; use drones only from such queens, and improve as fast as possible; having in view, first, the lightest colored bees; second, large; third, docility. By careful breeding to these three points, I believe we might soon have a fixed type, or "the coming bee."

Bennington, O.

For the American Bee Journal.

Clamps for Wintering.

E. D. MALLORY.

We had 6 colonies in Langstroth hives, which, after some deliberation, we carried into the cellar. I say deliberation, because it was never my opinion that was the best method of wintering, although recommended as such by so many of our best bee-keepers, and it was through their experience and judgment that I was led to adopt the plan, as we had only been keeping bees about 7 years at that time, and, consequently, knew but little about winter management practically. About the same time that we removed the above hives to the cellar, we purchased 3 colonies of hybrids in old box hives, one of which was quite strong, another very weak, and the third fair; with these we resolved to try clamps. We placed them on their bottom-boards about 4 inches from the ground, and banked earth around them about one-fourth the way up the hives; at the entrance we placed conductors about 20 inches long, so that the bees could have free egress whenever they chose to go out; this done, we drove stakes into the ground and put boards behind them to hold the straw and chaff, with which we packed them to the depth of from a foot to a foot-and-a-half, putting a cover over all to keep out the wet. Here we left them to find the result later on. In the latter part of February we made an examination of our colonies, commencing with the box hives, which we found in fine condition—dry, evident signs of

breeding, and quite heavy, and in returning them to the clamps we placed frames about 3 inches wide under the hives to give a little more circulation of air. Those placed in the cellar did not appear so favorable, they having been rather uneasy for some time; we brought them out, gave them a fly, and made a short examination of them, but found they were quite damp, with evident signs of dwindling, and a good many that flew out died before they could return. With the results of our two methods thus far, we concluded that it would be better to put the latter in clamps, too, than return them to the cellar, which we did, raising them from the bottom-boards and giving them plenty of air, and a free passage in and out of the hives. This spring we left them until quite late, and they came out almost full of brood, stronger, I think, than they were last fall by a quarter of their number, those in the box hives having extended their combs about $2\frac{1}{2}$ inches below the hive into the frame which we placed under them in February. With this success in clamps, I think it will be some time before we attempt wintering our bees in the cellar again.

Frankford, Ont.

For the American Bee Journal.

Theory is Not Infallible.

GASTON M. ALVES.

It is thought that bees with a fertile worker will not accept a queen. Prof. Cook, in his "Manual," page 92, says: "Yet they seem to satisfy the workers, for they will not brook the presence of a queen when a fertile worker is in the hive, nor will they suffer the existence in the hive of a queen cell, even though capped." I quote from my note book of this year: April 4th. Forced box hive and put swarm into hive No. 14 with empty frames; put box hive on stand of hive No. 1, and moved No. 1 to a new stand; April 8—Found new worker comb and eggs in hive No. 14 (thus it is certain the queen was forced with the swarm from box hive). April 25—Forced box hive (see April 4th) into hive No. 16, with small strips of worker foundation in frames; looked for young queen, but could not find one. May 4—Examined hive No. 16; bees making only drone comb; one drone comb contains eggs and brood; no other brood. May 16—Gave hive No. 16 worker brood from hive No. 6, to see if queen cells would be started. About a week afterward (no entry made of this) examined the hive and found two sealed queen cells on the comb given on the 16th of May, but as the cells were constructed almost horizontally, I badly bruised them in lifting the frame out. I then destroyed them and sent to Mr. J. T. Moore for one of his Italian queens. June 3—Received Italian queen by mail of J. T. Moore, and introduced her caged, in hive No. 16. Still found only drone brood and eggs, and again, after very careful search, could find no queen. Colony considerably re-

duced in numbers. June 4—Liberated queen in hive No. 16, and found her in the after part of the day well received. Now, all of this seems to me to be evidence satisfactory of the presence of a fertile worker in the above hive; and hence it follows that bees will both construct queen cells and readily accept a queen in the presence of a fertile worker. We may hence conclude that bees value a fertile worker slightly, and are always ready to accept something better; and that fertile workers are not pests as generally imagined, but are simply the indication of certain abnormal conditions, which the bees will always endeavor to correct if the means are placed within their reach.

Henderson, Ky.

[You have had proof almost positive that a fertile worker did occupy the hive, and that a queen was accepted, but it is an exceptional case.—ED.]

SELECTIONS FROM OUR LETTER BOX

Sweet Clover in Woods Pasture.—

Will woods pasture be too shady for sweet clover, to be successful for bee forage? We are having cold, rainy weather. Bees cannot fly more than half of the time. I have had 2 swarms. The hives are well stocked with bees, but there is a poor prospect for honey. I shall count on bees this year as I do on chickens. I never count on chickens until they are hatched and the rats have one week to work at them, then count the balance.

Villisca, Iowa. JAMES RENIAN.

[Unless the shade is quite dense, it will not be much detrimental to sweet or melilot clover for bee forage.—ED.]

Bees are Booming.—Bees wintered splendidly, and everything works all right yet. No frost to hurt fruit bloom (and trees blossomed very full), so bees have had a grand time. It has been a little cool at times, it is true, but they have built up very fast; 2 swarms May 25, and 27, and so on. My record says out of 40 colonies, 35 are marked A No. 1. Our prospects for fruit is grand, and if nothing interferes now, we will show Chicago some nice plums and peaches.

W. D. MARKHAM.

Hart, Mich., June 1, 1882.

How to Produce the Coming Bee.—

I will suggest to the bee-keeper who wishes to immortalize himself by breeding for the "coming bee," according to the programme of Prof. Cook, in the article from the *Rural New Yorker*. The best place on the Continent to fertilize his queens is the island of Long Point, Ont., in Lake Erie. It is 15 miles from the Mainland, abounds in the timbers, wild flowers and plants peculiar to that latitude, including an unlimited

amount of wild grape vines. The boats and steamers connect it with the main land twice a week, and the latter place is as fine a bee country as any part of New York State, while the climate is tempered by the waters of the lake, the coast for a few miles inland being the home of the apple, peach, plum, pear, and the finer varieties of the cherry, etc. On this island the bee-keeper can turn loose his choice drones, and bring his young queens there with a certainty as to the result.

D. P. NORTON.

Council Grove, Kans.

From Louisiana.—My bees are doing very well. I have 13 colonies; 10 are strong. I will extract on the 1st of June. Mr. Henry Steele is still feeding; has 140 colonies and is doubling back. Mr. M. A. Garrett all right with 35 colonies. I extracted half a barrel. Our thermometer stood at 84° on the 28th and 29th. I send you by mail two specimen flowers of honey plants; the yellow tassel comes from a tree which grows here in the South. It is said that it was introduced from China many years ago. The other I found by the road side; the bees were fighting over the nectar which it contains. What are their names? CHAS. SONNEMANN.

New Iberia, La., May 30, 1882.

[The yellow tassel mentioned above is from the tree commonly called China oak (*Quercus Chinensis*); the latter we have many times recommended as a most desirable honey plant—motherwort.—ED.]

Loss of Queen.—There are a great many causes for loss of queens, but I think I had an experience somewhat different from anything read or heard of. I had a small frame of brood, 4x10 inches, inclosed in a small box with glass sides, covered with sliding panels for observation, in which I had a queen hatch on the 15th of last August. She was large and nice, and was perfectly contented with her small home until the 20th of August, when at 1 o'clock she took a bridal flight and was out two hours, when she returned. I was standing on the look-out, and saw her enter the hive, and I immediately raised the panels from over the glass and saw at once that the bees had caught her and were tearing away the white thread-like appendage which was hanging to her when she returned to the hive. I watched the proceedings until I was satisfied they intended her destruction, as they had her by the wings and legs, and were using every effort to sting her, while the whole colony was in an uproar, and by this time they had taken every visible thing away from her that did not belong there, yet they persisted in her destruction until I had recourse to my smoker, and then it was hard to make them desist, until I could take her out, which I did until they were quieted inside the hive, when I returned her; but the same hostility existed, and I smoked the bees until they were as black as a chimney sweep, and all to

no purpose. Then I removed her and introduced her into another small hive, and she proved to be a perfect queen, producing workers and drones at will. What was the trouble? Was it the scent of the drone she met that caused the bees to attack her, or do all queens have to go through with this pow-wow on such occasions? If (and I shall never doubt it) they intended to kill her, does this not account for the loss of a great many queens? WM. M. BARNES.

Boaz, Wis.

[The circumstance you mention is a matter of not in frequent occurrence. We have heretofore supposed that the queen having been out an unusual length of time, had probably been deprived of her scent by long continuance in the open air, then having met a foreign drone, and returning immediately to the hive after contact with him, the bees may have mistaken her for an intruder. Had you, after her first release, put her under a comb-surface cage and placed the comb back in the center of the hive, she would have been fraternally welcomed after a few hours confinement. We had a fine young Syrian queen pass such an ordeal last summer, in which one wing was disabled, but after caging on the comb from one o'clock until evening, she experienced no further trouble.—ED.]

Have Dwindled.—Mr. G. M. Doolittle's spring report is my experience to a dot. In the fall of 1880 I put 35 colonies in my cellar, and in the spring, about the 20th of April, set out 34. Some of these I united, so that I had 24 good colonies, and 7 that I built up to good by fall. From the 24 that I worked for honey, I obtained 830 lbs. of box honey, in $1\frac{3}{4}$ lb. sections, and 200 pounds of extracted honey, besides what we used in the family and gave to the neighbors. Last winter was a very mild one here, and my bees used very little honey while in the cellar, but there came a warm spell about the middle of April, and I set them out, and—oh dear! how they have gone down ever since. I put 53 colonies in last fall, and set out 49 this spring. All appeared good, but it turned around cold in a couple of days, and my bees had only 4 days in April that they could fly, while May has not been much better. The little fellows tried their best to get out and work on soft maple and willow, but they dropped down and died, many of them on the alighting boards. I looked them all over the first warm day in May, and most of them had honey plenty; those that did not I gave combs of honey saved over on purpose for such emergencies, but in spite of all I could do, they have dwindled, died, and swarmed out, and with what I have united, I have 36 good and 2 poor colonies to begin the season with, if we ever get any warm weather so bees can work.

Fruit is in full bloom here now, and the bees would be very busy, but it has rained most of the time for two weeks, and been so cold they could not do much. The heavy colonies are breeding up fast, but it seems up-hill work for the light ones to get started. My Italians died off and spring dwindled more than the natives. I think the coming bee will be pure Italian and pure German brown bees crossed. Such of mine are larger, stronger and do not die or dwindle.

R. P. LOVEJOY.

Greig, N. Y., June 5, 1882.

Negroes as Bee-Keepers.—1. How far can bees see? 2. Why do negroes not keep bees; is it because

"The Lord doth love the negroes well,
And he always tells them by their smell?"

I have never known a negro who owned bees. E. C. JORDAN.
Stephenson's Depot, W. Va.

[1. How far bees can see we do not know. Worker bees are supplied with two sets of eyes—compound or ocelli, and simple eyes. Prof. Cook doubts not their eyes are best suited to long distances, as they depend more upon their keen sense of smell to guide them aright when the object is present. We have often thought one set of eyes might be adapted to a very distant range, while the other set were adapted to perfect observation in the dark, as we know much, and perhaps the most perfect of their work, is performed in the hive at night amid total darkness. Who that has passed through an apiary at midnight during a season of bountiful honey flow, has not heard the busy *roaring* of the bees within the hive, though several rods away.

2. We never saw nor heard of a negro who was a successful bee-keeper; and although excessively fond of honey, nine hundred and ninety-nine out of every thousand, would do without it, even if told to go to the hive and help themselves.—ED.]

Working Drones.—As I write, a neighbor has just called in to ask if drones worked. I replied, no. He affirmed that he had witnessed a colony, the drones of which were at work carrying in pollen as busy as the workers. The same colony have been killing off the drones since. I replied that it was an exception. What think you of it? Our bees have had a good spring harvest; working almost incessantly for 3 months, while yours have been frequently interrupted with frost and freezes. I am informed by a neighbor just from your city, that it was snowing there on the 23d, yesterday week.

W. A. MILLING.

Biard, Tex., May 31, 1882.

[There must be some mislake about the drones carrying in pollen.—ED.]

Too Cold and Wet.—I had last fall 12 colonies which wintered well and strong, but they have dwindled badly this spring, causing the loss of one. Most of them have but three frames of brood. There is not much show now for honey until fall or late summer. The weather is too cold and wet for bees to work much on what bloom there is. That open letter to Doolittle hits me exactly. I hope he will give a reply soon. I use hives holding 10 frames, $11\frac{1}{2} \times 12\frac{1}{2}$ inches inside. 1. For extracting honey should I have an upper story to get the best results, or is the one story roomy enough? 2. I tried sections a little last year, but the bees did not go up at all; why? 3. Are there any bees that can gather honey from red clover; mine do not? PAGE.

Shenandoah, Iowa, June 3, 1882.

[You will find Mr. Doolittle's answer to Dr. James' open letter, which was published in the BEE JOURNAL, page 329, in this number, on page 372.

1. For extracting we prefer the second story, as it gives an opportunity for tiering up, to meet exigencies of weather or time, and for ripening honey, when flow is very abundant. If but one story is used, then a "long idea" hive is often desirable, as with a very prolific queen, if but 10 frames are used, the labor of extracting will have to be continually in progress, or a light yield will be the result.

2. Your honey flow may have been very light, or the bees been too long storing in the brood chamber. Sections should be put on early in the season, if comb honey is wanted; that is, soon as the weather has become warm and settled.

3. There are several who claim their bees gather freely from red clover. We have frequently seen our bees working busily on it, but never when the flow was plentiful from other honey plants, nor do we believe any bees will do so.—ED.]

Putting on Sections.—In your answer to D. W. Belleme on page 331, question 4, your advise and my experience do not agree. I used to do as you advise, but found sometimes a difficulty in getting the bees into the sections after they commenced to store honey in the combs below. I now put on the boxes as soon as the bees have clustered below. Swarms thus treated have, as a rule, given a large yield of section honey. If not done within 24 hours, the bees will put so much honey in the brood combs as to materially interfere with the brood, leaving insufficient room for the queen. If honey is what we are striving for, on this point hangs success or failure. I hope other beekeepers will give their practice on this (to me) important point.

L. C. WHITING.

East Saginaw, Mich.

Boiling Honey.—My bees bred up very fast in fruit bloom season, and some time after that it set in cool and cloudy, with bad weather to gather honey to keep up brood rearing. I feared very much that I would have to feed largely, but now they are making a living, and have commenced to fill up with brood. Will Mr. Lowmaster please give a description of his drone trap, as I find it very hard to keep down black drones? I have 58 colonies of blacks, hybrids and Italians, and do not use any black drones? My bees wintered well on their summer stands in Mitchell hives. How will it do to let extracted honey stand 10 or 15 days, then bring it to the boil in large kettles, skim, put up in 2 to 4 pound tin cans, and solder while hot?

J. T. BRUTON.

Joplin, Mo., May 24, 1882.

[Without exceeding great care is used, the honey will be deprived of much of its flavor by bringing to the boiling point. Let it stand several days in tubs, pails, or barrels, covered only with thin, coarse cotton cloth, in a hot, dry room, or exposed in the sun. Protect against rain and night dews.—ED.]

An Open Letter to Prof. Cook.—Dear Sir: While you are under the firm conviction that the breeding of bees must follow the same laws as the breeding of cattle, etc., and that I concur with the opinion of Mr. Doolittle, who says in a late number of *Gleanings*, that from his practical experience he has been led to believe that the breeding of bees is not analogous to that of swine, sheep, etc., I would like for you to tell us in which way we are able to come to the same result with bees as with cattle, etc.? If it is possible to select the male and female with the different breed we wish to improve, how is this possible with bees? We certainly can select the female, but what about the male? Now, we suppose that all the progeny from a pure queen to have similar qualities, now why is this not so with the improved breed of cattle, horses, etc.? The breeders of the selected stocks are continually weeding, as from their best selected couple they breed from there are but a few which come to the standard. Now, if this is the case when we are able to select and manage the male, how can we attain such results, when we can only have drones and not one, unless all the drones from the queen we select for that purpose have all the good similar qualities required; then, if this is the case, why should all the males from a female bee have all the same qualities and not so in all the different improved breeds of cattle, horses, sheep, fowls, etc.? Trusting, sir, that you will not think that I oppose the working towards the improving of our present bee, though I have been working in that light for several years without result.

PAUL L. VIALON.

Bayou Goula, La., May 30, 1882.

Late Spring.—The spring has been very late; cold north and northwest winds are prevailing yet, so bees cannot work much more than half of their time. I received a large swarm May 26, which is doing well considering the chance. I expect more soon as the weather permits. 1. How is the best way to move a colony a short distance; it is standing under an apple tree, and has too much shade? 2. In putting tin tubes in the brood chamber, for winter passages, should they be removed in summer? I am delighted with "Cook's Manual of the Apiary." I think there is no book like it for the bee-keeper. Do not stop the BEE JOURNAL, if my subscription should expire; I am a novice at bee-keeping, and cannot get along without it. S. C. FREDERICK.

Coal Vale, Kans., June 4, 1882.

[1. Close the entrance at night; in the morning remove the colony to where you wish it to remain; let the entrance remain closed; about 11 o'clock jar the hive pretty roughly, and leave it for about 5 to 10 minutes; slant a board in front to nearly obstruct the entrance, and take away the entrance blocks. Let the board remain in front for several days.

2. Why use tin tubes at all? Shave a $\frac{1}{2}$ or $\frac{3}{4}$ inch round stick gradually to a point, and pierce a hole through each comb just a little above and forward of the center. If done in the fall, the bees will not close them again, and in the spring they can easily do so, as this is the most valuable portion of the brood-nest.—ED.]

Beetles.—I send you this day three dark-colored bugs that frequent my bee-hives, and annoy the bees. Will you please let us know what they are, and their habits, if known, and do so through the BEE JOURNAL.

J. A. P. FANCHER.

Fancher's Mills, Tenn.

[The "dark colored bugs" received from J. A. P. Fancher, Fancher's Mills, Tenn., are not bugs, but beetles. They are not found in Michigan, but are in our cabinet. The scientific name is *Euryomia sepulchralis*, Fab. Two near relatives, *E. inda* and *E. melancholis*, are found here, and are often found eating into ripe fruit, especially apples and peaches. Possibly this one has a sugar tooth, and seeks to satisfy its longings by pilfering the honey from the hive. I cannot think, from the habits of the beetles of this genus, that they could do any other injury. We might think from the name that they were after dead bees, but it is hardly possible. They doubtless seek the honey, and will not be in sufficient numbers to do much harm.—A. J. COOK.]

Hiving, Etc.—1. To hive a swarm, should I turn the hive top-side down over the swarm, after the frames have been fastened in place by cleats laid on the ends, and fastened by screws driven through the cleats into the rabbits? 2. My thin foundation is cut into sheets $5\frac{1}{2} \times 12$ inches, to fill the 1 pound section, should I cut it into sheets $3\frac{1}{2} \times 3\frac{1}{2}$ inches, and have a lot of small pieces left over, or had I better cut it into pieces $3 \times 2\frac{3}{4}$ inches? 3. I use cotton rags in my $2\frac{1}{2}$ inch Bing-ham smoker, and like them much better than punk; what objection is there to using rags? 4. According to Mr. Heddon's theory, I wonder if bacteria are in cider and honey vinegar; if not, what causes fermentation? In an 8-frame Langstroth hive, I should think we might adjust a super for extracted honey, and after the bees are well at work raise this super and put under it a super of 24 one-pound sections, with foundation and no separators. The weather is very backward here. Fruit trees are just leaving out. F. M. CHENEY.

South Sutton, N. H., May 27, 1882.

[1. To hive a swarm, place a hive where intended to stand, with foundation frames properly adjusted; slant a broad board in front, on which the bees can crawl up to the entrance; now shake the cluster into an empty box or keg, and pour them down in front of the prepared hive. There are two or three other good methods, but this is, perhaps, as little trouble as any.

2. Cut into pieces $3 \times 2\frac{3}{4}$ inches.

3. There is no objection to cotton rags in the smoker, except that they burn out quite soon.

4. Yes; bacteria prevail in everything that ferments or decays.

By using additional stories, tiering up is practiced to a considerable extent, both for extracted and comb honey.—ED.]

Bees Doing Well in California.—Our bees are storing honey very fast, and the prospects for a booming good yield of honey are much better than last year at this time. Sage, honeysuckle and California coffee are all in full bloom, and the weather is mild, enabling the bees to work all day. Wild buckwheat is just coming on, and other bloom in rotation. We feel safe to say that our honey harvest will be larger than for the past two years.

BRAY & SEACORD.

Warthan, Cal., May 29, 1882.

Prospect was Never Better.—The season has been very cold and wet here. White clover is beginning to bloom, and the bees are making good use of it, as they did not get much honey from fruit bloom. Bees wintered well, and are doing finely now. The prospect for a good clover crop was never better, I think, than now.

DANIEL BROTHERS.

Sarahsville, O., June 3, 1882.

Phenomenal.—Recently while looking over my bees, on opening a hive and picking up a frame with brood, I discovered a ball of bees which I could not understand. On separating them I found they were balling their queen—one that had wintered with them. I liberated her, but they followed her like a lot of wolves and attacked her again. I took her out and caged her. They had no other queen or any cell from which one could have hatched. Can you tell me the cause of such a phenomenon? I have had bees many years in Langstroth hives, and thought I had seen all the freaks bees are subject to, but this one beat me. The queen was stung so badly she died in a short time. The same colony is without a queen yet. I put into winter quarters 47 colonies, and took out 46. They have gathered a little honey from fruit blossoms, but the weather was so cold it was mostly a failure, and bees are now starving. I have fed a few. It rains every other day and is cold.

F. H. FINCH.

Sharon Center, O. May 15, 1882.

[If it were not that there was late brood in the hive, we would think the bees had some cause to supersede her; otherwise, it may have been a queen that gained admission to the hive and killed the one belonging there, after which the bees attacked her. Possibly an abnormal swarm, with their queen, entered the hive, and after destroying the queen proper, were forced out, leaving the intruding queen in custody. Being a phenomenon, of course there is no arbitrary way of accounting for it.—Ed.]

Good Increase.—I had 18 colonies at the beginning of the season, all in fine condition; have now 38 increase by natural swarming. First swarm March 29th; had 18 up to the 18th of April; had a rest of 28 days, and the others came out since. Had one swarm this morning, at 7 o'clock. In my 8 years of bee-keeping I never before had a swarm before May, nor as early as 7 o'clock a. m. Honey flow is immense from thistle and horse-mint. Brood chambers are all full and boxes and upper stories on 34 hives.

E. P. MASSEY.

Waco, Tex., May 29, 1882.

Upward Ventilation.—Since my last report the weather has been very unfavorable for the production of honey. We have had a great deal of rain, with low temperature. I never knew a cooler spring. We are just beginning to have warm weather in earnest, and the bees are gathering honey freely from white clover. I have taken off 1,200 lbs. extracted honey from a commencement of 256 colonies. I shall work 4-5 of my colonies for extracted honey. When I find my bees hanging out, with front and side entrances entirely open, I elevate the rear of the top of the hive and fold back a corner of the sheet from the

Langstroth frames to the extent of 3 or 4 inches, giving free circulation from top to bottom. It acts like a charm, and the bees are soon at work again.

O. M. BLANTON.

Greenville, Miss., May 22, 1882.

Kingbirds.—The bird mentioned by your Canada correspondent for a name, on page 347, is called kingbird, in this section. I believe that is the name by which they are generally known in the States. They are insectivorous, and considered very destructive to bees. Some have claimed that they destroy drones only, but that is a mistake, as has been proved.

CLARENDON BUTMAN.

Plymouth, Me.

[Kingbirds are numerous—too numerous—in the Central and Western States, with which we are familiar; but we have none decked in such feathers as the few which were sent us by Mr. Sanderson.—Ed.]

Doing Fine in Texas.—My bees are doing better, and making finer honey than I have ever before seen in Texas. They began swarming on March 10th. I then had 80 colonies. I now have 150, in Adair and Langstroth hives. The bees are very strong. I am busy now taking honey—commenced May 15th. I find it all nicely sealed. Horse-mint is splendid this spring. I think it the best honey plant we have. Corn tassels are fine. We are eating roasting ears. The prospects are grand for Texas this year.

S. M. COCHRANE.

Gonzales, Texas, May 29, 1882.

Disappointments.—We had the warmest winter I ever saw up to April 9, then set in cold and windy, so my bees could not work to do any good, all through April and May, with rains every 3 days, and then cold again. Bees strong and in fine shape, and a hundred acres of white clover in sight of my apiary, and gallons of honey wasting. I had 7 swarms; lost 3 queens this spring, and if the weather does not get better I fear our honey crop will be very light. My bees have done well considering the time they could work; a good many of the boxes are full of comb and partly filled with honey, and if we could have some dry, warm weather, they would soon do to take off, but to-day is cold, cloudy and windy, with mercury standing at 50° in the shade.

L. T. MOBBERLY.

Long Grove, Ky., June 5, 1882.

Myrrh on Bee Stings.—We feel to give Mr. R. L. Aylor, of Waterloo, Ky., our sincere thanks for his sting remedy, which is a few drops of tincture of Myrrh applied to the puncture. This is the best thing we have found. We have 52 colonies in good condition; the weaker ones have been greatly improved by following Mr. G. M. Doolittle's plan of strengthening and doubling up. No honey or swarming as yet.

DANIEL & MARY MOHR.

Manchester, Iowa, June 7.

Bad for Queen Rearing.—Clover is largely a failure here—wet and cold so long it is dwarfed; very fine stalked and bloom light. Bees are getting little honey for two days past. Have had three clear days now. Have got about 20 queens fertilized and 100 lost in flight; saw a number return and fall on the ground, not able to enter the hives. Such were unsuccessful in their flight. Some came out after 3 weeks' confinement in the hive on the first warm day and were successful; but bees would not receive them on their return, but damaged some and killed others.

A. SALISBURY.

Camargo, Ill., June 8, 1882.

Backward, Cold and Wet.—We have a very backward, cold, wet season so far; hard on our bees. I fear we will not get much honey this season. I have had two swarms of Italians this season; the first on the 10th of May, the second on the 25th, both from the same hive. It set in so wet and cold immediately, that I was afraid they would starve, so I fed them in the upper story, and happened to not put on the cover right when the other bees commenced robbing them the first thing I knew, so I smoked them in and shut up the hives, loaded them into my buggy and moved them away about 3 miles to my son-in-law's, where I opened them up and they seem to be doing well. It effectually stopped the robbing.

J. BREWER.

Lincolnville, Ind., June 6, 1882.

Doing a "Land Office Business."—Bees are doing a "land office business" here to-day. The spring has been so cold and wet heretofore that many bees have died of starvation. I think mine will be all right now, as I have been feeding sugar and honey.

THOS. LASHBROOK.

Waverly, Iowa, June 5, 1882.

Interesting.—Below are the dates for this year of the flowering of some bee plants and trees in this locality; also the time of drones flying and commencement of natural swarming. Latitude of this locality, 37°, 45'; long. W. from Washington 10°, 35'. Such a table as below from different parts of the country would be of much interest to bee-keepers: March 31—Peach and plum trees dropping their bloom; drones commenced flying; pears coming in bloom. April 2.—Cherries and apples beginning to bloom; 22—White clover beginning to bloom; 24—Locust beginning to bloom. May 1—Tulip tree and raspberry beginning to bloom; 11—Natural swarming commencing; 25—Catalpa beginning to bloom. June 4—Raspberry nearly out of bloom; tulip tree about ten days out of bloom; catalpa dropping bloom; locust was in bloom about a week. Bees worked well on fruit tree bloom, sugar maple, tulip tree and raspberry; indifferently well on locust, white oak, black (sour) gum, and red-bud (Judas tree); not at all on catalpa. They have not put a great deal of force on white clover as yet, preferring raspberry.

GASTON M. ALVES.

Henderson, Ky., June 4, 1882.

ESTABLISHED 1862
 THE AMERICAN BEE JOURNAL
 PUBLISHED WEEKLY

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 ".....	20 " "
" 13 " (3 months)....	30 " "
" 26 " (6 months)....	40 " "
" 39 " (9 months)....	50 " "
" 52 " (1 year).....	60 " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—a copy of "Bees and Honey."
" " 3,—an Emerson Binder for 1882.
" " 4,—Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper, cloth.
" " 5,—" " " "
" " 6.—Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
 Monday, 10 a. m., June 12, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—As the season is well advanced, sales of extracted honey are slow and prices remain unchanged. 1 um paying 7c for dark and 9c for light, cash on arrival. Good comb honey is scarce and rules high.
 BEESWAX—1 am paying 24c for good yellow wax, on arrival; 18@22c for medium grade, and 15@17c for dark.

AL. IL. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for extracted honey, in the retail way, is fair, and our sales for manufacturing purposes were very good of late. We pay 7@9c on arrival. Prices for comb honey nominal and demand slow.
 BEESWAX—Bricks 18@22c. The demand exceeds the offerings.

C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for honey is light, most of the trade finding fault with the best offered, as it is more or less candied. Values are not steady, prices being made to meet the views of the purchaser.

BEESWAX—Scarce, and in demand at 23@25c.
 R. A. BURNETT, 165 South Water St.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
 BEESWAX—Prime quality, 25c.
 CROCKER & BLAKE, 57 Chatbam Street.

CLEVELAND.

HONEY—There are a good many small lots of very nice white section honey coming in now from time to time. White sells readily at 22c.; second quality 18@20c.; Buckwheat, no sale at any price. Extracted, none in market.
 BEESWAX—25@30c.

A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—New honey is reported as being received at Southern points, but none has yet arrived in this market. Stocks of old are now quite insignificant. Fair to good qualities, particularly especially extracted, are in demand.
 We quote white comb, 13@14c.; dark to good, 7@11c. Extracted, choice to extra white, 7 3/4@8 1/2c.; dark and candied, 6 1/2@8c. BEESWAX—23@25c.
 STEARNS & SMITH, 423 Front Street.

NEW YORK.

HONEY—Scarcely anything doing in honey, and prices are entirely nominal. White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.
 BEESWAX—The market continues rather quiet, but the supply is light and prices firmly sustained. Western, pure, 24@24 1/2c.; Southern pure, 25@25 1/2c.

D. W. QUINBY, 105 Park Place.

ST. LOUIS.

HONEY—In fair demand. Strained selling at 8@10c.; comb scarce—nominal at 18@22c.
 BEESWAX—Prime in demand at 22@23c.
 R. C. GREER & CO., 117 N. Main Street.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Local Convention Directory.

1882. Time and Place of Meeting.

- July 25—Western Iowa, at Winterset, Iowa. Henry Wallace, Sec., Winterset, Iowa.
- Aug. 10—Maine State, at Harmony, Maine. Wm. Hoyt, Sec.
- Sept. 5—N. W. Ill. and S. W. Wis., at Rockton, Ill. Jonathan Stewart, Sec.
- Oct. 5—Kentucky Union, at Shelbyville, Ky. G. W. Denarea, Sec., Christiansburg, Ky.
- Tuscarawas Valley, at Newcomerstown, O. J. A. Bucklew, Sec., Clarks, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

When changing a postoffice address, mention the old as well as the new address.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

From Detroit to the Sea.—W. H. Brearley, of the *Detroit Evening News*, has issued and sent to this office a copy of his new tourists' guide book for the three \$20 July excursions "From Detroit to the Sea," and return, via the Grand Trunk R. R. The book is a decided improvement upon the former issues published annually during the six years that these excursions have been carried on, having 64 well edited and illustrated pages, and containing 43 maps engraved expressly for this year's edition. The title page of the cover is an exact copy in 10 colors of an oil painting of Glen Ellis Falls, near the Glen House, in the White Mountains, and is beautiful enough to frame. Every one contemplating a trip East this summer whether they intend going on these excursions or not, should send 30 cents and secure one. Those who do not wish to invest ten three cent stamps, in this guide book, should send one stamp for a circular.

Class in Bee-Keeping.

Application has been made to me to take students in Bee Keeping. I have, therefore, determined to begin a class on MONDAY, JULY 10, and extend through eight weeks. The instruction will include a study of the Anatomy and Physiology of the Bee, Queen-Rearing, Artificial Increase, Implements, Comb Honey, Extracted Honey, Bee Pasturage, Wintering, etc. I have a good library of Bee Literature, all Approved Modern Appliances, etc. My home Apiary has eighty colonies of Italian Bees, among which students can practice.
 O. CLUTE,
 Iowa City, Iowa.

JULY AND AUGUST, I will sell Italian J Bees, in Simplicity hives, for \$6 per colony. All queens from imported mothers. Safe arrival and satisfaction guaranteed.

D. S. BASSETT,
Farmsville, Worcester Co., Mass.

IN DISTRESS for want of Beeswax. We are now paying 25¢, cash, or 28¢, trade, for good yellow wax. Those of our friends who want large lots of foundation from us will have to send us the same amount of wax or wait till we can collect it, as our stock is about exhausted. Until further notice, we will sell thin foundation for sections at 55¢, per lb.; heavy foundation for brood combs at 45¢. No discount from the above rates.

A NEW BEE BOOK!

Bees & Honey

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,

Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper cover, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-keeping.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keltzsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Abingdon, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times, should keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec 4, township 7, south range 5 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (3 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber. It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address, THOMAS G. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

The Bee-keeper's Guide; OR, MANUAL OF THE APIARY,

By A. J. COOK,

Of Lansing, Professor of Entomology in the

State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee: the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book;

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—LEWIS T. COLBY.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—J. P. WEST.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—E. H. WYNKOOP.

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—A. E. WENZEL.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—W. VAN ANTWERP, M. D.

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—L'ABBE DU BOIS, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Palaska, N. Y.

We have perused with great pleasure this *guide mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

BALDWIN'S

SUBSIDY

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as *Caranodon Rondeletii*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1840. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 200 years no deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better. I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else; and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

To avoid loss in the mails, please send money by REGISTERED LETTER.

Only Imported by **HAYLOCK & JENNEY,** (Late HAYLOCK & Co.) 7 Dey St., New York. Sole Agents for America. 20wly

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by **THOMAS C. NEWMAN,** 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide, or, Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quincy's New Bee-Keeping, by L. C. Root—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee—This is a standard scientific work. Price, \$2.

Hives and Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bzierzen Theory—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof Cook's Essay, which is here given in full. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted to their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman—giving advanced views on this important subject, with suggestions what to plant, and when and how. Illustrated with 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand on the part of the consumer to gain the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions and diseases, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 Items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., June 21, 1882.

No. 25.

THE AMERICAN BEE JOURNAL

Published every Wednesday by

THOMAS C. NEWMAN,
EDITOR AND PROPRIETOR.

925 WEST MADISON ST., CHICAGO, ILL.
At \$2.00 a Year, in Advance.

WEEKLY—(52 numbers) \$2 a year, in advance.
Three or Six Months at the same rate.

SEMI-MONTHLY—The first and third numbers of each month, at \$1.00 a year, in advance.

MONTHLY—The first number of each month, at 50 cents a year, in advance.

Any person sending a club of six is entitled to an extra copy (like the club) sent to any address desired. Sample copies furnished free.

George Neighbour & Sons, London, England, are our authorized agents for Europe.

Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

A Clever Scheme.—Messrs. Williamson & Bro., a very enterprising firm of Lexington, Ky., have ordered 500 copies of "Honey as Food and Medicine," with their business card in detail printed on the page following the title, in addition to a display card on the first page of cover. They are quite extensive dealers in honey, in addition to their supply business, and will find this the most practical, as well as the cheapest method of reaching both producers and consumers. In lots of 500 or 1,000 we can make a still further discount from dozen rates, and parties ordering can have their card printed in their local printing office if they desire. As we have the plates electrotyped, we can fill orders for large quantities very speedily.

The McGregor, Iowa, *News* says: "The publisher of the AMERICAN BEE JOURNAL may well be proud of its great success. The honey and bee business during the past year was not encouraging in some localities, but Thos. G. Newman is not a man to be dismayed by one bad year. The BEE JOURNAL will continue its weekly flights.

"Leaves from my Portfolio" is the title of a book of about 250 pages, by the Rev. W. K. Burr, M. A., of Belleville, Ontario, Canada, a copy of which we have received from the author who is an ardent apiculturist, and a constant reader of the BEE JOURNAL. It contains many literary gems, and is a valuable addition to our library.

We regret to hear that a large shipment of queen bees, on the way from the Island of Cyprus to Mr. D. A. Jones, of Beeton, Ontario, were caught among the icebergs in the Gulf of St. Lawrence, and all but two perished by its chilling power. This is a great loss, it being the first importation this season from Mr. Frank Benton, who has charge of Mr. Jones' apiary in Cyprus.

An immensity of white clover bloom is developing itself everywhere, and the linden trees are very full of buds. Propitious weather is all that is needed for a large honey harvest.

We have received a copy of the Cornell University Register for 1881-2. The next term commences Sept. 19. The department of agriculture is quite a feature of this Institution, and the advantages it offers are within the reach of every man who has made good use of the instruction afforded in the public schools. The fee for tuition is \$25 a term. It is located at Ithaca, N. Y.

Since the death of Mr. James Vick, of Rochester, N. Y., we learn that his large seed business is to be conducted by his four sons—the oldest of whom is named "James Vick." All of them have been educated in the business from boyhood. We hope they will worthily wear the mantle of their late father, and manage the vast business with the same excellent judgment which he displayed throughout all its departments.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

Who Gets the Profits?

The *California Apiculturist* for June has the following excellent article, and excepting one or two trifling inaccuracies, it is well worth consideration by every honey producer in that sun-gladdened State:

That there is a large profit made on honey by some one, is quite evident from facts that cannot be denied. That the bee-keeper does not make it is also evident, and only needs past experience to establish the fact.

We are reliably informed by residents in many of the eastern and western States, that when they purchase our honey there at retail they pay from 20 to 40 cents per pound for it. Dealers in San Francisco pay from 5 to 7 cents for it, and then deduct the weight of the cans at that, leaving the producer from 4 to 5 cents per pound, after deducting freight and all other expenses. Now, *who gets the profits?* There is a profit from 15 to 30 cents somewhere, and this is not all. The San Francisco dealers often sell and reserve the cans, or repack in small packages in order to secure a larger gain, and then sell the original packages back to the producer, after having robbed him of them. This imposition has been, and is undoubtedly practiced now. The apiculturists of Southern California have openly and publicly denounced this unfairness and have asked, through their associations throughout the honey districts of the State, that a reasonable tare be adopted on cases commonly used for 60 lb. cans, which would be from 12 lbs. to 14 lbs., but their requests have been disregarded, and a tare of 16 lbs. to 18 lbs. has been exacted, these tares including the cans.

These honey dealers doubtless have a ring and fix their own prices, as have the fruit packers and other dealers done. Nine-tenths of the honey producers in this part of the State are dissatisfied with the San Francisco market and are determined to ship around it to some other market. European dealers are making bids for our products, and many will try the experiment there this season. Shipments made to many of our eastern cities have been much more profitable than those made to San Francisco. No deduction for packages are made outside of San Francisco, as far as we have been able to learn. When the retailer sells our honey or other canned goods, he does not deduct the weight of the cans. Why this exaction from the honey producer? It is evidently a gross injustice that should not be tolerated.

Until a different system of marketing honey is adopted impositions of this kind will be practiced by the swindling rings that control the market. Why is it that the eastern beekeepers get a remunerative price for their honey? The reason is plain, they place their honey upon the market in an attractive form—in small packages, neatly labeled. By the small package system they reach the

consumer in a more direct manner, thus avoiding the middlemen to a great extent. When we adopt the same system we will avoid swindlers and break up the rings.

The trifling inaccuracies to which we referred above, are the prices at which California honey usually retails here. For honey in sections they generally rule at about 20 to 30 cents, and extracted retails at about 15 to 20 cents; of course, this is strictly at retail, and not in job lots, which are much lower sometimes. But in the main, the sentiments of the article are correct.

In view of the complications likely to arise, and which had already arisen, the *BEE JOURNAL* long ago urged upon bee-keepers the necessity for adopting small kegs in making their shipments to distant markets, and the desirableness of 1 lb., 2½ lb., 5 lb., and 10 lb. tin pails, always neatly and tastefully labeled, and with the name of the producer prominently printed thereon, where intended for retailing to the consumer direct, not only as a practical method of advertising, but as a guarantee to the consumer of the genuineness of the article; and it is a gratification to allude to the happy results which have been obtained by following the course we suggested. Many progressive bee-keepers are realizing remunerative profits and rapid sales, where formerly their product was a drug on the market, and their returns anything but satisfactory. Where a good, neat package of honey has been sold once at a reasonable price, it is not a difficult matter to sell it again.

We have always deplored the employment of middle-men where it was possible to dispense with them. Their time is valuable—much more so, usually, than that of the bee-keeper or other producer—their expenses for clerk hire, storage, rent, etc., are large—a considerable capital is required for the successful prosecution of a commission or brokerage business, for advances to be made and goods lying idle, earning nothing—and all this must be paid by the producer eventually. The commission man, if honest, will look to the consignee's interest; if prudent, will look to his own, and all are prudent. His own percentages must be realized, though the shipper be bankrupted; claims of the consumer for tare must be rebated, though the producer knows his own scales to be correct, and cooerage claims must be al-

lowed, though the shipper was never so careful.

The producer should always be willing to allow an *honest* tare, for if a package be represented to contain a certain number of pounds, it should not fall short one ounce, rather, an ounce over; but he should carefully weigh the keg or pail before filling, and afterward firmly resist any extortion for tare when selling.

Avoid rings if possible. They are usually of no benefit to anybody but themselves, and are always organized to encompass some one, either producer or consumer. The interests of producers and consumers are to a great extent identical; those of the middle-men are antagonistic to one class, and sometimes both. We are not of opinion that they are dishonest or unfair in their transactions, but with them business is business, and the bulk of the net profit from produce of any kind, most usually remains in their own pockets.

Glucose in California.

The *Apiculturist* is evidently in earnest in assuming to forward the interests of bee-keepers in California, and every person in that State, who is dependent upon apiculture, should give that paper a generous support, and, if necessary, strain a point to sustain it. The following spirited article appeared in the June number:

It is beginning to be doubted whether the cans of "honey" put up by the fruit canneries of San Francisco contain the genuine article. The member of our company living near San Francisco has heard reports that men who have worked in some of these factories say that they *do* use glucose to mix with the honey they buy at a sacrifice from the produce dealers of San Francisco. A bee-keeper, in writing to our associate, says that he has seen any number of barrels of glucose in front of fruit canning establishments in San Francisco. The associate editor has seen 2 lb. unsealed covered cans of honey offered in stores in and about Oakland that sell for 30 cents apiece. On asking if they contained pure honey he was told that "it did not make much difference whether it was or not, so long as consumers could not tell the difference." It seems to us that these factories would not care to can pure honey, for, as is well known, they are for making large profits. If the above statements are true, it is time the practice was stopped. The managers of this journal are about seeking evidence on this score and will, if they are able to make out a case, have complaints sworn out against the violators of the law. It is time that the apiarists put their

honey on the market in their own small packages and reap the profits.

We hope the determination expressed to investigate the matter, and if glucose has been used in honey, to institute legal proceedings, will prove no idle boast, but that the law will be enforced to the fullest extent. Bee-keepers in California owe it to themselves to sustain the *Apiculturist* in its efforts to elevate the standard of their honey.

It has become a fixed maxim in the Eastern, Northern, and Central States, that pure honey will granulate to a greater or less extent, and with this as a test, it is becoming an easy matter to dispose of pure extracted honey at all seasons; but California honey has become more difficult of sale, because of its usual liquid state, and the claim put forth that it does not granulate. Its most extensive sale in our Eastern markets has been to unprincipled parties, who have bought it solely with a view to mixing with glucose syrup, and retailing as "strained" honey. With a pure article, put up in neat, popular packages, there will be no necessity for California apiarists to discount the prices of any other country in the world.

MISCELLANEOUS.

Bees in California.—Mr. J. E. Pleasants, in the *California Apiculturist*, gives the following item on the present prospect for honey in that State:

It were useless to deny that the frequent drouths which have been experienced in the last few years have a discouraging look for the business, but a man can scarcely be called wise who neglects to gain wisdom from his failures, and disasters are often of value in the way of experience, and many a lesson has the *pobre abejero* learnt from the drouths which, even in this much favored country, he is freely treated to.

In the last 7 years there have been two total failures in the business—1877 and 1879, and a partial one in 1880. As a natural consequence, many who were engaged in this pursuit got very much behind financially, and they were looked upon with pity for being so simple as to be engaged in such a precarious occupation, and the question was often asked of the poor bee-keeper by thoughtless ones, "Why don't you have an orange orchard, or a vine yard, such business' pay much

better all the time?" The prudent bee-keeper thinks of the wise proverb, "Speech is silver—silence is gold," and refrains. If he would, he could say: "There is no human undertaking that is certain. In this vale of tears every occupation has its lights and shadows, and our turn will eventually come." It has come. The future now looks very bright for the bee-keeper. He has had a long rest of more than a year, therefore he is more than ready to put on his visor, and buckle on his armor, and go into service with renewed strength and vigor, for his prospects are very encouraging. The yield of honey will be large judging from appearances up to date.

The editor of the *California Apiculturist* adds his testimony as follows:

The season, as we have heretofore stated would be late, in consequence of the late rains. In our locality, as in many others, the sages, wild alfalfa and other leading honey plants are now beginning to bloom, and the bees have commenced storing surplus honey. We are informed that in other localities bees have not commenced to swarm, which may be attributed to their weak condition, and that some apiarists are discouraged and are rendering their surplus comb into wax. In our own apiary our bees are storing honey well, considering the season, which we fear will fall short of our previous expectations. . . .

It may be better than some expected it to be, but we will wait and see, at the same time advising those who have any to hold on to it, as the price is bound to go up. By the telegraphic dispatches we notice that "Old Nick," or something else, is playing havoc back in the East. The laugh won't be on their side this time, at any rate.

Mrs. Fairchild, of Pomona, under date of May 20, writes:

"The honey harvest in this section will not sustain the hopes that were entertained by bee-keepers a month or more ago. Like the prospective wheat crop, honey will be short. We will be satisfied this season with half a crop, and many others will not fare so well as that. In fact, we have as yet no assurance that we will have any to dispose of. Our hopes all hang on the quantity and quality of the white sage blossoms. Last year there was very little nectar in the flowers. With 600 healthy colonies of industrious workers yet to hear from, we must wait for further returns before we can form any definite conclusions regarding the coming crop. The oldest apiarist avoids answering the question: What will the harvest be?"

Mr. C. M. Drake, of Santa Paula, writes May 10, as follows:

The honey prospects look dubious. I don't expect more than half a crop at utmost. Fog is coming up to-day for the first time in several weeks. If it continues it will help us out, but the ground is not wet down far enough. The hills are drying up, but the sages look fair as yet. I think

the bloom will not last long when it does open on them. Still, all is guess work till June. Then we can tell pretty well what the crop will be.

Use of the Honey Extractor.—The *Indiana Farmer* gives the following:

The full benefit of the honey extractor can only be appreciated in seasons like the indications predict the present one will be. When honey comes on slowly, bees are very loth to build comb, and will fill every empty cell in the hive before commencing the construction of new comb. At times the honey will come in very fast for a day or two, then again slack off, and in times like these, we can only get the benefits by having plenty of empty combs in which they can store the honey without stopping for its construction. We frequently secure twenty-five or thirty pounds from weak colonies or nuclei late in the season, by giving them plenty of empty combs which probably would not have made a pound of comb honey.

A rather curious circumstance happened in the country, not far from Somerville, one day this week. It was sunshiny and warm and a young lady sat in the parlor playing the piano, with all the windows thrown open, when a swarm of bees, attracted by the music, entered a window and settled on the piano.—*Somerville (Ala.) Falcon.*

Local Convention Directory.

1882.	Time and Place of Meeting.
July 25—	Western Iowa, at Winterset, Iowa.
	Henry Wallace, Sec., Winterset, Iowa.
Aug. 10—	Maine State, at Harmony, Maine.
	Wm. Hoyt, Sec.
Sept. 5—	N. W. Ill. and S. W. Wis., at Rockton, Ill.
	Jonathan Stewart, Sec.
Oct. 5—	Kentucky Union, at Shelbyville, Ky.
	G. W. Demaree, Sec., Christiansburg, Ky.
	Tuscarawas Valley, at Newcomerstown, O.
	J. A. Bucklew, Sec., Clarks, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—*Ed.*

The Western Iowa Bee-keepers' Association met at Winterset, Iowa, May 25, 1882.

Reports were received from the various bee-keepers, from which it was gathered that the loss since last autumn has been about 16 per cent.—nearly all from spring dwindling. The winter was one of the most favorable for bees; the spring the worst known for years, being cold and wet.

The main topic for discussion was "Methods of Increase." The universal opinion was in favor of artificial swarming and judicious dividing.

Samples of domestic preparations made from honey were duly sampled. Convention adjourned to meet in Winterset, July 25, 1882.

HENRY WALLACE, Sec.

CORRESPONDENCE

For the American Bee Journal.

The Non-Progressive Bee-Keeper.

MRS. A. M. SANDERS.

I s'pose all these progressive folks
With their patent hives and lotions,
Call me a stiff old fogey.
'Cause I don't adopt their notions ;
I've kept bees nigh on forty years,
And yet these Yankee nobbies
Think they can teach me something new,
With their new-fangled hobbies.

'They say they've got some kind of thing—
I guess they call extractor—
That sings the honey from the combs ;
And, then, it is a fact, sir,
They'll drain the honey from the cells
Then let the bees refill it,
And almost every day or two
They'll go and rob and steal it.

I give my bees the first best chance
To make their own free living,
Then take whatever they have left,
And thank them for the giving ;
And then they've got a patent stove
'That, when they choose to make it,
Will pour a mess of stifling smoke
Into the bees—"plague take it."

I have been told they melt up wax,
And call it comb foundation ;
And quilts, and clamps, and other sorts
Of fools' conglomeration.
They've got to swindle honest folks,
And get their hard-earned money,
With striped bees and hives that hold
Two hundred pounds of honey.

When you have lived as many years
As I, I think you'll see
That patent hives are not the things
'That they're cracked-up to be ;
Those monstrous yields of honey
From one hive they receive—
Well, I want to see it 'fore
I say that I believe.

I stick to my old hemlock gums,
Without chaff or any fixtures ;
And I don't have to feed my bees
With flour and glucose mixtures.
But I suppose the world will move
On in the same old way,
For swindlers they will advertise
And make their business pay.

Sheridan, Mich.

Bienenzeitung (German).

My Opinion of Cyprian Bees.

JOHANN STAHLALA.

Although requested by several parties to publish my opinion of Cyprian bees in the columns of the *Bienenzeitung*, I did not like to do so, until I had well tried this race of bees in my apiary. But now I feel myself in duty bound to make my opinion public. Count Kolowrat, to whose kindness I am indebted for having my entire apiary alive with genuine Cyprian bees in their most perfect purity and beauty, wrote to me in the spring of 1877 as follows :

"To you, right reverend sir, having grown in our love and esteem as the author of many sterling articles on apiculture, I recommend my golden child, with the ardent desire that you will judge of it without prejudice, and that when the time comes you will inform me of your experience with it, be it good, or the opposite from it."

If any bee-keeper who possesses scarcely one genuine or hybrid colony of Cyprians, may permit himself to judge thereby of the entire Cyprian race, then I think it will be admissa-

ble for me to do so, as I have had, during the last two years, a great many Cyprian colonies in my apiary. For in the previous year I had 71 Cyprian-hybrid colonies, with one genuine, and in the present year I had in the summer 87 strong Cyprian colonies in my bee-garden, and after removing the hybrid colonies, I have ready for wintering 73 colonies of pure Cyprians ; and as several bee-keepers in my neighborhood brought last summer a number of small colonies into my bee-yard, to have Cyprian queen cells placed in them, and the young queens fertilized by my Cyprian drones, the number of Cyprian queens that were altogether reared this year in my bee-garden reached up to 108. From this it may be seen that opportunities enough were offered me to test the qualities of the Cyprian-hybrid bees, as well as those of the pure Cyprians. As certain as I was last year, that all of the colonies in my garden, with the exception of one, were Cyprian-hybrids, just as certain am I now, that my Cyprian queens of this year, with very few exceptions, have been fertilized purely Cyprian.

Count Kolowrat, when even the purity of his Cyprian bees was questioned and the assertion was made, that his apiary, too, was filled throughout with hybrids, sent last summer for a fresh colony of Cyprians, and, through the kindness of that gentleman, was it made possible for me to rear my queens of this year from the brood of the recently-arrived original queen, and, as my apiary stands quite isolated, for, in the town I live, and in the surrounding villages no bees are kept, my queens of the present year, with few exceptions, were purely fertilized.

Following this introduction, I will now describe the bees themselves. The Cyprian bees are similar to the Italians, but have many distinctive marks, by which they plainly differ from the Italian bees, and those are :

1. The true characteristic or essential mark of distinction, by which, according to my experience, a pure Cyprian colony can be distinguished from an Italian is this, that all pure Cyprians, without any exceptions, are more or less yellow on the lower part of their hind bodies, changing into black at the point of the body, while the Italians—even the handsomest—are entirely black upon the lower part of their body. Some of the pure Cyprian colonies have such beautiful yellow workers, that only the extreme point of the body appears black, and the yellow part underneath their bodies looks as glossy as if covered with a coat of varnish, and for this reason one can recognize them immediately as Cyprians, when noticing any of them crawling over the glass near the entrance, even when several paces away from them. But if bees are found among a colony that are coal black upon the lower part of the body, then it is a Cyprian-hybrid colony, even when the remainder of the workers have the marks of the Cyprians, and are perhaps more beautiful yet, than the workers of a pure Cyprian colony. For a few of my

hybrid queens from last year had such beautiful workers, that a layman would have pronounced them as genuine ; but they could not be genuine, for neither myself nor anybody else in my neighborhood owned any Cyprian drones. Last year, a larger or smaller part of my workers in all the hives were black ; this year I cannot find a single black bee among my Cyprians.

2. Pure Cyprian workers are somewhat smaller, slender, like a wasp, their bodies ending in a sharp point.

3. The hair-growth of the genuine Cyprian bee, especially upon the breast, is a light yellow, and of a lighter shade than that of the Italian.

4. The first 2 rings of the hind body are orange-colored, and these rings are yellow the entire width, while among the Italians, many workers are found that have only two narrow yellow stripes, and sometimes only one.

5. The last white rings of the hind part of the Cyprian workers are broader than those of the Italian, because the small, white hairs forming these rings are longer.

6. The Cyprian bees have between the wings, in the center of the little backplate, a yellow spot, which I have never found to be of such a light yellow on the Italians ; but the color of this spot is not of the same shade on all the bees, on some it is a little darker.

7. The genuine Cyprian bees seal the combs, especially those of an older date, strikingly ash-grey, while the Italians seal brown.

8. The increase of the Cyprian workers, the pure as well as the hybrids, is multitudinous in the spring. I have never noticed such an increase, neither among the domestic nor among the Italian bees, which latter are by all means superior to the domestic in increasing. All that visited my apiary expressed their surprise over the gigantic colonies which I was able to show to them last spring. I, for this reason, was compelled to divide many colonies, and had to form nuclei, and from those undivided I had to take several sealed brood combs, so as to create space. But I furnished to my bees neither flour, nor milk, nor eggs, as artificial food. Among my Cyprian colonies I noticed not as much inclination to swarm as is the case with Carniolan bees. Only 3 natural swarms did I receive this summer, while other bee-keepers in this locality had a great many natural swarms. It is possible and even probable that, if I had not divided the strongest colonies, and had not taken away from the others so many brood combs, I would have had more natural swarms.

The natural consequence of this extraordinary strong increase of the workers in the spring, is, that the Cyprian bees gather more honey in the summer than any other bee I know of ; for where there are many workers, much can be accomplished.

This superiority of the Cyprian workers, so highly important to the practice, did not escape the keen sense of observation of Count Kolo-

wrat, for this noble-minded gentleman, who is a skilled master in judging of the different bee races, told me that, according to his best knowledge and conscience, the Cyprian bees possessed the greatest ability of performance. When I visited Count Kolowrat last summer, and he questioned me how the pure Cyprian colony which he had sent me was doing, I answered: "That colony is so strong that I had to take from it when I left home 3 combs of brood, fearing that they would swarm during my absence; but I have never found any honey in this hive." Then the Count said to me: "When you have returned home you will find the hive full of honey." And so it was. Returning home after an absence of 5 weeks, I found that the entire hive was filled with combs of honey. It was the same this summer, all hives, the colonies of which I had not divided, abounded with honey, and I therefore had to bring the extractor into motion, although the present year is not looked upon by bee-keepers as a favorable one.

10. Here I will remark, that the collecting propensity which manifests itself with the Italian bees, through a greater liking to rob than is the case with our domestic bee, is developed in a yet greater degree among Cyprians. Therefore, it is well to pay more attention to the Cyprian bees, after the honey gathering is over, than to the Italians, so that their natural collecting propensity may not degenerate into a robbing propensity. Last fall, one afternoon when absent from home, I was robbed of a whole colony.

11. If the genuine Cyprian bees remain strong in the fall, too, then one has greater hopes of bringing them safely through the winter than would be the case with the Italians; for it is well known, that the Italian bees, after the expulsion of the drones, grow weaker from year to year, and never go as strong into wintering as the Cyprian bees. As I had casseted those colonies this fall that had Cyprian-hybrid queens, I did not know finally, into what colonies I should put the bees from the casseted colonies, for as all the colonies were very strong, I did not like to overfill them.

12. The Cyprian drones are, with only few exceptions, of a beautiful yellow color on the top of the hind body, as also on both sides of the same; and I have never noticed this in like manner among the Italian drones, which is, furthermore, confirmed by the masters of bee-keeping, for they say that the pure Italian drones are entirely dark, with only a very indistinct, yellow-looking stripe upon their hind body. I found in my apiary this summer a few drones who were marked yellow nearly all over; they could really be called apistic beauties, while the first drones in the spring were of a dark color.

13. I found it in truth confirmed, what Count Kolowrat had stated to me as his experience, that the Cyprian queens begin much later with laying drone eggs than the Italian or domestic queens. I therefore wrote

to the Count on the 24th of last May, that I could see a few drones only in three hives in my apiary, notwithstanding the fact that the colonies were quite strong already, and, as I desired to give to all of my colonies pure Cyprian queens, I felt quite a longing for Cyprian drones. For this reason I employed, when I found that the queens showed little inclination towards laying drone eggs, all the means at my command to increase the number of Cyprian drones, so that I could count with greater certainty upon a pure Cyprian fertilization of the young queens, and my desire was fulfilled. In July thousands and thousands of beautiful drones came flying into my garden. The young queens did not have to look long before finding a Cyprian drone. In this manner I had 55 young Cyprian queens, daughters of the original queen from the Island of Cyprus, fertilized between July 22 and 24, in about 3 days.

Here let me remark, that my experience in reference to the fertilization of the daughters of the original queens, does not agree in full with the experiences of Count Kolowrat, for, while the daughters of the original queen in his apiary furnished, every one of them, a throughout yellow posterity of workers, notwithstanding the fact, as stated by him, that some of those queens had come in certain contact with black drones, I have found that 3 daughters of the original queen from the Island of Cyprus brought forth many black (nearly coal-black) workers, and proved themselves, therefore, Cyprian-hybrids, while all the other daughters of the original Cyprian queen had such beautiful workers for her children, that the heart of a passionate apiculturist must have filled with joy when looking at these golden darlings.

If the Italian bees have bribed the eyes of many a bee-keeper, on account of their handsome dress, so that he could find no rest until he saw himself in possession of the Italians, and saw them fly around in his garden, then the Cyprian bee—the genuine—must indeed charm the eye of any apiculturist who has never beheld them in their uniform splendor; the more so, because they possess, besides their more beautiful dress, many valuable qualities which the Italians lack. It is not surprising, therefore, that many a bee-keeper after having seen these beautiful and industrious little insects, cannot withstand the desire of coming into possession of them.

14. The Cyprian queens are smaller than the Italians, and have a very long and pointed hind body. In reference to their color, they vary the same as the Italians. Among them I find some that are dark, some are yellow, and some brilliantly yellow. After issuing from their cells, they are mostly similar to the Cyprian workers. The first two segments of the hind body are of an orange-yellow too.

But the upper part of the hind-body, commencing with these orange-colored rings, changes into black towards the pointed end of their

bodies; the sides of the hind-body are in most cases light yellow, more beautiful than those of the Italian or those of the Cyprian workers, and the lower part of the hind part is a pale yellow. I had a queen this year upon which nothing black at all could be detected, only upon the point of the body could be noticed an almost imperceptible darker shade of yellow. All to whom I showed this queen assured me of having never before seen such a beautiful queen. Unfortunately, and through my own fault, I have subsequently lost this queen.

The offspring, though, do not always take after the queen; for many a darker queen has yellow workers than another, which is of a beautiful yellow, and has been purely fertilized. The lighter or darker color of the workers takes its origin from the Cyprian drones with which the queen has come in direct connection while being fertilized; for, the first Cyprian drones this spring were darker, and though the Cyprian queens that were fertilized, at that time were fertilized pure, yet the workers (their daughters) were much darker, than the workers of those queens that were fertilized later, when I already had many, very beautiful yellow drones in my apiary.

The light color of the Cyprian queens changes likewise into dark or dark-red when they are getting old, as is the case with the Italians. The pure Cyprian queen which I in the previous year received from Count Kolowrat was of a reddish-yellow; this summer she had already changed into dark-red.

15. Finally, I will mention another distinction of the Cyprian bee, namely, the famous sting-fury of the Cyprian bees, about which we have read a description in the *Bienenzeitung*, on account of which it was attempted to deny to them their fitness for a large apiary. I have practiced a great deal with these bees in my large apiary during these two years, and have had, therefore, many opportunities to obtain experience in this regard. Last year, as well as in the present, I have for the second time given new Cyprian queens to all the colonies of my large apiary. I furthermore had to take all the combs from the hives last spring, because I desired to exchange the old-fashioned sticks for frames, brush off the bees from them, insert the combs into the new frames, and get the cabinet-maker to nail down the ledges in the hives, after which I let the bees that had been brushed off from the combs run back into their hives; besides all this, I had to form several nuclei—had to look quite frequently if the queens were fertilized, and in the fall, if the bees possessed sufficient food and proper combs for the winter. As may be judged by the above, I have had in this connection a great deal of experience. But, it will be said, what was your experience in reference to the stinging propensities of these bees? Tell the truth! Have you not been killed by these beasts that take so much delight in stinging? And I answer: No, I am alive yet, and they give me great joy!

Never have I owned such industrious, strong and beautiful bees. It is true, I occasionally was made cognizant of the fact that the Cyprian bees do not belong to a stingless species, and that they possess great expertness in the application of formic acid plasters, but during these two years I have frequently busied myself during a whole afternoon in my apiary, in company with my assistants, without receiving a single sting. I have during that time acquainted myself fully and in detail with the manner of treating the Cyprian bees, having had opportunities sufficiently to learn all about their natural proclivities, temper, etc., and I now know how I have to manipulate the former colonists of the Island of Cyprus.

If you are acquainted with the temper of a human being, with whom you stand in close relationship, then you very soon will know how to act towards him, so as to retain the friendly relation. According to my experience, the Cyprian bees possess a choleric temper. They are, consequently, very irritable and easy become violently angry, and, therefore, they require a treatment which must be compatible with their temper.

But psychology teaches us that man, when in the possession of a choleric temper, will easily fly into a violent passion, when deeply insulted, and if you continue to provoke him while he is in this violent state, he will grow still more violent; on the other hand, though, if you yield to him, or you clear his path, he will be, after a while when his anger has cooled down, one of the best of men. The same it is with the Cyprian bees. For animals, too, have various tempers.

If you carefully avoid everything which would also irritate bees of another race, viz: all sudden opening of doors, all opening of the hives when the wind is blowing, or rain is coming down, all noise near an open hive, every violent shaking of the combs, every hasty manipulation in the hive itself, then they will allow themselves to be handled the same as the Italians. But if you irritate them, or offend them seriously though whatever it may be, they will easily grow very wrathful, particularly when a strong colony has not been opened for a long time and they are not accustomed to the opening any more, they will turn their eyes upon the bee-keeper with a very hard look in them. If you leave such an excited colony to themselves for a while, so as to give time to their anger to cool, you can continue to work near them after a lapse of about two hours with perfect safety. This precautionary measure I have closely followed.

But many bee-keepers increase this proclivity to sting among their bees, because when they see them angry they try to subdue them by force, using smoke or water to accomplish this, instead of yielding to them or giving them time in which to recover from their rage.

I endeavor to avoid everything which might seriously offend the bees. But when it did happen that I had offended through carelessness some

strong colony, and I noticed that they intended to make war upon me and had even then already pressed into my hand or face a pointed ultimatum, then I did not attempt again to gain the upper hand by the use of smoke or water; I played the role of the prudent, *i. e.*, I yielded, closed the hive and departed, paying, in the meanwhile, a visit to some other colony; when after an absence of about two hours, I returned in humility to the hive containing the warlike colony, and began to work quietly and cautiously, we were again the best of friends. If this had not been my own personal experience, I would be slow to believe that a colony which had been full of rage in the forenoon, could be as meek as a lamb in the afternoon. Here the French proverb is well applied: *Tout par douceur et rien par force.*

Further, I must remark that I have done my apistic work during daytime mostly at such hours when the older bees (being more inclined to sting) were out upon the pasture, so as not to irritate them unnecessarily, for then I had nothing to fear from the young ones; near very strong colonies I worked during the late hours of the afternoon, the old bees were then at home it is true, but they were tired out from their day's labor, and were not so quarrelsome.

But, although the Cyprian bees are somewhat more quarrelsome than the Italians, I nevertheless prefer the Cyprians, when comparing the qualities of both races with each other. And even if the Cyprian bees did not offer anything preferable to the Italians, I like them better than any other bee for the only reason, that they very soon grow strong in the spring and remain strong in the fall, for, as everyone knows, strong colonies are profitable.

Even if the principal motive of most people in keeping bees is to derive profit from it, the beauty of the bees is nevertheless highly valued by such people, and the beautiful and at the same time more profitable bees are better esteemed by them, than those that are black (*Omne tulit punctum qui miscuit utile dulci.* This is my opinion of Cyprian bees.

In expressing my opinion in only a few words, it is as follows:

Count Kolowrat—whom nobody can charge with mercantile speculations—spoke the truth when he told me last year that he considered the Cyprian bee, according to his best knowledge and conscientiousness, as possessing the greatest performing ability. I fully agree with his statement, for, as I have just as large an apiary—although not such a handsome one—as Count Kolowrat, I was enabled to convince myself of the truth of his statement. Therefore, my opinion agrees entirely with the opinion of this esteemed gentleman.

In conclusion I will yet say: Count Kolowrat deserves the thanks of all apiculturists who have Cyprian bees in their apiaries, or who intend to procure them, on account of his introducing the Cyprian bees into our country!

I, for myself, as well as in the name of all such bee-keepers, herewith express to him this gratitude for his great sacrifices, for his disinterestedness and his kind efforts to render service to others.

For the American Bee Journal.

Care of Comb Honey—No. 3.

G. M. DOOLITTLE.

Having the honey all glassed and graded as I told you I did in my last, the next thing we wish is crates or cases for I believe the putting of honey upon any market in bulk is a bad practice, and for shipping honey to a distant market crates are a necessity. A difference of two cents per pound is generally made between honey in bulk and honey nicely crated, while the crates and crating should not cost one-half of that amount. I get out my crate stuff in the winter all ready to nail together, so as to be as near ready as possible for all things connected with the honey harvest. If I purchased my crates of a supply dealer I should do so in the winter, so as to have all in readiness, for it is much better to have a few crates left over than to be obliged to wait, and perhaps lose a good chance of selling our honey because our order is sent at the last moment, when some unexpected delay is almost sure to happen.

For the 2-lb. or prize box there is nothing better than the prize crate, which holds 12 boxes or sections; but for the 1½-lb. box I prefer a crate holding only 9. The demand for small sections seems to be in small quantities, for these small crates are frequently bought by one person, and thus the retailer never opens them, but sells by the crate instead of by the section. Having concluded how many sections I wish in a crate, I pack them together the way I wish them to stand in the crate, and then measure them, which gives me the exact size I want the crate, inside measure, and no guess work about it. Much of the annoyance to supply dealers would be saved if all would adopt this plan. In the making of crates there is one item I wish to speak of. In handling and shipping comb honey, it will always leak more or less from the many accidents it is exposed to, and if the crate allows this leakage to run out at the bottom down on the next crate, the floor, etc., it tends to lower the price of our production. To prevent this, some of our apiarists have the bottom of their crates halved into the ends and nailed both ways, to secure as nearly as possible a tight joint, but for all this the joints get wrenched apart more or less in shipping and leaky crates are the result. To obviate this leakage of crates, I adopted the following plan last fall, which proved entirely satisfactory:

Take good strong manilla paper and cut it two inches larger each way than the bottom of your crate is, inside measure. Now get out an inch board large enough so it will just go

inside of your crate easily, and place it upon the paper so that the paper will project equally on all sides, when the sides are to be turned up all around and the corner pressed over nicely, making a joint like that on a baking tin. Lift out your board and set your paper dish in the bottom of your crate, and you have something which will hold all running honey till it is full. We all know that if any honey leaks from the combs that the sections will be more or less daubed upon the bottom of them, and in taking from the crate they are ready to soil everything the touch. To avoid this I saw the ends of the crates 3-16 longer than the piled up sections are high, so as to give room to lay 3-16 inch strips across the bottom of the crate for the sections to rest upon. These strips I get out $\frac{3}{4}$ of an inch wide, and so arrange them that the edges of the sections come on these strips, thus leaving a 3-16 space under nearly the entire section. Thus it will be seen that all the leakage is kept inside the crate, and that the sections are kept all clean besides.

We are now ready to crate the honey by placing the sections in the crates, putting the best side of each grade on the outside; but do not put any of a lower grade in the same crate. After a crop of any kind is graded, it is always customary to put the best, or face side of said grade out. Having previously weighed the crate, and the weight of it being marked on the same as tare, I now fill it as above and nail on the cover with wire nails, which will drive without jarring enough to crack the combs. I space these nails at equal distances, using three at each end. Over the heads of these nails I drive brass-headed furniture nails, which cover up the heads of the other nails, and give the crate a neat, tasty, finished appearance. Also, when the crates are filled up those on top rest on these brass-headed nails, and thus the tops of our crates are not all marred and bruised up.

Now with a wood-rasp and sandpaper, the corners and all rough places are smoothed off, when the crates and contents are weighed and set down as gross weight above the tare. Draw a line and subtract the tare, setting down the net weight, when the crate is ready for hauling to market. In crating the honey I always place it in the crate the same side up it stood while on the hive, as, from experience I am led to believe it can be transported more safely that way than bottom-side up. In hauling to market, as far as possible I have the combs run crosswise of the wagon, as the motion from side to side of the wagon, is greater than endwise. Get a good platform spring-wagon and load it, so the springs carry the load easy and there is little danger of breaking the combs. In loading honey great care should be taken to set it down without jarring, and always lift the crate to move it, instead of sliding it. I have frequently seen men slide a crate of honey along on the bottom of a wagon or car till the bottom struck the head of a bolt or some uneven surface, when every comb in

the crate would be broken by the wrenching the crate received by such careless handling. If our honey is to go by rail it should be placed in the car with the combs running lengthwise of the car, as the coupling of the cars is about all the danger there is of breaking the honey when shipped by rail. By placing the crates a foot or two from the front end of the car, and having the combs run as above, there is but little danger of breakage if the Railway employees will handle it carefully.

This ends the CARE part of these articles.

Borodino, N. Y.

For the American Bee Journal.

The Wintering Problem.

JAMES HEDDON.

Need I offer any apology for presenting this theme again. I believe I need not, when it remains a fact that it is still not understood. In this article I wish to take a retrospective survey of the ground I have come over, in an earnest and honest effort to unravel this problem.

First. It may be in place to hastily survey some of my critics. To me they seem to be divided into about two classes. Among one class are those who feast upon mirth, imagination and ridicule. A sort of "Jack Horner," who stick in their thumb and pull out a plum. Oh! what a brave boy am I." A class who think they see some one going down hill, and so they kick at his sled. Then the other class, whose earnest enthusiasm for the important truths is their only inspiring motive toward controversy.

On page 70 and 72 of this year's *Gleanings*, these two classes are faithfully represented in our "cold hard fact," "box-elder" novelist, and the well known extensive observer and honey producer, George Grimm.

After thanking Mr. Grimm for his splendid compliment, one that from its source settles deeply into my feelings, I feel it a duty, and an act that may be productive of good, to argue with him upon the few points of difference between us. I hope that his fair, earnest and scientific spirit may act as a contagion between us. But first I want to hastily review the ground I have come over in trying to get nearer to the solution of this far-off problem. All who had reasoned publicly upon the subject, had, as is usual, reasoned from the center to the circumference. As all had failed to find what to me seemed reasonable causes for the effects that had come under my observation, I resolved to try the method of reasoning the other way, from the outside toward the center. This plan often very easily solves problems that the other method leaves only in deeper obscurity. Let me illustrate: Years ago I saw a gentleman hand another a three-jointed foot-rule, and ask him if he could open it just three times and no more and open all, and from him every time. I saw him puzzle over it

many minutes, when he handed it to me. Though I had never thought of the puzzle before, the thought struck me, that the converse of the proposition must also be true, viz, that the rule would shut three times toward me. I thought I would try that first, and see how matters look through the other end of the telescope. You know the result: Simplicity simplified.

Once more. After astronomers had searched the solar system for more planets, and with their best glasses could find no more, Mr. Leverrier, the celebrated French astronomer, said "there is another planet beyond the orbit of Uranus." Now, instead of saying I will look for it, he said I will look for its effects upon Uranus, and by so doing he theorized a chain of facts in regard to its size, period of revolution, etc. Though having seen nothing, he felt that he knew right where the body of matter would be at a certain day and hour; so he wrote to Dr. Galle, of Berlin, to look for it with his better instrument at that particular time, and in a certain locality, which he did, and which resulted in the immediate discovery of the now well known planet of Neptune.

Whether right or wrong in my deductions leading to my lately written opinions upon the subject of bee cholera, dysentery, or diarrhea, or whatever name you may choose to call these effects, I reasoned in this way:

1st. Evolution is now denied only by the ignorant, egotistic or prejudiced. The third law of evolution is, substantially, "Nature is at war with itself," each organism is warring for the ascendancy over some other; one being can live because another dies. One is the nutrition for the other, from man back to the lowest form of a bacterium. All three of the kingdoms feed upon each other.

Many higher forms of animal life live only upon high forms of animal life, including man, as either the consumed or consumer. Many higher forms live on a mixed diet of both animal and vegetable. It is not only true that higher forms devour lower forms of life, but the converse of the proposition is also true. Very low forms of both animal and vegetable life feed upon the highest type of animal life, man, as well as upon lower forms. In the face of these demonstrated facts, is it unreasonable to look somewhat in this direction for the cause of bee dysentery, when we know that an attack of these germs produce similar symptoms in other animals? But we realize that there is a peculiar condition with bees during winter. We know that to void in the hive is dangerous; we therefore believe that bees can survive in this climate, where they are for a considerable time closely confined to the hive, only because of this peculiarity, which is, that they as a rule eat a food that after the nutritive and heat-making elements are extracted, the residue can be passed off by sensible and insensible transpiration. May it not be that the excep-

tions to this rule cause dysentery? Throughout all nature, health is the rule, and sickness the variation from that rule, so to speak. The inherent tendency is to live. The outward tendency that you die so others can live. From this line of reasoning my first statement was "dysentery, produced by an over amount of animal or vegetable matter in the food."

At that time I supposed that bacterium was an animal germ, but now I believe it, from good authority to be vegetable, but it is one of those active forms, as mold, etc., that possesses the calamitous capability of reproducing itself in vast hordes, in a space of time proportional to its size. As I use the words "vegetable matter," I mean solid, such as bee-bread, or floating pollen in the honey. Of course, I am aware that honey itself belongs to the vegetable kingdom. From my first thoughts and proposition upon the subject, I have not as yet seen any cause, either from observation or the reasoning of my contemporaries, to change my mind. Through the grounds of the original proposition I have been forced to vacillate from one idea to another according as new evidences and deductions were brought up. Such oscillations should be approved, and not censured, for they are the necessary results of honest investigation, and the leaders to the solution of the problem. But, then, we have among us men that, though not celebrated for their experience or logic, are wordy and vigorous, and this energy must be exercised, and it finds its outlet in making up faces and caricaturing the supposed unpopular.

But Mr. Grimm says that "disease in the human race does not in all cases necessarily originate from the same source." True; but some diseases do (scarlet fever), and these that do are distinguished from those that do not, by their specific symptoms. No disease heired by human flesh has more specific symptoms than bee dysentery. Mr. G. thinks that the following conditions may either by themselves, or variously coupled together, all have more or less effect to produce dysentery, if I understand him correctly: Eating too much pure bee-bread, fermented honey, fermented bee-bread, long confinement, with variable temperature, impure air, and dampness. Others add to the list many other conditions, among which are cold, cider, and Langstroth hives, and some even credit it to human laziness.

Now that most of the conditions mentioned above may act as aggravations upon the cause, I do not deny, and if bacteria is the cause, I am free to admit, that dampness and warmth at some time, and in some place, caused the bacteria to germinate. But I have never been convinced that cider would produce dysentery. Added to my own experience is that of Mr. Grimm, and all point to the fact that cider is not a cause direct, if at all. I have to-day more belief in the pollen theory than the bacteria hypothesis.

I will hastily run over a few facts

for the reader to draw his own deductions from. Cider—I have had my bees winter nicely with much cider in the combs.

Pure air and dampness—I saw Mr. Balch's bees come from a close unventilated room, dripping with water, and combs all moldy, in excellent condition. I have seen the same on other occasions. I had bees winter well under ground, in a hole like a grave, when the combs were nearly ruined with moldy rot. I saw about 40 colonies come from a little unventilated clamp, made so small that they filled it almost solid, in the best condition I ever saw bees enjoy in April. I saw about the same number come from the same clamp, one year later, all dead with dysentery—every bee.

Cold and long confinement—I have seen, and have many credible reports of splendid successes in out-door wintering where severe cold and long confinement were present. In the northern part of this State, where their losses are hardly as great as in southern Indiana, such a state of affairs is to be expected.

Varying cold and long confinement—I am not so sure about. I do not now recall a case of the kind here, for in varying winters the variation is usually great enough to prevent long confinement. That is the class of winters that I should most dread, because early breeding would likely result, and then the handling and consumption of pollen in confinement, and consequent dysentery follow.

Fermented honey—How can I look on this as a cause, when I have never known it to exist in any apiary only as an effect. I have found that the honey soon gets thin, after the warmth of living bees is exchanged for the damp carcasses of dead ones. In this climate, out-doors rivals our poorest cellars, for a damp atmosphere; in fact, it far exceeds them. Yet in a cellar of the driest nature, I have had my colonies die like rot, and leave plenty of thick, rich basswood and other honey, with combs dry, but badly daubed. I never saw a moldy comb in that cellar.

I ask you to believe me that I, as well as many others, have seen all the possible causes referred to by Mr. Grimm present in a radical form, and many in various combinations where no dysentery resulted. I have also seen it in its worst form, where not one of these causes existed that I could discern, except healthy appearing bee-bread, and nearly always brood. Now, all that has to be done to shut this theory out in the cold with the rest, is to show us a case of dysentery where the bees have no bee-bread in the combs, nor floating pollen in the other stores, as in case of pure, properly made granulated sugar-syrup. It will not do to point to a case of survival, where the combs contained pollen. We all know that all winds do not blow away houses, but we further know that they bounce up into the air from no other cause. If colonies thus prepared with pure stores free from pollen in all shapes do have the disease under any other

circumstances, I shall be forced to admit that the main cause is something else, and, at best, pollen only an adjunct or aggravation, if any damage at all. I would say to the "Jack Horners," do not rake up any old half-forgotten cases, where sugar was fed with honey, or on top of it, or in combs that contained pollen; hold your explosive desire to beat somebody, till some man like Prof. Cook, who has the close practical ability to make a comprehensive test, and the acknowledged integrity to make his decisions satisfactory to us all, will put the matter to a test that shall wind up all further discussion.

Dowagiac, Mich.

For the American Bee Journal.

Reply to Mr. P. L. Viallon.

PROF. A. J. COOK.

Mr. Paul L. Viallon, Dear Sir:—I take pleasure in replying to your courteous letter; the more so as you are one whose tact, energy and superior skill, coupled with sterling honesty, has done very much to brace the "dollar queen business" into its present proportions.

I cannot see how that any observing bee-keeper of experience can hold that the laws which govern in the breeding of the higher animals do not prevail in the breeding of bees. Surely bees vary. Surely they transmit their peculiarities. Then certainly, here as elsewhere, selection guided by close study and observation is all important. Mr. Viallon recognizes these facts practically, and hence his well-earned reputation. I wish prices would sustain him in exercising even far greater care. I do think that we are enabled by care to select our drones to a large degree now. In our apiary only two or three colonies now have drones. I believe that if there was pecuniary inducement, that such wise and painstaking breeders as Mr. Viallon, could even now select his drones. It would require great skill, much pains and no small labor, but it could, I think, be done. I will not tell how, as no one could afford to practice if I did. If I am mistaken, a method would be forthcoming if the prospective gain therefrom would warrant the labor and study requisite. Alas! under the present system it will not.

True, breeders of cattle, etc., do have to weed out. Breeders of bees will have to do the same to reach perfection. You know, Mr. V., that a queen—no queen—will always reproduce all of her good qualities. I would have you know, also, how to breed from the best drones only, and select as carefully in your males as in your queens.

To sum up then: 1st. I have not the least doubt but that the laws that govern in breeding are uniform in all animals. 2d. It is as important to select our drones as to select our queens. I believe it is possible to do this now, with great labor, and if not, that man can invent a way if the inducement is offered. 3d. Selection and weeding

out must be carried to the same extent as in other animals.

To conclude, my friend, I have never had a doubt that you lacked one whit in earnestness, honesty or good purposes. I believe that you are doing much to make the system you uphold with your practice less damaging; but I cannot believe that an art like that of queen-rearing, that demands the highest and best ability, can ever reach the high ideal so desirable, unless stimulated by at least a respectable compensation. If it can, it forms an exception among the vocations of the world.

Lansing, Mich., June 7, 1882.

For the American Bee Journal.

A Visit to the Texas Convention.

W. K. MARSHALL.

The Texas Bee-Keepers' Convention met at McKinney, Texas, April 25, 1882. The Convention was well attended, considering that Texas has but recently begun to make any advance in bee-culture. We met in the grove in which Judge Andrews' apiary is situated. The Judge has some 300 colonies of bees, all brightly-colored Italians. He uses the American hive, and for a number of years has been breeding the light-colored Italians. He is an amateur bee man, and more than any man I have ever seen keeps bees for the fun of the thing. He has some of the most beautiful queens I have ever seen.

Texas has a diversity of sale and production, and, of course, has some localities better than others for the culture of the bee. Eastern Texas, along streams, affords good bee pasture. In Northern and Western Texas the prairie lands, especially along the streams, bees have done well. In these localities the ratan vine and the horse-mint are the great honey producing plants. In Eastern Texas we have the ratan vine, linden, sumacs, chinkapin, and, in the fall, the golden-rod and cotton.

Though this was but the third meeting of the State Association, we had representatives from quite a number of counties.

The Convention owes its origin and success largely to the efforts and influence of Judge Andrews. The hospitality of the Judge, and that of his estimable family, made the members of the Convention feel quite at home, and they spent a most enjoyable time in his beautiful grove, among his 300 colonies, just in the height of the swarming season. A number of important manipulations were conducted in the presence of the Convention.

The Convention discussed a number of important subjects, such as "Should we breed for color?" "Does the impregnation of the queen affect her drone progeny?" "What is the best hive for this climate?" "How to secure the largest amount of honey, and where, and how to market it?" It was agreed on all hands, that several of the subjects that interest the Northern bee-keepers so much are of

no interest to us here, such as how to winter, and the causes and cure of dysentery. There is no trouble in wintering in this climate, and dysentery is almost entirely unknown.

The outlook for our industry is quite inviting. In 1865 I imported my first Italian queen—probably the first ever imported to this State. Now they are scattered all over the State, and intelligent bee-keepers are spread through all sections of the State. Quite a market for honey has sprung up in our large towns.

At our Convention there was a manifest disposition to spare no pains nor expense in securing the best strain of bees. The Cyprians, Syrians and albinos are all being tested this year. The population is crowding into our vast territory, and next year we will, in all probability, be able to report vast progress in our favorite industry. The prospect for a large yield of honey this year is good.

Marshall, Tex.

For the American Bee Journal.

The Dollar Queen Traffic.

O. O. POPPLETON.

I see that the columns of the JOURNAL are again being filled with articles on the "dollar queen" business, but have noticed that not a single one of the scores of such articles have been written by one of that class of bee-keepers who are the most interested in the discussion, viz: the buyer and user of such queens. As one of that number, I will try and add my mite.

The article from Prof. Cook's pen, in a late number of the BEE JOURNAL, I regard as the ablest one yet written on that side of the discussion, and also the most candid, with possibly two or three exceptions, especially the one from Mr. L. C. Root, but both in my opinion have allowed a theory to lead them into an error. All that part of the Professor's article in which he speaks of the great desirability of taking special pains in the breeding of our bees, meets with my hearty commendation; but I utterly dissent from his opinion, that "the dollar queen traffic stands directly in the way of the best achievements."

The truth is, that the theory which Prof. Cook's article so ably advocates is magnificent as a theory, but it is utterly impossible for our thousands of practical bee-keepers to carry it out. He essentially admits this fact when he says, in one place, that he "cannot find time with his numerous duties to do this as he thinks that it ought to be done," and in another, that "he would do this work if he had time to give to it, and had capital to warrant the undertaking." If the Professor, with his abilities and surroundings, cannot even attempt to carry out his own theory, how can he expect our average bee-keepers to do so? Americans are a practical people, and American bee-keepers are not one whit behind their neighbors in that respect, and practical theories are the only ones that will be approved in the long run, and if the

Professor with an assured income from another source, can find neither time nor capital to carry out this theory, certainly neither myself nor the hundreds of others who are dependent on their bees for the wherewithal to buy bread and butter for themselves and little ones, can be expected to do so. None except those who have large capital and a peculiar situation can possibly do this work. He says in his article that "to breed the ideal queen will require such a rigorous weeding out that only a small proportion of the queens reared will be suffered to live." May I ask if this very fact does not prevent our bee-keepers from even attempting to breed the ideal queen, however desirous all may be to do so, for such a course would destroy all idea of obtaining any revenue from our bees? If the obtaining a revenue is not our prime object in keeping bees, then I have thoroughly mistaken the aims and objects of our business.

I understand that the vital point which Prof. Cook makes is, the cheapness that untested queens can be procured for destroys any large demand for higher-priced, better queens, and, therefore, no one could sell enough queens at a high enough price to pay for rearing them as he suggests. Boil this entire discussion down, and that is really the only seemingly tenable point raised against the "dollar queen traffic," and if true, we would all of us be forced to admit the strength of it; but, honestly, I do not believe that point is true.

We can all of us remember how much was said in the bee papers a few years ago, about the extra vigor and value of daughters of imported mothers, and how this idea so industriously circulated, caused nearly every one when ordering queens to demand of the seller that they be the daughters of imported queens. I am not fully posted in the business, but am satisfied that within two or three years after the inauguration of the "dollar queen traffic," the demand for imported queens at a high price was at least doubled. Scores, yes hundreds of practical bee-keepers in our Northern latitude will buy early queens at a dollar each, and make them pay too, who neither would nor could buy them at two or three dollars each, and let me assure Prof. Cook that if either himself, L. C. Root or any other bee-keeper of equal reputation for honesty and ability, will raise queens as he thinks they ought to be raised, they would never have to send them to be tested before being purchased, and at good round figures too, and every one who sells dollar queens would be forced to use these particular queens, or retire from the business in disgrace. In other words, the "dollar queen traffic" itself, instead of being the greatest hindrance, would be the greatest incentive to the best achievements, for it would force the purchase of hundreds, where otherwise only scores of the high-priced queens would be bought.

Prof. Cook says he has purchased several untested queens, and won a blank each time. In his "Manual"

he says about the same thing, only he there specifies three as the number purchased, and I presume the indefinite number mentioned in his late article are the same ones spoken of in the Manual. I know of an instance where a bee-keeper lost more money, had more variation, and got many more poor queens on hand, by purchasing a very high-priced selected tested queen, than the Professor did by his purchase of three untested ones, and I would like to suggest to him, that the circumstance I mention is just as good proof on which to found an argument against high-priced tested queens, as his trial of only three untested ones is good proof of the right of his argument against that class of queens. There are so many exceptions to general rules affecting bees, that we have long ago learned that a few experiments proves very little, especially on so broad a subject as the qualities of different kinds of queens. No one can give an intelligent opinion of their value, unless on theoretical grounds, without having used a score or so of them, better yet, if their experience covers the use of several scores.

A common argument against dollar queens is to cite the example of Hammond, Bates, Booth, and others in the breeding of live stock. This is right if one only draws the correct conclusions. How much of the stock bred by these men has ever been purchased by the common farmer? How many of those \$2,000 animals, recently sold in Chicago, went to others than fine stock breeders? I venture to answer, not one. What would we think of the wisdom of a common dairyman owning a score or so of cows, investing from \$2,000 to \$5,000 in the purchase of a single animal to improve his herd, when he could purchase an animal practically as good for one-tenth the money. Let our Cooks, Jones, and Roots go to work and produce as superior a strain of bees as Bates and Booth did of cattle, and my word for it, every dollar queen-breeder, and nearly every large bee-keeper, will obtain one or more of the improved queens, without regard to price; but the wildest theorist would not expect ordinary bee-keepers to purchase them by the dozens each year, as some of us do of untested queens. Instead of being a hindrance, I think the selling of dollar queens bred from such stock would do far more toward the universal improvement of bees over our entire country, than anything else that can be done.

The common mistake of those who oppose the "dollar queen traffic" is, they think there is more value in a decided improvement of the bees owned by a few bee-keepers, than they do of a lesser rate of improvement of all the bees in the country. Take a pencil and figure up the relative values of a ten per cent. improvement of all the bees in the country, and a fifty per cent. improvement of the bees owned by a score or a hundred of our leading bee-keepers, and what is the result? Of course, the buying or selling of dollar queens prevents no one from improving his own

stock all his circumstances will allow him to do, but sends the direct descendants of our best stock broadcast among the mass of bee-keepers, who are forced to realize every dollar they can from their bees to supply immediate wants.

I have bought and used nearly 150 untested queens during the past few years, and had intended in this to have told how I use them, and some of my experience in buying them; but have already strung this out too long, so will defer that to some future time, if this discussion continues.

I do not want any one to think I intend this as a reply especially to Prof. Cook's article. I speak of that as I have, because it seems to go right to the gist of the matter, in the plainest and most direct manner of anything I have seen. Neither do I wish anyone to think I am opposed to breeding the very best queens we can get. I simply wish to oppose the strong effort being made to pull down a system of selling queens which has been of large benefit to me in my business, and I presume to others also.

Williamstown, Iowa.

For the American Bee Journal.

Texas Letter—Italian Bees Wanted.

MILES HADAWAY.

MR. PRINTER:—I hear you print a bee paper, and I want you to send me one to look at, to see if I like it. They tell me you always have much nice readings in it about that queer little crittur that has a sweet tooth in its mouth and a sharp sticker in its tail, as Anne Strother's father told the old bee-hunter down at Powett's Tanyard last summer. I have been keeping bees here three years in the old fashioned way, that was thought very good away down east forty years ago and longer, where I was born and raised. But somehow I can't get along with them here, as old uncle Brewster used to do in Hockanum when I was a boy. Why he used to have lots of hives, and honey by the tubful every fall, when he took up his skeps with the brimstone rags. But here we often get nothing at all now. Whether the miller moths that are so plentiful here eat it all up, or the troublesome busy ants carry it all off, I don't know, and with all my watching could never find out. I sometimes think the bees get bewildered among the many strange flowers we have here, and cannot tell where to look for the sweet; and it were no wonder, such odd-shaped things they are. Maybe if we had other sorts of flowers, apple and cherry blossoms and such like, and hollyhocks and asters, such as they was used to of old, or had other bees better suited to the flowers here, we might do first rate in this climate where the busy fellows could work almost the year round without interruption. Well, cousin Upson was to see us when he come out prospectin', and he told us some wonderful stories about a new kind of hives they have to home, in which the bees build combs as straight

as a ruler on sticks, and the nice little whirligig twirlabouts with which the honey can be shaken out of the combs right into dishes, all ready for the breakfast table. I half believed his yarns when he promised to send me one of these shakers next spring; but Mehitable, my wife, says there was a queer sort of a smirk on his face, and he gloared so slyly with his eyes while he was a telling and we was a listenin', that she's sure he was only trying to bamboozle us by his talk. I'm not so sure about that. Then he told us, too, about a new sort of imported bees, with striped backs and harmless queen stings that never hurts nobody, and can be handled, like well-riddled rye, without gloves, in the hottest weather. Wife doubted again, but I think there's a good deal of truth in the story; for when I was in Austin to buy a plow for neighbor Crume and a new collar for my horse, I hear some talk about such queer bees in the bar-room of the tavern. The chap that was a telling about them had a patent hive to sell, too. It wasn't one of them with the straight comb sticks that cousin Upson spoke about, but the man called it the Moth Worm Banisher. He said it was so fixed that when a moth touched it at night a scratcher strikes a lucifer match, and straightway the sudden flash and glare of light frightens all the moths within fifty feet, and away they go, harum-scarum, with a grand flutter and flourish, seeking to hide in outer darkness. That I think is a good invention, for these moths are troublesome and hard to catch, and the best way is to banish them right off. But about them new imported bees the man said he could not see any great good that came of them after all the fuss made about them, except that they made their honey from red clover tops instead of white, and hunted up all sorts of out-of-the-way flowers in by-places and roadsides, which the old kind of plain bees never thought worth looking at. Besides, he said, that while farmers could only make hay while the sun shines, these new comers would make honey, shine or no shine. This seemed to be saying something more for them than uncle Upson knew; and as everybody in the room appeared to believe what the hive seller said, because he had no interest in the matter, I think there is a good deal in it, and wish I had some. Mr. Printer, can't you put me in the way of getting a swarm? I would like to have them soon. Can't they be sent by telegraph, so as to come before Christmas? Swarming time begins here soon after New Year, when the drones have got over their holiday frolics. How much will they cost, though? If they are very dear I could not afford the expense till after the next cotton crop is made. They say a queen sells for five and six dollars! Just think of that! A little insect about an inch long selling at the price of a yearling colt! If the workers sell in proportion, won't they come high, as cousin Zeke reckons it out? Or if you put them down at even a picayune apiece, and there are thirty thousand in a

hive, only think what a decent hive would come to, by the rule of three! Then there's the freight too, if they come by telegraph, for the ticking clerk in the office always figures that out high; and so I am afraid that, if sent by that line, they might in the end cost more than they would come to. Aunt Dinah says she has read somewhere in the Penny Whistle Weekly, (which she gets every now and then at the grocer's around some articles she buys), that they now send these bees, or some kind of bees, by mail. That, I think, must be a good joke! Why, you might as well send a basketful of hornets by express. Phew, I'd like to stand at a safe distance away and see our sober-faced, steady old postmaster open the bag when they arrived! Wouldn't he make tracks in a hurry, and feel worse nor if he had a dozen big fleas in his ear? No, no, that's a little too tough a yarn to be swallowed by any but a greenhorn, though it is in print. But have those bees I will, sooner or later; and if they don't come quite as dear as cousin Zeke reckons it out, I'll get you, Mr. Printer, to have 'em sent by rail and steam even if they don't come till after Christmas. I'd have them sent by express, but that moves as slow in these parts as our old ox team used to do in old Middlesex, on Saturday nights, when we had bitched up to go sparking. Don't forget to tell the man who sells and sends them, to be sure to give them food enough for such a long jaunt, as the poor things musn't be let starve on the way. Tell him, too, to pack them well and hurry them forward—"with speed and care, right side up!"

Before I close, Mr. Printer, I want to say further, that when cousin Upson was here he told us there was great fuss just now away up in the old States, about some wonderful improvements in bee-keeping, which he said they call "scientific bee-culture." Now what is that? How is it made? How big is it? Is it patented? Does it go by machinery? Is it hard to learn how to work it? Or must you go to a sort of school or college to study how to manage it, till you get the hang of it gradually? Couldn't an old man learn to fix it up, without leaving home? How is one to get science into a bee gum, I'd like to know? That's a little above my huckleberry, as we used to say at Haddam school, when a hard question came up, and puzzled the head scholar of the class, though we had to work it out, for all that. Well, well, there was no lightning telegraph in them days, and nobody then dreamt of gold in California; so there may be something new in managing bees, though the wise man said, long years before I was born, There's nothing new under the sun. You'll print all about it, I suppose, and we'll see what it is when the paper comes. Send it on at once anyhow, or somehow.

Palo Pinto, Texas, Nov. 3, 1870.

N. B.—Wife says, be sure to ask whether it's certain that the new bees can make honey. Our old ones are

rather poor hands at it, and some years don't let us have any. Now, even if the striped fellows should produce six times as much, it wouldn't amount to anything, after all; for in Deacon Downer's school we were always told that 6 times 0=0; and we had to believe it, for not even the smartest boy in the class could *prove* that it wasn't so, and the Deacon ever insisted on *proof*.

SELECTIONS FROM OUR LETTER BOX

But Two or Three Warm Days.—Cold here yet. We had a frost here this morning; you could scrape it up in piles on the tin covers of my bee hives, still it was not hard enough to kill anything. We have had but 2 or 3 of what could be called warm days here this season. The mercury has not been above 80° only one day, while last year it was above 90° several days during May. Apple blossoms are now nearly gone here, but on the hills the trees are in full bloom. Last Thursday (8th) the bees got some honey from the bloom, but a rain in the afternoon stopped work, and it has been cold ever since. Glad to see others are prospering.

G. M. DOOLITTLE.

Borodino, N. Y., June 12, 1882.

Madeira Wine.—The recipe for Madeira wine from honey on page 339 is a correct translation of Dzierzon's in Berlepsch's great work. The only omission at the end is: "the bottles containing the wine should be buried in the sand—kept moist by being sprinkled now and then with brine." Berlepsch, quoting Dzierzon, says: "After a few years this wine is worthy to be served on the tables of princes." The only objectionable feature in the recipe is the old chemical superstition that a bright copper or brass kettle is not dangerous to use. It is really astonishing how tenacious a hold the fallacy has upon the people that, as long as they do not let the fluid get cool in a bright copper vessel, there is no danger.

L. K.

Savannah, Ga., June 2, 1882.

Buckeye Honey.—Bees in this locality have had a hard time this spring, and many kept in the old way have died in May. I wintered 19 colonies. All came through in good condition. I commenced feeding in March to stimulate them, in which I succeeded and on the 8th of April the strongest had 6 to 8 frames full of brood; then came a cold wave, and since that time I have been feeding at spells. Once, before I was aware of it, the bees had uncapped nearly all the young brood, and eaten the food from the young bees. Nearly all of the honey this spring has come from the buckeye. I am satisfied, if the spring

had been favorable, considering the strength of my bees, I would have obtained 50 pounds of honey per colony from buckeye. It commenced blooming the 2d of May, and is in bloom yet. The honey is white as that from linden, and I like the flavor better. There was some honey from crab apple bloom in it, which I think improved the flavor. WM. MALONE.
Oakley, Iowa, May 26, 1882.

Outlook has Never been Better.—The outlook for honey has never been better than this season, and the honey bee interest is largely on the increase. We bid you God speed in battling for a pure honey against the glucose combinations, and for a higher strain of bees. W. K. MARSHALL.
Marshall, Tex., June 12, 1882.

Good Following Bad.—I had 43 colonies in the fall of 1880, and lost 41 of them. The 2 colonies left were very weak. One of the two colonies swarmed twice, and I made a two-story hive of the weaker colony and extracted 100 lbs. from it; the other gave me 100 lbs. of box honey and some extracted. Last spring I began cleaning out the hives of dead bees, and setting them back on the summer stands for the bees to finish cleaning up the honey. As I could not buy any bees handy, I began to wish for some bees to come along, and, sure enough, the last day of May a fine swarm came along and went into one of my hives. That raised my spirits a little. So I kept on, thinking or wishing, or something else, and on the 4th of June 2 more came; in a few days another came, making 4 in all. The first that came gave me 5 boxes of honey, worth \$1.25 per box, and swarmed once, besides we extracted from the old colony in August right smart. The third colony that came swarmed twice; which makes 11 colonies to winter. I packed 8 of them in big boxes that I made for that purpose several years ago. Not one colony lived in them that winter, but I am going to try it again. I put 2 bricks on some of them, and corn-cobs on 2, besides chaff and straw. In the BEE JOURNAL for December, 1870, is a letter from Texas, that ought to be reprinted for young bee-keepers.

H. M. NOBLE.

Swedesburgh, Iowa.

[The letter is republished in this number.—ED.]

Doing Well on White Clover.—I am glad to be able to say my bees are doing well, although April and May were miserable months. I kept my bees breeding by constant feeding. I wintered 26 colonies without any loss, and have increased this spring so far to 47, all in fair condition for white clover, which is now blooming, and upon which my bees have been very busy the last few days, which is really the first harvest they have had this season, as the fruit bloom was all frosted. WM. B. McCORMICK.
Uniontown, Pa., June 10, 1882.

Something New.—One day during the first week in May, I opened a hive containing a fertile worker, and in destroying her brood discovered some young worker bees coming out of the cells. I was surprised, but said nothing about it, for fear I might be laughed at. Yesterday I examined the colony again, and found 10 or 12 in a patch of brood from 5 to 6 inches square. Have any of our more experienced apiarists ever witnessed anything of the kind, or read of the like? I would have liked for a scientist to have seen them. This is a very discouraging season so far; starvation prevailed during swarming time; larvae was destroyed and brood uncapped, so that colonies are not as far advanced now as they were on the last day of April; and all this is not the result of a scarcity of bloom, but the cold confined the bees to the hives, and the nectar went to waste, if any was secreted. I am not able to enumerate the number of colonies lost, but there have been many.

ROBERT CORBETT.
Manhattan, Kans., June 9, 1882.

Scientific Pleasantry.—

Two prodigies this age has shown—
In Art sleek Oscar's flower has blown,
In Science Wiley reigns alone.

Let "Riley" quickly stand aside,
It was a Hooster—well, he never lied—
A "scientific joke" is what he tried.
Evansville, Wis. II.

Splendid Prospects.—Bees have been doing splendidly the past few days, and the prospects are now very good.

WILLIAMSON & BRO.
Lexington, Ky., June 14, 1882.

Honey Locust.—Bees are just booming on the honey locust; indeed, I am beginning to think it equal to basswood, where it is abundant. There are, perhaps, 200 large honey locust trees in my vicinity. Most of them are loaded with racemes of blossoms. The bees have partly deserted fields of white clover, and their music can be heard all day long in the tree tops. This morning I had a swarm by 6 o'clock. Work in sections is going on finely.

C. H. DIBBERN.
Milan, Ill., June 14, 1882.

No Nectar.—For the last 3 or 4 years there has not in this part of Missouri, been enough nectar at any time to support bees—saying nothing of surplus—that is when bees could get it. This spring we had a fine apple and peach bloom; also crab apple, with many other blossoms in the timber; but not a day that the bees could get out after it. I have fed and tried to save them, but to no purpose; they are all about gone. We have not had any honey to eat for years, so I have concluded to raise sorghum for table use, since all other sweets are adulterated. I live in a newly settled country, where the people make "war" on white clover; no clover is sown—nothing for bees until Spanish-needles, and they have been worthless for the last three years; we may as well sow onions as buck wheat for bees. Scarcely a bee is living in this part of

the country, and I guess the harvest will get better before we hear the "hum of bees" again.

P. P. COLLIER.
Rush Hill, Mo., June 10, 1882.

Rain Needed.—Bees here never wintered better than last winter, and the opening of spring found them in splendid condition. April was cold and wet, and May cold and dry, with heavy frosts almost every night, which killed nearly all the fruit blossoms, leaving nothing but dandelions that bees could obtain anything from. Unless rain comes soon there will be but little white clover; it has just begun to blossom, but is drying up fast. There has been no swarming yet, and drones are flying from only a few of the strongest colonies. Taken all together, the season since the first of April is the worst that we have had for twelve years, and unless a change soon occurs for the better, the present will prove a most disastrous season for bees.

O. E. COOLEY.
Bluffton, Iowa, June 14, 1882.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., June 19, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—I am paying 7c. for dark and 9c. for light extracted.
BEESWAX—Choice lots are worth 25c. here; bright yellow, 24c.; dark to good, 17@22c.
AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—For Extracted we pay 7@9c. on arrival. Prices for comb honey nominal and demand slow.
BEESWAX—Brings 18@22c. The demand exceeds the offerings.
C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for comb honey is light, prices being made to meet views of purchaser.
BEESWAX—Scarce, and in demand at 23@25c.
R. A. BURNETT, 165 South Water St.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
BEESWAX—Prime quality, 25c.
CROCKER & BLAKE, 57 Chatham Street.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.
BEESWAX—The market continues rather quiet, but the supply is light and prices firmly sustained. Western, pure, 24@24½c.; Southern pure, 25@23½c.
D. W. QUINBY, 105 Park Place.

ST. LOUIS.

HONEY—In fair demand. Extracted selling at 8@10c.; comb scarce—nominal at 18@22c.
BEESWAX—Prime in demand at 22@23c.
R. C. GREER & Co., 117 N. Main Street.

SAN FRANCISCO.

HONEY—The first consignments of new arrived this week, including comb and extracted. Some new extracted in half barrels was placed at 8c., and so on new comb, of very good quality but not extra white, sold at 16c.
We quote white comb, 14@16c.; dark to good, 8@12c. Extracted, choice to extra white, 8@8½c.; dark and candied, 6@7c. BEESWAX—23@25c.
STEARNS & SMITH, 423 Front Street.

CLEVELAND.

HONEY—As there is no honey in market, we have no quotations this week.
A. C. KENDEL, 115 Ontario Street.

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 ".....	20 " " "
" 13 " (3 months)....	30 " " "
" 24 " (6 months)....	40 " " "
" 36 " (9 months)....	50 " " "
" 52 " (1 year).....	60 " " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ill.

Special Notices.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—	a copy of "Bees and Honey."
" " 3,—	an Emerson Binder for 1882.
" " 4,—	Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,—	" " cloth.
" " 6,—	Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 50z.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Neltnor's Fruit and Flower Grower is on our desk; it is edited and published by John C. Neltnor, Turner Junction, Ill., at 75 cents a year.

The Villa Bohemia, by Marie Le Baron, published by Kochendoerfer & Urie, 200 Broadway, N. Y. This is a very interesting little story of 250 pages. Price 50 cents.

Do not let your numbers of the BEE JOURNAL for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

When changing a postoffice address, mention the old as well as the new address.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Ashland, Pa., June 3, 1880.—A case of spavin that came under my observation was entirely cured by one bottle of Kendall's Spavin Cure, and the horse sold afterwards for \$200.
 25tf Yours truly, C. H. BARNARD.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

ELECTROTYPES

Of Engravings used in the Bee Journal for sale at 25 cents per square inch—no single cut sold for less than 50c. THOMAS G. NEWMAN, 925 West Madison Street, Chicago, Ill.

Queens Bred for Business

Full Colonies of Cyprians or Italians, in well-painted Langstroth Hives, \$9; Tested Cyprian or Italian Queens, of last year's rearing, \$5; Young Queens, Tested pure, \$3; 3-frame Nuclei, standard Langstroth frame, untested, \$5; Fertile Workers, 60c. to \$1. We can supply anything pertaining to the bee business.

ROYS & MORGAN, Columbus, Wis.

TIN POINTS for GLASSING HONEY

Cut by machinery; are much cheaper and better than hand-cut, and perfectly straight; 1,000 to 5,000, 25c.; 6,000 to 10,000, 22c.; over 10,000, 20c.; 6c. per 1,000 extra by mail. Samples for 3c. stamp. W. C. GILLETTE, LeRoy, Genesee Co., N. Y.

NEW IDEAS.

Foundation ready for business, sheets bound with a light wooden rim, sample 6c; Bee's Tongue Register, sent by mail for \$2.25; Italian Queens improved by a new process; Italian or Black Bees for sale in a hive adapted to migratory bee-keeping—can be securely closed for moving in one minute. For particulars address JOHN H. MARTIN, Hartford, N. Y.

THE BRITISH BEE JOURNAL AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is published monthly, and contains the best practical information for the time being, showing what to do, and when and how to do it. It is edited and published by C. N. ABBOTT, Bee-Master, School of Apiculture, Farnham, Southall, London.

We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.50 per annum.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 15x20, which is intended for any size of frame. Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " 10x18 "	8 00
For 3 " " 10x18 "	10 00
For 4 " " 10x18 "	14 00
For 3 frames of any size, 13x20 "	12 00
For 2 " " 12x20 "	12 00
For 4 " " 13x20 "	16 00

923 West Madison Street, Chicago, Ill.

Class in Bee-Keeping.

Application has been made to me to take students in Bee-Keeping. I have, therefore, determined to begin a class on MONDAY, JULY 10, and extend through eight weeks. The instruction will include a study of the Anatomy and Physiology of the Bee, Queen-Rearing, Artificial Increase, Implements, Comb Honey, Extracted Honey, Bee Pasturage, Wintering, etc.

I have a good library of Bee Literature, all Approved Modern Appliances, etc. My home Apiary has eighty colonies of Italian Bees, among which students can practice. O. CLUTE, Iowa City, Iowa.

Be SURE

To send a postal card for our Illustrated Catalogue of Apian Supplies before purchasing elsewhere. It contains illustrations and descriptions of everything new and valuable needed in an apiary, at the lowest prices. Italian, Cyprian and Holy Land Queens and Bees.

J. C. & H. P. SAYLES, Hartford, Wis.

A NEW BEE BOOK!

Bees & Honey

OR THE
Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,
Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.
925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.
A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.
We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.
Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.
Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.
A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.
New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.
Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.
Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.
Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.
A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northwest of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 18th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; and the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY,

By A. J. COOK,

Of Lansing, Professor of Entomology in the

State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—*LEWIS T. COLBY*

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—*J. P. WEST*

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—*E. H. WYNKOOP*

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—*A. E. WENZEL*

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—*WM. VAN ANTWERP, M. D*

It is the latest book on the bee, and treats of both the bee and hive, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—*L'ABBE DU BOIS*, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Puhiski, N. Y.

We have perused with great pleasure this *vide mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. For all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

Price—Bound in cloth, \$1.25; in paper cover, \$1.00, by mail prepaid. Published by

Scribner's Lumber and Log Book.

NEARLY A MILLION SOLD. Most complete book of its kind ever published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interest, etc. Standard book throughout United States and Canada. Ask your booksellers for it. Sent for 35 cents post-paid.

G. W. FISHER, Box 238, Rochester, N. Y. Also for sale at the BEE JOURNAL Office. 21 2w6m.

PURE HOLY-LAND QUEENS.

I make a specialty of rearing pure Holy Land Queens, and have now more than 100 colonies in their purity. All Queens bred from D. A. Jones' Imported Queens. Dollar Queens, before June 20, \$1.25 each; after that date, single Queen, \$1.00; 6 for \$5.00; 12 or more, 75 cents each; Warranted Queens, 25 cents more each. Tested Queens, \$2.50 each; Italian Queens, same price.

MENDELSSOHN PIANO Co's.

PIANOS

\$850 Square Grand Piano for only \$245.

PIANO STYLE 31 Magnificent rosewood case elegantly finished, 3 strings, 7-1-3 Octaves, full patent cantanote scales, our new patent overstrung scale, beautiful carved legs and tyre, heavy serpentine and large fancy moulding, full iron frame, French Grand Action, Grand Hammers, in fact, every improvement which can in any way tend to the perfection of the instrument, has been added.

Our price for this instrument, boxed and delivered on board cars at New York, with fine Piano Cover, Stool, Op. and Book, only \$245.

Reduced from our late wholesale factory price, \$295, for 60 days only, to have this beautiful Piano introduced. This is now, by far, the greatest bargain ever offered the musical public. Unprecedented success! Tremendous demand for this style! Order at once.

This Piano will be sent on 15 days' test trial. Please send reference if you do not send money with order. Cash sent with order will be refunded and freight charges paid by us both ways if Piano is not just as represented. Several other special bargains: Pianos, \$160 up. Over 15,000 in use, and not one dissatisfied purchaser. Handsome Illustrated Catalogue mailed free, giving the highest testimonials ever awarded any manufacturer. Every Piano fully warranted for 5 years. SILENT MUSIC 3/4 price. Catalogue of 3,000 choice pieces sent for 3c. stamp.

MENDELSSOHN PIANO CO., 21smly Box 2958, New York.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as *Carcharodon Rondeletii*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 400 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better. I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE. AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Day Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by THOMAS C. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.—Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quilby's New Bee-Keeping, by L. C. Root—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject. \$1.50.

Novice's ABC of Bee-Culture, by A. I. Root—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Dzierzon Theory—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey; the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof. Cook's Essay, which is here given in full. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how. Illustrated with 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 Recipes for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., June 28, 1882.

No. 26.

ESTABLISHED IN 1861

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

Published every Wednesday by

THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR,

925 WEST MADISON ST., CHICAGO, ILL.

At \$2.00 a Year, in Advance.

WEEKLY—(52 numbers) \$2 a year, in advance.
Three or Six Months at the same rate.

Any person sending a club of six is entitled to an extra copy (like the club) sent to any address desired. Sample copies furnished free.

George Neighbour & Sons, London, England, are our authorized agents for Europe.

Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

The National Convention.

Prof. Cook, President of the North American Bee-Keepers' Society, writes under date of June 19: "As I know the readers of the AMERICAN BEE JOURNAL will be glad to learn, I hasten to announce that the North American Bee-Keepers' Society will, without doubt, meet in Washington Park Hall, just across Washington Park from the Exposition Building, Cincinnati, O., during the last week of the Exposition, Oct. 3d to 5th. Let all bee-keepers see that excursions are arranged for that week. We have already one promised from Detroit. Round trip only \$15.00. The announcement will be made officially by the Secretary in a few days.

Prospects More than Bright.—As we advised our readers weeks ago, the "silver lining of the clouds" is now almost an assured fact. From every quarter come the most encouraging hopes, and every southern breeze is burdened with the sweet perfume from white clover, which was never more plentiful than now. Linden, heartsease, horsemint, and other flowers give promise of great abundance, and with ordinary favorable weather for the remainder of the season, in most locations where were heard the frequent groans of despair will be sung the glad psalms of joys realized. The prospects for an abundant honey harvest were never better than now.

Articles for publication must be written on a separate piece of paper from items of business.

New Book for Farmers.—We have on our desk a new work that will be of untold value to the farmers. It is called "The Farmers' Practical Encyclopedia," and contains "a systematic and practical treatise on every subject pertaining to farm and home life in America." It contains over 1,200 quarto pages, is elegantly bound in 2 volumes, and is published by Chapman Brothers, Chicago. The article on bee-keeping is very thorough, and embraces every part of progressive bee-culture. It extends over 14 pages, and is beautifully illustrated. In recommending the encyclopedia to the farmers of America, we feel that we are doing them a kindness, for it gives to the farmer, in his own sphere, in behalf of his own interests and profession, a literary work of extraordinary high character, exhaustive, complete and practical. It embraces the entire scope of rural life in every department. It contains the gist of many thousands of volumes, prepared by the most scientific, experienced and practical men on this and the European continents, and therefore contains a larger amount of well-timed and valuable information than can be found in any work of its scope yet published.

Fairs.—Any of our friends who may intend to visit fairs, will be furnished with copies of the BEE JOURNAL for distribution to bee men they may meet there, by sending us a request stating how many they can take care of. We will also send two large, colored Posters to enable them to get up a club, if they wish to do so.

We have received the Premium List of the "Northwestern Industrial Association" to be held at Minneapolis, Minn., on Sept. 4th to 9th, 1882. It contains no premiums for exhibits of honey, bees, or beeswax.

Drones—Are they Auxiliaries?

Mr. Wm. Maxwell, Edgerton, Kans., furnishes the following information regarding his experience with the barberry bush, which will be read with interest by all horticulturists:

In the AMERICAN BEE JOURNAL of June 7, page 361, I see an inquiry by P. J. Swain, concerning the barberry plant, and Prof. Burrill's remarks thereon. Now, I want to relate a bit of experience that I have had with this shrub. I have had it a great many years on my grounds, and much admire its beauty, and find it to be considerable help to the bees during the short time it remains in bloom; it also makes a good inside hedge, but is not strong enough to be depended upon for an outside inclosure. Some 6 years ago I planted one side of my peach orchard with it, intending to hedge it all around; three years since it began to bloom finely (it seldom bears any fruit in this locality), and was truly "a thing of beauty." About the 15th of May I discovered that my peach trees were peculiarly affected, the leaves were covered with a sort of mildew, turned white, and crimped and twisted; the fruit turned white and dropped badly, and the whole tree had a leprous appearance; the fruit was not all destroyed, but was badly damaged; the next year the same thing occurred. Well, in conversation with an eastern man he remarked that the barberry caused wheat to rust, and the farmers did not tolerate it; I at once concluded I had the key to my peach disaster, and accordingly ordered every barberry on my premises cut down, and now my peach trees and fruit look as fine as I could wish, and are perfectly free from leprosy. I am satisfied that the profuse light pollen caused the trouble. I have not discovered that my wheat was affected by it, but I have never had any wheat within less than 80 rods of the barberry. Let me hear from others. Now, as I am a novice in the bee business, I want to make an inquiry or two. I have a few colonies of bees—some Italians and some hybrids—all the queens pure, but some impurely fertilized. The drones of the impurely fertilized are darker than the pure ones, with shining black heads, while the pure ones are lighter colored, with claret-colored heads. This peculiarity of the color of the head I never discovered in any other instance, and would like to know whether it is a characteristic of pure drones? My observations with my drones seem to disprove the commonly received theory of pure queens producing pure drones, although impurely fertilized.

Scientists and theory hold that the drones of pure queens will be themselves pure, regardless of how the queens were mated; but many beekeepers of long and close observation have of late years cited many exceptions to the rule. We have often thought there is much yet to learn re-

garding drone production and their functions in the hive. It sometimes seems almost improbable that nature would be so lavish with drone progeny, if one only was conducive to the prosperity or perpetuation of the colony, while the queen progeny, upon which existence itself depends, should be so exceedingly limited, and the instinct of the first emerging should impel her to immediately destroy all possibility of succession.

Who that is familiar with the inner economy of the bee hive, has not observed the hundreds of drones in a strong colony, during a rapid honey flow, apparently as busy on the combs in which honey is being stored as are the worker bees, and it is quite a common occurrence to observe them thickly congregated on the cells in which are freshly deposited eggs and newly hatched larvæ, as though by their presence they assisted in incubating the eggs, or furnished the natural heat necessary for the larvæ. More particularly have we observed this when, after a season of rapid breeding, a cold windy spell of several days' duration visits us, and our bees, as if with one general impulse, flock to the grocery stores in hordes, often in two or three days depleting a ten-frame colony to one or two spaces. We have within the past month had colonies containing seven frames of eggs and brood in all stages, depleted to two frames of workers, and "powerful weak" at that. If drones do no "family duty" in the hive, how is it possible to rear a hive full of drones, when the queen is but a drone-layer?

It is a curious fact, when honey is coming in most rapidly, when the glad, joyous midnight roar can be heard rods distant from the hive, when the bees during daylight with frenzy rush over each other pell-mell in their eagerness to go for fresh loads of nectar, and returning wearily drop on the alighting-board close to the entrance and crawl in, then can be found the drones thickest in the hive or among the boxes where the newest, thinnest honey is being deposited; but let the honey-flow altogether cease, and the work of the drones be no longer required, and they will be herded on the outer or sealed combs, and if the dearth continue, they will be driven from the hives entirely. Who can assert that they do not perform an important function in assisting to ripen the honey, or extracting the water from it, quite as necessary as the gathering of it? That hordes

of drones are necessary we do not think; but we are not certain that they may not be too rigorously excluded from the hives. That they are extraordinary gormandizers we do not think, for we have never been able to discover on the outer combs, where the honey has been once capped or sealed over, and where the drones have been all herded perhaps for days, a single cell which has been uncapped by them, and robbed of its store of sweet. There is much concerning the drones which is not yet understood, at least by us, but we have no doubt a great deal will in time be learned, and perhaps many theories held at the present time be modified.

"Red-headed" drones, though in the minority, are by no means exceptional, and are frequently found in large apiaries of Italians, all apparently equally pure.

Since the above was in type, the *British Bee Journal* for June has been received, in which we find the following remarks on the subject of drones by its editor:

In the forthcoming translation of Dzierzon's *Rational Bee-Keeping* will be found a remark by the author to the effect that drones serve no purpose beyond the fertilization of queens, and to this we have taken exception, as follows: "We cannot accede to the author's assertion that the fertilization of queens is the 'sole purpose' of drones' existence. It is well known that when a swarm has left a hive there is often but a handful of worker bees left at home to care for the huge mass of brood in all stages that the hive contains, and should a cold night follow a swarming day, as is often the case, this handful of workers would find it impossible to maintain the necessary heat in the hive, and there would be great loss of brood and bee life. In this condition of things, the drones, the great majority of which are stay-at-homes (few accompanying a swarm) are of immense service, maintaining heat which otherwise the few workers would be compelled to generate for themselves, and setting the latter free to nurse the newly-hatching larvæ. It is true that when the young queen has hatched, and been fertilized, and the weather becomes cold, the drones are slain; but at that time there will be little, if any, unsealed brood in the hive, while thousands of young bees will have hatched into life, rendering the hive populous, and the drones unnecessary. Nor must it be forgotten that drones are not usually slain until "cool weather sets in," or, in other words, until the honey harvest has ceased, a fact upon which is hinged a belief, in our mind, that they are of service in helping to evaporate the honey prior to its being sealed for winter store. Many have noticed the large number of drones

often to be found in supers, and though it is generally supposed they are there as consumers only, it by no means follows that such is the case. The old saying, 'Give a dog a bad name,' etc., is fully carried out with drones, and no one seems to seek for or believe there are any good qualities in them, yet, as many will doubtless be able to substantiate, some of the best results have been achieved in hives whose drones were at least numerous. In that case the thought has been, if the bees did so well with that immense number of drones to keep, what would they not have done without them? ignoring the possibility that the drones may have assisted in procuring the good results. And is it not true that under the present system with drone-traps on during the honey harvest many have cause to complain that their supers, though filled, are left unsealed by the bees? We have hundreds of times seen bees returned from the fields give their honey to drones, and have as often seen drones with their heads in honey cells. Is it certain that the drones in this case are not in a sense honey-carriers? We know they have no honey sacs, as have the workers, but that will not make our suggestion ridiculous. The bees prepare the food for the nurseling bees in their stomachs. May not drones prepare honey for storage in a similar way? They have no honey sac to collect it in, their duty lying at home except on special occasions at certain hours of the day. Bee-anatomists who search only for what they hope to find may perhaps overlook truths that have not been suggested. But let the influence be what it may, we cannot believe the drone to be as useless as he is accredited."

Food Poisoning.

In the BEE JOURNAL of May 31st, we gave an instance where cheese, manufactured from milk produced by cows that had been fed glucose meal, had "rotted down in thirty days," and gave a recital of some of the dreadful consequences which would result from the consumption of such poisonous food. As proof that our opinion was well founded, we reprint the following telegram to the *Inter-Ocean*, dated Adrian, Mich., June 19, 1882:

Since Friday evening last some seventy-five people of this city have been poisoned by cheese. Whole families have been suddenly seized with violent vomiting and purging, and in many cases severe illness has resulted. In one case, that of John L. Smith, only the most vigorous treatment prevented a fatal result, while to-day several men who had partaken of the cheese were so ill that they could not attend their labors in the Lake Shore and Peninsular car-shops. The cheese was sold by several grocers, but was the product of one

factory on the 20th of May last. A microscopic examination shows the cheese to be filled with minute parasites, but the deleterious effects are believed to have arisen from the presence of an accidental or otherwise dangerous substance. The affair certainly demands an official investigation, and the cheese should be submitted to a scientific analysis.

It is not difficult to anticipate what an investigation will demonstrate, nor to place the blame for this extensive poisoning just where it belongs. Glucose is undoubtedly at the bottom of it all. Unless some stringent repressive measures are adopted by Congress, poisoning will become as common as are now the lesser ills, our nation will become one of chronic dyspeptics, and our successors will be effeminate and perhaps imbecile. In fact, it is difficult to enumerate the evils which will result from the constant consumption of poisons that will cause cheese to "rot down in thirty days," and imperil at one time the lives of "some seventy-five citizens" in one small community. Life and health are no longer safe; the most substantial articles of food are adulterated with deadly poisons, and milk, the first food of nature, is drawn from the udder a poisoned stream.

We have long held that Congress possessed the Constitutional right to regulate the traffic in and manufacture of food adulterations, as also, to restrict or prohibit the sale of adulterated food. By a recent ruling of the Court of Appeals, even State laws can prohibit the manufacture of deleterious food of any description. The following extract from a late number of the *St. Joseph Herald*, cites a case in point:

Missouri has a new law forbidding the manufacture or sale in this State of any imitation of butter, no matter whether represented to be genuine or not. The oleomargarine interest made a desperate fight in a test case, carrying it to the Court of Appeals on the question of the law's validity. The decision is that the prohibitory act is Constitutional. "A statute prohibiting the manufacture and sale of any article of food made in imitation of a wholesome article in common use," says the court, "which imitated article is so repugnant to the tastes and prejudices of our people that they will not eat it when advised of its real character, but only when cheated into the belief that it is the genuine article, in resemblance of which it is made, is a statute fairly within the police power of the State, not opposed to any provisions of the Constitution of the United States, and the wisdom of which is not to be called into question in the judicial courts; and this is so,

although particular samples of such imitating articles may, in the opinion of scientific men, be as wholesome and beneficial an article of food as the original substance in imitation of which it is made." The effect of this decision will be the suppression of several factories in St. Louis, where the sale of imitation butter, made from lard, beef fat, and other materials, has been extensive.

The decision of the Court of Appeals covers more ground than even we had assumed. We had no doubt it was Constitutional to prohibit the manufacture and sale of deleterious articles, under any but their right names, not only as a matter of commercial policy, but as a sanitary measure; the Court decided "A statute prohibiting the manufacture and sale of any article of food made in imitation of a wholesome article in common use... is a statute fairly within the police power of the State, not opposed to any provisions of the Constitution of the United States, and the wisdom of which is not to be called into question in the judicial courts... although particular samples of such imitating articles may, in the opinion of scientific men, be as wholesome and beneficial an article of food as the original substance in imitation of which it is made."

When an article has a tendency for evil far in excess of any good which it can accomplish, and the principal use of which must be in a fraudulent manner, if it is not a matter proper to be legislated upon and prohibited, except under special restrictions, then, surely, there is no cause for legislation, and Congress had better renounce all power to protect the people. Glucose is as much a public abuse as oleomargarine or suine, and far more dangerous in its consumption, because of the multiform shapes in which it is imposed upon the public. Congress *must* legislate upon the subject of food adulteration.

☞ We have received the premium list of the Thirtieth Annual State Fair to be held at Indianapolis, Ind., Sept. 25 to 30, 1882. In it we notice \$25 as premiums for honey, \$2 for wax, and two diplomas for bee-keepers' supplies. These amounts ought to have been ten times as large, and more varied.

☞ Do not let your numbers of the BEE JOURNAL for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

AMONG OUR EXCHANGES

MISCELLANEOUS.

Watch Them.—The *Indiana Farmer* gives this advice to beginners:

Watch all colonies closely that you have lived on empty frames, and see that they build the combs straight. Watch all colonies that have cast a swarm, and see that a young queen does not hatch out and lead off a second swarm.

Watch all colonies and nuclei containing young queens, that they do not become queenless by the young queen being lost while on her bridal trip. Watch all queenless colonies that they do not become infested with fertile workers. Keep a frame of uncapped brood in the hives that have been queenless any length of time. Watch the sections of comb honey and take them off just as soon as sealed over, to protect their pearly whiteness. Watch all combs packed away, that the worms do not destroy them. If you find any signs of their work fumigate with brimstone. Watch that the entrance to the hives does not become clogged with grass and weeds.

Watch the source of the honey supply in your immediate locality and see where it can be improved by planting.

Watch your neighboring bee-keeper and see if he has better success than you. If so, why?

Watch and remember what you see.

Watch and you will be sure to improve by the care taken.

Unused Honey Resources.—A late number of the *Chesterfield, Eng., Courier*, has the following very sensible communication from one of its contributors:

A few months since in an article on "Agricultural depression" you called the attention of your readers to some of the minor products of the farm, and pointed out that one of the best remedies for the present distress was to give attention to sources of profit which have hitherto been much neglected, and not to allow the foreigners to take out of our country for eggs, poultry, fruit, etc., large sums of money that would be better in the pockets of our own people.

Now without staying to express my own opinion on these matters—which might not, perhaps, quite accord with yours—will you kindly allow me to direct attention to one of these minor industries of the farm and cottage garden which certainly at present is not very productive, but which under better management might prove a source of considerable profit to the small farmer and cottager, as well as a most interesting occupation and amusement to those who have more leisure, I mean the keeping of bees.

It will be seen from an advertisement in your columns that the British Bee-Keepers' Association is kindly sending an expert to give a lecture in Chesterfield on bees and bee-keeping, and it is arranged that this lecture shall be given in the Stephenson Memorial Hall, on Saturday next, at 3 p. m., under the presidency of W. Gladwyn Turbutt, Esq.

Those of your readers who will take the trouble to attend—and as the lecture is entirely free, it is only the trouble—will, I think, be surprised to find what an extremely interesting pursuit bee-keeping is and how very remunerative it may be made under a proper system of management, at least in ordinary seasons and situations.

The old wasteful and cruel system of murdering the poor bees to obtain their honey—almost equivalent to slaying a cow when a jug of milk is wanted—was, it is true, seldom profitable, as indeed it did not deserve to be, but the modern method, which Mr. Blow will explain and illustrate on Saturday, will show all who care to learn how these industrious little creatures may be made to afford great pleasure and profit to all who treat them properly.

To show the importance of the matter I may say—and all who really understand the matter will bear me out in asserting that during last summer tons, literally, of honey was wasted in the immediate neighborhood of Chesterfield for want of laborers to gather it in—those who should have been working in this harvest for us having been burnt in the sulphur pit in the previous autumn, or worse still, left to perish of hunger and cold for want of due care and attention.

We hope, however, that the spread of information on the subject and the consequent establishment of better systems may soon place us in a better position, so that when another such season occurs, we may be able to gather in a large share of the rich gifts a bountiful Providence supplies, and that this country may not be dependent on other lands for the supply of what we carelessly and ignorantly allow to run to waste at home.

A Mule's Amusement with Bees.—A California exchange gives the following:

I was visiting a gentleman who lived in the vicinity of Los Angeles. The morning was beautiful. The splash of little cascades about the grounds, the buzz of bees, and the gentle moving of the foliage of the pepper trees in the scarcely perceptible ocean breeze, made up a picture which I thought was complete. A mule wandered on the scene. The scene, I thought, could have got along without him. He took a different view.

The mule had wandered up close to a large bee hive, and got stung. His eyes lighted up, as if that was just what he was looking for. He turned on the bee hive and took aim, and fired. The bees swarmed.

They lit on that mule earnestly. After he had kicked the last bit of bee hive so high that he could not reach it any more, he stopped for an instant. He seemed trying to ascertain whether the 10,000 bees which were stinging him meant it. They did.

The mule turned loose. I never saw anything to equal it. He was enveloped in a dense fog of earnestness and bees, and filled with enthusiasm and stings.

I had no idea how many bees a hive would hold until I saw that bee hive emptied on that mule. They covered him so completely that I could not see any of him but the glare of the eyes. I could see from the expression of his eyes that he didn't like the way things were going.

Not only was every bee of the disturbed hive on duty, but I think the news had been conveyed to the neighboring hives that war had been declared. I could see bees flitting to and fro. The mule was covered so deep with bees that he looked like an exaggerated mule. The hum of the bees and their moving on each other combined in a seething hiss. Numbers were telling on him. He looked distressed. He had always been used to kicking against something, but found now that he was striking against the air. It was very exhausting.

He finally got so he did not rise clear of the ground, but continued to kick.

The intervals grew longer and longer, until he finally was still. The bees stung on. He looked as if he thought that a mean, sneaking advantage had been taken of him.

I retired from the scene. Early next morning I returned. The sun came slowly up from behind the Eastern hills. The light foliage of the pepper trees trembled with his caress. His golden kiss fell upon the opening roses. Bees could be seen flying hither and thither. The mule lay near the scene of yesterday's struggle. Peace had come to him. He was dead. Too much kicking against nothing.

Bees and Honey at Fairs.—The *American Agriculturist* for July contains the following:

At the last National Convention, which was one of the most pleasant and profitable bee-meetings ever held in America, it was resolved to make an effort to have many fine exhibitions at the State and district fairs of 1882. In England and other parts of Europe, these exhibitions are conducted on a grand scale, and excite much interest. They are thought to be great educators, and to stimulate the honey market to a large degree. It is important to secure the offering of generous premiums. The State and Central Societies of Michigan have already secured favorable action by two of the largest Agricultural Societies of that State. Let all other societies do the same. It is probable that in no other way can the interests of bee-keepers be so rapidly advanced.

Light versus Dark Italians.

W. Z. HUTCHINSON.

Mr. Aaron Benedict says that it "is much easier for the careless breeder to rear dark than light-colored Italians, hence they are ready to praise the kind of bees they have, and if queen-breeders, they can send out all the hybrid queens they can rear, if dark."

The testimony of all queen-breeders, and my own experience agrees with their testimony, is that to breed for and obtain light color in bees is one of the easiest traits to be obtained by breeding. In reply to the remark about the breeders of dark bees being able to send out hybrid queens, I would say that queen-breeders do not rear their queens from hybrid queens. It is just as easy, and requires no more work, to rear queens from a pure queen, than to breed from a hybrid queen. What breeder would be so foolish as to send out hybrid queens for pure queens?

Mr. B. says: "I believe if these advocates of dark Italians had queens that were light-yellow, and produced all light-yellow bees, they would sing a different tune." In reply I would say: show me the advocate of dark Italians who has not also tried the light Italians before "singing his tune."

Mr. B. says: "It is the instinct of all honey bees to gather honey." Just so, but does not Mr. B. know that some bees possess this instinct in a greater degree than others, or else with the instinct is joined a greater ability?

Again, Mr. B. says we should have "in view, first, the lightest-colored bees; second, large; third, docility." To make the joke complete, he ought to have added, fourth, honey producing qualities. In my opinion, honey production, hardiness, prolificness, amiability and color should be bred for in the order named, but I fear that some have bred in the reverse order.

The editor of the *Instructor*, in an editorial in the May number, expresses my views so exactly, that I hope I may be excused for quoting his concluding paragraph, he says: "We do not claim that the dark Italians are best simply because they are dark. Although there is undoubtedly a natural difference in many respects in the two strains, we think the difference is caused principally from the majority of bee-keepers having bred almost exclusively for color, without paying enough attention to other points equally or more important, such as vigor, prolificness, honey gathering qualities, etc. If color is not gained at the expense of these qualities, well and good. But we fear that in too many instances it is.

When breeders begin to realize that color of itself amounts to nothing; that queens may be as yellow as a gold piece and still be worth nothing as producers of business bees, then, and not till then, we may expect to see a general improvement in the race." Rogersville, Mich.

California Apiculturist.

Evaporator for Extracted Honey.

W. W. BLISS.

In the first engraving A shows an opening two inches wide, covered with wire cloth extending the whole length of the tank, and the whole is covered with a narrow roof, to keep out the rain; B is an iron rod to hold the upper part of the tank together and keep the roof from spreading; C C are posts, 3x4 in.; F is a piece of 3x4, extending across from post to post under the bottom, and is let into the posts 1½ inches, to support the weight; D is a honey gate; E E are pieces of iron bent around the posts, and bolted to F to keep it from spreading apart at the bottom. Or instead of these bent irons, an iron rod as at B, may be run through the

FIG. 1—End View.

legs below the tank, or both rods and bent clasps may be used and thereby secure additional strength.

In the second illustration A A A A are window glass. B B B are the posts; C C C are the ends of the bolts; D is the honey gate. The tank is made of two-inch plank, and is 7 ft. long, 3 ft. wide, and 20 inches high, all inside measure. The ends should set back from the ends of the sides about two inches, and let into the sides and bottom about ¾ of an inch. The roof should be made tight, so that it will not leak; one side is made of boards; the other side has glass in it, so as to let in the sun, and should face south.

To put in the lining, go to the tinshop and buy some sheets of I. C. tin, and have the tinner turn the edges for clinching, as they do for roofing. Lay the bottom out on a floor, hammer down the clinches, and solder all tight. Take the measure of the inside of the tank, and then turn up the edges and ends of your bottom to that size, making it ¼ inch smaller all around than the inside of your tank. Now put the bottom lining in its place; begin on one side and put in the rest of the lining, one sheet at a time, clinching and soldering as you go. The lining should be bent over the top of the tank, and nailed to the outside with lath-nails.

A tank like the above ought not to cost more than \$15.00 and will hold about 3,000 lbs. of honey. When completed the whole of the woodwork should be treated to one or two coats of black or some other dark-colored paint that will absorb the sun's rays and add to the evaporating powers of the tank.

It would be difficult to tell just how fast it would ripen newly extracted honey; it would depend upon the weather and how thick the honey is when extracted. If the weather is cloudy, cold, and damp, it would not ripen the honey as rapidly as it would

FIG. 2—Side View.

if it was clear, hot and dry. Here in Los Angeles County, an evaporator the size as described above would (if full) ripen rather thin honey in about 4 or 5 days; it depends upon how thin the honey is, and how thick you want it. You can extract the honey before it is capped over, if you have clear weather to ripen it in.

Los Angeles, Cal., May, 1882.

Specimens of *Apis Dorsata*.

WM. F. CLARKE.

Well, I have seen her, and him—worker and drone—two of each, in alcohol. These four insects represent the price of a farm, and are all our friend Jones has to show, as yet, for his Oriental pilgrimages, and those of Frank Benton, in search of "the big bee of Java."

It is a big bee, and no mistake, about four times the size of *apis mellifica*. I am not much of an entomologist, and this description is not meant for the eye of Prof. Cook, or any other scientific expert in the appearance and ways of that division of the animal kingdom called *Insecta*. I can only give the crude impressions of one who has been familiar, sometimes too much so, with our common and improved races of bees.

The *bigness* of this bee is what first strikes the ordinary observer, and next to that its beauty. It is golden-banded like the Italian, and silver-banded too, but with a more decided and larger black terminus to the abdomen, in this respect resembling the Cyprians and Syrians. A bee curled up in alcohol, does not display itself to the same advantage as when on the comb or on the wing, but this bee, stretched out, must be a well-proportioned, handsome insect. The body is large and roomy, giving great capacity for honey carrying; and the wings are long and broad,

showing great power in flight. The head is remarkably small and tapering, and if, as is probable, the length of tongue is in proportion to the size and shape of the head, we may hope that this bee will be able to rifle the red clover of its luscious treasures. Its weight, however, will bend over the stoutest stalk of clover, and this may create difficulty in operating on the blooms. Most likely any advantages we may obtain from the advent of this insect, will be the result of judicious crossing. The drone is comparatively small, not so long, I think, as the worker, but aldermanically corpulent, like all drones. I would hazard the opinion that he is not too large to mate with the bees we have. The possibility of a cross the other way is more doubtful to my mind, for if the Java queen is large and long as compared with the worker, like the races of bees which we now have, she must be not only an Amazonian, but a Brobdignagian creature. If we get even a hybrid variety from *apis dorsata*, our hives must be greatly enlarged, and if we breed them pure, our hives must be quadrupled in size. Frames, honey extractors, comb foundation machines, perforated zinc, honey sections, etc., must all be made on a larger scale. If the mandibles are long, strong, and sharp in proportion to the other parts of this bee's body, I am afraid they will puncture fruit, and then there will be trouble in the camp. At present we have pretty clear evidence that our bees do not puncture fruit, but only avail themselves of the sweet juices liberated by wasps, hornets, and birds. It will be an evil day, if it ever comes, when fruit culture and bee-keeping cannot flourish, side by side.

But, what of the sting? That's my chief trouble in view of the coming of *apis dorsata*. It is all I can do to get along with the moderately-sized stings that now menace the adventurous bee-keeper. When hundreds of thousands of live daggers half an inch long are whirling around in the air, each with a gigantic insect "ready, aye ready" to use it on a poor bee-hated amateur apiarist like myself, I think I shall sigh with the poet,

"O for a lodge in some vast wilderness,"

and betake myself to parts unknown and unfrequented by *apis dorsata*. But Mr. Jones assures me that they are very amiable insects, and though formidably armed do not know the use of their deadly weapon. It may be so. We know that the horse and the elephant are ignorant of their power, or they would not submit to be bully-ragged about by that tyrant man. But suppose a cross between the Cyprian and Java. Horror of horrors! There will be nothing for it but to take a back seat in

"Some boundless contiguity of shade"

too dense for a bee to penetrate.

I am not much of a microscopist, and Jones' microscope is not of very high magnifying power, but if my observations were correct, the sting of *apis dorsata*, like that of the bum-

ble-bee, is without barb. Let us hope it will also be found to be without virus, and that the "big bee of Java" will be like the big Shanghai fowls in disposition, as compared with the game breeds.

Among other attractions that may be trumpeted forth to attract a large attendance at the next annual meeting of the North American Bee-Keepers Society, there is this, that Mr. Jones will exhibit his four precious Java bees on that occasion. Meantime, for the next four months, I shall have the high satisfaction of holding some such colloquy as this with not a few of my bee-keeping rivals: "Have you seen *apis dorsata*?" "No." "Well, I have."

Parthenogenesis in Bees.

PROF. A. J. COOK.

In the current volume of the *Scientific American*, page 186, there is given an abstract of some experiments of one Abbe Giotto Ulivi, in reference to parthenogenesis among bees. The conclusions drawn from these experiments are as startling and absurd as would be the assertion that the progeny resulting from mating the horse and the ass would be anything but a mule. The statements made not only contradict some of the most thoroughly settled truths of science, but actually contradict the every-day experience and observations of every intelligent and observing apiarist. I should not think that these wild assertions were worthy of notice, only that some of the papers, even the bee papers, give the article a place, and make editorial comments that would lead one to think that there was good ground for the opinion that Huber, Dzierzon, Langstroth and a host of others were all mistaken, and did not see what they said they saw. Is it possible that one unknown man's mere assertion shall weigh more than the testimony of many widely known and thoroughly reliable men, and they, too, often men of the very highest scientific attainments?

The following are the points which are denied, most of which are easy of demonstration, and some of which are proved by the daily experience of every bee-keeper:

1st. Queens are impregnated outside of the hive, and while on the wing; 2d, they are fertilized but once; 3d, drones are killed in mating, and some of the genital organs torn off; 4th, the eggs which hatch into drones are not impregnated, and so the law of parthenogenesis is true among bees, so far as the drones are concerned; 5th, eggs from virgin queens will hatch and all of the bees be drones; 6th, some worker bees will lay eggs. Such bees, known as fertile workers, have never mated, and all the eggs from them produce drones.

That queens are fertilized without, and not within the hive, is very easy of demonstration. In fact it is demonstrated in nuclei hives by the

hundred every year. I have demonstrated it in several ways. I have clipped one of the wings of queens many times, just as they emerge from the cells, and in every case I had a drone-laying queen, if she laid at all; though in many cases there were scores of drones in the hive. Of late years I have had only drones in one or two of my choicest hives, having taken care to keep them from all the other hives; and in my small or nuclei hives I seldom have any drones. In such cases, if Ulivi is correct, fecundation would never occur; yet I almost never fail to secure fertilization. I have often shut the young queens in the hives, often with drones, and never would I secure fertilization till she was allowed to fly forth. From our every-day experience it is hardly possible to refrain from the conclusion that Ulivi is a fraud.

It is just as patent that queens are only fertilized once. My queens that are in droneless hives, and with wings clipped so that they cannot fly out, are, of course, utterly precluded from a second mating, and yet they remain fertile and lay worker eggs just as long as other queens that have good wings, or are surrounded with drones.

It is not so easy to prove that drones are killed or mutilated in the sexual act, though I have little doubt that it is true. I have seen several cases of bumble bee mating, and in every case the drone was killed. The honey bee is so nearly related to the bumble bee that it is very certain that the same is true of it. Again, the drones, if held in the warm hand on a warm day, will experience orgasm, and at once die. Mr. D. A. Jones found that he had lost a great many more than the usual number of queens as they flew forth to mate, on his islands last summer. This is easily explained on the theory that the drone expires in the sexual act and falls to the ground and drags the queen with him. In the water she would not be able to rise, and of course would be lost.

Of course, I do not positively know by actual observation that the white thread that hangs from a queen as she comes from mating, is a portion of the male genital organs. But I have found, with many others, that queens I had shut in the hives for five days after they had emerged from the pupa state, and then let out to fly, would, without exception, commence laying if the white thread was appended to the abdomen, even though there were no drones in the hive, and would fail as surely to lay worker eggs, when the white filament was absent. I have had several experimental queens reared in the early spring, before there were any drones, and they would fly out every day and return, but never carry the filament attached to the abdomen. Any one can easily try this, and will become convinced very soon that with no drones there will be no thread.

That drone eggs are fecundated, will be very surprising to the many apiarists that have reared queens when there were no drones, in late fall and early spring, and found that there were abundant eggs laid, but

that all produced, without exception, drones. Ulivi's assertion that eggs remain over the winter, might find credence before the days of foundation, but now it will fall so flat that it will have only two dimensions.

Ulivi's last statement—that there are no such bees as fertile workers—makes me think of Byron's remark in reference to Bishop Berkley: "When Bishop Berkley said there was no matter, it was no matter what Bishop Berkley said." It is an exceedingly unfortunate time to throw such a remark at American bee-keepers. Our new bees—the Syrian and Cyprian—will give us fertile workers with more facility than Ulivi can make unwarranted statements. Such an assertion needs no refutation in America, no matter what is true in Europe.

Michigan Agricultural College.

[Prof. Ulivi has written a long letter to *L'Apiculteur* for June, 1882, published in Paris, France, replying to many strictures that had therein been made to his peculiar theories. The editor of *L'Apiculteur* announces the close of the debate in the following words: "We now declare the affair heard on both sides, and consequently the debate closed. If we judge correctly, the author of fecundation in the hive will now have to talk to the wind!"—Ed.]

Farmers' Home Journal.

What is a Fertile Worker?

G. W. DEMAREE.

Several correspondents have of late substantially asked the question which we have chosen for a caption to this article, "What is a fertile worker?" The question is a fair one, and is of sufficient importance to justify an answer in detail. The question is usually answered by saying that a fertile worker is simply a worker bee that possesses the power or functions to lay a few eggs, which hatch out drones only. "Is this all?" It is all that we can see with our eyes, but if we study the natural history of the bee (*Apis mellifica*), the phenomenon resolves itself into a proposition supported by an abundance of reason, and is certainly just what we must or might expect as a result of the peculiar laws that govern in the process of perfection of the queen honey bee.

The worker bee is a female in every respect that the queen is. The same egg which produces a worker bee, when under the conditions adapted to that end, will produce a queen when placed in a position favorable to the development of a queen. I have demonstrated this proposition time and again by removing the infant larva from the royal cell in a hive of black bees, and substituting for it a worker larva of the same size from Italian stock. If skillfully done, you will change the bees in that hive and demonstrate to your entire satisfaction

that the difference between the queen and the worker is simply and solely a matter of development. It is a well-known fact that a queen is good or indifferent in exact proportion to her development.

With these facts before us, the question, What is a fertile worker? is logically answered. A bee reared in accordance with nature's laws governing the processes which perfect the undeveloped (female) worker bee, though sufficiently developed to enable her to lay a few eggs, is not a queen; she is a fertile worker. Worker bees being undeveloped females, is it not reasonable and probable that some of them will be more developed than others, and that now and then one may be sufficiently developed to lay a few eggs?

Such are the facts, and they are supported by reason.

Christiansburg, Ky.

London Journal of Horticulture.

Progress of Bee-Keeping in England.

A. PETTIGREW.

In practical and scientific apiculture considerable advancement has been made during the last ten or twelve years. Though slow the progress has been certain and encouraging. Many clever apiarists of the present time had not mastered the rudiments ten years ago. This advance has been made amidst the discouragements of unfavorable and disastrous seasons for bee-keeping in England. If the country had had seven years of sunshine out of the last ten instead of seven years of cloudy and unpropitious weather, the value of bees to the community would be better known and consequently more highly appreciated. Notwithstanding the inclement seasons and unfavorable harvests, bee-keeping is moving onward in the right direction. Knowledge is spreading; inventions great and useful are introduced; old and experienced men use them with advantage and grasp the whole subject of bee-keeping more firmly. Many young men who a few years ago were commencing attention to the subject have advanced and are expert in all manipulations in the apiary. Much knowledge has been widely spread during the last few years, and almost everywhere happy results are already evident. We predict that the progress will increase, and that bee-keeping will yet become a source of happiness and profit to thousands of the rural population of Great Britain and Ireland.

During the last ten years we have lamented the misfortunes of beginners, for two destructive seasons killed every bee in some gardens; in others one-half, two-thirds, or three-fourths were lost. Other seasons, not destructive, but unfavorable for honey-gathering, caused great disappointment amongst beginners. Some lost heart altogether, and some thought that a change of hives from straw to wood, or wood to straw, would bring success. In many cases the change was made at some expense

without better results. Apiarists are, however, very hopeful. A few days ago I had a letter from an experienced bee-keeper in the north of Scotland, who is anticipating a bright and successful future not remote. And why should he not? People who plant orchards look hopefully forward, and derive encouragement and pleasure by considering the future. Bee-keepers who have been successful some years are like other successful men in expecting greater success in the future.

The introduction and use of artificial comb foundation is a marked improvement in the management of bees. Supering is made easy by the use of these foundations—easy for both bees and their masters. By filling supers and sections with the foundation the bees readily adopt them, and soon begin to thin the wax and lengthen out the cells, and make them ready for the reception of honey; thus the bees have less wax to secrete and more honey to store. The stronger foundation used for brood combs are as useful as those used in supering, for if given to first swarms at the hiving time, breeding commences at once, even before the cells are finished the eggs are deposited on the foundation, and the cells are afterward built around them. If supering is made easy by employing comb foundation, progress in breeding is also made by their use. We thank the American bee-keepers for the invention and introduction of comb foundation.

We are also, I think, indebted to the American bee-keepers for the introduction of sectional supers, which are useful in the retail honeycomb trade. Sections of 1 lb. and 2 lbs. of comb are very salable, easily handled and carried. These small sections when well filled are so presentable and tempting on breakfast and tea tables that commendation is quite unnecessary. If exhibited for competition at honey shows they should be judged by number or weight from a given hive or from a single apiary. Larger supers of glass and wood are more sensational in exhibitions. Bee-keepers who study profit will use the kind of supers most salable in the market. Last season our glass supers, nearly 20 lbs. each, were sold at 2s. per lb.; straw and wood supers at 1s. 4d. and 1s. 6d. per lb.

The attention that is now given to the comforts of bees by advanced men is another evidence that progress is being made. A few years ago hives were not sufficiently protected in winter. Bees are natives of a warmer climate than that of England, and therefore suffer much in our cold winters. Many bee-keepers now know this and cover their hives well in winter. For many long years the most advanced bee-keepers in Scotland have covered their straw hives effectively. The advanced men of the bar-frame school are now having hives made with double walls, and fill the cavities between the walls with chaff. This is a great improvement, and in severe winters these chaff hives may be trusted to protect the

bees. The honor of the invention of the chaff hives belongs to America. One more invention or discovery will perfect the bar-frame hive—namely, a material more porous than wood, which will permit the moisture of bees to pass through and out of the hives. We have so many clever beekeepers seeking improvements now that I believe the discovery will be made soon. Meanwhile many men are doing what they can to ventilate the wooden hives and make their bees more comfortable during winter.

Evidences of progress in bee-management could be easily drawn from many points of practice now extensively followed. One pleasant feature of the progress already made by beekeepers I would like to notice. It is the fact that they now write and speak more kindly of those who differ from them in opinion than they did some years ago. The best men amongst us—the real Samsons of beekeeping—refrain to a great extent from employing dogmatic language. They know well that whatever is true in science and the practice of beekeeping will advance steadily, and sooner or later establish itself. On many questions much can be said on both sides; therefore let us act on the principles of “free trade” and fair play in exchanging opinions, always remembering “kind words never die,” and also that “charity never faileth.”

Bear in mind that great results more frequently come from perseverance than from great strength—“A falling drop will cave a stone.”

Bowdon, England.

For the American Bee Journal.

How to Hunt Bees in the Woods.

F. M. JOHNSON.

You require a small box (which can be made of any kind of wood). The box is of a slanting shape, and should be made according to the following dimensions: Bottom, 4x6 in.; sides, 4 in. at one end and beveled down to 1½ in. at the other; end pieces—one, 4x4 in., the other 1½ deep by 4 in. long. The top should be a separate piece, and made as follows: Width, 4 in.; whole length, 12 in. cutting down 4 on one end for handle, and inserting a glass 3x1 in. flush with the under-side at the other end, as near the end as convenient.

The box should contain a piece of honey comb about 1¼ in. in thickness, which should be scented with bee-bait (the directions for making this are given below), covering the bottom of the box. Taking the box in the left hand and the cover in the right and approaching the bee while at work on the flower or shrub, you insert the box under the bee and quickly putting the cover on the top (in such a manner that the light can shine in), you have the bee secure in the box, then put the box on a stake 3 or 4 feet high, taking care not to jar the box more than necessary. Then shove the cover down so as to shut out the light from the glass, when the

bee will go to work on the honey, which can be ascertained by holding the ear to the box, as it will cease its “humming” as soon as it commences on the comb. Then the cover can be taken off and the bee will remain on the honey. Then take a position where you can have an unobstructed view of the box and its surroundings, and wait for the bee to come out, which it will do in from one to three minutes, and commence circling in the air, gradually enlarging the circles until it finds its latitude at which it will immediately start in a direct line for its home, and here care must be taken to accurately mark the direction it goes. You must now wait for a short time, when the bee will return and re-enter the box, which it will repeat as long as the box remains. If the tree should be near by other bees will accompany it on its second or third return; if at a great distance it will take a longer period for the bees to “double up.”

If you have gotten 15 or 20 bees at work on the line you can safely take the box to a point as far distant, in the course the bee has taken, as you choose, being careful not to pass where the bee is likely to tree, as they will not follow the other way. Now open the box again, and if you are on the line the bees will find it in a very few minutes. If they do not you will know that you are off the line or have passed the tree and should move your box to a point that you know is on the line. This is to be repeated until you run the bee to its tree.

If you have but a few bees it will be necessary to shut them in the box and move them in this manner from 30 to 60 rods at a time, then open your box and wait for them to go and return. This is to be repeated until you have found the tree.

Cross lining is important. If anything should prevent you from following the bee in a direct line from where you first start it, you can move the box a distance to the right or left and start it again, by which means you can center the bee on some prominent object whereby you can invariably locate the tree within a radius of 5 or 6 rods.

Half an ounce of tincture of Annis mixed with a half dozen drops of oil of Organum, to be kept in an airtight bottle.

Instead of using honey in your box, put a quantity of granulated sugar in a bottle and dissolve it with cold water until it becomes a thick syrup, and fill the comb in the box with this liquid, which is better than the real honey.

Comb or Extracted Honey.

F. L. DOUGHERTY.

In answering the question—“Which is the most profitable?” I would decide at once in favor of extracted honey. The phrasing of the sentence implies that the bees are to be worked for the best results, the greatest profit, regardless of other considerations. Still, in deciding which is the most profitable in individual cases, various circumstances and conditions must also be considered, and can only be decided by each one for themselves.

As to the relative amount which can be secured in ordinary seasons, the yield of extracted will double that of comb honey, and at other times it may be possible to secure quite a fair crop of extracted honey, while the bees would not have one pound of comb honey. As, no doubt, all of you know, the secretion of honey depends almost entirely on atmospheric conditions. There may be several days at a time when the bees will scarcely gather anything, when on account of favorable weather, a few days will come when the flowers seem literally filled to overflowing with nectar, and these few days may constitute the entire honey yield of the season. If at times like this, the hives be well filled with plenty of empty combs, the amount gathered will be surprising, but if the bees must stop to build the comb in which to store the honey, the surplus secured will be but very little, if any at all.

In producing extracted honey, particular attention should be given to quality, and every drop should be well ripened before it is closed up in casks, cans, or jars. None but a thoroughly good article should be placed on the market, as the price and future sales will depend very much on the quality of honey you offer.

As a general thing the difference in price between extracted and comb honey ranges at from 5 to 8 cents per pound, but where you have a good home market at retail, extracted honey will bring within a few cents of as much per pound as comb honey. As far as practicable each grade of honey should be kept separate. In order to do this a vigilant watch should be kept of the different bloom. The white clover honey should be extracted closely before the basswood blooms. A little clover in the basswood honey, however, will not do the harm that would result if the proportions were reversed. Basswood honey has a peculiar flavor, and it should not be allowed to become mixed with any other kind of honey.

As to how fast the honey should be taken, we think it makes but little difference in its quality, providing it is given the proper care afterward, and we would like to impress on your

minds the very great importance of this care. New extracted honey should stand in open mouthed vessels for quite a while before being closed up, so as to become thoroughly ripened. It should also be borne in mind, that with the extractor we are likely at times to take every pound of honey in the hive, and if at a time like this, the flow of honey should cease suddenly, the bees must be fed, or they are likely to perish for the want of necessary stores. A necessary point to be taken into consideration is the time necessarily required in extracting honey, for during good yields the honey must be removed every third or fourth day, for generally colonies run for extracting are not so likely to swarm, unless neglected, and are very full of bees.

Northwestern Wisconsin.

The N. W. Wisconsin Bee-Keepers' Convention met in LaCrosse, Wis., June 9, 1882, at 10 a. m., Pres. Markle in the chair. Minutes of last meeting were read and approved.

Wm. Lossing moved that the meetings hereafter take place about May 1 and October 15. Carried.

The President called for a report from all the members present as to the successful wintering of bees the past season. The loss reported was about one in fifty.

W. Lossing complained of being troubled with a species of bee-destroying bird. The bird he said was a trifle larger than the kingbird, of a brownish color, with white breast. He said he shot 57 in one day.

Pres. Merkle complained of being troubled a great deal with the kingbird, and thought the best way to dispose of them is with a good shotgun. He asked the opinion of the members as to the best bee-hive, and it was generally agreed that the Langstroth was the best; at any rate, a hive to be better must be on the same principle.

The question arose, "Would it be proper for the Society to place a price on honey, and to appoint some one to mark it according to grade?"

Mr. Lossing was of the opinion that, as he understood G. J. Pammel to say he would open a honey depot at LaCrosse, all the members could let him have their honey, and he would dispose of it as he best could.

Question—Does bee-keeping pay to make a specialty of it? Upon this question quite a discussion arose. After several members gave a statement of their bee account, it was agreed that it does pay.

Question—What is the best method for compelling the bees to work in the second story? Answer—Take one or two frames of brood from the brood chamber, and put them, with a few bees, into the second-story, when the bees will take care of the brood and commence work in that apartment.

Question—Has any one seen a queen in the act of fertilization, and what were the results to the drone? Mr. Lossing said that his assistant had

seen a case, and that the drone died instantly, showing that it performs one duty.

Question—How does a bee get pollen on its legs? Answer—It takes the pollen from the flower with its tongue, and puts it on one of its fore legs, from whence with a quick movement it transfers the pollen to the hind legs.

Question—How does the bee get the pollen off? Answer—It backs into the cell and shoves the pollen off with its middle legs.

Question—What queen cells produce the best queens? Answer—Remove the queen from a strong colony that has plenty of brood and eggs, then cut a strip of comb from the bottom of a whole comb with eggs in, about one inch wide, giving the bees plenty of room to build large queen cells. Select the best from the whole number, and you will be pretty certain to get good queens.

The President spoke of the effect of extracted honey on the market. He looked upon it as a great evil, and only there to make room for fraud.

Messrs. Lossing and Pammel rebutted the remarks of the President, after which he expressed a determination to buy a honey extractor.

The Convention adjourned.

G. J. PAMMEL, Sec.

Madison, Wis., Convention.

The monthly meeting of the Madison, Wisconsin, Bee-Keepers' Association, was held at Madison on Saturday, June 10, at 7.30 p. m., and was presided over by Prof. R. B. Anderson. Papers were read by Dr. J. W. Vance, C. Spangenberg, D. D. Danilch and Prof. Anderson.

Mr. C. Spangenberg, on the subject of swarming, said: The month of June is the real swarming month among bees. It then often happens to bee-keepers, who like to have large swarms, and do not care to increase the number of hives more than absolutely necessary, that they are at times troubled with the so-called swarming fever. Although we may have destroyed all the queen cells one day, the same hive may show signs of swarming the next day, and this may be followed by a second attempt, nay, even by a third and fourth, simultaneously, so that we get a genuine revolution in the apiary. To suppress this, I open the hive and sprinkle a small amount of water over and between the frames, which at once quiets the bees. Then I either give them more room or make a new swarm by taking two or three frames of brood and bees, out of each of these hives, or the same excitement will occur again the next day; for at such times they work continuously on queen cells. As the swarming fever keeps the bees away from their work of making honey, it is necessary that the bee-keeper should be on his guard to prevent the occurrence of such periods.

Prof. R. B. Anderson gave the following on bee-keeping and its advantages: Our fields and forests pro-

duce immense quantities of flowers that can be utilized and made to increase our wealth, if bee-keeping as a pursuit is properly encouraged and adopted.

I know but very little about bees, but it has occurred to me to ask how much the wealth of our state and country might be increased by a judicious adoption of bee-culture. We know that we cannot raise wheat and potatoes on the same piece of ground at the same time, but it seems that bee-keeping instead of interfering in any way with the productiveness of a farm, is absolutely beneficial to the plants from whose flowers the bees gather their pollen and honey. Nor does the keeping of bees require much of the bee-keeper's time. I heard a farmer who keeps about 50 colonies of bees and sells about \$200 worth of honey every year, say that he considered this money clean profit, since the bees took care of themselves and claimed no part of his farm for their special feeding. He added that the bees were his only animals that did not annoy him. His horses, and cows, and sheep, and pigs were always after him, teasing him for something to eat, while his bees only asked to be let alone.

As stated, I should like to know to what extent our food produce could be increased by a judicious adoption of bee-culture the country throughout, and I think the results of a fair calculation should be pressed into the notice of the public. They tell me bees will go miles after their pollen and honey, and that therefore every man in the city might keep bees, and in this way furnish his household with the necessary amount of pure and delicate sweet. I do not know how this may be.

I suppose if every family in Madison went into bee-culture, the supply of pollen and honey from flowers would be exhausted, and the amount of honey we should get would be much smaller in proportion than if only a third of our citizens kept bees; but then, on the other hand, the honey-yielding flowers and trees might be vastly increased without any great effort on our part. Indeed, I do not think a selection of trees and flowers with reference to the needs of bees would lessen the beauty of our streets and gardens, and in many instances the gain to be received might stimulate many of our citizens, who now neglect their shade trees and flower gardens, to plant more trees and raise more flowers, thus positively adding to the beauty of our fair city. Bees need intelligent care, but the amount of time required to see to them is so small that no other business in which the bee-keeper is engaged need suffer on account of his bees.

The meeting adjourned to the evening of July 8th, at which time others will present valuable papers.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

SELECTIONS FROM OUR LETTER-BOX

Motherwort.—Please give name of plant inclosed, and its value as a bee plant. The bees work on a small bunch in our yard from morning until night, notwithstanding we have the most profuse white clover bloom. It is now six feet high, and full of bloom from root to top. It seems to secrete honey during the entire day. Weather fine and bees doing splendidly.

O. N. WEAVER.

Minerva, Ky., June 19, 1882.

[It is motherwort, and an excellent honey plant. Scatter the seeds from your small patch along the lanes and fence corners. It will take care of itself thereafter.—ED.]

Sudden Transition.—A more discouraging spring could hardly happen, than that just past. It would have been very disappointing had it followed three good winters and summers; but coming upon the heels of three years that had gone from bad to worse, and then to worst, it was disheartening indeed. One could examine bees in the last days of February; March was encouraging, as a whole, and the first ten days of April all the most ardent lover of apiculture could have wished for; but from that date frosts, cold, rain, and winds were the order of the day, so that the middle of May found bees starving and unable to leave the hive, even had there been bloom, until June. But at this date the prospect is really fine for the future. White clover is indigenous here; and so abundant that it is almost a pest, crowding out other grasses. An abundance is in bloom now, and the ground is matted with that which came from the seed this spring, and which promises to bloom this year; so that we shall probably have a much longer honey season than usual, while the flow is already abundant. A week ago bees were on the verge of starvation, and now supers must be put on or the queens will be crowded. Even melilot sown last winter is branching and will bloom this season. Near my hives is a patch of five acres of white, alsike, common red, and mammoth clovers. The hybrids and blacks favor the white; but alsike is the favorite with yellow bees, though they work on common red where the corollas are shallow, and I have seen them working between the flowerets. On mammoth clover I have not seen a honey bee this spring. Sometimes, though rarely, I have seen them on white and alsike at the same flight. Flowers are unusually fragrant this spring, and especially blackberry, and bees took to it as well as they ever do to raspberry. I am heartily glad to see the JOURNAL take a determined stand against adulteration; but I have not the slightest hope in repressive measures, though preventive

measures are practicable. When we come to understand the nature of the soil, in its relation to society, and enact laws that will effectually prevent the divorcement of labor from the land, adulteration, with a thousand other crimes will be prevented, and not till then. One-third of our farms are rented; half of them are mortgaged; and the price that labor pays to get at the soil is all that can be made above a hard living; hence, so many are driven into necessity, and by necessity, or the dread of it, into crime. No amount or kind of legislation will avail until we cease this foolish attempt to legislate wrong into right—night into day; and until we are not only willing but do follow natural right and justice.

WM. CANN.

Murrayville, Ill., June 12, 1882.

Questionable Borrowing.—I see that my "Mating of Queens" is inserted in the *Iowa Homestead* and in the *Iowa Live Stock Journal*, without credit to your paper. I furnished only one copy, and that one to you.

Des Moines, Iowa. J. M. SHUCK.

[This questionable method of filling up a paper occurs frequently—in fact, too often to be always pleasant to the enterprising publisher who secures his corps of contributors at a considerable outlay of time and much trouble. We feel great pleasure in having correspondence, editorial and other matters copied from our columns and properly accredited; but when they are appropriated as though prepared for and appearing originally in such paper, we feel as would a merchant who had been robbed of part of his stock in trade.—ED.]

Rearing Queens in Utah.—Since I last wrote to you I have been engaged in queen-rearing, as quite a few have expressed a desire to have a queen from my bees, they being Italians, the bees in this city mostly being hybrids, and a few of the black bees. I divided on the 16th of May, and in a few days after had 10 queen cells in 2 of the hives which I had divided. On the 22d I took 4 of those cells and gave them to a bee man in this city, he taking an active part in assisting me in the queen business. On the 30th of May my first queen was hatched, with 3 cells still remaining in the hive. I formed 4 nuclei by taking 7 frames from my remaining hives. One of the queen cells I left in the hive I divided was $2\frac{1}{2}$ inches long from the face of the comb. I thought that it would be a prize queen, but in examining the comb a few days after, I found the prize cell gone and no queen in the hive. I also took the queen that hatched the 30th, having taken it out on a frame of foundation where I found it first. My method of introducing the queen was in this manner: I took the frame of foundation which I had kept and put it into one of the nuclei wherein the

queen cell had not hatched out, but was torn down, and last week I found her in the same hive laying and apparently at home. The bees get plenty of water in this district, as we irrigate our gardens every week, and have a pure stream of water pass our door all the time. JOHN DUNN.
Tooele City, Utah, June 14, 1882.

Prospect Good for Basswood.—Bees are doing nothing with us in Canada at present. The white clover is only beginning to blossom. I had to feed some of my bees; they killed off most of their drones; some of the colonies drove them out till the ground was covered with them. Do you think they will swarm after killing the drones? The hives are full and running over with bees ready to gather the honey. I think in a few days we will have a flow of honey. There is a good prospect for raspberries, and white clover is beginning to blossom. There is promise of a basswood honey harvest, as the trees are full of blossom buds. WILLIAM COLEMAN.
Devizes, Ont., June 16, 1882.

[Yes; they will provide more drones when they become strong enough, and the weather and honey-flow are favorable for swarming.—ED.]

Coffee A Sugar for Winter.—Apple blossom season closed on the 12th inst. in this locality—fully two weeks later than last year. Bees have been booming in consequence, and have occupied about one-half of the day time in securing the nectar. The rains and extremely cool days and nights have been detrimental to them, but they have done well. White clover promises to be abundant, and will be out in about a week when the bees will "boom" again. This is also about two weeks or more later than last season. My colonies number 30, mostly Italians. They came through last winter with little loss, wintered, as usual, on summer stands, in double-walled chaff hives; 20 colonies are ready to go into the boxes soon as the honey flow commences again, and the others will be ready for the basswood flow, which I have seldom known to fail in this locality. My bees were wintered in 1880 and 1881 without loss, out-of-doors in chaff hives. I practice stimulative feeding in the spring to get my bees ready for the first honey flow, and have usually been successful. I have never had a case of dysentery in my apiary. I fed pure coffee A sugar for fall and winter stores, but never any glucose or grape sugar, or poor honey. Pure coffee A sugar is the best for wintering bees, and if a case of dysentery can be shown where a colony has been wintered on this alone, I have yet to find it out. Of course, this must be melted so as to be of the proper consistency, and then fed early enough to give the bees time to cap it over. Do not trouble about pollen, that will take care of itself—the greatest trouble about it is that too frequently there is an excess of it, and that is detrimental to the health of the colony. If I remem-

ber correctly, I read an article in the BEE JOURNAL early this year from a bee-keeper of about 40 colonies, who professed to have fed about 500 lbs. of bran or rye flour in his own apiary; possibly I am mistaken, but think not. To say the least, I cannot see how it was done, and what the necessity was. Beginners are often troubled about getting bees started in the surplus boxes. I have had but little trouble in that way; first supply the boxes with starters of natural comb or foundation, and then raise a frame of brood or honey from the brood chamber to the storage apartment, and the bees will commence business at once, unless the hives be too warm; in that case, give good ventilation. The vacant space in the brood chamber must be supplied with a frame of foundation or comb. E. F. SMITH.

Smyna, N. Y., June 15, 1882.

Spring Dwindling.—Bees wintered well in this part of the country. One man living near me only lost one colony out of 106 up to the time he took them from the cellar, but since the bees were put on the summer stands they have gone back a good deal, owing to the cold, windy weather we have had in the month of May. The loss of bees since putting them out this spring, up to the present time, will range from 10 to 25 per cent., and a good many of those remaining are not in a promising state.

S. HINMAN.

Dundona'd, Ont., June 14, 1882.

Queen Shipping Cages.—As the safe shipping of queens by mail does not seem to have yet reached perfection by every shipper, I will give a little of my own experience in that line—not as a shipper, but as a receiver of queens. During the last few years I have had sent me between 100 and 200 queens, by about a dozen different breeders, no two of whom have put up their queens in exactly the same manner. Some lots reached me all dead, some all alive, with attendant bees bright and clean as when first started on their journey, and some in all kinds of condition between the two extremes. The shipper who has had the most uniform success, uses the old-fashioned wood cages, sends about 8 or 9 attendant bees with each queen, and provisions with candy in the cages and a sponge or bit of cotton saturated with honey at the sides of each cage, with wire-cloth between the bees and the honey. This man has sent me some 50 queens in all, every one of them having reached me not only alive, but clean and bright, and what is still more uncommon, the same is true of all their attendant bees, with the exception of one bee only. It is a great advantage to know that a certain number of queens is sure to arrive in good condition within one or two days of a known time. My poorest success in receiving queens in good condition has been with those sent in Peet cages. I supposed this experience of mine was unusual, until I was told by an extensive shipper, while at the National

Convention last fall, that after having lost heavily by using this cage for shipping purposes, he had abandoned it, and gone back to the old-fashioned wooden cages. I do not know by experience how unpleasant it must be to a shipper when he receives notice of a loss of queens while in transit, but I do know how much it bothers a receiver to take dead queens out of the postoffice, and have to wait two to four weeks for others in their place.

O. O. POPPLETON.

Williamstown, Iowa.

Enigmatical.—I send you to-day, by mail, a queen cage with a piece of comb partly filled with sugar. This was stored in the past 10 days, and I am at a loss to account for it. You will observe that the honey has become solid as fast as deposited, and it is out of the question to extract it. I am at a loss to know what to do. I cannot extract, and the hives are about full; bees are idle for want of room. I have about 400 wired frames in this condition. Will you please examine and advise? I cannot tell what the honey is stored from; the hives have been extracted regularly this spring, so it is not old honey.

H. N. WILDER.

Forsyth, Ga., June 17, 1882.

[The piece of honey referred to above has been received, and it is a great curiosity. There are no cells capped on the piece sent us, but the honey in them, which is white as basswood honey, is crystallized quite solid in the cell, with a watery appearance. These pellets or crystals can be lifted out entire with the point of a knife, and do not exhibit that tendency to crumble or run generally found in granulated honey. The strangest feature about the honey is its taste, which is neither like honey nor sugar, but more nearly that of epsom salts, sweetened—at least the sample received appears so. We do not know what it could have been gathered from, never having seen anything like it before; nor can we advise what to do with it, as we do not know what effect it will have on the bees. If it will agree with them, it might be saved over for spring feeding, but we would be afraid to attempt to winter on it, at least without having experimented with its sanitary effect. You might have some competent chemist in your city analyze it.—ED.]

Things Look Brighter Now.—This has been the worst season on bees I ever knew, but things look brighter now. We are having a good flow of honey now. It has also been the worst spring for queen-rearing I ever experienced.

D. A. PIKE.

Smithsburg, Md., June 15, 1882.

Difference in Location.—I have 10 colonies in the country on the river bottom, and 18 here in Clarinda. Today I went out to see how they were getting along in the country, and found they had gathered but little honey, while those I have here are breeding nicely and in some hives are sealing up new honey. The distance between the two places does not exceed two miles, and I cannot account for it, unless it is a washing rain that swept off the river two days before, almost missing us here, just giving us a gentle shower. We have more white clover here than on the bottom; but out there is sumac and basswood—the former now almost ready for the bees. I think when we figure up at the close of the season, that the results from the country will compare favorably with those in town. I have succeeded beyond my most sanguine expectations in making comb foundation. After taking a lesson from Mr. Craig in Missouri, I melted the beeswax, and the first dip I made peeled off the plate without trouble. Feeling somewhat elated at my success, I kept on until I had 40 lbs. of nice sheets, and afterward succeeded as well with the machine as in dipping.

J. L. STRONG.

Clarinda, Iowa, June 14, 1882.

Large Yield Expected.—This spring has been so late, cold and wet here that it has been very discouraging to bee-keepers. My bees wintered excellent in my plastered hives, on the summer stands, better than those in single-walled hives in the cellar. They went into winter quarters with a good supply of honey, but it was so warm and pleasant in February the queens commenced laying early and rearing brood, which caused the consumption of a great amount of honey, and the cold rainy spring and unfavorable weather caused them to spring dwindle badly. Some colonies died. On the first day of June the weather changed from ridiculous to sublime; white clover put in an appearance, and bees are now "booming;" in fact, I never saw bees gather honey and rear brood so fast as during the last week. They are working in sections and swarming in every direction. Bee men that a month ago were blue as indigo, now feel like "the cow that jumped over the moon." We are having a large white clover bloom, which is our principal honey resource, and I look for a big honey flow from this out.

A. W. FRISK.

Bushnell, Ill., June 19, 1882.

Osage Orange for Honey.—Bees in this county wintered extra fine. The first of April they were strong in numbers, but the cold and wet weather has had its affect. Fruit bloom done but little good. The 4th of May was a glorious honey day; the bees worked with the spirit of desperation till 4 o'clock p. m., and then the blizzard struck. The next day that was good (June 9), my 25 colonies all flew strong. I kept a close watch of all colonies, and when their honey was exhausted I fed moderately with

quite thin sugar syrup. Although it rains every other day, white clover is plenty and is yielding honey remarkably well—people come along and tell me my bees are swarming. The air is melodious with their joyful hum, the combs are being lengthened out very fast along the top-bars. Tomorrow I shall put on a good many cases of sections. All kinds of vegetables are at least three or four weeks late. We are pretty sure now of about 2½ months of fine white clover bloom. Heartsease, one of the best of honey plants with us, is very plenty in wet cornfields, and is there to stay. I feel as though my prospects were never better for a good, big honey crop. I think swarming will commence in about a week or ten days. I am more than pleased with the BEE JOURNAL. I admire the way you sting adulterators. I inclose a few Osage orange blossoms. The bees work on them very eagerly. PHILIP P. NELSON. Manteno, Ill., June 21, 1882.

A Screen to Protect from Robbers.—I make a frame of 1x2 inch strips, 3x6 feet, and 6 feet high; line it all around with mosquito bar; put an oil-cloth on top to darken it, and put a door in one end, with wire-screen or mosquito bar covering, and hang it on hinges, as you would a screen door. When robber bees are around and I want to open a hive, I place this over the hive, go in and shut the door. When done, move the screen from over the hive, and all will be safe. J. T. BRUTON. Joplin, Mo.

Working on White Clover.—Bees are doing finely now, and have worked on white clover since June 10. To-day the weather is cold and chilling, with rain. Had my first swarm June 16. I will have new extracted honey in a few days. G. J. PAMMEL. La Crosse, Wis., June 19, 1882.

Early Swarming.—I had a swarm of bees, a very large one, the 30th day of May. It looked queer to see a swarm of bees flying in the air when the trees were not yet leaved out, though the dandelions were in blossom. My bees are in fine condition, storing honey from raspberry blossoms in sections, of which there is an abundance. G. H. ADAMS. North Nassau, N. Y., June 19, 1882.

Satisfied with Prospects.—I have 18 colonies of bees, and all are doing well now. GEORGE KIME. North Liberty, Ind., June 22, 1882.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **etich words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10	per cent. discount.
" 8 ".....	20	" " "
" 13 " (3 months).....	30	" " "
" 26 " (6 months).....	40	" " "
" 39 " (9 months).....	50	" " "
" 52 " (1 year).....	60	" " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,
925 West Madison Street., Chicago, Ill.

Special Notices.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—a copy of "Bees and Honey."
" " 3,—an Emerson Binder for 1882.
" " 4,—A Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,—" " " cloth.
" " 6,—Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
 Monday, 10 a. m., June 19, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—1 am paying 7c. for dark and 9c. for light extracted.
 BEESWAX—Choice lots are worth 25c. here; bright yellow, 24c.; dark to good, 17@22c.
 AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for honey is quiet. Extracted brings 7@10c. on arrival. No comb honey on the market worth mentioning, prices nominal.
 BEESWAX—Scarce, and brings 20@25c. on arrival.
 C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for comb honey is light, prices being made to meet views of purchaser.
 BEESWAX—Scarce, and in demand at 23@25c.
 R. A. BURNETT, 165 South Water St.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
 BEESWAX—Prime quality, 25c.
 CROCKER & BLAKE, 57 Chatham Street.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.
 BEESWAX—The market continues rather quiet, but the supply is light and prices firmly sustained. Western, pure, 24@24½c.; Southern pure, 25@25½c.
 D. W. QUINRY, 105 Park Place.

SAN FRANCISCO.

HONEY—Several small lots of new are on the market, but there have been no sales reported beyond those mentioned last week, which were to fill urgent orders. Quotations are entirely nominal, with little prospect of any movement until prices are lower.
 We quote white comb, 14@16c.; dark to good, 8@12c. Extracted, choice to extra white, 8@8½c.; dark and candied, 6½@7c. BEESWAX—23@25c.
 STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—In fair demand. Extracted selling at 8@10c.; comb scarce—nominal at 18@22c.
 BEESWAX—Prime in demand at 22@23c.
 R. C. GREER & Co., 117 N. Main Street.

CLEVELAND.

HONEY—As there is no honey in market, we have no quotations this week.
 A. C. KENDEL, 115 Ontario Street.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Special Notice.—This number of the BEE JOURNAL completes the first half of the volume for 1882. A few have only subscribed for six months, and their subscriptions expire with this number. To all such we desire to remark that by sending on their renewal *at once*, they will not only prevent the annoyance to themselves of missing the regular visits of their old friend—the Weekly BEE JOURNAL, but they will save us much trouble in taking their names off from our mailing lists, and then re-entering them within a short time. We hope all will renew at once or else send us a notice by return mail, if they desire its visits continued.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 50z.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The postal law makes the taking of a newspaper and the refusal to pay for the same, theft, and any person guilty of such action is liable to criminal proceedings the same as though he had stolen goods to the amount of the subscription.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Ashland, Pa., June 3, 1880.—A case of spavin that came under my observation was entirely cured by one bottle of Kendall's Spavin Cure, and the horse sold afterwards for \$200. 25tf Yours truly, C. H. BARNARD.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Three years ago St. Julian, the great California trotter, was unknown: the same may be said of Kendall's Spavin Cure. Now both have a world-wide reputation. Why? Because they both have merit. One is a great trotter, the other is the most successful remedy ever discovered to be used on man or beast. 26w4t

CLUBBING LIST.

We supply the Weekly *American Bee Journal* and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both All postage is prepaid by the publishers.

A NEW BEE BOOK!

Bees & Honey

OR THE
Management of an Apiary for Pleasure
and Profit; by

THOMAS G. NEWMAN,
Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is fully up with the times, in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Lankstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the large can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$10.00 Extractor, 13X20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 Lankstroth frames, 13X13 inches.....	\$8 00
For 2 Lankstroth " " 10X18 " "	8 00

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

THE BRITISH BEE JOURNAL AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is published monthly, and contains the best practical information for the time being, showing what to do, and when and how to do it. It is edited and published by

E. N. ARBOTHNOT, Bee-Master,

School of Apiculture, Park Road, Southall, London. We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.50 per annum.

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee: the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book;

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY.**

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. P. WEST.**

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**E. H. WYNKOOP.**

This book is just what everyone interested in bees ought to have, and which, no one who owns it, will ever regret having purchased.—*Mich. Ear.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL.**

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—**W. VAN ANTWERP, M. D.**

It is the latest book on the bee, and treats of both the bee and the hive, with their impurities. It is of value to all bee-raisers.—*Ky. Live Stock Journal*.

It is a credit to the author as well the publisher. I have never met with a work, either French or foreign, which I like so much.—**L'ABBE DU BOIS**, editor of the *Bulletin D'Apiculteur*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Plunksi, N. Y.

We have perused with great pleasure this *vade mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, \$1.25; in paper cover, \$1.00, by mail prepaid. Published by

THOMAS G. NEWMAN,

974 West Madison Street, CHICAGO, ILL.

"RED TAPE!"

Who will be the first to copy? 25,000 IN USE.

If you buy the Original Patent Bingham Bee Smoker, you will aid the inventor of improved bee smokers—get the best, that never go out—always please—never is complained of—the standard of excellence the world over—better and handsomer this season than ever before. Price per mail, postpaid, from 65 cts. to \$2. Our patents cover all the smokers that will burn sound stove-wood, or do not go out. If you buy our smokers and honey knives first, you will have to buy no others.

Patented, 1878. PRICES: Haended to By Mail, Customer. Postpaid.

Table listing various Bingham Bee Smoker models and their prices. Includes 'Wide shield Conqueror, 3 inch', 'Large Bingham Smoker (wide shield)', 'Extra Bingham Smoker (wide shield)', 'Plain Bingham Smoker, 2 inch', 'Little Wonder Bingham Smoker, 1 3/4 inch', 'Bingham & Hetherington Honey Knife, 2 inch'.

Scribner's Lumber and Log Book. NEARLY A MILLION SOLD. Most complete book of its kind ever published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heading, bolt tables, wages, rent, board capacity of cisterns, cardwood tables, interest, etc. Standard book throughout United States and Canada. Ask your booksellers for it. Sent for 35 cents post-paid.

G. W. FISHER, Box 238, Rochester, N.Y. Also for sale at the BEE JOURNAL Office, 216 Main St., New York.

PURE HOLY-LAND QUEENS.

I make a speciality of rearing pure Holy Land Queens, and have now more than 100 colonies in their purity. All Queens bred from D. A. Jones' Imported Queens. Dollar Queens, before June 20, \$1.25 each; after that date, single Queen, \$1.00; 6 for \$5.00; 12 or more, 75 cents each; Warranted Queens, 25 cents more each. Tasted Queens, \$2.50 each; Italian Queens, same price.

I. R. GOOD, Nappanee, Elkhart County, Ind.

Bees and Queens

FULL COLONIES of ITALIAN BEES, From my Apiaries. QUEENS and NUCLEI IN SEASON. Satisfaction guaranteed. Circular on application. J. H. ROBERTSON, Pewamo, Ionia Co., Mich.

PAINÉ & LADD,

HALBERT E. PAINE, WASHINGTON, D. C. LATE COMM' PATENTS. STORV B. LADD, Solicitors of Patents and Attorneys-in-Chief. Patent Cases, 1693m

MENDELSSOHN PIANO Co's.

PIANOS

\$850 Square Grand Piano for only \$245. PIANO STYLE 32 Magnificent rosewood case elegantly finished. 31 strings, 7 1/2 Octaves, full patent cantante agraffes, our new patent overstrung scale, beautiful carved legs and knee, heavy serpentine and large fancy moulding, full iron frame, French Grand Action, Grand Hammers, in fact, every improvement which can in any way tend to the perfection of the instrument, has been added.

Our price for this instrument, boxed and delivered on board cars at New York, with the Piano Cover, Stool, and Book, only \$245. Reduced from our late wholesale factory price, \$850, for 60 days only, to have this beautiful Piano introduced. This is now, by far, the greatest bargain ever offered the musical public. Unprecedented success! Tremendous demand for this style! Order at once. This Piano will be sent on 15 days' test trial. Please send reference if you do not send money with order. Cash sent with order will be refunded and freight charges paid by us both ways if Piano is not just as represented. Several other special bargains: Pianos, \$100 up. Over 15,000 in use, and no one dissatisfied purchaser. Handsome and Illustrated Catalogue mailed free, giving the highest testimonials ever awarded any manufacturer. Every Piano fully warranted for 5 years. SHEET MUSIC 1/3 price. Catalogue of 3,000 choice pieces sent for 3c stamp. MENDELSSOHN PIANO CO., 215mly Box 2958, New York.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as Carcharodon Rondelliti. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 500 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better. I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me. "Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE and OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

To avoid loss in the mails, please send money by REGISTERED LETTER. Only Imported by HAYLOCK & JENNEY, (Late HAYLOCK & Co.) Sole Agents for America, 7 Dey St., New York, 20wly

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by THOMAS C. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide or Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quincy's New Bee-Keeping, by L. C. Root.— The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject. —\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.— This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.— This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.— This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.— A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.— Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Dzierzon Theory;—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Honey, as Food and Medicine, by Thomas G. Newman.— This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.— This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof. Cook's Essay, which is here given in full. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive in Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey: Harvesting, Handling and Marketing.— A 24-page pamphlet, by Ch. & C. P. Dadsnt, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman.— Giving advanced views on this important subject, with suggestions what to plant, and when and how. Illustrated with 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees, Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.— No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.— A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200000 items for Gas, Steam, Civil and Mining Engineers, Mucchinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., July 5, 1882.

No. 27.

THE AMERICAN BEE JOURNAL

Published every Wednesday by

THOMAS C. NEWMAN,

EDITOR AND PROPRIETOR.

925 WEST MADISON ST., CHICAGO, ILL.

At \$2.00 a Year, in Advance.

WEEKLY—(52 numbers) \$2 a year, in advance. Three or Six Months at the same rate.

SEMI-MONTHLY—The first and third numbers of each month, at \$1.00 a year, in advance.

MONTHLY—The first number of each month, at 50 cents a year, in advance.

Any person sending a club of six is entitled to an extra copy (like the club) sent to any address desired. Sample copies furnished free.

George Neighbour & Sons, London, England, are our authorized agents for Europe.

Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

An Important Hint.—The Chicago *Times*, in an extended notice of a recent publication entitled "Food Frauds," speaks as follows of "glucose mixed with a little of the honey produced by the bees: Its test is one of difficulty and the best way is to beware of the neat glass jar bearing the trade-mark of a New York or Chicago dealer, and to buy the tin pails or common fruit-cans with the name of the producer on the vessel." We have time-and-again advised bee-keepers to label their honey packages with an attractive label, giving their name and address, and also simple directions for liquefying the honey when it becomes granulated. It is an important matter, and in the near future the name of the producer will sell the honey when no assurance of the dealer could do so.

Our Method.—The clipping of the queen's wing having become a matter of acknowledged good policy, as we knew it would, the question naturally arises, What is the best method for clipping it? We have tried all plans, and find the quickest, easiest, and the least risk attending the following: Lift from the hive the comb on which you find the queen, slant it toward the hive with the lower end resting on the ground and the upper end against the hive, make no rapid motions to alarm the queen, but deliberately wait till she is in a position that you can grasp the end of one wing between the thumb and forefinger of the left hand, then with a sharp pocket-knife and an up and backward motion cut off about one-

third of the wing. If deliberate in your movements, the queen will not become nervous, nor will she be aware she has been meddled with, no scent of the fingers will be left on either her wings or body, and no commotion created in the hive.

Bees and Honey.—We feel highly gratified at the general favor our new book, entitled "Bees and Honey," is meeting. The following, from S. A. Knapp, LL.D., Dean of the Iowa Agricultural College, is one among many of similar import: "Your very excellent work on bees and honey is at hand. I have examined it with some care, and find it an exceedingly valuable contribution to the science of bee-keeping."

Illinois Industrial University.—We have received the elaborate and neatly printed Catalogue and Circular of the Illinois Industrial University, for 1881-82. This University was established under the auspices of the United States, the State of Illinois, and Champaign County, and ranks among the best in the country, with a full and able Faculty, and its corps of lecturers and instructors cannot be excelled. The number matriculating as students since its opening is 1,698. T. J. Burrill, M. A., Ph. D., is Professor of Botany and Horticulture, and Vice President. Our readers have formed a pleasant acquaintance with him through his instructive answers to botanical queries in the BEE JOURNAL.

We are in receipt of the Annual Catalogue of Columbia Veterinary College and School of Comparative Medicine, New York City. The Faculty embraces a list of twenty-three learned professors and lecturers, some of whom are scientists of national reputation.

Foreign and Domestic Crop Prospects.

Reports of a most encouraging character come from all sections of the United States. Wheat, although a trifle less in acreage, is far above the average in quality and yield, and corn, oats, potatoes, etc., never promised better. A dispatch from Sedgwick county, Kans., dated June 26, says: "Two-thirds of the 100,000 acres of wheat in this county has been cut and is now in shock. The average yield will be unprecedentedly large, and of the finest quality. Farmers declare they never saw such fine grain. Many fields will yield *thirty to forty bushels to the acre*. The acreage of corn, nearly 130,000 acres, is growing rapidly and is very promising. Such other crops as potatoes, oats and barley all promise more than the ordinary yield." And not only is this true of most of the grain-producing districts, but in the river valleys, where floods and overflows prevailed so disastrously earlier in the season, a most bountiful yield of cotton, corn, etc., is probable. As we stated last week, there is now every prospect of a fully satisfactory honey yield from nearly all portions of our country. Despite the unusually late frosts, fruit will not be such an utter failure as many predicted. It is really too bad that the "croakers"—the human ogres who are always harping of hard times and ruin to come—those who are not content with feeling gloomy themselves, but must persuade others to view only the darkest side of everything—should be disappointed in their predictions. We have for several weeks counseled our readers to look on the brighter side; that the gloom was only the precursor of better things coming, and we know all will join in rejoicing over the fruition of our hopes. With the comparatively few disappointed ones we sincerely sympathize, as well as with those who have been ruined in the tornado's path. It will be a melancholy satisfaction to them that they are exceptions.

Mr. A. Pettigrew, in the London, Eng., *Journal of Horticulture*, of June 15, gives the following gloomy picture of bee-keeping there this season:

If all the districts of England are as unfavorable for bees at present as that of Cheshire, feeding—vigorous feeding—should be considered the most important duty of the apiarist. Hives are very full of bees, and large hives well filled with bees require much food—at least a winebottle full of syrup each every day. Indeed,

that is hardly enough to keep a hive containing forty thousand bees in health and prosperity if no field pickings are obtained. The season here has been so unfavorable that drones have been killed as soon as born in hives not vigorously fed. All young bee-keepers should know that colonies on the point of swarming require a great amount of food, and that if the pinch of starvation is felt the bees are much discouraged, lose their balance, and for the time being abandon the idea of swarming.

It is also reported from England that their crop prospects are of a gloomy nature. There has been neither sun nor warmth, and in many districts torrents of rain have fallen. It seems likely, therefore, that the demand from England this year, for American food supplies, will be very great. The outlook everywhere for American farmers and bee-keepers is very good, both as regards yield and prices, and continued prosperity is almost guaranteed.

♦♦♦♦♦
 "Almost Persuaded."—We devote much space this week to the discussion of Mr. Blow's interesting paper, "A Bee-Keeper's Experience in the East," read before the British Bee-Keepers' Association, on May 10th. Mr. Cowan, it will be observed, was very grateful to Mr. Blow, for his pluck in going to Cyprus, to divide with America (for the credit of England and English bee-keepers) the honor of having seen Cyprian bees in their native haunts, and studying their habits and disposition at home, and to satisfy Mr. Cowan that there was really an American in the Island of Cyprus in charge of and successfully manipulating a Cyprian apiary. While Americans will go down in sackcloth and ashes because the gentleman "does not think it is right for them to have everything their own way," the world will rejoice that Mr. Cowan is at last "almost persuaded" that all of Messrs. Jones' and Benton's letters about their Cyprian apiary is not mere bombast; and what a consolation it will be to those gentlemen that he at last is convinced! *Gloria in excelsis*. We are, however, pleased to observe that Mr. Blow neither assumed that it required much pluck nor great self-sacrifice, to visit Cyprus after Mr. Benton had been a two years' resident there, and had surmounted all the obstacles, so that a quiet study of the Cyprian and Syrian bees, in Americanized frame hives, was a comparative pastime and luxury.

The Cultivation of Honey Locust.

The *Nebraska Farmer* gives the following valuable instructions regarding the planting and treatment of honey locust for hedges:

The secret in hedge-growing of any kind, is well directed care and attention during the first three or four years, and if this be given to honey locust it will make a hedge every time. The plants must be good ones, vigorous and thrifty—and should be about the same size together, and not plant small and large ones promiscuously. Before setting, make the ground along the line rich and mellow. After setting out the row must be cultivated and kept clean until the hedge is matured or finished. Let the plants grow the first year undisturbed, and then cut them down within three inches of the ground; the second year, seven inches from the ground; third year, twelve inches; fourth year, twenty-five inches; sixth year, thirty-three inches; and the seventh year, height desired for fence. This takes seven years, but the fence is good after the fourth year.

In view of the increasing destruction of our forests, and the great cost of fencing material, any substitute for good fences will be eagerly sought after by the thoughtful farmer. Osage orange has been extensively tried and experimented with, but it fails to fill the bill, there being many very objectionable features about it, chief among which are its inability to stand excessive cold winters; but the honey locust is free from this objection. As an attractive hedging nothing can excel it in appearance, and certainly nothing is easier of cultivation. When allowed to grow in tree form it becomes a beautiful shade tree, and the timber is among the most valuable. For honey-producing it stands among the best, and bee-keepers will do well to alternate the honey locust with linden and tulip tree or poplar, as it comes into bloom before the linden, and is a more certain producer, though not so bountiful. Bee-keepers should liberally ornament their grounds with it, and try its virtues for hedging.

☞ Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

☞ Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 8oz.

Bees from Syria and Cyprus.

The following is the discussion on this subject at the British Bee-Keepers' Association, after the reading of the paper by Mr. T. B. Blow, entitled "A bee-keeper's experience in the East," which will be found on page 327, and is taken from the *British Bee Journal* for June.

In answer to a member Mr. Blow said that he attributed the smallness of the Cyprian bees to their breeding in old combs continually. He thought the bees would develop by the culture of this country, from the fact that the queens were not small. Some of the queens that he sent out were small owing to long confinement in their hives. The Cyprian and Syrian queens are not quite so large as our English queens. The people in Cyprus do not remove the old comb for years, simply removing the back combs only.

The Rev. T. Sissons said he thought Cyprians were the handsomest bees we had in the world. They were not only remarkably handsome but cheerful. Their notions of *meum* and *tuum* were rather peculiar. They seemed to have proper notions of *meum*; they defend *meum* with remarkable courage. He was afraid they were not bees for a clergyman to keep, as their notions of *tuum* were exceedingly vague. They were thoroughly demoralized; they went out, got all they could, and gave up nothing. He had been working with them for about two years, and he found no increase of size. The queens were about the same size; and the workers did not increase. Nor did he think, judging by their appearance, were they likely to increase. They appeared to be quite different from the Ligurians. But he found them excellent workers, working early and late, and in all weathers; they propolized with wax. With regard to their tempers he was bound to say that you must understand them if you are to manage them. They were like some people whom he knew, who, provided they are well managed, were the best of friends; but if you tread on their favorite corn they are awkward to deal with. These Cyprian bees must be approached in a peculiar way. In the first place, smoke does not appear to affect them; in fact he had given up the attempt to approach them with smoke; the law of strong attachment to *meum* came out there. If, instead of using smoke, you sprinkle a little water and sugar, that diverted their attention. He found that they were more troublesome toward the end of the year than at the commencement; they seemed to be specially indignant then to any one taking away the property which they had accumulated; he rather admired them for it. He thought that the Cyprian bee was well worthy of culture in this country. During the present summer he intended to go in for more of the Cyprian bees.

In answer to a member Mr. Blow said the cylinders were packed in

large stacks, and the spaces in front between the cylinders were cemented with mud; a small hole was pierced at the bottom of each cylinder, and through this hole the bees entered. They had no alighting-board. There was a great difference between the Syrian and Holy Land bee,—a much greater difference than between Syrian and Cyprian themselves. The latter were, in his opinion, almost identical, and really did not deserve to be treated as a distinct variety. But there was a marked difference between the Holy Land bees and the Cyprian, the Holy Land bee being differently shaded, and very much more downy. There was a great difference between the Cyprians, the Syrians, and the Ligurians; the Ligurians were much more robust than the two former. With regard to the increase in size, he thought that a couple or three years' experience was not sufficient. A decrease in size has probably been going on for many generations—he supposed for a thousand years; although we give them better combs we could not expect them to increase at once. In transferring his hives he had to use a hammer and chisel to break up the clay cylinders, therefore they could imagine the bees getting slightly irritated. He found it was useless to smoke them; but when he used one of those vaporizers, and well sprayed every bee in the hive, then he rarely got a sting. The Cyprian and Syrian queens were much more lively than the English queens. In the first twenty or thirty colonies that he transferred the operation took place in the open air, he found the queens were not always in the hive, though they had evidently been there very recently; he was certain they took flight, because he caught the queen in one case as she was flying. After that he removed them into a room and transferred them there.

The Rev. T. Sissons said the Cyprian bees were more sociable if they were put in company with some other hives. Where a hive was allowed to stand alone the bees were much more wild than those which were found in company with others. They are something like ourselves in this respect—in society we were more amiable than men who dwell in the woods.

Mr. Blow said that from the little he saw of the bees in Cyprus he thought there was no doubt they were much larger than our English bees, and much stronger on the wing. There was, too, a marvelous amount of honey in their hives. The way they flew out in the morning and came in loaded quite impressed one with their superiority. There was no doubt that the queens were far more prolific.

Mr. Cheshire, being called upon for a few remarks on the subject, said that he was afraid his experience would not help any one. The first Cyprian queen that came into his possession was in a diseased or injured condition; it had been originally the property of Mr. Jackson. Mr. Jackson told him that Cyprian bees did not hold to their combs so

strongly as others. Certainly he found that statement perfectly true with regard to the queen; she was blown off the comb—while he had one of the combs out of the hive—no fewer than four times. Besides, she was found outside the hive four times. With regard to the remark about the size, his experience lay in an opposite direction as to the queen; this queen never weighed more than the average English one. Mr. Benton sent him a Cyprian queen, and she did not weigh more than the average English worker, being small in the abdomen her bees were small. With regard to the size of the bee, he was inclined to think that they were likely to fall into a mistake on that point. There was an idea current that if they increased the size of the bee they were increasing its usefulness or fruitfulness. These two qualities, or ideas, did not necessarily run together. They must bear in mind that the carrying power of an animal was not in proportion to cube or square of its measurements. Supposing they took a horse and increased its size, so that it stood ten feet instead of five, they would have a horse which, upon mathematical grounds, would have only half the relative power. All who were acquainted with the laws of construction knew perfectly well that if they increased the height of a building they must increase the strength of the under parts, or they would not be able to support it. If they increased the size of the bee they did not increase its power proportionately. The bee visited an enormous number of blooms, and if you had a large number of bees of a smaller size you had really a larger number capable of visiting a larger number of blooms, and proportionately more honey gathered than in the case of a large bee gathering relatively a smaller quantity of honey in proportion to its size. He thought it had been shown that the social bees were smaller, and that those bees who lived by themselves were very much bigger. The first Cyprian queen, as he had said, was injured, and one had no ground upon which to form a judgment. The next Cyprian queen showed some remarkable peculiarities—she came from the north of the island; the bees she bred were not so bright in color as those bred by the first one. He had had four; they constantly raised queen-cells, and the bees evidently destroyed their own queen. The third queen, which he got from the north of the island of Cyprus, raised bees of a dark color. This last queen sent by Mr. Benton was going on fairly well. She was extremely small, her bees were small though bright, with regard to the tempers, the queen (the third in number that came into his possession) had raised bees that were not generally irritable, but if they were disturbed they were furious beyond expression. On one occasion, when he transferred a swarm from one hive to the other, he was stung at least a hundred times during the operation; they were utterly uncontrollable; yet these bees previously had been easily handled. They read

that bees were sometimes in an irritable condition without obvious cause. The third Cyprian queen that he got was sent by Mr. Abbott, who had written to say that she was not a pure Cyprian, though he (the speaker) was absolutely certain it was the same queen, because she was constantly before his eyes; she was the same queen that was brought to the Horticultural Gardens, and Mr. Abbott must have been mistaken in his judgment. He should like to ask Mr. Blow whether he saw in Cyprus any divergence or variety in color in the bees in one hive. Among the Ligurians there was certainly variety; at any rate, there was a great amount of difference between the color of the bees with his own queen. She did not breed evenly colored bees like the majority of Ligurians; they shaded in perceptible gradation, and he was inclined to think that they had not the pure species that some people imagined.

Mr. Walker said that he had read something on the subject of the size of bees, and it was a question that should be sifted out. Mr. Cheshire had said that those who knew mathematics would concur with the remark that they ought to be careful in increasing the size of the bee in order to get additional profit. If they increased the height of a horse to ten feet they might not get more strength, but if they increased the horse to the same proportions as Jumbo, they would have more strength. He should like to see the subject pursued and thought out.

Mr. Walker, having to fulfil another engagement, vacated the chair, which was thereafter filled by the Rev. E. Bartrum, who proceeded to say that with regard to the greater fecundity of the Syrian queen there was of course a tendency to extol the virtues of all new races. He did not think that they could arrive at any reliable information on the subject until they had tried repeated experiments, such as those Mr. Cowan had conducted, who kept a large number of his reserved queens and bred from queens not more than two years old, and the results were satisfactory. The moment it was found that a queen was not prolific, it was removed. It was only by carefully testing them in that way that they could arrive at any conclusion as to the prolificness or fecundity of the Ligurian or Cyprian bee.

Mr. Blow said with regard to those bees which had been brought from the north of the island of Cyprus, he might say that the bees he got from a village on the mountains at the north of the island were very much darker than any others he saw. He made a remark to Mr. Benton that he had some bees darker than the average of his Cyprian bees, but he (Mr. Blow) thought in all cases they were bred evenly. He did not find any bees that were very yellow with bees that were very dark; they were all dark. It was curious to note that the bees obtained at this village, which was nearly 2,000 feet above the level of the sea, were darker than those which he

obtained at another village, which was at a much lower level, being only a few miles from the sea. There was one more point he should have touched upon, that was, that the Cyprian and Syrian bees, especially the Cyprian bees, were much infested with a bee parasite (*Brasidacaeca*). One or two persons had written to know what was the matter; one remarked that the queen had three bumps on her. Mr. Cowan had said he took twenty-three specimens of the parasite from a queen. With regard to what had been said about *meum* and *tuum*, the Syrian bees were much more courageous in defense of their hives; they did not allow the black bees to alight on the hive, and they fly at them on the alighting board. Anyone alighting there was seized at once, and on all sides the black bees got worsted.

Mr. Cheshire said that the variety or variation in color of which he had spoken seemed to illustrate Mr. Blow's experience. Those bees which came from the north of the island were darker than the bees bred from the queens hailing from further east. That circumstance showed that they should not be too hasty in judging as to what were pure and not pure Cyprian bees.

The Chairman said that he bought some bees in the autumn from a distance of about five miles from his house. He found that they were as black as they could be, yet every bee in his immediate neighborhood had evidently some Ligurian blood. Therefore, if they had perfectly black bees about five miles from his house, surely in Cyprus there would be some diversity of color.

The Rev. T. Sissons said his experience was that the Cyprian queens were small, but what they lacked in size they made up in spirit. There was a man going to prove that all the great things in this earth were done by little men. While the Cyprian bees were small, they were wonderfully vivacious and prolific.

In answer to Mr. Peel (the Secretary), Mr. Blow said that when the queens arrived in England, at first they were a little smaller, but no sooner did they arrive than they began to raise brood. He believed in one or two cases they bred in the hive on the voyage, the bees traveling in the wooden boxes.

Mr. Cheshire having asked a question in reference to the Syrian and English queens depositing their brood in patches in combs, Mr. Blow replied that he thought in the case of the Cyprians and Syrians, the bees removed the pollen. He thought that was one point brought out by their gnawing powers, being able to remove the pollen readily. They found large patches, not a single cell being without brood, while in the case of the English bees they found that pollen was left in some of the cells. He thought, however, in the case of the Cyprians and Syrians, the pollen was removed also.

Mr. Cowan said they were much obliged to Mr. Blow for his excellent paper. It was very plucky of Mr.

Blow to go out to Cyprus, and he was glad he had done so for the credit of England and English bee-keepers. He (Mr. Cowan) did not think it was quite right for the Americans to have everything their own way. He had begun rather to doubt the existence of the Cyprian apiary. But he was glad to hear that Mr. Blow had met Mr. Benton, and that he was all right over there. With regard to the size of the Cyprian bees, they would remember some years ago he tried to get a larger breed of bees; and had foundation from America, with four and a half cells to the inch, and the bees certainly got larger; but he did not find that they were better than the ordinary-sized bee, in fact it made good what Mr. Cheshire had stated, that it was not the larger-sized bee which was the most productive. With regard to the Cyprian queens he had a few from Mr. Blow, and his (Mr. Cowan's) experience was rather curious with them. Wishing to test the prolificness of the queens, he took away comb after comb and gave them empty combs, and he found as fast as he put in the combs, they were filled with eggs; they seemed most prolific. He noticed that the bees were much smaller than our English bees. Last week he had a very curious accident to one of the hives. Every comb was well filled with brood, and the queen was laying beautifully. On Friday morning he found the queen dead on the alighting-board. He opened the hive and found queen-cells on almost every frame. That was his experience with Cyprians in raising queen-cells; he could not account at all for the destruction of the queen as she appeared most prolific, but there was no doubt she was destroyed. The queens were very lively, and he found some difficulty in dealing with them; they were small, and run about all over the place, and it was difficult to find them. If you had got them on a frame they would perhaps drop off on to the frames below; so that those who had Cyprian queens he would advise to carefully watch them. He wrote to Mr. Blow asking if he had noticed that the bees were covered with *Brasidacaeca*. Three out of four queens had them; one of them had twenty-three. He found that the Peet cage, which he had been lately using, was most suitable for the work of introducing. He had himself not had one failure in introducing them. You merely put the queen and a few workers into the cage and place the cage on the comb, not pressing it into the comb, but merely putting it on over some honey. The bees make their way into it in twenty-four hours, liberating the queen themselves. He was sufficiently sanguine as to success, or else he should not have tried them with such valuable queens.

A member having asked how long the work took after the colony was deprived of the old queen, Mr. Cowan said that he deprived the colony of the old queen and examined them next day, and he found in every case the queen was liberated by the next day. There was some candy in the cage, for the queen and bees to eat if

they required it; but the bees having to work their way through their comb, he thought, made them take to the queen. He concluded by saying he would have much pleasure in proposing a vote of thanks to Mr. Blow for his most interesting paper, and also for the trouble he had taken to visit Cyprus, and enlighten them on the way to manage the Cyprian bee.

Mr. Jackson seconded the motion, remarking that not only the Association but the whole community were greatly indebted to Mr. Blow for the perseverance and energy he had displayed in bringing a colony of the Cyprian bees to this country.

The motion was unanimously agreed to, the Chairman remarking that they were indebted to the Secretary, Mr. Peel, for introducing such a useful member as Mr. Blow to the Association.

Mr. Blow replied, observing that he had not lost more than twenty per cent. of the colonies on the road home. He had seen Mr. Benton's apiary, and what had been said about it in the American bee papers was quite true; he had a very large apiary there, having a large house and grounds for its management. With regard to queen-cells, Mr. Benton had told him that he frequently saw as many as fifty or sixty queen-cells raised from one colony.

Mr. Peel said one great advantage of the present discussion was that it elicited subjects for future papers, and he should be glad to hear that any of the gentlemen present were going to give a paper next month.

Mr. Stewart proposed a vote of thanks to the two gentlemen who had occupied the chair. Mr. Glennie seconded the motion. He said that Mr. Walker some years ago had made some experiments on himself with a view of ascertaining if it were possible to become inoculated with the sting of a bee; he had allowed himself to be stung a hundred times. He had the same experience as Mr. Walker, that the sting of the bee did not hurt one so much when he has been inoculated.

Mr. Sissons said it would render the shows more attractive if an addition to the prizes were given for the best examples of Cyprian, Ligurian, and black bees. There were some prizes for the handsomest queen in the department. He mentioned that the sting of the Cyprian bee was much more painful than that of the English bee.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

The postal law makes the taking of a newspaper and the refusal to pay for the same, theft, and any person guilty of such action is liable to criminal proceedings the same as though he had stolen goods to the amount of the subscription.

MISCELLANEOUS.

Clipping Queen's Wing.—The *American Agriculturist* gives the following on this subject:

It has been asserted that it injures the queen to have her wings clipped. This is not true. Structurally, the wing is very simple; it consists of a thin membrane, spread over veins which are firm, and consists of a double tube, one inside the other. The inner tube carries the air, and the outer the blood to nourish the wing. Clipping has been practiced by many of our best apiarists for years, and no one has detected the least harm from it. Ants do the same thing by their queens, and for the same purpose. The advantage of this practice is great. There is no danger of losing a colony. The bees will come forth from the hive, and the queen will, as usual, attempt to follow, but is unable to go with the swarm. The bees will generally cluster, though they may not; and as soon as they find that the queen is missing, will go back to the hive. The queen may get so far from the hive that she cannot return, but this is the loss of the queen, and is far less than the loss of a strong colony. In five cases out of six the queen will return all right.

This practice not only saves bees, but time as well. The hiving of swarms is often a great task, and when they alight, as they sometimes do, at the very top of a tall tree, it is well nigh impossible. This matter becomes still more serious when several colonies come forth at once. They often cluster all together, and the trouble of separation and properly hiving them is great. If the queen's wing is clipped, all of this is saved. One has only to go to the front of the hive, and as the queen comes forth, which is usually late in the exit, pick her up and put her in a cage; a tumbler turned over her in the new hive will do. Next remove the old hive a few feet temporarily, and put the new hive containing the queen on the old stand. It is well to fill the new hive with foundation, and to add one frame of brood, in all stages, from the old hive. The bees will soon come to the new hive, and when all have entered, the new hive may be put in the desired place, and the old one returned to its old stand. At nightfall, liberate the queen, and all is done. If it is desired to prevent any further swarming, we have only to examine the old hive, now nearly empty of bees, and destroy all of the queen cells but one, which should always be the largest. In this way hiving takes but a small amount of time and labor.

The best time to clip the queen's wing is when she commences laying. As soon as eggs are seen in the worker cells, which will be about eight days after the queen leaves the cell, we

should clip the queen, as then there are few bees, and it is easy to find her. If the wing is clipped before there are eggs, very likely she may not have mated. The queen only mates on the wing.

Until one has had some experience, the clipping better be done in-doors, before a window; if the queen escapes there will be no danger of losing her. She will fly to the window, and is easily caught. Catch the queen by the wings with the right hand, and let her feet rest on the left hand, taking care not to press her abdomen. She will not use her sting. With one of the fingers of the left hand, on which she is now resting, press down on her feet, so as to hold her. Then take a pair of small scissors, held in the now liberated right hand, and carefully cut off about one-third of one of the front wings. As the queen is resting on her feet, there will be little danger of cutting them. For years we have always clipped all of our queens, and have experienced only advantage. We could not think of keeping bees, and not practice this method.

Title to Fugitive Swarms.—The *Philadelphia Record* gives the following item relating to the capture and ownership of fugitive swarms of bees, which we reprint, as it is a question often brought up by bee-keepers:

Magistrate Krickbaum's knowledge of the law was put to the test one day last week to determine an ownership of a swarm of bees that settled on a tree near the house of Mrs. Flanagan, on Chew street, Germantown. The busy honey-makers were lived by Mrs. Flanagan after a fruitless attempt to find their owner. At this juncture, John Taylor appeared upon the scene, claimed the bees as the property of his father-in-law, and proceeded to take them away bodily. The bees objected to this procedure, and gave Taylor such a warm reception that he beat a hasty retreat. He soon after succeeded in enticing them into a thicket and carried them away. Then Mrs. Flanagan sought legal advice and obtained a warrant for Taylor's arrest on the charge of larceny, the law saying that ownership in swarming bees is vested in the original possessor only so long as he can keep them in sight. The affair was settled by Taylor surrendering the bees.

Abscending Swarms.—The *California Apiculturist* remarks as follows on this subject:

The great number of abscending swarms in this section of country are remarkable—never has there been so many known before. One man informs us that he has captured 32, another 20, another 13, and many others various numbers. These have been captured mostly by placing hives and boxes out upon the sides of the mountains or in tree tops. One gentleman says that he had a number of hives piled up near his house; his at-

tention was called to a few bees, cleaning out a hive; the next day, about 11 o'clock, a swarm came and took possession of the same hive. He was clearly of the opinion that the bees seen there the day previous were members of the same swarm, and who were in search of a dwelling in which to move, and were cleaning house when first discovered. The same thing was noticed several times with like results.

In Los Angeles, a man who had a number of empty hives sitting around on his premises had 20 or more of them occupied by runaways, who, regardless of the city bee ordinance, took up their abode in the city of the angels, and will undoubtedly contest their right pointedly with the city dads, should they get after them with a writ of ouster. We cannot account for so many, other than apiarists generally are discouraged on account of the unfavorable outlook and neglect their bees, which they should not do.

Antirrhinums and Bees.—The *Rural Canadian* says:

It is stated recently by naturalists that bumble-bees prefer obtaining honey from Antirrhinums, in preference to any other flowers, in which they have a monopoly over other bees, by a curious provision in the tubes of the corollas. They sit on and cling to the lower lip of the blossom, which bends down by the weight of the bee and makes an opening through which the insect thrusts its head and takes possession of the honey. The honey bee and other insects are not heavy enough to open the entrance. The bumble-bee appears to be aware of this advantage, and flies at once to the Antirrhinums, to the neglect of other flowers which other insects may have previously visited. A writer in the *Garden* says that the old flowers open more easily than young ones, and that while he had found that a weight of twenty grains was required to open the flowers, only three or four grains would bend the lower lip of some older ones.

Bee-Keeping in Maine.—The *Home Farm* remarks as follows:

Why should we not be a honey-producing state? There are thousands of pounds of honey daily going to waste during the honey season for want of bees to gather it; and we are not producing all the honey possible until we have bees enough to visit every honey plant every day, as the day's harvest is lost unless taken in its time. There is no more to-morrow on account of what is left uncollected to-day. The quantity of bees is not the only thing we want, we want every bee to exercise its greatest storing capacity. How are we to arrive at this? Not in the box-hive and the bees left almost without care summer and winter, which is the case, I think, with nine-tenths of the bees within a radius of twenty miles of the writer. We want the improvements that pertain to the business. Who would think of going to farming to-

day with the old wooden plow and other tools of that day—no one. Such things are superseded by other and better implements. So the box hive should be discarded and its place supplied by the best movable frame hive. . . . Now rally, all who are interested in bee-culture and let us see if we cannot drive out this fancy, put-up-stuff called honey, with which the market is glutted and which is a shame and disgrace to the name, and fill its place with good, nice, pure honey *not made with hands*.

Honey and Bee Shows in Wales.—Speaking of the late bee and honey show in Cardiff, Wales, the *London Journal of Horticulture* says:

The displays and lectures in the tent excited considerable interest, and proved a great feature of attraction in the show ground. Bee-keeping in Wales is in a most primitive state. With few exceptions the residents are entirely ignorant of modern and improved methods. Great superstition prevails, and in many cases visitors to the Exhibition left the tent with the impression of the expert possessing some supernatural powers over the bees. Great difficulty was experienced in obtaining bees for lecturing purposes, the owners considering it an omen of ill luck to sell them. One lady asserted that an equivalent to the value of the bees must be given in corn, and another could receive nothing save cheese made in Glamorganshire. These difficulties were, however, overcome by the kindly influence of Mr. A. Pettigrew of the Castle Gardens, Cardiff, himself an advanced bee-keeper, who was most assiduous in his labors to promote the success of the Exhibition. The Cardiff local Committee and the British Bee-Keepers' Association are greatly indebted to Mr. Pettigrew for his kind assistance in promoting the success of this department of the show. Mr. S. J. Baldwin acted as expert. The Rev. H. R. Peel, Mr. T. W. Cowan, and Mr. J. M. Hooker were in attendance during the show to give advice and assistance to the many hundreds of visitors who sought information upon the subject.

Practical Suggestions on Bee-Culture.—Under this heading the *Chicago Herald* gives the following:

There are many people who own a few colonies of bees and seldom, if ever, realize anything from them, while with a little exertion and study they might be made a source of great pleasure and profit. In the first place, no person should ever expect to be successful with bees who is not willing to give the subject a reasonable amount of time and careful study. The most successful bee-keepers are lovers of nature and have a fondness for these little marvels of industry. Those who would be successful with bees must always be ready in the proper season to administer to their

wants. Hence the neglectful, heedless and indolent are as sure to fail in apiculture as in any other calling. The inducements to bee-keeping are numerous; it affords a most pleasurable and healthful recreation for a person whose business or profession is confining.

Cook's Manual.—Concerning this excellent Manual of the Apiary of which the ninth thousand has just been issued, the *Home Farm* says:

Having either read in full or examined very carefully all the American bee books that have been published during the past 25 years, and having the most of them in our library, we can say most unhesitatingly that the best book on the subject of practical bee-keeping is that by Prof. A. J. Cook, of the Michigan Agricultural College, and known as the "Manual of the Apiary." The work has been revised, enlarged and mostly rewritten to adapt it to the results of the latest scientific investigations, and the best practical deductions upon the intricate and fascinating pursuit of bee-keeping. For a single book upon the subject we do not know of one so practical, so helpful, so plainly written as this.

Marketing Honey.—The *Michigan Farmer* gives the following advice on marketing honey:

The first requisite of success is to have your honey and your package clean and in good order. The label must not be soiled. Take a sample with you and solicit orders. Let your sample be a fair specimen of what you have. Visit the grocers on the day, and at the hour that they are least likely to be busy, so that they can afford to listen to you patiently. Let your price be reasonable, though sufficient to cover your expense, and pay for your trouble.

☞ We have received a handsome little volume entitled "The Inter Ocean Curiosity Shop." It is compiled from numerous queries and answers published in the *Inter Ocean* during the past year. It touches upon nearly all of the popular subjects of the day. Religious, Scientific, Historical, etc., and displays deep research and an almost boundless acquisition of knowledge upon the part of the author, Mr. T. D. McMillan. We consider it a valuable addition to our library, and it should be upon the table of every thinking man in the country.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Tree Planting, Cyprian Bees, Etc.

HON. L. WALLBRIDGE.

I was much pleased in reading the article upon Cyprian bees, in the BEE JOURNAL of June 21st. I obtained a Cyprian queen from D. A. Jones' first importation. The strictures in that article, though fuller than my observation, are very striking, and correspond with my own experience. The energy of the Cyprians is certainly superior to that of the Italians, and their propensity to sting is only one of the evidences of it; they are more prolific—this gives the advantage of strong colonies early. They defend their stores (*i. e.*, sting) with the same earnestness with which they gather; besides, the propensity to sting is very much over-stated. Even other bees are not equally docile at all times. The same is the case with the Cyprians. I have drones from a Cyprian queen mated with an Italian drone, that show the full dark color of the Italian sire, and other drones from the same queen showing the light color of the Cyprian—the difference very marked. I have frequently tried to get early queens by carrying over drones from a drone-laying queen (not fertilized), but never could get a queen fertilized until the drones appeared from fertilized mothers. I fear the Dzierzon theory is a fallacy. The two facts above seem to prove it. The following article I contributed to one of our papers, and send it to the BEE JOURNAL, as bearing upon the subject of tree planting for honey:

Almost every one does, or ought to, set out some trees every year. The fall of the year is generally recommended as the best time; it may be, however, well done in the spring. As this communication is intended for bee-keepers, it is well to consider what kind of trees to plant.

Basswood is certainly king, coming into blossom generally just as white clover goes out; it fills an important place in the bee-keeper's profits. If the bee-keeper fails to do well when the basswood is in bloom, he may count upon a poor return for that year. The linden and lime are other names in England for another variety of the same tree. Its honey-producing quality is its great recommendation to the bee-keeper—but to others it has advantages. For beauty, there is no tree that has so large and deep colored a leaf, and when it attains its growth it is valuable for timber. It is used for door-panelling and in many parts of carriages and sleighs, and its timber always commands a good price. It is thus useful during its growth, and at its maturity brings a nice sum of money for the purposes indicated. Compare it with the maple tree, so generally planted—what is that worth,

either during its growth or at maturity, except for firewood? The basswood has a luxuriant Southern foliage, and for beauty at least is equal to the maple.

Another tree of great value to the bee-keeper is the honey locust. This tree comes in bloom quite early, and is valuable on this account. The bees visit it almost in swarms, and the honey and pollen then brought in gets up the excitement in the hive, and breeding goes on at a rapid pace. Now this is the very thing bee-keepers want. They want strong colonies ready to gather honey when white clover comes in, and I know of no tree or plant which does so much to strengthen the colony early as this locust tree. Have your colony strong early; this is the secret of bee-keeping. Almost any colony will become strong in the white clover season; but then the clover honey is used up in breeding, and you don't get it as surplus. If you have no locust trees in your neighborhood, you should feed your bees, or abrade combs filled with honey already in the hive, changing combs to the center of the brood nest, thus spreading the brood nest and giving the queen an opportunity of laying, which she will be sure to do if you give her a fair chance.

Mr. W. C. Wells, of Phillipston, the largest bee-keeper in this part of the country, attributes the good success of city bee-keepers to the locust trees, as, by the good start from them, we get early brood, and are thus ready with strong colonies for the clover and basswood bloom. Besides the timber of the locust tree is very valuable; it is exceedingly heavy; a cubic foot of it weighs about 100 pounds, and is called mountain ebony. It is valuable for wagon hubs, cogs for mill wheels, and other things requiring great strength; if used for gate posts it is exceedingly durable. Messrs. George Leslie & Son, of Leslieville, Ont., furnish, amongst other valuable trees, the locust tree, of different varieties. They are all valuable, both for honey and timber. It certainly is the wiser to plant a tree which, on attaining maturity, is valuable as timber, than to plant one which, in the end, is not even valuable as a fence post, and not even valuable as firewood.

I am indebted to the *Canadian Horticulturist* for valuable suggestions on tree planting. The article appears in the February number, and is by Mr. N. Robertson, Government Grounds, Ottawa. It is too long to copy into this communication, but a few points may not be amiss. "Take the trees up so as to destroy as few of the roots as possible; cut the tops into what is called pole, eight or ten feet long, have a good root, a stem without blemish, and thus a rapid growing tree. Do not take a scraggy, stunted tree; and do not mind having the tree to stand as it did before removed, but plant the side having most roots on the side where the wind will be strongest. Let the hole in which you plant be much larger than the roots, and draw the roots out to their full length. Before you put in the soil, do not let the roots get dry, but give

them a heavy mulch of sawdust, manure or straw. This can be kept in place by a few spadefull of earth, and place the mulch over that a foot beyond the hole where the roots are." Belleville, Ont.

Rural New Yorker.

How to Transfer Bees.

W. Z. HUTCHINSON.

To transfer bees from box hives into those having movable frames, at the right time and in a proper manner, is an easy task; but to the novice it seems like quite a job. Unless one is very careful, he should transfer bees only when they are getting plenty of honey. When apple trees are in blossom is usually the best time. Clean all the rubbish and grass away from the old hive, spread a lot of sawdust around it, and do not leave a crack or crevice anywhere that the bees can crawl into. One will need a hammer, a saw, a chisel, a case knife, a goose quill with which to brush the bees off the combs, a smoker, some water and a cloth with which to keep all the honey washed up clean. If possible, it is better to have some one to help. Before commencing operations, one must be sure and get every thing that he will need. Commence about ten o'clock some pleasant day, when most of the bees will be in the field out of the way. Blow a little smoke into the entrance, wait a few minutes for the bees to fill themselves with honey, then move the hive back a few feet, and turn it bottom side up. Drive the bees down among the combs with smoke. From beginning to end, keep the bees in subjection. Notice which way the combs run, and take off first the side of the hive with which the combs are the nearest parallel. Cut the combs from the side of the hive by running the hand saw down. Saw off the cross sticks close to the side of the hive. Pry off one side of the hive, cutting the nails if necessary. The next thing is, how to get those crooked, and uneven combs out and get them into the frames. Cut out the first comb, lay it on a board, lay a frame over it; make a mark on the comb around the inside of the frame; cut the comb a little larger than the inside of the frame; spring the frame over it, and one comb is transferred. Sometimes the combs need fastening in, and there are different ways of doing it. One way is to make holes through the frame with an awl, then push thorns or sticks through these holes into the combs. Some use strings, and tie the combs in; others use little strips of wood that reach clear across the frame of combs, and are tied at the ends with strings or wires.

As fast as the frames are filled, hang them in the new hive, which should be placed on the old stand. Keep cutting out the combs and fastening them into the frames until they are all out, shaking the bees in front of the new hive. Some of the frames may have to be filled with small pieces of comb, but in a day or

two the bees will have them all fastened together, when the strings or strips of wood may be removed. In putting the combs into the new hive, the brood should be kept as near together as possible. If one attempts to transfer when honey is scarce and robbers trouble, he may have to do it in some building. Some bee-keepers drive the bees into a box before transferring; but a good smart hand would have a swarm transferred by the time that it could be thus driven out.

For the American Bee Journal.

A Friendly Chat with L. W. Vankirk.

G. M. DOOLITTLE.

As some seem to think that all Doolittle is after is to make a "big report," and as L. W. Vankirk has been the one to speak out what others have privately said, I wish to have a friendly chat with him, and thus explain some things which seem to some to be a mystery or contradiction. All cannot be said in one article in regard to any system of management, that could be said of it, no more than one chapter of the Bible could tell us of God's plan of salvation for man, and the reason I mistrust why a few of the multitude do not believe the Bible is because their mind dwells on a few dark parts, rather than take in the whole character of the Scriptures. Thus some of my friends have taken hold of certain parts of my writings and forgotten others which harmonize the mysteries. For instance, I have written "get the hive literally full of brood so that when you put on the boxes the bees must store the honey in the boxes if anywhere, as they will have nowhere else to place it. I have also written that after the sections were placed upon the hive, to let the hive alone as far as possible, unless you were obliged to open it to cut queen cells, replace a queen, or some such work of necessity. If I have ever written that the queen keeps the brood chamber literally full of brood at all times, it was not what I intended to write, for they do not. To get this brood chamber full of brood previous to the honey harvest has been a tax upon the queen, and as the honey harvest commences, and we stop exchanging the brood combs in the hive, the queen takes a partial rest, thus allowing the bees to fill the outside combs with honey, as well as a portion of the top part of each frame as the bees hatch therefrom, hence when the honey harvest closes, we have an average of about 25 lbs. of honey to the colony, which is ample to carry an ordinary colony from one honey season over to another.

It will be seen the point I have aimed at making in all my writings on this subject of brood-rearing, has been that a hive full of bees and brood at the commencement of the honey harvest tended toward success, while a hive full of honey or empty comb, with but few bees and little brood, tended toward disappoint-

ment. What would you think of a man who had a field of potatoes to hoe, that required the help of 100 men, who only hired two of them during hoeing time, and then near the harvest employed the 100? You would say too late, and the labor of the 100 men thrown away. Just so with bees which came too late for the harvest of honey. Again, why I use a small hive and desire the combs filled with brood before the honey harvest, is that the bees enter the boxes sooner and more readily. If we use a large hive that the queen cannot keep filled with brood, the first thing that the bees do is to fill all combs not occupied with brood with honey, before they make a start in the boxes, after which the tendency is to crowd the queen down. The more sealed honey there is between the brood and the boxes, the more loth the bees are to enter the boxes, and hence the large hive tends toward a small amount of surplus box honey. "Enough is as good as a feast," and 25 lbs. of honey in the hive the first of October, is just as good for the bees to winter upon as 50 lbs. Hence it will be seen that the 25 lbs. extra is a positive damage, to say nothing of its selling value if placed in the sections, as it would be were a small brood chamber used.

Again, I have told you how I unite bees in the spring to make them strong, and if I had not told you in another article that $\frac{3}{4}$ of my bees were good enough to need no uniting, the position that I "mix up thoroughly so as to give all an even start," would be well taken. But I have told you that all that were able to get in trim for the harvest alone were built up in and of themselves. How they are built up I have told you in the articles, "Production of Comb Honey." Once more, I have told you that I fed no sugar except in the spring of 1878, when I fed two barrels to keep my bees from starving. On the other hand, I have told you how in the fall of 1876 I united my bees down nearly one-third, so as to obtain honey enough for the rest to winter upon (thereby making the bees self-supporting), and thus given you a clue to where I got those combs of sealed honey. I always unite bees in the fall till all are in good shape for wintering, if they are not already so. I have said that after I had done all in my power to get my bees in good shape for wintering, I could not tell why they died, and I say the same thing to-day; but I am not willing to admit that my loss in winter balances my income from the bees, for bees have paid me a good income notwithstanding my losses during winter. I rejoice over the success of those who winter their bees every time, yet I am more proud of the man who can, with the bees he has left, double the income of my successful wintering friend, even if he does lose bees during bad winters.

Mr. Geo. T. Wheeler, who first introduced section boxes in a practical form, once said to me. "I can make 500 per cent. on bees during the summer, even if I have to buy bees every spring on account of loss in winter,

while those of whom I buy do not make 250 per cent. on their investment, total receipts all counted." Now, about reporting: In my younger days in apiculture, I favored the adoption of the plans of those who backed up what they advocated by good reports each year, and as I was writing my management of an apiary, I thought no harm would arise from letting the readers know how I succeeded. If Mr. Heddon and others whom we have learned to respect through their writings, would report their crop of honey each fall it would please more than the writer of this article I am sure.

In conclusion, I wish to say that I am very thankful to Mr. Newman and Dr. Tinker, for so ably defending me when I was sick, and placing me where this reply was unnecessary till I had the time to give it.

Borodino, N. Y.

Eichstaedter Bienenzeltung.

Importance of Having a Good Queen.

REV. DR. DZIERZON.

In every season the queen must be accompanied by worker bees sufficient to produce and retain an increased temperature in the hive. As the queen is not designed to build the breeding cells, or furnish the brood with food, the workers attend to that for her. She is rightly called the "mother of bees" because she gives life to all the young bees that exist in the colony, by producing the eggs which develop into the future workers and drones. The success of the colony and its perpetuation depends upon the fruitfulness of the queen. If a weak colony be given a prolific queen, it will quickly increase to a strong one and the strongest colony will soon be reduced to weakness, if the queen produce few or no eggs, either on account of advanced age or other defect. Being aware of these facts the apiarist should tenderly care for his queens, and especially to winter only such colonies as have very fruitful, faultless, and not too old queens. Many queens are nearly useless, even when young, and others still prolific in old age, but the latter are very liable to lose their strength and fruitfulness at a very inconvenient time, when they should be depositing the most brood and when substitution is very uncertain on account of the scarcity of drones. In consideration of this it is very advisable to supersede a queen in about the third summer; and the most favorable time is when the bees are swarming.

The first part of this operation will be the most difficult, especially if the colony is very numerous or has gathered much honey. One method which has been recommended is to allow the colony from which you wish to remove the queen to become quiet, then quickly remove her, place the young queen in the hive and the superseding is over—before the colony fairly realizes her presence. But there is no surety of success in this method, for the bees are often so at-

tached to the old queen, that they will not brook substitution and immediately destroy the intruder.

There are so very many plans given for catching the queen that the operation has become so simplified that it can easily be accomplished in the strongest colony. It is not necessary to look all over the combs and in every corner of the hive to find the queen, but you can easily locate her upon a comb, in any part of the hive. This is not done by inserting combs of honey—for the queen never takes honey from the cells but is fed by the bees—but by giving her an opportunity to deposit eggs without disturbance, especially drone eggs, which occupation best pleases her majesty. For this purpose choose empty brood-combs, or such as are only partially filled, for the queen will be in haste to occupy all space and fill the cells with eggs in order to close the brood. If you will examine that hive in 24 hours, without creating disturbance, you will, in nearly every instance, find the queen on this comb.

To get a queen out of a box hive, about the only way is to drum the bees out and allow the queen to pass out with them. There will be no difficulty in discovering an Italian queen from her golden color, for she excels the worker bees in brightness. The astronomer does not have to search the heavens when seeking Venus, Jupiter, or Mars, for they so far surpass the surrounding planets in brilliancy that they catch the eye at a glance. No more does the bee-keeper seek in vain his Italian queen, and in queen rearing this is quite an object. After the queen is captured and the colony becomes fully aware of its loss, the bees will build queen cells and rear a successor. We may also expect some "after swarms;" the first one will probably appear in about fourteen days, the time being varied by the strength of the colony.

But to those bee-keepers who are not seeking an increase of colonies but rather depend upon the honey harvest for their profits, the method we have given would be of no value. Such bee-keepers must immediately place a young queen in the colony from which the queen has been removed, in order to prevent after swarming and cause as little disturbance among the honey gatherers as possible. The new queen must be caged at least 24 hours, when introduced; some prefer placing a queen cell in the hive that is nearly developed, but this requires skill and patience. I have recently tried—and with much better success—hanging the entire comb containing the queen-cell in the hive which contains no queen. Queen cells are not scarce in the swarming season; every colony which has produced an early swarm will contain several queen cells which must be used at just the proper time, that is, when 9 or 10 days old, for if delayed longer, some may have fully matured, and if the bees are not inclined to swarm these new queens may destroy those remaining undeveloped, by biting through the cells. The bees usually place the queen cells

upon one or two combs; attention is necessary to distribute them sufficiently, that every queenless colony may be supplied with comb containing one or more queen cells. This method of superseding queens is certainly very simple and practical, as well as expeditious. Very little disturbance is created among the bees, and scarcely any interruption of labor. The young queen will soon become fertilized and commence depositing eggs. Should she by any means be lost or destroyed during the wedding flight, a new queen cell should be immediately inserted, and care should be taken to select one nearly matured that the bees may not become too much excited.

Carlsmarkt, Germany.

D. A. Jones' Method of Transferring.

WM. F. CLARKE.

When at Beeton, the other day, I was astonished to find Mr. Jones' home yard full of the most interesting collection of old gums, time-worn box hives, and other antiquated bee "fixins," that I have ever set eyes on. In anticipation of the arrival of a lot of Palestine queens, he had taken a tour through a secluded section of country inhabited mostly by colored people, and bought up about a hundred colonies of black bees, domiciled in these ancient homes. It only wanted a few weather-beaten straw skips to complete the picture of apicultural antiquities.

The Palestine queens were shipped too early in the season, got delayed among the icebergs in the gulf of St. Lawrence, and only two survived, causing an entry of \$1,000 to the wrong side of the profit and loss account in the Jones ledger. The weather was not very auspicious for transferring, but it had to be done, as many of the colonies were short of stores, and some were even swarming out in search of the food which a backward season failed to supply from early spring flowers.

Notwithstanding all the scientific appliances he has at command, Jones is the most "rough-and-ready" bee-keeper I have ever met with. He goes at the business of transferring like a regular backwoodsman, armed with an axe and a bowie-knife. "Bring a hive!" It is brought accordingly, and put in the place of the old hive, which is turned bottom side up, and set beside the new one. "Blow in some smoke." While this is being done, Jones is considering the best place for beginning the work of demolition. Whack goes the axe on the chosen spot. You would think the bees would streak out like lightning. But they don't. That blow with the axe seems to stun them. Soon a piece of the old hive is split off without damaging a bit of comb. More splitting, till the knife can reach the first flake of comb, which, on being loosened, is laid flat on a broad shingle. Presto! The bees are swept off into the new hive with a goose feather,

and the comb taken into a house near by, to be fastened into a frame. Flake after flake is thus treated. The bees soon begin to find the new hive, and multitudes of them march into it of their own accord. The operation is all over in about half the time it takes for the usual orthodox drumming.

This expeditions mode of transferring is only practicable when the old hives have little or no honey in them, as was the case with most of Mr. Jones' purchases. In buying black bees for transference, it is good policy to choose populous colonies with but little honey. The gathering season is close at hand, and with plenty of workers, there will soon be plenty of honey. It is a common mistake of beginners, in buying colonies in old box hives, to choose the heaviest. Instead of these, the experienced bee-keeper will pick out the colonies that are short of honey and strong in population. If a hive about to be transferred has a large amount of honey in it, the bees must be drummed out in the approved fashion, and the heavy combs removed with great care. Mr. Jones has a wire cage the size of his frame, into which he puts combs heavy with honey, after fitting them, and extracts the honey before putting the frames into the hive. This wire cage is an admirable contrivance. It consists of two leaves which are hinged, and shut closely on the combs, holding them in place. Any bits of comb containing honey can be fitted into a frame, put in the cage, and extracted by this means.

Many people are very awkward and unthinking about this process of transferring. I met with a man the other day, who had just been trying his hand at it. He drummed out the bees all right, and then proceeded to pry off the top of the old hive. It was pretty well stored with honey, and the consequence was, as might have been expected, that the whole interior collapsed "kersmash," killing young brood and wasting comb and honey at a wholesale rate.

It is astonishing how soon transferred bees, when the job is done properly, settle down to work in their new habitation, "clar up de kitchen," and become as contented as a family that has just moved out of an old log cabin or board shanty, into a comfortable new house.

Mr. Jones fastens the old combs into frames, with cedar strips projecting a little at the top and bottom, the ends of which are fastened with very fine wire. A bee-keeper who, like myself, was on a visit of observation at the Beeton apiaries, mentioned that he used small rubber rings in place of wires to fasten the strips. "Give us your hand," exclaimed Jones. On trial, we found the plan an excellent one.

Listowel, Ont., June 5, 1882.

Do not let your numbers of the BEE JOURNAL for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

For the American Bee Journal.
Wintering in Chaff Hives.

LUCIAN FRENCH.

In September, 1880, I transferred the bees from 6 of my old Langstroth hives into Root's chaff hives, and they have wintered without loss. One colony seems rather weak, but I think will live.

I packed 12 colonies in chaff—the same as in 1879; 3 died, and 2 were so weak that I took one colony from the cellar and put with them to save them. Six colonies in Root's simplicity hives were packed in straw and chaff in large dry goods boxes. One of these died, and 1 was so weak I united it with the others. Twenty-seven colonies on the summer stands came through all right. Of the 23 colonies placed in the cellar 11 died, 6 were very weak, and the remaining 6 were strong. Some bee-keepers in this section of the country wintered their bees on summer stands in the old-fashioned box hive, and met with little, or no loss, though they have but few colonies. I would like to know if overstocking has anything to do with loss in wintering?

I have been experimenting for a number of years, endeavoring to determine the best manner of wintering, and would be pleased to know the method L. James pursues; for surely the wintering of bees should be as simple as that of cattle, horses, etc. I am glad to see the awakening on this subject. I know there are very many attending circumstances to influence, and bring about this end, which we shall all be so glad to attain, and I think S. Valentine, on page 129 of the BEE JOURNAL for 1881, names some of the important causes of loss.

I have thus far had good success with Root's chaff hives, but as it takes "more than one robin to make a spring," I will not shout too soon.

Dexter, Maine.

Connecticut Farmer.

How to Introduce a New Queen.

H. L. JEFFREY.

The first requisite for the safe introducing of a strange queen is the right kind of a cage to use. As good a one as any is made of fine wire cloth about 8 threads to the inch each way. Cut a strip 3 inches wide by four long, turn the edges over on the long sides a quarter of an inch; this makes a hem and prevents raveling out; then pull out two or three wires on the ends, bring both ends of cloth and twist the wires together. Now you have a wire cage about $2\frac{1}{2}$ inches long by $1\frac{1}{4}$ inch across. Press it flat till it is a half inch oval; then tie two thicknesses of wrapping paper neatly over one end, as close to the end as possible, and trim off the edges of the paper above the string. Take a piece of sponge large enough to fill the other end quite full, wash the sponge perfectly clean and squeeze it dry. Saturate the sponge with honey, put

your queen in the cage and then stop the end with the sponge. She is now a prisoner in the cage between the sponge and paper, the honey in the sponge furnishing her with food. You are now ready to put her into the hive.

To prepare the hive for her, if a frame hive, open it and take out the queen if it has one; if not destroy all the queen cells if there are any. If the hive has any sealed honey over brood in the frames, uncap a small place on one of the combs, place the cage with the queen in between this and the next comb, bring the combs close enough together to hold the cage in place, then close up the hive and let them severely alone for 3 or 4 days. The bees will bite through the paper and let the queen out among them very quietly, and there is very little, if any danger of the new queen suffering any harm from the bees. In the last four or five years I have used this way of introducing queens in at least 500 cases without a single failure, and I have tried other methods without success.

Woodbury, Conn.

**SELECTIONS FROM
 OUR LETTER BOX**

After Swarming.—I commenced the season after the water went down with 70 colonies; they commenced to swarm on the 27th of March and continued to swarm up to the 5th of May. They suddenly stopped, and up to this time there has been just enough honey coming in for them to live on. At this time (the 5th of May) the honey flow ceased entirely, and I thought I would have to feed them to keep them from starving; but on the night of the 9th of May there came a tremendous fall of honey dew, when all the leaves with a smooth upper surface were covered. It accumulated in large drops, as if it had been poured from a spoon. On the 9th and 10th the bees were working like mad, and seemed to send out every worker that could be spared from the hive. They stored a great deal of honey in those two days; then came a heavy rain on the night of the 10th, and that ended the honey flow up to June 7th. That honey dew was a godsend, for if it had not come I would have had to feed nearly every colony till June 7th. The honey flow has been heavy up to date, and on the 13th inst. they commenced to swarm again. They have been swarming at the rate of 2 or 3 a day up till now. Young swarms that had only one-fifth of their frames filled with comb are swarming. Such as those I return to the hive after pinching off the queen cells, and clipping the old queen's wing. Some of them, after staying 2 or 3 days, will come out again with queen cells barely started. I have kept the honey closely extracted from them, yet they swarm. If they continue to swarm it will cut short my honey yield, for

it is high time they were turning their attention to honey-gathering. My neighbors' bees are doing the same way. If some more experienced bee-keeper would explain the cause, and give a plan to prevent so much swarming, I would be very grateful.

W. G. McLENDON.

Lake Village, Ark., June 21, 1882.

[The cause is that in swarming your colonies are never entirely depleted of field-workers. We think if you will hereafter adopt the plan of moving the parent colony from its old stand after a swarm has issued, and placing the new swarm on the old stand, you will have no trouble, as the mature field workers will desert the parent colony, and there will be no old bees to go with the first young queen when hatched.—Ed.]

Lamp Moth Trap.—We have had much rain and flooding the past four weeks, and such cold wind, it has deterred our bees from swarming early, but during the last few days the temperature has been about 90° F., and we are receiving some enormous large swarms. In spite of all our wet weather bees have done excellently. White clover has been with us two weeks or more, and promises a splendid yield of honey. I am trying the plan of setting a lamp in a pan of water in my apiary at night, and find it very profitable. It is sure destruction to the bee moth. My neighbor, Mr. David Witt, was last evening showing me his method of management, and called my attention to a strong colony which he said was "cutting down an awful sight of rubbish every night." Being anxious to know the cause, I send you a small package of it. 1. What is it, and what should be done with the colony? 2. Will bees do well put into a Langstroth hive, without either combs or foundation?

FRANK B. RIFE.

Malaby, O., June 11, 1882.

[1. The package mentioned above has not been received at this office.

2. Yes, the bees will do well enough, but they are very liable to build crooked. It is mistaken economy to suppose good foundation is an article of extravagance.—Ed.]

Storms in Kentucky.—After a few days of encouraging honey flow, the 16th of June opened with violent rain storms, continuing over the 17th, and accompanied by very high temperature, resulting in the destruction of great numbers of field workers, the sections in many hives presenting the appearance of those left by swarming. Work in the sections was suspended for nearly a week, and many colonies destroyed their drones, even to pulling them from the cells. This, at a time when linden was just opening, was discouraging indeed. This morning it is again raining more violently than ever, accompanied by very heavy winds and thunder, and everything

presents the appearance of a stormy day. Our bees appear to have abandoned clover for a white-blossomed weed that is a great pest in old meadows. It is now in full bloom. The prospects for a surplus of honey are very gloomy at this time. Queens have seemed to do their best to render the hives populous, but nothing could prevail against such wholesale destruction of workers, and so many adverse circumstances.

JOHN C. PEDEN.

Lawrenceburg, Ky., June 26, 1882.

[Our correspondent, we hope, will yet realize a good honey crop, despite the apparent unfavorableness of the weather. If summer and fall flowers are usually abundant in your locality, the weather of which you complain will be the very best for developing them. Last season your prospects were much gloomier than now, and yet the asters came in with an abundance of nectar never before equalled by it, and you rejoiced over the happy termination of your misfortunes. Even, however, if your worst fears are realized for this season, it cannot be expected that a territory as vast as ours, with a climate so varied, should every portion be equally as productive in one season, any more than that all soils should rival your famous blue-grass pastures, or that all herds of cattle should equal your incomparable shorthorns.—ED.]

Ready for Linden Bloom.—During the months of April and May, my bees got very little honey and as a result, feeding was necessary to keep away the pangs of hunger. I now have them in a condition where I can muster a large army of workers to take the field as soon as the linden blossoms, which will be in a few days. Mustard is blooming quite profusely now, and bees are working on it some. I saw some dogwood and elder blossoms to-day, but no bees about them. Does it yield any honey or not? The crop prospects here are good.

W. H. MARTIN.

Falls City, Neb., June 25, 1882.

[They undoubtedly both yield honey, but it is either difficult to obtain or obnoxious to the bees: it is seldom they are seen to work on either if anything else is in bloom.—ED.]

Bees have Prospered.—Notwithstanding the cold, backward spring, bees in this locality have prospered. I wintered 50 colonies out of 54. Have had a few natural swarms. Nearly all my colonies are storing honey in the surplus boxes, and some are ready to be raised up. White clover is in full bloom, is abundant, and everything looks promising for a good honey harvest.

Mrs. A. M. SANDERS.

Sheridan, Mich., June 23, 1882.

Improvement in Dispositions.—Bees are doing better. The Syrians are far more amiable than they were last year. Can it be handling? My class of 30 go among them with no protection, and receive no harm. They are a great improvement, I believe, on the Italians. I am very sorry for Mr. Jones. It is too bad. For his great enterprise—one of the greatest ever undertaken on behalf of apiculture. He gets only loss, and very little thanks.

A. J. COOK.

Lansing, Mich., June 23, 1882.

[Yes, Professor, you are right in your surmise; frequent careful handling, as we discovered years ago, will very much improve the amiability of almost any colony. Here, again, might arise a doubt, whether it is all instinct which teaches the bee that its proper manipulation is for its benefit, and not to do harm; and this, too, may have given rise to the thought that bees learn to individualize, for we frequently hear old bee-keepers say that their bees can distinguish them from strangers, when it really may be a peculiarity in dress or in the manner of handling.—ED.]

Motherwort for Bees.—Prospects for a honey crop are very discouraging here. Bees have built no comb in the sections as yet, and are not more than making a living. Cold and wet, with but little clover in bloom. Motherwort seems to be yielding more honey than any other plant so far. I have about 2,000 plants of it under cultivation in my experimental garden, and I think 10 acres of it planted the same as corn one way and drilled the other way, would support 100 colonies of bees.

W. T. STEWART.

Eminence, Ky., June 22, 1882.

Wired Foundation.—Will you please inform some of your old subscribers, through the BEE JOURNAL, if the wired foundation can be used in the body of the hive; it twists so I cannot use it? G. CHOLWELL.

Red Hook, N. Y.

[The strongest recommendations urged by the friends of wired foundation are that it is proof against twisting and sagging. We have used but little of it, and then only in an experimental manner, but were not troubled with its twisting.—ED.]

A Sad Accident.—On the 4th of June I started for Hammondsport, where I have a vineyard, when my horses became frightened and ran away, throwing me out and breaking my leg. I was badly bruised otherwise. I have been unable to attend to my bees since, and as it has been such weather that they required especial care, they have suffered in consequence. I have lost 5 colonies by starvation. D. S. McCALLUM.

Big Creek, N. Y., June 15, 1882.

A Valuable Seedling.—I herewith send you a specimen of white clover, which you see is very large, and the blossoms are perfectly white. It blooms from 12 to 15 days before the common or Dutch white clover or the alsike or red clovers. I first noticed it last year growing in front of one of my bee hives, and this year it has spread until there is a patch about 2 yards square, with the seed now ripe, while the common white clover near it, a specimen of which I send, is only coming into bloom. Is this a new seedling, or what is it? My bees are doing first rate, and the fields are perfectly white with clover.

H. BESSE.

Delaware, O., June 27, 1882.

[It is undoubtedly a new seedling, although the size and shape of the seeds differ materially from those of any other variety with which we are acquainted. It is, however, worthy of cultivation, and will prove very valuable because of its extra large size and early maturity. Do not neglect it.—ED.]

Late Feeding.—Bees came through the winter good, but we had a very severe spring on bees; some had to be fed as late as June 17th. They are doing well now, June 23d. It is strange how they have swarmed, even in May, without a pound of honey in the hives, and none coming in.

Hartford, Wis. I. S. CROWFOOT.

More than Doing Well.—The thin foundation is the knob of perfection *magnifico*. Bees are more than doing well now. Swarming has commenced.

P. P. NELSON.

Manteno, Ill., June 24, 1882.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 13 " (3 months).....	20 " "
" 26 " (6 months).....	30 " "
" 39 " (9 months).....	40 " "
" 52 " (1 year).....	60 " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—	a copy of "Bees and Honey."
" " 3,—	an Emerson Binder for 1882.
" " 4,—	Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,—	" " " cloth.
" " 6,—	Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
 Monday, 10 a. m., July 3, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—1 am paying 7c. for dark and 9c. for light extracted.
 BEESWAX—Choice lots are worth 25c. here; bright yellow, 24c.; dark to good, 17@22c.
 AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for honey is quiet. Extracted brings 7@10c. on arrival. No comb honey on the market worth mentioning, prices nominal.
 BEESWAX—Scarce, and brings 20@25c. on arrival.
 C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for comb honey is light, prices being made to meet views of purchaser.
 BEESWAX—Scarce, and in demand at 23@25c.
 R. A. BURNETT, 165 South Water St.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
 BEESWAX—Prime quality, 25c.
 CROCKER & BLAKE, 57 Chatbam Street.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.
 BEESWAX—The market continues rather quiet, but the supply is light and prices firmly sustained. Western, pure, 24@25c.; Southern pure, 25@26c.
 D. W. QUINRY, 105 Park Place.

SAN FRANCISCO.

HONEY—Our first consignment of new crop of comb honey was received last week from Hine's apiary, Los Angeles county. It was choice, white, straight combs, and well filled and capped. We sold the lot (about 1,000 lbs.) for 30c. per lb. Bob old comb and extracted are still on market, and sellers are pressing it at low figures. There is not enough doing to give more than nominal quotations. Private advices from the southern part of the State are to the effect that the yield will not be heavy, but the reports have not thus far influenced buyers in the least.
 We quote white comb, 15@20c.; dark to good, 8@12c. Extracted, choice to extra white, 7@8c.; dark and candied, 6@6c. BEESWAX—23@25c.
 STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—In fair demand. Extracted selling at 8@10c.; comb scarce—nominal at 18@22c.
 BEESWAX—Prime in demand at 22@23c.
 R. C. GREER & CO., 117 N. Main Street.

CLEVELAND.

HONEY—As there is no honey in market, we have no quotations this week.
 A. C. KENDEL, 115 Ontario Street.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

When changing a postoffice address, mention the old as well as the new address.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Three years ago St. Julian, the great California trotter, was unknown; the same may be said of Kendall's Spavin Cure. Now both have a world-wide reputation. Why? Because they both have merit. One is a great trotter, the other is the most successful remedy ever discovered to be used on man or beast. 26w4t

Bingham's Smoker Corner.

I have tried several kinds of Smokers, and none give such satisfaction as Bingham's; 'tis worth more to me than all the rest combined. Morning Sun, Iowa. J. E. KEARNS.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

STANLEY AGAIN AT LARGE.

We have now secured a quantity of bright yellow wax, and can furnish our thin foundation for sections on short notice. Owing to the rapid advance in the price of wax, we now quote thin foundation at 60c. per lb. for 20 lbs. or more. We shall be able to furnish a limited amount of heavy foundation at 45c. per lb., also thin points for glazing honey at 20c. per 100, and wire nubs of any size at manufacturers' list prices.

G. W. STANLEY & BRO.
 Wyoming, N. Y.

BEAUTIFUL QUEENS—Warranted Italians, \$1.25 each; Warranted Cyprians, \$1.50 each; Unwarranted Queens, \$1.00 each. Try one and you will want more. Address, 27w4tp REV. J. E. KEARNS, Morning Sun, Iowa.

VANDERVORT FOUNDATION

110 SQ. FEET, or 11 lbs. \$6; more at same rate; less, 60 cts. per lb., delivered at Express, Albany, N. Y. H. W. GARRITY, Coeyman's Hollow, N. Y.

A NEW BEE BOOK!

Bees & Honey

OR THE
Management of an Apiary for Pleasure and Profit; by
THOMAS C. NEWMAN,
Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.
925 W. Madison Street, Chicago, Ill.

Appreciative Notices.
Carefully prepared for beginners.—Farmers Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keltshburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiculture, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Logmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$10.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " " 10x18 " "	8 00
For 3 " " 10x18 " "	14 00

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. A. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the County, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,

923 West Madison Street, CHICAGO, ILL.

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book;

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY.**

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. P. WEST.**

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**H. WYNKOOP.**

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL.**

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—**WM. VAN ANTWERP, M. D.**

It is the latest book on the bee, and treats of both the bee and larvae, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—**L'ABBE DU BOIS**, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *valde medicum* of the bee-keeper. It is replete with the best information of everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, **\$1.25**; in paper cover, **\$1.00**, by mail prepaid. Published by

PIANOS

\$850 Square Grand Piano for only \$245.

PIANO STYLE 31 Magnificent rosewood 3 strings, 7 1-2 Octaves, full patent cantate agraffer, our new patent overstrung scale, beautiful carved legs and lyre, heavy serpentine and large fancy moulding, full iron frame, French Grand Action, Grand Hammers, in fact, every improvement which can in any way tend to the perfection of the instrument, has been added.

Our price for this instrument, boxed and delivered on board cars at New York, with fine Piano Cover, Stool and Book, only \$245.

Reduced from our late wholesale factory price, \$285, for 60 days only, to have this beautiful Piano introduced. This is now, by far, the greatest bargain ever offered the musical public. Unprecedented success! Tremendous demand for this style! Order at once.

This Piano will be sent on 15 days' test trial. Please send reference if you do not send money with order. Cash sent with order will be refunded and freight charges paid by us both ways if Piano is not just as represented. Several other special bargains: Piano, \$125 up. Over 15,000 in use and not one dissatisfied purchaser. Handsome Illustrated Catalogue mailed free, giving the highest testimonials ever awarded any manufacturer. Every Piano fully warranted for 5 years.

SHEET MUSIC ¼ price. Catalogue of 3,000 choice pieces sent for 3c. stamp.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as *Carcharodon Rondelietii*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better. I have been greatly benefited. My deafness being a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Day Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by THOMAS C. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide (or, Cook's Manual) of the Apilary.—Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Market Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bienen Kultur, by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Dzierzon Theory—presents the fundamental principles of bee-culture, and turns the facts and arguments to demonstrate them. 15 c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, uses, and preparation of Honey for the Market. Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how: 25 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees, Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains 1,200 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gliders, Metal and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Department of Apiculture.

It is proposed to have a professor of apiculture appointed in England as we learn from the *London Journal of Horticulture*. Mr. A. Pettigrew made the proposition, and being asked to name a person for the place, says :

The question of the country being ready for a professor was asked, and also if a man qualified for the work could be found. Those questions were answered as fully as it was thought desirable then. We have made considerable advances during the last two years, and it appears to me now that a new departure or fresh advance should be made as soon as the authorities will sanction it. Would you appoint one or two professors? Two. One for England, and one for Scotland and Ireland; both would have plenty to do. Have we any men amongst us ready for the work? Yes, I think we have two well qualified; but I hesitate to point them out by name, though I fancy no harm would be done to anybody by mentioning the names of the two gentlemen who appear to me most qualified as professors of apiculture. Mr. William Raitt, of Blairgowrie, I would nominate for Scotland and Ireland, and Mr. Frank Cheshire for England. Perhaps they would not accept such appointments if they were made. Both are advanced and enthusiastic bee-keepers, and good lecturers and instructors.

The AMERICAN BEE JOURNAL would heartily approve the choice of these gentlemen, knowing their ability to lecture as well as to impart sound instruction on progressive bee-keeping.

England is making rapid strides in progressive bee-keeping, and this is a step in advance of the United States, though in many things we have set them a wholesome example. We

have often thought what a boon it would be to thousands of our people in Illinois, especially those with a professional and literary turn of mind, and the many who are physically incapacitated from earning an honest and comfortable livelihood at hard manual labor, if a Professorship and Department of Apiculture were added to our already efficient and able Illinois Industrial University. It would open up the possibility of an independence to thousands of women who now eke out a miserable existence in the crowded cities, because the avenues of rural industry are comparatively closed against them. The apicultural field is broad; no State in the Union can boast of better natural facilities for honey gathering, and no State is more illy supplied with bees according to its resources than Illinois, and yet skilled bee-keepers, or scientific apiarists, can scarcely be employed at any price. Nothing is more needed than an apicultural department under State patronage, and nothing would contribute more to the State revenue in proportion to the outlay. The department could appropriately be combined with the Botanical and Horticultural, and if he could be induced to supervise it, no one could be found more competent to occupy the professional chair than Prof. T. J. Burrill, the learned scientist.

The Postmaster General recommends to Congress the reduction of letter postage to 2 cents; this will be a good thing, for many who now use postal cards would send letters, if the postage on them were but 2 cents. Some other changes are proposed, but none of them may be made. We shall see.

We have received price lists of bee-keepers' supplies from Roys & Morgan, Columbus, Wis., and J. D. Goodrich, East Hardwick, Vt.

Fertile Workers—So Called.

Dr. I. P. Wilson, Burlington, Iowa, forwards the following upon the above subject:

Is there such a thing as a fertile worker? No. Is there such a thing as a laying worker? Yes. The eggs of a virgin queen will hatch, and all the bees be drones. The eggs from a worker will hatch, and they, too, will all be drones. Both the queen and the worker are females—the one perfectly developed and capable of being fertilized, the other imperfectly developed, and not capable of being fertilized. There is no such a thing as a *fertile* worker, any more than there is such a thing as a fertile virgin queen, hence the term "fertile worker" is a misnomer, and should be abandoned by scientific bee-keepers. What do you say, Mr. Editor?

We must say, while we have the highest regard for Dr. Wilson personally, and the deepest respect for his opinions, we wholly disagree with his first negative. The admission that there are workers which lay eggs, and that those eggs will be productive of drones, is an acknowledgment *per se* that they are fertile workers, if we place any value upon the definition of the word "fertile," as given by the compilers of Webster's Unabridged Dictionary, which is almost universally acknowledged the best lexicon of the English language. The word is there defined:

FERTILE. [Lat. *fertilis*, from *ferre*, to bear, produce; Fr. *fertile*, Pr., Sp. and Pg. *fertil*; It. *fertile*.]

1. Producing fruit in abundance; fruitful; able to produce fruit abundantly; prolific; productive; rich; inventive; produced in abundance; as, *fertile* land or fields; a *fertile* mind or imagination.

2. (*Bot.*) Capable of producing fruit; fruit bearing; as, *fertile* flowers or anthers.

Syn.—**FERTILE, FRUITFUL.** *Fertile* implies the inherent power of production; *fruitful*, the act. The prairies of the west are *fertile* by nature, and will soon be turned by cultivation into *fruitful* fields. The same distinction prevails when these words are used figuratively. A man of *fertile* genius has by nature great readiness of invention; one whose mind is *fruitful* has resources of thought and a readiness of application which enable him to think and act to effect.

The first clause in the synonym covers and justifies the use of the word "fertile" as applied to laying workers, as also to virgin queens which lay eggs that will hatch drones, for each possesses the "inherent power of production." If there is any impropriety in the use of the word, it is in connection with the queen after mating, for it then implies a queen can only pro-

duce progeny after mating, when the reverse is true. A queen, as also all workers, under certain conditions, for aught we know to the contrary, possess the inherent power of production of drones, but not reproduction of kind, *i. e.*, workers or queens. It is true the derivations from the word "fertile," as frequently used, would imply an after preparation or qualification, as, to fertilize soil when it is already fertile, or the fertilization of the queen, when she is by nature inherently fertile. We might as appropriately claim that education was necessary to man to fertilize his brain.

We are not altogether certain that science has yet determined how far the queen possesses the inherent power of production. We do know that in the continued absence of a queen from a colony of bees, if there be no eggs nor larvæ from which to rear another queen, fertile workers are liable to be developed; or, if a young queen be reared and she fails to mate with a drone, she will be fertile with drone progeny only; or, if she be injured or become very old, she will lay only eggs which develop drones. Certainly, nature has had some wise purpose in providing for all contingencies with drone progeny, and there remains for science the deepest mystery yet unsolved, to determine how far the perpetuation of the colony depends upon drone progeny only; as also the economic necessity for fertile workers when all other resources have failed.

We can see no objection to using the words "laying worker;" but custom has sanctioned and legitimized the use of the word "fertile" in this connection, and certainly the strict definition of the term justifies its use.

Honey Labels.—We have received samples of some very attractive lithographic labels for honey, from Mr. D. A. Jones, of Beeton, Ontario, Canada. They are mainly intended for extracted honey in tin pails, but some are suitable for sections of comb honey. They are not only exceedingly handsome, but, being varnished, they will not easily become soiled. The figures of straw hives on nearly all of the labels may be objectionable to some apiarists having progressive ideas. These, however, could be omitted without detriment to the present handsome appearance of the labels. The BEE JOURNAL has urged the necessity of attractive labels, and Mr. Jones has happily caught the inspiration.

Saccharine Secrets.—This is the main caption of a lengthy article in the Chicago *Tribune* of July 6th. Our readers are undoubtedly aware that much time and money have been expended in the effort to make cane sugar from grape sugar—that is, to make from glucose a granulated sugar free from the gummy or waxy starch which characterizes all grades of glucose; but until quite recently, it appears, misdirected science has been unable to overcome the difficulties in the way of its successful accomplishment. Latterly, however, Prof. H. C. Friend, of Chicago, claimed to have discovered a method whereby he could transform 100 lbs. of grape sugar into 96 lbs. of perfect cane sugar. Now, as ordinary cane sugar contains but 86 to 96 lbs. of saccharine matter, it will readily be seen the *Professor* (if correct) would make a superior article from the bogus.

Finally, this wily Friend succeeded in persuading several capitalists to join him in his enterprise; a stock company was organized with a capital of \$2,000,000; machinery was purchased; quarters were fitted up, and the royal road to wealth seemed fairly opened. But unaccountable delays occurred. Anxious days spent by the stockholders were lengthened out into weeks, and these accumulated into months, and yet no *sweet* reward did the stockholders behold, excepting the beautiful samples which the *Professor* exhibited as the result of many successful experiments in his laboratory. Hope gave way to distrust; distrust gave way to despair; and this was succeeded by desperation. The Treasurer brought suit against the company for rent, and other parties brought suit for moneys advanced, while warrants were sworn out for the arrest of the friendly *Professor*, charging him with obtaining money on false pretenses. Probably many others will mourn the spasmodic collapse of the "Grape and Cane Sugar Refining Company," and anathematize the scientific "sheeny."

Transferring.—We wish to call especial attention to Mr. Heddon's article on transferring, on page 437. It is the most practical article on the subject we have yet seen in print, and will prove valuable to any person having bees to transfer. We have practiced a similar method upon several occasions, and had thought of writing an article on the subject, but have never been able to reach it.

Exceptionally Bad Honey Prospects.

New York generally, some portions of Kentucky, and districts in California seem especially unpromising for a large honey yield this season. Mr. J. P. Moore, Binghamton, N. Y., writes under date of July 4th:

The silver lining of the clouds you speak about in the BEE JOURNAL, has not been discernible to the naked eye of any bee-keeper of this State I think. Or if any of them had a glimpse of it, it has all fallen out by this time, as we are not going to get any surplus from clover, nor from anything else this season, unless we have a radical change in the weather. What we are afraid of now is that we shall not get honey enough to winter our bees.

Portions, or, perhaps, the whole of New York, and districts in other States, may be exceptions; but even yet, with favorable weather from this on, the honey yield will be good. Certainly there never was a more abundant white clover bloom in the United States than this season, and linden promises everything that could be desired from it. In illustration of our vastness as a country, the New York *Tribune* gives the following:

If the sun shines through the 24 hours on British territory it may also be said that the reaper runs all summer in the United States. The harvester fights it out on his line from middle spring to early autumn. At Americus, Ga., on the 19th of April, a ripe field of wheat was cut, and others in Texas and elsewhere not much later. Texas will finish in May, Tennessee in June, Illinois and Ohio in July, Iowa in August, and Minnesota may gather some late fields in September.

Undoubtedly summer and fall bloom will be equally good. Sweet clover is coming on rapidly, and though late, is thrifty and will be very productive of nectar. Fortunately, the districts spoken of form the exception—not the rule.

Venor's Forecast of the Weather.—He predicts a "cold and stormy autumn," and a very "severe winter." It will be well for bee-keepers to make preparations for such, and if it comes as this "weather prophet" intimates, they will not be "caught napping." He says:

The general outlook for the weather of the summer season in Southern and Southwestern sections is improving, owing to the continuance of very windy weather in Northern and Western sections of Canada and the United States. But a "windy spring makes a severe autumn;" therefore the outlook for the autumn of 1882 is increas-

ing in severity. My theory of "weather relationships" is working just now in a telling manner all over the Northern hemisphere, and I feel much greater confidence in predicting the periods of the more marked disturbances. Hence, I herewith reiterate my previous statements respecting "a very cold and stormy autumn," and early setting in of extreme severity, with heavy snowfalls, this reaching to remote southerly points. We are likely to experience one of the coldest periods in a long term of years during the early part of the winter of 1882-83, but the cold will come in a lump, and the latter half of the winter is likely to be mild and open, with an advanced spring.

Annals of Fort Mackinac.—We have received from Lieut. D. H. Kelton, U. S. A., a copy of an interesting book bearing the above title. The history and legends of the book are interspersed with several scenic engravings of ancient and modern times. We have had a personal acquaintance with Lieut. Kelton, of several years' standing, and this is just such a work as we would anticipate from a man of his accomplished education and discriminating judgment. In the preface to the work he says:

Besides information derived from official sources, including the records on file in the Fort, the old books of the American Fur Company, the records of the village and county of Mackinac, and of the churches of Mackinac and St. Ignace; old documents in the hands of private individuals have also been examined, and much matter obtained which it is believed has never before been in print.

Negroes as Bee-Keepers.—The *Indiana Farmer* republishes our item with the above caption, on page 378, with the following remarks:

To the superiority of Indiana's educational system then, belongs this credit, for we are pleased to inform our esteemed contemporary and its worthy correspondent, that we have several in this part of the country. One, a colored lady, living a few miles north of this city, has charge of thirty odd colonies and is fully up to the times. She gets a fancy price for all her honey, and grumbled not a little because some of the sections which we sent her were not all pearly white.

Our remarks were based upon our observations in the South, where ignorance and superstition prevail largely among the colored people. We suppose in Indiana they have had facilities and inducements for improving their knowledge regarding bees, as well as in everything else tending to elevate and enlighten the race.

Bee-Keeping in Ceylon.—Mr. J. Matthew Jones, Waterville, N. S., sends us the following interesting extract from a recent work entitled "Hoffmeister's Ceylon and Continental India," illustrating the primitive methods pursued in those countries:

The ground floor of a native's house at Mookha, in the Himalayas, contained the stalls for cattle, and the bee house. The latter occupied one whole side of the house in which the window slits were walled up, leaving only fly-holes for the bees on the lower edges; all the rest being closed with cow dung. The entrance to this apiary was on the opposite side from that to the dwelling houses, and it was with the greatest difficulty that I obtained permission to cross the threshold, as the people were afraid that I might take possession of their honey. I found within a perfectly dark chamber, three feet high, in which, resting on a low wooden stand, were the bee hives, a sort of square tubes formed of four planks, connected in front with the fly-holes, and open behind toward the dark room. When the honey had to be taken out, which was done in July or August, a fire of cow dung was made in this little chamber, the smoke of which drove the bees out by the fly-holes. They soon return, however, and build anew.

**MISCELLANEOUS.**

A Swarm of Bees on a Telegraph Pole.—The Philadelphia *Record* publishes the following item among its local news:

For nearly a week past a swarm of bees has been domiciled on a chimney-top over the buildings at the north-west corner of Third and Chestnut streets. Yesterday morning they migrated to the top of a telegraph pole on Third street, above Chestnut, and from the street the pinnacle looked as though it had been dipped in a pot of tar. Great crowds collected at the corner to view the curiosity. The interest heightened when at mid-day a telegraph lineman mounted the pole with a hive improvised from a soap-box and attempted to capture the bees. He preferred to coax the insects rather than drive them, but after a patient but unsuccessful effort he left the box in inviting proximity that the bees might hive themselves at leisure. There was no apparent diminution in the size of the swarm on the pole until just before 7 o'clock, when, reinforced by an assistant, the lineman swept them into a larger box and departed with his prize. He was inspired by a promise of \$12.50 if the swarm should be secured.

Do Bees Injure Sound, Healthy Peaches?—The Massachusetts *Ploughman* remarks as follows :

This question having been put to us some years ago, we have very naturally watched the operations of the bees on the peach trees ever since. The results of this examination have been to draw conclusions different from those entertained by many others. In consequence of this we have been slow to express an opinion, thinking possibly further observation might lead to a different conclusion, but as year after year only gives additional evidence of its correctness, we give to our readers the result of our observation, hoping by so doing to encourage closer observation and to draw out opinions.

The first year or two of observation disclosed the fact that the wasp evidently commenced the work of puncturing the fruit and that the honey bee followed. This at first led to the belief that the wasp was the first cause of the destruction; but, on further examination, it was observed that some of the trees in the orchard were entirely exempt from injury, and in fact, that some whole orchards were perfectly free from injury, not a peach being punctured; this led to a still more careful examination, when it was found that most, if not all, of the fruit punctured, had on one side a decayed spot before punctured. On some peaches the decayed spot was very small and on others quite large, but whatever the size, the wasp would puncture the fruit very nearly in the center of the decayed spot, which has led many to believe that the decay is caused by the puncture, when observation seems to prove that the decay invites the wasp to make the puncture. Being satisfied of this the next investigation was in a direction to ascertain the cause of the decay, when it was in every instance found to be the yellows. We have yet to see the peach orchard, the fruit of which has been injured by the bees that has not been struck by the yellows, and, so far as we have observed, the fruit of every tree that has the yellows will be attacked by the bees.

Knowledge of Bee-Culture.—The *London Journal of Horticulture* remarks as follows on the knowledge of the science of bee-keeping in Great Britain :

Within the last dozen years greater efforts have been made to spread a knowledge of apiculture than were made for more than half a century before in England and other countries; and what have been the results? A wider and deeper interest is taken in the subject, and a greater desire for knowledge has been created. In these times of extensive emigration it appears desirable to extend a knowledge of apiculture throughout the country. To know well how to manage bees profitably is worth very much to working men living in rural districts. Many such men who are versed in bee-keeping would not give the annual

average profits from bees for the rents of 2 or 3 cottages such as they live in. We shall doubtless hear reports of great and wide-spread success, and the story of the value of bees to the community will be better told and confirmed. It is known that in some colonies, and in certain districts of America, bee-keeping is an unfailing source of income to those who understand and practice it. The thousands of barrels of honey containing from 1 to 3 cwts. each that find a market in England every year tell us of busy people in countries rich in honey.

The bee-keepers' Association and some county associations kindred in character and objects, are making laudable efforts to teach apiculture. These associations are rising in public estimation, and becoming stronger financially every year. Much honor is due to the Rev. H. R. Peel, Hon. Secretary of the Bee-keepers' Association, who labors indefatigably to awaken public attention to the importance of bee-keeping.

"Open Secrets."—The *Farm, Herd and Home* very wisely concludes as follows :

Apiarian humbugs of one kind and another still infest the market, and bee-keepers, or those intending to become such, need be put on their guard against them. It should be understood that there are now no "mysteries of bee-keeping," except to the class who do not read publications on apiculture. The secrets of this business are all "open secrets." Any parties who offer by mail or otherwise to make known "new methods," by which fortunes can be speedily made out of bees, merely trade on the ignorance and credulity of the public. Patent hives, moth-traps, and all such devices for money getting, have had their day, and bee-keeping has been reduced to a business, the principles of which are the common property of all intelligent and well-informed apiarists.

Untested Cheap Queens.—The *Bee-keepers' Magazine* is now discussing the matter of the utility of cheap untested queens. The editor remarks as follows :

We think all queen breeders will agree that no one, whose time is of any value, can afford to properly rear queens and send them out, on individual orders, at \$1. We do believe that the vast majority of the so-called dollar queens are reared in nuclei, and some of them by the aid of artificial heat. In the South where hot weather prevails for so great a portion of the year the case is different, and the quality for endurance, of queens reared there by these loose methods is undoubtedly far superior to those reared in this climate. Queens exactly alike in all other respects should not differ in price \$2.00, simply because one has to be kept 21 days in order to see her progeny. Rather dear board for even a queen.

Bee-Keeping in California in 1873.—The *Semi-Tropic California* gives the following as a scrap of history on bee-keeping in that State :

In November, 1873, forty members of the Los Angeles County Bee-keepers' Association owned 1,406 hives of bees, which produced for the season, 68,268 pounds of honey. The average price for the product of that year was 22½ cents, whether sold in San Francisco or other markets. The largest apiary was owned by Maloy & Stone, and numbered 257 hives, and the smallest number reported was one hive owned by Mr. Orick. At that time but few of the bee-keepers of the county were acquainted with the better implements now in use by the bee-keeper of to-day, yet the results of the year's work was more satisfactory than in any subsequent year, so far as the financial result was concerned. At that time large tracts of land were lying uncultivated, and covered with honey-producing shrubs and plants, to-day those tracts are mainly under cultivation, either in orchard, vineyard or grain. The grain field, except corn, yields no nectar, and the bee-keeper, if he wishes to succeed, must plant or cultivate such crops as will produce honey, if he expects to do as well as was done in 1873. The new markets opened up by recently constructed lines of railways, give promise of greater demand for our unrivaled honey. So far as quality is concerned, we can fairly compete with the world, and nature has given to Southern California the climatic conditions for successful bee-keeping. If thoughtful, careful industry is turned toward the business, there is every reason to believe that better results may be obtained than was achieved by the bee-keepers of this country in 1873. It would be well for every bee owner to keep a careful account of this year's product of honey, the number of hives of bees owned by them, and the price obtained per pound for honey this year, and report the results to the Association at our November meeting.

The Objects of Fairs.—An exchange makes the following remarks on this subject :

The true position of fairs is schools of instruction. It is not enough that one may grow a better crop than another, but that he may instruct others how to obtain similar results. The object of exhibition is not merely to get a prize, but to incite others to good works. If one has grown a fine animal, a large crop, or made a valuable piece of machinery, he has had his reward already, and the object of exhibition is to show others what may be done and teach them how to do it. Especially can fairs become schools for the instruction of youth; they there learn to observe, and at sight to classify the various breeds of animals, becoming familiar with the characteristics of each, and their valuable qualities.

CORRESPONDENCE

For the American Bee Journal
Progressive Transferring.

JAMES HEDDON.

I was a little surprised at reading two articles in the last issue, from two of our leading correspondents, both giving directions for transferring bees, the same as has been given over and over again, in bee books and papers for the past 25 years.

Have we not progressed any? Is there no better method of getting colonies out of rejected hives, into those of our choice? I think there is.

Mr. Hutchinson says: "Pry off the side of the hive, cutting the nails, if necessary." Now, I would not do this at all, till all the bees and brood were out of it, but whenever I did do it, I would do so this way: The grain of the boards nearly always runs up and down, and all you have to do is to split off about 1 inch of each of the side boards that are nailed to the other two boards, taking away the part that the nails go through, and if the combs are previously loosened, the one side will nearly fall down. You can, on this plan, cut out the corner of most any box hive, and then cut the combs from the sides of the hive, and split these sides up into kindling wood as you go along, which gives you free access to the combs as you advance. It is so much easier, quicker and quieter a process than to "pry or cut the nails."

But I do not want any combs that have been fastened into frames by the use of "thorns, rubbers, sticks, wires," etc. I have transferred many hundred colonies, and have bought quite a number transferred by others (among them some of our most successful and skillful apiarists). I have examined transferred colonies in other apiaries where I was visiting, and I will tell you again, that I do not want any transferred combs in my yard.

True, once in a while we meet with a comb that is in perfect shape to fill our frame with choice, all worker cells, but such are the exceptions to the rule. I believe that, on an average, transferred combs are as much behind those naturally built in empty V guided frames, as these latter are behind those drawn from worker foundation, in full sheets and on wires.

When I transfer, I put 8 of these wired frames of foundation into my Langstroth hive, and with said hive and drum-box and smoker in hand, I approach the "old gum" and drive a prime swarm and the queen into this hive, which is a hive of beautiful combs 48 hours later.

After 21 days, the worker brood is all hatched and a new queen just begun to lay in the old gum. Now I can drive again, into another just such hive, or I can unite with my first drive, piling up the surplus soon, as I

please, whether I desire increase or not. In either case the forced queen, reared in the depleted "gum," should be killed, and if increase is the order of the day, a new queen from some other source is substituted for the second drive. Then is the time to do your splitting open of the "old gum," and you have some first class kindling wood, a nice lot of extracted honey (after you empty the old combs), and some comb to melt up into wax for more comb foundation.

Once try this plan, and you will see here, too, that new inventions suggest new and improved methods. Pure comb foundation, always a great boon, and now a staple, not only aids the bees in supplying their costliest substance, but it aids the bee-keeper in getting his combs straight, and more of them, in less time, getting his surplus combs perfect, controlling the blood of his drones, and consequently, queens and workers, besides revolutionizing the process of transferring.

Dowagiac, Mich., July 4, 1882.

Farmers' Home Journal.

How I Introduce Queens.

G. W. DEMAREE.

To introduce queens there are but two methods employed that differ materially. One of these methods is to cage the queen to be introduced, and to place the cage (wire-cloth) down right on the frames over the cluster of bees and cover the bees, cage and all, with the bee quilt, and let them alone forty-eight hours, then turn up the quilt till the cage is exposed to view; now draw out the sliding door and let the queen run out among the bees. Keep your eye on her, and if she is permitted to run down among the bees without being molested, close up the hive and wait fifteen or twenty minutes, then open the hive gently and look up the queen. If the bees are not ready to accept her, you will find her imprisoned in a ball of bees, generally on the bottom board. This we call "balling the queen." Don't be nervous or in too big a hurry; just take a large spoon and dip up the ball of bees and turn them out into a pan of water. This will cause them to release her, and set them to swimming for life. Pick out the queen by catching her wings between the thumb and finger. She *positively will not sting*. Never take hold of the queen by the abdomen, as you may injure her.

Now, return her to the cage and place it back just as before, and leave it twenty-four hours and try them again, and so on till she is accepted. She will generally be accepted without all this trouble, but not always. The queen will generally begin to lay in one or two days after she is accepted by the bees, and after she begins to lay she is as safe as if she had been raised in the hive. For this reason I keep a watch over her till she has deposited her first eggs.

The other method is to cage the queen on a comb taken from the brood nest. The comb is taken out and all the bees brushed off of it. The

queen is then placed on the surface of the comb, and an opened cage with thin, sharp edges placed over her and pressed slightly into the comb, thus imprisoning the queen. The comb is then hung back in its place. The bees will generally cut her out and accept her while all is undisturbed and quiet in the hive. If they fail, however, to liberate her in forty-eight hours, the comb should be lifted out and a partial opening made with the point of a knife under the edge of the cage. The inquisitive little subjects will see the point, and will proceed to liberate the queen.

As a modification of the above methods, I make the sliding door of my cages so that they will project above the bottom, or, rather, the top, when the cage sets wire-cloth down, and let this projecting sliding door pass up through a slit made with the point of a knife in the quilt, so that I can draw it out and thus liberate the queen without the bees knowing it.

Drones and Their Functions.

DR. J. R. BAKER.

While I read everything published in the columns of the BEE JOURNAL, every week, and have done so ever since its first issue, and while I feel that it is indispensable to me because of its scientific and practicable instruction on the different questions having a bearing on apiculture, I have wondered a good deal why, among all your able contributors like Messrs. Heddon, Dadant, Doolittle, Clarke, Demaree, and a host of others, that there seemed to be not one to dissent from the unreasonable theory that drones have no use in the economy of the hive but to impregnate the queens.

The comments of the editor of the BEE JOURNAL on the question: "Drones—Are they Auxiliaries?" and the extract he used in connection therewith from the *British Bee Journal*, which appeared in the AMERICAN BEE JOURNAL of June 28, seemed to me to be well timed. I have been skeptical on the seeming almost universal belief of the use of drones, for a long time; but my tongue refused to utter my thoughts, and my pen declared it was too feeble to enter the arena with those of the champions in the ranks of apiarists who adhere to the old notion that drones are simply dead-beat libertines.

It seems marvelous to me that nature should implant so strongly in the workers and queens the instinct to raise hundreds of drones in each colony if their only function is the impregnation of the few queens proportionately raised in any colony or any apiary; and that, too, when it requires only one drone to impregnate a queen and when once impregnated she is always so, as long as she is of use.

I hope Prof. Cook and other able men in our ranks will give the matter of the function of drones a "new

hearing," for I verily believe that this big, jolly, musical inmate of the hive has been terribly slandered.

This has been rather a peculiar season in this latitude. A part of the time bees have just "boomed," and then the wet and cold would stop their work altogether. My bees are in better condition now than they were last year this time, and yet I harvested a large crop of comb honey last season. The weather has ceased to be cold, but it has been wet and cloudy without let up for near a week. I never saw so good a crop of white clover here as we have this summer, and when the sun shines for a few hours the bees gather honey very fast. We have a good deal of linden in this locality, and catnip, figwort, heartsease and numerous other honey-producing plants, the names of which I do not know, abound; but the champion of them all is the horsemint, *alias*, bee-mint, camphor weed, sand-mint, wild bergamot, etc. It is one of the very best of yielders; lasts from 4 to 6 weeks, and the honey gathered from it is of superior quality. It commences to bloom from July 5th to 10th; grows on very sandy land, and literally covers our roadsides, commons, and uncultivated fields. I wonder if it is the same plant that the Texas bee-keepers speak of as so valuable with them?

London Journal of Horticulture.

Prolonging the Life of the Queen Bee.

DR. DZIERZON.

The celebrated physician Hufeland wrote a book on the art of prolonging human life. But if there can be a question of prolonging human life artificially, we might certainly expect to be able to prolong the life of bees, the more so as their term of life is attained under varying conditions and at different times of the season. While they exhaust their strength and die in about six weeks during the busiest time in spring and summer, bees reared late in the summer and in autumn look as strong and young on their first appearance in spring after six months' rest during autumn and winter as if they had only just left their cells. What is applicable to bees in general must equally apply to the principal bee in the hive—the queen, and to her I shall chiefly refer in discussing the question of the duration of life and the possibility of prolonging it.

This question is as interesting as it is of practical importance. The case of so small an insect as a queen bee, which leaves her cell at the end of 16 days, and might possibly be fertile and capable of propagating the species at the end of three weeks, to live to the age of four to five years or more, and to be able during this time to produce offspring to the number of about 1,500,000, has probably no parallel in the entire range of nature. The question as to the duration of the queen's life and the possibility of prolonging it is of a highly practical im-

portance where the introduction of a new and superior race of bees depends on a valuable queen bee, obtained, perhaps, at considerable expense. When a bee-master has no isolated apiary it is difficult to keep a race pure until a considerable number of colonies have been formed, which send out drones in large numbers. A bee-keeper of no great experience will also find it difficult to determine with certainty whether the young queen of a colony has been impregnated by a drone of her own race, especially when races do not greatly differ in color.

In rearing queens, bee-masters, therefore, as a matter of precaution, will always fall back upon the brood from the parent colony in the second, and even, perhaps, in the third year, and are anxious of course to preserve the old queen as long as possible.

The question as to whether and how the life of a queen may be prolonged, was suggested to me by a dispute which had arisen between Miss Titz of Lasswitz, a great Silesian bee-keeper, and a bee-master by the name of St.

Miss Titz, on the occasion of the Neissen meeting, showed some friends who paid a visit to her apiary, in addition to a number of curious objects, an Italian queen bee, which she stated to be six years old, adding that she had succeeded in keeping this particularly pure and valuable queen alive so long by keeping her from excessive breeding. Mr. St. was of a different opinion, maintaining that there was no doubt a young queen had been raised unnoticed, as, according to his long experience, the life of an Italian queen never exceeded three years. He further asserted that the eggs became developed in the ovary of the queen and pass involuntarily, it being impossible for any influence to be exerted on the ovary.

In my opinion Mr. St. is wrong on both points. Although six years and one month is certainly an unusually great age for a queen bee, it is not by any means impossible and incredible that she might attain that age.

Some years ago I myself had a queen which, though more than five years old, was still very active, and I have no doubt would have lived another year if I had not destroyed her. Sig. Irusehka assured me that he had had a queen which lived to the age of seven years. It appears, therefore, quite credible that the queen referred to lived to the age of six years, the more so as she was a fine and vigorous specimen, and was carefully kept from over-exerting herself.

There is no doubt whatever that it is feasible and in the power of the bee-keeper at one time to stimulate the queen to excessive breeding, and at another time to induce her to deposit few eggs or none at all. By keeping the entire colony quiet in spring as long as possible, premature breeding is prevented, and the queen does not waste her strength.

When once she has commenced laying eggs she knows perfectly well how to accommodate herself to circumstances and the requirements of the

colony as regards the number of eggs to be deposited. According to the quantity and quality of the food she has taken she produces and deposits as many eggs as the colony is capable of attending to. It is certain that the queen is also able to keep a mature egg back in the ovary for some time without injury to herself or to the egg, as she is often obliged to examine a number of cells before she finds one that is empty and suitable, and in which she deposits the eggs, which undoubtedly would have been deposited into the first cell examined by the queen if she had found it empty and otherwise suitable. A much larger number of eggs will therefore in the same time be deposited in an empty comb inserted into the brood nest, because on an empty comb she can pass from cell to cell, there being no need for her to examine any cell nor to pass any over. A comb containing 6,000 cells is often found full of eggs at the end of two days, which shows that a vigorous queen is capable of laying as many as 3,000 eggs a day. We might be inclined to consider that the queen was over-exerting herself at that rate, and in a certain sense we should be correct; but we must not for a moment suppose that such productiveness would fatigue or inconvenience the queen. She evidently discharges with energy and pleasure her duty to increase the population of her hive as much as possible, and the less hindrance she experiences in doing so the better she will be. The most vigorous queens, therefore, are always to be found in the largest colonies, where of course the number of eggs deposited is largest. Where the queen is obliged to discontinue laying eggs on account of the stock having but a small population fatal consequences seem to result.

In former years before the Italian bees had become acclimatized, which has now been fully accomplished after 29 years' manipulation, I frequently experienced the loss of Italian queens in weak colonies after they had commenced depositing eggs in spring, but were compelled to discontinue on a sudden change in the weather, because the bees were obliged to crowd together again into a thick cluster. The abdomen of the queen in such cases being found very much distended, the conclusion was forced upon me that the impossibility of depositing the eggs formed in the ovary had proved fatal to the queens.

This unpleasant occurrence has never happened in any of my strong colonies, undoubtedly because the queen was always able to deposit eggs regularly, even during cold weather. But the fact that queens in strong colonies are always in first-rate condition at the time of their greatest prolificness does not exclude the possibility, or even probability, of their becoming exhausted sooner, or dying prematurely. Professional physiologists alone will be able to answer the question as to whether a queen bee is only capable of laying a definite number of eggs, or whether eggs are produced indefinitely as long as the vital power of the queen lasts. Prac-

tically it might perhaps be decided by ascertaining how long the queen lives in Australia, where she lays eggs continuously, because nature reproduces flowers there without interruption throughout the year; and how long she lives in our own country, where the activity of the bees, and consequently the activity of the queen, is dormant for about five months of the year.

No bee-master is likely to think of economising the strength of ordinary queens. Every one is anxious that the workers should be as industrious and the queen as prolific as possible. But if it is a matter of keeping some especially valuable queens alive as long as possible, and the question arises as to whether it is possible to prolong their life artificially, we are obliged to answer in the affirmative.

Carlsmarkt, Germany, Feb. 22, 1882.

For the American Bee Journal.

How to Fasten Foundation, etc.

J. V. CALDWELL.

The utility of comb foundation depends to a large degree on the way it is fastened in the frames and honey boxes. I have not yet noticed any plan I like as well as the one I have been using the past two seasons, and which, if the directions are followed just as I give them, will be satisfactory to the user.

Go to your blacksmith and get him to make you a pair of good strong tongs, not too heavy or they will be hard to handle, and yet heavy enough to insure a good grip. The ends or gripping part should be made in the form of a T, and should be about four inches long on the gripping end. I have them made long enough to go inside of the 1-lb section. They should have on the ends two screw holes, that is, two on each side to take about $\frac{3}{8}$ inch screws. These tongs are to have wooden jaws. Take two pieces of hard wood as long as the jaws, and about $\frac{3}{8}$ inch thick, by $1\frac{1}{4}$ inches wide, and having made them smooth screw them on the inside of the jaws of the tongs. Your tongs must be made wide enough to take these in and have them pinch tight on the ends. The pinching parts should be rounded a little to prevent cutting the wax.

Now, then, to use, get out a block as large as your section inside, and $\frac{3}{8}$ inch thick, this is supposing your section is 2 inches wide, tack this block on your bench, lay your section over it, and you are ready to begin work. Lay your section with top side toward you, lay in your foundation with the edge next to you turned up about $\frac{1}{4}$ inch; it should be quite warm so it will mash to the wood. Your tongs must be kept setting in some soft water to prevent them from sticking and pulling the foundation loose.

Set your tongs in the section and pinch hard and your work is done. I should say also your block in the section must be kept wet, but do not get any water on the part of the section you are fastening foundation to. I

use these pincers to fasten the heavy foundation in the brood frames; in this case have your board to go inside of the frame made as large as the inside measure of the frame and $\frac{3}{8}$ inch thick, or a little thicker if your frame is a full inch wide. Fasten the board down and lay your frame over it; lay in your sheet of foundation with the edge next you turned up as before; the ends, also, should be turned up against the end bars of the frame $\frac{1}{4}$ inch; press down neatly all around, take one grasp with the pincers on the middle of the top-bar, then pinch on the end bars, then push on top-bar, lift the frame out, and if you have the job properly done, your sheet will hang perfectly true and straight, and cannot be pulled loose without tearing the foundation. If your pincers get sticky, use a little lye in the water.

Mr. Heddon has seen fit to denominate the Dunham machine as one of the difficult ones to use, claiming it to be a very sticky machine. Well, I must say he is either somewhat prejudiced, or does not quite understand using it. I say the Dunham is as easy to use as a common clothes wringer, provided, of course, you know how to make good foundation. We think nothing of running all day without spoiling a single sheet, and all perfect, well printed sheets. I think Mr. Heddon said about 75 lbs. was all 2 hands could print on the Dunham in one day. Well, my partner and myself ran through 150 lbs. in one day, and I went to the village, about a mile away, in the bargain.

On the Vandervort machine, on account of the sheets being narrower and very thin, we consider 50 lbs. a day's work. This of course, does not include the dipping of the sheets, which would make another article; but I will only say we dip by a plan far more speedy than any of the plans yet given.

Cambridge, Ill.

Our Home Science Gossip.

The History and Antiquity of the Bee.

A. F. MOON.

The magnitude of scientific apiculture possesses a national life.

Were we to go back no further than the last century and show the wonderful developments made in this one branch, its profits, incomes, and the immense increase of colonies, and the revenue that it brings to this country, it would by far excel any other rural branch in point of profit from the capital invested.

The history and workings of the honey-bee are wonderful indeed, affording man a great and beautiful study, as well as a good income for the time and labor given. From historical facts we are led to believe that the honey-bee has been a companion of man from the earliest civilization. Ancient records speak of them and their existence on the islands and coasts of the Mediterranean, also on the Black Seas. They were kept largely in the interior of

the continents of Europe, Asia, and Africa. We learn from the military expeditions of the ancients, that they were by them kept, and extended into Egypt, Syria, Italy, Germany, Greece, Sicily, and other countries. They are spoken of as being indigenous to those countries, and in no one instance have we seen in the annals of antiquity that the honey bee has been transferred from one country to another by human intervention or instrumentality.

Scientists have given this one subject deep thought. They have been able to trace the little busy bee far back in the dim dawns of history, particularly in the era of the "Sagas." We are assured of the existence of the honey bee and its fruit as being so invigorating. The bee marked the golden age in the mythology of the Egyptians, Greeks, and Romans, and not only with these did the honey bee occupy a very distinguished place, but it is significant of the intimate relations which must have existed at one period between the earliest civilized nations, and we find that it was the common faith of these people that the honey bee originated from the putrefying carcasses of oxen, and that the name of the Sacred Bull of the Egyptians is perpetuated in the Latin word *apis*.

The first traces of bee culture are found almost everywhere back in the Saga periods. Thus in Spain the Curetes dwelling near Tartess ascribed the invention of the art of procuring honey to their ancient fabulous King Gargoris, while the Greeks and Romans attributed this merit, as well as that of first placing bees in prepared habitations, and domesticating them, to their gods or the descendants of their fancied deities.

Farther back in prehistoric times, from which no written records, names or dates survive, there remain weapons, implements, and building materials, garments, and personal and beautiful ornaments, human bones, and many other things, all furnishing proof of civilization among the inhabitants, also unmistakable evidences or indications that the honey bee was largely cultivated. It is claimed that further back in the abyss of time, in those remote eras in the progress of the development of the earth, which preceded the elevation of the Alps, the various remains of fossil organisms, demonstrate the fact that a tropical climate once prevailed in what is now called Switzerland.

Petrified remains of various plants and insects, the enemies of bees and other things belonging to the animal kingdom, also a fossil honey was found. This occurred in the insect bearing stratum of the quarries of Oeningen; it was recognized by some of the professors as an *apis*, establishing the fact that the honey bee existed geologically as an inhabitant of our earth ages before the appearance of man, no doubt living in peace and harmony with their mother queen, guarding and protecting their stores, laying up their food for a time when needed. Unlike many other things,

no change has been made. They work without rules, plumbs, or guides. Since our first written history of the bee, its progress has been remarkable. Indeed Aristotle, Cato, Virgil, Pliny, Columella, and many more, wrote interesting accounts of the honey bee, of its cleanliness and activity, economy, etc.

Honey was spoken of as the food of the ancients; the tables of Romans, Grecians, and Persians were richly supplied with honey. History informs us that the Romans and Grecians brought honey as an offering to their gods, and the animals that were sacrificed were sprinkled with honey. The Israelites showed the wealth of the land of Canaan by declaring that it flowed with milk and honey.

We gather many interesting facts from the ancient apiarists' artificial queen having extended herself throughout upper Lasaita, Bohemia, Bavaria, Silesia, and other portions of Germany. Even Poland engaged in the business. Wheeler's "Journey into Greece" is quite interesting, describing their method of keeping their hives, which were made principally of willows. Wildman's account of bees, 1768, which was copied from a journey into Greece, affords many interesting facts connected with both bees and honey. When we trace this wonderful insect down to the present time, counting her millions of revenue to this country, we are forced to the conclusion that apiculture possesses a "national life." It is truly a great enterprise; world-wide in its branches; one of the grandest fields of industry that philosophers have ever entered. No one nation can ever enjoy it alone.

Rome, Ga.

For the American Bee Journal.

The Barberry Shrub Again.

PROF. T. J. BURRILL.

I have read with interest Mr. Maxwell's remarks in the BEE JOURNAL of June 28th, concerning the barberry and a disease of his peach trees. Now, it so happens that this peach tree disease is well known to me (see Transactions Illinois State Horticultural Society, 1878, page 157), as is the literature upon the subject of the rust of wheat and the barberry. While there is good reason to suppose that the fungus known as wheat rust (*Puccinia graminis*) does pass a kind of alternation of growth at times on the barberry, there is nothing but Mr. Maxwell's observation to connect this or any other fungus inhabiting the bush in question with that causing the disease mentioned of the peach tree. Further, the fungus which covers the peach leaves "with a sort of mildew," and causes them to become "turned white, and crimped and twisted," with "a leprous appearance," lives only on the peach tree, undergoing there its full development. It is a perennial parasite, but develops more or less on a tree once affected according to internal and external conditions.

I am so certain about this that I do not hesitate to say Mr. Maxwell's facts must be explained in some other way, and my certainty comes from a rather intimate acquaintance with the objects themselves, not from botanical reading.

As to wheat rust from the spores of a parasitic fungus on the barberry, a careful German investigator believed he had full proofs in the affirmative, but it is not hard to state that the wheat rust fungus in our country is capable of undergoing complete development without the barberry.

Some recent experiments also throw doubt as to whether there is, after all, any real connection between the two. Such things need a good microscope and a pains-taking manipulation of it.

Illinois Industrial University.

Translated from Bienenzeitung by A. Neighbour.

International Congress at Milan, Italy.

DR. FRIEDRICH KUHLL.

The congress took place in the splendidly decorated hall of the Technical Institute, No. 4, Piazza Cavour, on the 15th, 16th and 17th September last, and was attended by about 300 bee-keepers. The transactions at Milan did not commence until 8 o'clock in the evening, continuing till after midnight, while the day time was occupied in visiting the Grand National Exhibition and the objects of interest in the city, and in making excursions into the surrounding lovely country, and visiting a few of the largest apiaries.

Mr. Edward Bertrand, editor of *L'Apiculteur*, Nyon, Switzerland, commenced his very interesting discourse on "breeding queens" by saying that this was a particularly fit subject of discussion for the Congress, Italy being the country from which beautiful queens are dispatched to all parts of the world. The rearing of queens for export, he continued, had become quite a branch of industry in Italy, and the Italian bee-masters ought to endeavor to maintain the good name of their queens; it would further be necessary, he remarked, that those who procure queens for a foreign country should be fully convinced that the queens they receive from Italy really possess all the good qualities which will secure pure offspring. He had unfortunately experienced in the last few years that some queens which he had obtained from Italy died in the first year, while other queens turned out not to be very prolific, so that their colonies yielded but poor returns. He added that similar complaints had been made in Germany and America, and many bee-keepers, therefore, justly preferred those queens of the Italian race which had not been reared in Italy.

Mr. Bertrand considers it very important, in order to rear serviceable queens, that—1. The parents, both queens and drones, should be selected. 2. There should be a large number of young bees in the hives used

for breeding, because young bees are very apt to supply the larvæ with plenty of food. 3. There should be a large population in a colony in which queens are to be reared. He objects to queen-breeding in small colonies, because it would produce queens of a weak constitution, which on this account would not be very fertile. While on this subject the speaker mentioned that in Germany the great masters of bee-keeping, Dr. Dzierzon, Gravenhorst, and Dathe, first allow the royal cells to be sealed in colonies with large populations, and afterwards proceed to make small colonies in which to allow the queens to hatch. 4. The queen should only be allowed to breed during the time when the bees are able to obtain a good supply of honey. He and other bee-masters of his acquaintance had frequently observed that queens reared early in spring or in autumn deposited but few eggs and often died after the first year. He did not believe that feeding was a remedy in the absence of the other conditions, viz: warm weather and a plentiful supply of pollen. 5. Those larvæ which are chosen by the workers for rearing queens should not be more than a day old, in order that they may receive a plentiful supply of royal jelly as long as possible.

The discourse, which lasted over an hour, was followed by a debate of considerable length. I will only mention that Count Barbo expressed the opinion that Italian queens sent to foreign countries often do not give the desired results because of the frequently great difference in the climate and vegetation as compared with Italy. Prof. Sartori observed that Italian queens formerly brought a very good price in foreign countries, but their present market value was so low that breeders in Italy could no longer give the same careful attention to the rearing of queens they had formerly done.

Dr. Dubini was of opinion that in order to obtain good queens in future it is only necessary to let the number of young bees be in the right proportion to the brood that has to be attended to, and that queens may, without disadvantage, be reared by small colonies if the latter are allowed to have but a small number of brood cells. Prof. Sartori expressed himself in the same sense. Count Barbo proposed that a few queens partly reared in large colonies and partly by small communities, should be sent to Mr. Bertrand by the Italian Central Association of Bee-Keepers, and that he should be requested to note any differences as to vigor and fertility of the queens to be forwarded to him. Mr. Bertrand accepted this offer on condition that the queens to be sent to him should merely be numbered in order that he himself might not know which of them had been reared in large hives and which in small ones.

Mr. Bertrand read a letter from Mr. Newman, the editor of the AMERICAN BEE JOURNAL of Chicago, in which the latter requests the Italian bee-keepers to devote the greatest care to the rearing of queens.

The reading of this paper was followed by a discussion, during which Mr. F. Lancia de Broto, of Palermo, mentioned that the Sicilian bees, being a cross between the Ligurian and Egyptian races, deserve particular notice on account of their many good qualities.

Dr. Dubini spoke on the subject of hives with movable and immovable crownboards, and came to the conclusion that bees are quite as comfortable in the former as in the latter, in proof of which he referred to the American, English and Swiss beekeepers, who use chiefly hives with movable crownboard. In Italy, he said, the majority of hives were certainly made after the model of Baron von Berlepsch; still Dubini hives with immovable crownboard were also very much used.

Count Barbo reminded the meeting that the German beekeepers had almost entirely discontinued using hives with movable crownboard, because they found that these hives did not retain the heat so well as hives with fixed crownboard, and that breeding in them did not progress so rapidly.

Dr. Bianchetti recommended a hive of his own construction with movable floorboard and crownboard.

Several speakers expressed themselves against hives with movable crownboard, chiefly because they were of opinion that the chilling of the brood, especially in spring, might easily cause foul brood.

Mr. Marengi, of Bergamo, introduced the question, "Is it possible that combs which have been subjected to the fumes of brimstone may originate foul brood?" He related it had been observed in different apiaries that combs which had been exposed to the fumes of brimstone, and were afterwards given to healthy colonies, had, later in the season, contained cells infected with foul brood, while the brood in other combs not subjected to fumigation by brimstone which were inserted at the same time had remained in a healthy state. Mr. Locatelli, pharmaceutical chemist, did not think that exposure of the combs to the fumes of sulphur would cause foul brood, sulphurous acid being a disinfectant. He stated that he was in the habit of subjecting all his combs to the fumes of sulphur, and had never found it do any harm.

Before the meeting separated a committee was appointed to draw up a report as to the best means of improving the management of bees in Italy, and of gradually putting an end to the objectionable practice of killing bees by brimstone. The next Italian congress is to be held at Bologna in 1884.

Germany.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7057—that being our telephone number.

Alsacian Bienen Zeuchter.

Italian Bees as Robbers.

The following discussion on this subject took place at the late meeting of the "Societe d'Apiculture d'Alsace-Lorraine":

Mr. Bauer said: Heretofore I have not kept Italian bees, owing to their propensity for robbing, but as I am now the only apiarist in our village, and consequently no one else would suffer from them, I shall commence Italianizing my apiary next spring. Will I have trouble with them, for the reason I have mentioned?

Mr. Zwilling—The instinct to gather honey, which the Creator has given every race of bees, induces them to nibble and rob whenever they find an opportunity either by the neglect of the apiculturist, irregular feeding, or queenless colonies. The Italian bee possesses a greater instinct to gather honey than the inferior races of bees, and consequently an increased desire to rob. But it does not follow that no other race of bees could exist in their immediate vicinity without being robbed by them. For more than 10 years I have kept Italian and black bees in the same apiary, and have never discovered the Italians robbing their neighbors.

Mr. Bauer—Aside from the desire to rob, the Italian bee is said to possess other bad qualities, and in spring the superseding of queens becomes an epidemic.

Mr. Zwilling—I have discovered no greater mortality among my Italian queens than any others. We often hear the complaints of beginners, that their yellow queens are dead, and that they will hereafter keep only the Germans. This usually happens through mismanagement of the apiarist, and is not the fault of the bees. It is a fact that some beginners open their hives as early as February, and pull out comb after comb for the purpose of investigation, and by this careless exposure the queens are often destroyed, or the worker bees may have too closely surrounded the queen and smothered her.

Mr. Bauer—Is it true that the Italians get foul brood easier than other races?

Mr. Zwilling—It is very often said that foul brood does not exist in Italy at all. Foul brood germinates in weak colonies, where the numbers are insufficient to keep the brood warm. This happens frequently among the Italian bees, where the apiarist devotes his attention to the rearing of queens instead of worker brood.

Mr. Bauer—Does the Italian go into winter quarters in a weaker condition, and therefore sustains greater loss than any other race?

Mr. Zwilling—In countries where the autumn bloom is very limited, they will stop breeding earlier than the Germans, and, consequently, will not be as strong, but where there is plenty of late bloom, they winter equally well with any other race of bees. To those who keep bees for increase, I would recommend the Krainer bees. These queens are very prolific, and will continue breeding even during a scarcity of bloom, but the stores of honey suffer in consequence.

SELECTIONS FROM OUR LETTER BOX

A Bee House.—Our bees came out all right this spring. We have had one new swarm up to this time. One came out and settled in a large tree; we got them down and hived them, and when putting them in their place they all came out and went back to the old hive. Do not know the reason, unless they did not have a queen. They have just begun to work in the boxes, and are very strong. I think it is owing to the weather, which has been muggy and rainy that they do not swarm. We had a heavy rain last week which spoiled all the corn on the bottom lands; with that exception the crops are looking fine. Clover is abundant here, and lots of basswood, and I cannot see why the honey harvest will not be good this year. No bees around here only my 14 colonies. The following is a description of our bee houses summer and winter. Our winter house is 16 feet long by 9 wide and 8 high, frame, like any house, only ceiled up inside with 1 inch matched boards, under that building-paper and then the siding, which leaves an almost dead-air space. The floor is of common boards, then paper, then flooring; the top is ceiled, papered, and roofed, leaving a ventilator. Our summer bee house is simply a long shed 5 feet in front, 4 behind, and boarded up and lathed, with a row of grape vines 5 feet high in front, running on wires. We use our winter bee house for a shop.

S. T. WOOLWORTH.

Gratiot, Wis., June 30, 1882.

Honey from Red Clover.—My bees are now gathering honey from white and red clover. From appearances, they are doing as well on the latter as on the former. O. H. TOWNSEND.

Kalamazoo, Mich., July 3, 1882.

Deserted the Hive.—I had a swarm come out four days ago; I clipped the queen's wing, but forgot to put the cloth over the frames. I looked in yesterday and found the bees in the top of the hive, and building comb from the peak of the roof. I removed the bees and comb from the roof, and put on the cloth. Instead of going into the hive, the bees swarmed out and clustered in a tree, but soon came back into the hive. I found to-day that most of the bees had left and gone into another hive, not the parent colony. The clipped queen and a handful of bees remained in the hive. The forsaken hive had been painted about 10 days. What is the trouble, and what should be done? Please answer in the BEE JOURNAL.

CLARK A. MONTAGUE.

Traverse City, Mich., June 29, 1882.

[The trouble originated in removing the comb after the queen had deposited eggs in it. Had you given them a frame of brood and eggs after removing them from the roof, most likely they would have remained. There is no remedy now but to strengthen the few remaining bees with hatching brood from the parent colony, if you wish to preserve the queen, or return her whence she came.—ED.]

Subjects Anticipated.—I have been looking for a change in the weather. It rains every other day, and to make up for the dry day it rains twice the next, so the bees have but little time to work, and what honey is secreted is washed out by the heavy rains. We had a storm June 29, uprooting trees, blowing down barns, etc. The prospect is gloomy here—gloomy indeed. My bees have caught the swarming fever, notwithstanding the rain, and have increased from 33 to 74. I selected several subjects to write on, but when I get a new JOURNAL I find each subject discussed to my satisfaction, and much better than I could have done. I bid the BEE JOURNAL God speed in its onward career. G. W. ASHBY.

Valley Station, Ky., June 30, 1882.

Doing Better.—Bees are doing better since I last reported; swarming has begun in earnest. I extracted the first honey to-day. Owing to so much wet weather, the honey is very watery and thin. I never saw white clover so full of bloom. If the rains and cloudy weather would cease, I think the honey flow would be enormous. W. H. GRAVES.

Duncan, Ill., June 30, 1882.

A Hard Season.—I send you by this mail a sprig of flowers and a leaf from a tree which grows in my yard, and the only leaf or tree of the kind that I remember ever having seen. It has an army of flowers; many of the sprigs are 20 inches long, and the bunch of them together is enormous. I am very anxious to know what this tree is, as my bees live on it from morning

till night. I am a great lover of bees, though I know but little about them. I have 5 colonies in Langstroth hives, which are quite a curiosity in this county, as there are none of them here with us. The season is a very hard one to the industrious little pets. Mine are storing but little honey. Long life to the BEE JOURNAL. It is a perfect gem to a lover of bees.

J. C. WILSON.

Ridgeland, S. C., June 27, 1882.

[This beautiful tree is a native of China or Japan, in both of which countries it is now grown for shade and ornament. It is sparingly cultivated in several localities of our Southern States, but probably is not hardy at the North. Linnæus named the trees *Sterculia platanifolia*, from the resemblance of its leaves to those of the sycamore or plane tree, mostly on account of their large size. As a honey plant it is interesting to note that it is a near relative of the linden or basswood, everywhere so well known for the abundance and fine quality of its nectar, as well as for the delightful fragrance of its flowers. It is worth while, also, to bear in mind that there is an intimate connection between fragrance, nectar, and insects. Bees evidently possess a decided sense of smell and may thus be able to find a linden in full bloom from a considerable distance. I do not know, but, from the appearance of the flower and the nectar it produces, I hazard the inference that this *Sterculia* is, when in bloom, highly scented. Perhaps, after all, it is not so much of a hazard, for *Sterculius* was the name of a Roman god, so called (from *stercus*, manure) because he taught the agriculturists the use of manure. In this case, we may suppose Linnæus had before him a species of the genus not noted for the pleasantness of its odor, though the latter may have been sufficiently pronounced.

The structure of the flower of this, in so many ways peculiar, tree is evidently marvellously adapted to the visits of insects and their work in cross fertilization. The nectar at the bottom of the calyx-cup is protected from small insects by a dense plush of hairs, so that such insects as might creep under without touching the pollen bearers, and so plunder the sweet store without recompense to the plant, are efficiently excluded, while a larger, long-tongued guest is privileged to help itself (herself?) by pushing aside the fringe of short, matted hairs. The stamens and pistil are borne on a peculiar and altogether

uncommon prolongation of the axis or stem rising well above the nectiferous cup of the calyx. The pollen sacs themselves (anthers) are densely crowded upon the upper or outer end of this prolonged axis, which is itself here shaped into a cup at the bottom of which the five-parted pistil is found. Here again I cannot be sure from the specimen at hand, but there probably is secreted in this second cup enticing nectar, hid away and hardly accessible to many insects, though quite so to some invited favorites. To get it, however, an insect's proboscis must be effectually smeared with the adhesive pollen, to be carried away to another flower.

Has any attention been heretofore given to the *Sterculia* as a honey producer?—T. J. BURRILL.

It has not, that we are aware of.—ED.]

Doing Excellently.—The honey yield is good here this season. I have taken 134 lbs. of comb honey, in one-pound boxes up to this date. If the season continues as favorable as it has been the past six weeks, I will get over 300 lbs. of comb honey per colony. W. S. CAUTHEN.

Pleasant Hill, S. C., June 24, 1882.

From a Beginner.—I have taken the BEE JOURNAL for 6 months, and have obtained some valuable information from it. My father has had bees for 3 years before this, but kept them in boxes, nail kegs, or anything that came handy, sometimes getting a little honey, and sometimes none. Last fall he brimstoned the bees in a nail keg, which I think was a cruel way to get honey, and it was a poor lot indeed, which set me to thinking there was a better way. I subscribed for the BEE JOURNAL, and now have 8 colonies in frame hives, from 4 old colonies in box hives. The first swarm came on May 20, during apple blooming. The first came out just before noon. I got them down from where they had clustered, and they were going into the hive nicely when another swarm came out and went in with them, filling the hive full; the next day I put on the sections to give them room, but soon found that would not do; one of the queens went up in them and went to laying. I captured her and put her with 3 of the frames and adhering bees in another hive. Bees have been doing well on white clover, of which there is any amount here. I have taken off some sections from the first colony, and more will be ready in 3 or 4 days, while the old colonies have not commenced storing surplus yet, they having swarmed too much. The weather has been very favorable here for bees the past two weeks. We have had showers occasionally to keep pasture in good condition. 1. Where can I get barberry seed, and at what price? 2. What kind of a plant is it in size,

and where should the seed be sown?
3. What is first quality basswood lumber, suitable for making hives, worth, sawed right thickness and at the saw-mill?
ALFRED GANDER.

Adrian, Mich., June 30, 1882.

[1 and 2. Some horticulturist will probably give you all the information desired regarding barberry shrubs.

3. We cannot give a definite answer. Write to any lumber dealer, giving dimensions of what you want, and quantity. We cannot recommend basswood for hives—pine and poplar or white-wood are better.—ED.]

Motherwort.—Inclosed find a plant on which my bees are working from early morning till late in the evening. It must contain a great deal of nectar, judging from the way they work on it. This is the only stalk in the neighborhood that I noticed. Please name it. Bees are doing splendidly on white clover, and basswood is opening a new field for them. I have counted 198 trees within half a mile of my apiary, and all full of buds just beginning to open. The heavy rains this spring and summer kept the bees back some, but now they are making up lost time. We had a storm accompanied with hail and rain, that damaged the crops a great deal, prostrating the grain and clover on the ground. No such storm has been known in this place.

JOHN W. STURWOLD.

Haymond, Ind., June 27, 1882.

ANOTHER.—I herewith inclose a piece of spike from a plant to ascertain the name. The spikes grow about a foot or more long, and are in bloom all summer into fall. The plant grows 4 to 5 feet high, and has very many branches covered with these spikes, and is the best honey plant I ever saw. It was brought here from Pennsylvania by Mr. Musgrave, who found it wild and scarce. Bees are doing well in this locality. There will be considerable buckwheat in bloom in a week or two.

J. S. McALLISTER.

Columbus, Neb., July 3, 1882.

[The plants referred to are motherwort. It is needless for us to repeat that it is a most excellent honey plant, and worthy of more attention than it generally receives.—ED.]

Prospect Excellent.—I had 70 colonies this spring to commence with, all in good condition, with boxes on them all, nearly completed, and only awaiting capping, but no swarms yet, nor do I want any for 10 days yet. I never saw a season any better than the present one. White clover is abundant everywhere, and the bees are working on red clover just as much as they do on white clover. I hope all bee-keepers will try and keep the price of honey up, so that we can make up for what we lost last year.

F. G. KINNEY.

Bristol, Ind., June 30, 1882.

Captured While Laying.—I send herewith a fertile worker. On May 6th I removed from a vigorous Italian colony 4 frames of brood for the purpose of rearing some queens. The weather not being favorable, they produced but 3 cells, whereas they should have built 6 or 8. On the 10th day, or the 16th, we found two cells that contained young queens, and one empty cell; removed the two cells containing queens, destroying one that did not appear perfect, and placed the other in a nucleus. This hatched and proved to be a fine queen. After satisfying ourselves that the colony was still without a queen, and that the empty cell had never been occupied, we gave them a frame of brood filled with eggs and larvæ. I examined them on the second day, but found no evidence of queen cells. The eggs are hatched and the brood finely capped over. Making several careful searches for the cause of this strange behavior, our labor was rewarded on the 21st of June by finding this fertile worker in the very act of laying. She had deposited eggs in one comb over a space of about 4 inches, in worker cells. The bees are now extending the cells out, or making drone comb of them. The bees showed her the same respect by turning their heads to her and making room for her over the comb. She showed all the peculiarities of a young queen—frisky, etc. The prospect for a good honey season in this section is very discouraging; too much rain. I have extracted 3 gallons from 5 colonies. Can hardly get bees to start queen cells. W. A. BRADFORD.

Butler, Ky., June 26, 1882.

[The fertile worker and attendant bees arrived safely. With the exception of a more tapering waist, and more glossy abdomen, we would not have recognized her from the other bees, had her wing not been clipped. In nearly every Italian colony there are plenty of old bees presenting all the characteristics of this one. We give on page 441 of this issue, a very interesting letter from Mr. P. L. Viallon, relating to fertile workers, and Prof. Cook's instructive dissection and examination of the same with the microscope.—ED.]

Bees are Doing Finely.—Bees are doing finely here this season. I have just taken off 48 pounds each from some of my best colonies, white clover honey, stored in one-pound sections of the Forncrook style. Take the season so far, I think it ahead of any for several years for honey gathering.

E. W. WALES.

Disco, Mich.

Cold Wave.—This last wave of cold has stopped the clover honey flow; basswood is not yet in bloom, but will be in a few days. It is a pretty poor season here, so far.

JAMES HEDDON.

Dowagiac, Mich., July 5, 1882.

A New Clover.—Enclosed find stalks and flowers of a plant, which please give name and value as a honey plant; also, if good as forage for cattle. The plant grows and looks like Alsike clover, the blossom is pure white, resembling white clover, excepting much larger than either Alsike or white clover. It is evidently a variety of clover, but have never seen any of it before. It is in bloom considerably earlier than white clover. I found it growing in a field, but cannot account for its appearance there. Answer in BEE JOURNAL.

Altamont, Ill. JERRY THOMAS.

[A similar specimen, but not so large, was sent us last week by H. Besse, Delaware, O., see page 427. As the Alsike clover itself is said to be a hybrid, matured and fixed in Sweden, so these specimens may be of the same character, and this is more than probable, from the fact that Mr. Besse's is reproducing itself, and extending its area. As to its value for pasturage we cannot speak positively, but can see no reason why it should not be desirable, perhaps very superior. At all events, you owe it to yourself, as well as to community, to extend its cultivation till satisfied of its worth. It may, possibly, in the future, revolutionize our pasturage for cattle, sheep, etc., and our forage for bees. Certainly, its earliness of bloom will be a great recommendation of itself, if it should prove adapted to the bees.—ED.]

Honey Prospects in Ohio.—Bees in this vicinity have done but little in the way of honey gathering, until within a few days. Prospects for swarming are greater than for several years, even after being somewhat lessened by the damage done to fruit bloom in early spring. Many impoverished colonies were lost during the cold spell, but those that were properly fed, or lived through on their own stores, are likely to pay a good profit at the end of the season.

R. A. MOLLYNEAUX.

New Richmond, O., June 29, 1882.

Not One Pound Yet.—Bees are strong; swarming profuse; no honey; not one pound taken yet; weather very warm; lots of rain; linden just in bloom; fear we will have no harvest, but living in hope that the bees will fill up for winter. My bees have never worked a whole day since last April; hope somebody will get some honey.

C. H. DEANE.

Mortonsville, Ky., June 27, 1882.

Mercury at 50°.—Bees are doing well on white clover. Mercury was down to 50° on the evening of the 1st inst. Weather has been quite favorable for about 3 weeks.

E. N. LLOYD.

Fayette, O., July 3, 1882.

A Curious Circumstance.—Yesterday evening I was examining a nucleus containing fertile workers, and while holding the comb in my hands looking at several workers laying, they all—bees and all—at once flew off, and after flying a few minutes in the air, they settled on a plum tree close by. In fear that they would not return, I took the same comb and hung it against the cluster. I had hardly done that when they all ran on the comb and the fertile workers went to laying in a few moments. I counted as many as 15 laying at the same time, and others performing the same operation in their turn. After catching 8 or 10 and pressing their abdomens, I had 4 to show the egg, and in fear that I might lose the opportunity, I sent one of my assistants, who was present, to my drug store for a vial of alcohol, and on his return I caught several in the act of laying and put them in the alcohol. I send them to you by this mail. This is almost incredible, but it is the fact, and I am glad I had an eye witness. I intend bringing two bee-keepers of the neighborhood, in a day or two, to show them the workers laying while holding the comb in hand. My opinion is that every bee in that nucleus is capable of laying, as I saw at least 50 of them laying, and others simulating the act. I am almost inclined to send you that nucleus by express, at my expense, but will not confinement destroy their propensity of laying? What do you say? I trust that this may be of some interest to you, and hope to hear of the result of your examination of these fertile workers. I ought to mention that there are but about $\frac{1}{2}$ pint of bees in the nucleus.

PAUL L. VIALLOX.

Bayou Goula, La.

[The above is very interesting. The bees sent were no way peculiar, except that some of them had very large but rather short abdomens. I have carefully dissected six of them. In all I find eggs. The ovaries instead of being multi-tubular as are the same in the normal queens, have only two or three tubes, and the eggs instead of being indefinite in number, are so few that it would be an easy matter to count them. There was no sign of a spermatheca, and the poison sack was large, as in the workers, and not as in the queens.—A. J. COOK.]

A Failure.—My bee business is almost an entire failure this season.

R. WILKIN.

San Buenaventura, Cal.

Not so Bright.—I see by last week's BEE JOURNAL, you say prospects are brighter. Not as far as my apiary of 100 colonies is concerned. White clover here is scanty, small and no honey in it; bees killing off drones and scarcely gathering enough to live on. In fact, there has been no honey comparatively in fruit bloom, locust, or willow. Two rainy days would starve

$\frac{3}{4}$ of my colonies. Let us hear from other points of Canada.

J. C. THOM, M. D.

Streetsville, Canada, June 29, 1882.

Foundation Making.—1. Would it be advisable for a man with 65 colonies of bees to invest in a foundation machine? 2. What hive would you recommend? 3. Can an apiary be run to advantage without foundation? I find it difficult to get bees to build straight on the combs.

JOHN SHERRETTS.

Norfolk, Oregon.

[1. With the present spirited competition in manufacturing and selling foundation, we do not think it would be advisable to invest in a first class machine, even with more than 65 colonies. Many propose to work up wax at 10 to 15c. per lb.

2. At present we would recommend the Langstroth hive, and until a standard frame is adopted. There may be other hives just as good, or perhaps, a trifle better; but we will recommend it because it is quite as capable as any of all desirable manipulations.

3. It cannot. If the apiarist has a surplus of nice, straight combs sufficient to meet emergencies, then he can dispense with foundation; but, otherwise, he loses half the utility of his movable frames unless foundation be used. Again, no loss is entailed in the purchase of good foundation, even at a higher price than it is now selling, because with it a prime swarm can fill a 10-frame Langstroth hive with nice, straight combs in 48 hours, and make good headway in storing honey in it.—ED.]

Working in the Sections.—My bees are doing finely at this time. A swarm that issued May 8th, has on 40 one-pound sections. I took a peep at them this evening, and found they have several nearly filled, and most of the others started. I think this is doing pretty well, when they have only been on 6 days.

HENRY CRIFE.

North Manchester, Ind., June 28.

Why the Dysentery?—On the 3d inst., between 10 a. m. and 2 p. m., to prevent swarming I took from 1 to 4 frames of brood and bees from each of several colonies. I made one full colony, gave 3 frames to another, 2 to another, and 1 to another, and made 42-frame nuclei. I mixed the bees from the different hives to prevent their disturbing the queens. On the 7th, between 8 and 10 a. m., of the four nuclei I had three cases of dysentery, one so plain that the spots on the front of the hive stand as witnesses. The weather has been very wet, but the bees have been storing honey every day (perhaps 3 or 4 ex-

ceptions) since June 1st, with plenty of sealed and unsealed honey and pollen in the nuclei. Will Mr. Heddon tell us the direct cause of this, and why all four of the nuclei did not have it? Or, in fact, why they all (all the bees I handled on that occasion), did not have it? Or, why did any of them have it? By 1 or 2 p. m., on the 4th inst., there was no signs of the dysentery except the spots on the hives.

S. A. SHUCK.

Bryant, Ill.

[The illustrations given above present several very interesting problems, chief among which are the bacterium-pollen and the starvation theories. In neither case could there have been time for the development of bacteria, in no case was cold so intense as to place food beyond and pollen within their reach, nor was starvation so imminent that bees abstained from eating to eke out their stores for a more distant day. At all events, if bacteria, or pollen, or starvation, or all of these, are the prime causes of dysentery sometimes, they certainly are not at all times; and when the question is finally settled, it may be found that an undue disturbance, inhalation of too much moisture, and too rigid confinement are conducive to it.—ED.]

Immense Beginning.—The main honey harvest is over with us; the horsemint is drying up; weather dry and hot. Bees are getting some honey from mesquit. From 27 colonies (spring count) I have had 51 natural swarms, have taken 4,359 lbs. of extracted and 200 1-lb. sections, and could extract to-day at least 1,500 lbs. more, but do not want it—no time to take care of it.

J. S. TADLOCK.

Luling, Texas, June 29, 1882.

The Verdict of the Jury.—We have just received a copy of the most popular piece of music ever published in this country, called the "Verdict March," composed by Eugene L. Blake and published by F. W. Helmick, 180 Elm St., Cincinnati, O. It is written in an easy style, so that it can be played on either piano or organ. The title page is very handsome, containing correct portraits of Hon. Geo. B. Corkhill, Hon. J. K. Porter, and Judge W. S. Cox; also a correct picture of the twelve jurors who convicted the assassin of the late President. 40 cents.

Macmillan & Co. will publish immediately a little book entitled "Rules of Simple Hygiene, and Hints and Remedies for the Treatment of Common Accidents and Diseases," by Dr. Dawson Turner, revised and corrected by twelve eminent medical men connected with hospitals in London. It is reprinted from the eighth London edition, with additions. Price 50 cents.

ESTABLISHED 1861
 THE AMERICAN
BEE JOURNAL

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published **WEEKLY** as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 13 " (3 months)....	20 " "
" 26 " (6 months)....	30 " "
" 39 " (9 months)....	50 " "
" 52 " (1 year).....	60 " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,
 925 West Madison Street., Chicago, Ill.

Special Notices.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for one year, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2.—	a copy of "Bees and Honey."
" " 3.—	an Emerson Binder for 1882.
" " 4.—	Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper, cloth.
" " 5.—	" " " "
" " 6.—	Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
 Monday, 10 a. m., July 10, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—1 am paying 7c. for dark and 9c. for light extracted.
 BEESWAX—Choice lots are worth 25c. here; bright yellow, 24c.; dark to good, 17@22c.
 AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for honey is quiet. Extracted brings 7@10c. on arrival. No comb honey on the market worth mentioning, prices nominal.
 BEESWAX—Scarce, and brings 2@25c. on arrival.
 C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for comb honey is light, prices being made to meet views of purchasers.
 BEESWAX—Scarce, and in demand at 23@25c.
 R. A. BURNETT, 163 South Water St.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 8@10c.; dark 7@8c.
 BEESWAX—The market continues rather quiet, but the supply is light and prices firmly sustained. Western, pure, 26@27c.; Southern pure, 27@28c.
 D. W. QUINBY, 105 Park Place.

SAN FRANCISCO.

HONEY—Receipts are very light. Reports continue to be received from Southern California that the crop is not large. A prominent apiarist in Ventura writes that he does not believe there will be over twenty tons shipped from that county. Not much will be required, however, to satisfy the demand at the present firm views entertained by holders.

We quote white comb, 15@18c.; dark to good, 8@12c. Extracted, choice to extra white, 7 1/2@8c.; dark and candied, 6@8c. BEESWAX—23@25c.
 STEARNS & SMITH, 423 Front Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
 BEESWAX—Prime quality, 25c.
 CROCKER & BLAKE, 57 Chatbam Street.

ST. LOUIS.

HONEY—First receipts of new Texas (comb) offered to-day. Selling at 21@22c. per lb.
 BEESWAX—Prime in demand at 22@23c.
 R. C. GREER & CO., 117 N. Main Street.

CLEVELAND.

HONEY—As there is no honey in market, we have no quotations this week.
 A. C. KENDEL, 115 Ontario Street.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

The postal law makes the taking of a newspaper and the refusal to pay for the same, theft, and any person guilty of such action is liable to criminal proceedings the same as though he had stolen goods to the amount of the subscription.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

When changing a postoffice address, mention the old as well as the new address.

Do not let your numbers of the BEE JOURNAL for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Three years ago St. Julian, the great California trotter, was unknown; the same may be said of Kendall's Spavin Cure. Now both have a world-wide reputation. Why? Because they both have merit. One is a great trotter, the other is the most successful remedy ever discovered to be used on man or beast.
 26w4t

Bingham's Smoker Corner.

I have tried several kinds of Smokers, and none give such satisfaction as Bingham's; 'tis worth more to me than all the rest combined.
 Morning Sun, Iowa. J. E. KEARNS.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

Old Headquarters for Queens.

We will be prepared on and after July 10th, to ship Queens by return mail. We have the best strain of Italians in the country. Our Cyprians, Holy Land and Hungarian Queens cannot be excelled. No 75 cent or dollar queens for sale. Warranted Queens \$1.50, Tested \$2.00, very choice Selected Queens \$1.75 each. We also have dark and extra light-colored Italians. All Queens warranted pure and sent by mail. Send your address on a postal for my 21st annual circular and price list. 28wit HENRY ALLEY, Wenham, Mass.

HONEY

For the past few years I have made this excellent food my leading article. Having the best established reputation in this city as a dealer in PURE HONEY direct from the Apiaries, enables me to obtain the highest market prices. Your consignments and correspondence respectfully solicited.

A NEW BEE BOOK!

Bees & Honey

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,

Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price bound in cloth, 75 cents; in paper cover, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Algon, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lehanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

Orders filled in rotation, as received, if accompanied with the cash. 3w2ct

BEAUTIFUL QUEENS—Warranted Italians, \$1.25 each; Warranted Cyprians, \$1.50 each; Unwarranted Queens, \$1.00 each. Try one and you will want more. Address, 27w1tp REV. J. E. KEARNS, Morning Sun, Iowa.

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY,

By A. J. COOK,

Of Lansing, Professor of Entomology in the

State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—LEWIS T. COLLEY.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—J. P. WEST.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—E. H. WYNKOOP.

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—A. E. WENZEL. My success has been so great as to almost astonish myself, and much of it is due to the clear, distinguished information contained in Cook's Manual.—WM. VAN ANTWERP, M. D.

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-risers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—L'ABBE DU BOIS, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *vide necum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, \$1.25; in paper cover, \$1.00, by mail prepaid. Published by

THOMAS G. NEWMAN, West Madison Street, CHICAGO, ILL.

"RED TAPE!"

Who will be the first to copy?
25,000 IN USE.

If you buy the Original Patent Bingham Bee Smoker, you will not be the inventor of improved bee smokers—get the best, that never go out—always please—never is complained-of—the standard of excellence the world over—better and handsomer this season than ever before. Price per mail, postpaid, from 65 cts. to \$2. Our patents cover all the smokers that will burn sound stove-wood, or do not go out. If you buy our smokers and honey knives first, you will have to buy no others.

Scribner's Lumber and Log Book.

NEARLY A MILLION SOLD. Most complete book of its kind ever published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States and Canada. Ask your booksellers for it. Sent for 35 cents post-paid.

G. W. FISHER, Box 238, Rochester, N. Y.
Also for sale at the BEE JOURNAL Office, 26w6m.

PURE HOLY-LAND QUEENS.

I make a specialty of rearing pure Holy Land Queens, and have now more than 100 colonies in their purity. All Queens bred from D. A. Jones' Imported Queens. Dollar Queens, before June 20, \$1.25 each; after that date, single Queen, \$1.00; 6 for \$5.00; 12 or more, 75 cents each; Warranted Queens, 25 cents more each. Tested Queens, \$2.50 each; Italian Queens, same price.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame. Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches	\$8 00
For 2 Langstroth " " 10x18 " " "	8 00
For 3 " " 10x18 " " "	10 00
For 4 " " 10x18 " " "	14 00
For 2 frames of any size, 13x20 " " "	12 00
For 3 " " 12 1/2 x 20 " " "	12 00
For 4 " " 13x20 " " "	16 00

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small **White Shark,** caught in the Yellow Sea, known as *Carcharodon Rondeletti.* Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over **300 years no Deafness has existed among the Chinese people.** Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better.

I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WITNESSES CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Day Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by **THOMAS C. NEWMAN,** 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apinary.—Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apinary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bienen Kultur, by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Bzierzo Theory;—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Fonn, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing it.—A 24-page pamphlet, by Chas. C. P. Dabant, giving in detail the methods and management adopted in their apinary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman.—Giving advanced views on this important subject, with suggestions what to plant, and when and how; 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 2500 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and with its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

OLDEST BEE PAPER IN AMERICA

California Honey Granulates.—The editor of the *California Apiculturist* says: "We have noticed that California honey will granulate as often as it does not. It depends a good deal in what shape the honey was when it was extracted; if fully ripe, it is more apt to candy sooner."

Each succeeding year the unicorn sections become more popular, and, so far, the demand for them has doubled every year. Those intended to hold one pound of honey are the most popular for retailers of comb honey, while the producers generally prefer those holding two pounds. The more rapid sale of the former, however, will probably more than repay the producer for the trifle less in amount that the bees may store, from the fact of their small capacity. We must follow the lead of the market, demand what it may, if we would be successful.

Apiculture and Botany.—We observe our contemporary in California has adopted our special feature of combining apiculture with botany. Many bee-keepers in America owe much of their success to the encouragement and protection of honey-producing plants, suggested by the BEE JOURNAL. As the stock-raiser familiarizes himself with the grasses which furnish the best and most profitable grazing for his stock, so should the bee-keeper recognize and plant the flowers best suited to his bees, locality and climate.

We observed a bee on sweet clover on Monday last.

The National Convention.

The following is the official call of the Secretary, Dr. Parmly, for the Convention of the North American Bee-Keepers' Society. We hope there will be a large attendance:

The North American Bee-Keepers' Society will hold their 13th annual meeting at Washington Park Hall, Cincinnati, O., across Washington Park from the Exposition building. Time, Oct. 3rd to 5th, 1882. First session Tuesday, 10 a. m., Oct. 3. We are encouraged to hope that this will be a very profitable meeting, as we are promised papers from, and the presence of, a large number of our most prominent bee-keepers both in the United States and Canada, and essays and implements of the apiary are expected from abroad to add to the knowledge imparted by the research and inventive skill and methods of our countrymen.

EHRIK PARMLY, Sec.
New York, July 12, 1882.

Increasing Popularity of Cook's Manual.—So rapid has been the increasing popularity of "Cook's Manual of the Apiary," that we have recently been obliged to issue another edition, making 9,000 published to date. Apiarists have been particularly fortunate in the high order of talent devoted to the preparation of text-books, but "Cook's Manual" has rapidly taken the front position, and the Professor's scientific and practical education will enable him easily to keep his excellent book in the advance, as the frequency of the editions give him opportunity to anticipate the progressive steps.

In the Newcomerstown, O., *Index*, of July 6, 1882, we notice a long article describing the bee hive and supply establishment of Mr. R. L. Shoemaker, who, by an accident, lost his eye a few weeks ago. We are pleased to see that his establishment is of such large proportions.

Farmers Rejoicing.

The crop prospects throughout much of the country are very encouraging. The excessive rains, we are sorry to note, have been quite damaging to corn, which will require the most favorable weather from this through to make even a fair crop, but wheat, oats, rye, barley, clover, grass and potatoes, will be more than an average in yield and quality.

In Kansas the oats crop has increased from 280,167 acres in 1881 to 447,695 acres in 1882, and all reports say that it will be the heaviest crop ever harvested in that State. The wheat crop just harvested will reach over 30,000,000 bushels, and of superior quality. The acreage of corn will run 6 per cent. over last year, amounting to 4,500,000 acres, which, at 30 bushels per acre, will foot 135,000,000 bushels; it is expected, however, to reach 175,000,000.

A dispatch from Lincoln, Neb., says "each day strengthens the belief in a harvest such as was never known in the State before." Of rye the yield is much larger than in any year previous, and the wheat crop is larger and of better quality than the average. Oats and barley are heavy and of good quality. Wild and tame grasses look well, and potatoes and other vegetables were never better.

In one county in Indiana (Miami) alone, the present wheat crop will run over 1,200,000 bushels. Corn is not doing so well, being neglected by the farmers to secure their immense wheat crop.

So far as we can learn from different prominent points in Illinois, crops of all kinds, excepting corn, are very encouraging, even better than was anticipated a short time since.

A report from Dakota says "the prospect to-day has never been equaled. Wheat, oats and barley are heading out with a stand indicative of a crop simply enormous."

In Michigan the grain crops are hardly so flattering, but the yield will be a fair one.

We have no reliable data of late date from other States, but anticipate the generality of crops will be equally good, as complaints are soonest circulated when at all unfavorable.

Prices of live stock, especially hogs, have reached a fancy figure. We are told by dealers that the prices are purely fancy, speculative, and that they will have to be moderated considerably, as there is no real justifica-

tion for them. Of course, prices of other meats sympathize largely with pork; but, with the excellent pasturage, it will be impossible to keep up the figures on cattle and sheep, and hogs will then sympathize to a certain extent with them, or they will be more largely substituted for food.

Glucose in Fraudulent Uses.

Mr. Le Roy Whitford, Lecturer to the Chautauqua Co., N. Y., Pomona Grange, has kindly sent us a copy of an essay read by him before the Grange. We have not space for it entire, and give only that portion relating to the glucose traffic, which will be read with interest.

Published statistics show 21 manufactories of glucose and corn sugar in this country, turning out 1,200,000 lbs. per day from 48,000 bushels of corn. The consumption of this vast product is effected through fraud by mixing with sugar, maple syrup, candy, jelly, honey and other sweets.

It has been supposed that, although of so low and poor a sweetening power that nobody would accept it for sugar or syrup when unmixed, it was not necessarily unwholesome as an article of diet when well made, and the numerous instances of injury to health, and even death from paralysis and other diseases which are known to have resulted from its use were supposed to be due to the presence of a remnant of chemicals used in its manufacture. On the part of the manufacturers it is claimed that the sulphuric acid is all precipitated so that none can possibly remain in the product or in the refuse meal which is sold to farmers to feed to stock. Where the truth lies in this controversy is not of paramount interest to consumers. It is enough for us to know that its use for only a few years has alarmingly increased the frequency of Bright's disease, and also that certain new and dangerous maladies which are developing among the poorer classes are attributed to the use of glucosed sugars and syrups by many of our best medical authorities. I will only mention here, Jas. R. Nichols, editor of the *Boston Journal of Chemistry*, who states positively "that it does produce aggravated dyspeptic symptoms, and causes flatulency and painful affections of the bowels, and that its use in larger quantities as mixed with our sugars and syrups is deleterious to health." His very interesting article closes with the declaration, "That all consumers of sweets in this country are victims to a form of fraud which deserves the prompt attention of our law makers."

But it strikes me that the true cause of these effects upon the health may be concealed in the secret process by which the liquid glucose is converted into granulated sugar. This process is said to be unknown to

classical chemistry. Much as we owe to chemistry, it cannot be forgotten that from the days of the alchemists, when they tried to make gold from the baser metals they have been reaching after impossible things, and have often exclaimed "Eureka" too soon. The product of the laboratory may be identical in composition with that of nature and yet differ widely in its effect upon the human system. Nature, in some of her finer processes, is not to be approached by all the subtleties of the chemist's art.

Ask the chemist to tell you by his test what the difference is between a piece of Parian marble and a piece of the chalk cliff of England, and the answer from his laboratory will be that there is no difference whatever, both are carbonic acid and lime, and in the same relative proportion. Now ask him why they are not equally valuable as food for plants, and he cannot tell you.

A piece of carbonate of magnesia from the rocks of Hoboken treated with sulphuric acid is epsom salts. The chemist will pronounce it such and pure. But if given as a cathartic it will produce severe griping if not death.

Other instances might be cited showing that substances which are alike in composition are not always alike in their effects on the living organism, but it is enough for my purpose to show why grape sugar from corn starch treated with sulphuric acid is not as wholesome as the fruit sugar which is produced in nature's laboratory.

James' powders made from phosphate of lime and oxide of antimony, were found after 100 years to be good for nothing when made of calcined lime rock. The East India Company sued the manufacturer but could not recover, for chemists, Mr. James among them, decided that it was all right in every respect.

One word more in closing as to the remedies for the evils complained of.

And first I would avoid the use of these deleterious compounds by using instead pure articles purchased of producers. To thwart the consumers and at the same time turn an honest penny the glucose men bought the whole product of amber cane syrup of Iowa last year, mixed it with their stuff and then threw it on the market as pure.

Honey directly from the apiaries is almost never adulterated and as this fact is becoming well known an unprecedented demand is springing up for extracted honey to take the place of syrups. "The honey of the trade," as it is called, is no better, as it is manufactured in the great cities by such wholesale jobbers as the Thurbers of New York. If honey granulates in cold weather it is the best evidence of purity.

And finally, the only effectual remedy is to be sought in stringent laws against selling anything for what it is not, and the people have got to take this matter in hand and urge upon Congress a general law that shall put an effectual quietus upon these nefarious practices.

A Scurrilous Pamphlet.

"Des Vessies pour des Lanternes ou la science apistique du Comte G. Barbo, par Giotto Ulivi." This is the title of a pamphlet, the translation of which is, "The windbag for the nonsense of Count Barbo, by Giotto Ulivi." This with the accompanying volume contains about 130 pages; but the title is sufficient to disgust any honest seeker after truth. Count Barbo is a gentleman who devotes himself to the study of apiculture from a praiseworthy love for natural history, and has a discriminating judgment and scientific attainments which constitutes him one of the best authorities in Europe on all matters pertaining to the honey bee. Being wholly disinterested in all controversies pertaining to them (as we are quite sure he never reared a bee for traffic), he has in no way allowed prejudice to influence him in one of his conclusions, nor has impatience hindered him from making thorough and exhaustive researches into mysterious problems. From a personal acquaintance with Count Barbo, we feel assured that Ulivi's ridiculous bombast will only bring upon himself contempt, and increase the universal respect and esteem for the noble Count.

Bees as Tipplers.—Mr. W. T. Clary has kindly forwarded us several extracts from the *Farming World*, embodying a series of strictures from correspondents of that paper on Mr. A. C. Stipp, of South Carolina, for having advocated the use of the "old box gum" in preference to the movable frame hive of modern date. Altogether the correspondence is too lengthy for publication in the BEE JOURNAL, and we will have to be content with making the following amusing extract from Mr. Stipp's first letter, which has opened a fair field for attack:

A good fruit year is always a bad bee year. They may do very well in the early part of the season, but they will not do much after brandy time comes. They are great drunkards, and when they have plenty of brandy, which they always gather from the fruit and distill for themselves, like most other drunkards, they cease to accumulate and only go through with what they have. They neglect the more important duties of making a living, and mix their honey with their brandy and betake themselves to hard drinking until many of them die drunk, if they don't fill a drunkard's grave.

Distinguished Visitors.

On the 14th inst. we were agreeably surprised with a personal call from Mr. James Anderson, bearing the following courteous introduction:

T. G. NEWMAN, ESQ., *My Dear Friend*.—Allow me to introduce to you our most advanced bee-keeper in Scotland. To live in the West and not have the acquaintance of James Anderson, of Dalsy, Scotland, is not to be in the bee world. For 50 years he has held his own against all comers, and he it was who went to the first Crystal Palace Show in London, and completely revolutionized the mode of taking surplus. He is on a short visit in search of health, which I sincerely hope he will gain, and bring back a host of information to us from our "American cousins." Well do I remember your happy visit to Perth, and only hope I may be able some day to come and see you.

Yours, faithfully,

ROBT. J. BENNETT.

Glasgow, Scotland, May 22, 1882.

We met Mr. Anderson at the Perth, Scotland, bee and honey show, of which Society Mr. Bennett is the honored Secretary, and although Mr. Bennett's very welcome letter was not necessary to insure Mr. Anderson a cordial welcome, it lent a greater zest to our friendship for the distinguished visitor who bore such honorable credentials. We are glad that so far Mr. Anderson's impressions of our country have been most favorable, and he will take back to Scotland a foundation machine and various other implements of our most improved patterns. He goes from here to visit a son several years a resident in Texas, and from thence to visit another in Colorado. We wish him an agreeable visit in our country and a pleasant return.

On the same day (July 11) Mr. Patrick Robertson, of Newhall, Scotland, paid us a visit, bearing a letter of introduction which Mr. Bennett closes thus gracefully: "Kind regards, and hope you will have an extra good season. Has *Apis Americana* reached the top of the tree yet?"

Mr. Robertson's visit to the United States is for the purpose of making this a future home. He goes from here to Des Moines, Iowa, from there to Winnipeg, and thence to Los Angeles, Cal., where he intends engaging in bee and orange culture. He is a gentleman of affable address, discriminating observation, and much experience, and we wish and predict success for him, in whatever enterprise he may engage.

Bee-Culture in Florida.

Mr. W. S. Hart, of New Smyrna, Fla., has kindly sent us a copy of his circular issued under the auspices of the State Immigration Agent, and published in the Tallahassee *Floridian*. It is quite lengthy and interesting, but we confine ourself to making a few extracts. The circular consists of a series of questions and answers. We presume copies can be obtained, by sending a few stamps to pay postage, of Mr. Hart:

Question.—Does it pay to keep bees in Florida?

Answer.—Yes, in many portions of the State it pays as well or better than in any other State, and there are parts where bees can scarcely make a living.

Q.—What is the average increase and honey production per colony in an average year? A.—In good locations the average natural increase is from 1 to 3 and 150 pounds of honey. They often do much better than this. I have known one colony to increase naturally to nine strong ones, in one season, and give considerable surplus honey besides.

Q.—What enemies and disease do they have to contend with? A.—I have never seen or known of a diseased colony of bees in this State. Foul brood, dysentery, etc., are unknown here. The enemies are roaches, dragon flies, ants, moths, and birds; but Italian bees, well attended, will keep so strong in numbers that the combined efforts of their enemies seem to affect them but little.

Q.—What part of the State would you recommend for an apiarist to locate in? A.—Having never been in the northern portion of the State, I know but comparatively little of its honey resources. I am told that bees do very well in many localities, and one correspondent writes that his bees get the swarming fever in October, from a heavy flow of honey, which usually comes about that time. I am better acquainted with South Florida and consider the coast counties lying south of the northern limit of the mangrove tree (a little north of 29th parallel) unsurpassed for the industry.

Q.—Do bees get lazy after being in your State for a while? A.—No.

Q.—Do the bees gather the year round, what do they gather from, and what is the quality of the honey? A.—No, there are usually three and sometimes four honey seasons, with honey drouths between, each year. I will quote from an article of mine published in the *Florida Agriculturist*, of November 9th, 1881: "Our bees winter perfectly on the summer stands, and gather honey or pollen every month in the year. The first honey flow commences about the 1st of February and swarming about the 10th of March. In April or May we usually have a honey drouth of a few weeks, sufficient to check the swarming fever. Then comes the saw

palmetto, sweet bay, basswood, etc., giving a good flow of very heavy honey, of light, amber color, and excellent flavor. This flow lasts until the cabbage palmetto and mangrove come in, the last of June. From this on until about the 10th of August, the flow is continuous and heavy, the honey as handsome as can be produced, and of very fine flavor. A resting spell now comes for the bees, which lasts until the middle of September, when the fall flowers, and later, the saw palmetto berries, yield a surplus of darker honey, suitable for winter supplies or spring feeding. As bees fly here almost every day in the year, fall honey can be fed without fear of dysentery. Some of the leading honey and pollen-producing trees are the maple, willow, sweetgum, the bays, orange, myrtle, oak, basswood, hickory, youpon, mock-olive, saw palmetto, cabbage palmetto and mangrove, the last two of which come together, in the middle of the summer, and are unequalled as honey-producers by anything else in the whole vegetable kingdom known to the writer. They produce honey in abundance, of the finest quality, and we think it is safe to say, never fail to produce a good crop. We also have honey-producing vines and plants too numerous to mention.

Q.—Where is your market for honey? How do you ship? And what are the prices obtained? A.—We have a limited home market for extracted honey, at 8 to 10 cents, and comb 15 to 20 cents per pound; but most of the larger producers ship their crops to the markets of the North.

Q.—Are there plenty of bees for sale near you, and if so, what are the prices asked? A.—In my immediate neighborhood there are very few bees for sale, as nearly everyone who has any had rather buy than sell. But in many parts of the State where "improved bee-culture" is unknown plenty can usually be bought in log gums or in boxes at from \$1 to \$2 per colony.

Q.—Are there many engaged in the bee business near you? A.—There are quite a number of apiarists within a few miles of me, and some of them are skillful and well up in all the modern improvements, but I know of no other good point in the State that comes anywhere near being stocked.

Q.—How does Florida compare with California for bees? A.—Parties that are well posted and reliable, write me from California that they occasionally get very large crops of honey there, but that on an average, but one year in three can be counted on for much surplus, while occasionally they have a year that kills off thousands of colonies by starvation. Also, that the fruit-raisers and bee-keepers are at war, and the former are driving the latter into the mountains, "where no white man wants to live." Here in Florida our seasons are remarkably even in honey production, and we never have a year that a paying crop is not produced. Bee-keeping is antagonistic to none of our

industries and good men are welcome to any part of the State, no matter where they come from. From what I can learn of the matter I am confident that our good bee pasturage is not more limited in extent than that of California, and there six hundred men give their whole time to the business, while I do not suppose there are a dozen in this State but what keep bees merely as a side issue.

Living is cheap here, as but little clothing is required; wood is plenty for the gathering; a house can be built for a ridiculously small sum that will do until a better can be afforded. Fish and game are plenty, and vegetables do well where properly attended to. Good board can be had with a private family for \$3 to \$7 per week.

I am often asked what success I have had at bee-keeping, and so I have published my reports each year, but as this may reach many who have never seen them, I will say that in 1880 I started in the spring with fourteen colonies, increased to forty and took nineteen hundred pounds of honey. It was considered a poor year and I used no foundation. In 1881 I started with thirty-five colonies, increased to eighty-six, and took six thousand five hundred pounds of honey by actual weight; I also left about one thousand pounds in the hives that could have been spared without cutting the bees short in winter stores.

The California Honey Crop.

As we have heretofore said, the prospect for a short honey crop in California is now a realized fact, and it only remains for the bee-keepers east of the Pacific slope to insist upon a good price for their honey, and to take no less. The *Apiculturist* for July says:

In Southern California the principal honey season closes this month with the sumac bloom, which like most of the other honey producing plants that have preceded it, will not yield much honey this season, judging from present indications and state of the atmosphere. It has been our observation for several years past in this country that when the first flowers of the season fail to secrete nectar those that follow usually fail too. The weather continues cool with occasional indications of rain—this state of things debar all hope for but little more honey than perhaps will be needed to carry the bees through the winter with. In alfalfa localities bees will doubtless store some surplus.

The postal law makes the taking of a newspaper and the refusal to pay for the same, theft, and any person guilty of such action is liable to criminal proceedings the same as though he had stolen goods to the amount of the subscription.

MISCELLANEOUS.

Ancient Regulations Concerning Bees.—Mr. Kruegell has collected the following "bee laws" for the *Benenzeitung*:

1. Bees which live in the woods, or cling to fences, bushes, or out in the fields without being hived, are public property, and belong to anyone who secures them.

2. Honey or wax which has been gathered by wild bees, may become the property of whoever takes possession of it.—Cournelle.

3. But when bees have become domesticated in a hive, or elsewhere, they are the personal property of whoever possesses that place, and he is not allowed to destroy them by fraud, malice, or prejudice, or harm them in any manner.—Vandore.

4. By the same reason, the owner of a stray swarm, if he has followed and not lost sight of it, can claim and take possession of it no matter where it may have alighted, but if otherwise, it is the property of the person upon whose premises it may have settled and whoever shall seize it can be compelled to return the same.—Coullier.

5. Should the owner of any grounds, upon which a stray swarm of bees may have settled, endeavor to injure them in any manner, he forfeits all right and title thereby.—Argan. C. N. 564.

6. The "Code Rural" proclaims, that the proprietor of a fugitive swarm, who has followed it, even if it is lost to his sight for some time, may claim and recover it when found.—Codo Rure.

7. The Roman law does not coincide with the above statement.—Romain law, 584.

8. For this reason it is customary to follow a swarm of bees with a great noise.—Cournelle.

9. The usufructuary, (occupant, or tenant) farmer, lodger or any persons who possess ground property, with precarious right, have the right to use any swarms that have started from their property.—Cournelle.

10. But if the swarm has settled upon grounds possessed by a farmer, usufructuary, etc., it can only be used as an accessory to the grounds by the farmer, usufructuary, etc.—Cournelle and Vandore.

11. The administrative authorities have the power to forbid any person placing bees in towns, cities, etc., or in public squares, or highways, or any place where they may trouble or injure the public.—Vandore.

12. But about this restriction there exists no law or custom which prohibits the private individual from keeping bees in any place he chooses, upon his own grounds, or transport-

ing from one place to another to suit his convenience.—Vandore.

13. Should any person receive injury to himself or property by the aforesaid moving or displacement of bees, he may claim and recover full value of damage done.—C. N. 1382.

14. Bees, of course, are movable, but they become immovable when the proprietor places them to the account of the ground property.—C. N., 524.

15. The part owner of a swarm of bees, cannot force his partner to divide it. He must dispose of his part by auction.—Vandore.

16. The "Code Rural," sections 1, 2, 3, has forbidden the seizure of the hives and contents for any debts, unless these debts are not contracted toward the one who furnished them, or toward the proprietor of the grounds. Section 3 forbids the removal of the hives even, if seized during the months of December, January and February, but this prohibitory law is not mentioned in the "Code de Procedure," which states different seizable property, without including bees.

Koenigshopfen, Germany.

After California Honey.—The Oakland, Cal., *Tribune* says Mr. Joseph M. McCall, of Thurber & Co.'s New York house, was recently in California to purchase all the honey that may be offered him. That paper adds:

Mr. McCaul, it is feared, will find California apiarists rather slow and backward in disposing of this year's crop, unless they are offered a good price for it, as the yield has not been great, but the quality, nevertheless, is excellent. It is said that this year's harvest will not be more than one-fourth of a crop. Ventura county which produced 400 tons in 1878, will produce hardly twenty tons this year. Their agent will also purchase all the California wax that he may be able to find. In the past few years the demand for this product has more than doubled, principally on account of there being so much of it used in the manufacture of what is called comb foundation.

Harmless to Dairies.—Among the unsettled points, Mr. A. Pettigrew mentions the following in a late number of the London *Journal of Horticulture*:

A parsimonious old farmer whose clover fields were visited by our bees sorely felt that his fields would have been richer without them, and so convinced was he that his butter was impoverished by our bees that he trod to death all he possibly could, and threatened to use the horse roller when the bees were at work. On mentioning this to Dr. Lindley, 40 years ago, he said, "the old farmer was a blockhead," but that did not settle the question. Had the farmer just cause for complaint? If the 20 or 40 lbs. of honey gathered by bees from his clover fields daily had been left in the towers, would his cows

have yielded more and richer milk? This is a question which I have not been able to answer, and therefore, so far as I am concerned, it will remain unsettled. In hot weather flowers that yield honey do so constantly; and if not gathered by bees it is carried off by the atmosphere in odors. All honey thus carried off is lost to bees and their owners; as well as to farmers and their cows. The question now mooted is more easily understood than answered satisfactorily. Though difficult of solution, it may be well to think about it. White clover and trefoil (*Lotus corniculatus*), are the only pasture flowers that I can think of that yield honey to bees. Bees are of great service to farmers and others in their orchards and gardens, and in fertilizing field beans.

Bees and Clover.—The *Gentlemen's Magazine* gives the following on the advantages of bees to clover:

Bee culture has been powerfully advocated for the honey sake, and would probably be more general if sugar were not so cheap. There is, however, another advantage, which Darwin's researches have proved—viz. the action of the bees in fertilization of flowers. Every farmer who grows red clover for the seed sake is too familiar with the uncertainty of this crop, the seeds of which ripen with most vexatious inequality. Herr Haberlandt, who has followed up and confirmed the researches of Darwin in reference to these particular flowers, strongly recommends the rearing of bees on all clover farms for the special purpose of fertilization, even though their honey be disregarded. For it appears that clover is entirely dependent on insects for its fertilization, and chiefly upon bees. The form of the flowers and the manner in which the maturity of the lower florets precedes that of the upper florets renders the success or failure of a clover seed crop simply a result of the employment or non-employment of these humble farm laborers.

Keeping Bees in Texas.—Dr. J. E. Lay gives the following reasons why he keeps bees, in a late number of the *Texas Agricultural Journal*:

The following are some of the reasons why I keep bees: Their habits afford me quite an extensive field for scientific research. Endless experiments may be made with them that will elicit much profitable knowledge. The naturalist, the physiologist and anatomist can find in their study much that is useful and advantageous in their particular branches of learning. Indeed it is a field that the scientists may enter and find much material that is wonderful as well as most beautiful, to engage his highest thoughts. He looks upon new and strange wonders that continually call forth his admiration. It is a part of the great domain of nature that the most learned may not despise, but enter with the reap-hook of his genius and gather many golden sheaves.

The bee is an insect of the highest order, filled with nerves, blood-vessels, lungs, glands, and a finely organized brain. It also possesses a sting of great energy, by which it may defend its home and young and repel only intruders; and thus, in the protection of home, and in the defense of its young, it displays an instinct of the highest order that is rarely to be found in such degree except in man. Being thus wonderfully endowed by the Creator, they present to our minds a subject worthy of intelligent consideration.

Bee-keeping is looked upon as rather a small business, that depends largely upon the luck of the individual engaged in it, and not worth "fussing" after by men of skill and education. This accounts for the fact that one of the most pleasant as well as profitable industries of our great State has remained in the background, entirely neglected so long, simply because there has not been given to it a rational and intelligent investigation. That time is past, and thousands throughout our great land are engaged in scientific apiculture, and are reaping rich harvests of golden nectar each season, that is fast making them financially independent. It has taken its place as one of the great industries of our country. The time is close at hand, if not already upon us, when extracted honey will rank as one of the staples of the world. Yes, as staple as molasses or sugar—an article of food at once the most wholesome and pleasant to the palate of man that ever was bestowed by the hand of an indulgent Creator.

We have been taught to look upon honey as a rare luxury, exceedingly difficult to obtain, and only in small quantities, to be used on fete-days, or to be carefully stowed away for sickness. This is a grand mistake. The giver of all good did not so intend it, but He scattered the beautiful flowers over our land, pleasant both to our eyes and olfactory sense, and filled them with this golden sweet. Yes, lavished it around us in thousands of pounds, waiting, ready to be gathered by this wonderful insect, the bee, which is so easily made subservient to the intelligence of man, going forth as never tiring servants at his bidding, gathering and pouring into our store-rooms, not as a mere luxury, but as a rich, wholesome necessary food to gladden the young, the old, the rich, the poor, for indeed all may enjoy this blessing that are willing to labor for it only in an intelligent manner.

This portion of Texas is eminently adapted to apiculture. In this part, bees will live through any winter without any protection, if left with plenty of food. They will gather two crops of honey every year—a light-colored crop in the spring, that cannot be surpassed, and a wine-colored crop in the fall, which possesses an exquisite flavor, and in taste is preferred by some epicures to the light spring honey.

CORRESPONDENCE

For the American Bee Journal.

Extraordinary Yields in Texas.

B. F. CARROLL.

A barrel of honey from one colony! and still the great flow goes on. Never has there been such a flow of honey. The extremely mild weather, with an abundance of rain even up to the 10th of June, has given us one solid mass of horsemint. Over 3,000 acres of this grand honey plant within easy reach of my bees. Bees have increased over 500 per cent.—yes, often 10 colonies from 1, and now they are swarming. Seven swarms have gone to the woods to be messed up by bee-hunters, and yet I have 111 colonies, all from 40 in the spring, and I have sold 32 full colonies—all this increase is by natural swarming.

Moses T. French and W. R. Melton, the champion black bee men of old Navarro, have gone into conniptions over their great yield. Some of their best black colonies have given as much as 100 lbs., while Capt. A. S. Gill, of Purdon, Navarro County, from the under side of a bench on which a black colony was sitting, took 118 lbs. of choice comb honey. Bee-trees have been cut, and from 100 to 200 lbs. of comb, dirt and honey were taken. The demand for improved hives, etc., has been great, and it was almost impossible for me to keep hives to put my own bees in. I have been obliged to use oil boxes, cracker boxes, etc., to put bees in, in order to forward apiculture hereabouts. Being the first to introduce the frame hive, the people still call on me.

There are now around me the following bee-keepers: Dr. H. B. Ransom, 35 colonies; W. R. Melton, 71; Dr. C. H. Hart, 50; Westbrook & McAfee, 110; M. T. French, 35; Dr. W. S. Robinson, 20; R. Gowen, 10; G. W. Thomson, 11; B. F. Carroll (self) 111; Elizabeth Melton, 25; and about 75 colonies, here and there, from 1 to 5 in a place, giving a total of 553; with G. W. Acre, of Cross Roads, 25, and H. Forgey, Blooming Grove, 25—in all, 600 colonies in a radius of 7 miles. And in this radius 10,000 colonies could have gathered over 200 lbs. per colony. Honey is fast superseding glucose syrups, called honey drips, corn shuck, golden sweet, etc.

And now let me report what my bees did for me from horsemint. All the colonies I extracted close gave from 140 to 700.; being overrun and not having money to purchase supplies, hives, foundation, etc., I lost $\frac{3}{4}$ of the grandest honey crop ever seen in Texas. Now for that prolific queen I wrote about some time since. Up to June 1st I extracted 22 lbs. from spring flowers, and began taking mint honey June 1st from 3 upper stories, 54 lbs.; June 7, 3 upper stories, 75 lbs.; June 14, 4 stories, 75 lbs.; 14th, 4

stories, 112 $\frac{1}{2}$; 21st, 4 stories, 129 $\frac{1}{2}$ lbs.; 26th, 4 stories, 123 $\frac{1}{2}$; 30th, 4 stories, 115 $\frac{1}{2}$; July, 7, 4 stories, 68 lbs.; total, from one colony, 700 lbs.; nearly 5,000 lbs. up to date from all.

Hurrah for D. A. Jones' Cyprian bees! The best bees on the face of the globe. I expect bee-keepers ought to give me the premium for being ahead. Had I managed this colony rightly I could have obtained half a ton from it.

Dresden, Texas, July 7, 1882.

[Are we to understand our correspondent obtained 700 lbs. from one colony alone, or from one colony and its increase? If from one colony, what has been obtained by its increase, if any? If the honey flow, as we understand, is not yet through, we would like a report from this colony and its increase at the close of the season.—ED.]

For the American Bee Journal.

Glass versus "Tin," So-called.

LOUIS KNORR, M. D.

It certainly is the duty of every bee-keeper to scrupulously refrain from any action or practice whereby the purity of honey might be impaired. Now, I contend, on chemical principles, that leaving honey in contact, for a certain length of time, with tin so-called ordinarily, but properly speaking with the alloy of tin and lead, as is the case when honey is filled into tin pails for the retail sale, or filled into tin tanks for maturing it, or permitted to stay for some time in the extractors, must expose it to contamination with lead.

Many of the readers of the BEE JOURNAL will know that the ordinary sheet-tin is in reality sheet-iron coated with a thin film of an alloy of tin and lead. For hygienic considerations, it would be desirable that this film should consist of pure tin. But, unluckily, pure tin does adhere only with the greatest difficulty and rather imperfectly to iron. Thus the manufacturers of sheet-tin are compelled to use an alloy of tin and lead. Nearly everybody knows the injurious effects of lead, in all its chemical combinations, and even in the minutest quantities, if long continued, upon the human system. It is contended that a small amount of lead alloyed with tin is so thoroughly held by the latter that it cannot be attacked and dissolved by the sugars and acids, and thus cannot enter into our articles of food. Granted. But, as far as I know, hygiene has never solved the question—with the assistance of analytical chemistry—how great the amount of lead may be in the alloy without incurring the risk of injury to the human system. The great difference in the prices of tin and lead is a standing inducement for the manufacturers to increase the proportions of lead enormously, and to an injurious extent.

Some time ago I analyzed, for my

own satisfaction, a sample of canned tomatoes and one of canned peaches. The first, against my expectation, did not contain any lead; but the latter did to a considerable extent. Whether the tin (so-called) of the tomato-can contained less lead proportionately than the other can, or whether the sugar in the peaches could exert a greater action upon the lead than the acid in the tomatoes, I cannot decide. In the honey, the saccharine and acid principles must attack the lead in the so-called tin vessels. I could observe that, a couple of years ago, my extractor was considerably corroded by the honey that was, by mistake, allowed to stay for some time.

The French government has, some time ago, taken measures against the indiscriminate use of tin vessels for holding preserved food containing acid and saccharine substances. And I think bee-keepers ought to store their honey in glass or wood (how would paper-kegs impregnated with paraffine do?) as long as no discrimination is made in the trade between tin (rich in lead) for roofing purposes and tin for holding articles of food.

Savannah, Ga.

For the American Bee Journal.

How I Rear My Queens.

G. M. DOOLITTLE.

EDITOR WEEKLY BEE JOURNAL:—As this subject has engrossed so much attention, I should not have written on it but for the fact that upon the queen depends all there is of bee-keeping. The following I have already contributed to the *Magazine* on this subject, and should like you to give it in the *Weekly BEE JOURNAL*:

When we realize that all the bees of a hive are the offspring of one bee (the queen), and that the more bees we have in time for the honey harvest, the greater the assurance of a large yield of honey, we can form some opinion of the worth of a good, prolific queen, and of the disappointment which will await us if we have a poor, worthless queen in our hive. Nature provided a sure way to rear the highest type of royal descendants, and pronounced it good. Although many have been the plans devised to rear excellent queens outside of the natural swarming of bees, still I have yet to hear the claim that queens reared by any one of these plans are superior to those produced from cells, nursed and cradled by a full colony of bees preparing to swarm. On the other hand many do believe that queens so nursed and reared are better than can be produced by the ordinary plans which are used, myself included in that number. Therefore I rear, as far as possible, all my queens from cells produced by natural swarming. To accomplish this object, my best colonies are selected in early spring, which are stimulated to their utmost to get them to prepare for swarming as early in the season as possible.

But how shall we get our bees strong in time for the honey harvest is a question I am often asked, so I will tell how I manage: In early spring I go over all my bees and take an inventory of the number of spaces occupied by the bees, and also to see that each colony has honey enough to last them till warm weather comes which is told by the amount of sealed honey in sight. If but little sealed honey is to be seen the hive is marked and fed. As soon as pollen comes in freely, each hive is examined and the brood nest reversed, *i. e.*, the combs that have brood in them are changed so those having the least brood are placed in the center, while those from the center are placed on the outside. By so doing, the queen is incited to greater activity, and those combs which had the least brood in them soon have the most, thus giving quite a gain over letting nature take its course. In about 10 days the yard is gone over with again, this time taking a comb containing honey from the outside of the cluster, and often breaking their sealing to the cells by passing a knife flatwise over it; the brood nest is spread apart and this prepared comb is placed in the centre of it. This causes the bees to remove the honey and in so doing the queen is fed, thus causing her to lay much faster than she naturally would, and thus this comb is soon filled with eggs which means bees in the near future. In about a week the same operation is gone over again.

In order to get a succession of superior cells from my best colonies, it is necessary to keep them swarming as often as possible. To accomplish this I adopt this plan: As soon as they have become established in their new home, say in two days after the swarm has been hived, I insert 2 frames of hatching brood in their hive, and in 3 days more I give them 2 or 3 frames more, which soon makes their hive more populous than was their old home from which they issued. This causes them to swarm again in from 12 to 18 days from the time of hiving, which gives me another lot of splendid cells. Thus I keep my best colonies producing cells of the highest type as long as the honey season lasts. Thus I have given you my plan of getting queens that are acknowledged by all to be as good as any, and believed to be superior by some.

Having procured our queen cells, the next things in order are nuclei. There are many ways of making a nucleus, and the plan I see most recommended is to go to any hive populous in bees, and take from it a frame of brood, and one of honey, with all the adhering bees (being careful not to get the old queen), and place them in an empty hive, adjusting the division board to suit the nucleus. In 24 to 48 hours after they will have become aware that they are queenless, when a queen cell should be given them. Now, although a nucleus can be formed in this way that may work in warm weather, still in cool weather it would be a failure, and, according to my opinion, is not a good plan at

any season of the year, on account of the number of bees which will return to the hive from whence they were taken, thereby depopulating it to such an extent that the brood will mostly be chilled in cool weather, and seriously weaken it even in warm weather. Bees that have been used to a laying queen do not kindly take to brood for a mother; hence all go home that are capable of getting home. But should you happen to get the queen on these two frames, you would see that the bees would feel at home, and all but the old field workers would stay where the queen was.

From this fact, that bees will stay with their queen, I arrived at the following: Inasmuch as a queenless colony, with sealed cells, depend on those cells for a mother, if a frame of brood containing a sealed queen cell, with all the bees adhering to it, are put in a new hive, the bees will stay there the same as they would in the case of a laying queen, as given above. After thoroughly trying this plan, I have found it to work to perfection; and by making the nucleus hive perfectly tight, and shutting the bees in for 24 hours, opening it about dark, scarce one of the old field workers will go back to their former home.

Now for my plan of making nuclei! When all the queen cells are sealed in my queen-rearing hive, I get as many frames of hatching brood from different hives, in the yard, as there are cells in the hive, lacking the number of frames of brood the hive already contains. Brush all the bees off these frames of brood, and let them run back into their old hive, inserting frames full of comb or foundation in place of them. Now carefully fit one of the queen cells into each of these frames, and set all in the colony which produced the cells, and close the hive till 24 hours before the first of the cells should hatch. By this time enough young bees will have hatched to thickly cover all the combs, with scores still hatching every hour. Now get your nucleus hives all ready by making all as warm as possible, and having a nice fitting division board in each one, when you will go to your other hives and get a frame of honey, brushing all bees off of it, for each nucleus. Next take a frame from your queen-rearing hive—bees, queen cell and all—and place it with your frame of honey in your nucleus hive, and adjust your division board. The next day at night open the entrance, and you have a nucleus as good as any one could desire.

In this way make nuclei of all the frames which contain queen cells but one, leaving that to form a nucleus on the old stand. In about 10 days your queen will be laying, when she can be used as you desire. Thus I have given how I rear what I term *good queens*, which have given me the results I have reported for years past, and I claim such queens cannot be reared for \$1. When our dollar queen-breeders will rear all their queens in this way, I shall be willing to say that a \$1 queen will be just as good for honey-gathering purposes as a \$3 queen.

For the American Bee Journal.
A Visit to Baltimore, Md.

ARTHUR TODD,

Late of Bildah, Algeria, and Rambouillet, France.

A few weeks ago a friend, finding me to be an apiarist, induced me to join the Philadelphia Bee-Keepers' Association. In due course I brought forward the subject of breaking down prejudice against our pets, by the establishment in Fairmount Park, or other open space, of an apiary, where open air exhibitions could be given, etc., similar to those established on the Continent of Europe. The suggestion was well received, and the material for a model apiary was donated in a very short time. A committee was appointed to see what could be done, but I regret to say we found it too late for this year, but are promised powerful assistance for the carrying out of the idea next spring.

Having business in Baltimore, and finding there was quite an extensive queen-rearing establishment and apiary there, conducted by Mr. Lake, I duly applied for and obtained permission to make a call. This I did last week, and was well received, seeing everything in the city establishment, as also at the honey apiary some miles outside the city limits. The premises occupied by "Sunny Side Apiary" have a special interest for our craftsmen, for here it was that Colvin had his apiary, and here worked with him his friend Langstroth.

Mr. Lake has some Syrians, and right here I would say that they have one strongly marked characteristic in common with the North African variety. They scatter, and rush about the comb too much for easy examination. They rush to a bottom corner, form a knot of bees, and "flop" they go, falling into the hive or on the ground. Some colonies of Italians opened out before me were certainly the quietest strain I ever handled. There seemed to be quite a hum of joy when the hive was opened, and I made my examination without any veil or other protection without a single sting. One interesting colony is an Italian, an actual lineal descendant of the first Italian colony ever imported here. I believe imported by Mr. Colvin. They are a large bee, and I pointed out to Mr. Lake how, to my mind, they are the mountain race or Bellinzona bee, bred high up in the Italian Alps, while other and smaller-bodied Italians belong to the races bred in the Italian plains or lowlands. Years ago I noticed a great difference between the bees I imported from Bellinzona and those from Milan and Bologna. The true mountain Ligurian seems to me to be a stronger-bodied bee, and in ordering I would give the preference to them any day.

In what we may call the museum, was a hive of remarkable interest, being a bar-frame hive sent over to Mr. Colvin by King Otho, of Greece. This hive was originally made and used near Mount Hymmetus, in Greece, and is practically what is known in

Italy as a "Sartori three-decker." The walls are double, with air space. The lugs of the three rows of frames run into grooves cut on the inner shell of the hive, and the entire back of the hive forms a door moving on hinges which, when opened, at once discloses the entire interior of the hive, but has the disadvantage of forcing one to draw out every frame to get at any one frame in the rear.

At Mr. Lake's honey apiary I found some 400 to 500 colonies, many of them in really splendid condition, and notwithstanding the unfavorable few weeks preceding, I counted 75 one-pound boxes filled with capped honey on many colonies. This apiary Mr. Lake runs for honey in the one-pound box alone, finding that he can dispose of every ounce readily at 25 cts. per pound.

The bees had only worked on poplars and honey locust when I was there, and they appear not to touch or care to touch clover at all. In discussing with Mr. Lake the reason for this, I remembered how my old friend Monsieur Layens, in France, after careful investigation (he being a thorough botanist and chemist), advanced the theory that when the spring of the year is very wet, the clover yields little, or no honey, because those soluble constituents of the earth, the source of the honey secretion, had been by excess of rain washed beneath the surface to a depth too great for the root of the clover to reach.

Altogether I had a most enjoyable visit, and while not agreeing with all Mr. Lake's theories, that very fact lent zest to our conversation, and I came away after enjoying his hospitality, feeling I had added to my store of knowledge, and another to my list of bee friends.

Philadelphia, Pa.

Semi-Tropic California.

Bee Pasturage in California.

C. N. WILSON.

The very large area of land in Southern California now devoted to the cultivation of wheat and barley, that but a few years ago was covered with trees, shrubs and plants from which bees gathered honey, and the absolute certainty that even more of the wild trees, shrubs and plants yielding honey, must very soon give way to the requirements of agriculture, it becomes the apiarian who desires a good yield of honey, to prepare pasturage for his bees. In this semi-tropical climate the task is comparatively easy, as it requires but a few years to make groves of blue gum, acacia, locust and such other trees as produce abundant supplies of honey, yielding flowers at different seasons of the year. The blue gum begins to bloom at 5 years from the seed, and will grow on rocky or sandy soil where hardly anything else would grow, provided it is watered the first two years; it will bloom in February and March. The acacia is readily grown from seed planted just

as corn is planted, about the 1st or 15th of March, and cultivated the first year; afterwards it will take care of itself and bloom the second year from the seed, often commencing to flower in January, continuing until April. The black locust tree requires more moisture to grow well than the acacia, and is like it in this respect, that the seeds must be well scalded with hot water to make them germinate. The willow grows readily from cuttings, and should be planted from December to March; in very moist land it will do to plant as late as April. Doolittle extols the golden willow as a honey producer, and it would be advisable to experiment with this variety of the willow, and possibly it may be suited to this locality; it cultivated the first two years after planting, the several varieties of willow indigenous to Southern California will grow in nearly any soil. Every variety of fruit tree, except the fig, produces bloom, furnishing both pollen and honey. The apricot and peach, and some varieties of the pear will grow well in warm, sandy soil, even where there are no facilities for irrigation, and will the second year after planting produce both flowers and fruit; the fruit will not be so large or showy as that grown on damp or irrigated land, but will be sweeter and better. If the fruit merchant objects to the fruit for any reason, then crush it in the orchard and the bees will very soon convert it into first-class honey, which you can ship to Europe and get more cash for it than if you allowed the fruit merchant to have it.

Alfalfa yields a good quality of honey, and is in bloom every month in the year; it will grow without irrigation in any kind of soil, amongst stones, on such land as cannot be cultivated. Scatter the seed plentifully during the winter months, so that the winter rains may settle it into the soil and give moisture enough to cause it to germinate; keep sheep off the ground so planted, and let the alfalfa get a start, and nothing but gophers can eradicate it. Most persons think that alfalfa must have plenty of water at all seasons of the year in order to grow, but for bee pasture good results may be had from it without other moisture than that obtained from rain.

Sweet corn, when in silk and tassel, will ordinarily furnish large quantities of honey of a superior quality; in localities free from frost it may be planted at intervals from December to May, and give good pasture for 3 months, if not four, in the year; no matter if the corn never matures, the honey product will well repay the trouble and expense of planting, and the stalks if cut just when the bees quit gathering honey from the tassels will make a superior fodder for sheep, goats or cattle. Melons and squashes if planted early will yield large quantities of both pollen and honey, and will reward the bee-keeper for the trouble of planting, though he should get nothing else from them than the honey. Peas and beans yield honey from their flowers, but should be planted early in the spring, as the hot

sun destroys the nectar of their bloom, and unless the bean is irrigated in the summer season it will not be of much value as a crop. Every bee-keeper should make it a point to experiment with trees, shrubs and plants, so that whatever can be made available as a honey yielding help, in this climate of sunshine and country of wonderful vegetation, may be known and cultivated by the bee-keeper.

Our several associations would do well to devote considerable time and attention to the subject of bee-pasturage, for this question is of the very first importance to all of us.

For the American Bee Journal.

The Width of Sections, Etc.

JAMES HEDDON.

It should not be forgotten that when, by experiment, the width of sections was decided on as 2 inches, separators were the all-in-all that then went with them. Now the use of separators has been and is being abandoned by many of our best honey producers. Mr. O. H. Townsend, of Kalamazoo, Mich., now thinks that 1½ inches is a better width than 2 inches. In this we exactly agree. I have used that width for my 1882 crop. I made the change in my last winter's orders for sections. I used the 4¼x4¼ x2 inch sections, 6 sections in a division, and 4 divisions in a case. The divisions run across the hive. I now put 7 sections where 6 filled the space. I found that where no separators were used, the bees sometimes started their combs between the combs drawn from full pieces of thin foundation. Now this trouble is at an end.

I now get the benefit of the use of one more piece of foundation in every seventh section, which benefit is several times its cost. I find the bees cap over the honey sooner, and build the combs straighter. I presume Mr. Townsend is correct in saying that with these thinner sections the bees ripen the honey quicker and more perfectly, and that is the reason they cap over more promptly. Before, our sections used without separators overrun a pound in weight. Now they will come as near an exact pound as any size can be made to do. I am well satisfied with my surplus system, and it is worth a great deal to be satisfied with one's own fixtures, whether any one else is or not.

When I first saw the cut and read the description of the "Dean section case," on page 245 of this year's BEE JOURNAL, I was tempted to make some and try them. They have the advantage that they can be made of most any lumber. After revolving the practical use of this case over in my mind, and talking with an old Bingham hive owner and manipulator, I concluded I need not put any more honey in the old direction, experimenting with this case.

I thought the side boards would shrink and swell away from the

length of the end pieces to the broad frame. I dread complication. These wires, side-boards and pieces look formidable to me. I think I should prefer the Bingham style of "key" for clamping the frames. I have heard of these keys giving way, when lifting the hive, and the whole thing going "ker-smash." What if the "Dean case" should come that on a fellow when it contained 28 of those nice white combs? Wouldn't those bottom bars sag? True, when unclamped or unkeyed it comes apart nicely, but then, after all, is it not neater and handier to lift a section out of a solid case, when on the hives or when off, to invert the whole and push out the whole 28? A job of a moment only. If this system is best for the surplus department, why not for the brood department also? If it is for the latter, why don't Quinby's and Bingham's style of frame supersede the Langstroth frame, in the solid case with solid bottom? They have had time enough surely. I think I should prefer my old wire clamp method as shown in cut on page 159 of BEE JOURNAL for 1879, or in *Gleanings* on page 116, 1881, if I were going to use any clamp method at all. This is my second year's use of the solid, divisioned, no glass case, and, as above stated, the solid individual comfort I have taken, and am taking with its manipulation, is highly prized by me. All my help, and all my visitors, and those who have used them, like them best of all, so far as heard from. There is no patent on it, and did I feel able, I would give the readers a cut of the case.

They are made of common thin lumber, and any good mechanic can make them as they should be. I should be pleased to see them in general use, and all the reward I ask is the little honor due this little invention. If any better thing comes up, I shall be among those who rejoice in its use, and with smiles and dry eyes will gladly watch this case as it takes its march toward the silent portals of eternal forgetfulness.

Nebraska Farmer.

Practical and Scientific Apiculture.

T. L. VON DORN.

Every pursuit, every profession, every business enterprise must, in order to be made a success, rest upon certain known, fixed rules of action, based upon the accumulated knowledge of which practice has been shown the best fitted to obtain the best results. Scientific apiculture is comparatively of to-day's creation, yet its possibilities are encouraging enough to warrant all the careful thought, business accumen and energy that the best of us can offer. Fortunately many of the problems, obscure so few years ago as to be within the memory of almost all present, are solved, and instead of the doubt, uncertainty and mystery of the past, the greater part of the conditions requisite to success are well known and

are easily complied with. One element of success, however, at times, baffles the best of us, yet would seem to be of easy solution, notwithstanding the apparent uncertainty which now obscures this part of our occupation. Of course, I refer to the wintering problem, for let us so improve our bees that we get hundreds of pounds from every colony, and increase almost at will, yet, if, in the recurrings, we find that few of our colonies have survived the winter, or having survived, are indisposed or incapable of giving the best results, we have most certainly failed in this, which to-day is practically the greatest obstacle in scientific bee culture. I cannot believe, however, that the day is far distant when we shall surmount this as we have other difficulties apparently as great. Bees are warm-blooded creatures and I can see no reason why they should be an exception to other animals in regard to their care, and believe the question to be simply how to so care for them as to comply with known laws in such cases.

But practical apiculture rests upon more than the mere knowledge of what can be and should be done. It rests upon the unwritten part of our trade, which is quite as much to learn as the trade secrets of any other occupation, the knowledge of just when and how to perform the little operations that go to make up the day's labor; or, as it is commonly expressed, the "knack" of knowing just how and when to do it. You must know just what the condition of every colony is, and when occasion arises must aid them promptly promoting this, checking that, leaving nothing to uncertainty, in fact, you must live with your bees if you would close the season's labor with success.

How to obtain this knowledge is a matter for your careful consideration. Undoubtedly, if you were so situated as to make it possible, the advice and precept of some skillful apiarist would be preferable, but I imagine that but few are so situated and therefore it may not be amiss to refer you to such resources as will furnish reliable information. I confess it is with pride I can say to you that the works of our own countrymen, are pre-eminently the most practical and scientific. No one can read "Cook's Manual" without being impressed with the labor and research necessary to enable the author to place before the reader and carefully explain anatomy and physiology of the bee, and its bearing upon practical agriculture, or the years of toil which has made the "ABC of Bee Culture" what it to-day is, or the common sense of "Quinby's New Bee-Keeping." We should be proud of our countrymen. But with all your knowledge never neglect the little things that impress you at the time as new. Follow up your practice with careful study and investigation. Lay the foundation for success broad and strong, and when the superstructure is built it will long endure.

Omaha, Neb.

For the American Bee Journal

Not "More than Bright."

R. BACON.

The BEE JOURNAL of June 25th, says: "Prospects more than bright; from every quarter come the most encouraging hopes." Now, this being left out in the cold makes me feel rather chilly. Perhaps it is all for the best; other sections may feel the same and not like to mar your bright prospects. But permit me to say that one section, little Central New York (perhaps it is not quite large enough to be called a "quarter") has nothing good in the bee line to report. Bees are swarming but little, and have gathered but little honey up to date. Yesterday I called on a bee man at Oneida who has over 100 colonies. Less than one-third of his bees have swarmed, and some had begun work in boxes a very little, but no boxes half filled. He did not know any bees that were doing much. He is yet hoping the weather will change, so we will get some honey.

Last year at this date I had taken off more than half a ton of section honey; but now not one box finished, and not 10 colonies doing anything in the boxes. Now, if you feel like helping the bee men of this cast-off section, please turn those honey spouts (not your big western water-spouts) this way. We will set our houses in order, and will not scold if you daub us a good deal, nor will we dodge. We may do better in future—the summer is late.

Verona, N. Y., July 13, 1882.

[The prospects at the time the article alluded to was penned, were very bright. There were especial districts where they were more than excellent, others not so good, but, generally, they were more than bright. Nor is there cause for despondency yet. Had the weather been propitious, and prospects realized, even Central New York would have given a good yield. The season is late—very late—but the promise is abundant, if the weather is such the bees can gather it. Sweet clover is just coming into bloom with us now; last year this time they had been working on it a month nearly. However, we will have plenty of it, and summer and fall flowers will be immense. We hope Central New York will then come in for its share.—Ed.]

☞ A bear, wishing to rob a bee hive, laid himself down in front of it and overturned it with his paw. "Now," said he, "I will lie perfectly still and let the bees sting me until they are exhausted and powerless; their honey may then be obtained without opposition." And it was so obtained, but by a fresh bear, the other being dead.—*Exch.*

Local Convention Directory.

1882. *Time and Place of Meeting.*
 July 25—Western Iowa, at Winterset, Iowa.
 Henry Wallace, Sec., Winterset, Iowa.
 Aug. 10—Maine State, at Harmony, Maine.

 Sept. 5—N. W. Ill. and S. W. Wis., at Rockton, Ill.
 Jonathan Stewart, Sec.
 Oct. 3-6—North American, at Cincinnati, O.
 Dr. Ehrick Paruly, Sec., New York City.
 5—Kentucky Union, at Shelbyville, Ky.
 G. W. Demaree, Sec., Christiansburg, Ky.
 Tuscarawas Valley, at Newcomertown, O.
 J. A. Bucklew, Sec., Clark, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

California Apiculturist.

Ventura County, Cal., Association.

The Ventura County Bee-keepers' Association met at Santa Paula, on Saturday, June 10th.

In the absence of the president, Mr. Wilkin took the chair and stated the object of the meeting. He said the Association had been called together for the purpose of devising means to rid the country of foul brood. As the present was not a very busy time for bee-keepers, owing to the failure of the honey crop, he thought it a good time to make a united effort to get rid of the disease, and prevent if possible, its spreading to the mountains. He thought if it once got into the trees and rocks it would be impossible to check it, and bee-keeping would become a very precarious business. He suggested that a "foul brood inspector" be appointed to examine all apiaries where the disease existed, or was suspected to exist, and assist the owner to obliterate the disease.

Mr. Corey thought it too big an undertaking for one man; he thought there could be found eight or ten men in the country with sufficient experience to assist in the work; and an inspector, if appointed, should be vested with power to appoint a sufficient number of deputies to assist in the work, that it may be more thoroughly and speedily accomplished.

Mr. Strathearn thought that all the apiaries in the country should be examined and certificates of health issued to those whose apiaries were found free from disease, and if anyone refused to have their bees examined, it would be an evidence that their bees were diseased, and that they were concealing the fact in order to sell out, but if no one would buy bees except from those who could show a certificate from an inspector appointed by the Association, the practice of selling diseased bees would soon become obsolete, and all would be anxious to have their bees examined and the disease exterminated.

The convention coincided with Mr. Strathearn's views and voted to ap-

point an inspector, vested with the power to appoint deputies and issue certificates to those whose bees are found free from disease. R. Touchton was nominated for the position and elected by acclamation.

Mr. Corey moved that a tax of 1 cent per hive be levied on the members of the Association and requesting that all other bee-keepers in the county contribute and forward to the Secretary a similar amount, for the purpose of creating a "foul brood fund," to defray the expenses of the inspector and his deputies. Motion carried.

It was also thought advisable where but few diseased colonies were found to destroy them entire, and the loss thus sustained to be made up by the Association in bees, the owner bearing his proportion of the loss. As to the extent of the disease Mr. Edmondson reported that the disease had been in his apiary, but thought he had it reduced to less than a dozen cases, but was not certain; he said he would be very glad to have them examined by an expert, and the diseased colonies destroyed.

Mr. Grimes said he thought his apiary was entirely free from the disease, but nevertheless would be glad to have them examined, and if any cases were found he would destroy them; he expressed his willingness to assist in the work of eradicating foul brood, as did also Mr. Corey and others, who had had experience with the disease.

The convention adjourned to meet at Santa Paula, the first Saturday in August.

R. TOUCHTON, Sec.

SELECTIONS FROM OUR LETTER BOX

Drone Traps.—On the 4th inst. I bought a colony of Italian bees, that had no queen, but 11 queen cells. On the 11th inst. I opened the hive and cut out 10 queen cells, and within 15 minutes 4 of them emerged. I caged them and made nuclei hives for them and the queen cells. All the rest of my bees are blacks. 1. How can I catch the black drones? 2. Is there any kind of drone trap; if so, how can I make it? S. J. HOPKINS.
 Evansville, Wis., July 14, 1882.

[1. D. A. Jones, Beeton, Ont., has advertised and sold quite extensively a perforated zinc for the purpose of placing at the entrances, which, while too small in its perforations to admit of the passage out of well developed drones, will allow an entrance for worker bees.

2. There have been several contrivances gotten up for that purpose, but we are unacquainted with their details, and almost doubt the perfect utility of them.—ED.]

More Cheerful from New York.—I have had some bees for the past 3 years. I commenced with the chaff hive, and do not use any other, and have not lost a colony since I have been in the business. In the spring of 1881 I had 5 colonies. I let each colony throw off one swarm, and then cut out the queen cells, so my swarming season lasted only two weeks. I had 10 colonies in the fall, and sold about \$60 worth of honey in Syracuse at from 13 to 15 cents a pound. In May last, when I took them out of the chaff, I found every colony strong and healthy. I put 61 one-pound sections on each colony. I now have 19 colonies. I never saw bees do better than they are doing now; they work early and late, and in all kinds of weather. Although we have had a very cold, late, rainy season, I believe my bees will make up for lost time. Everything is growing rapidly here, and we expect a good crop. I would like to know—1. How to unite 2 weak colonies in the spring? 2. How to unite 2 swarms in swarming time? 3. How to unite 2 weak colonies in the fall? 4. In manipulating the bees, what kind and how much smoke to use. I am in the habit of using a smoker, and blowing a good quantity of tobacco smoke into the hive before I commence work.

EDWARD NEWCOMB.

Centerville, N. Y.

[1. As good a plan as any is to use a fresh hive, put it on a new stand, place the old hives one on each side, slant a board in front from the ground to the alighting board, remove one queen, cage the other in the center hive, then shake the bees in front, alternating frames from the two hives in shaking off.

2. Shake the bees on a sheet in front of the hive, in one pile, and remove one queen as they crawl up to the entrance.

3. There are several methods. Usually, quite late in the fall, if one queen be removed, then the frames of the two colonies be alternated in one hive, there will be no trouble.

4. Use any good bellows smoker, putting a live coal in the bottom, and dry, partly rotted wood on top, or cotton rags, you can make a sufficient smudge. We do not recommend the use of tobacco in smoking bees; nor an excessive use of any kind of smoke.—ED.]

That New Clover.—I have gotten myself into a fine box by sending you that sample of new white clover, as I have not the time to answer the numerous correspondents in regard to it, and those who are ordering seed, etc., from all parts of the United States and Canada. Now will the JOURNAL be so kind as to say I have no seed to send this year, but will have enough next year to spare in small quantities to the numerous apiarists of this

country (for I am now satisfied that the BEE JOURNAL is the right medium to advertise through, since my late experience). My bees are booming, and keep me busy extracting and taking off boxes, etc. The prospect at present is that the white clover will last for two or three weeks yet. The season is turning out better than we expected.

H. BESSE, M. D.

Delaware, O., July 12, 1882.

After-Swarming.—Mr. James Hobbart, of this place, has one colony of Italian bees that have sent out 5 swarms. The first one came out June 11, and the last one yesterday, July 13. Is not that an uncommon occurrence? Bees are doing finely; white clover in great abundance.

J. C. MARVIN.

Fairchild, Wis., July 14, 1882.

[After-swarming is not an unusual occurrence. We have heard of instances where after-swarms came out so numerous that the parent colony was ruined, there not being young bees enough left to properly conduct the affairs of the community. As many as 10 swarms from 1 have been reported. Of course, all were exceedingly small.—ED.]

Faith in Movable Frame Hives.—Since my last letter (June 14), we have had a week of steady rain, doing considerable damage to crops of all kinds. On low bottom land our bees seemed to be a little on the decline during the latter part of June, as there was so much rain fell that it washed all the nectar out of the blossoms. I have been a reader of the BEE JOURNAL since last March. I couldn't do without it, but I thought the movable frame bee hives were humbugs. Being determined to satisfy myself in regard to the matter, I drafted out and built a movable frame hive, somewhat after the pattern of the Langstroth. I put doors and glass in the four sides, so as to give me an insight. I gave them starters of comb foundation and put in a swarm the 21st of June, and in 14 days they had the hive filled with comb, and had brood capped over. I now see the convenience of movable frames. I expect to use them altogether next season. My neighbors worry my patience calling to see my new bee hive, and every one admires it very much. I am puzzled over two late swarms. The first one came out July 1st, clustered, and was hived. In the evening they swarmed out and went back into the old hive, leaving a small bunch of bees not more than a tea cup full in the hive. These remained six days, when they swarmed out and clustered on a willow tree. I examined them and the queen bee was with them. I brought her to the house and caged her, and the bees then went back to the old hive and went in, only to be dragged out and killed. The second swarm came forth July 2, and was a small one. I hived them with considerable trouble.

They remained about 3 hours and swarmed out and went back to the old hive, staying 4 days and swarmed again. There were about twice as many as at first. I hived them again, and in about one hour and a half they swarmed out and went back again, staying 2 days, and swarmed again (being the third time). There were four times as many as at first. I had now resolved to try an experiment. I spread down a clean tablecloth upon some boards I had prepared, and placed the hive at one edge. After shaking the bees down in front of the hive I sprinkled them cleverly with water, clipped my captured queen's wing, and dumped her into the middle of the pile, then drummed them all into the hive together. After they all went in, I gathered up the cloth in front of the hive and wound up the hive completely, leaving it remain until dark, when I carried it to the stand where I wanted it to remain, and took off the cloth. They are now working splendidly. Will you tell me the causes why did the first colony swarm out and the queen remain, and why did the second colony swarm and re-swarm so often, and then be forced to stay?

FRANK B. RIFE.

Malaby, O.

[In the first instance mentioned, after the bees deserted the queen in the hive leaving but a cup full, they became discouraged with the prospect of rearing brood in a hive so much larger than they could properly warm and fill. At the end of six days the bees had become strangers to the parent colony, and going in with empty honey-sacs, were mercilessly slaughtered.]

In the second case, the bees led by the queen swarmed and re-swarmed in each case to get reinforcements. They finally remained because the queen was clipped and could not go with them. There are many anomalous cases of swarming which are almost inexplicable, and require a careful study of the circumstances to account for it.—ED.]

Done Nothing.—Bees have done nothing here. The honey harvest is now over. I do not know of a box of honey being made in the county. The weather has been very fair for queen-rearing. We have had plenty of rain the past week, and that has prevented queens from mating.

HENRY ALLEY.

Wenham, Mass., July 6, 1882.

But Little Honey from Clover.—Bees have not done much thus far this season. White clover has been in full bloom for about a week; but it has given but little honey as yet—too cold and wet. I do not look for a large crop of honey in this section the present season.

C. BUTMAN.

Plymouth, Me., July 6, 1882.

Honey at Glucose Prices.—"The Coming Market," is the title of an article written by James Heddon, which appeared in the BEE JOURNAL, page 374, June 14, 1882, and is a timely warning to the honey producers of our land. It is an able article, and should be read and well considered by every one interested in the production and sale of pure honey. I, for one, most heartily indorse the language contained in Mr. Heddon's article. It seems to me that if every bee-keeper considered this matter in the same light that Mr. Heddon does, pure honey would not be sold at glucose prices. Last season our comb honey sold at wholesale for 20 cts. per lb., and our extracted at 15 cts. per lb., the majority of it being consumed in the village of Ashtabula. I believe the bee-keepers of the Eastern and Middle States should use every effort to stimulate and improve their home market, and then such men as Thurber & Co. would not have a chance to speculate on our honey by mixing it with glucose syrup, thus reducing the price of honey down to starvation prices. Our bees are doing well on the white clover. I think, by the way the bees work to-day, they have struck a new field of labor. Perhaps it is the basswood just coming into bloom. Our forests in this locality are lined with this honey-producing tree. I am very much pleased with the Weekly BEE JOURNAL.

V. H. ORMSBY.

Pierpont, O., July 6, 1882.

Honey Prospects in Kentucky.—Honey prospects are very poor here. Acres and acres of white clover in bloom, but the weather is not propitious for the secretion of honey. This month has been very cold so far. I received a letter to-day from C. F. Muth, of Cincinnati, and he says he will not get as much honey as he fed in the spring, but, as he also remarks, "as good Christians we shall console ourselves with the hope of better prospects in the future."

W. T. CLARY.

Clarysville, Ky., July 7, 1882.

Prospects for Remainder of Season.—Bees are doing well here now, and the prospects are good for the remainder of the season. White clover bids fair to yield well for two weeks yet. The great amount of rain that we have had will make a great abundance of bloom from wild flowers. Hartsease and smartweed are in many cornfields to the annoyance of the farmers, but to the benefit of the bee-keeper. An unusual amount of buckwheat has been sown about here. Bees are working well in boxes, and we are busy extracting from a part of our apiary, which is run for extracted honey. We are very busy.

F. A. SNELL.

Milledgeville, Ill., July 10, 1882.

Supers Full of Honey.—Bees have done finely here. Hives and supers are chock full of honey.

A. BENEDICT.

Bennington, O., July 12, 1882.

Statistics Wanted.—Bee-keepers in this State, who wish to forward the interests of apiculture, will please send me the name and address of the Secretary of the local agricultural society, as I wish to correspond with them in regard to the offering of premiums for the best display of honey, implements for the apiary, bees, etc. I would also like to have all bee-keepers in Massachusetts send me a report of the season's work, number of colonies, etc., as I wish to give a more complete report of the condition of bee culture in this State than has ever been published before, at the meeting of the National Society in October. Bees are doing very poorly in this section this season; no honey and but few swarms.

E. A. THOMAS, *Vice Pres.*
for Mass. of N. A. B. K. Society.
Colerain, Mass., July 10, 1882.

[We hope all bee-keepers in Massachusetts will promptly respond.—ED.]

Just Started in the Sections.—My 70 colonies of bees have just started in the sections, but it rains so frequently that they do not make much progress. They were nearly famished when red raspberries came into bloom, 3 weeks ago. No swarms have issued yet, and this is the situation of all the bees in this section. Still, clover is abundant and is yielding honey, and basswood will be ten days or two weeks later than usual, and may give us a good harvest.

LEROY WHITFORD.
Stow, N. Y., July 3, 1882.

Still Continues.—The prospects of a good honey crop still continue. So far I have taken off 7,000 lbs. extracted honey. We have occasional showers which contribute greatly to the improvement of the cotton, corn, and other crops. Fruit is very abundant.
O. M. BLANTON.
Greenville, Miss., July 9, 1882.

The Prospects Discouraging.—The weather has been so windy and stormy that bees have had very little chance to gather honey. Some colonies have not swarmed yet, and none have gathered much honey.
DR. J. A. MORTON.
Bethel, Maine, July 13, 1882.

Bees in a Starving Condition.—Bees just starving, with the 4th and 5th of July the coldest and most rainy days I ever knew in this month. If queen-rearing isn't up-hill business, call me a goose. As far as I hear, bees are generally in a starving condition throughout this State.
G. M. DOOLITTLE.
Borodino, N. Y., July 7, 1882.

Bees in South Carolina.—We have had an excellent spring for honey, until June 15th. Since then bees are gathering but little. We also have a boom in the bee business in this county. We are talking of organizing an association. H. S. HARDIN.
Chester, S. C., July 10, 1882.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10	per cent. discount.
" 8 ".....	20	" " " "
" 12 " (3 months)....	30	" " " "
" 16 " (4 months)....	40	" " " "
" 20 " (5 months)....	50	" " " "
" 52 " (1 year).....	60	" " " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street, Chicago, Ill.

Special Notices.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for one year, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—a copy of "Bees and Honey."
" " 3,—an Emerson Binder for 1882.
" " 4,—Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,—" " " cloth.
" " 6,—Weekly Bee Journal for 1 year, or Apiary Register for 200 Cols.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., July 17, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—I am paying 7c. for dark and 9c. for light extracted.
BEESWAX—Choice lots are worth 25c. here; bright yellow, 24c.; dark to good, 17@22c.
AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for honey is quiet. Extracted brings 7@10c. on arrival. No comb honey on the market worth mentioning, prices nominal.
BEESWAX—Scarce, and brings 20@25c. on arrival.
C. F. MUTZ.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for comb honey is light, prices being made to meet views of purchaser.
BEESWAX—Scarce, and in demand at 23@25c.
R. A. BURNETT, 165 South Water St.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c; dark 7@8c.
BEESWAX—The market continues rather quiet, but the supply is light and prices firmly sustained. Western, pure, 25@26c.; Southern pure, 26@27c.
D. W. QUINBY, 105 Park Place

CLEVELAND.

HONEY—The first new honey arrived this week, and 1 lb. sections sold at 25c. per lb. No extracted received as yet.
BEESWAX—25@28c.
A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—Not much arriving, and most of that is held above buyers' views. Some very white comb is offering at 16c. Buyers refuse to name more than 8c. for extracted of the choicest quality, but there are some lots of excellent body, color and flavor, which are limited at 9c.
We quote white comb, 15@20c.; dark to good, 8@12c. Extracted, choice to extra white, 7 3/4@8 1/2c.; dark and candied, 6@6 1/2c. BEESWAX—24@25c.
STEARNS & SMITH, 423 Front Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
BEESWAX—Prime quality, 25c.
CROCKER & BLAKE, 57 Chatham Street.

ST. LOUIS.

HONEY—First receipts of new Texas (comb) offered to-day. Selling at 21@22c. per lb.
BEESWAX—Prime in demand at 22@23c.
R. C. GREER & CO., 117 N. Main Street.

"Bad luck," when applied to bee-keeping usually should be stated as "bad management."

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Articles for publication must be written on a separate piece of paper from items of business.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 8oz.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

When changing a postoffice address, mention the *old* as well as the new address.

A Sample Copy of the Weekly BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Do not let your numbers of the BEE JOURNAL for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference

Three years ago St. Julian, the great California trotter, was unknown; the same may be said of Kendall's Spavin Cure. Now both have a world-wide reputation. Why? Because they both have merit. One is a great trotter, the other is the most successful remedy ever discovered to be used on man or beast. 26w4t

Bingham's Smoker Corner.

I have tried several kinds of Smokers, and none give such satisfaction as Bingham's; 'tis worth more to me than all the rest combined. Morning Sun, Iowa. J. E. KEARNS.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$16.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8.00
For 2 Lang-troth " 10x18 "	8.00
For 3 " " 10x18 "	10.00
For 4 " " 10x18 "	14.00
For 2 frames of any size, 13x20 "	12.00
For 3 " " 12 1/2 x 20 "	12.00
For 4 " " 13x20 "	16.00

A NEW BEE BOOK!
Bees & Honey

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS C. NEWMAN,

Editor of the Weekly Bee Journal.

It contains 100 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, **75 cents**; in paper covers, **50 cents**, postpaid.

925 W. Madison Street, Chicago, Ill.

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,

923 West Madison Street, CHICAGO, ILL.

BINGHAM SMOKERS.

PRIZE QUEENS FOR 1882. From the Evergreen Apiary.

REV. E. L. BRIGGS, of Wilton Junction, Iowa, will furnish Italian Queens from either of his Prize Mothers, as early in the coming season as they can be bred, at the following rates: Tested Queens, \$3; Warranted Queens, \$2; Queens without guarantee, \$1; Two comb Nucleus, with Tested Queen, \$4. Orders filled in rotation, as received, if accompanied with the cash. 3w29t

BEAUTIFUL QUEENS—Warranted Italian, \$1.25 each; Warranted Cyprians, \$1.50 each; Unwarranted Queens, \$1.00 each. Try one and you will want more. Address,

27wt9p **REV. J. E. KEARNS,** Morning Sun, Iowa.

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY, By A. J. COOK,

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY,**

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. H. WEST.**

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**E. H. WYNKOOP.**

This book is just what everyone interested in bees ought to have, and which, no one who owns it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL.**

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—**WM. VAN ANTWERP, M. D.**

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—**L'ABBE DU BOIS,** editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also, thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *vaude mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. If you are taking up interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, \$1.25; in paper cover, \$1.00, by mail prepaid. Published by

THOMAS G. NEWMAN, West Madison Street, CHICAGO, ILL.

"RED TAPE!"

Who will be the first to copy?
25,000 IN USE.

If you buy the Original Patent Bingham Bee Smoker, you will aid the inventor of improved bee smokers—get the best, that never go out—always please—never is complained of—the standard of excellence the world over—better and handsomer this season than ever before. Price per mail, postpaid, from 65 cts. to \$2. Our patents cover all the smokers that will burn sound stove-wood, or do not go out. If you buy our smokers and honey knives first, you will have to buy no others.

Scribner's Lumber and Log Book.

NEARLY A MILLION SOLD. Most complete book of its kind ever published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States and Canada. Ask your booksellers for it. Sent for 35 cents post-paid.

G. W. FISHER, Box 233, Rochester, N. Y.

Also for sale at the BEE JOURNAL Office. 221 26in.

PURE HOLY-LAND QUEENS.

I make a specialty of rearing pure Holy Land Queens, and have now more than 100 colonies in their purity. All Queens bred from D. A. Jones' Imported Queens. Dollar Queens, before June 20, \$1.25 each; after that date, single Queen, \$1.00; 6 for \$5.00; 12 or more, 75 cents each; Warranted Queens, 35 cents more each. Tested Queens, \$2.50 each; Italian Queens, same price.

MENDELSSOHN PIANO Co's.

PIANOS

\$850 Square Grand Piano for only \$245.

PIANO STYLE 31 Magnificent rosewood 32 case elegantly finished, 3 strings, 7-13 Octaves, full patent cantate agraffes, our new patent overstrung scale, beautiful carved legs and lyre, heavy serpentine and large fancy moulding, full iron frame, French Grand Action, Grand Hammers, in fact, every improvement which can in any way tend to the perfection of the instrument, has been added.

Our price for this instrument, boxed and delivered on board cars at New York, with fine Piano Cover, Stool, \$245.

Reduced from our late wholesale factory price, \$295, for 60 days only, to have this beautiful Piano introduced. This is now, by far, the greatest bargain ever offered the musical public. Unprecedented success! Tremendous demand for this style! Order at once.

This Piano will be sent on 15 days' test trial. Please send reference if you do not send money with order. Cash sent with order will be refunded and freight charges paid by us both ways if Piano is not just as represented. Several other special bargains: Piano, \$140 up. Over 15,000 in use, and not one dissatisfied purchaser. Handsome Illustrated Catalogue mailed free, giving the highest testimonials ever awarded any manufacturer. Every Piano fully warranted for 5 years.

SHEET MUSIC 1/2 price. Catalogue of 3,000 choice pieces sent for 3c. stamp.

MENDELSSOHN PIANO CO.,

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as Carcharodon Hondaletti. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better.

I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by THOMAS C. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping. by L. C. Root.— The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture. by A. I. Root.— This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book. by A. J. King.— This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.— This is a standard scientific work. Price, \$2.

Blessed Bees. by John Allen.— A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey. or **Management of an Apiary for Pleasure and Profit.** by Thomas G. Newman.— Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Hienen Kultur. by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Dzierzan Theory— presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine. by Thomas G. Newman.— This pamphlet discourses upon the Ancient History of Bees and Honey; the nature, qualities, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.— This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market. including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive Use.— Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.— A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management of the honey apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity. by Thomas G. Newman.— Giving advanced views on this important subject, with suggestions what to plant, and when and how: 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers. by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.— No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chleken Chleken. by A. J. Hill.— A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic. contains over 1,000 of Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 Items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Brokers, Golders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Apiculture in the State University.

On page 471, Mr. James Heddon very frankly gives his views regarding an apicultural chair in our Illinois Industrial University, but we are forced to differ slightly with him regarding the objects sought to be attained, and the qualifications of the Professor. We fear it would be as difficult a task to teach any person practical apiculture, as it would be to instruct any person in practical farming, practical house-building, practical banking, or practical dry goods vending. Practical apiculture, as with every other practical pursuit, requires much practical experience and a combination of many qualifications to make it successful as a specialty. Who would claim for a moment that the best law university in the United States can impart an education sufficient to insure a national reputation for its graduates? All the University or College can do is to prepare its graduates to receive the practical education.

In our State University we want a Professor or Chair of Apiculture, where the student can be instructed in the natural and physiological history of the honey bee; where the State will encourage the solution of many very important and vital problems, which now stand in the way of successful and special apiculture; where men of eminent talent will be set apart and given facilities for carefully and scientifically investigating causes of disease, and evasions of natural results. What specialist, if any, has the necessary time and facili-

ties for determining many questions daily arising, and which require the nicest scientific education to properly conduct their investigation. The very fact of there being a multiplicity of hives, theories as numerous as the bee-keepers themselves, and errors and hobbies as ridiculous as superstition, prove the want of more thorough education, and the lack of reliable authorities. With our present brilliant array of practical talent, such as can be found in every National, District, State and Local Convention, which meet periodically, and the several bee-papers to publish their frequent interchange of ideas, practices, successes and failures, the practical education will rapidly inculcate itself. But scientific, theoretical, positive education we lack, and mere individual, casual observation will not supply the want. In our introductory article on this subject we suggested the Illinois Industrial University, because we know of no institution so central, with such eminent talent for the purpose, and we mentioned the name of Prof. Burrill in connection with the department, because he possesses in a remarkable degree all the qualifications required to conduct the experiment to a happy success. In the one man is combined to a rare degree the botanist, entomologist, microscopist, philosopher, and scientific gentleman.

St. Louis Fair.—We have received the Premium List of the twenty-second St. Louis Fair, which opens Oct. 2, and closes Oct. 7, 1882. The premiums appropriated amount to \$50,000, of which best display of Italian bees receives \$20, black native bees \$20, imported queen \$10, comb honey diploma and \$10, crate of comb honey silver medal, crate of apiarian implements diploma and \$10, best bee hive, honey extractor, wax extractor, bee smoker, honey knife, and bee veil, each a diploma.

Lecture on Practical Botany.

We feel confident our readers all take a deep interest in everything relating to botany and entomology, so far as they are directly connected with bee-keeping. Dr. J. R. Baker, of Keithsburg, Ill., sent us two specimens, which Prof. Burrill describes below in his very instructive manner. One specimen has been the cause of much annoyance, on account of waxing up the feet of the worker bees:

I send two varieties of plants that are indigenous to this locality and give the names of both, if you please. In our ignorance here we call the one with the red bloom white root, or pleurisy root, but I don't know really what it is. The bees work on the bloom (which is very profuse) very eagerly, and seem to get honey from it freely. The flowers are beautiful, and if it is a good honey plant it would pay to cultivate it. It grows from 20 to 30 inches high, and is nicely grouped, a great many stocks springing from one base. The other specimen which I send is not yet in bloom, but it bears a yellow flower, on which the bees work very industriously in the early part of the day. The plant only grows from 6 inches to a foot in height, and the leaf looks like that of the locust. The sandmint or beemint, etc., of which I made mention recently in the BEE JOURNAL, I see Prof. Cook calls *Monarda fistulosa*. Your book entitled "Bees and Honey," is a magnificent little work. I have Prof. Cook's and A. I. Root's books, and I like them both very much, still I find much pleasure and profit in reading your "Bees and Honey." Every beginner in bee-keeping ought to have your book and it will do the veterans in the ranks good, too, I am sure.

No. 1. *Asclepias tuberosa*, butterfly weed or pleurisy root. This handsome plant, common in fields (hedgerows, etc.), meadows, and waste places with its leafy stem and conspicuous clusters of reddish-orange flowers, the latter appearing throughout the latter half of summer, certainly deserves attention. It is a beautiful thing seen at a distance, and its curiously contrived flowers merit the closest inspection and most careful interpretation. Bee-keepers, however, should observe another thing connected with the plant. There is a good supply of nectar, and bees are not slow to find it out, but many of them pay dearly for their booty. The pollen is lodged in cells with external slits, and collected small pear-shaped stalked masses, which are quite viscid or sticky. To reach the nectar the bee must press against the parts containing these waxy pollen masses, and are almost sure to with-

draw them adhering to the insect's body. Not unfrequently the feet become clogged with the amount of the viscid material from which extrication is impossible. The poor honey gatherer dropping upon the ground or lodging among the grass, struggles in vain for freedom, and dies for want of it. My observations, however, have not been full enough to warrant any statement of the real danger to which a colony of bees are thus exposed where the plant abounds. If I mistake not, the subject has been pretty well written up by some one.

No. 2. *Cassia chumærista*, partridge pea, wild sensitive plant. This common, yellow flowered plant is often very abundant in rather low grounds. The leaves are considerably alike those of its relative, the sensitive plant of the green-houses, and are slowly sensitive to touch. The flowers are very attractive to honey-loving insects, and are visited often in great numbers. At the base of each compound leaf there is a curious stalked, button-shaped gland, which also excretes a sweet fluid and which, therefore, attracts bees and wasps. What is this for? It is well understood that the nectar of the flower serves to secure the aid of insects in carrying pollen, and so favors cross-fertilization, but what advantage can it be to the plant to manufacture and exude the enticing substance far from the flower? From some observations made years ago, I think a possible explanation is offered. Will others seek to disprove or corroborate. It is manifestly injurious to the plant if cross-fertilization is a benefit, to have the nectar of the flower stolen by creeping insects, for they cannot readily pass from plant to plant. Now, if any such ascend the stem, these little stores from the leaf glands would be sure to receive attention, and thus the flower be more likely to escape. That ants do thus turn aside I have frequently seen; but something more. Wasps, during fair weather, are almost constantly busy about these leaf glands, and they appear to do yeoman service in keeping down all sorts of creeping things. What intricacy of plan, what marvellous adaptation of means to end!

Dr. J. P. H. Brown, of Augusta, Ga., writes thus: "We are having a delightful season—plenty of honey and lots of fruit. The crops are very fine and agriculturists ought to feel happy."

Drones and their Work.

Hon. G. W. Demaree, with his proverbial candor and usual ability, on page 472 treats of "queens, drones and workers," and "assumes when a proposition has long been accepted as a 'fact,' the burden of proof rests on the shoulders of those who wish to controvert and overthrow it." We have long had a *doubt* whether the poor drone has had full justice done it, but have only expressed a doubt, and gave our reasons for entertaining it. Had we known that our doubts were susceptible of being converted into accepted "facts" at the present time, we should have arrayed our proof as frankly as we intimated a doubt.

The first and third of Mr. Demaree's propositions we are not disposed to controvert at the present time, although we should not hesitate to do so if we thought they were founded on error.

We think, however, our correspondent is in error in saying no one colony will tolerate more than one queen, but the exceptions are so rare as to most fully establish the rule; and yet the very colony in which the intrusive queen might be soonest killed, will perhaps be the one to tolerate most drones. It is notorious, that bees are usually most prosperous when the drones are most plentiful, and it is possible that each contingency is to an extent dependent on the other. It is not proof that drones perform but the one single function, because tradition or theory accredits them with but one, or because we have no means of arriving at present at their specific work.

During two days of last week very industriously employed in assisting to extract, it was a noticeable fact that the colonies wherein the most drones were peacefully harbored, were in no wise deficient in quantity of honey, nor in its ripeness and quality.

Mr. Elias Clouse, who has been elected secretary and treasurer of a new Canadian Bee-Keepers' Society, organized on Jan. 13, 1882, writes us that though they have had but 4 meetings, the members now number 40. This is a good beginning for the "Norfolk Bee-Keepers' Association," and promises good results. The next meeting will be held at Simcoe, Ontario, on Friday, August 4, 1882, at 2 p. m.

Normal Excretions of Bees.

We publish on page 474 of this number, a very interesting communication from Mr. C. N. Abbott, editor of the *British Bee Journal*, discussing Rev. W. F. Clarke's question, "Do bees void dry excreta?" Mr. Abbott's article proves much observation and experiment, and apparently goes far to substantiate his conclusions; however, the writer fails to tell us whether the supposed dry excreta is a normal, healthy voidance, or the opposite extreme of the dysenteric voidure.

The writer's standpoint is well taken, that "bees can only void their excreta naturally when on the wing;" but it may be a matter of doubt whether any insect or animal can void dry feces, though frequently we come across those which are comparatively dry. And here arises a question as to the chemical composition of those dry grains or pellets frequently seen in shipping boxes, and sometimes on the bottoms of the hives. A careful analysis and microscopical investigation may determine the presence of beeswax to such an extent as to explain their appearance.

Again, if these pellets are the excreta of bees in a healthy, normal condition, then the amount of flight necessary is certainly very limited, if a box of the dimensions given by Mr. Abbott affords ample facilities, and it would be an easy matter for the apiarist to provide such, and periodically during a protracted or unusually severe winter, remove his colonies into a heated room, run them into a box of corresponding dimensions, give them a lively "shaking up," and again return them to their hives for another season.

As intimated by the learned writer, much more is involved in this question than mere idle curiosity, and we unite with our contemporary in hoping that the matter will receive the fullest investigation at the hands of the most scientific and progressive apiarists in all parts of the world. Those having the facilities, leisure and necessary expertness, have opportunity for a very interesting series of experiments.

Cincinnati Industrial Exposition.—We have received the circular of the tenth Cincinnati Industrial Exposition, which opens Sept. 10 and closes Oct. 7, 1882. The circular is a marvel of neatness and taste, and certainly is

a credit to the Exposition as well as the lithographers, and embraces liberal premiums for all the leading features in art, science, literature and agriculture—almost everything, except bees and honey.

Smoker Fuel.—Mr. A. S. Etherington, Melton, N. S., writes as follows:

I send you by mail to-day a sample of what I consider the best fuel for smokers. I think it is the same Mr. Heddon spoke of in *Gleanings*, No. 7, page 327. For four years I have been keeping bees, and I never used anything else, it giving me such satisfaction. I never tried to get anything better. Mr. Root says some one ought to supply this great boon to the apiarist. I would like for you to test the sample and pass judgment on it.

The sample is very good, and gives an admirable smoke, but no one would ever find it remunerative to supply the article at any price. The apiaries are very few in the United States the proprietors of which could be induced to purchase smoker fuel, and then the quantities wanted would be so very small that nothing but vexation would attend the traffic. We regret to write anything discouraging, but better that than delusive hopes.

Selling Honey at Fairs.

The Tri-State (Ohio, Michigan and Indiana) Fair Association have made a new departure, in the establishment of a Traffic Department. From their circular for 1882 we copy as follows:

With a view to the Traffic Department, no selling will be allowed in the large and commodious main building, which will be kept for exhibition purposes only, but sales-rooms or booths will be provided where all who arrange an exhibit in the main building or elsewhere in appointed places, can, for a reasonable rent, offer for direct sale on the grounds all manufactured wares of merit, or take orders for future delivery, under such rules and regulations as will guarantee square dealing, and protect both buyer and seller.

The fine art hall is well adapted to purposes not only of exhibition but also sales, and artists will be at liberty to take orders for their productions, subject to delivery at the close of the fair.

A traffic department connected with each of the fairs and expositions will be a great benefit to all who are producing for market, as it gives opportunity for extensive effective advertising, and a splendid opportunity for exhibiting goods and wares. The traffic department has for years been

a most important feature in connection with the English and Canadian fairs, and last year Mr. D. A. Jones' sales of honey at the Toronto Fair amounted to several thousand pounds, mostly in small packages, and at very remunerative prices. We hope bee-keepers throughout the United States will make it a point to be well represented at all the expositions and fairs offering the least encouragement, and force sales of pure, choice honey, upon consumers, and thus educate the public to its greater consumption. There should be much more honey consumed in this country, and with proper energy, a home demand can be created for our whole production.

MISCELLANEOUS.

The Smoker Useless with Cyprian Bees.—The editor of the *Bee-Keepers' Guide* gives the following as his experience with the new race of bees:

Our first season's experience with the Cyprians, revealed to us no very vicious peculiarities. They were restless and always running and queens hard to find, but last spring they seemed almost uncontrollable. We have one colony containing a high-priced tested queen with which it is difficult to have any dealing. We open the hive carefully and deluge the bees with smoke, and as it clears away the top of the hive will still be covered with bees trying to stand on their heads and whirling and maneuvering curiously. Then we carefully remove the side of the hive, and it becomes necessary to use more smoke. With the first frame removed, they renew the attack with fresh vengeance and by the time the second frame is taken out we are covered with bees, feeling through clothing in a manner which must give satisfaction to them. They then travel up pant legs inside and out, into sleeves and bee veil, and we find it necessary to adjourn for comfort's sake.

Should Cyprian bees be generally introduced throughout the country, smoke and fumigation will gradually drop out of the use of bee-keepers, as the Cyprian loses none of its activity when smoke is applied.

We think that no bee-keeper should feel contented unless he is owner of one such colony. But in case he has a very near neighbor who keeps a sample hive and whom he frequently visits during manipulating times, it would be a convenient way to obtain a knowledge of them without giving up the body to sacrifice. Soon we shall all come to enjoy the gentler race.

Had Enough of the Cyprian Bees.—The editor of the *Bee-Keepers' Instructor* remarks as follows about his Cyprian bees :

We had one nucleus of Cyprians last season, and as our readers will perhaps remember, stated that we handled them without difficulty, and thought they were not so cross as many claimed them to be. But we take it all back, for we have found, since ours have bred up strong, that they always have an end for business. They are troublesome to handle, paying little or no attention to smoke, and boil over the hive whenever it is opened. They sting most unmercifully on the slightest provocation, while the mashing of a bee seems to set them wild. Strains of these bees may differ, but so far as our experience goes we want nothing more to do with them. From the limited experience we have had with them we fail to see that they possess any superiority over the most gentle Italians. True, they are very prolific, but so are many of our Italians. We have decapitated the Cyprian queens (we now have two colonies), and have requeened with virgin Italians, preferring to run the risk of getting hybrids rather than keep the Cyprians. Ours may be hybrids, and for that reason we do not wish it understood that we speak for the Cyprians in general, but only so far as our experience goes; although we believe it corresponds very closely with that of the majority of those who have tried the Cyprians. At any rate we will rest satisfied for awhile with our experience, not so much for our dislike of stings (as they effect us but very little) as the fact that they are too much like "Banquo's ghost"—they will not "down" when we wish to close the hive, no matter how much smoke we pour into them.

Fumigating Bees.—Mr A. Pettigrew, in the *London Journal of Horticulture* remarks thus on the above named subject :

Doubtless Mr. Raynor is correct in stating that fumigating bees with the smoke of Thyme and other substances is practiced in foreign countries, and his quotations put the matter beyond question. For aught I know the practice of using smoke to fumigate bees may have been known at an early date in Great Britain. But James Bonner, bee master, Auchencrow, Berwickshire, who wrote and published an able work on bees in the year 1879, does not appear to have used smoke or known of it in his day. Bonner's book fell into my hands for the first time a few weeks ago. After Bonner's day my father was perhaps the most extensive bee-keeper in Great Britain for many years. Both he and Bonner practiced artificial swarming without using smoke of any kind. How Bonner proceeded I do not know, but my father simply fixed a cabbage blade in front of his face, turned up his hives and drummed and drove swarms from

them in the manner we now do with the use of smoke to prevent stinging.

One autumn when my father was in Edinburgh selling his harvest of honey he met an Irishman, who offered to instruct him how to carry a hive of bees fully exposed up and down the streets without getting a sting, for a gill of whisky. The bargain was struck, and "the secret" thus obtained was worth all the whisky in the city to my father and to hundreds of bee-keepers besides, and doubtless to thousands of apiarists during the last 10 years. The use of smoke from fustian and corduroy rags makes bee-keeping comparatively easy and pleasant work; and though I am courageous enough amongst angry bees with smoking rags in my hand, I would not like to undertake to swarm 50 hives artificially without the use of smoke. Without the least disposition to question the truth of what Mr. Raynor says about the use of smoke being known long before the Irishman's day, the probability is great I should never have known it, and never have been a bee-keeper at all, but for the Irishman and the gill of whisky in Edinburgh.

Equalizing Colonies.—The *Indiana Farmer* remarks as follows :

For the best results it is necessary that all colonies be made good and strong by the time the honey harvest begins. The frames of comb should be well filled with brood, and the hives full of bees. With only a few colonies, all seemingly in the same condition, we find some colonies will far outstrip others in brood rearing and be ready for the harvest before it comes. Frames of brood should be taken from the strongest and given to the weakest and in this way equalize the colonies before harvest commences. It will not perceptibly injure the strong colony, and will soon put the weaker one in working condition. In building up weak colonies by this method, it is better to do the work in the middle of the day, when the bees adhering to the combs can also be added as they will nearly all be young bees and will stay where put. In all manipulations of this kind first ascertain the whereabouts of the queen, so as not to transfer her with the combs.

Bees Gathering Pollen.—The *Grange Bulletin* remarks as follows :

A bee never gathers pollen from more than one variety of flowers on the same trip or visit. If so, why is there such a perfect sameness of color and appearance of both little pellets carried by the bee. We do not assert that all the bees gather and bring in the same kind of pollen at the same time, but that each bee gathers only one kind the same trip, and may collect various kinds during the day. It is also a well established fact that a bee never gathers pollen and honey on the same trip to replenish their stores with, but may gather pollen one trip and then bring in honey the next trip. How grand and wise has

the Great Architect been in His distribution of knowledge to the little honey bee in the visiting of the various flowers for pollen which is so useful in the fertilization of the same in its most perfect order, producing perfect fruits and seeds of their special kinds in their seasons. Hence, we say study well Nature's grand laws as well as the habits of the little bees and manage them accordingly.

Local Convention Directory.

1882.	Time and Place of Meeting.
July 25—	Western Iowa, at Winterset, Iowa. Henry Wallace, Sec., Winterset, Iowa.
Aug. 10—	Maine State, at Harmony, Maine. Wm. Hoyt, Sec.
Sept. 5—	N. W. Ill. and S. W. Wia., at Rockton, Ill. Jonathan Stewart, Sec.
Oct. 3-6—	North American, at Cincinnati, O. Dr. Ehrick Parmly, Sec., New York City.
5—	Kentucky Union, at Shelbyville, Ky. G. W. Demaree, Sec., Christiansburg, Ky.
	Tuscarawas Valley, at Newcomerstown, O. J. A. Bucklew, Sec., Clarka, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

The National Convention.

The following is the official call of the Secretary, Dr. Parmly, for the Convention of the North American Bee-Keepers' Society. We hope there will be a large attendance :

The North American Bee-Keepers' Society will hold their 13th annual meeting at Washington Park Hall, Cincinnati, O., across Washington Park from the Exposition building. Time, Oct. 3rd to 5th, 1882. First session Tuesday, 10 a. m., Oct. 3. We are encouraged to hope that this will be a very profitable meeting, as we are promised papers from, and the presence of, a large number of our most prominent bee-keepers both in the United States and Canada, and essays and implements of the apiary are expected from abroad to add to the knowledge imparted by the research and inventive skill and methods of our countrymen.

EHRIK PARMLY, Sec.
New York, July 12, 1882.

The bee-keepers of Boone Co., Indiana, are invited to meet in Lebanon, at Barton Higgins' office, over Jackson's bee hive, on the west side of the square, to organize an auxiliary County Association, on Aug. 10, 1882.

GEORGE J. FREY,
ORA KNOWLTON, } Executive Com.
JAS. H. OREAR.

The summer's meeting of the Cortland Union Bee-Keepers' Association, will be held in Cortland, N. Y., on Tuesday, Aug. 8, 1882.

M. C. BEAN, Sec.

For the American Bee Journal.

A Day With Mr. Heddon.

WM. F. CLARKE.

Thursday July 6th, was a red letter day in my diary. It was at once the longest and shortest day of the year, lasting from 6 a. m. until 1:30 the following morning. In fact, like an old-fashioned New England Sunday, it began on the previous evening. Crowded full of bee and other talk, the hours were all too few, and too quick in their flight. It was a great mistake to appropriate only one day, however lengthened at both ends, for a visit with Mr. Heddon. I left Dowagiac feeling like the darkey preacher who had taken a hearty meal of dried apples, full to bursting. And the trouble now is to give, within any tolerable dimensions, an account of my visit.

Mr. Heddon is respectfully requested not to read the paragraph I am about to write, because truth and justice compel a strain of eulogy which may prove too large a dose of dried apples for his good. Welcome more cordial, and hospitality more hearty could not have been extended to me if I had been an own brother or first cousin. The glimpses of family life were very pleasant. Mr. Heddon writes well but he talks better. He is indeed a lively, entertaining, and instructive companion. During all those quick-flitting hours, the conversation never flagged, and when the engine let off its two toots for a start, the regret was that so much was left unsaid. I wish Mr. Heddon believed as I do in another life, because then there would be on his part, as there is on mine, a prospect of some time or other having a full chance of discussing to our heart's content, the many themes on which it was a delight to converse. I have set the question pump on many a human fountain in my time, but do not remember ever finding one so full and apparently inexhaustible as Mr. H. He has thought out every subject for himself—looked at its many bearings—and you can hardly suggest a phase of it which has not already occurred to his own mind, been thoroughly canvassed, and assigned its due weight. In regard to bee-keeping, he is a living encyclopædia. What he doesn't know about it, is hardly worth knowing. Even when you cannot subscribe to his opinions, you are forced to admire the reasoning on which they are based, and the air of sincere conviction with which they are advocated. I felt it highly flattering to myself that we differed so little. N. B.—We did not discuss the pollen theory, having already done ample justice to that in the BEE JOURNAL, and finding so many other more pressing matters to talk about.

After an early breakfast, we proceeded to the apiary, which is located about a mile from Mr. Heddon's residence. It was a lovely summer day, and just in the thick of swarming-time. Mr. H., after full trial of all the methods of artificial division, has returned to natural swarming, as most sensible and experienced beekeepers have done, or are doing. You get the most industrious colonies, the finest queens, and the best results generally on this plan. In a large apiary, it is less trouble than any known artificial method. Where only two or three, or some half dozen colonies are kept, it does not pay to watch all the live-long day for a solitary swarm. But in this, as in many other respects, amateur bee-keeping is a vastly different affair from bee-keeping as a business. The idea that if natural swarming is permitted there is danger of the bees going off to the woods, is contradicted by actual trial and experience. With trees, and especially evergreens, adjacent to the apiary, the bees are pretty sure to cluster close by. Mr. Heddon has an orchard on one side of his apiary, and a grove of "grubs" (dwarfish oak brush), on the other. The bee-yard proper is entirely clear of trees. There was a lively time of swarming all the forenoon, but, invariably, the bees either betook themselves to the orchard or to the "grubs." If two or more swarms rose at the same time, a Whitman fountain pump was used to keep them separate. The mimic shower diverted the swarms, and kept them from uniting. Hives being all in perfect readiness, the work of gathering and hiving was quickly done. Mr. Heddon uses no hiving poles, bags, or other ingenious devices. The bees are allowed to cluster naturally; shaken into a large and light willow basket lined with burlap with a cover attached also of burlap, which is quickly thrown over the basket full of bees; carried to the hive, and poured out in front of it; a board about 2x4 feet having a spread of burlap on it, being laid flat on the ground in front of the hive. A turkey feather and a big iron spoon are used to direct the bees toward the entrance, and *presto*, the grand procession is formed for their future home. Let me commend the use of that big iron spoon. It works well, better I think than the feather, where the bees are clustered thick, as it does not tickle and irritate. Of course, it must be handled gently.

Mr. Heddon's hives are prepared for swarms merely by being thoroughly cleaned, and filled with frames provided with wired comb foundation. Mr. H. uses the Given press for making his foundation, and it certainly does most excellent work both for brood frames and section boxes. He is a strong advocate for wiring, and I saw ample proof in his apiary that the bees do not object to it. With every sheet of comb foundation securely fastened in this way, there is no further anxiety when a swarm is hived, and no need to go through the newly formed colonies in a day or two to see if any of the foun-

dation has broken down. I looked at hive after hive of bees that had been at work for a few days or a week, and prettier cards of comb I do not wish to see. But Mr. H. uses the finest of wire, and it is put in so skillfully, that the bees do not seem to know it is there. This is almost the only point in which Mr. H. departs from nature, in the management of his apiary, and certainly the results appear to justify his practice. There are many beekeepers who seem to take a pride in forcing novelties on their bees, but Mr. H. is not one of these. It is his constant aim to find out natural law and harmonize with it as closely as possible.

Swarming is an O-be-joyful process, and it seems too bad that the bees should be deprived of the fun of it. They work prodigiously hard most of the time, can they not have one glad holiday in the season? With what a zest and a vim they settle down to housekeeping when their little shindy is over! I know no plan of artificial division which they accept cheerfully. They are glum, confused, sullen, and morose-like; slowly and reluctantly accepting the situation, and going to work at the bidding of a stern necessity, rather than under the prompting of a happy and satisfied energy. As Mr. Heddon watched the glee of the merry little creatures, listened to their joyous hum, and saw them settle down contentedly in their new and nicely furnished homes; he recognized the fulfillment of a natural law; while I, beyond this, recognized the wisdom and goodness of their and my Creator. We didn't quarrel over it, but I suppose each of us thought we had the best of it: I am sure I did.

Mr. Heddon uses the Langstroth hive for two reasons: 1st, he likes it best; and 2d, it is the most popular, consequently the most likely to suit purchasers. He runs his apiary mostly for comb honey, using the extractor in the rush of the season, as a supplementary affair. He thinks this plan lessens the labor of the beekeeper, or rather spreads it over more time, as the section boxes can all be prepared before the busy season comes on. He is of the opinion that this method does not lessen the beekeeper's profits. I think he has got the matter of section boxes down to a fine point. His plan, as all attentive readers of the BEE JOURNAL know, is to have tiers of single section box cases. His sections are $\frac{1}{4}$ inches square. The cases are put on one at a time. As soon as the bees are fairly at work in one case, a second and then a third is put under it. His gridiron rack between the body of the hive and the cases work well. The bees fasten that, while the case is left readily movable. Mr. Heddon's principle is to let the bees do the heft of the work, while he superintends and regulates their industry. I think he is right. Many beekeepers encumber themselves with a lot of needless work, which the bees are able and willing to do for them.

One of the chief points of my curiosity was that of seeing the leather-colored queens and workers of

which we have read so much. I must own I have rather fallen in love with them. They are of large size, unsurpassed in industry, and by no means cross. Mr. Heddon does not breed for color but for business. His bees have three and sometimes four bands, but they are of a light brown, dusky hue. For years he has been cultivating strains that proved themselves the best workers, and is confident that he now has bees which gather largely from the red clover. He frankly calls them hybrids, and believes that there are strains of the German bee as good as any Italian, while the cross is better than either. He distinguishes between the brown and the black bee, a distinction that was new to me. His advice is to avoid the blacks altogether, as puny, irascible, and inferior workers. He kindly presented me with one of his average leather-colored queens, and she is now putting in her best licks beside my Italians and Syrians. I have no Cyprians. A colony of them that I had last year made my little apiary too hot for me.

Toward evening we took a drive into the country around Dowagiac. I was not favorably impressed with the bee-keeping resources of the region as I saw it from the village. But I got a different idea of it during our drive. The soil is a light, sandy loam. White clover luxuriates in it. Within a short distance of the village, basswood abounds. It is found on both high and low land, blooming early on the higher slopes, and later on the flats. The tulip tree, berry-bloom, and motherwort are abundant. Mr. Heddon has scattered the seeds of melilot here and there in waste places, and even around a large gravel pit, it is making a luxuriant growth where hardly anything else would flourish.

Mr. Heddon has the idea that even a good locality may easily be overstocked with bees. For the best results he would not have more than 50 colonies occupying one range. After that, though bees may do well, they will not accomplish their utmost in the way of honey-gathering. The percentage of stores will be smaller. This opinion surprised me and awakened some incredulity, but I was not prepared to contest it, in the face and teeth of Mr. Heddon's large and long experience.

Mr. Heddon's success as a bee-keeper has been encouraging. Those who know him do not need to be told that he is not an over-sanguine man. Indeed he is apt to get the doldrums now and then. Occasionally he has been suspected of presenting the sombre side of the business too conspicuously. Still, his own career has been such as to awaken ambition in the mind of any enterprising youth with a short purse, and the world all before him. He is only in the prime and vigor of life, yet he has about all the comforts he can use to advantage. A good home, a nice wife, three bright and healthy children, an eligible village property, an apiary yielding a livelihood and some profit—how much I couldn't find out—a healthy

business giving any amount of intellectual exercise, with occasional bits of enjoyable leisure, what more can a man desire? It has cost a large amount of hard work, and is the fruit of many years of steady perseverance in a chosen pathway not all bestrewn with flowers, but how many strive and toil just as much without these satisfactory results? The man himself is of course always an important factor in a career of success, and in no line of things is this more true than in bee-keeping. Without certain qualities, difficult of attainment, there is pretty sure to be failure.

Mr. Heddon does a pretty large supply business, but like others with whom I have met who are in the same line, thinks there is nothing in it. The business is too much cut up, and the competition too keen for a decent profit.

"We, us and Co." are not so formidable as I expected to find them. Mrs. H. beams with kindness and good nature, is a model hostess, but seems to think silence golden "before folks." Perhaps her spouse has the richer benefit, "all by his lone!" The children are too young to have opinions of their own as yet. The apprentices, two in number, would hardly presume to do more than ask information on bee lore from their experienced and able instructor. Fine, intelligent young fellows, they have indeed a valuable opportunity of acquiring the science and art of bee-keeping. I should like to have their chance myself for at least one summer, and would certainly try to get it, were I not parson and editor as to life-work, with bee-keeping as only a sort of by-play, or, as the ladies would call it, mere "knitting-work."

Listowel, July 14, 1882.

Country Gentleman.

Apiarian Exhibits at Fairs.

W. Z. HUTCHINSON.

Considering how little has been done in the way of exhibiting apiaries, implements, products, etc., at fairs, the Michigan State Agricultural Society offers quite liberal premiums in the apiarian department. In regard to the premiums offered in this department by other State agricultural societies, I have no positive knowledge; I do know, however, that some bee-keepers have complained in regard to the meagre premiums offered by the agricultural societies of their respective States; but if larger and better apiarian exhibits were made, it is more than probable that larger premiums would be offered, and the list extended. The dealer in apiarian implements, the bee-keeper who rears for sale improved strains of bees and queens, and the producer of large quantities of honey, all find an excellent advertisement in a carefully prepared, tastefully arranged, and appropriate exhibition of their wares at a State fair. The well-known apiarist, D. A. Jones, sold several thousand pounds of extracted honey last fall, at a fair in Canada. The

honey was put up in small tin pails and tin cans, and neatly labeled. The smallest package contained only two ounces of honey, and sold for five cents.

One great difficulty in exhibiting bees at fairs is that, if allowed to fly, they visit candy and fruit stands, and cider mills, causing so much annoyance that their exhibitor is soon told that he must either shut them up or remove them from the grounds. Perhaps the majority of the bees causing the trouble are from some neighboring apiary, but, as long as an exhibitor's bees are flying, the whole blame will be attached to them. To keep them confined during the journey to the fair, while it is in progress, and then on the homeward journey, is pretty hard on the bees; they become uneasy and many of them die. The only remedy is to carry the bees out each day, after the crowd has departed and the candy and fruit stands are closed, and allow them to fly. Here arises another difficulty; unless the bee-keeper waits until dark before closing the hive, the bees will not all have returned, while if he waits until the next morning before closing the hive, unless he is on hand "at the break of day," the bees will be out at work. There are two ways out of this difficulty; one is to get some accommodating watchman to close the hive after the bees have ceased flying, and the other is to carry a tent, bedding and provisions, pitch the tent upon the fair ground, and eat and sleep in it during the fair. By so doing, the exhibitor is always on hand to attend to his bees.

For the convenience and economy, many exhibitors whose almost constant attendance is required by their exhibits, prefer to live in a tent upon the grounds during the fair. An observatory hive—that is, one with glass sides—is necessary in exhibiting bees at fairs. In order that visitors may be gratified with the sight of a queen bee, it is well to have a single-frame observatory hive; that is, one just large enough to receive a single comb covered with bees. Of course, from one side or the other, the queen will always be visible, and sometimes may be seen depositing her eggs. The *British Bee Journal* for January contains a description of an excellent observatory hive for use at fairs. The hive is twice as long as an ordinary hive, and as it is only half filled with frames, there is space to move them apart inside the hive, and show the interior of the brood nest, the queen, etc. The frames are moved about by taking hold of narrow strips of heavy, folded tin that are attached to the ends of the top bars of the frames, and project through long narrow slots that extended the whole length of the upper side-bars of the wooden framework of the hive.

In a late number of the *AMERICAN BEE JOURNAL* are some excellent suggestions in regard to the manipulation of bees at fairs. Among other things it shows how a small space in one corner of a building or room may be divided off by means of a mosquito bar partition, and bees handled and

exhibited, and the secrets of the hive disclosed behind the mosquito bar partition, while the crowd outside looks on without fear. The entrances to the hive are through the sides of the building. The only objection that I see to this plan is that, if allowed to fly, the bees trouble the candy and cider makers.

Comb honey for exhibition may be stored in section boxes of different sizes. The largest size should hold, perhaps, two pounds, the next size smaller, one pound, while the smallest has only one-fourth of a pound. To give the honey a "gilt edge" appearance, the outside of each section may be covered with gilt paper; and then the sections can be piled up in the form of a pyramid, with the largest section at the bottom and the smallest at the top; or they may be piled up into the form of a church, castle or whatever shape the taste of the exhibitor may dictate. In order to show how honey is sent to market, it would also be well to have at least one nicely finished shipping crate filled with sections of honey. By partly filling section boxes with properly shaped pieces of wood, so as to leave spaces in the shape of stars, hearts, letters, etc., and giving them to the bees during a bounteous flow of honey, the bees can be induced to build comb in the fancifully shaped spaces and fill it with honey. Such devices as these attract considerable attention at fairs.

Extracted honey presents a fine appearance put up in glass fruit jars. Different sized jars can be used, and then arranged in some attractive manner. If candied, the honey could be exhibited in tin pails of varying sizes, and adorned with bright labels. A placard should be attached explaining the difference between extracted and strained honey; it should also explain about candied honey, how it can be restored to a liquid state by the application of heat, etc.

In making a display of beeswax, it might be caked in different sized vessels, and then piled up in the form of a pyramid. The largest cake might be made in a large tin pail, while the smallest might be run in the chimney of a small night lamp. Sheets of comb foundation can be shown just as they come from the mill; other sheets partly drawn out, and others fully drawn out into a complete comb. A placard should explain about comb foundation, what is it, how it is used, its advantages, etc.

The large implements used in the apiary, such as honey extractor, lamp nursery for hatching queens, bee hives, wax extractor and comb foundation machine, can stand by themselves upon the floor; while the smaller implements, like the honey knife, bee-veil, smokers and queen cages would appear to better advantage in a small show case. The display of bee literature would also look well if appropriately arranged in a show case.

Railroad companies charge nothing for carrying goods to and from the fair, and if the exhibitor carries a tent and boards himself, the expense

of attending a fair is not great. I have a bee-keeping friend who made an exhibit at our State fair last year, and received more than \$50 in premiums, while his expenses did not exceed \$5. He lived in his tent during the fair. Another friend, who lived so near the fair that he could go home at night, received last year more than \$40 in premiums.

Rogersville, Mich.

For the American Bee Journal.

Apicultural Professorship, etc.

JAMES HEDDON.

MR. EDITOR: It was always my part to feast on ideas in print. If I could have but one way to get at a good lecture, hear it delivered, or have it on paper, I would take the latter way, unless the orator was of the first order. I always had full faith in our agricultural college, State chemists, and more than all the rest, the important chair occupied by Prof. Cook, viz. entomology. The gratis pamphlet issued by the State, through Prof. Cook, is worth its weight in gold to the farmer or gardener, if I am any judge.

If bee culture has a sufficient outlet for its products, to warrant our producing all we can, as a nation, then I hail the State apiary and Professor and Lecturer on apiculture, as great auxiliaries to its proper development. But right here, I want to say that this Professor must be a Professor of *practical* apiculture, not speculative. He must not only have had an apiary in his head, made up of hives that his contemporaries have written about, but he must have had experience, and plenty of it, with one or more apiaries of size. I want to say, that the knowledge and system needed for the successful management of large, special apiaries, is vastly different from that needed for the best management of 10 to 25 colonies. I wish further to give it as my opinion that specialists will raise the honey of the future. I suppose, at this time, hardly any one doubts the last statement. Those who may, have only to cast their eyes back over the past decade to verify the truth that just in proportion as specialty has taken the place of the Jack-at-all-trades system, have we been able to have the produced and manufactured comforts of life, at a price within the reach of all. Every day we hear some one exclaim, "Well, well, I don't see how that was gotten up for that price?"

Honey production has been going rapidly in the same direction, for the past 15 years, since I have been connected with the pursuit. I know some men are capable of managing two or more kinds of business at once, but I call any man a specialist who keeps and means to keep colonies enough to occupy his field completely. Say 85 to 150 colonies, spring count. This number of colonies need a very different management, to get the most income from the least outlay of combined capital and labor, from that which is best adapted to a few

colonies, a point which I will try to clearly illustrate in an article in the near future.

In reply to J. V. Caldwell on foundation making, I will say that we have run two Dunham, one Root, three Vandervort, and three Given machines, and we know we can run off more sheets and more lbs. from the press than ever was run from any roller mill, as far as reported. When the sheets are off they are the same size they went on to the book, and the line is bulky and soft, and the base thin, and the bees work it much faster and into much more delicate combs than any rolled foundation I have ever made, or been able to get. I would like to have you find one of my students using any sort of foundation except Given, and they have made the experiments with me. I am aware that the Dunham, or any other roller mill can be set so as to run about as easy as a "clothes wringer," and it makes about as good foundation as the wringer, when thus set. The trouble with me was, I was trying to make foundation equal to the sample strips and pieces that had been sent me as specimen work. Well, perhaps I do not know of the best lubricators and methods of manipulation; I know I am not an expert mechanic. Let us know this truth, and let us couple with it the other truth, that we run off 27½ sheets of thin Given foundation by one lubrication of the book. Machines that make first-class foundation with this ease, are valuable to the less expert. During the present season I have sold several thousand pounds of Given foundation exclusively, and many others have used and sold much more, and is there not someone who will step forward and tell how the Dunham, Vandervort or Root foundation surpassed the Given among the bees? It seems strange that some one has not spoken out from among the dishonest or mistaken, against this new foundation.

Last season I had a strong opposer of the Given foundation who had not tried it. "He would, though." He ordered about equal parts of Vandervort and Given, to the amount of about 150 pounds; of both heavy and light. When he was, as I thought, under full sail with his experiments, I impatiently wrote for a verdict up to date. He replied (consistent with his former prejudices) that he thought he liked the Vandervort the best. I said no more. Neither has he. All I know further about his test is that early last spring he bought a Given press and book. Actions speak louder to me than words.

"Drones, their uses," by Dr. Baker interests me much. This Dr. B. has evidently not unwisely "entered the arena." As one of your readers, let me extend the right hand of fellowship to the Doctor. I think that in a way back number of either the BEE JOURNAL or *Gleanings*, I took somewhat the same position as the Doctor regarding the possible use of the hitherto supposed "dead-beat" drone. Knowing but little about it, and being a honey-producer to the extent of

the necessities of a growing family, and having but little time to experiment, I felt like leaving this theme to such men as Prof. Cook, who has done us such signal service on other and like problems of our pursuit. I do know that colonies do good work with no drones at all, as I have a majority on last year's full sheets of all worker foundation on wires, and I further know that some colonies do sometimes possess so many drones that they are nearly worthless as surplus honey colonies. In view of these truths, I am in favor of casting the drones entirely out of colonies that I dislike to have reproduce their like in my yard.

Mr. S. A. Shuck has asked me a question that I never pretended to be able to answer more than theoretically. I will say, however, that after reading his account of his manipulations carefully, I cannot see that either the bacteria or pollen theory are entirely shut out. I have always noticed that mixing bees of different colonies tended toward dysentery. I used to unite weak colonies in the fall (now I "take them up"), and they invariably had the dysentery first, and worst, as a class. One year ago last winter, I united three colonies into one only, and within 3 weeks they came out in front of the hive and soiled all about the entrance, and all winter long they laid out and buzzed and flew and mused about, and while about two-thirds of all the rest of the apiary died with the same malady, this colony survived, "but it was a tight squeeze." I have in my possession a letter from a gentleman of undoubted veracity, who tells me that he calls to mind two or three instances where whole apiaries have died with dysentery during June and July. Strong colonies that were in apparently perfect condition in the morning, would show signs at noon, daub everything up at night, and before the next night were silent as the tomb.

Dowagiac, Mich.

For the American Bee Journal

Queens, Drones, Workers.

G. W. DEMAREE.

When a proposition pertaining to bee-culture or any other industry or science once becomes an accepted "fact," the tendency is to cease further investigation. Under such circumstances error may find a lurking place for a time.

From the earliest period of the modern system of bee-culture, those best qualified to speak intelligently have substantially agreed upon the following three propositions, and have accepted them as well authenticated facts, viz.:

The queen is the mother of the colony, and has no other functions than to lay the necessary eggs, and to perform the queenly office, *i. e.*, the focal point of attraction resulting in what we call a normal condition in the hive.

The drone is the male honey bee—transient in existence, having no other function than to "mate" with the young queens.

The worker bees are undeveloped females, and perform all the labor pertaining to the economy of the bee hive, of whatever nature or kind.

Are the above propositions true? Of course I have no reference to the precise language which I have employed to state them, but substantially, are they true? I believe that the first and third have never been called in question, and the second not till very recently. If there is a bare possibility of a mistake as to the functions of the drone, the editor for calling attention to the subject in the BEE JOURNAL, of June 28, and Dr. J. R. Baker for his outspoken skepticism as to the truth of the proposition, so well expressed in his communication on page 437, issue of July 12, will deserve the thanks of all intelligent apiarists. Because if it should turn out that the presence of drones in a colony is necessary for other important purposes besides the very important one of fertilizing the young queens, why then, the somewhat expensive efforts to suppress and curtail their number by the use of all worker foundation, and the keen edge of the honey knife will sooner or later result in failure and ruin. But I assume that when a proposition has long been accepted as a "fact," the burden of proof rests on the shoulders of those who wish to controvert and overthrow it.

I hold that the function of the drone as stated in the above proposition, is as essentially necessary to the propagation and perpetuity of the race as that pertaining to the queen or workers. The mere fact that the office of the drone is limited to the one act of impregnating the queen, by no means makes him a "dead-beat libertine." He who created them "male and female," also assigned to each its functions, and both alike are legitimate. The drone, though quite gay in his season, is nevertheless an exceedingly modest insect, as I have learned, to my disappointment and disgust while prosecuting my experiments to discover a method to "mate" queens in confinement.

The short, gay, and seemingly useless life of the drone is in perfect harmony with the "eternal fitness of things." The duties of his office are few and alluring, but fraught with dire consequences. He sips the precious nectar for which he labors not, but he enjoys the feast at the sufferance of others. He basks in the balmy air and sunshine, but he returns to a home to which he can lay no claims, and is powerless to assert his inherent rights. Thus he flits through life till *functus officis* and speedily falls a victim to the monster so much dreaded by all animate nature.

I wish to remind Dr. Baker that "nature is wonderfully profuse in her ways." It is no harder to account for the superfluous number of drones reared under favorable circumstances than it is to account for the fact that

the atmosphere is literally loaded with pollen at times, when its chief office is to fructify the comparatively few seeds of the vegetable kingdom. No one colony of bees needs, or wants, or will tolerate more than one queen, yet I have removed more than 50 well developed queen cells from the combs of a single colony. Is this not also "marvelous?" I think that the facts which I have just cited are a fair offset to the argument based on the in-structive tendency of bees to rear a superfluous number of drones.

Now what is our experience? I have made it a rule for years to test by actual experiment the truth or falsity of every important accepted proposition in bee-culture, and discover more if possible. In order to improve my colonies of bees, I have been in the habit of encouraging some colonies to rear an abundance of drones, whilst other colonies were not allowed to have any drones at all. With this state of things in an apiary, it is not difficult to learn what part of the programme the drones fill best. They are liberal consumers, and that continually. No matter how crowded the colony may be for room, you will never see the "gentlemen" hanging on the outside with the workers; they could not be induced to leave the well filled cells for such cold comfort as that. Nothing will move them but the habit of their afternoon flight or the poured out wrath of the ireful workers. But I tried an experiment last season that settled the matter to my own satisfaction at least. I kept a drone laying queen at the expense of about 50 lbs. of honey. I found that the queen was able to keep the hive stocked with drones in exact proportion to the number of worker bees I supplied her with, from other colonies. She could do no more than this, and did no more.

To sum the matter up in few words, I have found that when there is a generous flow of honey, the honey-storing capacity of colonies with and without drones, is much the same, but when the flow is light, there is all the difference in favor of colonies that have no drone consumers.

Iowa Homestead.

Increasing Bees by Division.

O. CLUTE.

If, from any cause, a colony of bees be deprived of its queen at a time when there are in the hive worker eggs, or worker larvæ not more than three days old, the bees will at once proceed to rear queens from these eggs or larvæ. To do this they enlarge the cells around a few eggs or larvæ, say from 5 to 12, and feed the young bee on the royal jelly, then, instead of growing into a worker bee it grows into a perfect female, or queen, eight days from the egg this young queen is sealed up in the cell to undergo the final transformation. It remains sealed in the cell about eight days, and then comes out a full-grown queen, perfect in all its parts. But it

has not yet met the drone or male bee; it is not yet fertilized.

If the weather is warm and pleasant the young queen, on the fifth day after hatching, will fly out in the air, on what bee-keepers call "her wedding journey." She meets the drone, copulation takes place, and she returns to the hive a fertilized queen. She never leaves the hive again unless she accompanies a swarm.

Suppose, now, that a bee-keeper desires to increase his bees by dividing. In warm weather when honey is coming in, and when the hive is quite populous with bees, he takes an empty hive, goes to the colony he wishes to divide, smokes it, opens it, takes out half the frames and all the bees that adhere to these frames, puts them in the empty hive, and then shakes a large part of the bees from two or three other frames into this new hive, and also in some of the frames left in the old hive. He now removes the new hive to the place in which it is to be left.

Now, the queen of the old hive may be left in the old hive, or else she will be in the new hive. Whichever has the queen will be all right, it will go on as if nothing had happened, only it will have fewer bees. The hive that has no queen will have eggs and larvæ, and from these the bees will proceed to grow a queen, in the manner mentioned above. When the queen is grown and fertilized that colony will be all right.

This method of increasing swarms was formerly quite widely practiced. But it has important disadvantages, which have led the best bee-keepers to reject it in favor of the nucleus system.

For the American Bee Journal,

Bee-Keeping, and What?

EUGENE SECOR.

There is an old saying to the effect that one should not carry all his eggs to market in one basket. That would seem to hint that the pursuit of the specialist does not, as a rule, bring the most enjoyment, or is not the most profitable. Yet, specialists are benefactors of the race. When a person devotes his life to the development of one theory, or to the perfection of one practice, he ought to, and very often does, do much toward perfecting that branch. But mankind needs rest, recreation. It is necessary to the best development of both mind and body. A diversity of labor is restful. It takes the mind out of the rut. Besides, it broadens a man to think of more than one subject. A person can hardly be said to be educated who knows but one thing.

While it is true that bee-keeping may be made remunerative as an exclusive business, yet is it not better for the average bee-keeper to diversify employment by joining with it some other industry? If you answer yes, then what other employments naturally and profitably go with it?

Bee-keeping in the past was almost exclusively carried on by farmers.

This is one reason of so many failures. They did not require a rest of this nature. Their labor was diversified enough already. Because a man is a good farmer, is no reason why he is adapted to this business—in fact, is a reason why he is not. If he delights in his growing crops, if he wants to spend all of his working hours in the field, he will, generally, be too far from his apiary, and too tired when the bell rings for dinner, to give his colonies the needed attention. The hurry of spring work and the exhaustive labors of the summer will, in most cases, cause him to neglect the very little, but very necessary attentions which the bees require at these seasons, to make the balance on the right side of the ledger in the fall. I would not try to discourage farmers from keeping bees; but, unless they are adapted to it by nature—unless the bent of their minds is toward the details—the little things, and unless they possess energy enough to do the right thing at the right time whether tired or not, they can sweeten their pan cakes more cheaply with glucose than with honey of their own production.

Horticulture is a business which is well adapted to go hand-in-hand with apiculture. The fruit blossoms are among the first flowers in spring to gladden the busy toilers of the hive, and they, in turn, render the fruit-grower valuable assistance in the perfect fertilization of the flowers, without which a crop of fruit is impossible. Bee-keeping and fruit-growing are well calculated to go together, also, for the reason that everything can be under the eye of the proprietor. And again, the same qualities of mind are necessary in either case. The little things are looked after. Nothing is too insignificant to receive attention at the proper time. The love of study and investigation is developed by a continual association with nature's choicest productions. What more fascinating, and at the same time remunerative, employment could engage the mind of man or woman, than these combined? There are few towns in the United States, outside the larger cities, where the markets are fully supplied at all seasons with either fruit or honey. These home markets ought to be supplied by home production. There is money in the business. Look at the tin cans piled in every back alley in all our villages, which have come to us filled with products that ought to be raised at home, giving employment to the idle, bread to the hungry, and pleasure to both producer and consumer.

Another occupation that, in all country places, could well be located by the side of the apiary is blacksmithing. What pleasanter recreation, when resting from the labor at the anvil, than to watch the busy workers that never seem to tire, as they come in laden with the nectar that rejoiceth the heart of man, yea, that maketh his bones fat? When the heat of the day and the added heat of the forge drives him to seek the cooling shade, how delightful to contemplate that his assistants in la-

bor are only too glad of the sunshine to increase his and their treasures. My grandfather, who lived before the Revolutionary War, was a blacksmith, and one of the most successful bee-keepers of that period. The shop and the apiary divided his time. He kept from 50 to 75 colonies, and sold honey for 5 and 6 cts. per pound.

There are many other occupations that might be profitably and pleasantly coupled with bee-keeping, if the taste of the person leads him to habits of thought and study.

The minister may find respite from sermonizing, while he pursues, for an hour a day, the study of nature, through these the most interesting and instructive of nature's works. And to the credit of the profession be it said, that foremost among the bee masters of the world, stand the names of clergymen.

The lawyer might find it easier to return to his "brief" after an hour spent in the open air among the "free commoners." His clients would not suffer by reason of his rest.

The doctor could afford to study the wonderful mechanism of *apis mellifica*, and the medicinal virtues of honey, and if, in consequence, he should prescribe more honey and less pills, nobody but the pill-makers would suffer.

The student could master the sciences just as well if master of the science of bee-keeping, and the relief from his daily task would be as complete as though he played base-ball or pulled an oar.

Space will not permit me to enlarge further on this subject at this time. Various are the employments with which bee-keeping would alternate as a recreation to the benefit and happiness of all interested.

Questions about Honey Plants.

WM. PAXTON.

MR. EDITOR:—I enclose for name three honey plants which I value in order as numbered, though on longer acquaintance I may reverse it for want of a better name. I call No. 1 snowdrop. It grows wild and quite abundant on the Big Sioux and Missouri bottoms. No. 2 we call vervain; just coming into bloom; is a long and continuous bloomer and much visited by the bees. No. 3 I met for the first time while picking the other specimens, and call it the welcome stranger. It is a single plant growing in a hog lot, about 4 feet high. Finding bees on a single plant growing among a profusion of milkweed and snowdrop, attracted my attention, and since picking the specimen it occurs to me I may have found the highly lauded Simpson honey plant. If so, how can I best propagate—scatter in hog lot, waste places, or in a grove. In this land of wild flowers only, the honey harvest is late. My bees have only kept healthy brood-rearing up to July 4. Since then they are very busy. Some basswood a mile

away, milkweed and snowdrop plenty. Last season I think my bees were more advanced, and thought rape their best pasture. This season rape is not so plenty, and seems to yield poorly. Of white clover I found a single plant by the railroad switch, not larger than my hand, last spring. It grew to a clump 3 feet in diameter, and many seedlings appeared. This spring it grows and blooms finely, and my bees take to it as if an old acquaintance. I have nowhere seen white clover grow more luxuriant or abundant than in Eastern Iowa. It beats Ontario badly. Even the famous Canada thistle thrown in, will scarce equal it. If this region proves equally good, and the present small start would indicate it, then with additional groves for shelter, we will have a good honey region. In May I divided my strongest colony to receive a queen just shipped. She came dead, and since then I have changed the queen weekly, and have two colonies as strong as any in the yard. I had another queen shipped from Indiana on the 26th of June. She came on the evening of July 3d, and also dead. Why the queen should be over a week, while the card announcing the shipment came in less than 3 days is what I cannot understand.

N. W. Iowa and S. E. Dakota.

[1. *Symphoricarpos occidentalis*, or wolf berry.

2. *Verbena stricta*, or mullein-leaved vervain.

3. *Scrophularia nodosa*, or figwort (Simpson honey plant). This latter yields an abundance of nectar, but is very attractive to wasps as well as bees. It is curious to note that on such a plant the bees usually work downward, while the wasps visit the lower flowers first, then the higher in order.—T. J. BURKILL.

We do not know the better method of cultivating Simpson honey plant. Perhaps some of our correspondents who have experimented with it, will give full directions through the BEE JOURNAL.—ED.]

Rural New Yorker.

Practical Hints in Apiculture.

PROF. A. J. COOK.

It is the object of this paper to call attention to a few practical questions in apiculture, which, in the opinion of the writer, are not sufficiently considered even by many of our best beekeepers.

POOR QUEENS.—How often do we notice, in reading the reports of beekeepers, that some colony in the apiary gave results that far eclipsed those given by most of the others; while others seemed to gather but little more than their own needs required. Every attentive apiarist who observes closely, has noted the same fact in his own experience. The con-

clusion is obvious: some queens are superior, while others are practically worthless. The most successful cattle breeders, even with the best breeds, find that to achieve the best results they must continually weed out from their herds, selling off those that vary from the highest standard of excellence, and valuing above price some members of their herds. Bees are no exception to this law, and that apiarist is most wise who closely watches his bees, killing the poor and worthless queens that are sure to appear, and supplying their places with others reared from queens and, so far as possible, mated to drones, which are the descendants of the choicest queens in his bee yard. My first advice then is: Don't retain any but the very best queens. Constantly improve, by the most severe selection, the quality of your bees.

STIMULATIVE FEEDING.—It is well known to all students of apiculture that have had experience with Italian and German bees, that breeding ceases whenever the bees fail to find honey. But to keep the colonies strong we must secure continuous breeding, which can be secured by feeding a little each day whenever breeding ceases from a failure of the honey harvest. Neglect of a little thoughtful care in this direction takes largely from the pockets of our bee-keepers. With the new Syrian bees this seems unnecessary, as they breed continuously irrespective of the honey harvest.

STRONG COLONIES.—Another great error consists in tolerating weak colonies in the bee yard. The heading of this paragraph is the golden rule in apiculture, in spring, in autumn, indeed, at all seasons; if neglect has brought weak colonies, unite them, as weak colonies give no returns, and are sure to fall an easy prey to the bee moth, to robbers, and to the other ills that stand in the way of success.

INCREASE OF COLONIES PREVENTED.—To secure strong colonies, preparatory to a large yield of surplus comb honey, and not to thwart our own plans by inducing the swarming fever, has been the sore puzzle which has confronted most beekeepers. True, this is usually accomplished by proper care to ventilate, to shade the hive, and to so increase the space within the hive that the bees shall not become discontented with the old home and essay to move out into a new. Yet who has not found that, despite all these precautions, the bees will sometimes reject all overtures in their mad fury to move into new quarters? In case this inordinate desire to swarm is manifest, there is still a way to satisfy the bees without lessening the working force in the hive. If the bees seem determined to swarm usually there are several cases: if there is one, let the first swarm be placed in a new hive. When the second swarm—I refer to a swarm from some other hive—comes out, it will likely be on the same day: put this in the hive that swarmed first, after having destroyed all the queen cells in that hive. This colony is just as

strong now as it was before, in brood and bees, and the bees will be satisfied to settle down to work in the sections. A third swarm can be put in the hive from which came the second swarm; a fourth into the third, etc. We thus have increased but one, have satisfied the bees and still have kept all the colonies strong. If desired, at the last we may unite the swarm that issued first with the young bees and brood left in the hive from which issued the last swarm, in which case we have not increased our number at all. If we now give plenty of room there will be no further attempt to swarm, and we are almost sure to secure the best results in surplus honey.

Lansing, Mich.

For the American Bee Journal.

Do Bees Void Dry Excreta?

C. N. ABBOTT.

This subject appears to be still one of uncertainty, if I may judge from a letter by Wm. F. Clarke, on page 374 of the BEE JOURNAL; but any one having a doubt on the matter may in a few hours satisfy himself that bees do void dry, *i. e.*, solid excreta, if he will take the trouble to do so.

Let him take a clean, new box, about 15 inches square and 9 inches deep, and have a 3-pound swarm of bees in it; when they are quiet, let him reverse the box and cover the top with a sheet of perforated zinc, or with open strainer canvas to prevent the bee's escape, let him now take the box of bees, with the zinc or canvas side uppermost, to the nearest railway station, and send them a journey of about 40 miles out and home again, and if, after returning the bees to their hive, he does not find thousands of grains of dry excreta on the bottom of the box he may conclude that I have deceived myself, or that I am an imposter. The test is a very simple one, and I can but wonder that it is necessary to suggest it in a land where bee-culture is so largely developed.

Mr. Clarke does not agree with me that "protracted confinement" produces "dysenteric symptoms," but I hold to my assertion, the conditions being as stated by me, *viz*: when bees are confined to their combs during a 24-hours' journey by railway. I have dealt with many hundreds of purchased colonies and swarms, but I have never set a full colony out after a long journey without very decided evidences of "dysenteric symptoms" exhibiting themselves, and I believe them, in all such cases, to be the perfectly natural outcome of a physiological condition of things which seems to have escaped the notice and the cognizance of otherwise the best beekeepers in the world, to this date. I say "the cognizance" because, although I have many times, in the *British Bee Journal*, which has a worldwide circulation, alluded to the fact, no one appears to have recognized it, though it presents a subject for investigation as to muscular developments and uses, such as doubtless many of

our (and your) great bee anatomists would take delight in investigating.

My standpoint is: Bees can only void their excreta naturally when on the wing. I do not put this forward as a theory, but as a fact, and upon it base a theory that the construction of the bee is arranged to that end, that its home under ordinary conditions should never be fouled. Herein is a very great deal more than appears at first sight, but I venture to assert that if sought out faithfully and well, it will be found that the muscles that give the power of flying, govern in a sense the power of discharging excreta.

Mr. Clarke does not believe "that protracted confinement produces dysenteric symptoms if the bees are in such a state that they can void dry excreta," which is equivalent to saying, one cannot be frozen, and boiling hot at the same time, but transition from the one state to the other may be so rapid under certain conditions that it is easy to assume, and to prove, also, that bees that at one time were capable of voiding dry feces, would become dysenteric after very slightly protracted confinement under other conditions. Twenty-four hours' confinement to full combs, on a railway journey, being considered "protracted" in the one case, while twice 24 days' quiet confinement through stress of weather in a hive "well found," would but be talked of as a nice time of natural rest for the bees.

Mr. Clarke further says, "when we have discovered the conditions under which bees discharge dry feces only, we shall have solved the problem of successful wintering," and to this I in a measure agree, and in the meantime claim to have discovered one of those conditions.

Of my position in regard to this matter, though hailing from England (the old country, where so little is supposed to be known of bee-culture by the majority of American bee-keepers), I am as certain as I am that the sun will be in the meridian at noon to-morrow; but lest I might be "tripped," through not bringing all my arguments to bear at once, I forbear enlarging for the present, and hope my American friends will believe, as is most true, that my object herein is for the general common weal.

I thank Mr. Clarke exceedingly for making the opportunity for me to offer this contribution to apian science, and which, if thought worthy of notice, I trust will be discussed in the kind spirit in which he opened the question. I think, with him, the matter is not of curious interest only, "but highly practical," and I await with respect the opinions of American experts on the proposition.

Fairlawn, Southall, England.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

SELECTIONS FROM OUR LETTER BOX

Bees Going into Other Hives.—1. What is the reason that bees when they swarm sometimes go into another hive with other bees. We have one hive in our apiary that seems to be the center of attraction. Three large swarms went into that hive, and we had to put another hive on top of it. 2. What can we do? One colony that we left a few days and then put on the second story does not work good, while the colony that we put the top hive on right away is working nicely. 3. What reason is there for this? Bees are gathering lots of honey. Three colonies have brood in their honey-boxes. 4. Would it be best to take off brood and all? We have 28 colonies, and have realized about \$100 this year selling honey at 20 cents per pound here. Clover will stay about 2 weeks yet, and with basswood late swarms ought to gather enough to winter on. If they fail, I will lose a number. 5. What do you think about late swarms?

S. T. WOOLWORTH.

Gratiot, Wis.

[1. Probably for the reason that their scouts have found that hive but illy guarded, have effected an entrance and inspected the premises, and reported favorably. It is not of unfrequent occurrence for succeeding swarms to follow the same course as their predecessors, even to clustering in the same locality.

2. Let them stay, as there is probably but one queen now.

3. The reason may be from one of many causes. An examination inside the hive will reveal it.

4. Yes, and extract the honey, then give a fresh box.

5. If not too late to breed young bees and lay up stores for winter, they will do for increase, but not for surplus honey gathering, unless frost holds off quite late, and fall bloom is very abundant.—Ed.]

Behind Time.—We have had a backward season in this section for honey. Every blossom is from 10 days to 2 weeks behind time, and such a slaughter of drones never was seen the middle of June. The 1st of July brought plenty of raspberry and plenty of swarms. It is now time for basswood to open, but that is backward also. This section is getting to be a great place for buckwheat—about 200 hundred acres within reach of my apiary. But some folks do not like buckwheat honey; well, suppose they do not, it certainly is good enough to put on buckwheat cakes.

WM. C. CASSON.

Addison, N. Y., July 13, 1882.

Queen Cell from Fertile Worker.—Did any person ever have bees with fertile worker build queen cell and put the larva of a fertile worker in the cell, and rear a queen; if so, was she a good queen? Give her quality and size, and did she mate with a drone? I have one now in a capped cell. My bees are all in splendid condition, although the weather is extremely cool, or warm, or wet. The white clover was never better. Prospects for a fall crop of honey are splendid.

R. M. OSBORN.

Kane, Ill., July 17, 1882.

[With plenty of leisure on your hands, and an inquiring turn of mind, we hope you will institute a series of experiments, to see what will be the result of your capped queen cell with fertile worker larva. If the drones are not objectionable, why not devote the colony to experiments, and, if necessary, destruction?—Ed.]

Mr. Shucks' Problem.—With Mr. Shucks' bees (see BEE JOURNAL, page 44) they were so much excited by the general mixing up that they did not get over it until they had gone long without food and dysentery was brought on. Bees will not eat in a worrying condition. I have had bees have dysentery after 5 days' fasting, but food cured them; quite cured Mr. Shucks'.

E. B. SOUTHWICK.

Mendon, Mich.

[Our experience has been, that when bees are greatly disturbed is the exact time when they eat most. We have found this the most serious drawback with the Italians for extracting, for, if they are badly frightened and the second shake fails to free the comb from them, they immediately plunge into the cells after food, and it is a somewhat troublesome task to brush them out with the feather.—Ed.]

Rearing Drones.—I have one colony of black bees, and am getting an Italian queen, and, as I can sell a few queens this fall, would like to know—1. Can I compel the bees to rear some drones (the blacks have already killed off their drones around here) by feeding? 2. If I make some nuclei to rear queens, can I double them back so as to winter? Bees are doing very little here this season—too cold and wet I suppose.

Houghton, Ont. S. T. JACKSON.

[1. If a young queen, you will have difficulty stimulating drone-rearing this season, and for your climate could not get them in season for testing progeny this fall.

2. There is no trouble in doubling up; but you would be obliged to keep the nuclei constantly reinforced with brood, or the bees would be too old for effective wintering.—Ed.]

Fertile Worker.—I send you by mail a small piece of comb, lately taken from the hive of a neighbor. The queen, with nuclei, had been out of this hive for about 6 days only. You will find many eggs in the same cell. Is it a case of fertile worker? An answer will confer a favor on your correspondent. Does this number of eggs in one cell indicate a fertile worker? Is there any sure indication? PHIL REARDEN.

Jamestown, Col.

[If the colony was queenless six days, and you then found eggs in and near the center of the brood-nest, it was a pretty sure indication of fertile workers; and the fact of several being in each cell, is corroborative of there being several. We believe that those conditions which induce the development of a single fertile worker will also develop a plurality, so that there is the same probability of half a dozen, or more, as one. We have had young mated queens, when first commencing to lay, deposit from one to four eggs in a cell; probably because other cells were not properly cleaned out in time for their use. These, however, were in each case thinned down to one in a cell by the bees; the extra ones, probably, being put in other cells as fast as they were ready.—ED.]

Anticipations Realized.—Bees are doing exceedingly well. I am fully realizing my most enthusiastic anticipations. Everything indicates an uninterrupted flow of honey until frost comes. PHILIP P. NELSON.

Manteno, Ill., July 17, 1882.

Comb Foundation.—Bees have been doing very well here for the last month. Swarming in some cases has been excessive, and colonies are getting in good shape for winter. This is the first year that I have put swarms on foundation, and I find that it pays well. We will get very little surplus honey this season; but we have a large crop of wheat now harvested and ready for the separator, a tolerable crop of hay secured, and the corn growing finely. Farmers are happy. ISAAC SHARP.

Waveland, Ind., July 15, 1882.

Only Fair Weather Needed.—Bees are breeding rapidly now, but it is too cold for surplus. Magnificent white clover bloom, and all we need is good weather for the boom to reach us. Linden will open in two or three days, and is very promising. With fair weather the fall run cannot fail to be immense. Your JOURNAL is hailed with pleasure, and is an invaluable adjunct to every apiarian establishment as well as to the amateur. Have 35 colonies; first swarm to-day. L. S. BENHAM.

Alma, Mich., July 18, 1882.

Pasturage for Bees.—We have had the worst season for bees I ever saw—too much rain, wind, cold, late frosts, etc. I sowed in drills some mignonette and cleome, but the latter did not grow. I cultivated most of the mignonette until harvest, and it did well early, but since I quit cultivating the weeds and grass have choked it so badly that it is doing no good. The sweet clover I cultivated is fine, but the crop is so badly choked up and spindling, it is of no account. We have some motherwort and I like it well, but am not satisfied. For a general crop will it spread if sown broadcast on good, rich timber land? If sown early in the fall, on well-prepared ground, will it thrive and bloom the next year? I never knew any planted; it grows spontaneously here in rich fence corners.

A. MCKNIGHT.

Bible Grove, Ill., July 15, 1882.

[It ought to do well if sown broadcast, provided there is not too much timber. We planted some two years ago in the fall. It blossomed the following season, and is doing well yet.—ED.]

The Honey Harvest.—The honey crop here is an entire failure. The present season has demonstrated that there are other important prerequisites to a good honey yield, besides plenty of bloom. The latter condition has been present in profusion, but there has been but little nectar secreted, and less weather suitable for bees to have collected it. I have taken with the extractor a few gallons of honey, too thin for any use, and there has not been sunshine sufficient to evaporate it. There is still plenty of bloom, but continuous rain keeps the bees at home. My bees have not been busy in the fields two whole days at once, at no one time for weeks. The wheat and oats crops are better than they have been for years. The growing corn crop looks promising now, although much of it did not get the work it needed on account of the wet weather. Much of the tobacco crop is submerged in weeds and grass; much of it will be entirely abandoned and lost. G. W. DEMAREE.

Christiansburg, Ky., July 17, 1882.

Silver Linings.—After many fitful struggles the clouds have lifted and the silver linings glimmer over our house. Never before in the history of 30 years have I had to feed my bees in the month of May, but it is bread cast upon the waters, for those fed most are now returning the largest surplus, and I see no good reason why the honey season should not continue till Jack Frost nips the flowers.

J. W. BAYARD.

Athens, O., July 17, 1882.

Prospect Very Poor.—Up to this date bees appear to have gathered no honey from white clover. A good deal in bloom, but yields none. Prospect for honey very poor.

W. D. FOOTE.

Johnstown, N. Y., July 13, 1882.

Still Hoping.—The season has been very poor so far. It has been too cold and wet. Not one pound of surplus yet, and only one swarm, but if the weather keeps dry and warm I think we will get something yet. There is plenty of white clover. Basswood has a good appearance and will be out in about two weeks. A great many bees have died this spring. Nearly all of the loss was caused by starvation. Bees here are mostly kept in box hives. We have 43 colonies in Langstroth hives, double-wall. Lost 3 colonies this spring.

DICKSON BROS.

Lancaster, Ont., July 15, 1882.

A Large Honey Harvest.—My bees are doing well. I have about 25,000 pounds of honey extracted up to date. I would have had more, but two of my men are down with the fever. The weather has been unfavorable for the bees for the last few days. As soon as it clears off I will extract about 2,000 to 2,500 pounds per day. There are about 300 of my colonies that need extracting, which will give me from 4 to 6 gallons each this extracting.

L. LINDSLEY.

Waterloo, La., July 11, 1882.

A Peculiar Season.—This has been a very peculiar season here. The commencement of clover bloom, about June 10th, found bees very weak in numbers. Clover has given a good yield ever since that time, whenever we would have sunshine long enough for the grass to dry off; but sunshine has been the exception—not the rule. So far, bees have not been able to work over one-third of their time, and, of course, the amount of surplus honey is small. Colonies are more populous than they would have been if the honey flow had been heavier, and a fair yield can yet be obtained if we should have good weather the rest of the season. O. O. POPPLETON.

Williamstown, Iowa, July 15, 1882.

Exasperated.—MR. EDITOR: Your serene hopefulness is simply exasperating to bee-keepers who have not taken a pound of honey this season, and have fed the bees in May and part of June to keep them in condition. I think you will find those districts, which make a crop, to form the exception, and not the rule as you put it. Our only hope now here is the fall crop, and if the weather remains as it is (which is more than likely), we may have to feed for winter.

T. H. KLOER.

Terre Haute, Ind., July 18, 1882.

[Our correspondent has our sympathy in his disappointment; but if the mere recital, by the BEE JOURNAL, of general prosperity is so exasperating, with what bitter hatred must he read Mr. Nelson's cheerful letter in the first column of this page. We once heard of an old lady whose grandchildren had the mumps, but remarked, philosophically, "La, we don't care while the neighbors have measles."—ED.]

ESTABLISHED 1862
 THE AMERICAN
BEE JOURNAL
 PUBLISHED WEEKLY

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published **WEEKLY** as follows, if the whole is paid in advance :

For 4 weeks.....	10	per cent. discount.
" 8 "	20	" "
" 13 " (3 months)...	30	" "
" 26 " (6 months)....	40	" "
" 52 " (9 months)....	50	" "
" 52 " (1 year).....	60	" "

Discount, for 1 year, in the **MONTHLY** alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent., if wholly paid in advance.

Discount, for 1 year, in the **SEMI-MONTHLY** alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent., if wholly paid in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The **BEE JOURNAL** is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and **Weekly BEE JOURNAL** for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the **Weekly BEE JOURNAL** for one year, will be entitled to the following premiums. Their own subscription may count in the club :

- For a Club of 2,—a copy of "Bees and Honey."
- " " 3,—an Emerson Binder for 1882.
- " " 4,—Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
- " " 5,— " " cloth.
- " " 6,—Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Articles for publication must be written on a separate piece of paper from items of business.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 5oz.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the **BEE JOURNAL**.

Advertisements intended for the **BEE JOURNAL** must reach this office by Saturday of the previous week.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Do not let your numbers of the **BEE JOURNAL** for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference

Those who may wish to change from other editions to the **Weekly**, can do so by paying the difference.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
 Monday, 19 a. m., July 24 1882. }

The following are the latest quotations for honey and beeswax received up to this hour :

Quotations of Cash Buyers.

CHICAGO.

HONEY—I am paying 7c. for dark and 9c. for light extracted.
BEESWAX—Choice lots are worth 25c. here; bright yellow, 24c.; dark to good, 17@22c.
 AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for honey is quiet. Extracted brings 7@10c. on arrival. No comb honey on the market worth mentioning, prices nominal.
BEESWAX—Scarce, and brings 20@25c. on arrival.
 C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for comb honey is light, prices being made to meet views of purchaser.
BEESWAX—Scarce, and in demand at 23@25c.
 R. A. BURNETT, 165 South Water St.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.
BEESWAX—The market continues rather quiet, but the supply is light and prices firmly sustained. Western, pure, 25@26c.; Southern pure, 26@27c.
 D. W. QUINBY, 105 Park Place

CLEVELAND.

HONEY—Comes in very slowly, and is readily sold at 25c. per lb. for 1 lb. sections. No larger sections received yet. Our experience in the honey trade for the past 25 years, teaches that during the whole year there is no better sale for honey than August and September. The demand at this time is greater and prices as high as at any time during the year, especially for comb honey. Extracted probably sells better later. No extracted has thus far been received, but it could be quoted at 10@12c. **BEESWAX**—25@28c.
 A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—Not much arriving, and most of that is held above buyers' views. Some very white comb is offering at 18c. Buyers refer to name more than 8c. for extracted of the choicest quality, but there are some lots of excellent body, color and flavor, which are limited at 9c.
 We quote white comb, 15@29c.; dark to good, 8@12c. Extracted, choice to extra white, 7@8 1/2c.; dark and candied, 6@8 1/2c. **BEESWAX**—23@25c.
 STEARNS & SMITH, 423 Front Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
BEESWAX—Prime quality, 25c.
 CROCKER & BLAKE, 57 Chatham Street.

ST. LOUIS.

HONEY—New Texas comb (when the combs are perfect) brings 20@22c. Quote strained at 8@10c.; extracted at 12c. per lb.
BEESWAX—Prime in demand at 24@25c.
 R. C. GREER & CO., 117 N. Main Street.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

- For 50 colonies (120 pages).....\$1 00
- " 100 colonies (220 pages)..... 1 50
- " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

When changing a postoffice address, mention the *old* as well as the new address.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

AT LULING, TEXAS.

A NEW BEE BOOK!

Bees & Honey

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,

Editor of the Weekly Bee Journal.

It contains 100 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napa, Cal.

Contains vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

The Bee-Keeper's Guide;

OR,

MANUAL OF THE APIARY,

By A. J. COOK,

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculteur*, Paris.

I think Cook's Manual is the best of our American works.—*LEWIS T. COLBY*.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—*J. P. WEST*.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—*E. H. WYNKOOP*.

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—*A. E. WENZEL*.

My success has been no great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—*WM. VAN ANTWERP, M. D.*

It is the latest book on the bee, and treats of both the bee and hives, with their improvements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—*L'ABBE DU BOIS*, editor of the *Bulletin D'Apiculteur*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *vade mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, \$1.25; in paper cover, \$1.00, by mail prepaid. Published by

THOMAS G. NEWMAN,
West Madison Street, CHICAGO, ILL.

"RED TAPE!"

Who will be the first to copy?
25,000 IN USE.

If you buy the Original Patent Bingham Bee Smoker, you will aid the inventor of improved bee smokers—get the best, that never goes out—always please—never is complained of—the standard of excellence the world over—better and handier than any other that ever before. Price per mail, postpaid, from 65 cts. to \$2. Our patents cover all the smokers that will burn wood, stove-wood, or do not go out. If you buy our smokers and honey knives first, you will have to buy no others.

Patented, 1878.

PRICES:

Wide shield Conqueror, 3 inch	Handed to Customer, \$1.75	By Mail, Postpaid, \$2.00
Large Bingham Smoker (wide shield), 2 1/2 inch	1.50	1.75
Extra Bingham Smoker (wide shield), 2 inch	1.25	1.50
Plain Bingham Smoker, 2 inch	1.00	1.25
Little Wonder Bingham Smoker, 1 1/2 inch	50	65
Bingham & Hetherington Honey Knife, 2 inch	1.00	1.15

Scribner's Lumber and Log Book.

NEARLY A MILLION SOLD. Most complete book of its kind ever published. Gives measurement of all kinds of lumber, logs, and planks by Doyle's Rule, cubical contents of square and round timber, staves and heading bolt tables, wages, rent, board capacity of cisterns, cordwood tables, interests, etc. Standard book throughout United States and Canada. Ask your booksellers for it. Sent for 35 cents post-paid.

For sale at the BEE JOURNAL Office.

PURE HOLY-LAND QUEENS.

I make a specialty of rearing pure Holy Land Queens, and have now more than 100 colonies in their purity. All Queens bred from D. A. Jones' Imported Queens. Dollar Queens, before June 20, \$1.25 each; after that date, Honey Queen, \$1.00; 6 for \$5.00, 12 or more, 75 cents each; Warranted Queens, 25 cents more each. Tested Queens, \$2.50 each; Italian Queens, same price.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have standard over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches	\$8 00
For 2 Langstroth " 10x18 " "	8 00
For 3 " " 10x18 " "	10 00
For 4 " " 10x18 " "	14 00
For 2 frames of any size, 13x20 " "	12 00
For 3 " " 12 1/2 x 20 " "	12 00
For 4 " " 13x20 " "	16 00

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small **White Shark**, caught in the Yellow Sea, known as **Carcharodon Rondeletii**. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over **300 years no Deafness has existed among the Chinese people.** Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthy noises in my head, and hear much better. I have been greatly benefited. My deafness being a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by
THOMAS C. NEWMAN,
925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.—Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. Fully up with the times, including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bienen Kultur, by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Dzierzon Theory;—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Peas, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c. per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey: Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how; 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees, Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 Recipes for Gns., Steams, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Glaziers, Metal and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

Death of Edward Townley.

Mr. J. W. Winder, Thibodeaux, La., writes us that much rain prevails in Louisiana, and the honey crop is short in his section. He also sends us a clipping from the Cincinnati *Times-Star*, announcing the death of Edward Townley, who was the author of a book on the management of bees, and was enthusiastic in his devices for the production of honey:

Another old citizen of Cincinnati has just departed this life, and this time it is the venerable Edward Townley, who died at his residence on Mt. Auburn at 5:30 last evening. Mr. Townley was born in Elizabeth, New Jersey, in 1802, making him at the time of his decease 80 years of age. He came to this city in 1848, and established a good business as a carpenter and builder. He began the cultivation of bees and the manufacture of honey and built up probably the largest trade in this industry to be found in the State. Mr. Townley has lived a quiet life at his cosy place on Mt. Auburn for many years, performing his duties as a neighbor and friend with conscientious fidelity. His death removes a citizen for whom all entertained respect. He leaves four children, John, Edward, Eugene and Kate. The sons are all well known and successful business men of this city, Mr. Ed. Townley being Secretary of the Enreka Insurance Company, and Mr. John Townley President of the Commercial Insurance Company.

Dr. J. W. Norris has issued a call for a State Convention of bee-keepers, to be held in Oregon City, Ore., on Wednesday and Thursday, Oct. 25 and 26, 1882, at which the attendance of all interested in bee-keeping is invited.

Beeswax and Pollen.

Mr. Henry Hibbard, Pecatonica, Ill., writes as follows:

I send a sample of wax, and wish you to state through the next BEE JOURNAL, or by letter, what is the cause of its being in this shape. I sent 45 pounds to be made into foundation: 13 pounds was my own wax, tried out with wax extractor, and 32 pounds I bought of a man that I have every reason to believe perfectly straight and reliable. He said that it was made up in a clean kettle and dipped off of water. It was a good quality of wax—dark-yellow and tough, and pronounced nice wax by a number of bee-keepers. I sent it off to be manufactured into foundation, and received in return, 20 pounds of foundation, and the balance such stuff as I send you in a box. I am puzzled to know why the wax did not work up into foundation the same as that received with from one to two pounds shrinkage, as it has done before.

The sample sent us is pollen, and was the settling or sediment at the bottom of the cakes. It is not uncommon to see nearly $\frac{1}{4}$ of a cake with this sediment, especially where it is skimmed wax. With the wax extractor this sediment scarcely prevails, and the wax is worth 3 to 5 cents more per pound, unless the bottoms of the cakes of skimmed wax are liberally scraped. Of course, we cannot know to what extent this pollen prevailed in your shipment to the manufacturer; but we have seen many combs which contained less wax than pollen.

Sweet Clover.—Good reports are beginning to come in regarding sweet clover. H. W. Garrett, Coeyman's Hollow, N. Y., in a private letter of July 26, says: "Sweet clover is now in full bloom, and my bees are harvesting with a rush." We expect to hear many good words for it before the season is through.

"Silver Linings" Again.

C. H. Dibbern, Milan, Ill., writes under date of July 26:

I see there is a disposition on the part of some to make sport of your "silver linings." Well, we have seen the "linings" here for 2 or 3 weeks. I have new swarms that have gathered 50 to 60 lbs. of as nice section honey as I ever saw. Weather is very favorable, and bees doing better than for some years.

Prospects, so far as floral indications pointed in nearly all sections of our country, were never better than this season. The great majority of our correspondence reports white clover abundant, and bloom unprecedented; linden very liberal in bloom; fruit bloom was plentiful; locusts, etc., above the average; but the atmospheric influences in many sections have been unpropitious. In some districts, when the weather was dry so bees could be in the fields, heavy winds prevailed from the northern points of the compass, so that nectar failed to reach the surface of the flowers.

Many peculiarities have been reported this season, chief among which were strong colonies and bees in good condition; but no honey—some reporting hives full of bees, and they almost starving. Where the weather has been favorable, the honey crop has been tremendous, some bee-keepers having already realized a good harvest, and the "bees are still booming." One bee-keeper stated he had already realized 100 lbs. of extracted honey per colony, spring count, and the "harvest but commenced." We saw last week second swarms with the second and third stories filled with brood and honey, awaiting the extractor, while the bee-keeper in charge remarked that it was probably true "bees will not swarm if given plenty of room," but he "found it impossible to give them plenty of room," at the same time pointing to a mammoth colony which had thrown off three swarms, and were again clustered outside, their three-story hive being filled to repletion. Swarming which usually prevails in June and the first week in July, has this season been delayed till the last week in July. In this section of Illinois linden is now in its prime, and where it is accessible, bees are deserting white clover to work on the linden, although the clover is still abundant. Should fall flowers be as abundant as we anticipate, the "silver lining" with many

will be changed to a golden hue, while we still think many who are waiting and longing, will be "disappointed with happiness." Of course, nature may be lavish with her floral decorations, but if the elements be not favorable, the "sweetness will be wasted on the desert air," or driven back to mother earth.

Italianizing an Apiary.

Many bee-keepers will probably wish to put their apiaries in order this fall to Italianize them next season, and for this class the following hints from Mr. W. T. Clary, Clarysville, Ky., may have especial interest:

I have quite recently purchased an imported queen, for the purpose of requeening my apiary. I have 28 colonies of Italians more or less pure, and propose giving each doubtful colony a queen bred from my imported one, and letting them mate as they will, and requeen again next spring early, letting these young queens of this season's production produce the drones, and furnish the the queen again from my imported one. 1. Can I succeed by this means in having all my colonies pure? 2. Will the drones bred from these young queens (allowing more or less of them to have mismated) be as pure as if bred from an imported queen of known purity; or should I admit of drones being bred only from those queens whose progeny show the mother to have been purely mated. This is a question that I can hardly decide on, but what the mating of the queen has more or less bearing on the drone progeny. Should there be any doubts on this question, I would rather purchase two imported tested queens, and rear all my drones from one queen and queen cells from the other. Please give me your views on this question. 3. Would it not be the better way for me to form a nucleus for each colony where I desire to replace the queen, and have a laying queen bred in this nucleus to give the old colony before removing their old queen, or would you advise removing the old queen and giving the colony a ripe cell? I intend to start my cells as you advise, by removing all the brood from a strong colony, and I shall, after cells are ready for insertion in nuclei, divide the brood from the colony removed into nuclei.

1 and 2. The gist of the "Dzierzon Theory" is to the effect that the drone progeny of a pure queen will be equally pure, regardless of the mating; but the worker progeny will be hybrid if the mother be mismated; and hence the queen progeny of an impurely mated queen will be hybrids, as also the drones of the latter. The question has frequently been raised by very respectable authorities, that the mating of a queen of one kind of

bees with a drone of another, will to some extent change the nature of the drone progeny. Our experimental observations have been very unsatisfactory.

3. Yes, decidedly better; for then you have but a short interregnum between one queen and the other. The interruption in reinforcing the colony will amount to only the necessary time to introduce your new queen. If a ripe cell be given, it will require an average of 10 to 12 days to bring forth the queen, mate her, and for prolific laying, while if a queen be nursed in a nucleus, it will require but 48 hours to safely introduce her—perhaps less time—and time is valuable.

Persons intending to rear queens next season with which to Italianize their apiaries, should procure the queen-mother at once, so as not only to test her bees this fall, but to rear at least one batch of queens, in order to test her queen progeny, even though they mate impurely. Bees are much like everything else, each one having some peculiar trait more prominent than others. Some queens excel as queen-breeders; some may produce superior drones, and others may be indifferent in everything. The latter class are not wanted, as it would be folly to consume time in changing stock without some compensating gain, which cannot be found in color alone. Besides, by rearing even a single batch of queens the previous season, it is possible one or more may be properly mated, thereby giving Italian brood with which to strengthen the old queen for drone-breeding in early spring. If the intention be to buy the queens with which to re-stock, then by all means buy this summer, when they can probably be bought cheaper, and if wintered in the colonies there will be no hybrid drones to embarrass you the following season.

A mistake is often made in buying the first queen, many supposing a young queen the most desirable kind with which to re-stock the apiary. We would advise the purchase of a vigorous, prolific, last year's queen, whose queen progeny, if possible, had been tested, and that produced docile, vigorous workers. A well matured mother breeds better queens and is more productive of early desirable drones. Do not expect to buy a good queen-mother early enough in the spring to Italianize your apiary, for fall will overtake you with the work but half accomplished; and *do not*

confide too much in theories, no matter by whom sanctioned nor how long venerated.

Order a good queen-mother from a reliable breeder, telling him what you want and for what, and do not higgler over the price. If he is an honorable man, you will not regret it.

MISCELLANEOUS.

Apiculture in Germany.—Mr. F. A. Hanneman, in the *Bienenzeitung* thus contrasts bee culture in America and Germany.

Every man is a pupil in the school of life. Science and his hard earned experiences are his teachers. But it sounds curious, to talk about a German and American school in apiculture—to mark sharp lines, as Mr. Dadant has done in an article published in the *Bienenzeitung*. Has Mr. Dadant forgotten that movable frames, and comb foundation were not invented in America, but have only been more successful there than in Germany, and that the inventors are Dr. Dzierzon, Baron Von Berlepsch, and Mr. Mehring? He should have said, Germany has the merit, and America has the profit. It is entirely owing to the climate, that Germany is not reaping the fruits of her science. American bee-keepers use frames longer than they are deep, but we do not consider this an improvement, it is merely a system of management peculiarly adapted to that country and climate.

Healthfulness of Honey.—An exchange remarks as follows:

American people are lovers of sweet and consume an average of 40 pounds or more of sugar for every man, woman and child of our population. To meet this demand, millions of dollars' worth of sugar are imported annually, and millions of dollars' worth of honey are allowed to go to waste from want of bees to collect and put in proper shape for the use of man. It is not as generally known as it should be that honey may be employed for sweetening purposes instead of sugar, for most of the purposes for which the latter is used. But could we supply it to the extent of diminishing our imports of sugar to one-half their present proportions, millions of dollars would be saved for the purposes of business in our own country. But far above all money considerations would be the use of a pure sweet upon the health of the people instead of the vile compounds now sold as sugars and syrups. The healthfulness of honey as food has been admitted from the earliest

writers down through the centuries to the present time. Hence we have nothing to fear from the free use of honey, while recent developments show we have much to fear as to health in the use of adulterated sugars and syrups. But the price of honey in the past has had much to do in keeping it from the tables of men of limited means, who did not possess the workers to collect and store it for them. Honey is a vegetable production, appearing in greater or less quantities in every flower that nods to the breeze or kisses the bright sunlight in all this heaven-favored land of ours. It is secreted in the flower for the purpose of attracting insects, thus securing the complete fertilization of the female blossoms. Hence it follows that all the honey we can secure in the hour of its presence in the nectaries of the flowers, is clear gain from the domain of nature.

Pollen and Dysentery.—Mr. A. Pettigrew in the London *Horticultural Journal*, says:

That adult bees live on honey and do not eat pollen at all I steadfastly believed for more than forty years. Two or three years ago Mr. Raitt stated in a private letter to me that a highland lady fed her bees on barley bannocks, that he had found the husks of pollen grains in the excrements of his bees, and that such excrements changed their color if the bees were fed on peameal. This statement was quoted into the pages of this Journal. This evidence appeared satisfactory and conclusive, and I said so at the time, though I was convinced that bees can live and be healthy for months on honey or syrup alone—or, in other words, without pollen or meal of any kind. Other writers have said that pollen contains the nitrogenous element necessary to maintain the muscular strength of bees. Much has been written and spoken on this point without giving facts to support it. Not so with Mr. Raitt, who gave substantial evidence for his statements. Many hundred colonies of bees have died of hunger with plenty of pollen around them, while they have been sitting on cells of pollen; but whoever heard of bees dying of hunger with honey beside them?

Bee-Keeping in Egypt.—The *American Cultivator* remarks thus, on the manner of keeping bees in Egypt:

The Egyptians exhibit great skill in their manner of cultivating the bee. As the flowers and harvest are much earlier in Upper Egypt than in Lower, the inhabitants profit by the circumstance in regard to their bees. They collect the hives of different villages on large barges, and every proprietor attaches a particular mark to his hives. When the boat is loaded the conductors descend the river slowly, stopping at all places where they can find pasturage for the bees. After having thus spent three months on the Nile the hives are returned to

the proprietors, and after deducting a small sum due to the boatman for having transported the hives from one end of the river to the other, he finds himself suddenly enriched with a quantity of honey and wax, which is immediately sent to market. This species of industry procures for the Egyptians an abundance of the production of the bee, which they export in considerable quantities to foreign lands. In the counties of Yorkshire and Lancashire, England, when the moors are covered with a species of heather called ling, and which blossoms in August, covering this barren heath with a beauty scarcely equaled in any other country, distant bee-keepers load their hives in wagons, and having previously engaged quarters for them with the farmers who dwell on the confines of the moor, the hives are conveyed to their ranges, where they remain a month or six weeks. Comparatively empty hives when carried away are brought back full of honey, and many weak colonies are thus enabled to winter over without loss, while the best ones have large quantities of honey and wax removed from them, the product of about two months in the year. The hum of the busy bees and the blooming of ling enliven a scene which, during the other ten months of the year appears but a dreary waste, at best but a pasture for the black faced heath sheep, or a breeding place for grouse, hares and foxes, and hunting ground for England's aristocracy. Of late years many of these moors have been enclosed, the lands cultivated, and are producing an abundance of potatoes, oats, barley and grass.

The Labor a Bee Performs.—The following combinations of figures, from the *Michigan Farmer*, will give a faint idea of the ceaseless, patient and rapid work performed by the honey bees during the few short weeks when everything is favorable for a good honey harvest. Is it a matter of wonder, that the days of the worker are "dwindled to the shortest span?"

It is estimated that 125 clover blossoms contain one gramme of sugar. As each blossom consists of 60 calyces, at least 125,000 by 60, or 7,500,000 calyces must be rifled to afford a kilogramme of sugar, and as honey contains 75 per cent. of sugar, it requires 5,600,000 calyces of clover to yield a kilogramme of the former; hence, we may imagine the countless number of flowers that bees must visit to be able to stock their hives with honey.

Attractive Packages.—An exchange indorses our advice regarding neatness in preparing honey for market as follows:

In marketing honey, this point should never be forgotten—that a good article in an attractive shape will always command the highest price, the best reputation and a steady demand.

The Transportation of Bees to India.—Mr. F. Cheshire, in the *London Journal of Horticulture*, gives the following results of his first shipment of bees to India:

Questions connected with the different races of bees, their specific variation in structure, temper, size, industry, and power of endurance, are receiving unwonted attention; and as a result plans of packing which have enabled colonies to endure prolonged confinement under circumstances of peculiar trial are more than commonly interesting.

During 1878 and 1879 I sent two colonies and two nuclei *via* the Red Sea to Bombay; the bees after their unshipment had a further journey into the interior, entailing an incarceration of nearly forty days before they reached their then owner, an Indian gentleman of distinction. The nuclei carried each four of my half Woodbury frames, as used by me formerly for queen-rearing. These were well stored with sugar, while the backs of the boxes contained pouches cut off from the bees by perforated zinc, and into these pouches sponges filled with water were occasionally put during the voyage. Perforated zinc covered the frames above, while the boxes were made 2 inches deeper than accommodation of the frames required. No other precautions were taken except that the combs were well fixed and the frames secured against lateral sway. Both nuclei arrived in capital condition.

The two colonies, one black and one Ligurian, each contained eleven frames of Woodbury size, three of which had sealed brood to supply young bees to replace the gaps made in the ranks of the adults. The hives had each a half story beneath and a half story above, the lower half story having its sides of perforated zinc while the same material went over the top. The bees were thus able to cluster under or over their frames as they might desire, while the dead would simply fall clear away from the combs and so no longer incommodate the living. The device of pouches and sponges was added as with the nuclei. The blacks arrived with stores nearly exhausted but in perfect condition. The Ligurians were starved "dead to a man," as my esteemed correspondent expressed it. With the one exception, the cause of which is clear, the bees survived their long journey and endured the baking heat of the Red Sea in the hot season. No combs collapsed and the mortality was not destructively great. The success, however, ended here, as the accompanying quotation from one of the owner's letters, in which he refers to the nuclei only, will show.

"You will be sorry to hear that I saw the last of my bees about ten days ago. Both the Ligurians and the blacks at first went on all right, the latter having bred and brought forth a good progeny last August, and the former having built new combs to a considerable extent, when about

December I felt that both hives began dwindling away in numbers. Previous to that I had noticed that they had two very powerful enemies in the common garden lizard and the rats. I destroyed nearly every one of the former in my neighborhood, and took measures to prevent the latter getting to the hives; but I could not find out the cause of the gradual disappearance of the bees. In December, January, and February, by constant feeding, I induced the bees to stay in, and then there was no diminution; but they could not be kept in longer when the sun got hot, and very few returned. The last to disappear were the two queens, and I never saw a dead bee on the floor-board. I am afraid swallows and such small birds must have preyed on them. I am going to domesticate some of our native bees in my empty hives."

It is regrettable that this attempt at acclimatization failed, but the fact of the safe transit of the bees through considerable difficulties is in itself at least interesting.

Bee Notes for August.—The *American Agriculturist* gives the following as its "Bee Notes for August:"

In many parts of the country there is a great dearth of nectar-bearing flowers this month—only enough to keep the bees at breeding. If the bees secure no honey, they should be fed sparingly, a very little each day, so that the queen may not stop laying. In this way the brood rearing can be kept up, and there will be abundant bees to secure a rich store of autumn honey, and insure safe wintering. If the queen once stops laying, it is often very difficult to start her again. Some bee-keepers say that feeding does no good, as upon trial the queen still refuses to lay. In all such cases the feeding was commenced too late. We have tried experiments in this direction for many years, feeding part of our colonies, and omitting to feed others, and have always found the importance of feeding abundantly demonstrated.

Whenever the bees are not gathering honey, their industrious instincts lead them to become free-booters, and robbing once commenced, woe to the weak colonies of the apiary. Nuclei are also very likely to fall a prey to these pillagers. Nothing more quickly induces robbing than the spilling or leaving of any honey or syrup about the apiary. Let the bees once get a taste, and they become ravenous, and are at once on the rampage to appropriate the property of others. Such a spirit of plunder may also be engendered by too frequently opening the hives during these times of enforced idleness. The colony robbed should have the entrance nearly closed, so that only one bee can pass out at a time. Then almost any colony will defend itself, unless it has become entirely despirited, when it must be closed up entirely, or carried into a cool room for a time. If closed, give sufficient

ventilation, that the bees may not smother.

Strong colonies are those that bring profit, and such will defend themselves against robbers at all times. The Italian bees are far less liable to suffer from robbers than are the blacks, while the Syrians are rarely thus troubled. Robbers that attack a Syrian colony find they have "caught a Tartar."

NOTES.—The Syrian bees are more than sustaining their reputation. They have all of the points of superiority possessed by the Italians, magnified, except that of amiability, and as they are handled, they are becoming very manageable. This year our queenless colonies are very peaceable, while last year they were exceedingly irritable. Their late and early breeding are points in their favor. For prolificness, they are marvels. They are superior in the points where Italians fail; they are slow to leave the hives on very windy days, a trait which natural selection would develop in the windy regions of Syria, and they are ready to go into the sections to store their honey.

Bee and Honey Show in England.—The following is an account of the bee and honey show at the Royal Agricultural Fair in London, during the second week in July:

The British Bee-Keepers' Association, under the auspices of the Royal Agricultural Society, have arranged an excellent display of bees, hives, and appliances used in the more advanced methods of bee-keeping. These annual apiarian exhibitions have formed part of the Royal Agricultural Society's programme since the Kilburn Show held in 1879, and have increased in popularity in each succeeding year. The present Exhibition of bee-keeping appliances at Reading far surpasses any of its predecessors. The present unsettled state of the weather has, however, greatly militated against the production of honey, and in consequence many of the entries in the honey classes did not appear at the Show.

Observatory hives stocked with bees and their queen are a great feature in the show. The first, second, and third prizes in this class were all awarded to Mr. T. B. Blow, of Welwyn, Herts. Mr. Blow also gained first prizes for the best collection of appliances adapted for modern bee-keeping and for comb foundation, the latter being prepared by a machine in the presence of the Judges. Messrs. Neighbour & Son, of Regent street, and Messrs. Abbott Brothers, of Southall, have also an excellent display of goods in the several classes, the former taking second and the latter third prizes in the class for the best exhibition of hives and other appliances.

Mr. Jos. Wood, Anamosa, Iowa, writes: "My bees are booming; I cannot keep up with them for the past week."

For the American Bee Journal.

Apis Mellifica—Its Poison.

JAMES HEDDON.

FRIEND NEWMAN.—The following article I wrote for the *Homœopathic Physician*, a monthly Journal of Medical Science published in Philadelphia, Pa. I am trying a remedy that has been kindly presented to me by the Homœopathic Society, and will be able to report its results later:

At the request of Dr. Ballard, of Chicago, I herewith give a brief account of my peculiar experience with the poison from the honey bee. I have been a specialist in apiculture, for the past 14 years, and have learned something considerable about the business; have consequently neglected learning other things, among which anatomy and materia medica are conspicuous. You will, consequently, please accept my plain statements given in the parlance of an unprofessional.

I am 37 years old, nervous-sanguine temperament (in the extreme), weigh 135 lbs., and have good health, but excessive general nervous irritation, mostly in the form of mild chronic neuralgia. My voice has always indicated rather weak bronchial organs; never had a cough, however, before I experienced bee-poisoning. I began bee-keeping on a somewhat extensive scale, in the year 1878. As stated before, it has been my sole occupation ever since. I have had as many as 550 colonies, in 3 apiaries, at one time.

Seven years ago, I began to notice an itching sensation in the ears. This would come on at times, and after about two years, it extended to the glands inside the mouth, and near the root of the tongue. After about one more year, the sensation began to be very severe in the roof of the mouth, just around and in front of the palate. It was at this time that I first discovered that the affection had a connection with the bees. To sweep the floor of one of my rooms, where bees had fallen and been trodden upon, was sure to bring on this sensation at once. Next, I found, that to open a hive and breathe the odor of the bees (especially if not thoroughly subdued) would also cause the trouble. But, business must be attended to, and I persisted in working among the bees and bee hives, till the itching and tingling sensation crept down the bronchial tubes all around about the lungs. One night after a day's work among the bees, I woke up about midnight with the asthma.

A celebrated travelling doctor, examined me "free," and gave me some medicine for \$10.00, and told me I had a case of "bronchial" asthma, that looked wicked. He looked at my throat (shortly after a bee had) and

"must have something done for it at once." I was not sure then that bee-poison was the cause.

Finally, I began making tests; leaving the whole business for two weeks, I was almost entirely clear of all, except the first symptoms in the ears, which only troubled me occasionally.

The first breath of bee-poison I inhaled, on my return, was followed by all the former symptoms, seemingly in an increased degree, and in ten minutes my throat turned red, and clearly showed severe irritation. I resolved to hire more help, add to the business of honey production that of manufacturing and selling bee-keepers' supplies, and in that way absent myself from contact with the virus to a greater extent, and yet keep busy.

I have done so, and am in consequence quite free from the trouble most of the time. But if I at any time come in contact with the poison, my symptoms seem to be as radical as ever, yes, even more so. I will cite one instance. All apiarists know that often when a maddened threatening bee flits around one's head she generally discharges into the air her poison. It is recognized by the nasal organs only. Now, I have found that this occurs when none of the five senses of the healthy bee-master recognizes it.

One day last autumn, after I had kept from all contact with the poison for some weeks, and had no troublesome symptoms, I stepped into my yard, when an ugly bee passed within about 8 inches of my face, discharging poison as she passed. About one half-hour after I was seized with perhaps the most severe paroxysm of my experience. First, symptoms were an almost unbearable itching, tingling sensation, of the roof of the mouth, and so on down the breathing tubes as far as they extend; then an asthmatic filling-up sensation. For more than 8 hours I could not speak aloud. For two or three days I could not raise my voice above common conversation. All passed off, leaving me as well as ever, by keeping away from the poison. In correspondence with one Italian and one German, of large apicultural experience in the old countries, I learn that such cases are known there.

When we bear in mind the fact that the older system of honey production, as practiced in the old world, and in this country till recently, did not bring the operator into any such near or constant contact with the bees, and that cases where individuals in this country, working upon the improved system, for any such length of time as 14 years as a specialty, are very rare, we have reason to look for the development of many more such cases as my own.

Dr. Ballard expresses the desire to doctor my case upon the homœopathic system; to which I assent, knowing, as I think I do, that the homœopathic treatment possesses that splendid feature over all other schools, that if it don't cure it don't kill. I will here say publicly, what I said by letter to

him, that "faith" will play no part in any possible cure of my case.

I know that the laws of hygiene point strongly to the claimed base principle of Homœopathy, but I have always failed to get any effect from homœopathic remedies, given by professed thoroughbreds. I can at most consider the science as one only vaguely understood at best. Still its successful operations force all the other schools to step down on a level with it, to say the least, in all observing and thinking minds.

Any questions bearing upon the case, will be answered promptly and with pleasure, for I think I may safely say in the name of our fraternity, that a specific remedy for these symptoms, coming from any school, will put us under many obligations to that school.

For the American Bee Journal.

Cheap Queens, Light Bees, etc.

AARON BENEDICT.

Several years ago I stuck three stakes to steer to, and as I keep my eyes constantly on them, following up, I find them precisely in range. The lighter-colored and larger the bee, the more docility. I have already proven to my satisfaction that the smaller and blacker the bees, the more vindictive they are. I do not advertise queens for sale in any paper at present, and shall keep right on improving my bees until I get a fixed type—bees that will breed true to the feather. I am conceited enough to believe that when I get a bee to suit me, it will suit most anybody, for I am hard to please with anything like a hybrid or black bee.

There has been considerable said about the cheap queens of late. Nearly all that advertise such queens do not guarantee their purity. They can send out all the impure queens they rear, such as a careful breeder would behold on sight; some guarantee these queens reared from imported mothers only. My experience is to take an average of five imported queens, and it would take a careful breeder five or six years of careful breeding to produce as good as we already have. I put the dollar queen-breeder, and the advocates of dark, leather-colored Italians in about the same class. One sends out all the queens he rears, whether pure or impure, scattering broadcast all grades of bees, and probably not a thoroughbred queen in the whole lot; the other sends out dark, leather-colored queens, and if they produce dark bees, the purchaser gets just what he bargained for. There is another class of breeders who make it their steady aim to breed bees as bright-colored as they can, and they have succeeded in producing what appears to be a distinct variety of bees. Such breeders cannot afford to sell queens for a dollar each. I believe the time will come when such queens will bring a price somewhere near what it costs to rear them.

I do not find fault with dollar queens,

for they are worth that to any man who wishes to multiply colonies, if he can get such queens as he wants. To multiply colonies rapidly, a laying queen should be kept in the old as well as in the new colony. The old queen leaves with the first swarm, and the parent colony is queenless, and as a rule, it will be 18 to 21 days before the young queen commences to lay. By giving this colony a laying queen at once, at the end of 21 days there will be as many eggs, larvæ, and brood as there was when the old queen went away. This is my plan of multiplying colonies.

Bees always commence with larvæ 3 or 4 days old to rear queens, if they have them, and never with eggs or larvæ just hatched, unless compelled to. Larvæ just hatched is fed with a white milky substance, the same as the worker larvæ always receives—royal jelly is too strong. I once put an empty frame of comb in the center of the hive where I had my breeding queen; 24 hours after I took it out, and found the cells supplied with eggs. I cut this comb in small strips, and gave these to queenless bees. The bees commenced enlarging the cells, putting in royal jelly before the eggs hatched. Over 20 queens were reared from these strips, and they were the most unsightly batch of queens I had ever seen. They were all colors, and some not larger than a worker bee. I have since noticed the same small inferior queens. Where I had removed a queen as soon as she commenced to lay, the bees commenced too soon with jelly on the eggs or larvæ. Some think the cause of those small queens was that the bees commenced on larvæ too far advanced as workers; I never knew bees to commit that blunder. Bees are wiser with their instinct than men with their reason.

Bennington, O.

Southern World.

A Lesson from the Bees.

T. S. ARTHUR.

A murmur of impatience came from the lips of young Wentworth as laying aside his palette and brushes, he took up his hat and with a worried manner, left the studio, where, with two or three young men, he was taking lessons and seeking to acquire skill in the art of painting. He was at work on the head of one of Raphael's Madonnas, and was, with the warm enthusiasm of a young artist in love with the beautiful, seeking to transfer to his canvas the heavenly tenderness of her eyes, when a coarse jest from the lips of a fellow student, jarred harshly on his ears. It was this that had so disturbed him. Out in the open air the young man passed, but the bustle and confusion of the street did not in the least calm his excited state of feeling.

"A coarse, vulgar fellow!" he said angrily, giving voice to his indignation against the student. "If he is to remain in the studio, I must leave it.

I can't breathe the same atmosphere with one like him."

And he walked on aimless, but with rapid steps. Soon he was opposite the window of a print seller. A gem of art caught his eye.

"Exquisite!" he exclaimed, as he paused and stood before the picture. "Exquisite! What grouping. What an atmosphere. What perspective!"

"Ha, ha!" laughed a rough fellow at his side, whose attention had been arrested by a comic print. "Ha, ha, ha!" And clapping his hands against his sides, he made the air ring with a coarse but merry peal. He understood his artist fully, and enjoyed this creation of his pencil.

"Brute!" came almost audibly from the lips of Wentworth, as all the beautiful images just conjured up faded from his mind. And off he started from the print window in a fever of indignation against the vulgar fellow who had no more manners than to guffaw in the street at sight of low life in a picture. On he moved for the distance of one or two blocks, when he paused before another window full of engravings and paintings. A gem of a landscape, cabinet size, had just been placed in the window, and our young friend was soon enjoying its fine points.

"Who can be the artist?" he had just said to himself, and was bending closer to examine the delicate treatment of a bit of water, over which a tree projected, when a puff of tobacco smoke stole past his cheek, and found its way to his nostrils. Now Wentworth was very fond of a good cigar, and the fragrance that came to his sense on this particular occasion was delicate enough of its kind. In itself it would have been agreeable rather than offensive; but the vulgarity of street-smoking he detested, and the fact of this vulgarity came now to throw his mind again from its even balance.

"Whew!" he ejaculated, backing away from the window, and leaving his place to one less sensitive, or capable of a deeper abstraction of thought when anything of true interest was presented.

"I will ride out in the country," said he. "There, with nature around me, I can find enjoyment." So he entered an omnibus, the route of which extended beyond the city bounds. Alas! here he also found something to disturb him. There was a woman with a lapdog in her arms, and another with a poor sick child, that cried incessantly. A man partially intoxicated, entered after he had ridden a block or two, and crowded down by his side. Beyond this, the sensitive Wentworth could endure nothing. So he pulled the check string, paid his fare and resumed his place on the pavement, muttering to himself as he did so: "I'd a thousand times rather walk than ride in such company."

Two miles from the city resided a gentleman of taste and education, who had manifested no little interest in our excitable young friend. To visit him was the purpose of Wentworth when he entered the stage,

which would have taken him within a half a mile of his pleasant dwelling. He proposed to walk the whole distance rather than ride with such disagreeable companions. The day was rather warm. Our young artist found it pleasant enough while the pavement lay in the shadow of contiguous houses. But, fairly beyond these, the direct rays of the sun fell on his head, and the clouds of dust from the passing vehicles almost suffocated him. Just a little in advance of him, for a greater part of the distance, kept the omnibus, from which the woman with the lapdog and crying child got out only a square beyond the point where he left the coach. The drunken man also soon left the vehicle. Tired and overheated, Wentworth now hurried forward, making signs to the driver; but, as the driver did not look around, his signs were all made in vain; and he was the more fretted at this for the fact that the passenger who was riding in the omnibus, had his face turned towards him all the time, and was, so our pedestrian imagined, enjoying his disappointment.

Hot, dusty, and weary was our young artist, when, after walking the whole distance, he arrived at the pleasant residence of the gentleman we have mentioned.

"Ah, my young friend! How are you to-day! A visit, I need not tell you, is always agreeable. But you look heated and tired. You have walked too fast."

"Too far, rather," said Wentworth. "I have come all the way on foot."

"How so? Did you prefer walking?"

"Yes; to riding in the stage with a crying child, a lapdog and a drunken man."

"The drunken man was bad company, certainly. But the crying child and the lapdog were trifling matters."

"Not to me," answered Wentworth. "I despise a woman who nurses a lapdog. The very sight frets me beyond endurance."

"Still, my young friend, if women will nurse lapdogs, you can't help it; and so, your wisest course would be to let the fact pass unobserved; or at least uncare for. To punish yourself, as you have done to-day, because other people don't conform in all things just to your ideas of propriety is, pardon me, hardly the act of a wise man."

"I can't help it. I am too finely strung. I suppose—too alive to the harmonies of nature, and too quick to feel the jar of discord. Do you know to what you are indebted for this visit to-day?"

And Wentworth related, with a coloring of his own, the incidents just sketched for the reader; taking, as he did so, something of merit to himself for his course of action.

"Upon what were you at work?" asked his friend, when the young man finished speaking.

"On the beautiful Madonna, about which I told you at my last visit."

"It is nearly completed?"

"A few more touches, and I would have achieved a triumph above any-

thing yet accomplished by pencil. It was in the eyes that I failed to succeed. They are full of divine tenderness, that only a magic touch can give. Raphael was inspired when he caught that look from heaven. I had risen, by intense attraction of mind, into the perception of the true ideal I sought to gain, and the power to fix it all on canvas was flowing down into my hand, when the jar of discord produced by that vulgar fellow scattered everything into confusion and darkness."

"And so the Madonna remains unfinished?"

"Yes, and I am driven from work. Here is another day added to my list of almost useless days."

The friend mused for a little while, and then said, somewhat sententiously—

"You must take a lesson from the bees, Henry."

"I will hear a lesson from your lips, but, as for the bees."

And he shrugged his shoulders with an air that said—"I can learn but little from them."

"Let us walk into the garden," said the friend rising.

And they went out among the leafy shrubs and blossoming plants, where butterflies fold their lazy wings, and the busy bees made all the air musical with their tiny hum.

"Now for the lesson," said the young artist smiling. "A lesson from the bees. Here is a sprightly little fellow, just diving into the red cup of a honeysuckle. What lesson does he teach?"

"One that all of us may lay to heart. There is honey in the cup, and it is his business to gather honey. Just beside the crimson blossom, and even touching it, hangs an ugly worm, spinning out the thread of his winding-sheet; but the bee does not pass the flower, because of its offensive presence, nor will he hasten from it until he has extracted the honey-dew. Now his work is accomplished; and now he has passed to the clover blossom, which his weight bends over against the deadly night-shade. But the poisoned weed is no annoyance to him. So intensely pursues he his search for honey, that he is unconscious of its presence. Now he buries himself in the blushing rose leaves, 'heeding not and caring not,' though a hundred sharp thorns bristle on the stem that supports the lovely flower. And now, full laden with the sweet treasure he sought, he is off on swift wing for the hive. Shall we observe the motion of another bee? Or is the lesson clear?"

The countenance of Wentworth looked thoughtful, even serious. A little while he stood musing, as though his perceptions were not lucid. Then turning to his wise and gentle reproving friend, he grasped his hand, saying, with a manner greatly subdued:

"The lesson is clear. I will go back and finish my Madonna, though a dozen vulgar fellows haunt the studio. I will have no eyes or ears for them. My own high purpose to excel, shall make me blind and deaf to anything that would hinder my on-

ward progress. Thanks for the lesson of the bees. I will never forget it. Like them, I will gather the honey of life from every rich flower in my way. Let the weeds grow high if they will, I shall not regard their presence."

For the American Bee Journal.

Sundry Items from New York.

J. E. MOORE.

I have been reading the articles in the Weekly BEE JOURNAL on the "honey prospects," and as I see none from this part of the State, send a few items from Genesee county. The season, so far, has been peculiar, and although the apiarist has been hoping for better things all along, if the weather continues as it has been much longer white clover honey will be hard to find in this part of the State.

As the season was two weeks later than usual, and the fields gave promise of abundant clover bloom, I thought the weather would be more favorable than had it blossomed earlier, and so made preparations for a large yield; but, although the bloom has been most abundant, very little honey has been gathered. The rotation has been three days high winds then storms, followed by one or two days fair weather. We had rain on the night of the 17th, followed by warm showers on the morning of the 18th, up to 9 a. m. By 10 o'clock it seemed as though I never saw the bees bring in honey so fast, and I went out of the bee house several times, queen cage in hand, thinking the bees were swarming. This continued until noon of the 19th, when the wind commenced rising, and still continues, so that my expectations that the "boom" had come at last seem likely to be blasted.

These high winds are invariably cold. At 9:45 this morning the temperature in the sun was 88°, while in the shade it was only 67°. To sum up, the clover bloom has been most abundant, but the atmospheric conditions have been altogether against the secretion of honey by the flowers. I do not agree with Mons. Layens' theory, mentioned by Mr. Todd, as the cause of no honey in clover. The linden is not in bloom yet, and I notice the buds are not so abundant as last year.

When I boxed the hives, we had 67 colonies of Cyprians and 15 of Italians. Have had 15 Cyprian and 1 Italian swarm. I never worked among bees that handled easier than the Cyprians do in hiving swarms. On some accounts I like them better, and on some not as well as the Italians; but shall be better able to judge as to their merits at the close of the season. I think they hold their own better in the spring, and are more active than the Italians. Their sense of smell is wonderfully acute, so that if there is the least chance given they are very neighborly, and if one has combs filled with bee-bread and honey, set them in an empty hive and leave

the cover off long enough to turn around three times, then cover up and they will take care of it. Why, I have had them cut combs down to the partition walls about $\frac{1}{3}$ distance down from top bar. Hark! what's all this buzzing mean? . . . Well I have hived a second swarm of Cyprians. I have put back all second swarms, as I think their presence will be needed in the boxes; but this was such a nice large one I thought I would hive it, and as the queen was with them (all old queens are clipped) I shook them into the hiving bag.

When bees swarm from the hive where the queen is clipped, if you want the bees to return to the hive without clustering, cage the queen as soon as possible and put her in the hive; or, if you prefer clustering, tie the cage on a bush suspended on a pole, following the bees to a tree or bush.

Byron, N. Y., July 20, 1882.

For the American Bee Journal.

Bee-Keeping in Massachusetts.

F. C. BOWDITCH.

Of my thirteen colonies twelve began April in fair condition. The spring here, as everywhere else, was very backward. I commenced feeding on April 8, and by care I was able to get and keep my colonies strong during our cold and discouraging May. Consequently when fruit bloom began my bees literally fell upon it; and we had about two weeks good honey flow and the eleven colonies I ran for extracting, filled their two story hives and began on a third story. On the 21 of July I extracted from the second stories alone 300 lbs. of fine honey, leaving the first and third stories, so far as they contained any honey, untouched. On the same day, right in the midst of clover and linden bloom, the bees began to kill their drones, and I regard it as very fortunate I did not extract too closely, as they have barely held their own ever since and many combs are almost empty.

I think if I had had empty old combs to give them I should have secured a much larger crop, but they had to draw out foundation, which takes time, and a sheet of foundation just drawn out will not hold more than three-quarters as much honey as a tough old comb. Three hundred pounds does not in quantity really amount to anything, but then there are some not very far off who have none at all, so I feel encouraged.

None of my eleven colonies swarmed or had any nuclei made from them, so you will see I directed their whole energy to honey gathering. We have every reason to expect and look forward to a good yield from golden rod and asters, as the conditions for it appear just right; last year it failed entirely.

I have noticed in the JOURNAL several articles, the writers of which claim that the production of drones can be stopped or controlled by using worker foundation, and several an-

swers *per contra*, that the use of foundation would not accomplish that result. I find I *cannot* prevent my bees from rearing some drones; they will take a worker comb and lengthen out the cells, or they will cut the worker cells down to the bases and build drone cells in their place, they *will* have some drones; undoubtedly the use of foundation prevents a very large number of drones, but that it will entirely prevent their being reared, I am not willing to admit.

I have one colony of bees that are very peculiar; they are the most vicious of hybrids, and last year I thought I would Italianize them. I made two attempts, and each time with great care, but they killed the queen both times, until it became so late in the autumn that I decided to wait till this season. Last May I tried again, and they killed the queen, and I, not to be outdone, tried another. I saw her go in at the entrance and the bees feed her and lick off the honey I had rolled her in, and I found the next day that no cells were started so I supposed, of course, all was right; but yesterday I found she had been killed as usual, and a small black queen reigned in her stead. I shall try again and again till I succeed. I have tried several methods such as letting the bees gnaw her out of the cage, shaking off the bees in a box and letting her run in with them, and other ways which I have used with success in other cases, but they seem to have made up their minds to have their own way. I think in the last case they actually accepted the queen at first and then killed her afterward; they are a curious lot.

Brookline, Mass., July 21, 1882.

From the Century for June, 1882.

The Bee-Pastures of California.

JOHN MUIR.

When California was wild, it was one sweet bee-garden throughout its entire length, north and south, and all the way across from the snowy Sierra to the Ocean.

Wherever a bee might fly within the bounds of this virgin wilderness—through the redwood forests, along the banks of the rivers, along the bluffs and headlands fronting the sea, over valley and plain, park and grove, and deep leafy glen, or far up the piney slopes of the mountains—throughout every belt and section of the climate, bee flowers bloomed in lavish abundance. Here they grew more or less apart in special sheets of no great size, there in broad, flowing folds hundreds of miles in length, zones of polleny forests, zones of flowery chaparral, stream-tangles of rubus and wild rose, sheets of golden composite, beds of violets, beds of mint, beds of bryanthus and clover, and so on, certain species blooming somewhere around all the year.

But of late years plow and sheep have made sad havoc in these glorious pastures, destroying tens of thousands of the flowery acres like fire, and banishing many species of the best

honey plants to rocky cliffs and fence corners, while, on the other hand, culture thus far has given no adequate compensation, at least of kind—acres of alfalfa for miles of the richest wild pasture, ornamental roses and honeysuckles around cottage doors for cascades of wild roses in the dells, and small, square orchards and orange groves for mountain belts of chaparral.

Only ten years ago, the Great Central Plain of California, during the months of March, April and May, was one smooth, continuous bed of honey bloom, so marvelously rich that, in walking from one end of it to the other, a distance of more than 400 miles, your feet would press more than a hundred flowers at every step. Mints, gillias, memophilas, castilleias, and innumerable composite were so crowded together that, had ninety-nine in every hundred been taken away, the plain would still have seemed extravagantly flowery to any but Californians. The radiant, honey-full corollas, touching and over-lapping, and rising above one another, glowed in the living light like a sunset sky—one glorious blaze of purple and gold. Down through the midst flowed many a river, the Sacramento from the north, the San Joaquin from the south, with noble tributaries sweeping in at right angles from the mountains, dividing the plain into sections fringed with trees.

Along each river and tributary there is a strip of bottom-land, countersunk beneath the general level, and wider toward the foot-hills, where magnificent oaks, from three to eight feet in diameter, cast grateful masses of shade over the open, prairie-like level. And close along the water's edge there is a fine jungle of tropical luxuriance, composed of white rose and bramble bushes and a great variety of climbing vines, wreathing and interlacing the branches and trunks of willows and alders, and swinging across from summit to summit in heavy festoons. Here the wild bees revel in fresh bloom long after the flowers of the drier plain have withered and gone to seed. And in midsummer when the "blackberries" are ripe, the Indians come from the mountains to feast—men, women and babies in long noisy trains, oftentimes joined by the farmers of the neighborhood, who gather this wild fruit with commendable appreciation of its superior flavor, while their home orchards are full of ripe peaches, apricots, nectarines and figs, and their vineyards are laden with grapes. But, though these luxuriant bottoms are thus distinct from the smooth, treeless plain, they make no heavy dividing lines in general views. The whole appears as one continuous sheet of bloom, bounded only by the mountains.

My first view of this central garden, the most extensive and best defined of all the bee pastures of the State, was obtained from the summit of the Pacheco pass, about the middle of April, 1868, when it was rejoicing in all its glory. Along the eastern horizon rose the mighty Sierra, white and

jagged with snowy peaks along the top, dark with forests in the middle region, and purple with grasses and flowers and chaparral at the base, and blending gracefully in smooth hill undulations into the glowing yellow plain, which, like a cloth of gold, was seen flowing away to north and south as far as the eye could reach; bazing and vanishing in the distance, distinct as a new map along the foot-hills at my feet—the sunny sky arching over all.

Descending the eastern slopes of the coast range, through beds of gillias and lupines, and around many a hillock and bush-crowned headland, I at length waded out into the midst of the glorious field of gold. All the ground was covered, not with grass and green leaves, but with radiant corollas, about ankle-deep next the foot hills, knee deep or more five or six miles out. Hereopsis, corethrogyne, grindelia, etc., growing in close social congregations of various shades of yellow, blending finely with the purples of clarkia, orthocarpus, and crotalaria, whose delicate petals were drinking the vital sunbeams without giving back any sparkling glow.

Because so long a period of extreme drought succeeds the rainy season, most of the vegetation is composed of annuals which spring up simultaneously and bloom together at about the same height above the ground, the general surface being but slightly ruffled by the taller phacelias, pentstemons, and groups of *Sabia carduacea*, the king of the mints.

Sauntering in any direction, hundreds of these happy sun-plants brushed against my feet at every step, and closed over them as if I were wading in liquid gold. The air was sweet with fragrance, the larks sung their blessed songs, rising on the wing as I advanced, then sinking out of sight in the polleny sod, while myriads of wild bees stirred the lower air with their monotonous hum—monotonous, yet forever fresh and sweet as every-day sunshine. Hares and spermophiles showed themselves in considerable numbers, and small bands of antelope were almost constantly in sight, gazing curiously from some slight elevation, and then bounding swiftly with unrivaled grace of motion. Yet I could discover no crushed flowers to mark their track, nor, indeed, any destructive action of any wild foot or tooth whatever.

The great yellow days circled by uncounted, while I drifted toward the north, observing the countless forms of life thronging about me—lying down almost anywhere on the approach of night. And what glorious botanical beds I had! Oftentimes on awakening I would find several new species leaning over me and looking me full in the face, so that my studies would begin before rising.

About the first of May I turned eastward, crossing the San Joaquin between the mouths of the Tuolumne and Merced, and by the time I had reached the Sierra foot-hills, most of the vegetation had gone to seed and become as dry as hay.

All the seasons of the great plain are warm or temperate, and bee-flowers are never wholly wanting; but the grand spring time—the annual resurrection—is governed by the rains, which usually set in about the middle of December or the beginning of January. Then the seeds, that for six months have lain on the ground dry and fresh as if they had been gathered into barns, at once unfold their treasured life. The general brown and purple of the ground, and the dead vegetation of the preceding year, give place to the green of mosses and liverworts and myriads of young leaves. Then one species after another comes into flower, gradually overspreading the green with yellow and purple, which lasts until May.

The "rainy season" is by no means a gloomy, foggy period of constant cloudiness and rain. Nowhere else in North America, perhaps in the world, are the months of December, January, February and March so full of bland, plant-budding sunshine. Referring to my notes of the winter and spring of 1878-9, every day of which I spent out-of-doors, on that section of the plain lying between the Tuolumne and Merced rivers, I find that the first rain of the season fell on the 18th of December. January had only six rainy days—that is, days on which rain fell; February three, March five, April three, and May three, completing the so-called rainy season, which was about an average one. The ordinary rain storm of this region is seldom very cold or violent. The winds, which in settled weather come from the north-east, veer round into the opposite direction, the sky fills gradually and evenly with one general cloud, from which the rain falls steadily, often for several days in succession, at a temperature of about 45° or 50°.

More than 75 per cent. of all the rain of this season came from the south-east. One magnificent storm from the north-west fell on the 21st of March. A massive, round-browed cloud came swelling and thundering over the flowery plain in most imposing majesty, its mossy front burning white and purple in the full blaze of the sun, while warm rain poured from its ample fountains like a cataract, beating down flowers and bees, and flooding the dry water-courses as suddenly as those of Nevada are flooded by "cloud-bursts." But in less than half an hour not a trace of the heavy mountain-like cloud-structure was left in the sky, and the bees were on the wing as if nothing more gratefully refreshing could have been sent them.

By the end of January four plants were in flower, and five or six mosses had already adjusted their hoods and were in the prime of life, but the flowers were not sufficiently numerous to affect greatly the general green of the young leaves. Violets made their appearance on the first week of February, and toward the end of this month the warmer portions of the plain were already golden with myriads of the flowers of rayed compositæ.

This was the full spring time. New species bloomed every day. The sunshine grew warmer and richer. The air became more tuneful from day to day with humming wings, and sweeter with the fragrance of the opening flowers. Ants were getting ready for their summer work, rubbing their benumbed limbs, and sunning themselves on the husk-piles before their doors, and spiders were busy mending their old webs or weaving new ones.

In March, vegetation was more than doubled in depth and splendor; claytonia, calandrinia, a large white gilia, and two nemophilas were in bloom, together with a host of yellow compositæ, tall enough to bend in the wind and show wavering ripples of shade.

In April, plant-life as a whole reached its greatest height, and the plain over all its varied surface was mantled with a close furred plush of purple and golden corollas. By the end of this month most of the species had ripened their seeds, but undecayed, still seemed to be in bloom from the numerous corolla-like involucres and whorls of chaffy scales of the compositæ. In May, the bees found only a few deep-set liliaceous plants and eriogonums in flower.

June, July, August and September was the season of rest and sleep—the winter of dry heat, followed in October by a second outburst of bloom at the very driest time of the year. Then, after the shrunken mass of leaves and stalks of the dead vegetation crinkle and turn to dust beneath the foot, as if it had been baked in an oven, *Hemizonia virgata*, a slender, unobtrusive little plant, from six inches to three feet high, suddenly makes its appearance in patches miles in extent, like a resurrection of the bloom of April. I have counted upward of three thousand flowers, $\frac{5}{8}$ of an inch in diameter, on a single plant. Both leaves and stems are so slender as to be nearly invisible amid so showy a multitude of flowers. The ray and disk flowers are both yellow, the stamens purple, the texture of the rays being rich and velvety, like the petals of garden pansies. The prevailing wind turns all the heads round to the south-east, so that in facing north-westward we have the flowers looking us in the face. In our estimation, this little plant, the last-born of the brilliant host of compositæ that glorify the plain, is the most interesting of all. It remains in flower until November, uniting with two or three species of wiry eriogonums, which continue the floral chain around December to the spring flowers of January. Thus, although the main bloom and honey season is only about three months long, the floral circle, however thin around some of the hot, rainless months, is never completely broken.

How long the various species of wild bees have lived in this honey-garden nobody knows; probably ever since the main body of the present flora gained possession of the land, toward the close of the glacial period. The first brown honey bees brought to California are said to have arrived

in San Francisco in March, 1853. A bee-keeper by the name of Shelton purchased a lot, consisting of 12 colonies, from some one at Aspinwall, who had brought them from New York. All the hives contained bees when landed at San Francisco, but they finally dwindled to one colony, which was taken to San Jose. The little emigrants flourished and multiplied in the bountiful pastures of the Santa Clara valley, sending off swarms the first season.

Local Convention Directory.

- 1-8-2. Time and Place of Meeting.
 Aug. 10—Maine State, at Harmony, Maine.
 Wm. Hoyt, Sec.
 Sept. 5—N. W. Ill. and S. W. Wis., at Rockton, Ill.
 Jonathan Stewart, Sec.
 Oct. 3-6—North American, at Cincinnati, O.
 Dr. Erick Parmlly, Sec., New York City.
 5—Kentucky Union, at Shelbyville, Ky.
 G. W. Demaree, Sec., Christiansburg, Ky.
 Tuscarawas Valley, at Newcomerstown, O.
 J. A. Bucklew, Sec., Clarksville, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

The National Convention.

The following is the official call of the Secretary, Dr. Parmlly, for the Convention of the North American Bee-Keepers' Society. We hope there will be a large attendance:

The North American Bee-Keepers' Society will hold their 13th annual meeting at Washington Park Hall, Cincinnati, O., across Washington Park from the Exposition building. Time, Oct. 3rd to 5th, 1882. First session Tuesday, 10 a. m., Oct. 3. We are encouraged to hope that this will be a very profitable meeting, as we are promised papers from, and the presence of, a large number of our most prominent bee-keepers both in the United States and Canada, and essays and implements of the apiary are expected from abroad to add to the knowledge imparted by the research and inventive skill and methods of our countrymen.

ERICK PARMLLY, Sec.
 New York, July 12, 1882.

The bee-keepers of Boone Co., Indiana, are invited to meet in Lebanon, at Barton Higgins' office, over Jackson's bee hive, on the west side of the square, to organize an auxiliary County Association, on Aug. 10, 1882.

GEORGE J. FREY,
 ORA KNOWLTON,
 JAS. H. OREAR, } Executive Com.

The summer's meeting of the Cortland Union Bee-Keepers' Association, will be held in Cortland, N. Y., on Tuesday, Aug. 8, 1882.

M. C. BEAN, Sec.

SELECTIONS FROM OUR LETTER BOX

Will it Pay.—1. Could a person keeping about 25 colonies of bees find sufficient profit therefrom to pay his expenses, if the latter were very moderate, including an extractor and a few other necessary articles? 2. Would an apiary of 100 colonies of Italians produce an income of a few hundred dollars per annum?

ROLLAND MACDONALD.

Montreal, Quebec.

[1. Everything favorable, 25 colonies would give a handsome profit on running expenses.

2. Mr. Doolittle's report for 9 years, gives an average income of \$1,380 per annum, with less than 100 colonies as basis; but he has, perhaps, been more than usually fortunate during the series of years. However, with the same judgment in the selection of location and assiduity in managing business, bee-keeping will pay as well as any other pursuit.—ED.]

My Season's Work this Far.—I had last fall in the yard and cellar of my own and neighbor's, 28 colonies; 16 of which were in Roop's winter protector hive. All wintered safely except one, which lost its queen; three more were in other winter hives and wintered successfully; and 9 in Roop's common hive and wintered in cellar, of which we lost 2; leaving 25 out of 28, all in fair condition. Most of them were very strong until within three weeks; the season was very wet; no honey was gathered through fruit bloom, except to keep up brood-rearing. The same through red raspberry bloom, here at Carson; Mr. Roop took 40 colonies of young bees and all on dry combs and foundation ten miles in the country, to a red raspberry patch, which filled up rapidly and filled one crate each, in a short time, ready to tier up. Then we had another dearth until three days ago, when they commenced on basswood, and yesterday and to-day are working very nicely. I have not secured 5 lbs of new honey as yet and have only extracted perhaps 10 lbs. of old honey this season. Nor have we had a swarm until to-day; the first one came out at 8 o'clock this morning. I have made 13 nuclei which are as strong as the parent colonies and ready to tier up for extracting. Other of our neighbors have been bothered with too much swarming, but those in Roop's winter protector can be nearly kept from swarming. We have 15 colonies in Roop's winter hives that have 27 frames covered with bees and a crate on top, all well supplied with bees and are putting in honey to-day at a rapid rate. Mr. Roop's bees at home have done no better than ours, unless it be by swarming which was caused by not letting them

in the side chambers. All the honey we are to get must be basswood and fall honey; one rain would spoil all hopes for white honey.

OPHIR R. GOODNO.

Carson City, Mich., July 22, 1882.

Drones as Comb-Builders.—Seeing several articles lately on the use of drones, I will add my mite as a sort of mitigation for the "lazy fathers of the hive." M. T. French, a neighbor bee-keeper, came after me to extract some honey for him on the 1st inst. I took out about 400 lbs. for him, and while there I saw a colony of black bees, in an American hive, building comb on the front of the hive, and as there was considerable comb I began to watch them work. I saw fully one-fourth of the outside bees were drones, and they seemed to be as busy as the others. On a close watch I found them actually working the wax; yes, building comb, and Mr. French told me he had carefully watched them for nearly a week, and he was satisfied that they were actually building comb. We are having splendid rains. The mint (*Monarda punctata*) is freshened up, and the bees are again working finely on it and cotton, Jamestown weed, cockle-burr, "thorny careless," lambs-quarter, and other prairie flowers. I am trying to get up a statistical report of bee-keepers and number of colonies in the county. Will forward as soon as made out. Texas has been gloriously blessed this year. Plenty smiles over our fields, orchards and apiaries. God be praised for this abundance.

B. F. CARROLL.

Dresden, Texas, July 17, 1882.

Disposition of Bees.—The temper of bees is an effect, the causes of which comes from two sources, viz, inheritance, and treatment. My observations regarding their disposition (which have been more than ordinarily careful, since I have been breeding for good nature), have taught me that bees that are carelessly handled are the crossiest; those let alone, next; those that are properly handled, gentler than either. This, as far as treatment is concerned. Breed from your gentlest and best honey-gathering colonies; never undertake to handle your bees, till you have settled the question of "who is boss," beyond all doubt. Smoke first and jar all you wish afterward, and your bees are not offended. Jar first, and smoke all you please afterward, and they show anger and resentment for days afterward.

JAMES HEDDON.

Dowagiac, Mich.

Transferring.—To-day is July 19, but, so busy have I been, that not until now have I read Mr. Heddon's article on "Progressive Transferring," in the BEE JOURNAL of July 12th. My article was written nearly two years ago, and was originally published in the *Country Gentlemen* of April 21st, 1881, instead of the *Rural New Yorker* as credited in the BEE JOURNAL. Since writing that, I have learned a better way of getting off

the sides of the hives, and that is just exactly as Mr. Heddon describes it. I now fasten in combs, by tacking light strips of wood to each side of a frame, removing the strips after the bees have fastened in the combs. Mr. Heddon's method of drumming out is certainly convenient, but does it pay to allow a hive to stand queenless three weeks, the young bees "loafing" about, and fairly aching for some brood to care for? In all essays where the beauties of artificial swarming are dwelt upon, this one point, that of leaving no colonies queenless, is the leading "beauty." I have had no experience in thus leaving colonies queenless, and should be glad to know if, setting aside the getting of the combs emptied of brood, so that they can be made into comb foundation, whether it is any advantage to so transfer. W. Z. HUTCHINSON.
Rogersville Mich., July 20, 1882.

Entomological.—I send you by this mail a box containing a beetle. Please tell what species, and whether beneficial or not; also some balls from an oak tree, with a leaf attached. An insect appears to have come out of each one; what is the cause of the balls, and tell something about the insect? If not too much trouble, please answer through the BEE JOURNAL.

R. VAN DUSEN.

Arcadia, N. Y.

[The beetle is *Alaus oculatus*, one of our largest spring or jumping beetles. The specific name *oculatus* comes from the large eye-like spots on the thorax. The beetle is gray with numerous dashes of black. The eye-like spots are velvety black, circled with gray. The length of the beetle is 1½ inches. Like all of the Elater family (Elateridæ), when placed on its back, it can by a bound regain its feet. The larva or grub eats the unsound wood in old apple trees. I have found it also in other trees.

The galls are the common oak apples. They are formed by an extra growth, due to the sting of an insect in this case, *Cynips confluens*, which belongs to the order Hymenoptera, and so is no distant relative of our bees. The sting is attended by egg-laying, and the larva which comes from the egg, feeds on the apple which the sting causes. The oak is a favorite with these gall-flies, there being many varieties of apples, and many species to produce them.—A. J. Cook.]

Poor Honey Season.—I started with 18 colonies, have increased to 51, taken 180 lbs. extracted and 56 lbs. of comb honey. Bees are Italians and hybrids, with one Syrian, which did the best for extracted honey.

J. C. MISHLER.

Ligonier, Ind., July 22, 1882.

Hanging Broad Frames.—I think it a great improvement to hang the broad frames of the surplus arrangement for comb honey upon metal rabbits, by means of ears or projections of sheet-iron bent at right angles and nailed on the end pieces of the frame, leaving off the top bar. The sections are much more easily handled where the top is open, while a blanket keeps them clean. Is there any patent on this arrangement?

RUSTICUS.

[We are not aware of any patent on the above described arrangement.—ED.]

Bees Stings for Deafness.—On page 441 vol. 18, No. 28 is an article headed "Not so Bright," from J. C. Thom, M. D. Streetville, Canada, who wishes to hear from other Canadian points, in regard to bee forage. White clover has been in bloom over three weeks, and seems to secrete plenty of honey, and bees are doing well with us. On the 27th of May, a bee friend from Waterloo, wishing to see an Italian queen in my possession; the day was a little rainy and foggy, and not very pleasant to open a hive of bees. However it was done, but we could not find her, on account of the heavy mist falling. I aroused the bees so that I was obliged to cover them up. In this I got stung on the back part of my left ear which has been deaf and of no use to me over 25 years. Two weeks later, I received another sting, but on the inside of the ear, close to the ear-drum, which was somewhat painful at the time. Thank fortune, the sting I received from those bees has restored my ear to hearing again.

JOSEPH M. WISMER.

Jordan Station, Ont., July 18, 1882.

A Large Yield in Maine.—There is now a fair prospect for a large yield of honey in Aroostook county. I never saw such a flow of the nectar as for the last 10 days, from Alsike clover, which is now in full bloom. We have had all we could do to furnish hives, fixtures, etc., for the bee-keepers in this vicinity, and for ourselves. We are running our apiary on Doolittle's plan, and have profited by so doing. I do not know how we should get along without the BEE JOURNAL. It comes to us regularly every week, with something new and interesting, and it is very encouraging to beginners to read how others are doing in different parts of the country.

HENRY TILLEY.

Castle Hill, Me., July 20, 1882.

Worst Season ever Known.—We are having, thus far, the worst season ever known in this locality for the production of honey. That "silver lining" does not make its appearance yet. Basswood is in full bloom; only one tree in five has blossoms, and not much honey from it yet. We heard of bees starving in the middle of June. Ours are building up nicely, and will probably get enough to winter with.

JOHN H. MARTIN.

Hartford, N. Y., July 21, 1882.

More Motherwort.—I send to you by this mail a sprig of flowers that grow wild in this part of the country, and it is covered with bees from morning till night. I would be obliged if you will inform me through your valuable BEE JOURNAL what is its name. I am a beginner in bee-keeping, and I like to work among them. I had 4 colonies this spring, in box hives, and sent for 2 Langstroth hives, which are occupied with black bees, and 3 colonies in American hives. They all seem to be very strong and are working well; but I have no surplus yet. They are now working in the boxes.

A SUBSCRIBER.

Elmira, N. Y., July 24, 1882.

[The specimen sent is motherwort, mention of which has been made several times in the BEE JOURNAL.—ED.]

No Honey Yet.—Prospects for a crop of honey are very poor. I have 125 colonies of Italian bees, and have not had one swarm yet, neither have I obtained a pound of honey. They will not average 2 lbs. of honey to the hive if I should extract every drop of it. They are full of bees. I think I shall get some basswood honey; it is not in blossom yet, being two weeks later than last year. Last winter was very open, and all the clover was killed. I have kept bees for 20 years, but never had them do so poorly.

W. C. WELLS.

Phillipston, Ont., July 17, 1882.

Not Discouraged.—Bees have done very poorly here this spring, but are doing well now on clover and various other plants. I put 7 colonies in the cellar last fall, lost 2 during the winter, and the rest I lost after taking them out in the spring. I think they starved, as they gathered no late honey last season and reared no brood, leaving old bees to winter. I was not discouraged, however, but purchased 3 colonies last spring and shall try again.

A. J. ABBOTT.

North Paris, Maine, July 23, 1882.

Colored Bee-Keepers.—In ante-bellum days I was a slave-owner, and I believe I know the Southern negro as well as any one, and it is a notorious fact that there is a peculiar musky scent about these people not found in the white races; but, I dare say, this scent would not be more objectionable to our little pets than whisky or tobacco. I am well acquainted with a host of negro bee-keepers; one married a girl that formerly belonged to me, and I have often counted as high as 20 colonies in his yard. Jake Smith, f. m. c., near Dresden, has several colonies in American hives. Ben Younger, f. m. c., has several. He told me a few days ago his bees were doing well. It is true that this people are very superstitious, but if you will show me a man that is entirely free from superstition, I will show you hairs in the palms of your hands. They are taking some interest in fruits and bees, and are sending

their children to the free schools, and the day is not far distant when scientific bee-culture will be practiced, or rather carried on, by these dusky sons of the Old World, as well as their more informed brethren.

Dresden, Tex. B. F. CARROLL.

This Year is "Badder."—Bees are doing very poorly here. The season was so wet and cold, the bees could do but very little in the way of collecting honey, although everything bloomed profusely in the early part of the season, such as apple, pear, cherry, plum, peach, and tulip trees, raspberry and blackberry. White clover was very scarce, owing to the drouth last year. The basswood or linden was a failure here this year. Last year was very bad here for bees, and as the little boy said, this year, so far, is "badder." We hope to get some surplus honey from fall flowers. Catnip and buckwheat are now in bloom, and blackheart (hydro-piper) will soon be. I have a small patch of sweet clover, and I think it is the "boss" bee plant for honey. I will have nearly an acre of it next year. I had 7 colonies in the spring; I now have 15, all strong except one.

THOMAS J. WARD, J. P.

St. Mary's Ind., July 25, 1882.

Hay for Shading.—Bees are booming on basswood, while I am writing, with the thermometer at 90° in the shade, and this suggests the importance of some kind of shade for our hives. We have tried putting on a handful of newly cut grass, timothy or some long grass is best, as by spreading a handful each way you have a protection to keep the sun from the sides of the hive. Before the grass gets too dry, put it away in the barns, and lay on a new crop. Thus you not only protect your bees from the sun, but do your "haying" at the same time. We have noticed that a colony works much better if shaded all day, than if left uncovered until they begin to roar with the heat.

G. W. STANLEY.

Wyoming, N. Y., July 24, 1882.

Prospect Yet Good.—Until now the prospect for surplus has looked blue, but basswood is just opening and we feel in hopes of a fair crop yet. The weather has become dry and hot and is more favorable for secreting honey. Last year basswood opened July 1st, and it has been our main reliance for surplus the past 3 years, and we esteem it the best honey we get. I had 12 acres of alsike clover in bloom this year, but it did not yield much honey. I think we are overstocked with bees here, which may be the principal reason why we do not get more clover honey.

W. H. S. GROUT.

Kennedy, N. Y., July 24, 1882.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published **WEEKLY** as follows, if the whole is paid in advance:

For 4 weeks.....	10	per cent. discount.
" 8 ".....	20	" "
" 12 " (3 months)....	30	" "
" 24 " (6 months)....	40	" "
" 36 " (9 months)....	50	" "
" 52 " (1 year).....	60	" "

Discount, for 1 year, in the **MONTHLY** alone, **25 per cent.**, 6 months, **10 per cent.**, 3 months, **5 per cent.**, if wholly paid in advance.

Discount, for 1 year, in the **SEMI-MONTHLY** alone, **40 per cent.**, 6 months, **20 per cent.**, 3 months, **10 per cent.**, if wholly paid in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

The **BEE JOURNAL** is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly **BEE JOURNAL** for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Premiums.—Those who get up clubs for the Weekly **BEE JOURNAL** for one year, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—	a copy of "Bees and Honey."
" " 3,—	an Emerson Binder for 1882.
" " 4,—	Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper, cloth.
" " 5,—	" " " "
" " 6,—	Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Articles for publication must be written on a separate piece of paper from items of business.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 8 oz.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the **BEE JOURNAL**.

Advertisements intended for the **BEE JOURNAL** must reach this office by Saturday of the previous week.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Do not let your numbers of the **BEE JOURNAL** for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., July 31, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.
CHICAGO.

HONEY—I am paying 7c. for dark and 8c. for light extracted.
BEESWAX—Choice lots are worth 25c. here; bright yellow, 24c.; dark to good, 17@22c.
AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for honey is quiet. Extracted brings 7@10c. on arrival. No comb honey on the market worth mentioning, prices nominal.
BEESWAX—Scarce, and brings 20@25c. on arrival.
C. F. MUTH.

Quotations of Commission Merchants.
CHICAGO.

HONEY—The demand for comb honey is light, prices being made to meet views of purchaser.
BEESWAX—Scarce, and in demand at 23@25c.
R. A. BURNETT, 165 South Water St.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs. 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c; dark 7@8c.
BEESWAX—There is a good demand for beeswax, and arrivals are quickly picked up. Prime lots have sold at 28c., and at the close 30c. is asked. Western, pure, 27@28c.; Southern pure, 28@29c.
D. W. QUINBY, 105 Park Place

CLEVELAND.

HONEY—Comes in very slowly, and is readily sold at 25c. per lb. for 1 lb. sections. No larger sections received yet. Our experience in the honey trade for the past 25 years, teaches that during the whole year there is no better sale for honey than August and September. The demand at this time is greater and prices as high as at any time during the year, especially for comb honey. Extracted probably sells better later. No extracted has thus far been received, but it could be quoted at 10@12c.
BEESWAX—25@28c.
A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—There is more inquiry, and an improvement in bids. Considering the light stocks, considerable has changed hands within the week. Market for extra clear extracted and choice comb is quite firm.
We quote white comb, 16@18c.; dark to good, 8@12c. Extracted, choice to extra white, 9@9½c.; dark and candied, 7@7½c.
BEESWAX—28@30c.
STEARNS & SMITH, 423 Front Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
BEESWAX—Prime quality, 25c.
CROCKER & BLAKE, 57 Chatham Street.

ST. LOUIS.

HONEY—New Texas comb (when the combs are perfect) brings 20@22c. Quote strained at 8@10c.; extracted at 12c. per lb.
BEESWAX—Prime in demand at 24@25c.
R. C. GREER & Co., 117 N. Main Street.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

When changing a postoffice address, mention the *old* as well as the new address.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Emerson Binders.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

TO COLORADO BEE-KEEPERS.

CAUTION.

Having obtained LETTERS PATENT Number 246,099 for Dunham Foundation Machine, making comb foundation with base of cells of natural shape, and side-walls brought up to form an even surface; also on the foundation made on said machine, I hereby give notice to all parties infringing my rights, either by manufacturing said machines or foundation, as well as to all parties purchasing machines as above, other than my manufacture, that I am prepared to protect my rights, and shall prosecute all infringers to the full extent of the law. FRANCES A. DUNHAM, DePere, Wis. 23mt

ELECTROTYPES

Of Engravings used in the Bee Journal for sale at 25 cents per square inch—no single cut sold for less than 50c. THOMAS G. NEWMAN, 925 West Madison Street, Chicago, Ill.

THE BRITISH BEE JOURNAL AND BEE-KEEPER'S ADVISER.

The BRITISH BEE JOURNAL is published monthly, and contains the best practical information for the time being, showing what to do, and when and how to do it. It is edited and published by C. N. ARHOTT, Bee-Master, School of Apiculture, Farlawn, Southall, London. We send the Weekly AMERICAN BEE JOURNAL and the British Bee Journal, both for \$3.50 per annum.

Fruit Evaporators,

To be used on a common cooking stove, capacity 3 to 5 bushels per day. Price, complete, \$10; in the flat, partly put together, for \$8. A few agents wanted. For particulars and prices for Evaporators, Queen Bees, etc., address JOHN H. MARTIN, Hartford, Wash. Co., N. Y. 9smly

Be SURE

To send a postal card for our Illustrated Catalogue of Apianian Supplies before purchasing elsewhere. It contains illustrations and descriptions of everything new and valuable needed in an apiary, at the lowest prices. Italian, Cyprian and Holy Land Queens and Bees. J. C. & H. P. SAYLES, Hartford, Wis. 4sm15t

MY 16-PAGE PRICE LIST of Italian, Cyprian and Holy Land Bees, Queens, Nucleus Colonies and Apianian Supplies, will be sent to all who will send me their name and address on a postal card. H. J. BROWN, Light Street, Col. Co., Pa. 14smft

HIVES AND SECTIONS.

We are in better shape than ever to furnish Bee Hives and Sections, having remodeled our machinery, and put everything in tip-top order for the coming season. We make a specialty of our

“BOSS” ONE-PIECE SECTION.

We have not sold any rights to manufacture, therefore we are the sole manufacturers in the United States. Send for Price List.

JAS. FORNCROOK & CO.

Watertown, Wis., Dec., 1881.

NOTICE—Some persons having infringed upon our Patent “One-Piece Section,” we hereby give notice, that we shall prosecute all manufacturers. We shall not molest bee-keepers for USING those purchased before Dec. 1st, 1881, but hereby caution them against buying any except those bearing our stamp. It has been reported by some that it is our intention only to prosecute beekeepers for using those One-Piece Sections heretofore purchased; this is wholly untrue and false. JAS. FORNCROOK & CO. Watertown, Wis., Dec. 15, 1881. 51mtf

HEADQUARTERS IN THE SOUTH

For the manufacture of BEE-KEEPERS' SUPPLIES. Dunham and Root Foundation a specialty. Italian Queens and Bees from March to November. Send for my Illustrated Catalogue. 5mtf PAUL L. VIALON, Bayou Goula, La.

G. OLM's Comb Foundation Machine.

Send for Sample and Circular. 18mtf C. OLM, Fond du Lac, Wis.

Italian Bees, Queens and Sections.

Untested Queens, in May, \$1.50 each; in June, \$1.25; July and after, \$1; per dozen, after July 1, \$10. Sent by mail, with directions for introducing. Italian bees by the half pound, same price as untested queens. One 2-comb nuclei, without queen (Gallup frames), in May \$3, June \$2.50, July and after \$2; 2-comb nuclei, with the standard Langstroth frames, 25 per cent. more. Sections—Planned dovetailed sections, 4 1/2 x 1 1/4 x 1 3/4, \$4.50 per 1,000; 5 1/2 x 5 1/2 x 1 3/4, \$5 per 1,000. Sections of this thickness do not need tins between them to insure straight combs, and the bees can ripen up and seal honey faster than in combs with deeper cells. See testimonials in March number of *Gleanings*. Please remit by P. O. money order, by registered letter, or by draft on New York or Chicago. Address, O. H. TOWNSEND, Kalamazoo, Kalamazoo Co., Mich. 19mtf

EXCELSIOR

HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have con-sidered to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or method standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and moving sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

Table listing various models of honey extractors with prices, such as 'For 2 American frames, 13x13 inches... \$8.00'.

ALFRED H. NEWMAN, 923 West Madison Street, Chicago, Ill.

HONEY

For the past few years I have made this excellent food my leading article. Having the best established reputation in this city as a dealer in PURE HONEY direct from the Aparies, enables me to obtain the highest market prices. Your consignments and correspondence respectfully solicited.

E. T. FLANNAGAN, Royal Hill Apiary, Belvidere, St. Clair County, Ill. 5wly

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 10 miles of the Apalachicola river; the soil is a rich, sandy loam, covered with timber. It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address.

THOMAS G. NEWMAN,

923 West Madison Street, CHICAGO, ILL.

BINGHAM SMOKERS.

I can sell the above Smokers at MANUFACTURERS' PRICES, by mail or express, at wholesale or retail. All the latest improvements, including the CONQUEROR.

Send for my 32-page Illustrated Catalogue of Bee-keepers' Supplies of every description.

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY, By A. J. COOK,

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculteur*, Paris.

I think Cook's Manual is the best of our American works.—LEWIS T. COLBY.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—J. P. WEST.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—E. H. WYNKOOP.

This book is just what everyone interested in bees ought to have, and which, no one who owns it, will ever regret buying purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—A. E. WENZEL.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—Wm. VAN ANTWERP, M. D.

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

I am credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—L'ABBE DU BOIS, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Palaski, N. Y.

We have perused with great pleasure this *vade mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, \$1.25; in paper cover, \$1.00, by mail prepaid. Published by

THOMAS G. NEWMAN, West Madison Street, CHICAGO, ILL.

"RED TAPE!"

Who will be the first to copy?
25,000 IN USE.

If you buy the Original Patent Bingham Bee Smoker, you will find the inventor of improved bee smokers—get the best, that never go out—always please—never is complained of—the standard of excellence the world over—better and handsomer this season than ever before. Price per mail, postpaid, from 65 cts. to \$2. Our patents cover all the smokers that will burn sound stove-wood, or do not go out. If you buy our smokers and honey knives first, you will have to buy no others.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as *Carcharodon Rondelleti*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better. I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by THOMAS C. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiculture. Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quincy's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Biene Kultur, by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Bzierzon Theory—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Poam, Wines, etc.; and Honey as Medicine with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman—giving advanced views on this important subject, with suggestions what to plant, and when and how: 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Latest Prospects for Honey.

Districts where but a short time since only discouragement and doubt prevailed, are now beginning to assume a cheerful aspect. Kentucky, perhaps, started out early in the season with the brightest prospects of any State, but an abrupt change in the wind-current, followed by snow, frost and cold rains, soon destroyed all hopes of an immense spring yield, but left the bees generally with sufficient stores for summer consumption, and since that time colonies which were previously strong have been but self-sustaining. A few weeks ago Mr. John C. Peden, of Lawrenceburg, that State, wrote very discouragingly. Now, however, he writes that bees are working "on both red and white clover, and that in comparison with the past they are like a tornado. Sections that have been on the hives for six weeks, in a half-finished condition, are being finished up, and new ones started in a way that is real encouraging." With Kentucky's notoriety for fall flowers—asters, etc.—we anticipate there will yet be a good yield in that State. Last season the bulk of their crop, if we remember rightly, was obtained in September, October and November, after all hopes of a surplus had been abandoned.

From New York, Mr. G. M. Doolittle supplements his former gloomy notes, with a postal dated July 29: "The past three days have been splendid for bees. The combs which showed nearly starvation for the bees a few days ago, are now glistening with honey, and enough has been already stored for a winter supply. A few have

commenced work in the boxes.... Am thankful for the winter supply already obtained." Mr. G. T. Wheeler, of Mexico, in the same State, writes under the same date: "Blossoms commenced to open, accompanied with honey weather, and the bees work as though they expect to make up for lost time. I expect to hear that Doolittle's bees have stored bass-wood honey by the ton the past week." From the other backward districts of New York we expect to hear equally as good reports, with the addition, perhaps, of cheering prospects for a heavy fall yield. Should fall frosts be tardy in coming, New York, we think, will generally report very large fall yields.

In the district in Iowa where prospects were least encouraging, a complete revulsion has taken place, and the yield is almost without a parallel. Mr. William Malone, Oakley, Iowa, in a letter of July 27th, says: "after waiting and feeding so long, the honey wave struck us July 10th, and I never saw such a heavy yield as from that time until the present." Mr. Malone hived a swarm July 15, in a 2-story Langstroth hive, with 20 frames of foundation. In 8 days he extracted 40 pounds of honey from the second story, and the lower one was full.

The latest advices from Messrs. Dandant & Son, at Hamilton, Ill., in the Mississippi Valley, report the "bees still booming." In that district last season the honey harvest was very light, owing to the drought, and the above parties were obliged to adopt the migratory system with their colonies to reach honey bloom. Mr. J. Lee Anderson, at Lawrence, McHenry County, Ill., Aug. 4, says: "We are having the largest honey crop this section ever witnessed. A second crop of white clover is coming on where one has been cut off for hay. The in-

crease of swarms is over one hundred per cent."

In our own neighborhood the late swarming is unparalleled. Frequent rains, with a hot, humid atmosphere, have encouraged honey secretions, and, although the bees can only work at intervals, it is wonderful to contemplate the honey they gather. Should frosts be tardy in their appearance, the asters, goldenrods, Spanish needles, heartsease, bergamot, and other honey-producing flora will be most abundant; and the excessive breeding yet being kept up, will give ample opportunity to gather fall honey for winter stores, besides a liberal surplus for market. White clover at this writing (Aug. 5) is yet as plentiful as ever, but deserted for the magnificent sweet clover (*Melilotus alba*).

Yet, with the prospective liberal production of honey this season, beekeepers need borrow no anxiety about prices. In Europe the crop promises to be very light, while in California there will be comparatively none for export. Agents of European and Eastern houses have found it impossible to have their orders filled there, for a strictly first-class article, and will have to look to the Eastern markets and those of the Central States to supply the demands of trade, while the foreign consumers will be obliged to draw on the Atlantic, instead of the Pacific Coast. Beeswax is already ranging at fabulously high figures, and we now believe will never decline to its former quotations. We therefore advise all to put up their honey in first-class marketable shape, properly grading it, and to make no sacrificial sales in order to effect an early disposal.

Increasing Popularity of Cook's Manual.—So rapid has been the increasing popularity of "Cook's Manual of the Apiary," that we have recently been obliged to issue another edition, making 9,000 published to date. Apiarists have been particularly fortunate in the high order of talent devoted to the preparation of text-books, but "Cook's Manual" has rapidly taken the front position, and the Professor's scientific and practical education will enable him easily to keep his excellent book in the advance, as the frequency of the editions give him opportunity to anticipate the progressive steps.

Articles for publication must be written on a separate piece of paper from items of business.

Bee-Keeping in Our University.

We cannot now recall the name of a solitary apicultural writer of prominence, whom we would prefer to have criticised the editorial matter or general management of the *AMERICAN BEE JOURNAL*, than Mr. James Heddon or Rev. Wm. F. Clarke. Both are independent in their opinions, ingenuous in their expressions, and candid to admit it when convinced of error. On pages 501 and 503 of this number, they have reviewed the editorial which appeared on the first page of our paper of July 26th, and to save space we will answer both articles with one.

First, without wishing to rob Mr. Clarke of his introductory consolation, we must insist he is no "peacemaker;" as between Mr. Heddon and ourself there is no dispute—perhaps scarcely a controversy—and we believe not a difference of opinion regarding apiculture in our University, when that gentleman has maturely considered the subject.

Mr. Heddon has partly understood our position, and so far agrees with us: but in order more fully to explain we must review his several propositions in order. If we must have theories, then, of course, we want *correct* theories: but less of theories and more of *scientific facts*—sound, hard, solid facts—are what we need, and so long as each must grope along in the theoretical wilderness, with but the glimmering hand-lamp of a half-obsolete theory to guide him in his search, he may pass and re-pass the scientific truth, and not be able to recognize it. Nor do we think that by practice alone—real bread-and-butter practice—will we be able to "separate the correct from the incorrect," except upon scientific principles; therefore, we would have a practical apiary in connection with the University, where science can test and demonstrate all the abstruse facts which go to make successes and failures in bee-keeping. We would have the apiary self-sustaining if possible, but certainly its continuance should not be dependent alone upon the amount of revenue, *i. e.*, "food and clothing" it earned. Nor would it be a generous valuation to expect the scientific knowledge gained to be equal to the capital required to "stock an area of one apiary's flight."

It certainly would be no detriment to the graduated student to spend a season in some practical apiary, run upon scientific principles, even though

"the necessity for dollars and cents" was its corner-stone, and every comb of honey represented a feast for a famishing family. Even the backwoodsman with his rimless hat, and shirt-sleeves and breeches serrated at the elbows and knees, found it a long fast watching for the exit of a woodchuck from the stone-heap in which there was none; and still there was no other meat in the house. Necessity may be a stimulous, but is not the guaranty of success. It is not the practical laborer whose family eke out a subsistence on the fruits of his toil, that does most in webbing our country with railroads, but the engineer who plans his work; to the men who drive the nails and place the bricks we are not most indebted for our wonderful factories and magnificent houses, but the science-cultured brain that tells them where to drive the nails and how to place the bricks. And so with all successful professions and labor. The practical labor is necessary to completion; but the scientific preparation is necessary for conception and oversight or direction.

If the University education will polish and enlarge the talents for bee-keeping, the practical will quite rapidly follow the acquisition of the science. Tact, as commonly applied, is but a make-shift for the present, while talent insures a success in the future, and perhaps after the emulative strife between the apiarist who runs with tact as his sole guide and he who has talent for his support, it will be found that the latter's five colonies, at the end of a series of years, have netted more profit than tact's initial fifteen colonies.

With Mr. Heddon's fourth paragraph we cordially agree in the main; but to his fifth we must take exceptions, and will answer his closing question, Yankee style, by asking another: Were you employing a superintendent for your extensive apiary for a series of years, and the choice was offered you between a graduate of the Michigan Agricultural College with a view to making apiculture a specialty, and one who had received a year's practical experience in some extensive apiary where tact was the system adopted and bread-and-butter the motive, which would *you* employ, all other things being equal? Would you not expect to devote as much time to weeding out pernicious theories, inculcating wholesome precepts, and creating proper conceptions, with the

latter, as would make the former his superior? Let us make the question more abrupt: How many thoroughly practical apiarists, in the United States, have you in your mind's eye that you consider competent to impart a practical education, even in two or three years, that will insure success, unless science be combined with it? We cannot now recall even one successful apiarist, much of whose time has not for many long years been occupied in acquiring a scientific education, and whose every progress in science has not been dearly bought with a reverse—and why? Because the dollars-and-cents standard of the apiary allowed of no interruption in its practical working to investigate scientific problems, until dire necessity forced the solution on the apiarist, and it became a matter of choice between obviating and ruin.

Mr. Clarke eloquently enlogizes Prof. Cook, and we believe he reverences him as a scientist and respects him as a man, yet we think he does him great injustice with his doubt. That the Professor has never felt called upon to abandon an eminent position, where the benefits derived from his instructions cannot be estimated by dollars and cents, to demonstrate that he is eminently practical, should give rise to no doubt of his ability. But were it so, then how necessary that we should have a Professor of Apiculture, to whom we can look for the scientific facts in connection with our favorite pursuit, knowing that no one in our ranks is comprehensive enough to demonstrate all its branches.

Mr. Clarke agrees with Mr. Heddon, and we agree with Mr. Clarke, and have often so stated, that in the future much of the honey of commerce will be produced by specialists. If we are right in our surmise, then how necessary that every facility be afforded to acquire the fullest preparatory education. What argument can be adduced to promote education in the natural sciences, that will not apply with equal force to apiculture in our universities? Where is the State or community that would not receive its proportion of benefit, through an increase in revenue, if this were one of the higher branches taught? The future history of bee-keeping would not show so many vacant places, caused by the dropping out of those who had placed reliance upon their fancied practical skill, and whose con-

fidence advanced them beyond their scientific attainments.

We raise no objection to the establishment of a practical apiary, provided it be under the jurisdiction of the Professor, for it is as absolutely necessary he should have the best facilities for solving his problems and demonstrating their solution, as that the chemist have his crucibles, the astronomer his charts, and the engineer his compasses.

Death of Mr. A. F. Moon.

We learn with regret that Mr. A. F. Moon, of Rome, Ga., died at his home, at 4 a.m., on Wednesday, Aug. 2, 1882, aged 58 years.

Some of our readers will remember that Mr. Moon wrote us a private letter, dated Jan. 16, 1881, concerning his misfortunes, and feeling assured that bee-keepers everywhere deeply sympathized with him, we published a portion of it on Feb. 9, 1881, as follows:

The past has been a most unfortunate season with me. I have received no honey, and had no queens or bees to sell, and have not been able to transact any business, on account of my lameness, which ended in the loss of my limb. In fact, I was compelled to go on crutches all the season. I am somewhat better now, but have not been to our postoffice since the 11th of last May, which is only 2 blocks from me. This, you know, is hard for a man accustomed to walking and stirring around. The Weekly came in to-day's mail, which just fills the bill; it is just what all bee-keepers want—a Weekly BEE JOURNAL. Long may it live, with success to its editor.

For several weeks it was known that the amputation of the entire leg would be necessary, and this was finally submitted to as a dernier resort to save life, on Tuesday Aug. 1, 1882, but, alas, he died the very next day.

Mr. Moon obtained his two first colonies of bees in 1834, when he was 11 years of age, by hiring out to get the means to purchase them: he kept bees continually up to the day of his demise—always keeping abreast of the times, by giving the fullest energies of his active mind to progressive, practical and scientific bee-culture: he was a specialist, and at home in every department of apiculture.

He helped to organize the "Michigan Bee-keepers' Association," was one of its first executive committee, and became its second President. At the meeting which organized the "North American Bee-keepers' Society," he was elected Chairman, and though the Rev. L. L. Langstroth was

elected its first President, being absent, Mr. Moon presided over the first National Convention, in 1870.

In 1873, he moved to Georgia, and at Rome edited and published *Moon's Bee World* for three years, when it was suspended and its subscriptions unfilled, were supplied by the AMERICAN BEE JOURNAL.

Since then his health has been declining, and mortality has been struggling for the mastery. About a year ago he commenced an article for the BEE JOURNAL in these words:

"Time, with his sickle, is mowing the days and hours. Seasons come and go; days and months, like the seasons, succeed each other. Summer, with all the joyous anticipations that could be produced by the warm and genial rays of the sun and change of the season, will soon give place to autumn, and this to cold, bleak winter."

At least "the winter of death" has come to him. His later articles were written while he was suffering great pain of body, but now that is all over—mortality has triumphed and our friend has been laid low by "the all devouring scythe of time." His busy life is ended, and his race is run! All that is left to us now is to draw "the mantle of charity" over his short comings, emulate his earnestness and zeal, and when we, too, are called upon to pass through "the valley of the shadow of death," let us hope to be as peaceful and confiding as he!

The National Convention.

We have received from Prof. Cook the following circular relating to the above convention. We greatly regret we shall not be able to attend, but circumstances beyond our control will make our absence imperative. We regret it more especially, as this will be a most interesting meeting, and those who can attend will be more than repaid the expense and loss of time:

The next meeting of the National Bee-keepers' Association promises to be a grand success. Such men as D. A. Jones, A. I. Root, James Heddon, O. O. Poppleton and Dr. J. P. H. Brown have promised attendance.

It is expected that the Association will visit in a body, the apiary of Mr. Hill, of Mount Pleasant, which is one of the best conducted in the States.

Mr. D. A. Jones will exhibit specimens of the bees of the Indies, including the famous *Apis dorsata*.

There will also be exhibited at each intermission, microscopic preparations, showing structure of the sting, mouth-parts, etc., and of the so-called dry feces of bees.

Let some bee-keeper of each leading city look after railroad rates. It will be the last week of the great Cincinnati Exposition. This is a great attraction, and will make it easy to secure reduced rates. Round trip tickets from Detroit are promised for \$5.
A. J. COOK, *President.*

Rev. L. L. Langstroth.—We have received the following letter from Mr. Langstroth, which we know will be read with more than usual interest by the thousands of apiarists who have a tender regard for him, and wish him health for years yet to come.

Oxford, Ohio, July 26, 1882:

My health for the last few months has considerably improved, but not enough to permit me to resume my pen with any freedom. In the 45 years since I began to keep bees I have never known so poor a season for honey. The strongest colonies of some of our largest bee-keepers have not a cell of sealed honey, and only a few days supply on hand, and yet the bloom of white clover has been and still is unusually good, and the weather apparently all that could be desired.

Very truly your friend,

L. L. LANGSTROTH.

Oxford, July 26, 1882.

The American Express Company money order system is the cheapest, safest and most convenient way of remitting small sums of money. Their rates for \$1 to \$5 are 5 cents; over \$5 to \$10, 8 cents. They can be purchased at any point where the company have an office, except Canada, and can be made payable at any one of the company's 4,000 offices.

Paid orders are filed in the Treasurer's office, and always accessible for reference, and the remitter gets a receipt for money sent.

For safety, when sending money to this office, all should get either a post office or express money order.

One of our exchanges says: The *Montreal Witness* has been to the expense of getting a special telegram from Toronto which says: "A young lady at Riverside Suburb has been severely injured about the face and neck by bees which were attracted by the profuse trimmings of artificial flowers on her hat." The Canadians who will believe that will believe anything.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

MISCELLANEOUS.

Bee Pasturage.—The *Indiana Farmer* has this to say about providing pasturage for bees:

The necessity for providing pasturage for the bees is becoming more apparent each season. As the land becomes better tilled, many of our best honey producing plants become extinct. There are many plants that yield immense quantities of honey, and by studying the habits and time of blooming, will give us an idea of what to plant to keep up a rotation of blossoms, so that there need be no total cessation of the honey flow from early spring to frost. Our roads and by-ways are lined with worthless weeds, but with a little care they may be filled with honey producing plants. Sweet clover, catnip, mother-wort, borage, boneset and figwort, are all good honey plants, and bloom from the first of July to frost. Whether it will pay to crop for honey as is now done for butter or milk, we are not as yet certain, but the question is being thoroughly discussed, and will lead to positive facts in the near future. Many acres of honey plants have been sown in the last two years, and we hope to have some reports of practical tests before long. A friend of ours has a couple of acres sown to several kinds of mints, and he is very enthusiastic over the result. He gave us a sample of a very aromatic flavor and fine in appearance, and says also his entire crop of last year was flavored with the mint, giving much satisfaction to his customers, many of whom preferred it to the clear white clover honey.

Bees Fertilizing the Clovers.—The *Farmer and Manufacturer* for August gives the following item on this subject:

Darwin's researches have proved the action of bees in fertilization of flowers. Every farmer who grows red clover for the seed sake is too familiar with the uncertainty of this crop, the seeds of which ripen with most vexatious inequality. Herr Haberlandt, who has followed up and confirmed the researches of Darwin in reference to these particular flowers, strongly recommends the rearing of bees on all clover farms for the special purpose of fertilization, even though their honey be disregarded, for it appears that clover is entirely dependent on insects for its fertilization, and chiefly on bees. The form of the flowers and the manner in which the maturity of the lower florets precedes that of the upper florets, renders the success or failure of a clover-seed crop simply a result of the employment or non-employment of these humble farm laborers.

Breeding the Best Queens.—The *Grange Bulletin* gives its views on this subject in the following language:

We deem it a very great mistake to suppose that the queen that can lay the greatest number of eggs in a given time is therefore a desirable queen; but it a queen bee is capable of laying 500,000 eggs in a life time, shall we have them laid in two or four years? We should prefer their being laid during the longer period. All such questions should be well studied and properly digested by the apiarist as well as giving a strict adherence to natural laws governing the bees. When we look into the laws that govern the production of animal life, we find that one law obtains from man down through all the grades of lower animal life, viz., "The animal after his kind." While climate and surroundings have their influence, man is still man, whether barbarous or enlightened, and his domestic animals when bred with any special peculiarity or trait in view, have developed the traits desired, while there are many desirable traits in our present strain of Italian bees that should be fostered in breeding. Queen breeding is a mechanical art, and should be better understood by those who make such loud professions and furnish too many cheap and worthless queens for the unsophisticated novice, who too often meets disaster and loss for want of a better knowledge of the true principles that should govern all business connected with successful and practical apiculture. Avoid all queens reared in small nuclei or weak colonies.

Still Breeding.—The *Indiana Farmer* gives its views of the prospect of the remainder of the season for bees, and their condition for winter, thus:

Usually there is a dearth of honey-producing flora from the middle of July to the latter part of August. But the copious rains of early summer, and cool nights have retarded the growth of white clover, and induced the growth of fall flowers to such an extent, that the bees are still finding work to do. Weak colonies and nuclei are breeding very fast with a prospect of going into winter quarters in good condition.

The Difference.—From an exchange we glean the following amusing paragraph:

When an old-fashioned merchant in New Jersey came to look over an order made out by his new-fashioned clerk, the other day, he looked up over his spectacles, and said, "James, I see you have spelled shugar without an 'h.'" "Yes, sir, that's the proper way." "But I have spelled it with an 'h' for the last twenty-nine years." "Can't help that, sir. Sugar should not be spelled with an 'h.'" "Well, mebbe it shouldn't," sighed the old man, "mebbe it shouldn't. I presume that this mixing in glucose does make a difference somewhere."

CORRESPONDENCE

For the American Bee Journal.

Theoretical Bee-Culture.

JAMES HEDDON.

I think I can accord with the BEE JOURNAL in regard to the value of theory. The editorial on the first page for July 26th, contains about the facts in the case. We want theories—correct theories—and the only way that I know of to separate the correct from the incorrect, is by practice. If you mean that the apicultural part of the University shall teach the theories of bee-culture only, I am exactly in accord with your ideas; but if there is to be a small theoretical apiary connected with the University—one that has no food and clothing anxiously looking and longing for, and depending on its success, and this arrangement, together with its scientific, theoretical teacher, is expected to turn out pupils that shall be practically equal to the amount of capital it will require to stock an area of one apiary's flight—here is where we differ still.

Every graduate from this University will need to serve an apprenticeship in some apiary run to the necessity of dollars and cents. I have more faith in the capture of the woodchuck when "you've got to get him, there is no other meat in the house."

This University apicultural education will polish and enlarge one's talents, but polished talent so often fails where practical tact succeeds, that the bystanders all wonder. To be sure, talent attracts admiration, but tact commands respect. Talent's 5 pounds of honey is not worth as much as tact's 15 pounds—not to eat—only in some minds.

This theoretical education is a grand step towards fitting one's self for a practical one to follow it; but this latter education will hardly be obtained at any school, with or without an apiary attachment, and any attempts made in that direction will, I think, be abortive.

Please place before your mind's eye two young men, one just from our Michigan State Agricultural College, the other from a year's practice at work in a large honey-producing apiary—both just starting for themselves with 50 or 100 colonies—which would you expect to succeed best?

Tact, or the right way of doing the right thing, is catelting, and to be caught one must come in contact with those who have that practical complaint. To the teaching of any correct theory, all hail; but I hope I am not to understand this schooling to stand for a competency? I think I do not understand you so, and this argument is only made to show why I wrote as I did in the BEE JOURNAL of July 26th, when I understood that the school was expected to turn out scholars for the successful proprietors of apiaries.

Dowagiac, Mich.

For the American Bee Journal.

St. Joseph, Mo., Inter-State Exposition.

R. S. MUSSER.

The following is the premium list of the Apiarian Department of the Inter-State Exposition to be held at St. Joseph, Mo., on Sept. 4 to 9, 1882, of which Mr. D. G. Parker has been appointed superintendent:

PREMIUMS.

Display of Italian bees, 1st prem., \$5; 2d prem., \$3.

Display of black bees, \$2; \$1:

Display of queen bees, \$3.

Display of imported queen bees, \$5.

Display of beekeeper's tools, implements and fixtures. Only dealers in these articles can make this entry, \$15.

Best and largest display of honey in comb, \$10; \$5.

Best and largest display of extracted honey, not less than 25 lbs, \$5; \$3:

Largest assortment of seeds for honey plants, \$2.

Exhibition of a colony of bees in hive, including their handling and best method of subjugation to be practically illustrated on Friday, Sept. 5, 1882, \$5.

Honey extractor, \$2.

Honey knife, diploma.

Bee smoker, diploma.

Atomizer, diploma.

Bee feeders, diploma.

Comb foundation, diploma.

Felt blankets, for covering brood frames, diploma.

Bee veils, diploma.

Gloves, rubber gauntlets, diploma.

Sections all in one piece, diploma.

Sections, dovetailed, diploma.

Wax extractor, diploma.

SWEEPSTAKES.

Best display of honey, \$25. Exhibitors competing for sweepstake premium will not be permitted to enter same honey for other premiums.

For largest and best display of comb honey and in the best marketable condition, \$25. The honey entered for this premium must be from the apiary of the exhibitor, and must not be entered in any other class.

SPECIAL PREMIUMS.

By O. A. Sandusky, St. Joseph, Mo., for the best display of comb honey, in 1 or 2 lb boxes, \$5.

Also, for the best crock or firkin, not less than 20 lbs, \$5.

The Secretary is authorized by Hon. Jas. N. Burnes to purchase and pay for 20 lbs of premium honey, awarded a lady resident of any other State than Missouri, \$20.

The Secretary is authorized by Hon. Jas. N. Burnes to purchase and pay for 30 lbs of first premium honey, awarded a Missouri lady, \$30.

Gen. James Craig, of St. Joseph, Mo., will purchase and pay for the best 30 lbs of comb honey, exhibited in 1 or 2 lb boxes, \$15.

These premiums, amounting to \$191, are very liberal—more so than any other association has offered. A large number of persons have commenced the "bee business" since our last exhibition, and the display will, no doubt, be large, notwithstanding the

honey season has been anything but satisfactory so far. It has been too wet and cold, giving but little honey from white clover. If it continues as warm for the next two weeks as it is at present, we can rely on a good display of comb honey at our exposition. So far, only those who fed their bees in the months of March and April have taken off any surplus honey.

I am satisfied that the only way to manage an apiary in the early spring, is to feed the bees three table spoonfuls of pure sugar in a saucer filled with water every morning. It should be placed where the bees can reach it without being exposed; this will insure a populous colony ready to go to work when the honey season opens. It makes no difference how much honey the bees have on hand; this plan will pay.

St. Joseph, Mo., July 27, 1882.

For the American Bee Journal

Bee Notes from Mississippi.

OSCAR F. BLEDSOE.

The season this far in this locality has been encouraging for bee-culture. It is being fully demonstrated to me, that an apiary well managed will pay well here. I have sold a quantity of honey in this town in the 1 lb. section, though heretofore honey has been very slow sale as brought in from the country in buckets, etc. The 1 lb. section, with a beautiful comb of honey in it, seems to be irresistible. I have on now 2,000 of them that will soon be full. As to the increase of bees, there seems to be no limit to possibilities in that direction. I commenced the season with 45 colonies; lost about 15 swarms from not having queens' wings clipped, and now have 130. My trouble has been too much swarming; I checked it all I could. Many of my hives were too small. Severe experience has taught me to clip the wings, or one wing, of every queen, and to prepare large roomy hives and plenty of them before swarming season commences. It takes about 4,900 cubic inches inside measure for a powerful colony of pure Italian bees in this locality, and then the surplus has to be depleted regularly during honey flow.

I am now supplying all hybrid and black colonies with pure Italian queens. I rear my queens thus: Take 2 or 3 frames, with bright comb, and place them in the colony you breed from, so that they can be easily gotten at and removed. Look at them every morning. As soon as the queen gets on one of the combs she will till both sides with eggs as far as honey will allow her. When you have eggs, remove the comb. You now have eggs laid within 24 hours. Take one or two frames and nail two pieces across inside parallel with the top-bar, and at distances of about 3 inches. Cut the comb into strips about $\frac{1}{2}$ inch wide and shave off one side of the strips nearly down to the eggs or foundation. Dip the side shaved off in wax barely melted, and quickly fasten to the underside of the top bar and the two cross-pieces; take a small spoon and

run some wax alongside of the strips so as to hold them still better. You now have frames with eggs not over 24 hours old, and the cells pointing downward. There is a charm and fascination to the bees in having the cells point down instead of being horizontal. It seems to conform to their idea of how eggs out of which queens are to be made should be placed. They illustrate this instinct in the fact that when they are filling a hive with comb they will build nice tender queen cells here and there in irregular and roomy places where they can conveniently point them down, though they have not the slightest swarming impulse at the time. After awhile when the impulse comes, the queen sharing it lays eggs in three cells, and the young queens are developed.

Having the frames with strips of eggs, go to a vigorous colony—one with enough bees and energy to be building comb, and occupying at least 1,400 cubic inches of space. Remove the queen and all combs having brood except two. The brood combs left should have unsealed brood and pollen, and as few eggs as possible, also let the combs left be black and tough. Place your frames with strips between the two brood combs, fill any vacant places with empty combs, close the hive, and you have conformed perfectly to the requirements of nature in your endeavor to produce the finest queens. The reason I leave the brood combs, is that I do not know but that bees use the young larvæ in making the royal jelly, and if they had only eggs the queens might be dwarfed on this account. Let me ask older beekeepers, do bees use young larvæ in making royal jelly? There is little danger of the bees making queen cells in the two brood combs, the cells being horizontal and tough. Open the hive between the 2d and 3d days, and remove any larvæ in cells started in the brood combs. The bees will remove the royal jelly to the cells on the strips. By this method you will rear large, long queen cells, and plenty of them, in beautiful rows easily removed. With a sharp knife I cut underneath the cells close to the wood, taking a portion of wax that is very convenient to hold the cells when you put them between the frames in the nuclei to which you introduce them. You can remove the cells on the evening of the 11th and morning of 12th days. Say you put in eggs July 3d, remove the cells during the 13th and morning of the 14th. I believe by the above method as good queens can be reared as bees are capable of rearing, notwithstanding the wise conservatism of Mr. Doolittle, who insists that Dame Nature cannot be equalled in that particular branch, though he is very bold to improve upon and assist her in many other departments.

As to negroes being bee-keepers, I will say, according to my life-long observation they have no taste for bee-culture, though many are well situated to engage in it. They love honey as fondly as a bear, but seem to be wanting in the capacity for that intellectual exertion necessary to under-

stand and practice advanced or true bee-culture. *Ex nihilo nihil fit.*

I forgot to say in connection with rearing queens, that I believe the dollar queen traffic has done great good. It is as easy to rear a fine queen as a poor one, and competition makes it to the interest of every queen-breeder to rear the best and satisfy his customers. What is the difference to me between a fine warranted dollar queen from Mr. Alley or Hayhurst, and a tested one? It is merely a difference of time, for they would be bound to make it good if the queen did not produce all three banded workers. Let the dollar queen traffic continue through the omnipresent U. S. Mail, and disseminate Italian and Cyprian blood wherever bees are kept. I am glad to see the Lone Star State has excelled any yield hitherto reported from a single hive. Evidence from all quarters shows that much can be done at bee-culture in the South by the application of intelligence to the industry.

Grenada, Miss.

Translated by A. Neighbour.

Winter Temperature Required by Bees.

DR. DZIERZON.

In the hot climate of Syria, Ethiopia, and Brazil bees do not suffer harm from the heat; and while in our country they keep perfectly well in a hot summer and mild autumn, they are supposed to perish during a cold winter from excessive heat. Who can comprehend these contradictions? In two cases only is this conceivable. First, if the whole atmosphere is heated to such a degree as almost to melt the wax, causing the combs to break, which is reported to be the case in the neighborhood of Aden in the Red Sea; and second, if a large colony get excited while the entrance is closed. In such an event the heat in a short space of time may become so great as to cause the combs to break. Many of the colonies sent to the exhibitions at Cologne, Erfurt, and Potsdam, with large population and abundant honey, but meeting with an accident on the way, arrived in this condition. I may also refer to the case of a bee-keeper who, in order to keep back a swarm which was on the point of issuing simultaneously with another swarm, quickly closed the entrance of the hive, and shortly after found the bees suffocated and the wax in a melting state.

But I deny that a colony of bees can be ruined or injured by excessive heat when the entrance is open, and I consider it to be quite impossible. For if the temperature in the hive should have been raised somewhat high, as it might be during a necessary removal of the hives, a portion of the bees rush out of the entrance as soon as open—a number of bees, which return immediately, and by setting up a terrific hum expel the excessively hot and foul air from the hive, which in a short time re-establishes quietness among the bees. But if quick fanning should prove of no avail, because the air that rushes into the hive is just as

hot as the air which is driven out, the bees may be seen to hang out, which we frequently have an opportunity of observing on sultry days in the summer. In winter even we may happen to see bees hanging out if the colonies have a large population and are kept in rather a warm place. When my apiary, containing sixty colonies and many empty hives, was completely destroyed by fire in 1846, I had an opportunity of observing the behavior of the bees during the heat which human beings were unable to endure. The hotter it grew the larger the number of bees became which hung out, but otherwise they remained perfectly quiet until they were finally seized by the flames and consumed. Thus the bees know how to shift for themselves even during an unbearably great heat, as long as relief is possible. If, however, Dr. Krasicki wants to make us believe they suffer and perish from excess of heat in winter while the entrance of the hive is open, they would be the most stupid creatures on earth. Dr. Krasicki surely will not be able to plead that the cold does not permit the bees to move to the entrance of the hive to establish ventilation, as excess of heat and excess of cold, or the absence of heat, are contradictory terms, the one excluding the other.

But does not Dr. Krasicki produce arguments and evidence in favor of his peculiar opinion—that bees, like Polar bears, can stand cold better than heat; at least, better during repose in winter, and that they are more likely to perish from the latter than from the former? He certainly states his reasons, but they are such as you might expect to hear. They become valueless if examined closely. He relates how a colony in a log hive, the door of which had given away, survived extremely cold weather, and how another community existed for several years in a hollow tree with a large opening through which the bees entered. But what is there particularly remarkable in this, and what does it prove? I myself have had similar experience, of which I have given an account on various occasions. Let us consider the bees retired into the very centre of the structure of combs, the latter being covered with hoar frost, and the passages between the combs, so to speak, filled up with feathers, or we may consider the cluster of bees wrapped up as in a feather bed. As long as the bees keep close to the honey they are able to brave the most severe cold, no matter whether the hive be closed or open. An open door or a good size entrance is a real advantage to bees, because the vital air (oxygen) cannot so easily become exhausted as when the door is tightly closed or when there is only a small entrance, closed, perhaps, with ice.

In the winter of 1845 I had an opportunity of noticing the appearance of the interior of hives after being exposed to extremely cold temperature for a considerable time. A truly Siberian winter continued without interruption from the beginning of February till Easter. I had many of my colonies in wooden boxes, and even those in heavy log hives taken

into my warm room when the bees were on the point of perishing, in order to save as many as I could. But what a sight it was whenever I opened a hive!

In Germany, indeed, we can only desire such a mild temperature for our favorites, but we cannot create it. In the struggle for existence the bees will always have to battle against their greatest foe, the cold. It will remain our business to protect them against this enemy as much as we possibly can for the well-being of the bees and in our own interest, for the more honey is saved by the protection afforded the larger will be the quantity which we can harvest.

For the American Bee Journal.

Bee Department of the Tri-State Fair.

DR. A. B. MASON.

The following is the apiarian part of the Premium List of the Tri-State Fair Association, which holds a fair here (Toledo, O.) every fall. The fair begins Sept. 4th, and holds till the 16th. Entries can be made so that the exhibits can begin on the 4th, and they may be made till six o'clock p.m., Sept. 12th. There will be no charge for entries in this department:

PREMIUMS.

Comb honey in most marketable shape, not less than 20 lbs., 1st. \$4; 2d, \$2.

Extracted honey in most marketable shape, not less than 20 lbs., \$4; \$2.

Crate comb honey in most marketable shape, \$4; \$2.

Display comb honey in most marketable shape, product of one apiary during 1882, \$5; \$3.

Display extracted honey in most marketable shape, product of one apiary during 1882, \$5; \$3.

Display apiarian supplies, \$5; \$3.

Display bees wax, \$2; \$1.

Display, Italian, Cyprian, or Syrian queens, \$3; \$2.

Colony Italian, Cyprian or Syrian bees, including its public manipulation, \$5; \$3.

Apparatus for making comb foundation to include everything necessary for its manufacture, \$8; \$5.

Comb foundation, mill or press, \$4; \$2.

Honey extractor, \$2; \$1.

Bee hive for all purposes in the apiary, \$2; \$1.

Bee hive, glass or exhibition, \$2; \$1.

Honey vinegar not less than one gallon, \$2; \$1.

Best wax extractor, 1st prem., Weekly BEE JOURNAL 1 year; 2d prem., *Gleanings in Bee Culture* 1 year.

Best winter and summer bee hive combined, 1st prem., Weekly BEE JOURNAL 1 year; 2d prem., *Gleanings in Bee Culture* 1 year.

Best comb foundation for brood chamber not less than 5 lbs., 1st prem., Weekly BEE JOURNAL 1 year; 2d prem., *Gleanings in Bee Culture* 1 year.

Best comb foundation for surplus honey, not less than 3 lbs., 1st prem., *Cook's Manual of the Apiary*; 2d prem., *Gleanings in Bee Culture* 1 year.

Best display of comb foundation, 1st prem., Weekly BEE JOURNAL 1 year; 2d prem., *A. B. C. in Bee Culture*.

Best one piece section, not less than 50 sections, 1st prem., *Gleanings in Bee Culture* 1 year; 2d prem., *Bee-Keeper's Instructor* 1 year.

Best dovetailed section, not less than 50 sections, *Bees and Honey*.

Best packages for extracted honey with labels, *Bee Keeper's Instructor* 1 year.

Best bee smoker, *Bee Keeper's Instructor* 1 year.

Best honey knife, *Bees and Honey*.

Webster Thomas & Sons, Somerset, Ky., publishers of the *Bee Keeper's Instructor*, offer a pure tested Italian queen as a special premium for the best comb honey in the most marketable shape, not less than 20 pounds.

The Association offers a Traffic Department this year as an experiment, "the special object of which is to enable all who arrange an exhibit to introduce all meritorious products in their line into immediate and general consumption, not only making the week (or two weeks) one of sight-seeing and recreation, but profit to both exhibitor and visitor." The special features of the first week will be a competitive military drill, etc.

Any exhibitor having honey or apiarian supplies in any quantity to sell, can for a reasonable rent, offer for direct sale on the grounds, all manufactured wares of merit, or take orders for future delivery, under such rules and regulations as will guarantee square dealing, and protect both buyer and seller.

I am not financially interested in the Fair Association, but am very anxious that the bee-keeping fraternity shall make a creditable exhibit, not only of articles entered for premiums, but also of every article used in our specialty, in large quantities for sale on the grounds. Let all who intend to exhibit, and those intending to enter the Traffic Department, make early application, so that ample room, etc., may be provided. From five to ten cents will take a person by street-cars, from any depot in the city to within a short distance of the fair grounds.

Every bee-keeper, but one, that I have consulted, is desirous of organizing a Tri-State Bee Keepers' Association during the fair, to hold its meetings annually during the fair, and it is suggested that the meeting for organizing be held on the fair grounds Wednesday afternoon, Sept. 13th, and then hold one or more sessions each day or evening during the week. We hope to induce the Editor of the AMERICAN BEE JOURNAL; the Editor of *Gleanings*; Prof. Cook and other well-known apiarists to be present and aid in organizing such an association, and give us lectures on our specialty during the fair, and we hope to make the occasion so interesting and profitable that bee-keepers will find it to their advantage to be present.

Reduced rates for passengers and freight have been secured on all railroads coming here; any information in regard to which, with rules and regulations, and entry blanks of

the fair association will be furnished free on addressing the Secretary, John Farley, Toledo, O., or Dr. A. B. Mason, Wagon Works, Toledo, O.

I don't know who the Vice-President of the N. A. B. K. Society for Ohio is, and I hope I am not "treading on his toes," but it seems to me that so important a fair as the Tri-State ought not to be ignored.

I hope to get permission for such bee-keepers as may desire to bring tents and camp on the fair grounds thus reducing the expense of a one or two weeks' stay. I will answer any inquiries in regard to it as soon as decided by the association.

Wagon Works, O., July 27, 1882.

For the American Bee Journal.

That Professorship.

WM. F. CLARKE.

An old and not yet obsolete book says: "Blessed are the peacemakers." In accordance with its teachings, I like to harmonize disputants, especially when it can be done in so pleasant a way as to say, "You are both right." This, I think, is precisely the case with the controversy between the editor of the BEE JOURNAL and Mr. Heddon, in regard to the proposed apicultural professorship. In my humble judgment, gentlemen, you are both right. To fill the office in question, a man is needed possessed of scientific attainments in entomology and botany sufficient to enable him to give ample instruction concerning the structure, physiology, and habits of the bee; also to inform his pupils fully as to the classification, uses and culture of the various plants that yield honey. A man is also needed to give practical teaching in bee manipulation. Without the latter, all will be theory, and mere theorists are always bunglers. The question is, can we get these two sets of qualifications combined in one professor? I doubt it. Prof. Cook is perhaps the nearest approach we have to this rare combination, and while he is unsurpassed, perhaps unrivalled, as an apiarian scientist, both he and his most sincere admirers will readily admit that there are those who can beat him hollow as a practical bee-keeper. This is no disparagement to him whatever, because eminence as a scientific professor, and distinction as a practical bee-keeper, are scarcely possible to one and the same individual. Each is business enough for any one man, and he wins glory enough who is truly great in either of these departments of study and labor.

To make a complete equipment for a school of apiculture, we need two professors, one of scientific and the other of practical apiculture. Then we will have a "full team." Except on this plan, it will be only a "one-horse concern." Mr. Heddon has well said, that the management of a large apiary conducted purely with an eye to business, is very different from the care of a few colonies of bees. He is also right in the opinion that in the future, bee-keeping will be largely in the hands of specialists. These will

need special training. Some may think I magnify bee-keeping too much when I say that, like the professions of law and medicine, it needs not only the collegiate, but the working education. You cannot make a good lawyer merely by attendance on law classes. He must work in an office and do business in the courts. Nor can you make a good doctor by putting him through a course of medical study. He must walk the hospitals, and see practice. Neither can you make a good bee-keeper by mere attendance at college. He must spend a season or two with a first-class bee-keeper who is handling a large apiary.

The BEE JOURNAL has nominated a Scientific Professor, and though he is a stranger to me except by name, I take the JOURNAL's word for it that he would be "the right man in the right place." Now, let me name the Practical Professor—James Heddon. If there is a better man for the post in the whole United States of America, all I can say is, I don't know him. When I was in Mr. Heddon's apiary, not long since, and found him giving his invaluable instructions to only two students, I could only wish he had *two hundred*, and that I was one of them.

Since writing the foregoing, I have come across the following extract from the *Examiner*, which is too excellent a clincher of what I have said to be omitted:

"Let it be understood, then, that the college does not undertake to turn out merchants, or journalists, or lawyers, or engineers. What it does undertake, and what it accomplishes when students make faithful use of their opportunities, is to prepare young men to become the best kind of merchants, journalists and engineers. The college-bred man has to learn his trade or profession like any other; but he will learn it quicker and better, and pursue his chosen calling with more success, than any man of equal ability and application who has been less thoroughly trained."

All of which is just as true in its application to the best kind of bee-keeping.

Listowel, Ont., July 29, 1882.

Translated from L'Apiculteur Alsacien-Lorrain.
Comb Foundation-Making in Germany.

DR. REISSER.

MY DEAR FRIEND:—This time a few lines concerning the manner in which comb foundations are made.

The machine used by our section of the Society in their manufacture was furnished by M. Herm. Greve, gunsmith at New Brandenburg, and cost 33 francs and 75 centimes (\$6.28). It consists of two plates of zinc, in which the bases of worker cells are cut, and which, consequently, exactly fit when one is placed upon the other. These plates are fastened upon beechwood planks.

The following are the details of the process: Put the wax which is to be used, and which should be pure, into a tin vessel large enough so the zinc plates can be dipped in it and even

moved about a little. This vessel is itself placed in a large kettle or boiler containing water kept at a temperature of 50° or 90° C. (176° or 194° F.). When the wax is once liquefied, one of the plates is moistened with a solution of common soda and dipped into the wax-bath once or twice according to the thickness which it is desirable to give to the sheet, after which the plate with the adhering wax is immersed in cold water. The strips of wax which extend beyond the zinc-plate are trimmed off, and the sheet of wax is then gently detached and placed in a box between two layers of blotting-paper. The work continues thus until the wax is exhausted. Then one by one the sheets are taken out in order to be stamped on the side which is still smooth. The plates are moistened with soda, a sheet softened again by a momentary immersion in tepid water is placed between them, and they are then put under pressure. This sheet, when sufficiently pressed, is carefully loosened from the plate, passed through cold water to remove the coating of soda which it has, and then placed in the box as before; then the whole is weighed down by a smooth board and weight of some sort in order to secure evenness of surface.

Theoretically foundation-sheets thus made cost two-thirds less than those we buy, but in reality this proportion is incorrect. The following are the reasons:

1. The wood to which are attached the zinc-plates becomes warped, in consequence of the repeated washings, bending the metal with it, and thus in a short time the surfaces of the plates become irregular and the sheets of wax are pressed too much in some places, holes being even produced, while in other places they receive no pressure. The plates should be screwed to cast metal. Another imperfection is, that they have no handles. One can supply this deficiency by attaching a cord, or, better still, a bent screw, which must be removed when pressure is applied. This inconvenience, it is true, only occasions a loss of time.

2. Notwithstanding the soda-wash which is used, it is not always easy to detach the sheets of wax from the plates, and more than one breaks, whence comes the necessity of remelting. But each sheet put back into the melting-vessel conveys with it some soda, however little it may be, and after quite a number of broken sheets have been returned, the wax in the bath only gives those that break like glass and have an objectionable color. The quantity of soda is increased at each dipping of the plate itself.

3. The press required must be very strong. I defy the inventor of this method to succeed with a copying-press; it would not stand the test a half hour. Such an implement as is needed is not to be found in every house, nor even in every place. Furthermore, it is difficult to measure the pressure exerted; either it is insufficient and the bases of the cells are not shown, or it is excessive and the sheets are crushed.

4. Simple immersion in water does

not remove all the soda. It would be necessary to leave the wax more than a week in the water-bath, and renew the water quite often. But the foundation would become very brittle, and a large number of the sheets would break with the least handling. I know only one way of cleansing them, that is to lay one sheet after another on a wash-board, take them to a fountain or to a stream, and, with a soft brush and an abundance of water to wash the sheets of wax until the water used no longer effervesces. Eight to ten minutes are indispensable for each sheet. It may be considered good fortune if a quarter of them are not broken by this process.

Lievre, Germany.

Local Convention Directory.

1882.	Time and Place of Meeting.
Aug. 10—	Maine State, at Harmony, Maine. Wm. Hoyt, Sec.
Sept. 5—	N. W. Ill. and S. W. Wis., at Rockton, Ill. Jonathan Stewart, Sec.
Oct. 3-6—	North American, at Cincinnati, O. Dr. Ehrick Parmlly, Sec., New York City.
	5—Kentucky Union, at Shelbyville, Ky. G. W. Demaree, Sec., Christiansburg, Ky.
	Tuscarawas Valley, at Newcomerstown, O. J. A. Bucklew, Sec., Clarkis, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

The National Convention.

The following is the official call of the Secretary, Dr. Parmlly, for the Convention of the North American Bee-Keepers' Society. We hope there will be a large attendance:

The North American Bee-Keepers' Society will hold their 13th annual meeting at Washington Park Hall, Cincinnati, O., across Washington Park from the Exposition building. Time, Oct. 3rd to 5th, 1882. First session Tuesday, 10 a. m., Oct. 3. We are encouraged to hope that this will be a very profitable meeting, as we are promised papers from, and the presence of, a large number of our most prominent bee-keepers both in the United States and Canada, and essays and implements of the apiary are expected from abroad to add to the knowledge imparted by the research and inventive skill and methods of our countrymen.

EHRIK PARMLLY, Sec.
New York, July 12, 1882.

The bee-keepers of Boone Co., Indiana, are invited to meet in Lebanon, at Barton Higgins' office, over Jackson's bee hive, on the west side of the square, to organize an auxiliary County Association, on Aug. 10, 1882.

GEORGE J. FREY,
ORA KNOWLTON, } Executive Com.
JAS. H. OREAR, }

Read before the Am. Inst. Farmers' Club.
Bee-Keeping and Other Pursuits.

T. SHERMAN.

In traveling this, the rural districts of New England, at the present day, one is painfully impressed with the melancholy contrast to the New England of our father's time.

Then, jolly, thriving farmers, well-cared for farms, smiling fields and peace and plenty, greeted the eye on every hand. Prosperity and happy united families was the rule everywhere; now, these are the exceptions. Families are, very generally, broken up: the daughters are in the factories, and the sons have emigrated to the west, carrying with them the snap and grit of the typical Yankee. Even now, the sturdy boys are, by the hundreds, leaving the old crib and seeking new homes beyond the "Father of Waters." In hundreds of instances that have come under the observation of your—perhaps cynical—essayists, while tramping with knapsack and staff, farm houses have been seen in the crazy-looking condition, so graphically depicted on the blackboard by our accomplished fellow husbandman, Dr. Gerrish. Farms have gone to waste and are tenanted mainly by the idle and skittish, or by those who are as worn out as the farms themselves, and a general air of discouragement and despondency too prevails.

The experienced tiller of the soil who presided over the *Tribune* has been under the sod for many years; but his counsels to the young man to "go west" are still impressed on the minds of Yankee lads, and the papers of yesterday tell us that over three hundred have already gone this spring from the little State of Vermont to Dakota.

And so this sad state of affairs among the down East peasantry becomes yearly more and more pronounced, and but for her ten thousand factories New England might in time again become the howling wilderness that our progenitors found it.

The agriculturist of the West, from his prolific virgin soil, on his stoneless prairie, is munificently rewarded for his labors—labors, too, far lighter than his forefathers knew of. He finds his profit in growing wheat and corn, in raising cattle and sheep, in the dairy products of butter and cheese, and in many other industrial pursuits, which bountiful nature supplies him with the soil and climatic conditions favorable for. But what is the man in the East to do now on his comparatively sterile lands? With him, what with a cold, flinty, unilluminable soil, unpropitious climate, and unlovable conditions generally, it requires severe toil and a grinding frugality that amounts to a cruel deprivation of the essentials for health and comfort to make both ends meet. He is oftentimes forced to subsist on what the storekeepers won't take of him—sour bread, measly pork, the ubiquitous unbaked dough pie (fla-

vored with dibb), the inevitable doughnut, and other equally fructifying edibles.

Such a life and such a fare belittles the man, and as his prosperity often depends upon the potato yield, discussion upon that esculent is the one topic dearest to his heart, and the aesthetic tastes of his hard-working wife can find no higher expression than in the pretensions sunflower and the ungraceful hollyhock.

No wonder, then, that the country is like poor Ireland, full of absentees. No wonder, either, that the bitter problem is present, "Is life worth the living," under such heart-chilling conditions?

Is it surprising that the young fellow solves the problem with a "no?" With tears in his eyes, but resolution in his heart, his other shirt tied up in a handkerchief, the traditional 50 cents and a few doughnuts in his pockets, the revised New Testament in his bosom, and the dear old mother's blessing on his head, he trudges off and helps to build up the Empire of the West.

But we propose, to-day, to speak on the affirmative of this question, and to try to show that "hope may yet spring eternal in the breast" of the stay-at-home New England farmer, and that he may even there become again not merely happy and prosperous, but perchance a bloated capitalist.

Having the facts, figures, results, and experiences to demonstrate the truth of the statement, we unhesitatingly assert that.

1st. Dairy Farming can be and is made to pay handsomely. Our worthy President and our honored associate Dr. Trimble, gladly testified to what they saw on the Starr Ranch, at Litchfield, and there are other dairy farms showing equally good results, some perhaps better, why not hundreds of them? Need we send to Iowa for our butter, when Maine, with her bleak and merciless atmosphere, carries off the prizes at our agricultural fairs?

2d. The production of poultry—ay, smile if you will—can, with proper management, let us emphasize the words—proper management—be made largely remunerative, and will draw a line under the word largely.

3d. Pisciculture, where one has the location for it, will we are assured by the Hon. Mr. Roosevelt, rapidly roll in the shekels, and make plethoric the money bags of the farmer. Trout-raising, at any rate, we will subscribe to, from a very limited personal experience.

4th. Arboriculture will always pay; but, of course, here the question of time is an important factor; yet we may say, neglect not to set out trees, for they grow while we sleep, and are ever things of beauty and utility.

5th. Fruit trees, as a specialty, we cannot too strongly urge upon you, for with intelligent care and nursing they will reward you with golden fruit. The saturnine idea of our worthy and well-meaning but distressingly narrow-minded Puritan progenitors we have happily grown

out of. They, dear, good souls, taught that through the apple, in the days of old, came "original sin;" and through the apple of latter days comes the cider mill, and from the cider mill to the gin mill the transition is an easy one. So our good uncle, for once with a fanaticism commendable for its honest self-sacrifice, cut down his orchard.

6th. Viticulture has not received the attention it deserves, and probably—we may say probably—on account of the same grim Puritan rigidity in regard to wine drinking.

We would remark—*en passant*—that the most luscious grapes it has ever been our good fortune to meet with on this continent, were presented to our enraptured gaze and our pampered palate, in Canada (on the Vermont line), and the most glorious orchard of apples, pears and plums we found near Brattleboro, Vt., and all these both vines and trees, had been in bearing for years. Why not profit by such rich experiences? Why not export 1,000 barrels of apples where we now send one?

Then, too, we have been told from this platform, in language positive, if not strictly classical—that silk culture can be successfully carried on in New England, but upon that point our opinion is a little shaky.

We insist upon it, however, that the other industrial pursuits herein mentioned, whilst being refining and elevating to a degree, may also be made remunerative beyond the dreams of advice.

Relinquish then the unequal contest between the plow and the rocks, the hoe and the potato bug, and let your "Jerseys" and your "short-horns" regale themselves in sweet fields and pastures green, and they will do their part to enrich your tables and your coffers, bring a wealth of bloom into the cheeks of the bonnie little folks, and help keep your boys prosperous and contented at home. But don't forget the fruit trees.

All this, however, falls short of our purpose, which was, and is, to direct attention mainly to another and still more lovable industry, and so our thesis is: The apiary, or bee culture, as a source of profit to the New England farmer.

Why the New England man in particular? Because that part of the country was the original habitat of the bee, as it was the home of the kind of trees and flowers which seem to have been made for its special delectation, and whose sweets it takes the most particular delight in ravishing.

Our beloved friend, Dr. Trimble, has so thrilled and delighted us with his exquisite delineations of insect life and habits, that it seems rude temerity to venture into his special field of investigation; but, from our heart of hearts, we love our dear little dumb friends, the bees, who so faithfully play their part in the divine economy.

Excuse us if we do not go into any wild atheistic craze over the doctor's fantastic measuring worms and his

hairy caterpillar, but for us the honey bee sufficiently "fills the bill."

As amateurs in entomology, we have found infinite pleasure in the study of other humble creatures of the insect world, but chiefest of all commend us to the little winged elf that goes about doing so much good, that not only aids to fructify the blossom, but "gathers honey all the day from every opening flower."

It, of all God's beautiful creation, most and best justifies its existence, patiently and untiring working for prosperity, and content with a bare subsistence for itself.

With it, it is ever work and worship. The merry little thing tells it all in its cheery hum. Does it need a vivid imagination to find in its pleasant buzz a doxology? An anthem of gratitude, welling ever from a surcharged heart, for the gift of life and joyous sunshine? If you think it does, then you have not, as we have, enjoyed an intimate friendship with the happy fellow. Its brief life is a sermon (and we know what a good sermon is, for have we not been fortunate enough several times to hear our friend and brother farmer, the Rev. Mr. Lightbourn). Yes, the bee's life is a good practical sermon, and its creed should find ready acceptance in every well balanced mind.

In it we find the realization of our ideal communist. Is it not so, Mr. Sharp? for its efforts are always for the good of the whole phalanstery and for generations to come after. Its own life is ephemeral, but six weeks at the most, while engaged in active business life; six weeks of cheerful toil and its work is ended; but its "children may well rise up and call it blessed."

Let us for a few moments contemplate its model home. What does it reveal? Contentment, order, immaculate cleanliness, brotherly love, and industry; no dissipation, no staying out o' nights. Bah! we leave this wretch to the enjoyment of his own billious captiousness.

But true it is that the lady of the house, albeit a lady of high degree, is an exemplary wife and mother. A short bridal tour; this, of course, is the correct thing, *en regel*, and then a return to the home of her youth to receive the congratulations of her numerous, admiring friends; no cards, no cake, no refection but plain bee bread, with honey syrup and an unanimous pæan of rejoicing. Ever after, this ever to be praised royal matron remains at home and attends to the family, with whom (and with society in general) she is ever kind, gentle and amiable, wisely or unwisely, preferring, however, not to have any other ladies in the house.

To Bee-Keepers in Florida.

To assist in making out my report to the National Society, I would consider it a great favor if bee-keepers all over the State of Florida would write down what the general character of the season has been and its effect on the bees of their neighborhood, the

results of his own and his neighbors' labor in their apiaries since last September, and anything else worthy of note connected with the industry, and send the reports to me by Oct. 15th, as the National Convention commences Nov. 3rd, and my report must be in Cincinnati by that time. Every thing promises well in this section for an unusually large crop of late honey to come in November and December, that can not, of course, be included in the reports. Would be glad, however, to have the prospect for a late crop included in reports.

W. S. HART, *V. P. for Florida.*
New Smyrna, Fla., July 28, 1882.

The bee-keepers of Boone Co., Ind., are cordially invited to meet at the office of Barton Higgins, Lebanon, Aug. 10, for the purpose of organizing an auxiliary county bee-keepers' society, by request of committee.

SELECTIONS FROM OUR LETTER BOX

Fall Transferring.—Please inform me through the BEE JOURNAL, if it will be prudent to transfer bees from old box hives to movable frame hives during the month of August. If you recommend the transfer, please give all the information necessary to insure success.

A. D. DARBY.
Baton Rouge, S. C.

[If you are certain of honey flow sufficient, after the transfer is made, for the bees to gather winter stores, then you had better transfer at once. You will find all the necessary information in the BEE JOURNAL of July 12th, page 437. We have on several occasions practiced a similar method with great satisfaction.—ED.]

Hybrid Bees.—I am a mere novice in the bee business. I commenced last spring with 13 colonies, 2 of which were in a starving condition when spring opened; 5 of those colonies were in movable comb hives and 8 were in old log and box hives. I have increased by artificial swarming to 37, and lost 7 or 8 swarms which came out during my absence. I now have them all in movable comb hives, and have taken from them 586 lbs of beautiful comb honey in section boxes, and have used no comb foundation. All black bees, except one colony of Italians, which I got to experiment on. They are all in excellent condition, and are storing honey very fast. I am congratulating myself on my success as a novice, but, doubtless, I owe a great deal of it to the reading of the BEE JOURNAL. I have found several puzzles, one of which I will mention. I sent for an Italian queen in May last, and introduced her in June. I thought her to be the only Italian queen within 100 miles of here, as I had never

seen nor heard of any nearer than that to this place. The queen, I suppose, was injured in transit, as she was a long time unfruitful after her arrival, but finally, commenced laying, and has been gradually improving since, but the mystery is, since her introduction I have found scattering Italian bees in several other hives, and several swarms have been captured, which were mixed with Italian bees, and in every instance that has come under my observation, there were pure Italian bees and pure black bees, and some which appeared to be mixed. Now, will you please give me some light in explaining how this mixture comes? I also inclose a small piece of a vine which is very abundant here in the bottoms, and blooms nearly all summer. I wish to know its name and rank as a honey plant.

B. L. CLEMENTS.

Queen City, Tex., Aug. 1, 1882.

[Drones from your Italian queen have met the young queens from your black colonies, and those of others. Thus accounting for some being apparently Italian, some black, and others mixed.

The vine is called tie-vine, and is an excellent honey-producer.—ED.]

Bees in Arkansas.—The past winter was very favorable with us for breeding. We have had no frost since the last of February. Our honey season opened about March 1. Swarming began the 25th, and they are swarming yet. It is of no use to clip the queen's wings, clipped or not they will swarm, and half of them abscond. Our honey resources are maple, willow, red bud, wild plum, peach, apple, poplar, honey locust, sweet gum, blackberry, persimmon, and sumac in abundance. Did you ever hear of bees gathering honey from poison ivy? I think my bees are, as they cluster upon it very thickly. There are quantities of other honey plants, too numerous to mention, in which our bees find sweet nectar. I have 80 colonies in Langstroth hives, and 60 in box hives. I have extracted 3 and 4 times from the upper stories, and taken surplus as often from the box hives. I never lost a colony in wintering, except by starvation, or dysentery.

FRANK THIAVILLE.

Forest City, Ark., July 18, 1882.

[Poison ivy (*rhus toxicodendron*) furnishes an abundance of pollen and some honey.—ED.]

Bees in Colorado.—In a late copy of the BEE JOURNAL I see an article on fugitive swarms in California. In 1879 there were only a very few bees in this county or State, and none known to be in the forest. Now, July, 1882, there are bees to be found everywhere in the town and on the farms, also every suitable tree in the forests seems to be pre-empted. I know of at least 30 colonies taken from trees and off of bushes where they clustered after swarming, during this and the past season, and many swarms are

seen in the air moving to new locations. Bees winter well out-doors without protection, and as the mountains are covered with flowers from May 1st till frost, there seems no lack of honey. Our most experienced bee-keeper, Dr. W. D. King, of Boulder City, kept bees in the mountains near our present location for a couple of years, and one colony made for him 400 lbs. extracted honey in one season, and I notice just now that honey comes in so fast that the queens are crowded for room to deposit eggs. Does not this look like Colorado is destined to be a great bee country? PHIL. REARDEN.
Jamestown, Col., July 28, 1882.

Beautiful Foundation.—By this mail I send sample of foundation that I, and many others, are using with good satisfaction. I will operate a mill at the coming National Convention, if Mr. Heddon will meet me there with his press. J. VANDERVORT.
Laceyville, Pa.

[The sample received is intended for surplus boxes, measuring 41 inches long by 4 wide, and weighs just 1½ ounces—or, nearly 15 square feet per pound. It would be an interesting feature in the National Convention, if a competitive exhibition of the practical workings of several of the approved foundation machines could be arranged.—Ed.]

Journeyings in America.—After leaving Chicago on my way from Scotland to Texas, I visited Mr. Chas. Dadant's apiary at Hamilton, Ill. For every lover of the industrious little insect, such an apiary as Mr. Dadant's holds great attractions. I inspected the various departments, saw them make comb foundation, introduce queens, and in fact the whole routine of progressive American bee-keeping. I have met one bee-keeper in America who has not impressed me favorably, and he was, as we would say in Scotland, "warloch" looking. But Mr. Dadant was the soul of hospitality, and my sojourn at his home will be remembered as one of the bright spots in my trip. I begin to realize more fully that bee-keeping is not mere child's play, and that with many years of experience, there are avenues brimming with knowledge yet unexplored. JAS. ANDERSON.

Quincy, Ill., July 30, 1882.

Real Encouraging.—In my report of a month ago, I gave you a very discouraging account of our honey prospects for this season, but you replied with words of encouragement that seem now about to be realized. Our skies brightened some two weeks ago, and after a few days of dry weather our bees commenced again to work on both red and white clover, and to-day, in comparison with the past, they are a regular tornado. Sections that have been on the hives for six weeks in a half completed condition are being finished up and new ones started in a way that is real encouraging. I would

be glad to have you see, smell and taste some of the small amount of honey that our bees have managed to gather during our long, wet weather. It would test the skill of an apothecary to get up anything to beat it. It seems to be a compound of everything that is bad in the way of honey, and to a taste that has been educated by using our nice white clover honey, it is simply disgusting.

JOHN C. PEDEN.
Lawrenceburg, Ky., July 26, 1882.

Returning Swarms.—Last year I bought an Italian queen and introduced her into a black colony. This spring I took the colony about a mile out into the country. I divided them June 10th. The old queen was great on the increase, so I divided again June 26th, to keep them from swarming. I paid but little attention to them until word was sent me that my nice Italian swarmed July 21st. I went out the next day to examine the hive, and found no queen, but the hive had 20 queen cells in it, three of them capped. I left them until the next day and examined again, but found no queen. I cut out all the cells but one, and moved the hive so that a hive with a queen cell stood where the old queen had swarmed from: just a week from the day that my bees swarmed, the family heard a great roaring among the bees; they said the yard was full of them, but did not swarm as they supposed they would. I examined the hive where stood the old hive, and sure enough, there was my old queen back again, and settled down to business. She had destroyed the queen cell, and had part of a comb filled with eggs. I should like to know whether this is a common occurrence or not? I supposed that when bees swarmed, they went to stay. I know but little about handling bees. What I have learned has been from "Bee Culture" and the BEE JOURNAL. This is my first year's effort, and I have 20 colonies doing well. NATHAN M. WOODMAN.
Bushnell, Ill.

[We frequently hear of swarms being hived and deserting their new quarters after two or three days, sometimes returning to the parent hive, but oftener to parts unknown. We do not know why they might not become dissatisfied after the lapse of a week and return, especially with a dearth in honey flow, and a new hive and population on the old stand.—Ed.]

Making up for Lost Time.—We have had the worst season for bees I ever saw up to July 20th, when basswood blossoms commenced to open, accompanied with honey weather, and the bees work as though they meant to make up for lost time. I expect to hear that Mr. Doolittle's starving bees have stored basswood honey by the ton the past week. King-birds do catch worker bees, and don't you forget it. I have seen them take the bees right from the basswood blos-

soms every day this week. Powder and shot are the best remedy. I am using Given and Vandervort foundation in 5x6 sections. As an experiment, I filled several cases with sections filled with each kind of foundation, and in every case, the bees drew out the Given and stored it with honey before they commenced on the Vandervort. This was a surprise to me, for the Vandervort was so handsome to look at I thought the bees would go for it as soon, if not before, the Given. I find alsike clover and southern thornless raspberry profitable to raise for bees. GEO. T. WHEELER.
Mexico, N. Y., July 29, 1882.

The Honey Wave.—After waiting and feeding so long, the honey wave struck us July 10th, and I never saw such a heavy yield as from that time until the 27th. It is mostly from linden, though some from red and white clover. I hived a swarm of Cyprians on the 15th in a 2 story Langstroth hive, with 20 frames of foundation. In 8 days I took 40 lbs of honey from the upper story, and the lower one was full. It is said that second swarms are led off by virgin queens. Do they mate while swarming, or after? WM. MALONE.

Oakley, Iowa, July 27, 1882.

[We have tested the matter to our satisfaction that they mate afterward. In cases of this kind we have found that more or less of drones are harbored by the new swarm for four or five days, after which they are given the cold shoulder and nuceremoniously ejected.—Ed.]

Progressive Transferring.—Please let me say to Mr. Hutchinson that in my method of transferring I keep the old queen occupied, to a great deal better extent, than he does in the transferred combs. I lose the interest on the use of the 8 sheets of foundation 25 days, till I can make up the old hive. I gain many times that amount in the extra room I give my queen. He has but one queen at work by his methods, why should I be required to have two? I never noticed any loss by any loafing, but if Mr. H. does on testing this method, he can easily drive them into the new hive every 2 or 3 days, as fast as they hatch out. Try this method, Mr. Hutchinson, and you will never go back to sticks, wires or strings, and patched combs. It is the neatest, safest, surest and most profitable method I ever tried out of very many.

JAMES HEDDON.
Dowagiac, Mich.

Introducing Queens.—The new use of the smoker for introducing queens, as suggested by Mr. Jones, on page 410 of the BEE JOURNAL for 1881, has been more valuable to me than the subscription price of the JOURNAL. I have tried it, and can introduce queens with perfect satisfaction.

WM. ROBERTS.
Vaughansville, O., July 29, 1882.

Dysenteried Nuclei.—Do you suppose that mule thought the bees were eating honey after he had kicked over the hive? I will give \$10 for a queen whose working progeny all fill themselves with honey when badly disturbed, and do not sting when filled. What a pleasure to handle such bees, even if they did get some honey away from the extractor.

E. B. SOUTHWICK.

Mendon, Mich.

Mr. Southwick thinks the cause of my bees having dysentery was their refusing to take food. The dysentery was caused in less than 24 hours, and the bees took food to excess. In my statement on page 444 of the BEE JOURNAL, it should read 4th where it reads 7th. I have since observed another case of dysentery in a 2-frame nucleus in a neighbor bee-keeper's apiary, and if the particulars in these cases will be of any value, I will give them if desired; also the observance of the mating of a queen, and some facts concerning drones.

Bryant, Ill.

S. A. SHUCK.

[We would be pleased to have Mr. Shuck, and all others, give all facts that may come within their knowledge which have a bearing upon important questions constantly coming up for discussion, and especially those relating to vital matters, such as dysentery in bees, mating of queens, and peculiarities of drones.—ED.]

Progressive Transferring.—Had Mr. Heddon's article on transferring, and the one on width of sections, been written in May, I should have been at least \$8 better off to-day. I have 15 colonies in the Heddon hive, and you can judge of the value to me of the article on progressive transferring. I send you a wire presser for fastening foundation in frames. Please give it a trial, using No. 30 wire, and report. I shall get no surplus honey this year. Basswood not yet in bloom, but will come out in a few days.

F. M. CHENEY.

South Sutton, N. H., July 29, 1882.

[The wire-presser consists of a bradawl handle, in which is inserted a No. 2 sewing needle to about $\frac{3}{8}$ its length, somewhat slanting, the head is then ground off to leave about $\frac{3}{8}$ of the eye. We have had no opportunity to test it, but doubt not it will do its work satisfactorily.—ED.]

Which Queen Goes?—When a swarm issues, which queen goes, the old or a young one? I commenced a year ago last spring with 3 colonies, divided once around, and had 2 swarms. One colony died before winter set in; and this spring I lost one by starvation. I now have 10 good colonies. I have learned some by experience, and more through the BEE JOURNAL. My bees are mostly hybrids. Z. G. COOLEY.

Norwalk, Iowa.

[The old queen always goes with the swarm.—ED.]

Bees Doing no Good.—We have an abundance of white clover, but bees are not working on it. Basswood was only one week in bloom. If the fall flowers do not furnish more nectar, I will have to feed my bees to bring them through the winter, for we will have a severe one. Catnip and motherwort are the only plants bees are working on now. No surplus in this part of the State.

JOHN STURWOLD.

Haymond, Ind., July 28, 1882.

[It is seldom we wish any man mistaken, but we hope your prediction of a severe winter will prove you a false prophet.—ED.]

Breeding Up.—I have 12 June and July swarms in old box hives. Some of them are in fair condition considering the time they have been lived, but the majority are quite weak, and will not live through without feeding—what is best to be done with them? Please answer through the BEE JOURNAL. MARK THOMSON.

Canton, O., July 28, 1882.

[If honey is not coming in sufficiently fast to keep up rapid breeding, better feed a little each day, and trust to fall flowers for winter stores. Should they fail, then will be time to feed for winter.—ED.]

Honey from Daisies.—Do bees gather honey or pollen from the common white daisy, and if so, is it injurious to them for winter stores? They have worked on daisies some in this section this season. I never knew them to work on it before. Some bee-men think that it will kill the bees to winter on it. JOHN H. GREEN.

Maine, N. Y.

[We never knew bees to work on daisies, but suppose if they do so it is for the honey; and do not imagine it will be injurious. They winter on honey from the mountain laurel, which is quite poisonous to humanity.—ED.]

Maple Sugar.—Please inform me through the Weekly BEE JOURNAL, if bees can be wintered on pure maple-sugar?

W. B. BROWN.

Lebanon, N. H.

[We would be afraid to attempt it, except as an experiment.—ED.]

Prospects Brighter.—Basswood is now in full bloom, and the past three days have been splendid for the bees, the mercury standing at 90° in the shade at noon, and 70° at 5 a.m., which is favorable for the secretion of nectar. The combs which showed nearly starvation for the bees a few days ago, are now glistening with honey, and enough has been already stored for a winter's supply by the majority of my colonies, while a few have commenced work in the boxes. A small surplus may yet be in store for we New Yorkers if the weather continues favorable. My dish is right side up at least, and I

hope for the best. I am thankful for the winter supply already obtained.

G. M. DOOLITTLE.

Borodino, N. Y., July 29, 1882.

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance.

Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 ".....	20 " "
" 13 " (3 months)....	30 " "
" 26 " (6 months)....	40 " "
" 39 " (9 months)....	50 " "
" 52 " (1 year).....	60 " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent., if wholly paid in advance.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent., if wholly paid in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for one year, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—a copy of "Bees and Honey."
" " 3,—an Emerson Binder for 1882.
" " 4,—Aplary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,—" " cloth.
" " 6,—Weekly Bee Journal for 1 year, or Aplary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 3oz.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Emerson Binders.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Do not let your numbers of the BEE JOURNAL for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference

When you meet with an accident, get a sprained ankle, or otherwise injured, don't go to the expense of sending for a doctor, but apply Kendall's Spavin Cure, and you will experience instant relief.

32w4t

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., August 7, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—I am paying 7c. for dark and 9c. for light extracted.
BEESWAX—Choice lots are worth 25c. here: bright yellow, 24c.; dark to good, 17@22c.
AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for honey is quiet. Extracted brings 7@10c. on arrival. No comb honey on the market worth mentioning, prices nominal.
BEESWAX—Scarce, and brings 20@25c. on arrival.
C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for comb honey is light, prices being made to meet views of purchaser.
BEESWAX—Scarce, and in demand at 23@25c.
R. A. BURNETT, 165 South Water St.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.

BEESWAX—The demand for beeswax has been rather moderate, and though small lots are held about the same, large lots would have to be shaded. Western, pure, 27@28c.; Southern pure, 26@28c.
D. W. QUINBY, 105 Park Place

CLEVELAND.

HONEY—White comb honey, in 1 lb. sections, continues to meet with ready sale at 25c. as fast as received. No 2 lb. sections received as yet. A small lot of extracted has been received, but none sold, therefore cannot give quotations. BEESWAX—25@28c.
A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—The general impression is that Kern and Tulare furnish rather poor honey. As a rule, the honey heretofore received from that quarter has not been of extra quality, but as an exception we note the receipt of some comb from Lemoore, Tulare county, which for whiteness and general excellence would be hard to beat in any part of the State. Some comb of superior quality from Los Angeles, raised by A. V. Hale, is commanding in small lots 20c. The same price was paid for last year's yield. The honey is perfection itself. Dark comb, no better than "C," sold this week at 12c.
We quote white comb, 17@18c.; dark to good, 8@13c. Extracted, choice to extra white, 9@9½c.; dark and candied, 7@7½c. BEESWAX—28@30c.
STEARNS & SMITH, 423 Front Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
BEESWAX—Prime quality, 25c.
CROCKER & BLAKE, 57 Chatham Street.

ST. LOUIS.

HONEY—Selling fairly at 18@20c. per lb. for comb, 7@8c. for strained, and 10@12c. for extracted—top figures for choice well handled only. Sale 20 lbs., strained at 8c. BEESWAX—Sharply higher, under a scant supply and brisk demand. Prime at 25c. early, to 27@28c. later.
R. C. GREER & CO., 117 N. Main Street.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

HENRY ALLEY,
WENHAM, MASS.

I see by Sept. No. of *Gleanings*, Mr. O. E. Coon wishes to know where he can procure Italian queens that will produce yellow drones. Mr. Coon can get queens from Henry Alley, Wenham, Mass., that will produce yellow drones and yellow bees with three bands; no two-banded bees among them, and the worker bees are workers, as good as the best. They are very docile (can be handled without bee-vell), and are very hardy. I have had Italian queens from Mr. Alley since 1878, and have never known a queen to produce a dark-colored drone, and the worker bees need not be put on a window to show their three bands. They will show them when empty. C. J. ALDEN, Oakdale, Wis., Sept. 7, 1881.

The queen I had of you is a Jewel; \$10 would not buy her. They are the best honey-gatherers I have.
FRED. LEWIS, Camden, Maine.

I have bought queens of you for 10 years; you have always given me the best workers as well as the brightest stock. DR. MCKAY DOUGAL, Seneca, Mo., July, 1882.

Your bees stand No. 1 here, JNO. T. NEWTON, West Richfield, O., July 15, 1882.

Warranted Queens, \$1.25; the largest, brightest and most perfect selected, \$1.50 each; Tested, \$2 each. No money required until the Queen is received.

Only Cyprian, Italian and Holy Land Queens for sale. 21st Annual Circular sent on application. Queens by return mail in most cases.
32w4t HENRY ALLEY, Wenham, Mass.

AT LULING, TEXAS.

I breed PURE ITALIAN BEES AND QUEENS for sale; manufacture Hives of any style and Comb Foundation. Dealer in Novice Honey Extractors, Blingham Snarkers, and everything used by modern bee-keepers. Write for prices. Bees-wax wanted.
14w38t

J. S. TADLOCK.

FLAT-BOTTOM COMB FOUNDATION,

high side-walls, 4 to 16 square feet to the pound. Circular and samples free.

J. VAN DEUSEN & SONS,
Sole Manufacturers,
Sprout Brook, Mont. Co., N. Y.

BEESWAX.

I wish to buy a quantity of good yellow Beeswax. I am paying 25c. per pound, delivered here, Cash on arrival. Shipments solicited.

To avoid mistakes, the name of the shipper should always be on each package.

ALFRED H. NEWMAN,

923 West Madison Street, CHICAGO, ILL

PRIZE QUEENS FOR 1882.

From the Evergreen Apiary.

REV. E. L. BIGGS, of Wilton Junction, Iowa, will furnish Italian Queens from either of his Prize Mothers, as early in the coming season as they can be bred, at the following rates: Tested Queens, \$3; Warranted Queens, \$2; Queens without guarantee, \$1; Two comb Nucleus, with Tested Queen, \$4. Orders filled in rotation, as received, if accompanied with the cash. 3w36t

EVERY FARMER AND MILLER

SHOULD HAVE FISHER'S GRAIN TABLES, 192 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest; wages tables, wood measurer, ready reckoner, plowing tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. Ask your bookseller for it. Sent post-paid for 40 cents. Agents can make money selling this book.

For sale at the BEE JOURNAL Office.

65 ENGRAVINGS.

The Horse

BY B. J. KENDALL, M. D.

A TREATISE giving an Index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents.—Sent on receipt of price, by

THOMAS G. NEWMAN,

DUNHAM COMB FOUNDATION—40c. per pound; extra thin and bright, 10 sq. ft. to the lb. 48c. Send for samples. Wax worked 10c. per lb. F. W. HOLMES, Cooperaville, Mich. 13wly

THIS PAPER may be found on file at Geo. P. Rowell & Co.'s Newspaper Advertising Bureau (10 Spruce St.), where advertising contracts may be made for it in NEW YORK.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 2 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00	
For 2 Langstroth " " 10x18 " " " " " " " " " " " "	10 00	
For 3 " " " " " " " " " " " "	10 18	
For 4 " " " " " " " " " " " "	10 18	
For 2 frames of any size, 13x20 " " " " " " " " " " " "	12 00	
For 3 " " " " " " " " " " " "	12 1/2x20 " " " " " "	12 00
For 4 " " " " " " " " " " " "	13x20 " " " " " "	16 00

A NEW BEE BOOK! Bees & Honey

OR THE
Management of an Apiary for Pleasure and Profit; by
THOMAS C. NEWMAN,
Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Palaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 8 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

The Bee-Keeper's Guide;

OR,

MANUAL OF THE APIARY,

By A. J. COOK,

Of Lansing, Professor of Entomology in the

State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 15 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—LEWIS T. COLBY.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—J. P. WEST.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—E. H. WYNKOOP.

This book is just what everyone interested in bees ought to have, and which no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—A. E. WENZEL.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—WM. VAN ANTWERP, M. D.

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—L'ABBE DU BOIS, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *vide mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, fishermen know it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better. I have been greatly benefited. My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1. and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by
THOMAS C. NEWMAN.
925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apilary. Entirely rewritten, ably illustrated and fully up with the times, on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quilby's New Bee-Keeping. by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture. by A. I. Root.—This embraces "every thing pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book. by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee.—This is a standard scientific work. Price, \$2.

Blessed Bees. by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apilary for Pleasure and Profit. by Thomas G. Newman.—Third Edition. Fully up with the times, including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Blauen Kultur. by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Dzierzon Theory;—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine. by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey; the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c. per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use.—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apilary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity. by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how for 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers. by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees, Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Cholera Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic. contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 Items for Gas, Steam, Civil and Mining, Engineers, Machinists, Millers, Blacksmiths, Founders, Miuers, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

A Disturbance in Cyprus.

We learn by a dispatch dated at Larnaca, Cyprus, Aug. 10, that a great anti-Christian demonstration has occurred. At the funeral of a Moslem who was found murdered, and whose death was attributed to the Christians, the outbreak occurred. The police are in full sympathy with the mob, and all is in a state of anarchy. A score of Christians were arrested, one was killed, and many fled to the mountains for safety. At the time of this writing (Aug. 11) further disturbances are feared. The brevity of the dispatch may give rise to apprehensions all over the world for the safety of Mr. Frank Benton and wife, who are residents of Larnaca, and from whence their correspondence has heretofore been dated. We think all fears for his safety are needless, because Mr. Benton is a man who is most likely to ingratiate himself in the favor of any community in which he may reside, and in Cyprus, as in fact in all countries of the Old World, Americans are in great favor. With the business and higher classes, they have become especially popular on account of their intelligence and energy; and with the lower classes, on account of their liberal views and peculiar form of government at home. Europeans, especially those of Eastern Europe, have a marked preference for the American people and the United States government, regarding them as the true exponents of national freedom. Any mishap to Mr. Benton might well be considered a national calamity, and would be regretted by the bee-keepers of the

Death of Jesse C. Estlack.—Mr. I. N. Whitely, writes us from Denver, Col., of the death of Jesse C. Estlack, which occurred at Littleton, Col., Aug. 5, 1882. Mr. Whitely says:

Mr. Estlack was born in New Jersey, Dec. 6, 1818, and removed to Colorado in 1859. He was an energetic and enterprising farmer and bee-keeper, and through industry and economy has accumulated a large property. He leaves a wife and family to mourn the loss of a kind husband and father, and the community the loss of a worthy citizen.

We have received from Mr. James Heddon, Dowagiac, Mich., one of his queens which produces the "long, leather-colored, docile workers," sent here to be tested upon her comparative merits. The workers accompanying her were fine, large, well-developed bees, and though not as yellow as some Italians we have, nor as "frisky" as our Syrians, yet they are perfect beauties. The queen is a fine specimen of regality, and when released from her introductory prison, marched down among her Syrian subjects with a royal, dignified movement that seemed to command the respect and devotion she undoubtedly deserves. We expect to render no disparaging report concerning her progeny.

We regret to learn that on the night of Aug. 5th, the residence of Mayor W. J. Andrews, ex-President N. A. B. K. Society, at Columbia, Tenn., with contents, and several colonies of bees, were destroyed by fire. Loss over \$5,000, on which there was an insurance of only \$2,500.

The "Gap" in the Honey Season.

O, for forty acres of sweet clover (melilot) now, to fill up the gap between basswood and the autumn flowers that come in August and September. The acre we have tells the true story of what we ought to have.—JAMES HEDDON.

If it was not for the sweet clover, bees would be idle. Still, they keep up their hum of rejoicing from sunrise until dusk, bringing load after load of transparent nectar, that God, in his all-wise providence, causes to be secreted in the bloom of melilot or sweet clover.—H. W. GARRETT.

We give in this number two communications of especial interest to bee-keepers, either of which will be worth many times the subscription price of the BEE JOURNAL to any apiarist who will profit by the information contained in them. One is by Dr. G. L. Tinker, with "Notes on honey plants," page 517; the other by J. G. Steer, subject, "Cultivation of Simpson honey plant (figwort)," page 518. Both are highly practicable, and come at a time to allow of the fullest preparation to profit by them.

In this connection it may be well to remark this season has been a peculiar one, and just now is the time when the "gap" is occurring between basswood bloom and fall honey flowers. In a few localities, particularly Dr. Tinker's, this gap is not so noticeable, but, as a rule, there is a serious break in the natural bloom which is quite damaging to the fullest possibility of a honey yield. Fortunately for us, we are in the vicinity of an abundant sweet clover pasturage, which not only supplements the white clover harvest, but curtails it by reason of enticing the bees from it before the nectar has ceased to flow, and even renders basswood scarcely desirable. Wherever sweet clover prevails this season, we anticipate there will be no cessation in the honey yield till closed by the advent of winter. With even a moderate amount of it, bees will still keep up their breeding as vigorously as ever, and be in the strongest condition to take advantage of the more plentiful fields of buckwheat, goldenrods, asters, heartsease, Spanishneedle, bergamot, etc.

We introduce this article with two extracts from this paper. The first, written by James Heddon, gives evidence of a deep sense of duty, and a carefully formed opinion, which will carry conviction to thousands of readers who have been deliberating and waiting for some just such practical authority as Mr. Heddon to endorse the feasibility of planting for honey, and to suggest what to plant; and thousands will adopt his excellent hint, and in the future thank him for

his earnest expression. Mr. Heddon we think will, with the assistance of his initial acre of sweet clover, have a very satisfactory season's report to make at its close, especially should the weather be favorable for gathering from the late flowers.

The second extract is from a letter by Mr. H. W. Garrett, in New York. His is an expression of gratitude for bounties which are within the reach of all, with the expenditure of a little time and less money. His report comes from a State which has been peculiarly unfortunate in its realization of a good honey crop. He does not tell us whether his sweet clover was planted especially with a view to the yield of honey or whether it is a semi-spontaneous yield, being a survival and self-seeding from former cultivation for other purposes.

We feel grateful to Dr. Tinker for demonstrating the value of his golden honey plant, and especially for the information that it properly and seasonably sown, it will grow and bloom the same season sown. In this, and perhaps this only, it is superior to sweet clover, for many apiarists are too impatient or thoughtless to put in a crop, even with the assurance of large profits, where they have to await the second season before realizing from it, because their profits have heretofore been large and their returns speedy. With honey-producing as a specialty, however, the methods formerly prevailing will all, or nearly all, be changed; and in nothing will the change be so radical as in bee pasturage. To make of bee-keeping a specialty, it will be necessary to provide against the probability of crop failures, and in no way can this be done except by providing a certain and continuous honey flow. It is gratifying to know, that through the efforts and persuasions of the BEE JOURNAL, there are hundreds of shrewd, discriminating, intelligent apiarists in America at the present time experimenting with honey-producing flowers, and observing the effects of climate and soil not only on foreign plants, but also on those indigenous to our own country, and the next ten years may see as substantial improvement in this direction, as the past ten have witnessed in quality and appearance of product. Not until there are four months of continuous flow will bee-keepers be satisfied, and this we believe to be as possible as a continuous season of life-sustaining

vegetables. No bee-keeper is worthy to be styled an *apiarist*, who cannot in the not far distant future point to his cherished bee-pasture, and reckon with some degree of certainty on his season's yield.

Henry Alley, reports from Massachusetts as follows, dated Aug. 9:

For 17 days in succession my thermometer has been up to 90° in the shade, and on several days it indicated 99° and 100°. About everything in the shape of vegetation was dried up. Last night distant thunder showers brought us some rain, and all is changed this morning. Goldenrod is coming into bloom, and I look for plenty of fall flowers for my bees to feed on.

Last season we experienced a protracted drought here, but the sweet clover never failed us, and this season, although wet and cold weather has prevailed, the bees can recognize no "gap" in the honey flow, but are working merrily when the sunshine allows them to do so.

☞ Just a year ago this week, a small bee paper was started in New England and for 3 months it was issued weekly—struggling for an existence. It was then suspended, with the promise that after a rest of 2 months it would resume as a monthly. A few were inveigled into subscribing for it for 1882, but only one number has been published this year—and that not until April or May. It is therefore safe to conclude it "dead," and this will serve as its "obituary notice." It leaves a few subscribers who have been swindled out of the money advanced for subscription, and sundry debtors "mourn" because of misplaced confidence in trusting the publisher. Being one of the "mourners," last mentioned, we "speak that we do know."

☞ We notice an advertisement in the *Empire State Agriculturist* which should please even the most ardent cheap queen advocate—offering to "sell" a "beautiful untested Italian queen for fifteen cents!" If cheapness in queens is all that is desired, every one should now be happy! Wonderful bargains! Prodigious economy!! Only 15 cents for a "beautiful Italian queen"!!!

☞ Our new location, No. 925 West Madison St., is only a few doors from the new branch postoffice. We have a telephone and any one in the city wishing to talk to us through it will please call for No. 7087—that being our telephone number.

The Labors of the Drones.

Prof. B. Silliman, editor of the "American Journal of Science and Arts," published at New Haven, Conn., has sent us an old manuscript, written by the Rev. Elisha D. Andrews, Armada, Macomb Co., Mich., Oct. 7, 1851, giving the latter gentleman's views on several important points in bee-culture.

Prof. Silliman remarks that he found the old manuscript among his late father's papers, where it had been for many years. He desired us to look it over, and if anything of interest was discovered to print it in the interest of scientific bee-culture.

The Rev. Elisha D. Andrews states, in the manuscript, that the object of his writing it was to subject his "discoveries to a strict, scientific scrutiny and criticism." He then adds: "If they will bear this test, I am disposed to have them given to the world, as some little addition to the accumulating science of the age."

One part, in particular, is interesting to us at the present time, and that is in relation to the character and object of the drone bee. He says:

They are considered, as it respects the labor of the hive, an idle and useless race—only a nuisance as their name proverbially denotes. Now, this I consider a perfect slander. From 30 years' observation I can testify that there are no bees in the hive that pursue their work with so much ardor and zeal as the drones. It is true, they do not make their appearance abroad till the warm weather in May and June, and not in the early morning nor late in the afternoon, nor at any time when the weather is cold and damp, but they are never seen idly basking about the entrance of the hive, and in the middle of the day, when the weather is hot, they come out of the hive in great numbers and in great haste, rushing through and over the worker bees that lie idle about the entrance of the hive. There are no bees in the hive that seem to show such earnestness in their work as these poor slandered drones, but it may be asked, what are they about, that they are not earlier at work, and why do they retire before the other bees cease labor? Have we any right to suppose that they have no office to perform, and are quite idle while in the hive? They are such zealous workers when abroad, that I am inclined to be charitable, and believe they are employed in some work of benevolence when out of sight. Why may we not suppose that they are nurses of the young bee in the larval and chrysalis state, employed to brood over them and keep them warm, when the weather is at too low a temperature for their comfort and growth, and to feed and

nourish them as they need, and whenever the temperature of the weather rises to the necessary point, these nurses go forth in search of such food as the young demand? The zeal with which they labor seems very much like the promptings of parental or maternal affection.

The American Express Company money order system is the cheapest, safest and most convenient way of remitting small sums of money. Their rates for \$1 to \$5 are 5 cents; over \$5 to \$10, 8 cents. They can be purchased at any point where the company have an office, except Canada, and can be made payable at any one of the company's 4,000 offices.

Paid orders are filed in the Treasurer's office, and always accessible for reference, and the remitter gets a receipt for money sent.

For safety, when sending money to this office, all should get either a post office or express money order.

Local Convention Directory.

1882. *Time and Place of Meeting.*
 Sept. 5—N. W. Ill. and S. W. Wis., at Rockton, Ill. Jonathan Stewart, Sec.
 Oct. 3-6—North American, at Cincinnati, O. Dr. Ehrick Parmlly, Sec., New York City.
 5—Kentucky Union, at Shelbyville, Ky. G. W. Demaree, Sec., Christiansburg, Ky.
 Tuscarawas Valley, at Newcomerstown, O. J. A. Bucklew, Sec., Clarks, O.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

The National Convention.

The following is the official call of the Secretary, Dr. Parmlly, for the Convention of the North American Bee-Keepers' Society. We hope there will be a large attendance:

The North American Bee-Keepers' Society will hold their 13th annual meeting at Washington Park Hall, Cincinnati, O., across Washington Park from the Exposition building. Time, Oct. 3rd to 5th, 1882. First session Tuesday, 10 a. m., Oct. 3. We are encouraged to hope that this will be a very profitable meeting, as we are promised papers from, and the presence of, a large number of our most prominent bee-keepers both in the United States and Canada, and essays and implements of the apiary are expected from abroad to add to the knowledge imparted by the research and inventive skill and methods of our countrymen.

EHRICK PARMLLY, Sec.
 New York, July 12, 1882.

The summer meeting of the Mahoning Valley Bee-Keepers' will take place at Berlin Center, Ohio, on Saturday, Aug. 19, 1882, at 10 a. m. All interested in bee-keeping are invited to attend. Turn out. Do not forget your wife, daughter, son and lunch basket. We expect a happy and profitable time.

L. CARSON, Pres.
 M. HAUGHN, Sec'y.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
 Monday, 10 a. m., August 14, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—I am paying 7c. for dark and 9c. for light extracted.
 BEESWAX—Choice lots are worth 25c. here; bright yellow, 24c.; dark to good, 17@22c.
 AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The market for honey is quiet. Extracted brings 7@10c. on arrival. No comb honey on the market worth mentioning, prices nominal.
 BEESWAX—Secree, and brings 20@25c. on arrival.
 C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The crop of 1882 is beginning to come forward, and so far very nice goods have been offered. Sales range at 18@20c. per lb.; one pound sections selling at the highest range, when well filled and white. Extracted, few offerings and demand light at 8@9c.
 BEESWAX—25c. for prime yellow; dark 18@22c.
 R. A. BURNETT, 165 South Water St.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.
 BEESWAX—The market is quiet and the tone a shade weaker. Western, pure, 20@27c.; Southern pure, 27@28c.
 D. W. QUINBY, 105 Park Place

CLEVELAND.

HONEY—The market is quite active with us; it is beginning to come forward more liberally, and the demand is more fully met. For two days past we have not been able to sell for over 25c. per lb. for best white 1 lb. sections; of 2 lb. sections none have been received. Extracted we hold at 14c. for small packages, but have not made any sales.
 BEESWAX—25@28c.
 A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—The market is firm for extracted and choice comb. Offerings and demand are light. We quote white comb, 17@18c.; dark to good, 8@13c. Extracted, choice to extra white, 9@9½c.; dark and candied, 7@7½c. BEESWAX—28@30c.
 STEARNS & SMITH, 423 Front Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
 BEESWAX—Prime quality, 25c.
 CROCKER & BLAKE, 57 Chatham Street.

ST. LOUIS.

HONEY—A fair movement in strained at 7½@8. —one lot of 25 bbls. reported sold at 8c. Some new comb (choice white clover offered), but little sold—held at 18@20c. per lb.; extracted quiet at 9@10c.
 BEESWAX—Easier at 20@27c. for prime.
 R. C. GREER & Co., 117 N. Main Street.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

MISCELLANEOUS.

The Honey Yield, and Taxing Bees in California.—The *Semi-Tropic California* for August contains the following items:

The honey yield this season throughout California will be far from encouraging to our bee-men. These off years that are so frequent might be largely averted by turning more attention to growing certain trees and plants for bee forage.

The Supervisors sitting as a Board of Equalization for the County of Los Angeles, refused to lower the valuation as made by the County Assessor on the bees of the county, though some of the owners of bees in the county offer to sell all the bees they have at one-half the assessed value for this year. They are assessed at \$3 per hive.

Adulteration.—The *Bee-Keepers' Exchange*, for August, has a very strong article on the above subject, from the pen of J. K. Douglass, Neosho, Wis. It is certainly worthy of note that bee-keepers, especially, are unanimous in their condemnation of the frauds which prevail to so great an extent in adulterating honey, as well as other articles of food. We give the last paragraph of the article alluded to, which is as follows:

On page 308 of *Gleanings* for 1882, the editor expresses a hope that the price of honey will be so low this season that more than usual will be consumed, and on page 296 he tells of one way to cheapen its production. I will quote the suggestion for the benefit of those who may not have seen it: "Pretty soon, and the wax of the world will be gone. What shall we do? I will tell you if you won't be scared. For brood combs use wires and go back to our old paraffine experiments of years ago. Had we only put wires into the frames as we do now, we should have succeeded without trouble. For comb honey we can use a mixture of wax and paraffine that the bees will work out much faster than pure wax; and for our small $\frac{1}{4}$ sections. I think we can manage so that sagging will do no harm." So it seems that the honest producer of comb honey may have to compete with adulteration and fraud; for, of course, no honest man would think of selling comb honey built on adulterated foundation, for pure goods and any attempt to sell it for anything else would only result in failure. When I read the above extract I never thought of being scared, but I made up my mind that considering the frequent exhortations to honesty indulged in by it, that consistency

is not one of the jewels that adorns that much mentioned type writer. Any one who will adulterate food is both to be feared and despised—feared for the consequence of his nefarious practices and despised for harboring the motives that prompt their commission. It is possible that my views on the subject of adulteration are too radical for this progressive age, but I think one who adulterates food products, merits a much greater punishment than does the utterer of counterfeit money, as the value of health is greater than riches.

Syrian Bees.—Mr. E. R. Root, in the *Canadian Farmer*, sums up the character of the Syrian or Holy Land bees as follows:

In summing up a few of the good features of the Holy Lands, we find, from the above facts, first, they raise a great abundance of cells at one rearing; secondly, the cells are started so that they hatch at or nearly the one time; lastly, if the cells are not too much disturbed, the queen will hatch out strong and healthy.

Now, a word in regard to the Holy Lands as honey gatherers: My experience has led me to think they are equally as good as the Italians, and some say a little superior. Being originally reared in a hot, dry country, they have necessarily been obliged to gather honey at every opportunity available, or the race could never have existed. In this country, they of course manifest the same energetic disposition; and hence, as far as my observation goes, gather some honey after the basswood flows, even when the other bees are apparently inactive.

After what has been said I would not have it understood that I have any the less regard for the Italians than before; but, on the contrary, all things considered, I think they possess many qualities far superior to other races of bees, and will probably always retain the front rank.

My object in writing this is not to give the Holy Lands undue praise, to the exclusion of the Italians, but to bring forth a few of the good qualities which are justly their due. I do not deny that the Holy Lands have a few bad features; but these, I think, have been fully discussed before.

Handling Bees.—The *Indiana Farmer* gives the following on handling bees:

Many people are deterred from the keeping of bees by the dread of being stung, and many who have bees run them on the let-alone plan, simply because they do not understand the first principles by which they are governed. Only a few days since, a gentleman visited our yard, who owns a good many colonies, looking for, as he expressed it, some plan for their management with the least possible chance of coming in contact with their "business end." His dread of being stung was so great that we could hardly induce him to come within ten feet of a colony. After we had removed the

cloth, lifted out and replaced the frames in several without any signs of being stung, he began to think it was not such a terrible feat after all. Gentleness is the first and most important feature, as regards handling them. Quick, active motions and sudden jars will anger them very much at almost any time. We many times work in the yard all day long without having to resort to smoke to quiet them, still we would not recommend this plan to amateurs, as it requires considerable familiarity with their "business end" to be able to stand without flinching, when by accident of some kind, some half dozen resent your interference. It is not much trouble to start the smoker so as to have it handy in emergencies of this kind. In opening hives, avoid all sudden jars, remove the cloth by turning it back, commencing at one corner or end. If the bees show anger, blow a little smoke on them to drive them down out of the way, and you will soon become so familiar with their temperament as to know just how much they will need of this kind of treatment.

The Length of Life of Worker Bees.—A correspondent in an exchange gives the following on this subject:

I thought I would satisfy myself in regard to the life of the bee in the height of the working season. I had a colony of the little black bees, and on the morning of May 3d I killed the queen, and by carefully looking through their hive I found one black drone and destroyed that in the evening of the same day. I put in a cell for a yellow queen on the 2d of June. She was hatched out and there were a few yellow bees in the hive on the 30th, just 21 days from the time the eggs were deposited. On the 7th of July a few yellow bees were to be seen playing around the hive, and on the 13th of July, just 14 days from the time the yellow bees were hatched out, a few were seen at work with the black bees. Now any one can see that if the yellow bees hatched in 21 days the last black bees were all out by the 30th of June, and if the yellow bees went to work on the 12th of July, the last of the black bees must have gone to work on the 4th of July, making 14 days from the time they were hatched, unless one will go to work sooner than the other. This colony contained nothing but black bees, when the black queen was destroyed; on the 18th of July just 49 days from the time the black queen was destroyed, there was not a black bee to be seen about the hive. I opened it, and not one was to be seen inside. I know that the bees will live longer at other seasons of the year, and I thought this would be a good chance to test in the height of the working season. The hive was examined every day during the whole time, so that no mistake might be made. From the above it will be seen that the lifetime of a honey bee, in the busiest working season, is but four weeks or 28 days.

CORRESPONDENCE

For the American Bee Journal.

That Long, Long Day with Mr. Clarke.

JAMES HEDDON.

I always read the correspondence department of the BEE JOURNAL with great care. The first column, while not always containing the best matter, seldom or never contains anything but first class. The same we know is true of any column under the name of Wm. F. Clarke. When I see this name and this column both together, and my name thrown in for the subject, I am terribly interested. Then, when I come to a place I "must not read," I cannot read it quick enough, of course.

I am very glad to have been able to deport myself in such a manner as to win the esteem of a man of his ability, and feel compelled to thank him for his eulogistic words. I only regret that I fall so short of the ability he gives me credit for.

Regarding our religious controversy which he touched upon with so much feeling, I sought to be as honest with him upon that subject as upon the topic of apiculture, or as I would be in the discharge of a pecuniary obligation. If I am indebted to you I will not deny it; if I am asked how to successfully winter bees every time, I will frankly say, "I do not know how," if you ask me, "what of another life, where we may extend our pleasant controversies?" I must be honest and say, I do not know. If I have not had evidence that was sufficient to ground any belief either way in my mind, I must be honest and say so. If there is another life, and I find I was in that regard mistaken, I will not have to add dishonesty to my error. Whether there is or is not, it is so by a law in nature, and your opinion or mine will not change it. I have no doubt but that the honest will be as well fitted to enter such an existence as any one, and while here our whole attention and energies are needed in this one, as long as we are so surrounded with mistakes and crime. Right here, while upon this partially out-of-place subject, allow me to say that Mr. Clarke is an exemplary Christian minister, for while he recognizes in others opinions that differ from his own, even upon religious subjects, he fully respects and esteems the honest holder of such opinions. Belonging to the class who teach "Love your enemies," he does not hate his friends, nor those who have not in any way maltreated him. Mr. Clarke has a broad and generous feeling, and, as is usually the case, his Creator is equally broad and generous. These facts make Mr. Clarke a friend to those who honestly differ with him.

But, as ex-editor of the AMERICAN BEE JOURNAL, experimental apiculturist, and correspondent to all the bee papers, I need not say one word in

praise of Mr. Clarke's lively vigor as a contributor. His contributions are those we seize first of all, as the hungry child seizes the cake-plate first at the table. As I have often said, I look upon Mr. Clarke as our poetical contributor—the man whose pen portrays in pictures.

I must confess that I have never before been "looked over" by one who so closely scanned every detail of the apiary. I was not a little surprised at Mr. Clarke's accurate descriptions, and how few the errors made in detailing the same, even to his correct guess that in observing the new-born colony settle down in their new home, I recognized the fulfillment of natural law.

I was glad of the opportunity to convince so candid and intelligent an apiarist as Mr. Clarke, that our crosses between the dark Italians and brown German bees were as gentle as any bees he ever saw; also that they brought in the nectar in a manner excelled by none.

I wish Mr. Clarke, and many other apicultural celebrities, could have been here to see the "long, leather-colored, brown German bees" bring in the basswood honey. They had some reason to be cross when Mr. Clarke was here, though they were not. Basswood is now closed for 1882, and now is the finest opportunity to see these crossed (though not cross) bees dart for the large heads of red clover. O, for 40 acres of sweet clover (mellilot) now, to fill up the gap between basswood and the autumn flowers that come in August and September. The acre we have tells us the true story of what we ought to have.

Long will I remember the long day's visit with Mr. Clarke, and the different opinion I formed of the reverend gentleman from that I had formerly held.

Dowagiac, Mich., July 29, 1882.

For the American Bee Journal.

Sending Queens by Mail to Canada.

S. CORNEIL.

According to our revenue laws, animals imported for improvement of stock are admitted free of duty, but all parcels sent by mail are stamped at the Custom House at the international line (called the outport), directing the postmaster not to deliver the parcels till they are examined by the Collector of Customs as to duty. W. W. Cary & Son recently sent a batch of queens to a Mr. Webster in this county. No doubt they reached his postoffice safely, but the postmaster was obliged to send them to the Custom House at Lindsay for examination, where they remained till they died. If I mistake not, this was the second shipment to the same party lost in the same way, making altogether a loss to Messrs. Cary & Son, of nearly \$20, besides the loss and disappointment to Mr. Webster.

It seems the officials at some of the outports acting on their own better judgment, permit parcels containing queens to pass through the mails without being stamped for examination,

because queens have been repeatedly received here without being so stamped, and have been delivered by the postmaster directly to the consignees. Possibly the packages of queens sent out by A. I. Root may more readily show their contents than those sent out by the Messrs. Cary, which might account for their different treatment at the outports.

If the packages were marked thus, "Bees for Improvement of Stock," probably they would be allowed to pass through without further trouble. A safer way would be for the importer to order his queens to be sent to the postoffice where the nearest Custom House is situated, but bee-keepers are not always posted as to the regulations of Her Majesty's Customs.

If other shippers have sustained loss in this way, it might be well to report the fact to the Hon. L. Wallbridge, Bellville, Ont., who, as President of the Ontario Bee-Keepers Association, would, I am sure, most willingly represent the matter to the Minister of Customs, and ask him to instruct the officers at the outports to allow queens to pass through the mails without being stamped for examination as to duty.

Lindsay, Ont., Aug. 7, 1882.

For the American Bee Journal.

Notes on Honey Plants.

DR. G. L. TINKER.

The first flowers on the golden honey plant appeared July 29th, but it will not reach full bloom before the middle of August. The plants grown from the seeds sown last fall are nearly ready to bloom, but the flower buds on that sown the first of April have not yet appeared, although the plants are nearly as large. The tallest are about 5 feet, so that it seems the plant does not reach its full height the first year. The growth along the river from old roots is now (Aug. 1st) from 5 to 9 feet high; that from the seed being only 2 or 3 feet.

The best time to sow the seed is in the fall or late winter, before the ground ceases to freeze. Only a small portion of the seed sown in May or June will germinate. A quantity of seed was sown on the 2nd of June, 16 days after a few plants came up, which will bloom about Sept. 1st. The seed planted about the 1st of April came up in about a week, not one apparently failing to grow. The plants from seed sent to me by Mr. E. M. Coombs, of Indiana, prove to be identical with those growing here.

I have growing in my garden several kinds of honey plants, the most of them new, including six new kinds, the seed of which I received last fall through the kindness of Mr. J. S. Wood, the Vice-President of the Danish Bee Association. Four out of the six are varieties of the *Scrophularia*, viz: *S. vernalis*, *S. lateriflora*, *S. chrysantha*, and *S. lunciniata*. The two latter have already blossoms. Both secrete nectar freely, but the last is a small plant with procumbent stems, and difficult to cultivate. The *S. chrysantha* is a

vigorous plant, growing about 3 feet high, with a great profusion of flowers, which are a little larger than those of our indigenous figwort. It blooms from the 1st of July to the middle of August. The bees work on it with great relish, it being the first to be visited in the morning, and the last to be abandoned at night. I have counted 12 bees at work upon one plant at a time, about seven being the average number to a plant at work all day. One could well imagine what a roar of buzzing bees on an acre of this plant would make. It may be difficult to propagate, on account of the smallness of the seed. I will carefully test it and report again.

The *S. vernalis* is a large, easily propagated plant, and promises to be a decided acquisition. Its large green pubescent leaves now spread out over the ground a space of two feet for each plant, with a prospect of many flower stems. It is perennial, and will not bloom until another year.

The best method of propagating these plants, which will include the figwort or Simpson honey plant, is to prepare ridges in the fall of the year about 3 inches above the level of the soil, or high enough to shed water, and four feet apart. The seed should be sown in February or March, or before hard freezing weather ceases in late winter. Taking advantage of a thaw, when a drill a half inch deep should be scratched on the ridges and the seed thinly sown and covered. The plants appear later than ordinary weeds, are very small at first, and require care to cultivate, keeping all weeds down. After they are two inches high, they may be thinned out to a foot apart, or they may be transplanted readily by taking the soil with the roots.

From a comparison of many kinds of honey plants, I am led to believe that the most reliable and valuable have tubular flowers. The clovers, golden honey plant, motherwort, catnip, horsemint, teasel, sourwood, button-bush, bonaset, goldenrod, the asters, and the several varieties of the *scrophularia*, of which figwort is one, have all tubular flowers, which prevents speedy evaporation of nectar. On the contrary, there are few really good honey plants having open flowers. Among these the basswood and tulip tree stand first. In the former the nectar is secreted in the cup-shaped divisions of the calyx, which, with the protection of the corolla and stamens, hinders evaporation. The flowers of the tulip tree secrete a large amount of nectar, but, as it is greatly exposed, there is reason to believe that much of it is wasted.

The most open flower that I have seen is that of the spider plant, but it does not secrete a particle of nectar after 8 o'clock a.m., or if it does, it is all lost by evaporation. The flower opens about 5 p.m., and secretes nectar very rapidly. The bees then begin work, but darkness soon overtakes them. By morning a large drop can be seen in every flower, which if not taken by the bees soon disappears. Only about 4 hours of the day are available to the bees to work on this

plant. Although the drop of nectar is large, a very much larger quantity is secreted in the capacious flowers of the *Scrophularia chrysantha* and figwort, which form nectar continually night and day, but most freely when the sun shines.

The cloome, which is related to the spider plant, is a fair honey plant, the nectar being protected by a little bract upon the upper side of the stamens; but it is available to flies, ants, bugs, and bees almost without number. No other flower except the basswood is so pestered by all kinds of insects.

The mustards, including rape, the milkweeds, mignonette and buckwheat have all open flowers, and it is indisputable that this class of plants most often fails to supply nectar in any great amount. The most reliable honey plant, therefore, the one best calculated by nature for the honey bee is supplied with tubular flowers or with a corolla the divisions of which approximate in the form of a tube, as in the flowers of the white and sweet clover and locust, although the flower of the red clover is a perfect tube nearly one half inch long on the average.

The cultivation of annual honey plants, unless for some purpose other than their nectar, will scarcely pay the cost of yearly cultivation. But a good perennial can be made to pay a reasonable percentage on the value of the land to the bee-keeper. The perennial plants of this class that can be especially commended, are the motherwort, catnip, golden honey plant, and figwort. The three former being readily propagated, and able to contest the ground with any kind of weeds. The figwort, however, if well cared for the first season will hold its own afterwards. The most vigorous of all is the golden honey plant, the only trouble with it being that it takes a strong team and a good plow to turn a field of it under, when a crop of corn will eradicate it.

New Philadelphia, O.

For the American Bee Journal.

How I Extract Honey from Combs.

EUGENE SECOR.

I do not follow bee-keeping as a sole business, and am not trying to run a large apiary. I have only 19 colonies at present. I keep bees for the pleasure I find in pursuing the study, as well as for the profit there is in it; though for several years past I have made them pay a large interest on the investment. I am running some for comb honey, in sections, and the remainder for extracted honey, in two story hives. I keep a complete record of each colony, and by the method I pursue it is very easy to do so. On the top of each hive I keep a card with a memorandum of everything which is of interest.

When I wish to extract I take an empty hive, remove the cap of the hive from which I wish to extract (which is flat on top), and put the empty hive on it, raise the honey board (which is the old-fashioned

style, made of inch lumber), smoke the bees to drive as many as possible down into the brood-chamber, take out the frames of honey one by one, brushing off the bees with a bunch of asparagus tops, and place them in the empty hive. When this is done, I carry the honey into the cellar and put the hive on the scales, which are near the extractor, balance them, extract, and return the empty frames to the hive, balance again, and I learn the weight of the honey from that colony with but little trouble.

In a large apiary it might not be practicable to carry the honey into a building to extract, but I find it satisfactory, as it never excites robbers, and everything, except the honey I am getting, is stationary.

My extractor is a home-made affair, of my own design and manufacture, and although it has been in use for five or six years, it still works like a charm. I took the half of a molasses barrel, made a reel large enough to accommodate two frames, and got the motion by two horizontal wheels, one on the standard of the reel and the other fastened to the outside of the tub and connected by a band of twisted cord. The wheels are made of inch lumber slightly grooved, and one twice the diameter of the other. A peg in the large one answers for a crank. To keep the band from slipping, I wind it with smaller cord. The whole thing did not cost a dollar beside the "head-work."

Forest City, Iowa.

For the American Bee Journal.

Cultivation of Simpson Honey Plant.

J. G. STEER.

I see in the last number of the BEE JOURNAL a call for information on the cultivation of the Simpson honey plant. I beg leave to give a few notes through the columns of your excellent paper on the subject. My experience with it extends only through this season and last. I procured the seed and sowed in a bed of wood-earth very late—about the first of June. They came up poorly, but I got 200 set out, which blossomed in September and October, until after we had 2 or 3 severe frosts. Last spring they were the first living green to be seen. I took up the roots, some of which would not go in a half bushel, and divided them with a knife into as many sections as there were crowns started, sometimes as many as eight or ten. These I planted singly in rows 2 or 2½ feet high.

The idea is abroad that the Simpson honey plant is hard to propagate; I have not found it so. They need shade, and not too much water, as they will rot if too thick in the bed. The way I practice is this: If you have a small corner of timber land not too dense, clear it up and trim the trees up quite high, dig and level the ground and sow the seed thinly, and cover very lightly; reset them when 2 or three inches high, in rows 2 feet apart, and one foot in the row. If it is not seasonable, water and

shade them at first by means of a board laid on bricks over them. This all seems like a great deal of trouble, but after you get a start you can propagate more easily from the roots as above directed. Carefully save all your seed, and scatter it in all waste places, especially among trees if the shade be not too dense. Enough will grow and ripen—seed that will fall and come up thickly the next year, when you can set the plants out or let them grow where they are; when once started, they will care for themselves. I have briefly told you my plan of cultivation, or rather, propagation, for it will need no cultivation after the first year.

I will speak briefly of its qualities: It is a weed, but not pernicious. It began blooming here the first week in July, and for profusion of bloom I never saw anything like it. I have seen hundreds of bees on it, when not one was to be seen on the clover. It secretes honey constantly in wet or dry weather, and in such abundance that I have shaken it from the flower in drops. The rain does not affect it, as the flower hangs down, which is not the case with the spider plant. I have even found bees on it when it was raining too hard to be out-doors. In short, I consider it the very best honey plant grown, and do not mean to stop short of 10 acres of it. I shall not sow it on valuable ground, but think it will well pay to clear and trim up an acre of timber land each spring, and sow it, and, besides, it helps the appearance of things. I hope to hear from others on the subject of planting for honey, especially figwort.

For the American Bee Journal.

The Honey Harvest.

W. S. HART.

To help the editor to form an opinion of this year's crop of the United States, as soon as possible, I will say we had the poorest spring for bees within the memory of the oldest inhabitants, as a long continued drouth prevented all swarming, and in many cases so reduced the honey in the hives that feeding was necessary. In May, however, the dry spell "let up," and since then the bees have been doing well. Old ocean itself must lower several feet before our mangrove feels the effect of dry weather. Bees have been swarming for some weeks past, and I for one have lost quite a number of rousing swarms that would have largely increased my honey report, if retained. It is a new experience with me to have them come out and go to the woods, but my assistant was called away by the sickness of his wife, and I was left at the busy season without skilled help, and three small orange groves to see to besides my bees. I have, however, from 65 colonies on May 1st, taken about 6,800 lbs of honey, and expect to make it over 11,000 by the 10th of August. There is, probably, 2,500 lbs now in the hives ready for extracting. My neighbors' bees are doing splen-

didly, but I understand that away from where the mangrove grows, they have not done as well. The cabbage palmetto is now in bloom, so that the bees of the interior that have not already had a good harvest will have a chance to make a paying crop yet.

New Smyrna, Fla., July 28, 1882.

The Common Sense Bee Hive.

G. W. DEMAREE.

Mr. Warran Clayton, a gentleman formerly residing at this place, but now a resident of Georgetown, Scott County, Ky., being on a visit to his mother, who lives near neighbor to us, has just handed me the enclosed circular. He informs me that a certain party is working up this "patent hive" in Scott County, and that the people are going "wild over it." I regret to see this delusion on the part of so intelligent a people as I know the people of Scott County to be. Kentucky is destined to be one of the great honey-producing States. Her medium climate, neither too cold nor too hot, her rapid conversion into a great stock-breeding and grazing State, her mountains, rivers, creeks and brooks, her wonderful virgin forests covering her mountains and hills, and skirting her rivers and streams, abundantly justify the prediction.

The working up of delusive "patent hives" is not to the best interest of bee culture. The exaggerations indulged in by the venders of "common sense" or rather "common nonsense" hives, is sure to result in disappointment and disgust on the part of those who for the want of information suffer themselves to be imposed upon by designing sharps. The BEE JOURNAL is the acknowledged exponent of American Apiculture, hence its opinions coming from the pen of its widely known Editor, is of more weight than if coming from any private source. I would be pleased if the Editor would discuss the essential feature of the movable frame hive system—showing that all the appliances of modern bee-keeping can be attached and accommodated to any of the standard frame hives. That the system of honey-producing—"side" and "top" storing—may be followed while using any of the movable frame hives.

Christiansburg, Ky.

[We have never seen one of the "common sense hives," but would judge from the descriptive cut on the circular kindly sent us by Mr. Demaree, that it is virtually the Mitchell hive, with hinges at one side of the bottom, and a sliding cover. With these exceptions, its counterparts have long been in use in the Buckeye hive, Mitchell hive, long-idea hive, and various others of the one-story hives, where division-boards or followers are used for contracting the brood chamber. We see no features or benefits

to be derived from its use that cannot be obtained from any of the non-patented movable frame hives, while there are two serious objections to its use—first of which is the restriction upon its general use, in the form of a patent right, and the next objection is the sliding cover. We cannot imagine how this latter feature can be made anything but objectionable.

We do not object to patents on articles which have commendable features about them—when the principle is new or a philosophical or mechanical principle applied to machinery or implements, making real, radical improvements; but the adoption of an old, or, as is often the case, obsolete principle, with a slight divergence from the original, and the issuance of a patent deed to dignify it as an *improvement*, or as an indorsement of its originality, is to that extent legalizing a fraud, and should not be countenanced. The circular devotes about half a page to "reasons why this hive is the best in use," but fails to describe the particular features which make it such. We would advise our friends in Kentucky to "severely let it alone," as also all other hives which have no real merit on which to base a patent, but which are hampered with one to prevent their coming into general use. What we want in America is not more patents on bee hives, but more unanimity in the use of a standard hive, simple in construction and free for all to manufacture and use.—ED.]

For the American Bee Journal.

Increase of Colonies.

A. J. NORRIS.

After reading Prof. Cook's valuable hints on increase of colonies, on page 474 of the BEE JOURNAL, I would like to give my ideas on the same subject.

1st. By all means I prefer natural swarms.

2d. Keep the bees from swarming as long as possible by giving plenty of room for queen and bees; they will give a nice lot of beautiful early honey and a very large swarm by so keeping them back.

3d. When they do swarm, run the first swarm in a nail keg or box, and keep this until a second swarm issues; now have a hive ready with 10 frames (if you use the Langstrath hive) of foundation, or empty combs, and 48 sections filled with foundation; go to the hive where the second swarm has issued and take one comb of larve and exchange with one frame in the new hive. This will keep the queen in her proper place. Put the new hive where the keg or box containing the first swarm stood, and shake them out of

the keg or box in front of the hive and capture the queen if possible, as they go in; if not, get the queen from the second swarm, which you will now shake down in front of the same hive, return the queen captured to the hive from whence she came, after cutting out all the queen cells. Now you have only one queenless colony, and that will have a queen in 24 hours, 10 beautiful combs which the queen has commenced to fill, and 48 sections under headway. Now take the colony that is deprived of a queen and make 8 or 9 nuclei, selecting the largest and finest developed queen cells. These nuclei can be used to supply queens for later swarms.

My method of transferring is as follows: Have a hive prepared with 10 frames of foundation, drum up the swarm that is to be transferred (as has been described many times in the BEE JOURNAL), and shake them in front of the new hive; if more than one is to be transferred, serve them the same way; now let the old hives stand 14 days and drum up the bees that have hatched in all the old hives, and run them into new hives prepared as for new swarms; run as many in a hive as it will hold with the 48 sections on. Now open the old hives and cut out the honey and what worker brood there is left; fit the worker brood into frames if you have no queen to supply, fit in a choice queen cell, and give each multiplied colony only one frame of this patched brood and a queen cell; if there is any left, give it to the weaker colonies. If properly attended to, you will have no more increase from them. The best time for transferring is just at the beginning of white clover bloom, or at the beginning of any honey flow, when not cold enough to chill the brood or too late in the fall.

For the American Bee Journal.

The Utility of Untested Queens.

W. Z. HUTCHINSON.

FRIEND NEWMAN:—Has my reply to Prof. Cook in the *Rural New Yorker* of June 24th escaped your notice? or has a press of other matter prevented you from publishing it? It is as follows:

First allow me to thank Prof. Cook for his kind words in a late article in the *Rural* on the above subject; they are fully appreciated. When an argument is so conducted that at its close each party has a higher opinion of his opponent, there is but little chance for hard feelings; if every one was like Prof. Cook, all arguments would be so conducted.

The only point that I endeavored to make in my former article, and the one that I have so persistently argued in the bee papers during the past few months, is that an unjust discrimination is made by some writers in favor of the so-called "tested" queens, when the only difference under the sun between them and the so-called "dollar" queens is, that the tested queens are known to be purely mated.

while, until the progeny of a "dollar" queen hatches, it is uncertain how she has mated; but in nine cases out of ten, "dollar" queens turn out to be purely mated, and thus are eventually tested queens. As before stated, both classes of queens are reared exactly alike, and yet column after column of our bee papers have been devoted to the condemnation of "dollar" queens and not one word has been said against the tested queens. Tested for what? Tested for "stripes" and—\$2: "only this and nothing more." Does not Prof. Cook think that the rearing and selling of tested queens for \$2, or even \$3, have cheapened queens fully as much as the "dollar" queen traffic?

As to how a queen should be tested, Prof. Cook says: "I would have him wait to see if the requisite number of eggs, bees, and pounds of honey are forthcoming, and then, when such assurance was gained, I would pay him \$10 for the queen and make money." I heartily agree with him, but I fail to see how or why the "dollar queen traffic" prevents any breeder from testing his queens in this manner and then asking a corresponding price for them. In fact, some breeders have already taken a step in this direction, as they offer for sale "dollar" queens, "purely mated" queens, "tested" queens, and "selected tested" queens. If some reliable breeder will keep his queens until they are a year old and test them thoroughly, I do not think that he will experience any difficulty in selling his "selected tested" queens at almost any reasonable price.

Prof. Cook says: "Does Mr. H. think that our Short-horn cattle would possess their present excellencies had there been no greater inducements to hard and persistent effort than that held out to the bee-breeders of today?" Candidly, friend C., I do not, and until the mating of our queen bees can be as easily controlled as the mating of cattle, sheep and other stock, I do not think that there will ever be any greater inducements held out to the bee-breeders to improve their bees than there are at present, even if the "dollar queen traffic" should be swept away. There is some inducement to buy, even at enormous prices, improved breeds of cattle, sheep and horses, because, with ordinary care, the offspring of such stock will be pure, and will, likewise, command a high price; but there is no such inducement to the purchase of an improved strain of bees, because, even with the greatest care, the young queens may mate with drones from some scrub swarms in the woods.

I do not wish to be understood as saying that there are no inducements to the purchasing of improved strains of bees; far from it. The inducements are many, but they are not so great or so many as to the purchasing of stock the breeding of which can be controlled. To a certain extent, of course, the mating of queens can be controlled; we can Italianize all of the bees in the vicinity of our apiary, but to have each stock within three or four miles produce number one drones,

would be an almost herculean task. When fertilization in confinement, or something of the sort, is made practicable, then, I doubt not, there will be plenty of breeders who will set to work and will succeed in producing a superior strain of bees. At present, however, in order to obtain positive results and know how they were obtained, so that it can be done again and again; it is necessary to adopt the plan put in practice by Mr. D. A. Jones—that of breeding bees upon isolated islands.

No one would be more pleased than myself to see an improvement in our bees. I try to be unprejudiced in the matter, but to me it appears that the rearing and selling of "dollar" queens does not "retard the progress of American apiculture," or stand in the way of the best achievements; any more than the rearing and selling of native cattle, sheep and horses prevent or hinder the development, breeding and dissemination of improved breeds of these animals. Instead of being a damage, I think that dollar queens have been a benefit and a blessing to apiculture. Thousands now have the peaceable, industrious and beautiful Italians, who would yet have the native bees had the prices of Italian queens been kept at a high figure, while any breeder is free to improve his bees as much as he pleases, and if he succeeds in producing a superior strain, he need have no fears but what he can sell his queens at a high price.

Rogersville, Genesee Co., Mich.

For the American Bee Journal.

Dunham vs. Given Foundation.

J. V. CALDWELL.

The comparative merits of the different styles of comb foundation now offered by different manufacturers is worthy of the most earnest and careful attention of the apiarists of this country. That there is a decided difference, does not admit of a doubt, but which is the best? That is the important point to be decided by the average bee-keeper.

I have taken as my subject this evening two of the popular makes. The Dunham machine is, to me, like an old and tried friend, and the longer I use it, the better I am satisfied with the product of its matchless rolls. My brother apiarist, Mr. Heddon, thinks first class foundation cannot be made on this machine without a large amount of trouble and vexation of spirit. Well, in all deference to his longer experience with foundation machines, I must say I can and do make first class foundation on this machine, and work also that satisfies a large and most fastidious class of customers. Mr. Heddon claims for the Given machine, a thin septum, and large, deep, but soft outlines, and that the bees manipulated it much quicker than the rolled foundation. Well, as the "test of the pudding is in the eating, let us see how the matter stands. He says: "Hive a prime swarm on 8 frames of the Given

wired foundation, and in 48 hours, you have 8 splendid combs completed." This I grant, but I have repeatedly this season hived full, strong swarms on a set of 11 frames, 8x19, filled with Dunham foundation, and in 3 days it would be filled with comb and honey, and every comb drawn out in a perfect manner, and with no sagging whatever, but to accomplish this, three things are necessary:

1st. The foundation must be made of good, tough wax.

2d. It must be fastened to the frame in the most perfect manner.

3d. It must (in my opinion) be made on the Dunham foundation machine.

Now, if there is a better machine made I want it, and my customers also will demand it, but I venture the assertion that where I pound of the Given is made and sold, 100 pounds of the Dunham is disposed of in like manner; but I think the real cause of Mr. Heddon's discarding the Dunham machine was his inability to make it do good and speedy work. I gave in my last article a fair statement of the amount of good work I could do on the Dunham machine, and Mr. Heddon gave a partial account of his work on the Given machine. He says he made 271 sheets with one lubrication of the book, but I would be pleased to know the size of the sheets and the amount of time he used in doing the work. Of course, we want only the best foundation to use in our apiaries, then let us in a friendly spirit bring out all the good points in this important branch of our business.

Cambridge, Ill., Aug. 8, 1881.

For the American Bee Journal.

How to Exhibit at the Fair.

J. H. MARTIN.

As I have had some experience in exhibiting my products at our county fairs, I will give a few hints for the benefit of those who are now preparing for such an exhibit.

We all have a little selfish motive in the display of our articles. If we manufacture bee-fixtures, we wish to extend our trade; if we sell honey, our object is to let people know where the genuine article can be found.

The summer of 1879 was a very good honey season with us, our 100 colonies averaged nearly 100 lbs. each, our best gave us 208 lbs. of extracted, and our best yield of comb honey was 106 lbs. This was the best yield of honey that any one had ever obtained in this county. We felt like bragging a little, and the bragging took the form of an exhibit at our County Fair. The exhibitor generally wishes to make as much of a spread as possible. It is, therefore, well to put your honey in small packages. We put up our 208 lbs. in pint fruit jars, and put six jars in a neat basswood crate. The crate was made so as to hold the top and bottom of the jar firmly, while the sides were open, giving a good view of the honey when the whole was piled up crate upon crate in pyramidal form.

Our comb honey was also put up in narrow crates of different lengths, with glass sides. In placing such an exhibit, it is a good plan to get before a window if possible. Your liquid honey will then show to good advantage. All of the honey should be carefully graded, basswood, clover and buckwheat. A few jars of each kind should be opened, and a few teaspoons in readiness to let those who desire test the different qualities of honey. Much can thus be accomplished toward educating people in relation to the taste of honey from different plants.

By the side of the honey exhibit should be the wax exhibit. The wax should be run in cakes of different size and shape. Our pile of wax was finished out with a sharp-pointed cone, with two small flags attached to it. Foundation in sheets, thick and thin, in wired frames, in sections, in long narrow ribbons looped up, and in various colors if you choose. A pretty centre for your wax exhibit is a beautiful wax cross and clinging vine.

It is needless to advise the exhibition of a foundation machine, extractor, knives, queen cages, etc., for these are the first things the bee-keeper usually thinks of, and will have a prominent place.

Finally, the observatory hive should be upon exhibition, and where the crowd can easily see it. We have seen several descriptions in the bee papers of late about such hives; but there is one point in my hive unlike any we have seen described, I will therefore tell how I make an observatory hive. My first hive was made to be placed upon a shelf, and if a person wished to look at the bees and queen the hive was passed around. Such a hive is in danger of being tipped over, or the glass smashed. I therefore improved my hive by placing a two inch block under the centre of the hive, in this was bored an inch hole; another board was provided with a peg two inches in length to fit this hole. This board was securely screwed to the shelf. The hive could thus be turned readily upon its centre, and it was placed where the crowd could stick their noses right against the glass. That hive was a success. There was a crowd of old and young around it all of the exhibition hours to see the queen bee. I have seen many a pair of spectacles adjusted to get a good view of her. The observer would then go off at a tearing rate to hunt up somebody else on purpose to see the queen bee.

An observatory hive should not be crowded too full of bees; just enough to cover the comb. It is a good plan to adjust the bees to the comb before you leave home. A comb at least a year old should be selected, with some sealed honey, plenty of empty cells, and perhaps, a little hatching brood. If you get a sensible queen in the hive, she will deposit eggs right before folks, and you will then have a clinching argument for those who do not believe there is a queen, or that one bee lays all of the eggs.

I think the above plan for an exhibit, with as much more as you wish to add, will give ample room for

almost any bee keeper to spread himself. Above all, do not attempt too much. Exhibiting bees on the wing will not work at a common county fair. We attempted too much once on a time, and made a failure of it.

One more point: insist on having your exhibit all together in one place. At some fairs your hive would be put in class 8, division 4, your honey in class 2, division 6. To divide your exhibit up in this way would destroy its utility and charm entirely. See the managers of the fairs several days beforehand, explain just what you want and how much room you want; get your location, and be on hand early in the morning on the first day of the fair. If the managers do not give you a good space, or if they go back on you, as they do sometimes, do not exhibit a thing at their fair, and if anybody tries to crowd you out of your space, or crowd on at each end, you can first remonstrate, then reason, and if that don't keep them off, then fight.

I could give several more items in relation to this subject, but I must save a little of my ammunition for a few of the other bee papers. I did think of writing my experiences all out for the BEE JOURNAL, then do as some of our eminent friends do, commence at the last paragraph and write back to the beginning and send it to *Gleanings*; then commence in the middle and write both ways and send it to the *Exchange*; then go over it diagonally for the *Magazine*, then take it on the bias for the *Instructor*, and so forth.

Hartford, N. Y., Aug. 9, 1882.

The National Convention.

We have received from Prof. Cook the following circular relating to the above convention. We greatly regret we shall not be able to attend, but circumstances beyond our control will make our absence imperative. We regret it more especially, as this will be a most interesting meeting:

The next meeting of the National Bee-keepers' Association promises to be a grand success. Such men as D. A. Jones, A. I. Root, James Heddon, O. O. Poppleton and Dr. J. P. H. Brown have promised attendance.

It is expected that the Association will visit in a body, the apiary of Mr. Hill, of Mount Pleasant, which is one of the best conducted in the States.

Mr. D. A. Jones will exhibit specimens of the bees of the Indies, including the famous *Apis dorsata*.

There will also be exhibited at each intermission, microscopic preparations, showing structure of the sting, mouth-parts, etc., and of the so-called dry feces of bees.

Let some bee-keeper of each leading city look after railroad rates. It will be the last week of the great Cincinnati Exposition. This is a great attraction, and will make it easy to secure reduced rates. Round trip tickets from Detroit are promised for \$5.

A. J. Cook, *President*.

SELECTIONS FROM OUR LETTER BOX

Foul Brood.—Bees have done very well here this season, so far. White clover has yielded good until about the first of August. On 10 swarms (spring count) and increase, I have put 725 one pound sections, and taken off 300, while the rest are from $\frac{1}{2}$ to $\frac{3}{4}$ full now, and 4 swarms went to the woods that I know of. I do not know how many more, as I have not watched them while swarming. My bees have had foul brood 4 years. Four years ago last May I spread the brood and inserted empty combs until the bees deserted one side, and cold weather coming on chilled it, and in a few weeks it was the foulest hive I ever saw, and the bees dwindled entirely away in 2 or 3 weeks more. The next two seasons were poor for honey, and the disease damaged them about 25 per cent. Last season and this being both good for honey, it has not damaged them more than 10 per cent. They are strong now and doing well, though I can see a little in every hive from the larvae just beginning to melt down with it to the capped, perforated cells. I am thinking of brimstoning them this fall, and buying a new lot. Do you think I can keep them in the cellar where I did the others, and put them on the same ground without their getting it? I would like to know the experience of others who have kept foul brood several years.

E. W. FELTON.

Hastings, Minn., Aug. 5, 1882.

[We believe the cellar can be fumigated and disinfected so it will be safe to keep the bees there, but we doubt using the same stands and grounds, unless the winter be very severe.—ED.]

Customs Duties.—I purchased one of Mr. Jones' colonies of best Italian bees, which I received on the 30th of May. I had a good, strong swarm July 3d, which I had to put into a hive of empty frames, having written to Mr. Jones, as I thought, in good time for foundation, but as I learned since, he was too busy to attend to it in time, but I have received it since. I got a second swarm on the 11th, not so large as the first, still, I think, doing nicely, so I am now rejoicing over three good colonies of Italians. I am not boasting of having done anything great, neither do I feel capable of anything like that yet. I read of some who have had a shorter practice, outstripping me wonderfully; however, I take courage and go on in my own feeble way, and I do not know of anything that I could delight more in than working among bees. For the second swarm, I took a few of the best out of some old combs that I had by me, and fitted them into the frames the best way I could, by pegging them in, which the bees have fastened. I took a full

frame of honey from No. 1, and put into No. 3, for I have numbered them by making the figures 1, 2, 3, and gummed them on the hives in order, and as Nos. 1 and 2 are pretty strong in bees, I have taken two more frames to-day from No. 1, having both honey and brood, and put them into No. 3 to strengthen them in preparation for winter, and placed in No. 1 frames of foundation. I state this by way of inquiry, as to whether I have done right, or could have done better in some other way? I see but very few drones indeed; neither do I see any drone cells in any of the combs. I cannot say whether the queen of No. 3 has been mated or not, but a short time will tell. Will you please give me such information as you consider necessary on this subject, supposing it to be the case? I see in the present volume of the BEE JOURNAL, in answer to an inquiry whether there is any customs on "Bees and Honey sent to Canada." I think it is, and the answer is, there is not. I got that work from you, and was charged 15 cents customs, the book being valued about 30 cents. That makes the price pretty high. I find the BEE JOURNAL and "Bees and Honey" choice companions, real necessities; to possess and use them is to enjoy the beauties of nature.

EDWARD MOORE.

Barrie, Ont., July 21, 1882.

[You did well in building up your third swarm from the two stronger. The queen with the last will have no trouble in mating, as the bees with an instinct almost equal to inspiration, provide for these contingencies.

There should have been no duty demanded on the book. When works are sent singly, either by mail or express, to actual readers, and not for traffic, they are not liable to customs duties.—ED.]

Good Season in Utah.—The prospect of a booming harvest for the bee-men of this county are beginning to be realized. There has not been a better year for the development and the true worth of the bee to be made known than the present year, although we have had some very cold storms that have kept the bees from doing many times what they desired to do. Out of 16 bee-keepers this spring, with 77 colonies of bees (5 having died since T. W. Lee reported to the Convention in Salt Lake City, April 6th), we now have 171 colonies, and 20 bee-keepers. The yield of honey I am not able to give at present; 3 swarms took to the mountains, and these swarms belonged to some of our old hands at the business. The honey yield would be much greater if we had more extractors, only 8 being in this settlement, and 20 should be the number, as those that have them cannot very well spare them around. I think the motto of Prof. Cook, "keep your colonies strong" is a good one, as I have done it in 2 colonies, and have taken 30 lbs. of honey from each top story of the 2 hives every week for the past 3 weeks.

I find the bees in some of my colonies are killing off drones as they get stronger. Our honey yield is not over yet, as we have plenty of lucerne, clover, corn, squash, flowers, etc. Sweet clover we also have, but it is going all over our field, and would be better without it if not controlled better. Would it be wisdom to use old comb that was in hives which were infected with dysentery? Would it not be better to melt the comb?

JOHN DUNN.

Tooele City, Utah, July 27, 1882.

[We cannot recommend using old combs where the bees have died from any cause; nor would we use moldy combs, except singly, and then only in very strong colonies, where they can be cleaned up thoroughly in two or three hours.—ED.]

A Honey Plant.—I send a honey plant for name, the last in bloom, and a profuse honey plant the first half of the season. We are having a dearth of honey-producing plants. Corn is just coming in tassel. J. D. ENAS.

Napa, Cal., July 19, 1882.

[The honey plant is *Heteromeles arbutifolia*, for which I know no common name. It belongs to the *Rosaceæ*, or rose family, and was formerly put by some botanists in the genus *Crataegus* or Hawthorns. We shall not, therefore, be surprised to learn of its attraction for bees, though its kindred with us do not retain long these attractions. The species is, so far as I know, confined to our western coast, except as it has been disseminated by man. It is esteemed worthy of cultivation as an ornamental shrub, but is not hardy in this latitude, east of the mountains. Its immediate relatives are natives of China and Japan, none of which bear out-of-door exposure with us.—T. J. BURRILL.]

Width of Sections.—An article appeared in No. 19, page 297, of the BEE JOURNAL, in regard to the use of $1\frac{1}{2}$ inch sections. Another in No. 29, page 456, entitled, "Width of sections, etc." This is a very interesting subject to me, and must be to all beginners, and I would like to hear the opinions of others on this point, for if we can get $\frac{1}{2}$ more honey without the expense and inconvenience of separators, and gain $\frac{1}{2}$ in space, it is a gain and saving worth looking after.

A BEGINNER.

Syracuse, N. Y., Aug. 7, 1882.

All Swarms and No Honey.—Bees in this locality have done nothing this summer. All swarms and no honey this far. Italians are working finely now, and will gather some surplus honey. I think we will have a splendid fall harvest, on account of the recent wet weather.

WM. HARTMAN.

New Harmony, Ind., Aug. 7, 1882.

Cleaning Wax Extractors.—This has been a very poor season for bee-keepers here. In the spring it was too cool for queen rearing; later, came almost continuous rain, bees losing fruit bloom. White clover blossomed, but yielded little nectar. Of basswood we have none worth mentioning. We shall have a few swarms, but little surplus honey for the year of 1882. Please tell in the BEE JOURNAL how to clean the basket of a wax extractor. W. R. YOUNG.

Myersville, Md., July 31, 1882.

[Perhaps the most convenient method is to immerse the basket in boiling water, when the wax will melt from it, and can be skimmed from the water when cool; or it can be wiped off by taking from the water and rubbed while hot. A strong solution of sal soda or benzine is said to remove the wax very readily by dissolving it, when it can be wiped off with a coarse cloth.—ED.]

My Report to Date.—From 10 colonies, spring count, I have had 300 lbs. of comb honey, 100 lbs. of extracted, with an increase of 9 colonies. I may say that all of this honey was obtained from poplar bloom, in May; since that time the bees have been barely making a living. White clover was scarce and did not yield much nectar. Last fall in September we had a yield of honey from some source unknown sufficient to winter on. What may be expected this fall I cannot say. Taking it altogether, the season has been unpropitious. My smoker trade has helped me out of the drag very materially and I am in no wise discouraged. As I cannot do without the "JOURNAL" I herewith remit my subscription money.

W. C. R. KEMP.

Orleans, Ind., Aug. 9, 1882.

"Apis Mellifica."—Tell Mr. James Heddon to use a large dose of "aqua frumenti distilatum" just before going into his bee yard, and that it will not kill him; one poison kills another, just as quina to cinchonism cures malaria, or whisky, snake bite. I am no whisky head either. The honey season is over here. The bees are hanging out and lying around, nothing to do. Aster and the fall weed bloom will be in now in 10 days, then we'll have business.

J. A. BURROW, M. D.

Santa Fe, Tenn., Aug. 7, 1882.

Sweet Clover the Only Hope.—It is now very dry in this vicinity. White clover and linden are with the things that were, and if it was not for the sweet clover, bees would be idle. Still, they keep up their hum of rejoicing from sunrise until dusk, bringing load after load of transparent nectar, that God, in his allwise providence, causes to be secreted in the bloom of melilot or sweet clover.

H. W. GARRETT.

Coeyman's Hollow, N. Y., Aug. 7.

Dividing and Introducing.—Having received an Italian queen by mail, I opened a strong colony of blacks, hunted up the black queen and set the frame she was on in a new hive, placing alongside of it another frame of honey and capped brood, with adhering bees from the same hive. I then filled up the new hive (which contained the black queen) with frames of foundation, and placed it on the old stand. I next moved the old hive from which the black queen had been taken, to a new stand a short distance away, opened it and caged the Italian queen on a frame of honey and capped brood. She was released after 48 hours and moved about among her young subjects. The old bees by this time had apparently all left the hive and gone back to the old stand and joined their old queen. I examined the hive containing the yellow queen daily, and found the combs covered thickly with young bees, which were constantly emerging from their cells, but for two weeks scarcely any bees have appeared at the entrance of the hive, or gone out in quest of stores. A limited number are beginning work from the Italian queen's hive, while the hive where the old black is ruling seems as busy and populous as originally. The question is, was my practice the correct one? or, if not, how should it have been bettered? E.

Highlands, N. C., July 29, 1882.

[Your practice was quite right, as far as safety goes, but a little troublesome. You have seen but little work from the colony where the Italian queen was placed, because you depleted it entirely of field workers, and the young bees left were all engaged in nursing and brood-rearing.—ED.]

Fertile Worker.—Mr. Osborn's letter in the BEE JOURNAL of the 17th ult., describes this bee similar to a case we had last fall. We found a queenless colony with a fertile worker. There was no brood in the hive except a few capped drones and three large queen cells attached to drone comb. On examination, we found the queens all dead. They had evidently lived until within a day or two of hatching. From all appearance, they were as well-developed queens of their age as I ever saw. What caused them to die has remained a mystery. It being too late in the season to rear a queen, we purchased a Cyprian queen. The bees kindly received her. She is now filling her third hive by natural swarming this summer. M. BROTHERS.

Fineastle, Ind., Aug. 2, 1882.

Ground is Baked like a Brick.—Our harvest of white honey is over, with but small surplus. Fearful hot and dry, and owing to the extreme wet previous to July 10th, the ground is baked like a brick, and vegetation is drying up. I do not expect any honey from buckwheat, on account of drouth. G. M. DOOLITTLE.

Borodino, N. Y., Aug. 7, 1882.

Mr. Shuck's Problem.—I see a reply to Mr. Shuck's problem, which I believe to be incorrect, as I divided several colonies, which had the effect of giving them dysentery. The first I only noticed after three days, being absent for that time, but two others had the entrances debauched within one-half hour from the time of dividing. My bees, as yet mostly blacks, have the last few days been working on red clover. Allow me to widely differ from Mr. Heddon in his way of transferring. In the spring brood would be apt to chill, and they would be apt to be robbed then and later. I know of one man who tried the plan on the 24th inst., and a colony of Italians drained the old box of honey in a few hours. Basswood is just opening, and the trees are covered with bloom. So far there is nothing to crow about.

R. F. HOLTERRMANN.

Fisherville, Ont., July 27, 1882.

[There is no need to drive so close as to risk chilling, and a very little trouble will avoid the danger of robbing for a few days, when new bees will be numerous enough to take care of the stores. It seldom, however, occurs that transfers will be made by this method when the weather is cold enough to endanger chilling, as it can be done as well during a honey flow as at any other time; whereas, by the old method, it is desirable to do so before there is a great deal of brood and not much new honey.—ED.]

Juneau County, Wis.—One thing sure, we are happy with our bees for there is generally an abundant flow of the nectar in this region to support the bees and to produce from a little to a fair yield of surplus honey. For many seasons I have never failed to see the bee-keepers about the villages with their little boxes of honey for sale, and they never had much trouble in getting them off their hands. But, under the old management, and from the pressure of other duties, the yearly honey crop was always light, and there might have been times when little or no honey could have been bought within the limits of this county. A change has come over this business, so that under what is styled modern bee-culture, the production of honey has been prodigiously increased here until there are many tons of the precious sweet gathered in annually and put in the most desirable shape for the market and the consumer, and what cannot be disposed of in the local markets, is shipped to other parts of the world. But, happily there is a growing demand for the article at home, and the local market is being well supplied from the apiaries of the Hon. C. H. Grote, the Rev. H. V. Train and Mr. Franklin Wilcox, gentlemen who stand among the most learned, and at the same time most practical bee-men of Juneau County. They manage to keep their bees through the long and dreary winters,

which are quite frequently very cold in this latitude, although the last winter was a very mild and pleasant one, favorable to the safe wintering of bees. But with the first of March there came cool and gloomy days, clouds were hanging overhead in a threatening manner the whole month through, and it seemed as if winter was about to commence in earnest. To say that it was a disappointment, after having had such pleasant passage by the winter months only to get into a backward spring-time, is but a feeble expression; still, the weather was never bitter during the spring opening. April and May were not very good, still during those months and up to the present time there have been but a very few days that the bees have remained at home all day long. The present week has been a week of the most beautiful showers that I ever saw, and the clouds are still flying in haste towards the southwest, and as the light from the sun occasionally bursts forth through some of the openings above, the merest showers of rain are sometimes seen falling in the sunlight and producing scenes worthy of attention. The atmosphere is warm, the fields of buckwheat are getting whiter, and the bees are on their wings every hour during the day-time. From the present view of things about here, one would think of a heavy yield of surplus honey in the next few weeks to come, and of a mild winter following.

JOHN MORRIS.

Mauston, Wis., Aug. 5, 1882.

Entomological.—I herewith send you a worm that I caught on the alighting-board of one of my hives. When taken, it was about one inch in length, nearly blood-red, and about $\frac{1}{2}$ an inch thick. Please give it a name. S. C. FREDERICK.

Coal Valley, Kan.

[The "worm" is the caterpillar of a silk-spinning moth, *Bombycidæ*. It was only accidentally upon the alighting-board of the bee hive. It feeds only on green leaves, and I judge upon those of the soft maple, but the specimen is not in condition for me to certainly pronounce upon the species.—T. J. BURRILL.]

"Golden Dollars vs. Golden Bands."

—Mr. Benedict says, "There is another class of breeders who make it their steady aim to breed bees as light-colored as they can, and they have succeeded in producing what appears to be a distinct variety of bees." Perhaps this is true, but the majority of us keep bees for the honey that they will gather, and we care little whether the bees are a distinct variety or not, so long as the honey is forthcoming. We care much more for the golden dollars than we do for golden bands. Mr. B. further says, "Such breeders cannot afford to sell queens for a dollar each." Will he please tell us why it is any more expensive to breed from light-colored stock than from dark? Light-colored, home-bred queens can be obtained for breeding purposes of

reliable breeders, at much less figures than can imported queens, such as, at least, the majority of the breeders of dark bees and queens bred from.

W. Z. HUTCHINSON.

Rogersville, Mich., Aug. 4, 1882.

Whose Loss is it?—Two months since I received an order for a copy of Cook's Manual, which I can certify was immediately sent him by mail, properly addressed. The person who ordered it, now informs me that the book has not been received by him. I would like to know if it is right for me to suffer the loss and send him another copy? Please answer this question in the BEE JOURNAL, and oblige both the buyer and THE AGENT.

[The loss is undoubtedly for the person ordering it, if it can be shown that it was properly mailed. Had it been registered, (costing 10 cents extra) it could have been traced, but now it cannot. Some dishonest employe of the mail service probably "appropriated" it. When such is ordered from this office and lost, we usually divide the loss with the person ordering, and although we have nothing to do with this transaction, we will send a copy to the person losing it, upon receipt of one-half of the price of the book, so as to save hard feelings between bee-men.—ED.]

My Honey Crop.—I have already taken from my bees over 2,000 lbs. of as nice honey as I ever saw, and can take about 1,000 lbs. more in a few days. This season has been a very fair one with me, although the old style bee-keepers in this county have complained of the scarcity of honey and have secured very little surplus, and even that in bad shape. Honey is selling for 20c per lb. in 2 lb. sections, and 15c per lb. for extracted.

L. J. DIEHL.

Butler, Ind., Aug. 4, 1882.

Honey Enough to Winter On.—Bees have done nothing here this season. Strong colonies have now almost enough to winter them. September may yield us a surplus.

JOS. M. BROOKS.

Columbus, Ind., Aug. 5, 1882.

Iron Lugs for Hanging Broad Frames.—I note the letter of Rusticus, in No. 31, 1882, about hanging broad frames without top-bar. I have sent out a number of hives with the device spoken of, and send you herewith two pairs of lugs, or projections, for the purpose. I now make my broad frames with wooden separators fixed permanent, nailed to stay, top bar removable, not nailed; and then with these metal projections, wide frames of sections are very handy. Two frames are placed face to face in the hive, and you have all the advantage of a four-inch box the size of the frame; after work is well started, turn half of the frames around and all the advantages of separators are secured, and none of

the disadvantages. To take out sections, pry off the top bar and all is easy. I have used them four years. No patent. J. M. SHUCK.

Des Moines, Iowa, Aug. 3, 1882.

[The metal projections mentioned consist of cast iron, so made as to screw on the tops of the end-bars of the broad frames, and rest on the rabbits. Mr. Shuck describes above their method of using too plainly to require any attempt on our part, or to be misunderstood.—ED.]

Afraid of Robbing.—My wife, self and one boy have attended 78 colonies and some 8 or 10 nuclei. Have taken 6 30-gallon barrels of honey (about 2,161 lbs.) with the extractor, and between 700 and 800 lbs. of comb honey. We have a good home market at 20c. for comb and 10c. for extracted honey. The harvest is just closing with us. Black sumac and privet or buck bush are our main resources for July. We will now have a honey dearth till the 1st of September, when will come the aster or hybrid Spanishneedle, which gives us our largest crop in valley locations. I took most of my comb honey in 2 lb. sections, and found ready sale for it. My hives are full of honey and capped, and I fear that the queens will be crowded out. The bees are ill-natured, and I fear robbing if I extract any more. What would you do in such a case? I am using all the foundation they will draw out. J. T. BRUTON.

Joplin, Mo., Aug. 5, 1882.

[Do your extracting mornings and evenings, when the bees are not flying much. It will be necessary, of course, to do the extracting in the honey-house, or a room that will be secure against intrusion. You can lift the outer frames in the morning, extract during the heat of day, and in the evening spread brood frames in the hive and return the empty combs, alternating them with the brood combs, or putting them in the center. Do not extract too close—four frames from each brood chamber should be sufficient.—ED.]

A Good Season.—The honey season here has been a good one; white clover has been in bloom for eight weeks. My bees have done well in the sections; am using the 1 lb. section, and like it very much. Bees had quit swarming, but to-day I had a large swarm come off. The prospect is good for fall honey, as the cornfields are full of smartweed, owing to the wet weather.

J. V. CALDWELL.

Cambridge, Ill., Aug. 7, 1882.

A Fair Yield Anticipated.—Bees doing ordinarily well. Very few swarms cast this far, and but little surplus stored. Should the wet weather continue, I anticipate a fair yield of fall honey.

JOHN Y. DETWILER.

Doniphan, Kan., July 31, 1882.

ESTABLISHED 1862
THE AMERICAN BEE JOURNAL
 PUBLISHED WEEKLY

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published **WEEKLY** as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 ".....	20 " "
" 13 " (3 months).....	30 " "
" 26 " (6 months).....	40 " "
" 52 " (1 year).....	60 " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent., if wholly paid in advance.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent., if wholly paid in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for one year, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—	a copy of "Bees and Honey."
" " 3,—	an Emerson Binder for 1882.
" " 4,—	Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,—	cloth.
" " 6,—	Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 8 oz.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Emerson Binders.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent postpaid by mail for 75 cents.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Do not let your numbers of the BEE JOURNAL for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

When you meet with an accident, get a sprained ankle, or otherwise injured, don't go to the expense of sending for a doctor, but apply Kendall's Spavin Cure, and you will experience instant relief. 32w4t

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

PLEASE NOTICE the price of Tested Queens in the advertisement of W. Z. Hutchinson. He has a large stock of these Queens on hand, and can fill orders promptly, 33w3t

HENRY ALLEY, WENHAM, MASS.

Queens Worth \$2.00 for \$1.25.

Large, handsome and beautiful. Every one warranted as good in all respects as tested queens. No loss of queens by mail in my new cages—all go safely. Safe arrival and purity guaranteed. Italian, Cyprian and Holy Land Queens by return mail. No money required until queen is received. 33w3t

Ten Colonies of Italian Bees

for sale at a bargain. Warranted Italian Queens, \$1.00 each. For particulars, address J. P. MOORE, Box 27, Morgan, Pendleton Co., Ky. 33w4t

WANTED—A situation with practical apiarist, by a young man, carpenter, of experience with bees in Germany. Wages required moderate. Will make himself useful. Address FREDERICK LORENZEN, 36 Cornelius street, Chicago, Ill. 33w4t

WANTED—A situation in an apiary, by a young man of 3 years' experience. Will work cheap, and endeavor to give satisfaction. Address, DANIEL W. DUFFIELD, Dearborn, Mich. 33w4t

To Foundation Manufacturers.

I have 80 lbs. of beeswax I wish made into comb foundation, some of it drone size, and some thin for boxes. Please send me samples and prices. Address, CHARLES FOLLETT, Osage, Iowa. 33w4t

40 TONS

Of Comb Honey wanted; York State preferred. Say how much of each grade you will probably have, size of section, how soon it can be in shipping order (the whole or part of it), lowest cash price, and address F. I. SAGE, Wettersfield, Conn. 33w4t

1882-Southern Headquarters.-1882

For Early Italian and Cyprian Queens;

Imported and Home-bred; Nuclei and Full Colonies. For quality and purity, my stock of bees cannot be excelled. I make a specialty of manufacturing the Dunham Foundation. Try it. If you wish to purchase Bees or Supplies, send for my new Catalogue, giving directions for introducing queens, and remarks on the New Races of Bees. Address, DR. J. P. H. BROWN, Augusta, Ga. 5smft

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 15x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " " 10x18 " "	8 00
For 3 " " " 10x18 " "	10 00
For 4 " " " 10x18 " "	14 00
For 2 frames of any size, 15x20 " "	12 00
For 3 " " " 12x20 " "	12 00
For 4 " " " 13x20 " "	16 00

A NEW BEE BOOK!
Bees & Honey

OR THE
Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,

Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-rising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keitsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they are not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (6 and 9) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber. It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unnumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,

923 West Madison Street, CHICAGO, ILL.

The Bee-Keeper's Guide;

OR,

MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the

State Agricultural College of Michigan.

—:—
320 Pages; 133 Fine Illustrations.
—:—

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

—:—
Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculteur, Paris.*

I think Cook's Manual is the best of our American works.—*LEWIS T. COLBY.*

It appears to have cut the ground from under future book-makers.—*British Bee Journal.*

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—*J. P. WEST.*

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—*E. H. WYNKOOP.*

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald, Monticello, Ill.*

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—*A. E. WENZEL.*

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—*WM. VAN ANTWERP, N. Y.*

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record.*

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—*L'ABBE DU BOIS, editor of the Bulletin D'Apiculture, France.*

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat, Pulaski, N. Y.*

We have perused with great pleasure this *nouveau* manual of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To us taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist, Quebec.*

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee-management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist.*

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor.*

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil

Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as *Carcharodon Kondeletii*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 3400 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthly noises in my head, and hear much better.

I have been greatly benefited. My deafness has been a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE, AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

To avoid loss in the mails, please send money by REGISTERED LETTER.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by **THOMAS C. NEWMAN,** 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping, by L. C. Root.— The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.— This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.— This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee— This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.— A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.— Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are "Bee Pastures," "Besting," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 100 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bienen Kultur, by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cts., or \$3 per dozen, postpaid.

Dzierzon Theory— presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Honey, as Food and Medicine, by Thomas G. Newman.— This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.— This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use— Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.— A 24-page pamphlet, by Chas. C. P. Dadant, giving details of the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman— Giving advanced views on this important subject, with suggestions what to plant, and when and how: 25 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.— No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chieken Cholera, by A. J. Hill.— A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Measurer, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzes, Golders, Metal and Wood Workers of every kind.

The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Statistics on Bees and Honey.

As the time rapidly approaches for the convocation of the North American Bee-Keepers' Society at Cincinnati (Oct. 3-5), State Vice Presidents should be preparing to make tabulated statements of the industry in their respective States. Heretofore but little concert of action on their part has been manifested, and except that the BEE JOURNAL gave each year an estimated approximation to the crop and business, no information has been furnished of the number of colonies of bees in the country, annual increase or diminution, net amount, kind and quality of honey produced, success and manner of wintering, and styles of hives in use. Of course these tables were in some respects most valuable data, but as we could only reach our readers, we could not deny that the tables fell far short of being accurate in their recapitulations, and after weeks spent in corresponding, in perplexity, and in uncomfortable headaches, we were still obliged to admit they were but estimates. Even then, with our self-imposed task as perfect as we could make it, we were assailed by some because it was incomplete, the parties finding most fault having done but little or nothing to help us in our work, not taking enough interest in a public enterprise to render their own private reports.

To be sure, the United States Census Bureau is supposed to give reliable tables upon all matters pertaining to the stable wealth of the country, but those reports are collated only once in ten years, and then the time is nearly half consumed till the next de-

cade before the report is published. If the President of the North American Bee-Keepers' Society was to issue a circular to the several State Vice-Presidents, urging the importance and necessity for brief tabulated statements to be submitted to the Convention, and by their Secretary to be massed in a general statement, it would afford a useful and fruitful theme for discussion and legislation by the Society. These Vice Presidents could urge the matter upon the bee-keepers in their respective States through the bee papers and agricultural publications, and by means of public and private methods, and thus could be accomplished much more than can be done by any single enterprise.

A correct and reliable report of this character would be a matter of national importance, and we believe can be accomplished only through the National Society. In this connection, it is gratifying to be able to commend several Vice Presidents who have already taken the initiative in this matter; but in order to make the report as reliable as possible, and avoid complications which may embarrass the Secretary, or entirely destroy the report's usefulness, we beg to suggest that President Cook or Secretary Parmlly furnish to each of the Vice-Presidents a tabulated form to be used in making up their reports. Uniformity will greatly assist in its compilation.

By referring to page 503, it will be seen there is a movement on foot to organize a Tri-State Bee-Keepers' Society, to comprise Ohio, Michigan and Indiana. The meeting takes place in the evening of Sept. 13. Prof. Cook, Thomas G. Newman, and many prominent bee-keepers have accepted invitations to be present.

Bees at the Michigan State Fair.

The managers of the Michigan State Fair are exhibiting a business energy worthy of the highest commendation, and in advance we predict for them the most interesting and successful Fair Week they have ever experienced. The following circular has been quite extensively distributed to bee-keepers, and will stimulate an appreciative response on their part, that will make the apiarian department one of the most attractive features of the Fair:

The Michigan State Agricultural Society are fitting up on the fair grounds at Jackson, Mich., a fine building for the exhibition of bees, honey and bee-keepers' supplies with a wire room in one part for the exhibition of bees. The Society offer premiums amounting to one hundred and fifteen dollars, the largest ever offered by any Agricultural Society in this country. It is open to the world and it is hoped and expected that each and every bee-keeper will avail himself of this opportunity and make one grand exhibition of bees, honey and supplies.

The last day of the fair will be a grand sales day, when each exhibitor can sell anything on exhibition and not wait until after the fair is over as heretofore. This will bring a great many bee-keepers on the last day; for they can buy and take off the grounds anything on exhibition. A large number of the leading bee-keepers have promised to be there and exhibit, and the display of bees, honey and supplies will be very large.

A special premium will be given to any lady making the largest and best display of bees and their products.

The fair commences on the 18th of September and will close the 22d. Any bee-keeper unable to attend the fair in person and having anything he wishes exhibited or sold, will send it by freight or express, charges paid, to H. D. Cutting, Jackson, Mich., when it will be taken care of according to instructions.

For any information write to H. D. Cutting, Clinton, Mich., chairman of committee for State Fair exhibition.

As with the Tri-State Fair, it will be seen, an opportunity will be afforded all exhibitors of apiarian products to dispose of their goods on the ground, thereby not only saving the expense and trouble of returning the goods home, but providing a highly appreciative market for the disposal of them, after having furnished transportation free, or at much less than usual rates for exhibitor and products.

It is highly gratifying to know that our earnest and persistent efforts for several years to cause the recognition, by the public, of bee-keeping as an important factor in our national wealth, is meeting with responsive action on the part of those who are entrusted

with the important duty of managing these popular expositions; and bee-keepers will be derelict in their duty to themselves and fraternity, and exhibit a selfishness worthy of a more ignoble calling, if they do not take the fullest advantage of every generous encouragement, and serve themselves by benefitting the public in making the most of these opportunities. We have no doubt the many tons of honey which will be exhibited at the Michigan State Fair, will be profitably sold before removal from the exhibition building.

A novel feature in the premium list is the mention of a special premium to the lady making the largest and best display of bees and their products. There are several quite successful lady apiarists in Michigan, and we would not be surprised if the special premium stimulated a very spirited competition not only for its capture, but for the sweepstakes also. We have for years had, in the BEE JOURNAL Museum, a section of honey produced by a Michigan lady apiarist, that would not take second rank in any exhibition, though it was one of a lot exposed for sale in a grocery store when we purchased it.

Wax Rendering.

Mr. Phil. Rearden, Jamestown, Col., propounds the following queries:

1. Please publish the best method of making wax from comb? I send you a flower on which bees have been working for 3 weeks, when they would not be found on any other flowers. 2. Can you give us the true name for it?

1. We think the use of the Swiss or Gerster wax extractor is the most economical and satisfactory method of rendering beeswax from combs, leaving the wax pure and of the highest market value, and requiring no especial attention or skill. The primitive method is with the use of the ordinary wash boiler, in which strips of wood, say 1 inch thick and 1½ inches wide are laid across the bottom, to prevent burning; make sacks of coarse strainer-cloth to hold about 1 peck each; warm and press your combs to get them in as small a compass as possible, and fill the sacks; put these in the boiler till it is well filled; place a board on top, with a weight on it to press down as the combs shrink from loss of wax; fill up with hot water and set on the stove. The weight should be heavy enough to submerge itself below the

surface of the water, and the latter should be replenished often enough to admit of dipping or skimming off the wax. Many use sal soda in the water when rendering the wax, but we do not like to recommend it, because a trifle too much is very likely to injure the wax, and rob it of its flavor; and we do not know that it assists any in speed.

The second query is answered by Prof. Burrill, of the Illinois Industrial University, as follows:

2. Crane's-bill or spotted geranium (*Geranium maculatum*). This is a very pretty and interesting plant, common throughout the northwest in woods and fields, but rare in New England. The thickened root is very astringent, and is collected for domestic medicine, and is, I believe, used by the physicians to some extent. The common name comes from the peculiar appearance of the fruit, which consists of five parts adherent to a peculiar elongation of the axis of the stem. At maturity these one-seeded parts separate elastically from the base, curling outward with a snap so as to throw the seed to some distance. There are ten stamens, five of which are longer than their brothers, and each has a honey-gland at its base, supplying a rich amount of nectar for the bees. The plant is worthy of cultivation in several respects.

The Weather for August and September.—Vennor gives the following as the forecast for this and next month:

August will be another month of storms and unusual rainfall with one or two remarkably low curves of temperature. I expect snowfalls will be recorded in extreme western and northwestern sections, and cold rains, at more southerly stations shortly after the middle of the month. October will be very similar, but of course colder.

September is likely to be the counter-balancing month of this most unpropitious season, and during this month everything should be done that can be, to house things safely against further wet and storm.

In the Middle and Northern United States and Canada, the weather is also likely to continue wet up to a late period, but two or more wintry belts of weather with snow-falls, are likely to be experienced in the latter portion of October and in November, after which rain will again set in. At New York the autumn will be very wet. In the Northwest early cold and advanced snow-falls are likely to be the conditions, while in December the cold may be intense.

Glucose or "Sugar" Meal.

Mr. George Thompson, St. Charles, Ill., sends us the following excellent extract from the *Marengo Republican*:

By the stench that arises from the "sugar meal"—refuse from glucose—which is being fed quite freely by some of the dairymen hereabouts, one might think that such stuff would make very poor milk and butter. And it does: it is one of the worst forms of food adulteration—injurious alike to the cows and those who use their products. Some cheese and butter factories will not use milk from cows that are fed with the stuff. No factory should. It is just as bad as oleomargarine, suine, or any other form of bogus butter. And then the dairy cows when worn out are brought to the butcher's block and cut up for meat. Such meat is just as deleterious as an article of food as the butter. With such refuse entering into the milk, butter and meat that people use, is it any wonder that scrofula, cancer, paralysis and kindred diseases, rage among the people, who, thoughtlessly perhaps, hold their breath and inquire, "What is the cause of so much disease?" It may not all lie at the door of "sugar meal," but it is a most fruitful source, and dairymen will sooner or later learn that it is very unprofitable stuff in every respect.

The *Republican* makes a most excellent and truthful point in its reference to the poisoning of the flesh which is sold in market from the cattle that are fed on the glucose refuse meal. If the cheese will "rot down in thirty days," from the impurities in the milk, is it not reasonable to suppose those impurities will more or less permeate the flesh, and cause therein a latent poison, to be taken up and developed by the human system, to the extent of destroying life itself? When the trichina became an alarming feature in the consumption of pork, thousands of persons abstained from its use, and substituted the greater use of beef therefor, supposing that the latter indeed would be free from disease, and, as a consequence, beef appreciated in value, and to a very large extent superseded the domestic use of pork; but where can we turn for a substitute for beef, if farmers and dairymen will persist in feeding glucose meal? So that every phase of the glucose traffic is a pernicious fraud, and everything should be condemned into which it enters—the poisoned sugar, poisoned syrup, poisoned honey, poisoned milk, poisoned, rotten cheese, poisoned beef, and everything else where it affords a profitable field for substitution and fraud.

Wise Precaution.—There is a strong tendency among the people of this country to be led astray by novelties and pretentious advertisements of fortunes to be obtained without giving an equivalent. Many papers now-a-days contain more or less advertisements for some new and superior variety of vegetable, fruit, or berry, and a limited number of seeds, plants or cuttings to be sold at extortionate prices. In fact, one is led to believe that the great aim is to obtain something new, on which to assume a great number of superior features, trusting to the credulity of the public to make profitable sales. As indirectly bearing upon this subject the *Rural Canadian* says:

The eminent and venerable pomologist, Charles Downing, does not consider it safe to give a decided opinion on any new strawberry or raspberry short of five years' trial. If all were similarly cautious, much money would be saved in the purchase of untested novelties.

We have no doubt that there are many varieties of corn, potatoes, cabbages, and, possibly, almost every species of fruit, grain and vegetables, which would be benefitted by having the same extended test applied.

☞ We have just received a letter addressed "T. C. Newman, Chicago, Ill.," enclosing a post office money order for subscription to the BEE JOURNAL. In a city like Chicago, there are several hundred persons bearing the name Newman, and unless great care is used, valuable letters are lost, and correspondents frequently blame us, when the fault is all their own. In the case referred to above, the letter was wrongly delivered by the postman, and the party to whom it was addressed sent it to us. Unless positive about our name, address your letters to the "AMERICAN BEE JOURNAL, Chicago, Ill.," when we will get it without delay, as there is no other paper of that name in this city.

☞ We have received, too late for insertion this week, an article entitled "Queen Shipping Cages," from W. Z. Hutchinson, Rogersville, Mich.; also one of the cages described, containing an untested queen and 10 workers. The article will appear next week, with comments.

☞ Articles for publication must be written on a separate piece of paper from items of business.

British Honey Shows.—The British Bee-Keepers' Association held its annual metropolitan Show of bees, hives, honey, etc., during the first week of this month. We have news only up to the day of opening, Aug. 3d, when about 300 entries had been made. The Exhibition Committee have arranged to conduct an examination of candidates who are desirous of gaining certificates of proficiency in the art of bee-keeping. Eighteen candidates have entered for such an examination, among the number being several schoolmasters.

The Show of the Berks and Bucks Association was held at Buckingham, on Tuesday, the 25th of July, in connection with the Show of the Horticultural Society. A remarkably fine day, together with the numerous attractions of the flowers, vegetables, dead poultry, eggs, fruit, hives, honey, bee-driving, etc., drew together a large concourse, not only of the middle and lower classes, but of the nobility and gentry of the town and county, the clergy being especially conspicuous by their numbers. The prizes were numerous, and included hives, bees, honey, and public manipulations with bees.

☞ A Colorado correspondent wishes to know how he can dispose of a fertile worker and save the colony? Remove the hive from its present stand and put an empty one in its place; take out a comb from the colony, shake and brush all the bees off, cage a mated queen on it, and put it in the empty hive on the old stand; now shake and brush all the bees from the combs, successively, on the ground 3 or 4 feet in front of the hive on the old stand, and fast as clean put the combs in the same hive with the queen. Leave the queen caged with plenty of feed for 48 hours, then release her.

☞ On referring to our letter department, it will be observed Mr. A. B. Mason urges upon bee-keepers the importance of making early entries at the Tri-State (Ohio, Michigan and Indiana) Fair, to be held in Toledo in September. The enterprise of this Fair Association is worthy of a liberal support from bee-keepers, more especially as the managers propose to erect additional buildings for our accommodation. There should be no dilly-dallying in the matter, but make the entries liberally and promptly. Mr. Mason will give all the information that may be desired.

Local Convention Directory.

1882. *Time and Place of Meeting.*
 Sept. 5—N. W. Hill and S. W. Wis., at Rockton, Ill.
 Jonathan Stewart, Sec.
- 19—Michigan Central, at Lansing, Mich.
 E. N. Wood, Sec.
- 26, 27—Kentucky State, at Louisville, Ky.
 W. Williamson, Sec., Lexington, Ky.
- Oct. 3-6—North American, at Cincinnati, O.
 Dr. Ehrick Parmlly, Sec., New York City.
- 5—Kentucky Union, at Shelbyville, Ky.
 G. W. Demaree, Sec., Christiansburg, Ky.
- Tuscarawas Valley, at Newcomerstown, O.
 J. A. Bucklew, Sec., Clarks, O.
- Nov. 1—New Jersey & Eastern, at New Brunswick.
 J. Hasbrouck, Sec., Bound Brook, N. J.
- ✎ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Norfolk, Ontario, Association.

The fifth regular meeting of the above Association, was held at Simcoe on the 4th inst. There was a goodly number present, though not as many as at some of the previous meetings, which, undoubtedly, was the result of many of the members being engaged in harvesting.

The meeting was rather an interesting one, for there were a number of resolutions passed, that put the Association in good working condition; and there were several experienced bee-keepers present, who enlivened discussions. The Association passed a resolution to put forth their best effort toward making a display at the next exhibition of the Townsend Agricultural Society, to be held at Waterford, on the 28th and 29th of September, the above Society kindly agreeing to establish an Apiarian Department, and offer suitable prizes. This seems a move in the right direction, and we congratulate the above Society on its early acknowledgment of the importance of apiculture.

The Association now has 46 members, with a fair prospect of large additions. The next regular meeting will be held in the Town Hall at Waterford on Thursday, Sept. 28th, at 2 p. m. *ELIAS CLOUSE, Sec'y.*

The National Convention.

The following is the official call of the Secretary, Dr. Parmlly, for the Convention of the North American Bee-Keepers' Society. We hope there will be a large attendance:

The North American Bee-Keepers' Society will hold their 13th annual meeting at Washington Park Hall, Cincinnati, O., across Washington Park from the Exposition building. Time, Oct. 3rd to 5th, 1882. First session Tuesday, 10 a. m., Oct. 3. We are encouraged to hope that this will be a very profitable meeting, as we are promised papers from, and

the presence of, a large number of our most prominent bee-keepers both in the United States and Canada, and essays and implements of the apiary are expected from abroad to add to the knowledge imparted by the research and inventive skill and methods of our countrymen.

EHRIK PARMLY, Sec.
 New York, July 12, 1882.

✎ The Central Michigan Bee-Keepers' Association will meet Sept. 19th, at Lansing, in the Capitol Building. We call the meeting two weeks before the Annual Fair of the Central Michigan Agricultural Society meets, for the purpose of making the final arrangements for a large exhibit of bees, honey and apiarian supplies. A cordial invitation is extended to bee-keepers everywhere. The meeting will be of especial interest, and a large attendance is expected.

E. N. WOOD, Sec.

✎ The Kentucky State Bee-Keepers' Convention will meet in Louisville, Ky., at the Exposition Building Press Rooms, on Tuesday and Wednesday, Sept. 26th and 27th. All bee-keepers are invited to attend, and send essays, papers, implements, or anything of interest to the fraternity. The Exposition will be in full blast and cheap. Railroad rates from all points. *W. WILLIAMSON, Sec.*

MISCELLANEOUS.

Care of Comb Honey.—Mr. W. M. Kellogg, in the *Prairie Farmer* gives advice as follows:

The season of 1882 has been a bountiful one for the bee-keepers generally, though some claim only an average crop. But for those of us who have been successful (I will not say lucky) in getting a good yield of beautiful honey, it is well to look to its storage, so as not to lose all our hard earned sweets.

Many will dispose of their crop at once, and others will keep a part or whole of it for some time. It is a rare thing to find a colony of bees that does not at some part of the season have now and then a moth to lay a few eggs. In taking off comb honey, we many times also take along with it a few eggs of the moth stored in unnoticed nooks and corners. These soon hatch, and if we happen to be a bit careless as to looking after our honey, when we do go to get some, we very likely find our nice comb all tunneled with little fine webs, and completely ruined. To avoid this, we must watch our honey closely, and as soon as we see the very first signs of any moth-eating of the combs, give the entire lot a smoking with burning brimstone.

Place the honey in a large box, or small room; up a little way from the bottom of the box or room, put in a live coal in an iron dish, dump on a few spoonfuls of sulphur, and get out of the way or your nose may catch it. This should be repeated every few days till you are sure you have settled the affairs of all the hatched moth worms, for mind you, it don't kill the eggs to smoke them.

The smoke, unless too close and hot will not injure the honey, will soon evaporate, and tend to whiten the comb still more. We should keep our honey also, so that no new moth eggs can be laid in it. Clean off all the little bits of comb and propolis on the section so that you need not be ashamed to hand over your product to the most stylish customer.

Again many seem to think that honey can be stored any where as regards the place, upstairs or down cellar. Dampness will spoil honey in a short time, either comb or extracted, causing it to sour and foam, the comb honey bursting its caps and running down in a fearful mess. All honey should be kept where it is perfectly dry, if we would keep it in prime order. Not one cellar in a thousand is dry enough to store honey in.

Bees Blotting out Railway Signal Light.—The *British Bee Journal* says: We have been favored with a copy of a report on the above subject, which will, doubtless, be read with interest. It is as follows:

I have to report that the light of the down distant signal, working from Barton and Walton Station, was last night, at about 8.30, put out by a swarm of bees which had entered the outer case of the lamp through the ventilation at the bottom, and also smothering the inner petroleum case that prevented the air from getting to it, hence the cause of the light going out. The outer case was so full of bees that it was impossible for any more to get in, as every hole at the bottom of the lamp had bees which had forced themselves half way through, and it was impossible for them to get any further owing to so many being inside. The outer case was also smothered over outside with bees, which made it a very difficult task to drive them away so that the lamp might be relighted. A greater part of the bees inside we found dead, owing, no doubt, to the smoke and smell from the petroleum. I herewith inclose you two or three hundred, which prove that the bees had not been burned, but merely smothered.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

✎ When changing a postoffice address, mention the *old* as well as the new address.

For the American Bee Journal.

Reversible Frames, etc.—A Visit.

G. W. DEMAREE.

The 3d of August found me at Eminence, Ky., where some business matters required my presence. Having to wait for the evening train to return home, I improved the time by visiting the man of "reversible" frames, bees and plants—the well-known apiarist, W. T. Stewart, of Eminence, Ky. I found Mr. Stewart sitting in front of his photograph gallery perusing a copy of the AMERICAN BEE JOURNAL, right fresh from the mail bags. The old-fashioned hand-shaking that followed will certainly be pleasantly remembered by me. Dr. Ed. Drane, President of the Union Bee-Keepers' Association was sent for, and soon joined us, and now having that high functionary present, we went into a "Committee of the whole" on the "state" of the present, or rather past honey season. Mr. Stewart reported that he had not been favored with a single "bait" of honey this season, but still had sanguine hopes. He said the season had been contrary all along, and he would not be surprised if it did not take a turn and still be contrary, and give us a flow of honey in August.

Dr. E. Drane "really" did not expect much honey this year, therefore, he went in mostly for "increase," especially as next year is "bound to be a splendid honey season." The Secretary (that's me) had "slung out" about as much honey as he fed syrup to stimulate last spring, but it was "awful thin," and tasted decidedly "weedish." Dr. Drane thought the Secretary had "glucosed" his honey to make it go further. Mr. Stewart suggested that the bees, in their extremity, had licked up the honey and left the Secretary the water pure and simple.

The contents of the last issue of the BEE JOURNAL were examined to see if any "fault could be found with it." Dr. Drane wanted some of the stock of those drones which Mr. Carroll (page 490) saw "working the wax; yes, building comb." The doctor said that he was acquainted with Mr. Carroll, and that he is reliable; he wanted the drones. Mr. Stewart insisted that "drones don't do anything—*emphatically*, they don't."

At this juncture, the bell rang for dinner, and I "demurred," but Mr. Stewart "overruled." It is a real pleasure to be entertained by so noble a pair as Mr. Stewart and his estimable lady. Mrs. Stewart, who enjoys a good joke, says that her liege lord ought to store away "900 lbs. of honey for his own use," and I did not think her extravagant, after seeing him "get away" with things at the table. After dinner we repaired to the apiary

to discuss reversible frames, bees and honey plants.

Mr. Stewart's frame is reversible, and no mistake. It is an exceedingly ingenious contrivance, presenting the novel feature of being a fixed and a movable frame, at the will of the operator. Such a frame would be very convenient to those who keep bees on the migratory plan; but just why anybody should ever have reasons to turn the brood-nest topsy-turvy I imagine that no one knoweth.

Such a collection of bee plants I presume was never seen on one small tract of land, as may be seen surrounding Mr. Stewart's apiary. From the huge sunflower down to the little feeble creeper, with its wee bit of blossoms, can be seen there. It is a pleasure to see the yellow bees tugging at the figwort, motherwort, catnip, sweet clover, milkweed, and a list too long to be mentioned here. Mr. Stewart and Dr. Drane are exceedingly partial to the Italian. The former was once a student of the latter, and they agree amazingly well. I accuse them of letting their prejudice get the advantage of their usually good judgment, when they condemn so unsparringly the "new races" of bees without giving them a fair trial. It is not generally known that the Doctor is the identical "able bee manipulator," on whom Col. Nall, of the *Farmers' Home Journal*, got off that tough joke about a colony of Cyprians "flaxing him out," taking possession of a hole in the crown of his hat, and utilizing another hole in the unmentionable part of his pantaloons. The Doctor now lavishes his affections on the gentle Italians.

By the way, these well-informed bee culturists have a fancy for nice bees, and spare no pains or expense to improve their stock. They take much the same grounds that I have taken in my published article concerning the Italian race. They admit that "high grade" stock—borrowing the term from Kentucky short-horn breeders—such as many of the dealers and breeders are now "writing up" and selling under the flexible nomenclature of "dark" or "leather-colored" Italians, make good, profitable workers, but they would no sooner be found breeding from such stock than a short-horn breeder would be found breeding from "high grade," instead of thoroughbred stock. Every intelligent breeder knows that it is simply impossible to keep up "high grade" stock by breeding from "high grades," because the tendency is downward, as long experience has proven. If time shall prove that high grade stock is most profitable, why, still pure blood on one side of the parentage will be essential to success. As for myself, I have lost much confidence in the ability of the present generation of apiarists to perfect a satisfactory strain of bees possessing all the good qualities desired. There is no concert of action; too much diversity of opinion, and, perhaps, some selfishness. All these things are in the way of success.

The 7th of August is here, and we have no surplus honey. There has

not been so complete a failure in 20 years. Time and again have our bees entered the surplus apartments of the hives, as though they were about to reap a bountiful harvest, but the work had scarcely begun, when it was abruptly brought to an end by bad weather. We had some nice days between the 20th and 28th of July, and things began to look flattering, even at that late date, but there was a change for the worse, and since then it has rained nearly every day, and some days two or three times. I simply report these things as facts. We, who accept an overruling Providence, and are able to bear adversity, because we know that all things will work out for the best by-and-by. No grave is deep enough to bury our hopes. "So mote it be."

Christiansburg, Ky.

For the American Bee Journal.

My Strain of Leather-Colored Bees.

JAMES HEDDEN.

I have written some about my strain of leather-colored bees, crosses between the long Italians and brown German bees; I have also sent you one queen that not only produces such bees, but bees that are gentle to handle, and will surpass any bright Italians as honey-gatherers, as far as my experience goes. Look at her carefully; she is not large, but she lays largely, and her workers are large and long, and work on red clover as freely as on the white.

Last year most all sorts of bees worked on red clover more or less, but this season the weather has been favorable for a long growth of the honey-tubes, and yet nearly every colony in my apiary are at work on both first and second crops of red clover—the mammoth red clover as well as the smaller variety. Basswood is now over, and yet there is no robbing nor stinging in our apiary of 275 colonies. The work on red clover is the cause.

All this is the effect of 6 years' breeding for business, instead of bands. In this locality there are many other flowers besides red clover, that have tubes that strain the bees to reach. No one can breed from the best honey-gathering colonies without lengthening the proboscis of the worker, whether he aims at this point, or knows he is doing so, or not. As I stood in a patch of mammoth red clover yesterday, and counted four of these dark, leather-colored Italians on the heads of one stalk of first growth, slowly drawing in the long draughts of nectar. I said to myself: "Verily, for my new departure I am reaping my reward; our 10,000 lbs. of comb honey, in 1 lb. sections, now so nearly finished, will soon be nicely sealed." I did not ask to be forgiven for feeling jubilant over my success. This success is not at the expense of any one's failure, but *vice versa*. A bountiful crop blesses both the producer and the consumer. Right in the midst of my pleasant reverie came thoughts of the arguments of those who stickle

for the bright Italians, with just 3 gold rings (they are growing less I see), and I wished I could have had them, and the editor and readers of the BEE JOURNAL with me, to see and decide each for himself. I have done all I could for one of the number, by sending the BEE JOURNAL a queen for inspection and test. Tell us your judgment of her and the progeny when fully tested. She is, in my opinion, of too much value to be subjected to the abuse of a mail-bag, or be thrown about in the sun or frost, as often happens. So I sent her by express, paid, and feel that you will do your whole share if you find her a place, test her, and report to us all.
Dowagiac, Mich.

[We acknowledged receipt of the queen last week, and hope next season to be able to report how we find her progeny, without partiality or prejudice. We have often said the best bees will be found to possess the best colors, whether yellow, brown or black.—Ed.]

For the American Bee Journal.

A Crumb for the Curious.

EUGENE SECOR.

Bee books tell us that in about 8 days after the first swarm issues, we may expect to hear the "piping" of the queen, if the colony contemplates sending out an after-swarm. As an exception to this rule, and as something outside of my previous experience and knowledge, I hereby record the fact of the piping of young queens before any swarm issued. It happened in this way: July 26th one of my colonies sent off a swarm which was returned to the parent hive and an additional story added, hoping to cure the swarming fever. I supposed I had accomplished it, as they went to work vigorously.

Aug. 4th, as I happened to be near the hive, I distinctly heard the piping of two or three queens. That was contrary to my bee knowledge, except on the theory that the old queen had died. Next morning I thoroughly searched the brood chamber, and found the old queen present, eggs and brood in all stages, as in any prosperous colony. This circumstance tended to confirm the theory that the swarming impulse is controlled entirely by the workers; that they were determined to drive out the old queen and a swarm, and had been guarding the queen cells for that purpose. It was a strong colony. I extracted the honey from the second story, took off part of the boxes from one set over the upper story, which were filled, took several combs of brood out of the lower story, and hope they are now "controlled" for the season.

The season here has been only "fair." The first part of the summer gave no surplus, but as bees are now "booming," and as August is one of our best honey months, we yet hope to get a reasonable surplus. Bass-

wood gave no honey, nor the first crop of white clover. Sumac is a good honey plant here, and yielded bountifully. The fall flowers are now coming on grandly. Goldenrod, wild asters, artichokes, thistles, wild primrose, Spanishneedles, and various other honey plants are abundant here every fall, and yield nectar till frost comes.

Forest City, Iowa, Aug. 7, 1882.

For the American Bee Journal.

Mr. Abbott on Bee Excretions.

WM. F. CLARKE.

Personally, and on behalf of the bee-keeping fraternity on this side of "the great fish-pond," I thank our distinguished fellow apiarist, Mr. Abbott, for his interesting article on the excreta of bees, in the AMERICAN BEE JOURNAL of July 26th. Its only faults are excess of brevity, and of modesty. Mr. A., not having brought all his arguments to bear at once, we do not yet know how strong a case he may be able to make out. His great modesty, while an excellent example to all of us, is hardly necessary in view of his eminence as an apiarist. He is too "sound on his pins" to be in any great danger of being "tripped."

The main object of this communication is to draw out a fuller statement from Mr. Abbott on a subject which he seems to have studied very thoroughly. Its secondary object is to explain on a point or two in regard to which my article, on which he has been kind enough to comment, is not, perhaps, quite so explicit and clear as it might be.

As I understand Mr. Abbott, he considers that bees imprisoned for a short time under the circumstances he describes, will void dry excreta. The circumstances are those of confinement in a clean, new box, of small dimensions, and, if I am not wrong, destitute of comb. A longer confinement, say 24 hours, in a hive supplied as usual with comb, a railway journey being taken by the bees during the time specified will result in the development of "dysenteric symptoms."

During the briefer journey, I take it, the normal state of things is not sufficiently disturbed to cause "dysenteric symptoms." Moreover, if I am right in supposing the bees to be without combs, they would fast during this briefer journey. Instead of clinging to the combs, they would form chains and clusters, which would probably result in greater quiescence.

During the longer journey, they would undergo more excitement through protracted confinement; would perhaps over-load their stomachs with honey, with which we know they are apt to fill themselves during a disturbance of their natural quiet; and would, probably, run hither and thither over the combs, worrying and wearying themselves. All this would naturally tend to cause "dysenteric symptoms." And these would the sooner appear because they had fed, more or less, on thin honey, whose watery nature would be likelier to

produce this result than thick, old honey. Might we be warranted in thinking that this thin, unevaporated honey is akin to grass in the case of bovine animals, and the thick, old honey, similar to hay? If so, it would not be surprising if the summer excretions of bees were, like those of cattle, much looser than those voided in winter. The habits of bees in this regard during the summer season are not wholly matters of curiosity, as they throw light on the great question of wintering. Would Mr. Abbott kindly tell us if his experiments have led him to believe that in a healthy state, bees always void dry feces? The brief journey experiment would seem to indicate this. Yet I would not be surprised if it were otherwise, and if, during the active season, when honey, fresh from the flowers, is their constant food, their "bowels" were more "open," if one may use a human phrase, and they were in a state akin to that of mankind during the season in which vegetables and fruits are freely used.

Mr. Abbott says: "My stand-point is: Bees can only void their excreta naturally when on the wing." I do not quote this statement to combat it, though I should prefer to put it somewhat differently. I would say, this is their ordinary way of voiding their excreta. Mr. Abbott says, they void dry feces during a short railway journey such as he has described, and I presume from the statement of his stand-point, that he considers they do this when on the wing to that extent which the box permits, or else, he must mean that confinement forces them to an unnatural voiding of excreta. Colonies of bees that winter well, strew the bottom boards of their hives with the drv, brown, powdery atoms which I and others, including I presume Mr. Abbott himself, regard as excreta. At this time, they undergo protracted imprisonment, and are confined to their combs. So far their conditions are like those of the longer railway journey. But it is winter, and the bees are in quietude. There are different conditions; yet they void their excreta. They cannot get on the wing, and Mr. Abbott's stand-point is that only when on the wing can they perform this function naturally. I suppose he would say that winter confinement for so long a time as compels this voiding of excreta is an unnatural state of things. But to take this ground is virtually to assume that bees are intended to be natives only of such climes as admit of their taking wing "all the year round." Is this correct? Have we not reason to think that if we only understood the conditions required to winter them well in cold climates, they would be just as much at home in the higher as in the lower latitudes, within, of course, a certain limit? If so, then, while voiding excreta during flight is their usual habit, nature may have provided for their residence in cold climes, a way of relieving themselves which is not dependent on "the muscles that give the power of flying." I will not say that this is my "stand-point," but with my present lights, it is the view I am

inclined to take. Will Mr. Abbott kindly give us his views on this point?

Some bee-keepers take the ground that bees during winter retain their feces; that owing to their eating little, and that of highly concentrated food, their excreta during the winter season are comparatively inconsiderable; but that they accumulate, so as to be a source of discomfort, and render a "purifying flight" in mid-winter desirable. I do not agree with his theory, and while I would avoid dogmatism on a subject concerning which we are so much in the dark, would put forth this hypothesis: That nature has provided a secondary and supplemental mode of discharging excreta when flight is impossible, and that this is in the form of dry feces, which do not befoul a hive that is free from superabundant moisture. It is worthy of mention here, that some of our best bee-keepers, *e. g.*, Mr. Gallup and Mr. L. C. Root, have testified that bees which have gone through a long, hard winter satisfactorily, do not befoul the snow that may be lying on the ground, when they are liberated for their first flight in early spring. If this be so, then the discharge of dry feces during close confinement, must satisfy the calls of nature sufficiently, and it may be that a flight in mid-winter or early spring is not absolutely necessary for purifying purposes. Still, it is doubtless a relief and pleasure to stretch their wings, and get some out-door exercise once more.

This then, brings me to my statement, "I do not believe with Mr. Abbott, that "protracted confinement" produces 'dysenteric symptoms,' if the bees are in such a state that they can void dry excreta." I have italicised the latter part of this statement, because I wish to call special attention to what it involves. It is of so much importance, that I ought to have been more full and explicit in regard to it. I think it is not so much out of harmony with Mr. Abbott's views after all, if I had made it clearer, and he had taken in its entire significance. During the briefer journey he describes, the bees are in a state in which they can void dry excreta. They are not confined long, they do not gorge themselves with food, and they are not subjected to very severe excitement. But, during the longer journey, they are in a very different state. They have a more protracted confinement, they have access to combs full of honey and pollen, of which they are tempted to take too large quantities, and they are greatly shaken up and excited.

The desirable state for bees to be in during winter is one of comparative quiescence. They become semi-torpid, eat very little, are almost motionless, and perhaps drowse, or sleep. Like certain animals, they "hibernate." If they can be kept in this condition, I think they can and do void dry excreta. This is what I meant by saying, "when we have described the condition under which bees discharge dry feces only, we shall have solved the problem of successful wintering." I am glad to have Mr. Abbott say, "to this I in a measure agree." He adds, "in the meantime, I claim to have

discovered one of those conditions." It is doubtless obtuseness in me, but though it involves a confession of stupidity on my part, I must own that I don't clearly comprehend what that "one condition" is, except it be the small liberty of flight which a box destitute of combs gives. Will Mr. Abbott kindly explain more fully what that "one condition" is? I have read his article over and over again, without being able to come to a thoroughly satisfactory conclusion about it.

When I expressed dissent from Mr. Abbott's opinion that "protracted confinement" produces "dysenteric symptoms," I had in my mind's eye the fact that bees often endure a whole winter's imprisonment without any trace of dysentery showing itself in the hive. Perhaps, however, the protractedness is only a question of time, and that, at length, the bees must come to what Mr. Abbott thinks their only natural way of voiding excreta, or, as I would rather term it, the usual and primary way of doing it.

Mr. Abbott thinks it possible that "twice 24 days" quiet confinement through stress of weather in a hive 'well found,' might, under certain circumstances, be talked of as a nice time of natural rest for bees." Well, our best bee-keepers in the more northerly part of North America, are wrestling with the problem how to winter their bees during five times 30 days of "quiet confinement through stress of weather," and, if our worthy friend across the water can help us manage matters in such a way as to talk of this long period as a "nice time of natural rest for the bees," we shall be everlastingly obliged to him.

Bee-Keeping in Belleville, Ontario.

REV. W. K. BURR, M. A.,
Editor of Ontario Hornet.

With Mr. Heddon I may say that it is my part, too, "to feast on ideas in print." I have certainly been very much delighted with the many useful ideas contained in the justly valuable BEE JOURNAL. A brighter day is truly dawning for the apiculturist. New fields of investigation are continually opening. Men of eminent ability and capability are engaged in the work, not only in the discussion, but in the actual experiments which lead to the summit of success.

Dreamers never reach the summit,
Doers win the prize at last;
Dreamers sometimes seek to gain it,
But their chances soon are past.

Men, to succeed well in the apiary, must be men of energy and perseverance; they must examine their work in all its bearing; view it from different standpoints, and learn how to obtain the best results.

I agree with Dr. Baker, that drones are of use, but the term as applied to people (meaning idlers), this is what we should labor to avoid. There are, doubtless, a great many that keep bees that are too indolent to think, much less to study the works on bee

lore, and learn theoretically the successful management of the apiary. Very few in this part of Ontario have, until recently, taken any interest in bee lore; but the prospects for improvement are brightening. The BEE JOURNAL circulates here, and will doubtless do much in educating many who are now only keeping a few colonies of bees. I intend, when the busy season arrives, to endeavor to extend its circulation, and trust I may be able to send you a long list of subscribers.

Belleville, Ont., Aug. 7, 1882.

For the American Bee Journal.

Humor Practically Applied.

MRS. C. J. ALLISON.

"Who shall decide when doctors disagree?" is a mooted question; but it is an admitted fact, that on all questions pertaining to apiculture, especially weedy ones, the BEE JOURNAL settles them. We have learned so much from the failures as well as successes of others (*we*, that is Jeems and myself) we will give you some of ours.

As we had to feed our 15 colonies last season from the 20th of July to the last of August, we concluded not to divide much this year, so we only increased to 24 by swarming, and dividing and nuclei, and most of them had been doing splendidly, storing honey in the second set of boxes (American), when the swarming fever came over them, two swarms at a time—three absconding, this week, to our knowledge. I think we should have divided. However, we are but novices of only two summers' experience, hardly in the A B C yet (don't know as much as we did a year ago). Well, we went over the rest of them, cutting out their queen cells and giving two frames of foundation to keep their queen busy; but work seems suspended where they have issued. I intend next year to have them all divided and in working order by the middle of June.

We have an abundance of fall bloom, such as asters, goldenrod, smartweed, and old fields are blue with a weed called square-plant, also blue vervain, and a host of others. For 30 years I have had the black flag raised against weeds, and I am now hunting for them as so many greenbacks. Even the nasty Jamestown weed don't look quite as hideous, since I saw bees at work on it. I find my early education has been sadly neglected—why not take up the study of Botany now? It is said, Humboldt took up new studies after he was 80 years old.

What a lazy race we Americans are. The fact is, the great bread-and-butter question absorbs soul and body of most of us, and my ambition the last 2 years has been to have a *leettle* honey on that bread. So last spring, to make a success, we sent for seeds of catnip, mignonette, cleome, motherwort, spider plant, figwort, dandelion, sweet, white and Aliske clovers. Well, I tried to weed those beds out between showers, and at last concluded I didn't care so *very* much for honey; pre-

ferred sorghum. So when the weeds were as high as my head, Jeems had the pleasure of cutting them down with a scythe; but we think the clovers pay. We have half an acre of sweet clover, sowed a year ago last spring. In the fall and last spring it was just the thing for calves. As we have four hundred acres of land, most of it under cultivation, we have to look out for other live stock besides bees. Bees are only a side show for pastime, and to raise a little money to pay taxes on the land.

Do you pay a premium to the one who sends most weeds? I send you a few. The one labeled No. 1 we got of an old country doctor who keeps bees, (don't believe in bee papers or books). He called it burrvine, also, square-plant and bees work on it from June 1st. It is a fever plant, prized highly for its medicinal properties. No. 2 covers the fields, and is called square-plant, also vervain; No. 3 is square-plant; No. 4 is wild beet, my silver nectarine. We have not learned yet the figwort or Simpson honey plant. No one knows anything by those names; we want that, and spiderplant, and motherwort, and I think with the clovers we will be fixed. I have read a good many cook books, but I think the "Manual" will be the book for me.

I nearly forgot to tell you about a little experiment. We had two nuclei which were made up with queen cells 6 or 7 weeks, when about discouraged looking the combs over for her ladyship and eggs, I at last discovered eggs. I thought they were all right, but alas! they were pouched out into drone cells. One morning while looking one of them over, I found in a new comb half a dozen eggs in a cell; while studying what to do with the nuisance, a swarm came out, so we just poured them down in front of the hive, and in a couple of hours they were at work in the boxes. In the afternoon another swarm came out, so we put them in the other hive, but they quarreled some, and next morning absconded. I had inserted a queen cell in the last one a day before. Would that make the difference? This occurred a week ago. I examined the hive yesterday and found the queen cell still there. Well, forbearance ceased to be human nature, so I slashed it off and found dead larvæ. I gave them a couple of queen cells from a colony just swarmed. You see our apiary is run on the happy-go-lucky system, every one doing that which is good in her or his eyes. In my next I will tell you how that swarm panned out.

Noble, Ill.

[The plant you sent numbered 1, is motherwort, and is of considerable value as a medicinal herb, as well as for honey.

Putting the queen cell in the nucleus would make no difference in regard to the swarm remaining. The trouble, we think, was internal, *i. e.*, the bees in the nucleus had developed several fertile workers, and the bees swarmed out again to save the life of their

queen, as the mated queen and fertile workers would not all be tolerated in the same colony. The fertile-worker theory also accounts for the chrysalis dying in the queen cell which you afterward slashed off. The bees, in view of the presence of fertile workers neglected the cell, the embryo queen chilled and died, and the bees were satisfied and did not destroy the cell. We tried a similar experiment this season with a medium Syrian colony in which many fertile workers were developed, except that we caged the swarm-queen on one of the combs in the Syrian colony, then enlarged the entrance to its fullest extent, emptied the bees of the swarm in front, and encouraged them to enter the hive as rapidly as possible. At the end of 24 hours we liberated the queen, and with the exception of perhaps a score of bees killed (which we supposed to be all fertile workers) there was no further disagreement, and the colony is yet very prosperous. We think, had we not caged the queen when putting in the swarm, she would have been killed or the swarm would have deserted the hive. We are not giving premiums for the best collections of honey plants.—Ed.]

For the American Bee Journal.

Apis Mellifica Poisoning.

J. E. MOORE.

Being in the "same box" as Mr. Heddon, I felt quite interested in his article in the BEE JOURNAL, "Apis Mellifica—Its Poison." My symptoms, viz: itching of the ears, etc., are precisely as he describes them, only it settles in my eyes.

Last season in the month of August, I had some 40 to 50 queen cells to transfer, which must be done in 3 days, in addition to the other work of the apiary. My eyes had been troubling me some previous to this, and the lids were much inflamed when I had part of the cells transferred, but "business must be attended to," and I persisted in finishing the job. The result was that I was "off duty" for a week with my eyes bandaged part of the time. Three years ago I discarded the use of gloves altogether, and found the more I was stung the less I felt it at the time, but during the season of 1880 I began to feel those symptoms several days after being stung; and now, if I get stung I am sure to have them commencing 3 or 4 days after being stung. I think it poisons the blood, going into the circulation and locating in the weaker organs of the body. The ball of the eyes are not affected, but the upper lids, which at times are much inflamed and swollen so as to almost close the eyes.

I have tried a good many remedies

on the eyes and the best one is to dilute essences of peppermint in rain-water, and apply with a linen cloth. I find the use of glasses beneficial, and now always wear them while handling the bees, and using the London smoked

We have taken 112 two-pound boxes of white honey. This seems like "small potatoes and few in a hill" to one who has taken 103 such from one hive. As we have had fine rains during the past ten days, the prospects are good for the fall crop, provided we do not get early frosts.

Byron, N. Y., Aug. 14, 1882.

From Knowledge.

The Habits of Honey Ants.

GRANT ALLEN.

The Garden of the Gods in Colorado is a bit of show-scenery of the true American type—a green amphitheater, studded with vast ledges and cliffs of red sandstone, weathered here and there into chimneys or pillars, in which a distorted fancy traces some vague resemblance to the sculptured forms of the Hellenic gods. Hither, a few years since, Dr. McCook, of Philadelphia, went on his way to New Mexico, where he wished to study the habits and manners of a famous, but little-known insect, the honey ant. To his surprise, he accidentally stumbled here upon the very creatures he had set out to find. There are two kinds of entomologists: one kind, now, let us hope, rapidly verging to extinction, sticks a pin through his specimens, mounts them in a cabinet, gives them systematic names, and then considers that he has performed the whole duty of a man and a naturalist; the other kind, now, let us hope, growing more usual every day, goes afield to watch the very life of the creatures themselves at home, and tries to learn their habits and customs in their own native haunts. Dr. McCook belongs to the second class. He forthwith pitched his tent (literally) in the Garden of the Gods, and proceeded to study the honey ants on the spot.

Like many other ants, these little honey-eaters are divided into different castes or classes; for besides the primary division into queens or fertile females, winged ants or males, and workers or neuters, the last-named class is further sub-divided into three castes of majors, minors, and minims or dwarfs. But the special peculiarity which gives so much interest to this species is the fact that it possesses, apparently at least, a fourth caste, that of the honey-bearers, whose abdomen is distended till it is almost spherical by a vast quantity of nectar stored within it. Dr. McCook opened several of the nests, and found these honey-bearers suspended like flies from the ceiling, to which they clung by their legs and appendages. All over the vaulted dome of the ant-hill, these little creatures were clustered in numbers, their yellow bodies pressed tight to the roof, while their big round stomachs hung down behind from the slender waist, perfect globes of trans-

lucent tissue, showing the amber honey distinctly through the distended skin. They looked like large white currants, or sweet-water grapes; and as they were actually filled with grape-sugar, the resemblance was really quite as true inside as out.

Where did the honey come from? That was the next question. Everybody knows that ants are very fond of sugar, and they often steal the nectar in flowers which the plant has put there to entice the fertilizing bee. So much damage do they do in this way, that many plants have clothed their stalks with hairs, or sticky glands, on purpose, in order to prevent the ants from creeping up the stem and rifling the nectary. In other cases, however, plants actually lay by honey to allure the ants, when they have anything to gain from their visits, as in the case of those Central American acacias, mentioned by Mr. Belt, which have a nectar-gland on the leaf-stalk to attract certain bellicose ants, which so protect them from the ravages of their leaf-cutting congeners. Of course, everybody has heard, too, how our own species sucks honeydew from the little aphides, or plant-lice, which have often been described as ant-cows. But it is not in either of these ways that the honey-ants get their sugar. Dr. McCook had a little trouble in settling this matter at first, for the honey ants are a nocturnal species, and he had to follow them through the thick scrub, lantern in hand; still, he satisfactorily settled at last that they obtain the nectar from the galls on an oak, where it must simply be exuded as an accidental product of injury. The workers take it home with them, and give it to the honey-bearers, who swallow but do not digest it. They keep it in their crops ready for use, exactly as bees keep it in cells of the honey-comb. When the workers are hungry they caress a honey-bearer with their antennæ, whereupon she presses back a little of the nectar up her throat, and the workers sip it from her mouth. The honey-bearers, in short, have been converted into living honey-jars. They are thus passively useful to the community, for in this curiously-ordered commonwealth, they also serve who only stand and wait.

How could such a strange result as this have been brought about? Dr. McCook, though not himself an avowed evolutionist, has supplied us with facts which seem to suggest the proper answer to this difficult question. He has shown that the rotunds (as he calls them) are not, in all probability, a separate caste, but are merely certain specialized individuals taken at haphazard from the worker-major class. He saw himself in the nests many worker-majors, which seemed at that moment actually in course of transformation into honey-bearers. Now, it is easy enough to understand why these social insects should wish to store up food against emergencies. At all times, the queen, the young female ants, the males, and the grubs or larvæ are entirely dependent upon others for support. Hence, alike among bees and ants, stores of food

are habitually laid by, sometimes in the form of honey in combs and bread, as with the hive-bee; sometimes in the form of seeds and grains, as with the harvesting ants. During the winter months or the rainy season, when food fails outdoors, there must be some reservoir at home to meet the demand of the starving community. Under such circumstances, any trick of manner which tended to produce a habit of storing food would be highly useful to the nest as a whole; and, taking nests as units in the struggle for existence, which they really are, those nests which possessed any such trick would survive in seasons when others might perish. So the tendency, once set up, would grow and be strengthened from generation to generation, those ants which stored most food being most likely to tide over bad times, and to hand in their own peculiarities to the other swarms or nests which took origin from them.

A set of primitive ants, living upon the honey of the oak-galls, have no tendency to produce wax, like bees, because their habits with regard to their larvæ do not lead them to make such cells at all. The eggs and grubs simply lie about loose among the chambers of the ant-hill, instead of being confined in regular hexagonal cradles. Hence, the bees' mode of honey-storing is practically impossible for them; they have not the groundwork habit from which it might be developed. But the ants have a crop, or first stomach, in which they store their undigested food, before passing it into the gizzard, exactly as in fowls. When ants come back from feeding, whether on flowers, on aphides, or on galls, their crops are very much distended; and they can bring back the food to their mouths from these distended crops, to supply the grubs and their other helpless dependents in the nest. If, therefore, some of the ants were largely to over-eat themselves, they would be able to feed an exceptionally large number of dependents.

Dr. McCook observed that some very greedy workers, returning to the nest, fastened themselves upon the roof in the same position as the honey-bearers, and, in fact, seemed gradually to grow into rotunds. The other ants would soon learn that such lazy, overgrown creatures were the best to go to for food; and, in time, these gorgers might easily become specialized into a honey-bearing set of insects. The workers would bring them honey, which they would store up and disgorge as needed for the benefit of the rest as a whole. If the honey passed into their gizzards and was digested, they would be a positive dead loss to the community, and so the tendency would soon be eliminated by natural selection, because the nests possessing such workers could not hold their own in bad times against neighboring communities. But as only a very small quantity is ever digested—just as much as is necessary to keep up the sedentary life of such immovable fixtures—the effect is about the same as if the honey were stored in cells of wax. The ants, in

fact, utilize the only good vessel or utensil they have at their disposal, the flexible and extensible abdomen of their own comrades.

The greatest difficulty is to understand how the workers first acquired the habit of feeding these lazy members to such repletion; but as all ants "take toll" of one another, this is much less of a crux than it looks at first sight. A very greedy ant, which not only ate much itself while out foraging, but also took toll of all others in the nest, after it was too full to move about readily, would be in a fair way to become a rotund. And as it would thus be performing a useful function for the rest, at the same time that it was gratifying its own epicurean tastes, the habit would soon become fixed and specialized, till at last we should get just such a regular and settled form of honey-storing as we see in this Colorado species. Indeed, another totally distinct type of ant in Australia has arrived at exactly the same device quite separately, as so often happens in nature under similar circumstances. Whatever benefits one creature under any given conditions will also benefit others whose conditions are identical; and thus we often get adaptive resemblances between plants and animals very widely removed from one another in genealogical order.

For the American Bee Journal.

A Few Honey Plants.

L. H. PAMMEL.

This is the time of the year when good honey plants are more needed than any other, for it is in the month of August when the bee-keeper expects to reap the reward of his diligent labors, but should misfortune, or rather negligence be his lot, then he awaits in anticipation of the coming year; but should that prove a failure, he becomes discouraged and abandons bee-keeping. Small honey crops are not always the result of a poor honey year, but are more often due to a want of bee forage. I will describe a few honey plants which bloom during the month of August, that the bee-keeper should plant. I will first mention wild bergamot (*Monarda fistulosa*), which commences blooming about July 25th, and continues 4 weeks. This season it is 2 weeks late. It is an excellent honey plant, and is adapted to the bee-keeper who has only poor, sandy soil, where it thrives best. The honey gathered from this plant is very light and has a strong flavor, though not enough to injure its ready sale. Another excellent quality of this plant is that bees can gather nectar from it at all times of the day.

Another good honey plant I will describe as the hoary vervain (*verbena stricta*). This plant grows abundantly on the barren plains in the west, and blooms during the months of July and August. It has a dense spike of blue flowers, and attains the height of 2 to 4 feet. Of the other plants belonging to the same order, which are good honey plants, I will mention the blue

vervain, (*verbena hastata*) and white vervain, both growing on richer soil and attaining the height of 4 feet. They also bloom during the months of July and August. As a third-class of honey plants I will mention butterfly weed or pleurisy root (*Asclepias tuberosa*). It belongs to the order, *Asclepiadaceae*, milkweed family. Like nearly all the other plants of this order, it has some milky juice, but hardly noticeable. The flowers are a bright orange, and may be distinguished by their stamens and a hood-like, or ear-like appendage rising back of the anthers. As a honey plant I would give the preference to *Asclepias tuberosa*.

As a further example of the productiveness of honey plants belonging to this order, I need only mention the common milkweed (*Asclepias cornuti*), which is so well known to most beekeepers that it needs no description.

La Crosse, Wis.

SELECTIONS FROM OUR LETTER BOX

Indian Currant or Coral Berry.—I enclose you a specimen of a shrub that my bees are working on right lively. I never knew bees to work on it before till this season; they are out and at work on this plant by daylight, but it seems about noon that the bees desert it. Please give the botanical name, and if the same is considered a honey plant.

W. T. CLARY, P. M.

Claryville, Ky.

[It is *Symphoricarpos vulgaris*—Indian currant or coral berry, and has been several times noticed in the BEE JOURNAL as a honey plant.—ED.]

Hive Covers.—From the BEE JOURNAL, "Cook's Manual" and "A B C of Bee Culture" I have learned all the theory I have knowledge of, but theory and practice must go together, like faith and works—not much good alone. I think I have done splendidly for a beginning, notwithstanding the cold, backward, wet spring. I had 3 Italian colonies in simplicity hives last winter, and 4 colonies of blacks in box hives. Wintered in cellar without loss. I now have 24 colonies, all heavy enough for winter, 20 of them with Italian queens. I have taken only a little over 100 lbs. of honey, and have about 100 lbs. more in the supers. I was too anxious for increase, consequently have but little honey. I know now what it means when old bee-keepers say, "Keep your colonies strong." It means 8 or 10 combs full of bees both up and down stairs (in supers); it is from such that I get my surplus. My hives have flat covers, but they are not the thing. I have no shade, unless I put them under the apple trees, and am afraid that will hardly do. 1. Will it? Aug. 6th was so hot that two heavy

combs in the supers melted down, which makes a bad muss. I ran out of covers and covered a board with zinc, letting it down over the edge. They are water and storm proof. 2. How will it do for heat? When the zinc gets hot I cover with a loose board, which I imagine is cooler than a flat cover. 3. What is the best cover for shade and coolness?

JOHN YODER.

Springfield, Ont., Aug. 14, 1882.

[If your orchard is composed of standard trees, so the morning and evening sun can shine fairly on the hives, and the air have a free circulation around them, it will be as good a place as you can put them.

2. With a comb or gable roof, painted white, it will do, even in the sun, better than a continual shade.

3. Is answered in 1 and 2 above.—ED.]

Shuck's Problem.—The article by Mr. Shuck on "dysenteried nuclei," induced me to add my plank to the bridge which may yet carry us over the "Slough of Despond," dysentery, safely. In July, 1881, after basswood bloom, I made some nuclei early one morning. The evening before being rainy prevented me from making them according to my usual custom at evening. They were made in the usual way, by taking brood, shaking in bees, etc., the entrance to nuclei hives being left open. Two hours after, when the sun shone, there was as clear a case of dysentery as you ever saw in April. Everything near was bespattered. Could 2 hours be called long confinement? Was it pollen? There was none unless introduced with the brood. Is July weather cold enough to have that cause it? Was it moisture? The hive was dry and filled mostly with dry combs. Could they have been starved into dysentery in 2 hours? But, then, there is bacteria, that ghost that no one can describe and so hard to locate or strike a blow at. It may be it was "him." If it was because they had gorged themselves with honey, why do they not always show the same symptoms when forced to fill themselves unnaturally, as in making nuclei, extracting, etc.

Ithaca, Wis. C. A. HATCH.

Queen Cages.—Up to date of this I have had only three queens reported dead this season, and one of these was the result of an accident. I use a small wooden cage with sponge saturated with honey. I like a small cage best, as the queen is less likely to be injured by being thrown against the sides of the cage. Who can show a better record with any other cage? I am experimenting with a cage having a soft rubber lining, to prevent injury to the queen by being thrown around in the mail-bags. I am highly pleased with them so far, and I think I can manufacture them as cheaply as most other cages can be made.

E. A. THOMAS.

Colerain, Mass., Aug. 14, 1882.

Sowing Catnip Seed.—I would like to know the proper time for sowing catnip seeds? I had a very large swarm of bees yesterday, and am expecting another every day. I say let them come; I will give them honey from other hives to winter on. There seems to be a good flow of honey yet; the white clover and catnip are holding out splendidly.

WILLIAM WELLS.

Murrayville, Ill., Aug. 12, 1882.

[We prefer sowing catnip seed in quite early spring, but most any time will do; it requires but little attention.—ED.]

Tri-State Fair.—I wish to say to the bee-keeping fraternity who intend to make an exhibit in the apiarian department, or enter the Traffic Department at the Tri-State Fair in September, that it is very desirable all should make their entries, and apply for space at the very earliest time possible. All the space in the buildings now on the grounds is spoken for, and the Fair Association will erect additional buildings for the bee-keepers' exhibits, and they would like to know about how large to build. Any information will be gladly furnished free on addressing me. My bees are still gathering a surplus of honey, mostly from sweet clover and catnip. I commenced the season with 16 fair and 93 rather weak colonies, mostly hybrids. Now have 69 and nearly a ton of extracted honey. I have just hived a nice large swarm.

A. B. MASON.

Wagon Works, O., Aug. 15, 1882.

Late Swarming.—I have 25 colonies now; had 12 in the spring; had one swarm yesterday. The season has not been very favorable here this year for bees. My bees are storing honey now in sections, but not very fast. I do not expect much surplus honey; hives are all well filled with both honey and bees.

WM. JENNEY.

Shiloh, Mich., Aug. 15, 1882.

Linden a Failure.—My bees are doing nicely on white clover. Linden bloom is a failure this year, having been killed by the early frosts. Bee-keeping has been "up-hill" work in this vicinity for the past 3 years, and apiarists are nearly discouraged.

CHAS. FOLLETT.

Osage, Iowa, Aug. 7, 1882.

Crops were Never Better.—The heavy rains for the last two weeks have greatly checked the honey flow. To date I have 17,000 lbs. of extracted and 400 lbs. of section honey. Crops were never better.

O. M. BLANTON.

Greenville, Miss., Aug. 10, 1882.

Progressive Transferring.—Mr. Heddon has made it as clear as a whistle. I will candidly admit that his head has been clearer than mine upon this transferring question. Of course, the old queen is laying "all the same," whether she is in the old hive or the new.

W. Z. HUTCHINSON.

Rogersville, Mich., Aug. 11, 1882.

In Regard to Swarming.—I often have the question asked me: 1. "What bees go out with the swarm, and what stay in the hive?" *i. e.*, where is the dividing line when bees swarm? I have often asked that question, but cannot obtain a satisfactory answer. 2. Is it known? 3. Who decides the question which bees shall go, and which stay—is it the queen or is it the workers? 4. I wish your opinion of A. E. Manum's hive, as advertised in his circular? He has some 400 of them in use in three apiaries 5 miles apart. Very poor season; neither bees nor honey.

A. P. FLETCHER.

Ludlow, Vt., Aug. 8, 1882.

[1. The old bees go with the swarm, *i. e.*, all those that are able to assist in building up a new colony; of course, there will be more or less field-workers out when the swarm departs, and these remain with the parent colony.

2. Yes; you can decide the matter to your own satisfaction by examining a parent colony immediately after a swarm has issued. You will find comparatively few left in the hive, able to fly, except those actually employed when the emeute takes place.

3. Nature decides the question by spreading the swarming contagion, and it is no unusual occurrence to see hundreds of young bees lying around the alighting-board, on the ground, which had over-estimated their strength and could not fly away. These mostly find their way back into the hive.

4. A. E. Manum gives the dimensions of the frames in his Bristol hive, as 22 inches long by 9½ deep, inside measure, and 12 in number. This really makes it a modified Langstroth frame, and gives about the same upper surface as the standard Langstroth hive. It is a double-wall or chaff hive, having a 3-inch space between the outer and inner walls, which can be filled with chaff, cut straw, shavings, or other packing, for out-door wintering. If not too many complications, and we presume there are not, as Mr. Manum is a very practical man—it is an excellent hive.—ED.]

The Dzierzon Theory.—We commenced to keep bees two years ago, and then our stock consisted of 18 colonies of hybrids, excepting two, which were full Italians. We have now 64 colonies, and all are of the favored variety—Italians; have sold 12 colonies. The 64 now on hand are in fine condition, and ¾ of the queens are young, being reared this summer. We have had a fine flow of honey all the while; plenty for home consumption, and more than a hundred gallons to spare. If the Dzierzon theory

be true, why should the markings of the workers so frequently differ; that is, if a black queen should mate with a pure Italian drone, why should they not all show the same number of yellow stripes. M. S. WATERS, M. D. Bethel, Tenn., Aug. 12, 1882.

[By the Dzierzon theory, the crossing of the queen with a drone of another species or strain will affect the worker or female sex only in the progeny, the drone progeny being just as pure as was the mother; hence, queens reared from a pure queen which has met a black or other drone besides her own strain, will throw mixed drones as well as mixed workers. Thus we will see from a queen whose every appearance, as also whose drone progeny would indicate pure Italian blood, workers of every hue and shade. In other words, that by the laws of parthenogenesis, every queen is fertile, as well as under certain conditions the workers also, to produce male progeny; but that the connection of the queen with a drone is necessary to bring forth worker or female progeny.—ED.]

Rejoinder to Mr. Vandervort.—In reply to Mr. Vandervort's challenge to meet him at the National Convention, he with his roller mill and I with the Given press, to test the speed with which these machines can be made to make their best work, I must certainly decline to accept. First. It may be that I cannot attend. Second. It is much trouble and expense to take a 270 lb. apparatus so far, and having not one cent of cash interest in the press, and not deeming it wise or necessary to pay for being believed, I will leave the field to Mr. Vandervort, with these closing remarks: As a gentleman, my dealings have found Mr. Vandervort unexcelled; as a practical, mechanical expert, I count him second to none of my acquaintance; as a honey-producer and breeder, I hold him in the highest esteem. I have used several different makes of roller mills, and I count his the best I have used, but I count the press principle and its product superior to any and all roller mills known to me. Mr. Vandervort might demonstrate a fact, which I do not deny, that he is a better-skilled operating machinist than I, but that would not change the fact that here, in my house, as bungling as I may be, which lack of mechanical skill was felt by all the machines alike. I could turn off foundation three times as fast with the press as with the best Vandervort mill; yes, much faster and neater than I have ever heard of any one doing with any roller mill. I stated this because it was truth, and because such truths were expected from me once in a while. As my only pecuniary interest rests in the sale of the foundation made on this press (and no one has ever challenged its

superiority as far as I know), were I to speak from bias, I would say that "it was with much difficulty that the press made this excellent foundation," thus giving a second reason for deserving patronage. I prefer to be honest, trusting my success to that course. Many presses are now in use. Has not some person one that some roller mill is superior to, either or both in its manipulation and product? We have heard considerable from the other side. JAMES HEDDON.

Dowagiac, Mich.

Mountain Mint.—Please give name of plant enclosed and its value as a bee plant. It grows two feet high, and is a wild plant. The bees seem to work on it all day long. Will it pay to cultivate for the bees? They are not doing so well. They cluster on the outside of the hive, and we do not know the cause. Thought perhaps it was the color the hives are painted. They are a dark brown. Please state whether dark or light hives are the best for them. JOSEPH LEE.

Fallston, Md., Aug. 13, 1882.

[The plant is basil or mountain mint (*Pyganthemum lanceolatum*). It would be a good plan to scatter waste and sandy places with the seeds, but they would not repay especial cultivation. It is very common in the Central and Western States.

Your bees are clustered on the hives because honey-bound in the brood-chamber. The color of the hives has nothing to do with it, except, perhaps, to make them lounge on the outer instead of the inner side of the hives caused by the greater attraction of heat. White is the better color to paint them.—ED.]

Basswood Come and Gone.—Basswood has come and gone, and the result is no surplus in general. Honey that is taken out now is dark colored, and of very poor quality. We have had nice rains lately, which may make fall pasturage good, but surplus is out of the question here this season.

W. H. S. GROUT.

Kennedy, N. Y., Aug. 10, 1882.

Immense White Clover Crop.—I will try and give the prospects of a honey crop in this locality, and that is very poor. This is my 3d year since I commenced to keep bees. They done very well in swarming this season; I had 6 in the spring, now I have 13, and 2 went to the woods. Too cold and wet this season. We had no locust bloom, and very little linden, which was 2 weeks late, but the greatest white clover crop I ever saw commenced about the 10th of June, and is now, within the last day or two, disappearing. I have not taken any comb honey yet. I extracted 4 gallons out of my 2 first swarms. I hope better things this fall, and next season. My bees have done as well as any in this part of the country. I inclose to you a flower that

I find growing here, that the bees are working on in preference to anything else, that is, any other flowers that are growing about where this grows, and there are a good many other kinds. What is its value as a honey plant? It seems to grow on sandy, barren land the best. H. C. WHITLOW.

North Manchester, Ind., Aug. 11.

[The specimen of plant sent is a vervain, and an excellent honey plant.—Ed.]

Shipping Crates.—1. Is a shipping crate made of $\frac{1}{2}$ inch, or $\frac{3}{8}$ inch material, that will hold 12 two-pound sections? 2. Will the crate be returned or not? 3. Should the crate be weighed and marked before it is filled? W. T. HONENSIELL.

Monster, Ill.

[The top, bottom and sides should be $\frac{1}{4}$ inch, and the ends $\frac{5}{8}$ inch material.

2. The crates are not returned.

3. You can weigh and mark the crate before it is filled, or, if they average about the same, make a note in the bill, and deduct as tare from the gross weight; but always specify the weight, so the retailer will not be obliged to empty a crate before buying, to get its weight.—Ed.]

No Honey from Basswood.—Very little honey in this part of the State. Cold and rainy in white clover time. Basswood was in bloom 2 weeks, and weather was warm and dry, but it failed to yield or secrete honey. I have known more honey to be gathered in 5 days; only 20 lbs. to the colony, and an average of half a section of white; 175 colonies spring count; increased 25. Last year I obtained 100 lbs. of white honey, and doubled with increase. Prospects for buckwheat are good, but that may fail, like the rest. W. L. COGGSHALL.

West Groton, N. Y., Aug. 10, 1882.

Is Satisfied.—I am glad to say that the "cloud with silver lining" came this way long enough to give us a nice little shower of honey. The first of the season was very cool and wet, but about July 8th the weather cleared, and though still cool, we had a few days' yield from white clover; and on the 14th the bees commenced to work on basswood, and for 16 days strong colonies did nicely. On the 23d one of our colonies was set on the scales at 8 $\frac{1}{2}$ o'clock a. m., and at 8 p. m., it had gained 25 lbs., and on the 24th, from 6 a. m. until 8 p. m., it gained 22 $\frac{1}{4}$ lbs. Myself and son have taken from 50 colonies 3,800 lbs. of extracted and 800 lbs. of comb honey, and have sufficient in the hives to bring the amount up to 5,000 lbs. This, of course, is not a big yield, but when there is so much general complaint, we are thankful for such small favors. I am much pleased with Mr. Heddon's manner of transferring, as given in the BEE JOURNAL of July 12th, but should object to waiting 21

days before finishing up the "job," as by that time many drones would very likely be hatched, if the first colony be driven out during first bloom, and the bees, such as usually found in box hives, unless I did not care as to the stock I introduced into my apiary, and would much prefer to have a few irregular combs, which may be easily exchanged for foundation later in the season. A. J. HATFIELD.

New Carlisle, Ind., Aug. 8, 1882.

Robbing Parent Colony.—Bees wintered well around here last winter. I wintered 35 colonies on their summer stands, losing 2 queenless colonies. We had a cold, wet spring, so much so that the bees could not do anything till the first of June. They were in better condition on the first of April than they were on the first of June. They had to be fed till that time; since then they have done pretty well. I got 19 swarms, and 4 by division. One swarm that came off in July commenced to rob the old stand a few days after; the two colonies are about 50 feet apart; I have tried everything that I have heard of to stop them, but all in vain, so I shut up the robbers for 2 days and put them in the cellar. Everything was quiet then; on the second day, an hour before sundown, I put them out and they went to robbing again, so I guess I will have to take them a mile or two away for a month or two. One among the best ways to stop robbing, I find, is to take a pane of glass 10x12, or larger, and set it slanting before the entrance; the robbers will fly against it, and if they do find their way in, the guard will attack them, and if they fly up they will fly against the glass and fall back, only to be attacked again by the guards. The regular bees will soon learn their way out and in. 1. What is the reason of the old colony allowing the young swarm to rob them, and not allow no others to rob them. 2. How can I stop them. A. RICKENBACHER.

Gahanna, Ohio, Aug. 10, 1882.

[The parent colony allowed the robbing, probably, because they were powerless to prevent it, and, perhaps, the robbers themselves helped to repel others.

2. The better way we think, in this case, is to exchange places with the hives.—Ed.]

Crops Enormous.—The season here for the apiculturist as well as the agriculturist has been all that could be desired. Our crops of every thing that the earth produces have been enormous. W. S. RAINEY.

Columbia, Tenn., Aug. 12, 1882.

Reversible Frames.—Bees have done very well here this season. The season opened late, but has continued later than usual; white clover yielding honey nearly through July. If we get a full yield of honey we will have no reason to complain of the season's work. I have been using a reversible frame some this season; and am highly

pleased with it. After extracting a frame, I reverse it when I put it back in the hive, and in three days the comb is fastened to the bottom bar as securely as it is to the top bar, which is a great advantage in extracting, shipping bees, etc. Your combs are not breaking and falling out in manipulating them. I believe the "coming hive" must have a reversible frame. H. D. EDWARDS.

Delhi, Ill., Aug. 10, 1882.

Fall Italianizing.—I have some old black queens that I wish to supersede with Italians this fall, after honey harvest. 1. Which would be the best time, just as the flow of honey ceases or later, when done breeding, or just before going into winter quarters? 2. Can I take out the old queens and introduce dollar queens late, and then pack them up for winter?

HENRY TILLEY.

Castle Hill, Maine.

[1. It will be better to introduce the queens early as possible, so as to have time to introduce others should any disaster happen.

2. Yes; but we would not put it off that long, for the above reason.—Ed.]

Best During Fourteen Years.—My report of the honey season just past, is the best during the 14 years of my bee-keeping. I commenced the season with 30 good colonies, and 12 that in the beginning I did not expect any surplus from, but from the 42 colonies I have taken 630 lbs. of comb honey, and 3,700 lbs. of extracted, the best colony yielding over 300 lbs., and it being the best Italian colony in my apiary. I have increased to 84, all in the best condition for winter. I expect some late honey yet, as everything is very favorable. I had 7 swarms run away that I know of.

THOS. B. QUINLAN.

Cedar Rapids, Iowa, Aug. 9, 1882.

Bees Robbing.—There is no honey flow now and bees are following me around as I am working in the yard, trying to rob. From all I can learn, the present season has been the poorest for honey, in this State, for the past 13 years. G. M. DOOLITTLE.

Borodino, N. Y., Aug. 10, 1882.

Bees Increased 250 per cent.—My bees have increased by natural swarming 250 per cent., and are all full now in the lower story of the hives (I use Langstroth hives). They are storing honey in the surplus boxes, from buckwheat, catnip, goldenrod, and smartweed. We have plenty of basswood and this has been a wonderful year for white clover. No swarms until June 25. T. F. KINSEL.

Shiloh, O., Aug. 11, 1882.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

ESTABLISHED 1861
THE AMERICAN BEE JOURNAL
 GOSWELL BROS. PUBLISHERS

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10	per cent. discount.
" 8 ".....	20	" "
" 12 " (3 months)....	30	" "
" 24 " (6 months)....	40	" "
" 36 " (9 months)....	50	" "
" 52 " (1 year).....	60	" "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent., if wholly paid in advance.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent., if wholly paid in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for one year, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—	a copy of "Bees and Honey."
" " 3,—	an Emerson Binder for 1882.
" " 4,—	Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,—	" " cloth.
" " 6,—	Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 8 oz.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to *new* Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Emerson Binders.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Do not let your numbers of the BEE JOURNAL for 1881 be lost. The best way to preserve them is to procure a binder and put them in. They are very valuable for reference.

When you meet with an accident, get a sprained ankle, or otherwise injured, don't go to the expense of sending for a doctor, but apply Kendall's Spavin Cure, and you will experience instant relief. 32w4t

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Bingham's Smoker Corner.

Cyprians Conquered.—All summer it has been "which and t'other" with me and the Cyprian colony of bees I have; but at last I am "boss"—Bingham's Conqueror Smoker did it. If you want lots of smoke, just at the right time, get a Conqueror Smoker of Bingham. G. M. DOOLITTLE. Borodino, N. Y., Aug. 15, 1882.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

WANTED—Some one to buy half interest in an Apiary of 100 colonies. Said apiary can be increased to 300 if desired. All are in movable frame hives. No honey has been extracted to date. Would like to Italianize the whole. Locality good. The right man or woman can secure a good bargain. Inquire at Postoffice at Hillsboro, Wis., or address **Box 83, Hillsboro, Vernon Co., Wis.** [34w11] August 18, 1882.

GOLDEN ITALIAN QUEENS,

Bred from Imported Mothers. Single Queen, \$1; 6 for \$5. Purity, safe arrival, and satisfaction guaranteed. For particulars, address 34w1t F. H. SCATTERGOOD, Newgarden, O.

HENRY ALLEY, WENHAM, MASS.

Queens Worth \$2.00 for \$1.25.

Large, handsome and beautiful. Every one warranted as good in all respects as tested queens. No loss of queens by mail in my new cages—all go safely. Safe arrival and purity guaranteed. Italian, Cyprian and Holy Land Queens by return mail. No money required until queen is received. 33w3t

PRIZE QUEENS FOR 1882.

From the Evergreen Apiary.

REV. E. L. BRIGGS, of Wilton Junction, Iowa, will furnish Italian Queens from either of his Prize Mothers, as early in the coming season as they can be bred, at the following rates: Tested Queens, \$3; Warranted Queens, \$2; Queens without guarantee, \$1; Two comb Nucleus, with Tested Queen, \$4. Orders filled in rotation, as received, if accompanied with the cash. 3w26t

HONEY

For the past few years I have made this excellent food my leading article. Having the best established reputation in this city as a dealer in PURE HONEY direct from the Apiaries, enables me to obtain the highest market prices. Your consignments and correspondence respectfully solicited.

R. A. BURNETT, Commission Merchant,
 Successor to Conner, Burnett & Co.,
 28w13t 161 So. Water Street, Chicago, Ill.

AGENTS WANTED to sell Dr. Chase's 2,000 Recipe Book. Sells at Sight. Double your money Address Dr. Chase's Printing House, Ann Arbor, Mich

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, } Monday, 10 a. m., August 20, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour :

Quotations of Cash Buyers. CHICAGO.

HONEY—1 am paying 7c. for dark and 9c. for light extracted. BEESWAX—Choice lots are worth 25c. here; bright yellow, 24c.; dark to good, 17@22c.

CINCINNATI.

HONEY—The market for honey is quiet. Extracted brings 7@10c. on arrival. No comb honey on the market worth mentioning, prices nominal. BEESWAX—Scarce, and brings 20@25c. on arrival. C. F. MUTH.

Quotations of Commission Merchants. CHICAGO.

HONEY—The crop of 1882 is beginning to come forward, and so far very nice goods have been offered. Sales range at 1@20c. per lb.; one pound sections selling at the highest range, when well filled and white. Extracted, few offerings and demand light at 8@9c.

NEW YORK.

HONEY—White clover, fancy, 1 lb. bxs., 15@16c.; white clover, good to choice, 1 and 2 lb. bxs., 13@14c.; buckwheat, 2 lb. bxs., per lb., 11@12c. Extracted and strained, white, 9@10c.; dark 7@8c.

CLEVELAND.

HONEY—The market is quite active with us; it is beginning to come forward more liberally, and the demand is more fully met. For two days past we have not been able to sell for over 22c. per lb. for best white 1 lb. sections; of 2 lb. sections none have been received. Extracted we hold at 14c. for small packages, but have not made any sales.

SAN FRANCISCO.

HONEY—The market is firm for extracted and choice comb. Offerings and demand are light. We quote white comb, 17@18c.; dark to good, 9@13c. Extracted, choice to extra white, 9@9 3/4c.; dark and candied, 7@7 1/2c. BEESWAX—28@30c.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality. BEESWAX—Prime quality, 25c.

ST. LOUIS.

HONEY—A fair movement in strained at 7 1/2@8. —one lot of 25 bbls. reported sold at 8c. Some new comb (choice white clover offered), but little sold—held at 18@20c. per lb.; extracted quiet at 9@10c.

BEESWAX—Easier at 26@27c. for prime. R. C. GREER & CO., 117 N. Main Street.

Rev. A. SALISBURY

Camargo, Douglas county, Ill. 20 Years Experience in Queen Rearing.

Our Motto is: —"Low Prices, Quick Returns; Customers Never Defrauded." Italian Queens, ... \$1; Tested, ... \$2 Cyprian Queens, ... \$1; Tested, ... \$2 Palestine Queens, ... \$1; Tested, ... \$2 Extra Queens, for swarming season, ready, if we are timely notified. One-frame Nucleus, either Italian, Italian, Cyprian or Palestine, 8 frames, \$8. Safe arrival guaranteed.

20c. paid for bright wax. Money Orders on Tuscola, Ill. 1wly.

THIS PAPER may be found on file at Geo. P. Howell & Co's Newspaper Advertising Bureau (10 Spruce St.), where advertising contracts may be made for it in NEW YORK.

AT LULING, TEXAS.

1 breed PURE ITALIAN BEES AND QUEENS for sale; manufacture Hives of any style and Comb Foundation. Dealer in Novice Honey Extractors, Bingham Smokers, and everything used by modern bee-keepers. Write for prices. Beeswax wanted. 14w39t

J. S. TADLOCK.

FLAT-BOTTOM COMB FOUNDATION.

high side-walls, 4 to 16 square feet to the pound. Circular and samples free.

J. VAN DEUSEN & SONS, Sole Manufacturers, Sprout Brook, Mont. Co., N. Y.

BEESWAX.

I wish to buy a quantity of good yellow Beeswax. I am paying 25c. per pound, delivered here, Cash on arrival. Shipments solicited. To avoid mistakes, the name of the shipper should always be on each package.

ALFRED H. NEWMAN.

923 West Madison Street, CHICAGO, ILL.

EVERY FARMER AND MILLER

SHOULD have FISHER'S GRAIN TABLES, 192 pages, pocket form; full of useful tables for casting up grain, produce, hay; cost of pork, interest; wages tables, wood measure, ready reckoner, plowing tables and more miscellaneous matter and useful tables for farmers and others than any similar book ever published. Ask your bookseller for it. Sent post-paid for 40 cents. Agents can make money selling this book.

For sale at the BEE JOURNAL Office.

65 ENGRAVINGS.

The Horse

BY B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents.—Sent on receipt of price, by

DUNHAM COMB FOUNDATION—40c. per pound; extra thin and bright, 10 sq. ft. to the lb., 48c. Send for samples. Wax worked 10c. per lb. F. W. HOLMES, Coopersville, Mich. 13wly

A NEW BEE BOOK!

Bees & Honey

OR THE

Management of an Apiary for Pleasure and Profit; by

THOMAS G. NEWMAN,

Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up with the times" in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, 75 cents; in paper covers, 50 cents, postpaid.

925 W. Madison Street, Chicago, Ill.

Appreciative Notices.

Carefully prepared for beginners.—Farmers Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-raising.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

A neat and abundantly illustrated hand-book of apiculture.—American Agriculturist, N. Y.

New and valuable, and embellished with 160 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner with bees.—News, Keithsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allegan, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

It embraces every subject that can interest the beginner in bee-culture. The engravings perfectly illustrate the text.—Farm and Fireside, Springfield, O.

Embraces every subject of interest in the apiary, giving very thorough details of the management and manipulations necessary to make bee-keeping a success.—Farm, Longmont, Colo.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

It is a valuable and practical book, and contains a complete resume of the natural history of the little busy bee, as well as of all that one needs to know in their care and management.—Chicago Herald.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

It embraces every subject that will interest the beginner. It describes all the newest discoveries in the art by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive form. It is embellished with beautiful engravings, and is the most perfect work of the kind, for the price, that has ever come under our notice.—Farmer, Lancaster, Pa.

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN,

925 West Madison Street, CHICAGO, ILL.

The Bee-Keeper's Guide

OR,

MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the

State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book;

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY.**

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. P. WEST.**

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**E. H. WYKHOOP.**

This book is just what everyone interested in bees ought to have, and which, no one who owns it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL.**

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—**WM. VAN ANTWERP, M. D.**

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

I have never yet met with a work, either French or foreign, which I like so much.—**L'ABBE DU BOIS**, editor of the *Bulletin D' Apiculteur*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey-producing plants, and an extended account of the enemies of bees.—*Denocrat*, Pulaski, N. Y.

We have perused with great pleasure this *volume* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame. Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets. The \$8.00 and \$10.00 Extractors have no covers.

For 2 American frames, 13x13 inches.....\$8 00
For 2 Langstroth " 10x18 " 8 00
For 3 " 10x18 " 10 00
For 4 " 10x18 " 11 00
For 2 frames of any size, 13x20 " 12 00
For 3 " 12 1/2x20 " 12 00
For 4 " 13x20 " 16 00

EARS FOR THE MILLION!

Foo Choo's Balsam of Shark's Oil
Positively Restores the Hearing, and is the Only Absolute Cure for Deafness Known.

This Oil is abstracted from a peculiar species of small White Shark, caught in the Yellow Sea, known as *Carcharodon Rondellii*. Every Chinese fisherman knows it. Its virtues as a restorative of hearing were discovered by a Buddhist Priest about the year 1410. Its cures were so numerous and many so seemingly miraculous, that the remedy was officially proclaimed over the entire Empire. Its use became so universal that for over 300 years no Deafness has existed among the Chinese people. Sent, charges prepaid, to any address at \$1.00 per bottle.

HEAR WHAT THE DEAF SAY!

It has performed a miracle in my case. I have no unearthy noises in my head, and hear much better.
I have been greatly benefited.
My deafness helped a great deal—think another bottle will cure me.

"Its virtues are UNQUESTIONABLE and its CURATIVE CHARACTER ABSOLUTE. AS THE WRITER CAN PERSONALLY TESTIFY, BOTH FROM EXPERIENCE AND OBSERVATION. Write at once to HAYLOCK & JENNEY, 7 Dey Street, New York, enclosing \$1, and you will receive by return a remedy that will enable you to hear like anybody else, and whose curative effects will be permanent. You will never regret doing so."—EDITOR OF MERCANTILE REVIEW.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by
THOMAS C. NEWMAN,
925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiary. Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping, by L. C. Root.—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Bienen Kultur, by Thomas G. Newman, in the GERMAN language. Price, in paper covers, 40 cents, or \$3 per dozen, postpaid.

Dzierzon Theory—presents the fundamental principles of bee-culture, and turns the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, puddings, Pome Wines, etc., and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. Price, 10c.

Preparation of Honey for the Market, including the production and cure of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how; 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Pspcr, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 250,000 Items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gliders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Planting for Bee Pasturage.

Two of our correspondents propound the following questions in regard to planting for bee pasturage:

1. What time of year is best to sow sweet clover, and how much per acre?
2. Can I sow it this fall with grain?
3. Is it of any use for hay?
4. Where can I get some seed of the Simpson honey plant?

1. In early fall is best, then you will get some bloom the next season. If sown in early spring, catnip, cleome, motherwort, or mignonette can be sown with it to give a honey bloom the first season, after which the sweet clover will take care of itself. If sown alone, we would prefer about 8 to 10 pounds per acre; if with something else, 4 to 6 pounds per acre. It should be sown early enough to get a good freezing, which will not hurt catnip or motherwort. Cleome must be sown in the fall.

2. Yes.

3. We have heard the question answered both affirmatively and negatively; but think if cut early it would make excellent hay, certainly equal to red clover. We know it makes good stock pasture.

4. We do not know, but suppose it will be advertised in our columns by those who may have it for sale.

We have received complimentary tickets to the St. Joseph, Mo., Inter-State Exposition, to be held Sept. 4 to 9, 1882. We shall not be able to be present, but hope the apiarian department will be a very interesting and attractive feature of the Exposition.

Successful Honey Show.—In a private letter, Mr. John D. Hutelison, of Glasgow, Scotland, says their Caledonian Honey Show was a complete success in everything except the weather. The entry receipts amounted to £65 (\$325) for the four days, and he thinks had the weather been favorable, the receipts would have been largely augmented. He reports, on Aug. 10th, splendid weather, and a large number of the bees are away to the heather. He says: "Should the weather continue fine, we expect to have a large surplus of heather honey."

We have received the 25th Annual Premium List of the Knox County (Ill.) Fair. In Class J, of which Mr. C. W. McKown is Superintendent, there is quite a liberal list of premiums for the best display of honey, bees, implements, etc., and we predict Mr. McKown will make his Class one of the most attractive and successful at the Fair, even if compelled to make most of the exhibits himself. It is very encouraging to observe the interest being awakened in apiarian matters among the managers of fairs and expositions; but a few years, and no premium list will be complete without a liberal recognition of apiculture as one of the leading rural occupations.

At the recent Bee and Honey Show of the Caledonian Apiarian Society, at Glasgow, several entries were made for the premium for best colony of foreign bees, but the judges made no award, as none were deemed perfectly pure. This, we suppose, included Italians, Cyprians and Syrians. We can hardly imagine what could have been the standard by which judgment was rendered, if none of the eminent exhibitors could show a perfectly pure colony of foreign bees.

Practical Co-operation.

Bee-keepers have cause for congratulation, in view of the great interest recently being manifested by the managers and directors of the leading expositions and fairs in the country, in recognizing the importance of scientific apiculture. One after another they are rapidly falling in line, and one after another bee-keepers are appreciating the necessity of encouraging this liberality, and of doing their part toward making the bee and honey department of each of these popular gatherings as attractive and instructive as possible. It is the most feasible and remunerative method of educating the great mass of consumers to the desirableness of using a pure article of honey as a common diet, to the exclusion of the vile conglomerations now palmed off on the public as strained honey, etc. Once a suspicion is aroused against those swindlers, and it will soon deepen into a conviction; once convince the public your honey is pure and wholesome, and its use will become popular. Therefore, every bee-keeper placing an attractive article of honey on exhibition, and bees for manipulation, is not alone adding to the interest of the exposition, but is enriching himself by advertising his product, and benefitting the public by introducing a wholesome and economical article of diet for their consumption.

In this connection we cannot forbear calling special attention to the action of the Executive Committee of the Michigan Central Bee-Keepers' Society, in calling their Society to meet in Convention "two weeks before the Annual Fair of the Central Michigan Agricultural Society, for the purpose of making the final arrangements for a large exhibit of bees, honey and apiarian supplies."

This is feasible and practical co-operation, and will accomplish more permanent, remunerative good, than all the rings and resolves and wire-pulling could attempt, for it brings the producers face to face with their customers—the consumers, and gives each an opportunity to relate the special merits of his own goods. Again, it places the combined indorsement of a large and respectable society upon the special exhibit of each individual member, which will go further in the estimation of the public than the assurances of all the middle-men in the community.

The St. Joseph, Mo., Inter-State

Exposition is again coming to the front with a liberality worthy of the co-operation of every bee-keeper in the great Missouri Valley. One year ago they took the lead by placing the apiarian department under the efficient management of Hon. R. S. Musser, of St. Joseph, Mo., who, by his well-directed efforts and untiring zeal, succeeded in making it the most attractive feature of their truly successful exposition, and as a practical and notable result, the honey crop of the Missouri Valley failed to be sufficient to supply a remunerative home demand, and St. Louis and Chicago dealers have been obliged to make up a large deficiency. This year the St. Joseph Inter-State Exposition have largely increased their Society and special premiums, and their list is one of the most liberal in the country. It is worthy of mention, that the local bee-keepers appreciate the permanent benefits of last year's efforts to the extent of themselves offering special premiums to stimulate competition in the exhibits and perfection in the implements. The bee department this season is under the able supervision of Mr. D. G. Parker, who will himself enter the arena as an exhibitor of albino bees.

We give publicity to the following letter from Hon. R. S. Musser, of St. Joseph, Mo., bearing date Aug. 22, 1882:

EDITOR BEE JOURNAL: The weather for the last two weeks has been very favorable for a honey flow, and the bees have had quite a harvest.

A fine display of honey at the St. Joseph Inter-State Exposition is now an assured fact. The Exposition commences Sept. 5, and continues six days.

Mr. J. L. Smith, of Lawson, Ray Co., Mo., will exhibit several colonies of Cyprians and Italians.

Mr. D. G. Parker will exhibit one colony of albinos.

In making up the Exposition premium list, the premium for the best arranged bee hive was unintentionally omitted. Our enterprising fellow-townsmen, Mr. Frank G. Hopkins, comes forward with a special of \$10 for the best arranged bee hive for all purposes, and the Association will add its diploma. Here is a chance for practical invention among the enthusiasts in bee-culture.

The Association through its Secretary, C. F. Ernst, is doing everything to make the apiarian department a success.

The officers of the Association would be very glad to have you attend the Exposition this fall, so that you might see the result of your visit and interesting lecture last year, on Bees and Honey.

The premiums, general and special, amount to over \$200, and are the most liberal yet offered. Among the specials is one of \$20, for the best 20 pounds of honey exhibited by any lady not a resident of Missouri. This should awaken the emulative efforts of many of the fair apiarists, several of whom, notably Mrs. L. Harrison, Vice President for Illinois of the North American Bee-Keepers' Society, and the Misses Wilkins and Mrs. Baker of Michigan, are apiarists of no mean merit.

What with the many very able bee-keepers' societies and conventions to harmonize action and customs, and the liberal inducements and facilities being held out by fairs and expositions, we do not see how a more effective system of co-operation can possibly be inaugurated, especially if bee-keepers themselves turn out *en masse* to attend these conventions and fairs, and bear each his share of the burden in counseling wisdom and giving instruction. The fact of the apiarian department being novel and attractive, is proof positive that the public need enlightenment regarding its exhibits, and the more they are familiarized with it, the greater will be the demand for its products.

☞ We learn, by private letter, that Mr. Frank Benton has removed from Larnaca, Cyprus, to Beyrout, Syria. We have not been advised as to the cause of his change of location. Can it be that he is abandoning the propagation of Cyprian bees, and has removed to facilitate the rearing of Syrians with greater purity?

☞ We will supply sample copies of the BEE JOURNAL and large colored posters to any who may make a display at the coming fairs, to aid in getting up clubs.

☞ We have received the Catalogue of small fruits and grape vines, for 1882, of E. P. Roe, Cornwall-on-the-Hudson, N. Y. It contains 20 pages, embracing everything in his line.

☞ The census report, 1880, will make the largest book ever published. It will consist of 30 volumes, and will cost \$1,000,000. To be of any value, it ought to be issued to the public soon.

☞ When changing a postoffice address, mention the *old* as well as the *new* address.

AMONG OUR EXCHANGES

MISCELLANEOUS.

Honey and Bee Shows.—The *American Agriculturist* gives the following on Honey and Bee Shows in Europe and America :

One of the features of the apiculture of Europe is the holding of large exhibitions of bee products and apiarian implements. The bee journals of Great Britain, France, and Germany are full of accounts of these large and interesting Honey Shows. So great is the skill displayed in making the exhibits, and so attractive are the displays, that it is no rare thing for the Shows to be visited by kings and queens. Surely the European apiarists find it advantageous to make these exhibitions, or they would not continue them year after year at great expense of time and labor. Not only are these meetings noted for their beautiful honey shows, but numerous essays, lectures, and discussions in connection with them, serve as educators in apicultural science and art.

Heretofore the honey exhibits in America have consisted of a few pounds of second-rate honey and a little beeswax, tucked away in some obscure corner, and sandwiched in between maple-sugar and syrup and sorghum-molasses. The premiums have ranged among the cents, and occasionally, in some unusual cases, have even reached a dollar. There was nothing to induce producers of honey to make exhibits, and still less to excite the interest or attention of visitors. Of course bee-keepers are to blame for this state of things, as no business demonstrates its importance at exhibitions unless its patrons possess sufficient enterprise to push it forward. It is very strange that American apiarists who have gone to the front in every other line of agricultural progress, have been so slow to recognize the great opportunity to advance the interest of their pursuit by encouraging and patronizing these exhibitions of bees, honey, etc. Owing to the fact that some of our leading bee-keepers had visited Europe, and witnessed the substantial advantages that resulted from these Honey Shows, there were two successful exhibitions of this kind held in America last year. These were at St. Joseph, Mo., and at Toronto, Canada, and so attractive were they, that no other part of the Fairs received so favorable comment from the press. Tons of honey were on exhibition at Toronto, and thousands of pounds were sold there. Bees were also exhibited and manipulated at the Fair, and the exhibit was further aided by the display of all the numerous and valuable implements and appliances that aid the bee-keeper in his work.

The place to hold these exhibitions is in connection with the several State

and County Fairs of the country. The requisites to success are generally premiums, in keeping with the importance of apiculture, a separate building in which to hold the display, a room fitted with gauze, so that the bees can be manipulated each day, with no fear from stings, even by the most timid person. The honey should be taken in quantities, both comb in sections and extracted honey in jars and tin pails. This should be put up with the greatest neatness, and labeled in an attractive manner. Some of it should be put in glass crates, so as to teach visitors how to present the honey for sale at the groceries. There should also be a large exhibition of wax, foundation, implements, and extractors, so that the decision of the judges, who should be experts, may carry weight with it. The best colony of bees should be taken, so ventilated that the bees will not suffer, and arranged that they can be so shown that every visitor may see how easy it is to handle bees without harm. Wire gauze may be so arranged around the hive that there need be no danger of exciting the fears even of the visitors. If the bees are properly ventilated, and fed a little every day, they will not suffer by being taken to the Fairs.

Driving away Red Ants.—In *Our Home and Science Gossip*, the following experiment is given :

Professor Leidly states that when he purchased his present residence, while it was undergoing repairs, he noticed a fragment of bread left by the workmen in one of the second story rooms swarming with little red ants. Apprehending that the house was seriously infested, to ascertain whether it was so he placed a piece of cake in every room from cellar to attic. At noon every piece was found covered with ants.

Having provided a cup of turpentine oil, each piece was picked up with forceps and the ants tapped into the oil. The cake was then replaced and in the evening was found covered with ants. The same process was gone through the following two days, morning, noon and night.

The third day the number of ants was greatly diminished and on the fourth there were none. He at once concluded that they were all destroyed, but in the attic he found a few feeding on the dead house flies, which led him to suppose that the remainder had become suspicious of sweet cake.

He accordingly distributed through the house pieces of bacon, which were afterwards found swarming with ants. This was repeated with the same result for several days, when in a like manner with the cake, the ants finally ceased to visit the bacon.

Pieces of cheese were next tried with the same results, but with an undoubted thinning in the multitude of the ants. When the cheese proved no longer attractive, recollecting the feast on dead flies in the attic, dead grasshoppers were supplied from the garden.

These again proved too much for

the ants, and after a few days trial neither grasshoppers nor anything else attracted them. They appear to have been thoroughly exterminated, nor has the house since been infested with them.

Toads and Bees.—The *Canadian Farmer* says:

Those who keep bees need to look out sharply for toads. Go among the hives in the "gloamin'," and ten to one you will see a solemn toad beside each of them, with face upturned heavenward, as though praying. So he is, phonetically speaking; but phonography, with all its advantages, fails here, for you must spell that word with an "e." He is preying on your bees, and if you watch him closely you will see him, every now and then, dart out his long, slimy tongue, and gather them in with a celerity and gusto perfectly marvellous. Toads are valuable in a garden, but destructive in an apiary.

Manufacturing Supplies.—A correspondent of the *Canadian Farmer* takes exception to the views of the editor in the following language :

You say every bee-keeper should make his own hives (which advice is good), and I suppose make his own extractor, make his own comb foundation, and everything he uses, rear his own bees and queens. Now the same might be said of the farmer. He should make his own wagon, mowing machine and horse rake, ploughs, and all other implements, rear all his own stock. But how is he to get started, besides most of the above articles could not be made without proper machinery. It would not pay every bee-keeper or farmer to get such machinery, therefore, one gets it and manufactures for his neighbors, hence a supply dealer.

☞ The Northwestern Bee-Keepers' Convention will meet at Chicago, Ill., on Tuesday and Wednesday, Oct. 17 and 18, 1882. The office of the *American Bee Journal* has been kindly tendered as a place of meeting. A cordial invitation is extended to all bee-keepers, and especially those of the Northwestern States, to be present. The meeting takes place during the last week of the Inter-State Industrial Exposition, to enable all to obtain reduced railroad rates. First session at 10 a. m. C. C. MILLER, *Pres.*
C. C. COFFINBERRY, *Sec.*

☞ Those who may wish to change from other editions to the *Weekly*, can do so by paying the difference.

☞ We will send Cook's Manual in cloth, or an *Apiary Register* for 100 colonies, and *Weekly BEE JOURNAL* for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with *Bees and Honey*, in cloth, \$2.50.

For the American Bee Journal.

Sale of Comb Honey—No. 1.

G. M. DOOLITTLE.

Owing to pressure of business, a sick and helpless father to care for, and a large correspondence to keep up, I have not been able to give the last part of my series of articles as soon after the second part as I had expected to, but as this is the time we are all thinking about marketing our honey, perhaps these last will be in as good time as if written earlier. On page 390 we had our honey all graded and crated in nice shape, ready for sale at any time that we could get prices to meet our views as to the value thereof. How to best sell a given production is a question of vital importance. Many seem to overlook this fact, and by their actions tell us that a large production is about all they are after. I have known parties to pride themselves about the large production of butter they could get from a given number of cows, hurrying it off to market in an unseasonable time, and selling it at a low figure, thereby realizing less for their large production than did their more sagacious neighbors with $\frac{2}{3}$ the amount. Just so honey is often forced upon the market at a low price by those not posted, while the live bee-keeper will get nearly $\frac{1}{3}$ more for his crop from having a full knowledge of the value of his production.

Hence, after producing a crop of honey, the next thing to do is to thoroughly post ourselves regarding its value. We frequently see men selling nice honey at 12 to 14 cents per lb., when the same article was worth 18, claiming that the price they sold at was all they could get for it at the market they were in. This might be so, but the cause of so doing was, in not being posted regarding the price paid in other markets. Much honey is yearly sold in Syracuse, N. Y., at quite a low figure, while if the person selling was posted regarding the value of honey in Boston, New York and Philadelphia, such sales would not be made. Thus, these sales by parties not posted keeps the market so low that the wide-awake bee-keeper has no chance to place his production in a market near home. But how shall we ascertain the true value of our honey? By reading the BEE JOURNAL we can find out the market quotations in the different cities about us. Thus, if New York quotes honey at 20 cents per lb., our product is worth that less the expense of getting it there, and the commission charged by the merchant we consign it to. For example: to get the best express rates I go to Syracuse, N. Y., where the rate of \$1 for 100 lbs. is given on honey to New York City. As this is gross weight, the weight of the crates

must be deducted, by which we find that it costs about \$1 for every 85 lbs. of honey—say 12½ cts. per lb.—so it will be sure to cover all expenses of getting to market. Next deduct 10 per cent. for selling (as this is the price charged by most commission merchants), and we have 2 cents more, or 3¼ cents in all, which taken from 20 cents, shows that the actual value of our honey at home is 16¼ cents as compared with the New York market. Now figure on Chicago, Boston and other markets, and see if any of these will do any better, and in this way you can find out the highest value of your crop, and where it will pay you best to ship, thus being thoroughly posted in the matter. Having done this, we are prepared to sell at home or abroad.

First, then, I will speak of selling at home. Having ascertained the value of our honey, we go to our nearest town with an average sample of our honey, and ask our grocer what he can pay for honey. If he can pay *cash down* as much into 1 cent per lb. as I have found it to be worth by the above line of reasoning, I sell it to him. My reasons for so doing have been, that in case of selling outright I have the money at my disposal, and can often invest it so as to make more than the penny a pound would amount to before a return was made from the commission man, for selling on commission sometimes proves to be a slow process of disposing of our production. If our grocer does not offer us the price we have figured our honey to be worth, show him the quotations, and our line of reasoning, which will often change his opinion by convincing him that we are not trying to beat him, nor get more than our honey is really worth. Thus we make a tour through all the towns about us, and if we produce but a few hundred lbs., all can be disposed of, providing our friend who "sells for a song" has not been ahead of us. If we are given to peddling, there is but little trouble in selling quite a large crop throughout the surrounding country, but in this case the bee-keeper needs considerable time at his command. The price of the honey should also be put enough higher than we have proven the real value to be, to cover all the necessary expenses of retailing our crop. In selling in this way, a good plan is to go over the route, or send a boy a week in advance of the time we expect to sell, with a little honey as a sample, and printed slips telling what flowers the honey is made from, the price per lb., and when we shall come around with it for sale. Let the boy leave a small piece of honey at each house and one of the printed slips, and upon going around you will find the way opened for quite an extensive sale of honey in a retail way. Several years ago, being short of money to pay my taxes, and having a little second quality honey on hand, I started out on the above plan, to see if I could not meet this certainty ("taxes"), which is classed with "death" as being the only two certain things in this life. I left a sample and slip at 30 houses, which numbered 115 inhabi-

tants. According to the time appointed on the slips I was there with the honey, and the result showed 153 lbs. sold, or an average of 1½ lbs. to each person, thereby securing enough to meet the collector's bill and some to spare. However, as I dislike to peddle, I generally adopt other methods of sale; yet when a person has the tact to sell, there is no way more profitable than this in my humble opinion. My next will be selling in large cities and shipping on commission.

Borodino, N. Y.

For the American Bee Journal.

This Season's Honey Crop, etc.

J. R. BAKER.

My bees have not done so well up to this time, this season, as they did last. They have gathered enough honey to fill their brood chambers chock-full, and have stored a good deal of surplus; and they are now working very industriously. Should the frost be late in coming, and the weather be propitious from this time on, I shall have a very fair crop. As "hope is the anchor of the soul," I shall use it for my consolation until I realize its full fruition, or be compelled to take my place in the ranks of those who have had hope so long deferred that the heart has become sick.

And now, I have a little joke to tell on myself, and a word of encouragement for the ladies who contemplate engaging in apiculture. Mrs. Ellen Gray, who lives a fourth of a mile from where I keep part of my bees, concluded last fall that she would like bee-keeping, and asked me to sell her several colonies. I let her have 20 colonies in 10 frame Langstroth hives, for which she paid me eight dollars each. She knew positively nothing about the business, only what little she had gathered from a visit or two to my apiary, and the little she gleaned from my conversation on the subject, for you know bee-keepers will talk, and talk bees and honey, too. Well, when I made the sale of the 20 colonies to the lady, part of the contract was that I should give her such advice and instruction as I thought necessary to assist her to a successful career as an apiculturist. All the bees, both hers and mine, were put in one cellar for the winter, and when spring came and the cheerful sunshine began to warm this part of the world into new life; when the blue birds cheered our hearts with their merry notes at the funeral of old winter, and the buds of the willow and maple and elm commenced to unfold themselves under the inviting warmth of the king of day, the lady bee-keeper and myself commenced to talk bees with a relish that only those can appreciate who revel in the songs of birds and the beauty of opening flowers and the merry hum of the tireless bees, as they sweep over mountain and valley, garnering the precious nectar that is poured out in amber drops from the great and exhaustless storehouse of nature.

I performed my part of the work as

best I could, lending her Prof. Cook's "Manual of the Apiary" and the Weekly BEE JOURNAL, and selling her Mr. A. I. Root's "A B C" book. My student seemed very much interested in her new vocation, and learned, as I thought, very rapidly. Having much work to do for myself, as the season advanced, I had to let the lady look after her interests with but very little assistance from me. And now, ladies, I am humiliated, for the student has excelled her teacher in honey production, the first season after she embarked in the business! She has got, to date, twice as much honey from the same number of colonies as I have.

Mrs. Gray did not trust to "luck." She has no faith in it; but she went to work right, and victory is hers. She has 40 colonies in most excellent condition, half of them crowding the boxes and sections with beautiful honey, and a good prospect at present for harvesting a big crop by the end of the season. Who can show a more successful student? And who will say that ladies cannot make successful bee-keepers?

Keithsburg, Ill.

For the American Bee Journal.

Philadelphia, Pa., Association.

ARTHUR TODD.

The members of the Philadelphia, and Vicinity Bee-Keepers' Association, met in the evening of the 14th inst. at the residence of the Secretary, Mr. Hahman.

This gentleman has kept a colony or two of bees some years with varying success, but this year having made a study of the best literature he can obtain, has gone more scientifically to work, and with results eminently satisfactory. His visitor were well rewarded for any extra trouble in reaching Mr. Hahman's out-of-town residence by an inspection of his neatly kept and prosperous apiary. The mysteries of the hive were unfolded, and opportunity given to see comb foundation in process of being worked out, the queen bee, and all the little bees.

Mr. Hahman stated that he commenced the season with 3 colonies; about swarming time, he found a stray swarm on his grounds which, having supplied with a good home, they deigned to accept and so made his stock four. His first 3 colonies yielded five swarms which were all safely hived. Afterwards by division Mr. Hahman increased three, so that now at the end of the season he has 9 strong colonies, and 3 fairly good. He has sixty pounds of extracted honey which he will sell at 8c. per lb.—\$4.80. Forty pounds in section boxes, all sold at 20c. per lb.—\$8.00. Reckoning his increase in bees as eight colonies at \$5.00—\$40.00; this, together with \$12.80 for honey, makes the respectable sum of \$52.80 for profit account in 1882.

Having had a most enjoyable time the members returned to town, promising to renew the visit next year,

hoping on that occasion to be able to congratulate the worthy Secretary on still greater apiarian successes.

Philadelphia, Pa., Aug. 18, 1882.

For the American Bee Journal.

Given vs. Any Foundation.

JAMES HEDDEN.

In replying to Mr. Caldwell's article on page 520 of the BEE JOURNAL, I wish to say that we agree in three particulars of the discussion:

1st. The merits of the different styles of foundation are worthy the consideration of the apiarists of this country.

2d. That there is a decided difference does not admit of a doubt.

3d. That we should, in a friendly spirit, bring out all the good points in this important branch of our business.

But upon nearly every other point in his article we differ, and it seems to me Mr. Caldwell is surely in error. I will call the reader's attention to two facts: 1st. No report has ever been made in favor of any foundation, against the Given, by any person who used and tested both styles thoroughly.

Several reports have been made, and many more doubtless soon will be (I have quite a number of private reports), in favor of the Given over the Dunham foundation, by parties who have thoroughly tested both. As Mr. Caldwell has nowhere told us that he has ever tried the Given foundation, we fairly infer that he never has, hence, when he says he makes first-class foundation on the Dunham mill, do we not have the right to ask by what standard he uses the words "first-class"? How does he know? He further says his Dunham foundation satisfies a most fastidious class of customers. Now, I think I know how he comes by the idea that his customers are of a most fastidious class—first, because any supply dealer will soon think that, and second, he may have had his foundation found fault with by some.

He thinks I failed because I was not a good mechanic. Let us call it so. That proves that a poor mechanic can succeed nicely with a machine as well made and adapted to its purpose as is the Given press, since I have succeeded in making more sheets per minute and per hour than Mr. Caldwell has yet claimed, and that, too, with less daub and trouble of lubricating. I get the impression that Mr. Caldwell is of a conservative turn of mind: that he never says, "Give me better things, I want a better hive, a better bee, a better extractor, a better smoker, better foundation, etc., as did Langstroth, Vandervort, Coffinberry, Bingham, and others. He says: "Matchless rolls," "tried friend," "I am satisfied," "my customers are satisfied," etc.

How many of these customers do you suppose ever used Given or Vandervort foundation, either of which I found superior to Dunham foundation? How many of them ever used any foundation before? Had I been of this turn of mind I would once have

said of the first Root foundation, "I am satisfied;" then of the Dunham, "I am more than satisfied;" then of the Vandervort, "I am most satisfied;" then of the Given, "I am more most satisfied," then of the 1882 improved Given, "I am so satisfied that I do not want any more of these good satisfying things." But I say to Mr. Given, "Give us a better press and a better book." I have said so, and he replied, "In 1883 I will do it." In my judgment he will. The man who has outdone all others, can then look forward to the achievement of outdoing himself.

Mr. Caldwell says, "the test of the pudding is in the eating of it," and then follows by saying that I say: "Give a prime swarm on 8 wired frames of Given foundation, and in 48 hours (2 days) we have 8 splendid combs completed;" then says he has hived swarms on 11 frames filled with Dunham foundation, and in 3 days it would be filled with comb and honey, and every comb drawn out in a perfect manner. "Perfect" compared with what? One of his that dropped down? I do not see that, as he states it, he is ahead. But to accomplish this he tells us that three things are necessary: "1st. The foundation must be made of good tough wax; 2d. It must be fastened to the frame in the most perfect manner; 3d. It must (in his opinion) be made on the Dunham foundation machine."

Well, here is where the superiority of the Given wired foundation is established. 1st. Foundation made of any pure wax will stay perfectly in place, and be quickly drawn into perfect combs, that jarring, extracting and sun-heating will not displace. 2d. It need not be fastened to the frames at all. 3d. Such foundation cannot be made on the Dunham mill. Is the above what Mr. Caldwell calls a test? There may be as much difference in the success with which a bungler like me, and an expert, like Mr. Caldwell, would have in getting foundation rapidly and perfectly drawn, as in their ability to manufacture on the Dunham mill.

The only slight advantage I have over Mr. Caldwell is that I have owned two Dunham, three Vandervort, and three Given machines. I have made, used and sold, far and near, thousands of lbs. of these three sorts of foundation. I have conducted careful and comprehensive tests with the three sorts (Root included as the 4th), and that, too, in company with employees, students and visitors. I have also sent two and three sorts to parties ordering, and asked for tests and reports. I have also a part of the time employed an expert mechanic who is noted for his ability as a machinist, to assist in the manufacture of foundation. I found the press much the easiest to operate, and its products much the easiest for the bees to make into the best combs. During my experiments of former years, I had Dunham foundation made by various parties, the best of which was 83 lbs. made by Mrs. Dunham, and of this lot she wrote me she earned wax and all in the making. This, too, fell behind the Given of first

manufacture. The Vandervort, while not equal to the Given, always showed a superiority over the Dunham. Now, there are quite a number of Vandervort mills in use, and some in the hands of those who do or have owned Dunham mills, and I ask for a report from some of these parties who speak more from experience than prejudice. I have many one pound sections of honey marked "G," "V," and "D," and we are eating them on our own table, as we need them, and the G's are the only combs that you cannot detect that foundation was used in.

Mr. Caldwell closes by assuming that there is no better machine than the Dunham, because he says he "ventures the assertion that where 1 pound of Given is made and sold, 100 lbs. of Dunham is disposed of in like manner." I suppose he really thinks that extravagant statement is true. Should I allow my mind to reason down to my own little experience, I would think the same of the Given vs. the Dunham, because my trade is now all Given, the demand for Dunham and Vandervort running down so light I stopped trying to make these sorts at all.

But let us examine this specimen argument. Will Mr. Caldwell be so kind as to let us know how many pounds of foundation we shall have to sell from the Given mill next season to make that the best mill, and its work superior? I never knew before that you could make and sell enough foundation of any sort to make it the best foundation. By this reasoning the Root foundation excels the Given and Vandervort, if not all other sorts, Dunham included. There certainly was a time, only a few seasons ago, when the Root was the best mill, and its product the best foundation in the world, measured by this standard. This standard, given by Mr. Caldwell, is a great boon to apiarists; all we need to do now, to place all the styles of foundation in their proper class of worst, bad, good, better, best, is to take the foundation census.

Dowagiac, Mich., Aug. 17, 1882.

P. S.—At the "eleventh hour" Mr. Caldwell is saved; he says: "If there is a better machine made, I want it," and I say, Mr. Caldwell there is, and I look forward to the near day when you will know it as well as I do.

For the American Bee Journal.

No "Gap" Here in Honey Flow.

C. W. MCKOWN.

Some speak of a "gap" in the honey season. There has been no gap here this season since white clover first blossomed. It was 8 or 10 days later blossoming than usual, but the quantity was simply immense, and plenty of rain has kept it booming till the present time. The linden flow was extra good (though several days later than usual), and blossomed very unevenly; while the blossoms were dying on one tree, they were just beginning to open on the next. Thus it continued much longer than com-

mon. While it was at its best, the bees deserted the white clover to a great extent, but returned to it when the linden failed. There are about forty acres of buckwheat near my apiary, sown at intervals for five weeks. The first sown is now white with bloom, while the last is only cleverly up. Very many bees are at work on it, while some still cling to the white clover, and the sweet clover is by no means neglected.

I have not weighed the surplus from but one hive this season. Up to Aug. 7th it had yielded 203½ lbs. of extracted honey. This, mark you, is from a single colony, excluding the product of two swarms it sent out.

My bees are still swarming; had three swarms to-day. Such a long, steady honey flow has caused the queens to lay immensely, producing bushels and bushels of bees. I have put a great many swarms in with other colonies, which is not advisable, as in many cases I have found them queenless soon after uniting. I think No. 1 bees kill No. 2 queen, and No. 2 bees kill No. 1 queen. When swarms cluster together, I invariably have them together. I have had as many as four big swarms together in this way, and gave them room by tiering up, and it is wonderful how quickly they will gather 100 lbs. of honey. When they have clustered together at least one queen is safe.

I began the season with 60 and have more than doubled notwithstanding all the uniting, doubling up and piling together I have done. Think I shall have a big report to make when the season closes.

Gilson, Ill., Aug. 17, 1882.

For the American Bee Journal.

Queen Shipping Cages.

W. Z. HUTCHINSON.

To have queens arrive in good condition is very desirable to both shipper and receiver. To open a queen cage upon its arrival, and find the queen dead, is often a greater disappointment and loss to the purchaser than the sending of another queen is to the breeder. As Mr. Poppleton remarks, on page 411, it is a great advantage to know that a certain number of queens are sure to arrive in good condition within one or two days of a given time; and, to help bring about such a happy state of affairs, in general, please allow me to describe the cage and feed that I have been using the past year.

The cage is the old-fashioned wooden cage, made by sawing up ½ lumber into strips 1½ inches wide, boring 1½ inch holes, 3¼ inches apart from centre to centre, then boring two ½ holes close by the side of each inch and a half hole. Of course the holes are bored nearly through the strips of wood. With a ½ inch round iron a hole is punched through the thin partition that divides the large hole from the two small ones, and it is through these ½ inch holes that the bees gain access to the feed with which the ½ holes are filled. After a strip of wood

has been made up into cages, it is cut up into pieces of different lengths; some pieces containing only one cage, others two, while the longest pieces contain three cages. After reaching their destination, the cages are easily separated with a saw.
