ESTABLISHED IN 1861

THE AMERICAN BEE JOURNAL

Published every Wednesday by
THOMAS G. NEWMAN,
 EDITOR AND PROPRIETOR,
 974 WEST MADISON ST., CHICAGO, ILL.
 At \$2.00 a Year, In Advance.

Remit by money-order, registered letter, express or bank draft on Chicago or New York, payable to our order. Such *only* are at our risk. Checks on local banks cost us 25 cents for collection.

Free of postage in the United States or Canada.
 Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

Given's Foundation Press.

The latest improvement in Foundation. Our thin and common Foundation is not surpassed. The only invention to make Foundation in the wired frame. All Presses warranted to give satisfaction. Send for Catalogue and Samples.
 Twly **D. S. GIVEN & Co.,** Hoopeston, Ill.

HEDDON'S CIRCULAR, FOR 1882, NOW READY.

Send address, Post Office, County and State. Be sure to state whether or not you now have my 1881 Circular.

Wanted—Beeswax; also, a Student Apprentice. Address, **JAMES HEDDON,** Dowagiac, Mich.
 1w35t

SOUTHERN CALIFORNIA!

All about Resources, Climate, etc.
 What can be done here, what it costs to come, routes, when and where to go.
 The great Agricultural and Horticultural Paper of the Pacific coast.

Semi-Tropic California, AN ILLUSTRATED MONTHLY.

Subscription price east of the Rocky Mountains, \$1.00. Sample copy to any address FREE for three three-cent stamps.

Address, **CHAS. COLEMAN, JR.,** LOS ANGELES, CAL.
 Mention this paper. 49m4tx

Muth's Honey Extractor,

Square Glass Honey Jars, Tin Buckets, Langstroth Bee Hives, Honey Sections, etc., Apply to
C. F. MUTH,
 976 and 978 Central Ave., CINCINNATI, O.
 Send 10c. for Practical Hints to Bee-Keepers. 1wly

1882.--QUEENS--1882.

I am now booking orders.
 Warranted Italian Queens \$1.00, six for \$5.00; Tested do., after June, \$1.50. Cyprians, Unwarranted, \$1.00, six for \$5.00. Seed for circular giving description and recommendation from Postmaster and county officers. Money order office, Versailles, Ky.
J. T. WILSON,
 1mtf Mortonsville, Woodford Co., Ky.

IF YOU KEEP BEES, SEND TO J. A. OSBORNE,

Rantoul, Champaign Co., Ill., for Circular and Price List of Hives, Sections, Smokers, Honey Extractors, Comb Foundation, Bees, Queens, etc. All goods warranted. 1wly

Langstroth Hives & Sections.

Lewis' Improved One-Piece Section.

Objection has been made for the last two years, by Heddon and others, to the One-Piece Section, on account of the sharp corners made by the side-insets, and by others to the tendency of the bees to make the combs narrower at the insets. Our attention was called to these objections by receiving large orders for sections without the side-insets (one party ordering 30,000). We have now decided to manufacture them like the above cut, without side-insets. This improvement also enables us to make them at a lower price, as there is less labor on them. Price, \$1.50 per 1,000 on orders not less than 500. No charge for crating. No Patent on this Section.
 Send for new Price List, now nearly ready.

C. B. LEWIS,
 January 1, 1882. 1mtf Watertown, Wis.

ELECTROTYPES

Of Engravings used in the Bee Journal for sale at 25 cents per square inch—no single cut sold for less than 5c.
THOMAS G. NEWMAN,
 974 West Madison Street, Chicago, Ill.

CLUBBING LIST FOR 1882.

We supply the Weekly American Bee Journal and any of the following periodicals, for 1882 at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

Publishers' Price. Club.

The Weekly Bee Journal (T. G. Newman) \$2 00..

and Cleanings in Bee-Culture (A. J. Rood) 3 00.. 2 75
 Bee-Keepers' Magazine (A. J. King) 3 00.. 2 60
 Bee-Keepers' Instructor (W. Thomas) 2 50.. 2 35

**DAVIS' PATENT HONEY CARRIAGE,
REVOLVING COMB-HANGER.**

Tool Box and Recording Desk Combined.
Carries honey from the hive to the Extractor, a set of apiarian tools, metal-lined drawers for broken combs and fragments of wax, revolving comb-hanger, which holds comb firmly while pruning or cutting out queen cells, writing desk, and wash basin; will not break nor bruise combs; adjusts to fit all sizes of extracting and brood combs, and is less laborious to handle than the ordinary hand-baskets. Write your address on a postal card, and address it to
JOHN M. DAVIS,
30wly Patente and Proprietor, Spring Hill, Tenn.

Rev. A. SALISBURY
Camargo, Douglas County, Ill.

Warranted Italian Queens, \$1.00; Tested Italian Queens, \$2; Cyprian Queens, \$2.00; Tested Cyprian Queens, \$1; 1 frame Nucleus, Italian, \$4.00; 1 frame Nucleus, Cyprian, \$5; Colony of Italians, 5 frames, \$5.00; Colony of Cyprians, 8 frames, \$10.00. Wax worked 10c. per lb. Pure Comb Foundation, on Dunham Machine, 25 lbs. or over, 27¢. Send for Circular. 1wly

PARKER'S GINGER TONIC

Ginger, Buchu, Mandrake, Sillingia, and many of the best medicines known are combined in Parker's Ginger Tonic, into a medicine of such varied powers, as to make it the greatest Blood Purifier and the Best Health & Strength Restorer Ever Used. It cures Rheumatism, Sleeplessness, & dizziness of the Stomach, Bowels, Lungs, Liver & Kidneys, & is entirely different from Bitters, Ginger Essences and other Tonics, as it never intoxicates. Hiscox & Co., Chemists, N. Y.

Parker's Hair Balsam.
The Best, Cleanest, and Most Economical Hair Dress. Never fails to restore the youthful color to gray hair.
50c. and \$1 sizes. Large Saving Buylng Dollar Size.

Thirty-six Varieties of Cabbage; 26 of Corn, 28 of Cucumber, 41 of Melon, 33 of Peas, 28 of Beans, 17 of Squash, 23 of Beet and 40 of Tomato, with other varieties in proportion; a large portion of which were grown on my five seed farms, will be found in my Vegetable and Flower Seed Catalogue for 1882, sent FREE to all who apply. Customers of last season need not write for it. All seed sold from my establishment warranted to be both fresh and true to name, so far, that should it prove otherwise, I will refill the order gratis. The original introducer of Early Ohio and Hubbard Potatoes, Marblehead Early Corn, the Hubbard Squash, Marblehead Cabbage, Phinney's Melon, and a score of other new Vegetables. I invite the patronage of the public. New Vegetables a specialty.

James J. H. Gregory, Marblehead, Mass. 4m5t

The Original Patent
BINGHAM BEE SMOKER
AND
Bingham & Hetherington
HONEY KNIFE,
Send a card for testimonials, or half-dozen rates, to
BINGHAM & HETHERINGTON,
ABRONIA, MICH.

GOLD MEDAL Awarded the Author. A new and great Medical Work, warranted the best and cheapest, indispensable to every man, entitled "The Science of Life, or Self-Preservation," bound in finest French muslin, embossed, full gilt, 300 pp., contains beautiful steel engravings, 125 prescriptions, price only \$1.25 sent by mail; illustrated sample, 6c; send now. Address Penobscot Medical Institute or Dr. W. H. PARKER, No. 4 Bulfinch st., Boston. 22wly

FOR SALE—150 Colonies of Italian Bees in improved Quinby hives, in prime condition. 39wly L. C. AXTELL, Roseville, Warren Co., Ill.

65 ENGRAVINGS.

The Horse
BY B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents.—Sent on receipt of price, by
THOMAS G. NEWMAN,
974 West Madison Street, CHICAGO, ILL.

THE KANSAS BEE-KEEPER,

Devoted entirely to the best interests of those who keep bees. The question department, conducted by Dr. Wm. R. Howard, is of especial interest to beginners in bee-culture. Jas. Heddon will write a practical article for every number for 1882; 20 pages handsomely gotten up in book form. Every number worth the price of a year's subscription. Sample copies and premium list free to any address. Agents wanted.
SCOVELL & ANDERSON,
Columbus, Kansas. 28wtf

CALIFORNIANS ATTENTION.

FOR SALE VERY CHEAP,
a four-inch Dunham Machine, just right to make foundation for small frames. Everything necessary to go right to work.
S. S. BUTLER, M. D., Los Gatos, Cal. 51w4t

The Bee-Keeper's Guide;
OR,
MANUAL OF THE APIARY,
By A. J. COOK,

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 4,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:
All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY.**

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. P. WEBB.**

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**E. H. WYNKOOP.**

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL.**

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—**WM. VAN ANTWERP, M. D.**

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or English, which I like so much.—**L'ABBE DU BOIS**, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *vade mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, \$1.25; in paper cover, \$1.00, by mail prepaid. Published by
THOMAS G. NEWMAN,

VOL. XVIII.—1882.—No. 1.

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR,
974 WEST MADISON ST., CHICAGO, ILL.

TERMS OF SUBSCRIPTION:

WEEKLY—(52 numbers) \$2 a year, in advance.
Three or Six Months at the same rate.

SEMI-MONTHLY—The first and third numbers of
each month, at \$1.00 a year, in advance.

MONTHLY—The first number of each month, at
50 cents a year, in advance.

Any person sending a club of six is entitled
to an extra copy (like the club) sent to any address
desired. Sample copies furnished free.

CHICAGO, ILL., JANUARY 3.

"Hallelujah; 'Tis Done!"

This well-known and oft-repeated sentence expressed our feelings as we saw the last wagon load of BEE JOURNALS go to the post office, for the year 1881. It was a long and trying pull to get through with the first year of the Weekly; it involved the expenditure of considerable money, much labor of brains and hands, and, in the face of the all-but universal depletion of bees last winter, and its consequent depression on bee-keepers in the spring, it required a steady hand and dauntless courage to maintain the Weekly in these very trying circumstances.

"It is finished;" the first year of the Weekly BEE JOURNAL is complete, and we view it with satisfaction—believing that, as a Volume, it is second to none of its predecessors. The encouragement and general endorsement it has received is even more than our most sanguine expectations. The subscribers of last year are nearly all renewing their subscriptions for 1882, and, with their renewals, express their unbounded approbation. Many who have heretofore only taken one or two numbers a month, now desire it every week, and hundreds of new readers are already enrolled for 1882.

It is hardly necessary to say that, for the coming year, we shall devote all our energy, determined to make the JOURNAL even more interesting and instructive than it has heretofore been, if that is within the range of possibilities. Its record, character, power and usefulness, in the past, will be its guarantee for the future, ever keeping in view the one grand object of its existence, that of further-

ing the interests of honey producers, by losing no opportunity to create a demand for this God-given product, opening up new avenues for its use, creating new demands and eager purchasers, both at home and abroad—thus benefiting every honey producer.

With encouraged heart, we, to-day, commence anew the battle for progress—with the motto of "ONWARD" inscribed on our banner—fully aware that patient and persevering work will conquer all difficulties.

Neither financial depression, loss of bees, failure of the honey crop in some localities, nor the foolish jealousies and merciless abuse, heaped upon us by evil-disposed persons, has been able to materially hinder the usefulness of the BEE JOURNAL, nor, in the least, to retard its onward march. From year to year it has increased in size and frequency of issue, in order to give its thousands of readers and correspondents an opportunity to participate in an interchange of thought, and fully discuss the various topics of interest that are ever and anon presenting themselves to the apicultural world for investigation and decision.

In short, the Weekly BEE JOURNAL will continue to be the medium of the best thoughts of the most advanced apiarists of this age. It will keep abreast of the highest progress, favor the freest discussion, and, by every means in its power, advance progressive bee-culture.

Scotch Heather.

The true Scotch heather, *Calluna vulgaris*, the great honey producer of Scotland, has been found in America. As shown by botanical records, it exists at Tewksbury, Mass., on Cape Elizabeth, Maine, and in Cape Breton, Nova Scotia and New Foundland. Vick's *Magazine* contains the following historical record of the Scotch heather in America:

The existence of this plant in this country was a matter of great interest in botanical circles in the year 1861, and for some time afterwards. In that year Mr. Jackson Dawson, a gardener of Boston, made it known that the plants were growing in a wild state at Tewksbury. At first it was deemed incredible that it could be a native of this country. Dr. Gray took a great interest in the subject, visiting the locality and examining the plants. All the facts being elicited from those living longest on the farm where it grows showed a knowledge of the existence of the plants in that field as early as 1810, and the condition of some of the plants at that

time to be such as to warrant the belief that they were at least a hundred years old, thus placing their origin near the year 1700. That part of the country is sparsely settled, and at that early date was still more so, and the spot where the heather grows is quite an unlikely one to attempt its cultivation. After considering all the circumstances, Dr. Gray, writing in the *American Journal of Science*, said: "It may have been introduced, unlikely as it seems, or we may have to rank this heath with *Scotopendrium officinarum*, *Subularia aquatica*, and *Marsilea quadrifolia* as species of the old world so sparingly represented in the new that they are known only at single stations—perhaps late lingerers rather than new comers."

Later, in 1864, when it was fully confirmed, as had previously been stated, that this heath grew in New

The Scotch Heather.

Foundland, its indigenous character was quite accepted. Still later in the same year, it was announced that *Calluna vulgaris* was growing at St. Annis, on Cape Breton Island. And in 1865 the re-discovery of it in New Foundland occurred, near Ferryland, on the east coast, where there is a small patch of it. Since then, as already stated, it has been found in Maine and Nova Scotia.

The plant being found in all these places, under conditions so unlikely for its introduction, little doubt remains that it is indigenous, and the probability that it is so is strengthened when it is considered, as has been noticed, that it exists at the extreme western limits of Europe, Ireland, Iceland, and the Azore Islands. New Foundland, Nova Scotia, Maine and Massachusetts are where it might naturally be expected, if found at all

on this continent. It is to be hoped that our Halifax friends will guard with scrupulous care the patch of it they yet possess.

Planting for Honey.

It is but a very short time since all the inquiries about planting for honey were answered nearly thus: "It will not pay to plant anything for the bees, unless it is useful for something else." The BEE JOURNAL for August, 1880, page 361, took the opposite ground, and now, to plant for honey has become almost as popular as the reverse was before that date. To furnish flora for our bees is just as reasonable and wise as to furnish pasture for our stock, and the time is coming when those who lack natural flora, and do not provide flora for the bees, will be thought as *old fogyish* as those who prefer box hives, black bees and from 6 to 10 pound boxes for surplus comb honey. It is very pleasing to notice the agricultural, as well as other bee papers besides the JOURNAL, coming into line and advocating *progress* in this matter. The *Indiana Farmer*, of last week, advises bee-keepers to plant for honey, and adds:

We have not had the room and time for extensive planting ourselves; but so far as our personal experience goes, we are satisfied of the feasibility of the plan. We believe that it will pay in a financial point of view, and in the more settled districts is destined to become the chief corner-stone for profitable bee-keeping.

Yes, it "is destined to become the chief corner-stone for profitable bee-keeping;" there can be no doubt of it in the minds of reflecting, *practical* men. It will pay to have bees work on basswood or white clover for a week or two, how much more profitable will it be to give them *continuous pasturage*, from which to gather honey from spring till frost? This is self-evident, and settles all controversy! By all means, plant for honey. There are many good honey-producers, but none are better than sweet clover—and none can give a more continuous flow of honey from June till after it is too cold for the bees to fly.

On Dec. 31, 1881, Mr. W. F. Connor, 151 Water street, Chicago, made a voluntary assignment, and Elisha Moore, Jr., was appointed assignee. The liabilities are put down at about \$1,800, and the assets are nominal. So said the *Chicago Tribune*. Mr. C. had handled some honey, but we hope bee-keepers are not largely interested.

On page 395 of the BEE JOURNAL for Dec. 14, Mr. Heddon makes use of the following language, in speaking of comb foundation: "Every year I receive samples by mail, and wherever I have ordered a few pounds, I have never in a single instance received ever so small a lot equal to the samples. Nearly every piece of these samples betrays the use of soap." We have received several letters from foundation manufacturers in reference to this matter, all complaining of injustice done them by implication. Of course, this was far from Mr. Heddon's intention, who probably intended only to censure the frequent practice of selecting the finest specimens as samples of their general sales. We trust no further notice will be taken of this matter.

Many topics suggested by our correspondents for editorial articles are waiting until we can get time to write them. We hope soon to reach them—we are very busy now.

MISCELLANEOUS.

Progress.—The Iowa City *Republican*, in its report of the Fine Stock Convention, held at Iowa City, Iowa, says:

"Points of Progress in bee-keeping" by Rev. O. Clute, was the subject of an interesting address. The speaker, who has become well-known the country over, delighted an already tired audience with a wonderfully interesting impromptu talk. He explained his method of caring for bees, extracting honey, etc., illustrating his remarks by exhibiting his hives and other apparatus.

Progress of Bee-Culture in England.—F. R. Jackson, Esq., writes as follows to the *West Sussex Gazette*:

Although there are few pursuits which with a like amount of care and capital yield equally remunerative results, apiculture, as compared with other branches of industry, has been, till lately, much neglected in England. In May, 1874, several philanthropic and spirited gentlemen acquainted with bee-keeping, much interested in its pursuit, and convinced of the practical benefits resulting therefrom, formed a committee, and instituted the British Bee-Keepers' Association, for the encouragement, improvement, and advancement of bee-culture in the United Kingdom, particularly as a

means of bettering the condition of cottagers and the agricultural laboring classes, as well as for the advocacy of humanity to the industrious laborer—the honey bee. Under the auspices of this Association, the cottager soon found the hive bee the most profitable live stock, necessitating a very small outlay, and thriving with little expenditure of time, which could be given when most convenient. So successful has bee-keeping proved under the modern rational and humane system, that a hive of bees returns in ordinary seasons from 100 to 500 per cent. on its actual cost, many cottagers not only paying their rent by their bees, but realizing a considerable profit beyond this. Such success has attended the efforts of the British Bee-Keepers' Association, that numerous county associations have been formed, over three of which the Princess Christian, the Duke of Connaught, and the Archbishop of Canterbury preside. Many noblemen also, as Presidents and Vice Presidents, are interested in bee-keepers' associations, which are doing good work in their respective counties. Over the Parent Association, the Baroness Burdett-Coutts, ever ready to lead the way in encouraging works of practical utility, has for some time presided.

No county in England is more favorable for bee-keeping than Sussex, for which a Bee-Keepers' Association is about being started, and the name of a popular nobleman as its President, augurs well for its prosperity and advancement. A pursuit at once so interesting and profitable, should surely meet with the hearty support and co-operation of all who have at heart the comfort and well-being of the industrious cottager.

Wasted Sweetness.—Mr. W. Z. Hutchinson, in the *Rural New Yorker*, says:

There is, probably, enough honey that goes to waste for want of bees to gather it, to sweeten all of the pies, cakes and cookies that are baked. Upon nearly every eighty-acre farm there is enough honey secreted by the flowers each year to furnish its owner with "sweetening power" from honey harvest to honey harvest. It is admitted by our best apiarists that a few colonies in a place give better results than a large number; therefore, if the bees were scattered about, a few colonies at each farm, there would not be so much sweetness wasted. To be sure, there are, and probably always will be, people who make a specialty of bee-keeping, owning their hundreds of colonies; and this is all right; it is to such persons as these that we are indebted for the improvements that have made bee culture the safe, pleasant and profitable pursuit it now is; but this need not deter any farmer from keeping a few colonies of bees that will supply his table with that most delicious and healthful of sweets, pure honey. They will probably find bee-keeping to be one of the most fascinating occupations in which they were ever engaged.

Odd-Sized Frames.—In answer to a question in the *Bee-Keepers' Magazine* Prof. Hasbrouck, says:

There is one serious objection to your plan. The size of frame you propose would be irregular, and on that account your bees would be unsalable at anything like their real value, if you should ever want to sell. Bees sell best in Langstroth or American frames, and probably as much honey can be taken with one of these frames as with the other, and as much with either as with frames of any other size. The honey secured depends more on the locations and upon the experience and skill of the bee-keeper, than upon the size of the frame he uses. If you are sure that neither you, nor your children, assignees, or executors will ever want to sell bees, you can put them into whatever frames suit your fancy, as long as you can make one of the standard size of sections fit along side, and on top of it.

Don't think of using any irregular size of sections, even if you use an odd frame. The standard sections are kept in stock by supply dealers, and can be furnished cheaper, and on shorter notice than you can get any made to order. Besides they sell better when filled.

Antiquity of the Bee.—An exchange remarks as follows on this subject:

The bee bears the same relation to the other orders of insects that the Caucasian race bears to the other races of mankind; it is the highest type of insectian form and development. Endowed with instinct, and "a kind of reason, differing perhaps only in degree from that of man, these insects outrank all other articulates." In the fossiliferous history of our earth, the bee does not date far back, but is the last to appear upon the earth's surface.

- May—Champlain Valley, at Bristol, Vt.
T. Brookins, Sec.
- 25—Iowa Central, at Winterset, Iowa.
Henry Wallace, Sec.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Southeastern Michigan Convention.

The first annual meeting of the Southeastern Michigan Bee Keepers' Association was held at the Court House in Ann Arbor, Dec. 15, 1881. The meeting was called to order by the President.

Professor G. B. Steere, of the University, gave a very interesting address on "the Races of Bees," which imparted much valuable information. Speaking of the Asiatic races, he said: The large black bee was twice the size of our common bee, and built their nests under the limbs of trees, make a large quantity of wax and produce some honey. There are also the small bees that build their nests in rocks and hollow trees. These species of bees he thinks will not prosper in this climate. The large bee is very ferocious, and it is very dangerous to undertake to capture them. The small ones are not so bad, but do not gather so much honey. Bee hunting is a profession with the natives; wax being the principal product. The large bee is *Apis Dorsata*. The professor has a young man living with him that he brought from the Philippine Islands, whose father is a bee hunter by trade. Taxes and church rates are there paid in beeswax. The Professor expects to get more information through this young native.

Another species found in the mountains of Formosa, where the climate is similar to ours, gather a good quantity and quality of honey, are very docile, live in the walls of houses, and are familiar with the family. He visited the mountains in his travels around the world, became acquainted with the missionaries, and thinks that they may be secured through them. He was chosen a committee to correspond with them in order that some nuclei may be obtained.

Dr. Ashley was very enthusiastic over the plan, and said we will call *Apis Formosa* the "coming bee."

The following essays were read: on wintering bees by N. A. Prudden; on feeding by L. W. Bodwell; on queen rearing by C. K. Bennett. The President gave an address, and several discussions followed. The following officers were elected: For President, H. D. Cutting, Clinton, Lenawee county; Joseph Butler, of Jackson, Vice President for Jackson county; C. K. Bennett, Vice President for Washtenaw county; and C. Thomson Briton, Livingston county; J. H. Murdock, of Dexter, Recording Secretary; G. J. Pease, Ann Arbor. Corresponding Secretary, and N. Eastwood, Ann Arbor, Treasurer.

The time and place of next meeting was left to the President, Secretaries and Treasurer, as an Executive Committee.

N. A. PRUDDEN.

The Northwestern Wisconsin Bee-Keepers' Association will meet in the City Hall at La Crosse, Wis., on Jan. 2, 1882. Essays and discussions on important subjects concerning bees will be the order.

L. H. PAMMEL, Sec.

The Northeastern Bee-Keepers' Association will hold their twelfth annual convention in the Common Council Halls, at Utica, N. Y., on the 25th, 26th, and 27th days of January, 1882. The executive committee are determined to maintain the high standing and enviable reputation the association has justly gained in the past, and propose to outdo all former efforts on this occasion. From present indications the coming convention promises to be the largest and most interesting ever held in America. New features will be introduced, and business of vital importance will be brought before the convention that makes it the duty of every member and bee-keeper to attend. Essays and addresses are expected from Capt. J. E. Hetherington, W. L. Tennant, L. C. Root, James Heddon, Chas. Dadant, T. G. Newman, N. N. Betsinger, Dr. A. H. Marks, and others of America's renowned apiarists, on the most interesting topics of the day. If you wish to enjoy the benefits to be derived from the good work already in progress by this association, you will surely attend. All are invited; none can afford to remain at home. Articles and implements of the apiary for exhibition, etc., should be sent to the Secretary, at Utica, N. Y., who will take personal charge of the same and arrange all articles so as to compare favorably with others on exhibition.

DR. A. H. MARKS, *Pres.*
GEO. W. HOUSE, *Sec.*

The Nebraska State Bee-Keepers' Association will hold its annual meeting in Ashland, Neb., on the 12th and 13th of January, 1882. A cordial invitation is extended to all who are interested in bee-culture. Members will be returned to their homes by the railroad companies at 1 cent per mile.

T. L. VON DORN, *Pres.*, Omaha.
G. M. HAWLEY, *Sec.*, Lincoln.

The eastern New York Bee-Keepers' Union Association, will hold their ninth Convention, Tuesday, Jan. 10, at 10 a.m., at Central Bridge, Scho. Co., N. Y.

W. D. WRIGHT, *Pres.*
N. D. WEST, *Sec.*

The annual meeting of the N. W. Illinois and S. W. Wisconsin Bee-Keepers' Association, will be held in Temperance Hall, Freeport, Stephenson Co., Ill., on Jan. 17 and 18, 1882.

JONATHAN STEWART, *Sec.*

The Indiana State Bee-Keepers Association is called to meet in annual session, Wednesday and Thursday, Jan. 24 and 25, 1882, in the rooms of the State Board of Agriculture. By order of EXECUTIVE COMMITTEE.

The Texas State Bee-Keepers' Convention will be held at McKinney, Texas, on Tuesday, April 25, 1882.

Subscriptions may commence with the first number of any month in the year.

CORRESPONDENCE

For the American Bee Journal.

Foundation for Sections—A Review.

G. M. DOOLITTLE.

Just at the close of the honey season for 1875, I received from Wm. Hoag, of New York city, a package of comb foundation to use in boxes, he saying, as an explanation, that a great saving was to be gained by the use of it, as the bees would draw the side-walls out to full-length cells, thus making the combs out of the wax in the foundation. As it cost 20 lbs. of honey to make 1 lb. of wax, a saving of \$4.00 per lb. was gained, as honey sold readily at 25 cents per lb. at that time, and a pound of foundation cost but \$1.00. This was supposing, of course, that the pound of foundation would hold as much honey as a pound of natural comb, and as it all looked reasonable at first sight, I tested the matter by buying one pound of it.

As the honey season was so near being over, I had to feed some extracted honey to get the sections containing the foundation sealed over, when I had as nice-looking sections of honey as I ever saw built with natural comb. However, I was soon convinced that the claim of saving to the bees was erroneous, as upon cutting, or rather, trying to cut these sections of honey, the knife would stop when it came to the foundation, and upon examination (which was done by a little scraping and washing), I found I had my original piece of foundation untouched except as the bees had added their wax to it in building out the cells.

The next year more was used from different makers with like results, at which time I began to expostulate with A. I. Root, the most extensive manufacturer at that time, reasoning that in time our honey markets would be spoiled if we persisted in using such thick stuff as a base to the comb in our surplus honey. His reply was that "It has already grown into quite an industry, and we are using wax by the ton." Time passes, and 1877 finds me with plenty of foundation, made from my own wax, upon which many experiments were conducted; but at the end of the honey season we found all our honey built on foundation contained a thick base or "fish-bone" in the center. Again I expostulated with Mr. Root, but was met with the reply: "It is utterly incomprehensible to me the way you stick to your old notions on foundation; it has filled the markets with most beautiful honey."

About this time the BEE JOURNAL lifted up its voice of warning, and bee conventions resolved against its use for comb honey to such an extent that some of our large honey producers began to study on the matter of making a very thin foundation to overcome this difficulty. In due time the Van Deusen flat-bottomed foundation appeared before the public as a result,

and we had foundation so thin that it took from 10 to 14 square feet to make a pound. This seemed to be successful as far as the "fish-bone" was concerned; but as the bees had to change the flat bottoms into a lozenge-shaped septum, it began to be whispered around that it was not accepted as readily by the bees as foundation with a natural-shaped septum. However, this was far ahead of any brought before the public so far, and thus it could be readily seen that we were making some progress.

During 1880 we hear of still another advance, as Mr. Vandervort has succeeded in producing foundation running from 10 to 12 square feet to the pound, with a lozenge-shaped base, which is said to work equally as well as the Van Deusen, and having none of the objections urged against that. Thus, we find the Northeastern Convention, in February, 1881, giving that the preference over the Van Deusen. We now find A. I. Root falling into line, and advertising, in his price list, *very thin* foundation for comb honey, running at least 10 square feet to the pound, and our faith is now quite strong that comb foundation for section honey will prove a success, for "out of a multitude of counselors cometh wisdom."

Accordingly, last spring, to make a thorough test, I procured foundation of the following parties: A. I. Root, Medina, O.; G. W. Stanley, Wyoming, N. Y.; J. G. Whitten, Genoa, N. Y.; R. Van Deusen, Sprout Brook, N. Y., and Chas. Dadant & Son, Hamilton, Ill. That procured of Root was his own make, but proved to run only 6½ feet to the pound, instead of 10 as advertised, and besides, it was made of very dark, dirty wax. That from Stanley was made on the Vandervort machine, was very nice wax, and run 11 feet to the pound. Mr. Whitten's was made on a Dunham machine, and was the nicest I had ever seen coming from a Dunham mill, as it run 10½ feet to the pound, and was made of nice wax. Mr. Van Deusen's was the thin flat-bottomed, which is, I think, the prettiest foundation to look at of any I have yet seen. Of Chas. Dadant & Son I had both the Root and Dunham.

The Root run about 7½ feet to the pound, and the Dunham about 6. As to the quality of wax, I will say this last was the nicest of all. I filled 20 section boxes full within ¾ of an inch of the bottom with each kind, and marked the name of the party producing the foundation on each box. In due time these boxes were placed on the hives so that an equal number (six, one of each kind) was on each hive.

The different hives were examined at different times, and the result showed that the two kinds produced by Dadant, and that by Stanley, were worked upon about alike, and finished at nearly the same time. That produced by Root and Whitten was about a day later in being finished, while the Van Deusen was nearly three days behind the first named. This was taking the average time of the 20 colonies

which worked upon them. Thus we proved by experiment, at least, that it did take time for the bees to manipulate the flat-bottomed foundation.

After all were off the hives we were anxious to know which kind had the thinnest base, or, in other words, which was the most free from the fish-bone center so much has been said about. Accordingly, I procured a very sensitive pair of scales, showing the variation of ¼ ounce accurately, and upon these fixed a No. 16 wire (being square at the end) so it stood perpendicular. I now placed the section of honey on this wire, letting it down carefully till the square end touched the base, and then watched the scale till the wire passed through, noting down the number of ounces resistance produced by the base of the foundation on this wire.

Each of the sections was thus subjected to this trial in three different places, when the amount was footed up and an average made, and the average of the 20 sections taken. When this was done, the same number of sections containing natural comb were subjected to the same test and an average taken, which gave us this showing: A. I. Root's make showed the average pressure of 6½ ounces; G. W. Stanley's make (Vandervort), 4¼ ounces; J. G. Whitten's (very thin Dunham), 5½ ounces; R. Van Deusen's (flat-bottomed), 5 ounces; Dadant's (thin Root), 5¼ ounces; Dadant's (thin Dunham), 6½ ounces; natural comb, 4½ ounces. Thus it will be seen that the Stanley (Vandervort) foundation is even thinner than the natural comb, according to this showing; then in order comes the Van Deusen, Whitten (very thin Dunham), Dadant (Root), Dadant (Dunham) and A. I. Root (Root), none of which proved to be as thin as natural comb. These experiments were conducted carefully, to arrive at the truth of the matter as near as could be done in one season with 20 section boxes of each kind. This showing is very flattering indeed to Mr. Stanley.

I am in no way interested in the sale of any kind of foundation, consequently am not prejudiced in the least. One thing I wish to say about all foundation, which I have long believed to be so, but have had no chance to prove it so till the past season, which is this: At a time when honey is coming in moderately, say when a good colony is bringing in from 3 to 5 lbs. per day of extracted honey, comb foundation is a success in the surplus arrangement, but at a time when honey comes in with a rush, the same colony gathering from 12 to 20 pounds per day, it does not pay the cost, for my bees will fill a box having a starter of natural comb, and finish it, as quickly as they will one full of foundation by its side. All through basswood the past season, when honey was coming in slowly, the foundation was drawn out and finished before a box by its side with a starter was half filled, but when the rush came on from teal and red clover, those with starters were filled fully as quick, as has been my experience for several years before.

Borodino, N. Y.

Beautiful Bees.

J. W. WHITE.

"I do not breed bees for beauty, but for business." "I do not care for bands, but for honey." "The bees which gather most honey are the bees which look the prettiest." How many songs of this kind are sung and caught up and repeated all over the land, until the uninitiated would think that there must be some inherent weakness in beauty, and some peculiar virtue in uncomeliness. Is it true?

The all-wise Creator has given us a sense of the beautiful, and he ever seeks to gratify it in ten thousand ways. He has also given us a more or less clear perception that the beautiful and useful are in some way very closely related. Who, in beholding beautiful homes and lawns, beautiful farms and gardens, beautiful horses and cattle, beautiful fruits and grain, beautiful implements and machinery, and, not to add more, beautiful bees and honey, does not feel some gratification, and does not believe that in some way, excellent qualities are, or should be, embodied in their beautiful forms? Why do people pay more for honey put up in neat packages than in uncomely ones? Is it not because they know that the good and the useful are closely related.

For this reason I am in favor of beautiful bees, beautiful in form and beautiful in color.

BEAUTIFUL IN FORM.

This is the first and most important factor of beauty in bees, as it is of their use. Agility or rapidity of motion in the animal kingdom, in birds, beasts, fishes and insects, is found, in a corresponding form, graceful, long and tapering. The Italian bees are just as much superior to the blacks as their form is more beautiful. In looking over some old volumes of the BEE JOURNAL this morning, I found in vol. IV., page 57, the following from the pen of Charles Dadant:

"All (Italians) are alike in all hives, all have three yellow bands... and, above all, an abdomen more tapered—a body more slender, giving them a more graceful shape and brisker appearance than those of our would-be improved bees. As it is above all in the shape of the body of the workers, that their superiority over the black bees resides, we must adhere especially to the shape of the Italian bees."

The italics are Dadant's. Has not this point been lost sight of too much, and in the effort to raise many queens for the market, has not beauty, and hence superiority, been sacrificed in many cases to numbers? Long, slender, tapering queens and workers are the most beautiful bees, and they are the best.

BEAUTIFUL IN COLOR.

Form should never be sacrificed for color, nor is it necessary. Can we not have the best qualities, not only in the prettiest forms, but also in the brightest colors? There is no law of necessity by which they can be di-

vorced. The best fruits have the richest bloom. The best cattle may have the prettiest marks. The brighter color, as well as prettier form of the Italian bees, is the signal and promise of their superior qualities. When they are kept perfectly pure in the clear, bright atmosphere of America, they grow into brighter colors, and, if they retain their perfect form, are as good honey gatherers as the newly imported Italians, or even better. Is it not possible that a good deal of the contempt for light-colored bees has arisen from prejudice, or something worse? In most places, owing to more or less admixture of black blood, it is a good deal easier to raise dark or leather-colored Italians than it is to raise queens which will produce light, three-banded workers. The first Italian queens I ever had, I bought from Langstroth, Quinby and Cary. They were all warranted to produce three-banded workers, and they did it.

In 16 years' experience, I have found that the bright Italians, as a rule, are in no way inferior to the darker ones. This last summer I gave special attention to this, and found that my lightest-colored bees are the very best workers I have. As I saw in the papers so much about superior colonies of the dark Italians, I sent to a number of the most reliable and widely-known men who offered queens for sale. It cost something, but I got my money back, if not in better bees—in a better knowledge of what others are doing.

If these dark-colored Italians have not some black blood in them, their looks and their manners belie them. Possibly their mother, or their grandmothers had a taint of black blood in them before they left Europe. They may be good honey gatherers—so are the hybrids. A pure Italian queen which has mated with a black drone, the kind I had 16 years ago, will produce good workers, and the queens raised from her will be large and prolific, and their workers very energetic and industrious. But as yet, I have found nothing which pleases me so well as beautiful Italians—beautiful in both form and color.

One point more: Bees, as everything else, have their normal size. All queens under the normal size should be rejected, at least they should never be used to breed from. It may produce no apparent change to breed from small queens for one or two generations, but if persevered in, it may produce dwarfed bees.

When I first commenced raising queens, I had some quite small ones; some of them did well, and some of them laid small eggs, and their bees when they first came out of the cell, were too small. There is danger here. In all the queens I have bought for years from different parties, there was only one or two which were not below the normal size.

As the result of all my experience and observations, I say in all sincerity, let others have what they will, but give me the long, tapering, three-banded Italians, and if they have been long enough in this country to become naturalized, and to hang out the

American colors, so much the better. A bright and beautiful bee is the bee for me, the bee for honey, and the bee for money.

Milroy, Pa., Dec. 15, 1881.

For the American Bee Journal.

Handling Bees Without Protection.

WM. F. CLARKE.

I have just been reading a bit of Mrs. Harrison's experience in bee manipulation, as narrated in the *Practical Farmer* of Dec. 17, and enjoyed a hearty laugh over it. Her ladyship was in such a hurry to try "Hill's Devices" for successful wintering, that, to use her own words, "we forgot to put on our wire hat and gloves, until reminded of them by receiving a sting on the nose, another on the cheek, and a bracelet of them around our wrists. Although we were destitute of an audience, we expressed our mind pretty freely with reference to those who advise working with bees without any protection. After delivering this essay we retired to the house, pulled out the stings, and, donning wire hat and gloves, went out again to the apiary a much smarter though sadder woman." The above would read better to my notion, if "I" and "my" had been used instead of "we" and "our." Not only so, but we could then concentrate all our sympathy on one sufferer. I wish I had been the audience to have heard that piece of Mrs. H's mind which she delivered so freely in regard to those who advise working among bees without any protection. But I add my "Amen" to it all the same, that is if she didn't say anything stronger than "drat-em," or "confound-em," which, of course, being a lady, may be taken for granted. Still, if she felt like the school-girl who wished she were a boy just for a little while, when she dropped her school-books in the mud, I should not be disposed to blame her very severely.

Very absurd things are sometimes said by bee-keepers of high standing about the use of veils and gloves, and the idea is often conveyed that, having recourse to them, is proof positive of want of certain qualities essential to apian eminence. I wish this class of bee-keepers, as well as myself, had heard Mrs. Harrison's impromptu remarks on the occasion in question. Judge M, an old friend of mine, and an enthusiastic amateur bee-keeper, was one of those who would have been "hit hard" by Mrs. Harrison, if he had been within hearing of her cursory remarks. But he was converted a long time ago by a bit of personal experience. It was a favorite pastime of his to poke fun at me for using a veil and gloves, but one day he called on me and said: "I have come to own up; yes, I confess the corn. After this, I shall wear a veil and gloves in handling bees." He then went on to relate, that, the day before, he was taking an after-dinner look at his apiary, when, by some mischance, his foot slipped, and he fell heavily against a hive of

bees, knocking it over. Instantly, the disturbed occupants came at him with fire and fury. Fortunately, the grass was long, and there was a big Norway spruce, well brushed to the ground, close by. Quick as thought he dropped, and crawling forward got his head esconced in the evergreen brush. There he lay, the bees not standing, but flying guard all around him. They kept him prisoner till the shades of evening gathered, and he improved the passing hours by thinking over some law cases he had on hand, rising, at last, smarter and sadder, like Mrs. Harrison. To guard against possible contingencies, it is well to be protected.

But why does Mrs. H. use a wire hat? It is a stiff, clumsy affair, and gets unpleasantly rusty with the moist breath. Black netting is better. A veil of any kind is rather close and hot, especially in July weather, but a Turkish bath does one good, and I get several in the course of a season, without expenditure of money, or loss of time, as one of the casual advantages of bee-keeping.

Listowel, Dec. 22, 1881.

For the American Bee Journal.

Salicylic Acid and Foul Brood.

A. R. KOHNKE.

The difference of opinion as to the probability or possibility of curing foul brood, as stated in the proceedings of the Michigan State Convention, I consider very damaging to the bee-keeping public at large; the more so, when noted bee-keepers disagree on the subject. Mr. C. F. Muth says it can be cured by the use of salicylic acid, while Mr. D. A. Jones asserts he has thoroughly tested it, and found it of no use, indirectly hinting that he has another and surer remedy. From the nature of the disease, I doubt Mr. Jones having had a case of genuine foul brood. Nor will Mr. Townley's remedy stay the progress of the disease among his remaining bees, if it has attacked as many as 60 or 70 colonies, for he could not possibly know what colonies of the remainder had caught the contagion before the disease makes its appearance among the brood.

But, then, there is a great deal in knowing how to do a thing. It would take more space than I am allowed in this article to describe, minutely, the *modus operandi*, but I will say this much, if Mr. Jones knows of a better remedy, please let us bee-keepers have the benefit of it; if not, I make the following proposition to him: I agree to go to his apiary next summer, first week in July, to cure with salicylic acid a genuine case of foul brood, if he has such; if he has not, he may designate any other infected apiary accessible by railroad, lying between the Missouri river and 4th deg. long, east of Washington, and between the 40th and 45th degs. north latitude. If I succeed, he is to pay me \$500 and all expenses of traveling and boarding; if I do not succeed, he is to pay nothing, I assuming the loss of time and

money expended, provided, however, there is no foul brood in the neighborhood outside of the apiary treated, whereby bees in that apiary may be exposed to continuous contagion. It will take from 3 to 6 weeks to do it, according to whether or not there are many colonies, and badly diseased. My time would, of course, be worth more than the above sum asked, as I want to carry on some experiments at home, to do which I would have to engage a competent man; but I wish to remove all doubts with bee-keepers as to the curing of foul brood, and Mr. Jones will have the choice of either accepting my proposition, or acknowledging to have been mistaken as to his thorough test of salicylic acid.

Youngstown, O., Dec., 1881.

For the American Bee Journal.

Extracted Honey—No. 1.

JAMES HEDDON.

After wishing each other a happy and successful New Year, do we not all feel that our past year's discussions through the BEE JOURNAL, though they sometimes waxed warm, have been the means of giving us more light, and bringing us nearer to that point which we never can reach—perfection. Each of us may have thrown out some erroneous theories, but they served a useful purpose in arousing a desire to put truth in their place upon the part of others who knew the facts better.

Thus we are all helping each other slowly, but surely, up the hill of science. All we ask of each other is our last and best thoughts, honestly expressed, and that each accords to the other, freely, all the rights expected by himself; and he that is not willing to do this, is not yet morally or intellectually civilized.

I feel that no one should commence a series of articles upon the subject of "Extracted Honey," without mentioning the names of Chas. Dadant & Son, and referring to their little book upon this topic. If the value of a work consists in its candid, able and practical style, the quick adaptability of means to ends, and the profit to be realized by following its instructions, then, in my judgment, this little work on "Extracted Honey," for its size and cost, stands unrivalled by any book ever written upon the subject of apiculture. While the little work describes ways and means very different from what we would use to reach the same end, in each case the result reached is the same. In these articles I desire to pick up what stray heads of grain I can, that may have been left after Messrs. Dadants' harvest.

It may seem strange that a comb honey producer should choose this subject, but till within a very few years the greater portion of my production has been extracted honey. In this article I wish to consider the value of the commodity viewed from a palatable and hygienic standpoint. While my knowledge of chemistry is very limited, I know a few primary principles that I think apply directly to the

case under discussion. Honey is palatably enjoyed for its sweetness. Chemistry tells us that it ranks with glucose, in respect to that element, and that they are about one-third as sweet as cane sugar. This seems a bad defect—let us see:

Chemistry, also (like all sciences, modest and truthful) tells us that wood fiber (sawdust) possesses the same elements that glucose does. It admits it cannot see through it, sawdust is not sweet, and then asks, What is sweetness? No one being so well able to solve the problem, all look to chemistry with longing eyes, and she says, "it seems to me to be, simply, a peculiar arrangement of molecules that produce, by such arrangement, a certain sensation in the mouth called sweet."

Thus we see that at last the consumer is left to be the judge. This consumer has been in the habit, in the past, of calling honey the "sweetest of all sweets." If I am not much mistaken, all consumers of to-day who have judged only by their taste, believe honey to be first class in its sweetness. I remember reading in the BEE JOURNAL some years ago that honey was 88 per cent. as sweet as cane sugar. It seems that, after all, honey will assume for itself all the value established by the appetite. Chemistry may tell us to-day and to-morrow that glucose and honey are essentially the same—both grape sugar—of the same sweetness, etc., but that is not the impression upon the taste of man, or the health of bees. Any one who has taken a mouthful of glucose, was no doubt surprised at the lack of sweetness and general tastelessness of the stuff, notwithstanding that honey has been his standard. Now, if it should prove to be a fact that honey effects this sweet sensation in the glands of the taste only, that it fails to exhibit the same power in the stomach or in cookery, then that will be an argument against it as a staple, but largely in its favor as a luxury; perhaps so much so as to make it a staple luxury, like oysters, etc.

The indulgence in the pleasure of sweet-eating is, in this land of luxury and plenty, carried to excess, often to the extent of overbalancing the system. Of course, it is the principle of sweet acting upon the body below the glands of taste, that produces the bad effects. I am of the opinion that in honey we can "get the game without the blame," for I have never been able to eat enough of it yet to feel that my system was surfeited with sweet, as I have realized from excessive indulgence in cane and maple sugars.

The acute disturbances experienced by exceptional individuals, no doubt arise from their peculiar idiosyncrasies. Their stomachs probably contain, to an eminent degree, some peculiar elements that are very antagonistic to elements contained in the honey—some acids deposited by the glands of the bees, or some element in the floating pollen.

Most of us know that by subjecting honey to the degree of heat that boils water, for a short time, the particles of floating pollen appear to be either

discharged or dissolved; also certain acids seem to be discharged. Should the very least part of growth have begun (thus giving the honey a "twangey" taste), the degree of heat referred to destroys the bacteria, and honey, after being thus treated, will agree with many who cannot use it before such heating. This a point well for us to remember.

Were it not for the aid of that element heat, as applied to our food, there is little doubt but man would, to a far greater degree than at present, become a prey to these low forms of animal and vegetable life.

In comparing comb with extracted honey, little need be said. If extracted is more healthful than comb honey, I think it is only that which has been heated. The idea that wax, because indigestible is injurious, I deem a mistake. Physiologists tell us that the pylorus (the gate between the stomach and intestines) readily opens and lets through any indigestible substance, while it struggles long and hard with any food possibly digestible, and with the class difficult of digestion is where our trouble arises. One celebrated physiologist believes that a portion of certain kinds of wholly indigestible material, taken at our meals, serves a beneficent purpose. I would sooner think the particles of wax, so small as they are, were more favorable than otherwise.

I think the only question involving a discussion upon comb vs. extracted honey, is the one of greatest profit to the producer. I will touch that subject further on in these articles.

Dowagiac, Mich., Dec. 26, 1881.

For the American Bee Journal.

Improvement of Bees.

L. R. JACKSON.

Much has been said on this subject of late, and yet we are not agreed. Many queen breeders, and especially dollar-queen men, claim there is no improvement to be made in our Italian bees, and the best we can do is to rear our queens from imported mothers. Others claim they can be improved the same as other stock. I have said bees can be and have been improved, and I think the majority of successful honey producers agree with me in this.

Rev. A. Salisbury, in the AMERICAN BEE JOURNAL of May 9, page 74, says: "Our American Italians have been bred up to a high standard of excellence, and we want no step backward by importing inferior bees from Italy."

G. M. Doolittle, in his report for 1881, in *Gleanings*, page 527, says: "One thing we notice with pleasure which was that our colonies gave nearly an equal yield per hive. This is what I have been breeding for for the past few years, hoping to obtain like results from all, and not have one colony in the yard give a large yield and another nothing. When we, as apiarists of America, can bring our bees up to such a standard of excellence that all colonies will produce an equal amount of honey, and said amount be as large

as that produced by our very best colony of a few years ago, we shall have no further need of importing colonies, for *Apis Americana* will be the best bee in the world."

I have believed for three years that our bees could be improved until there will be but little difference in the amount of honey produced by any of our colonies. I find that my record book shows less difference each year since I have been trying to improve my bees, and I know I am not getting less honey, so it must be an improvement.

G. W. Demaree, in reply to an article of Doolittle's, says, on page 219 of the AMERICAN BEE JOURNAL: "Mr. Doolittle's advice, to breed from the queen whose colony produces the most honey, is a good theory, but in my opinion, poor practice." I have for years selected my best colonies for my queens and drones, and in my opinion it is the best thing we can do if we want good honey gatherers. Again Mr. Demaree says, on page 258 of the AMERICAN BEE JOURNAL: "To rear good queens we are told that we must select one colony to rear our queens from and another to furnish the drones to fertilize them, and we are ready for business. This looks quite business-like, and doubtless would answer well enough if the apiarist resided in some secluded spot where the wings of the honey bee had never fanned the air." Now, we do not claim that we can have every one of our queens mate with one of these select drones, neither do we claim it can be done at all times of the year, but we do claim we can have a large majority of our queens mate with these selected drones. I will give my plan of rearing queens. I breed for the honey gathering qualities, hardiness, and amiability. I select the queen that has given the largest amount of honey and has wintered best to rear my drones from; I then select as many of the next best as I wish to rear queens from. At least one of these queens must be selected from some other apiary to prevent too close in-and-in breeding. By the first of April I give each of these colonies a frame well filled with pollen, having been set away the summer before. I place plenty of drone comb in the hive. I wish to rear drones from, and have the other hives all worker comb. I remove all combs the bees cannot cover and place a chaff cushion on each side of the cluster and a good thick cushion on top of the frames. I now commence to feed each of these colonies what they will use each day, and give more combs as fast as they will use them until they are built up to full colonies. As fast as a frame is filled with drone brood I remove it to one of the other colonies and give another frame of drone brood until I have as many drones as I want. I continue feeding each day until the bees swarm; I then remove three frames having no queen cells. I place these in a new hive and place a chaff division board on each side, and place the queen on these frames with bees enough to cover them and return the rest of the bees to the old hive. In 5 days I divide the old colony up into

nuclei—2 frames and a queen cell. I now break my drone colony up into nuclei for the remainder of the queen cells. If I still have queen cells left and wish to use them, I take frames from the colonies that have not been fed, if there are any that can spare them. These young queens will be fertilized before colonies that have been left to themselves will have any drones flying. Further south than this we should begin work earlier than the first of April. These nuclei can soon be built up to good strong colonies. This plan, of course, would not do for rearing large quantities of queens for sale at the price queens are now sold. I am not in the queen trade, being one who believes if it pays to keep bees at all it will pay to keep them for the honey they will gather. I have never made an average of less than \$5.50 per colony for the honey sold, besides the increase, and have run as high as \$24.00 per colony for all the bees I had in the spring. This is over and above all expenses, except for the new hive, and that expense I count to the new swarm. Next year I will try a few Syrian queens crossed with Italian drones, and a few with the second cross with Italians.

Friend Doolittle, would it not pay you to write a book on bee-keeping? We all know you are a successful bee-keeper, and when we want advice we need to go to one who is successful. I would be glad to have a book written by you and would pay a good price for one. It is true we have a number of good works on the apiary, but I believe a work could be written on the practical management of bees that would be of more use to the honey producer than any of them, and I have confidence enough in your plan of managing bees to believe you could give us just such a work as we need.

Fairland, Ind., Dec. 26, 1881.

From Florida Agriculturist.

Bee-Culture in Florida.

W. S. HART.

To the industrious bee-keeper, the coast counties of Southern Florida offer a field of profit unsurpassed by any other section of the United States. Among these counties, Volusia is at present ahead in amount of bees owned and honey produced. Here we have none of the winter troubles incident to Northern bee-keeping, such as winter packing, carrying in and out of cellars and bee-houses, freezing, dysentery, dwindling, etc., the last two of which carried off 50 per cent. of all the bees in the north during the past winter. That dreaded disease, "foul brood," is also unknown here. Our bees winter perfectly on the summer stands, and gather honey or pollen every month in the year. The honey flow commences about the first of February, and swarming about the 10th of March. In April or May we usually have a honey drouth of a few weeks, sufficient to check the swarming fever. Then comes the saw-palmetto, sweet bay, basswood, etc., giving a flow of

very heavy honey, of a light amber color, and excellent flavor. This flow lasts until the cabbage-palmetto and mangrove come, in the last part of June. From this on until about the 10th of August, the flow is continuous and heavy, the honey as handsome as can be produced, and of very fine flavor.

A resting spell now comes for the bees, which lasts until the middle of September, when the fall flowers, and later, the saw-palmetto berries yield a surplus of darker honey, suitable for winter supplies or spring feeding. As bees fly here almost every day in the year, fall honey can be fed without fear of dysentery.

Some of the leading honey and pollen producing trees are the maple, willow, sweet gum, the bays, orange, myrtle, oaks, basswood, hickory, yupon, mock olive, saw-palmetto, cabbage-palmetto and mangrove. The last two of which come together in the middle of summer, and are unequalled as honey producers by any thing else in the whole vegetable kingdom known to the writer. They produce honey in abundance of the finest quality, and we think it safe to say, never fail to produce a good crop. We also have honey-producing vines and plants too numerous to mention.

Bees increase very fast, and, as the season is long, and the winter mild, even a small handful of bees can be safely built up into a strong colony in a short time.

The writer started this past spring with 35 colonies, which increased to 86; some were disposed of, and others run for comb honey or queen raising, so there were but 60 colonies worked exclusively for extracted honey. From these I took 6,210 lbs. of honey by Aug. 10. I have since taken a few hundred pounds—enough to make my crop foot up 7,500 lbs., without putting my bees on short allowance. Several of my neighbors have done nearly as well.

Transportation for our crop to all the large markets of the world by water is good, and getting better every year. Hive lumber is cheap. Living is inexpensive, and orange growing (our leading industry here), can be coupled with bee-keeping to the advantage of both.

The bee's a model citizen—ease, food, life, all is yielded to the public good; No individual interests weigh a grain; Where there are public interests to maintain; As in old Rome, when all were for the State, Rich helped the poor, and poor men loved the great.

New Smyrna, Fla.

For the American Bee Journal.

Notes from Western Missouri.

LEE ENRICK.

Another year is numbered with the past. A year remarkable for its extremes of heat and cold; of floods and drouth, and closing with weather mild and spring-like. But mid all these changes the BEE JOURNAL has never failed to make its weekly call, and in renewing my subscription for the coming year I know I will be

entertained and benefited as I certainly have been in the past.

The past winter was most disastrous to bees, as many empty hives forcibly tell. I had 105 colonies at the beginning of winter. When the peach bloomed I could count but 45. By natural swarming my number now stands at 70, and I think in good condition, in numbers and stores. The honey crop was a failure. From 40 colonies in two-story Langstroth hives, I extracted about 600 pounds, or an average of 15 pounds to the colony. From 30 colonies run for comb honey, I had no surplus. I sold my extracted honey readily at 15 cents per pound.

By this showing, any one can see that my bank account would be small if I depended on bee keeping alone. But I combine it with stock raising and farming, and so a failure of the honey crop is not so severely felt. The sweet clover certainly is to be prized as a honey plant; it blossomed longer than any other plant during the severe drouth of the past summer. I have been trying alsike clover, but it has not yet proved a success. I do not think it adapted to this climate.

Harrisonville, Mo., Dec. 28, 1881.

For the American Bee Journal.

Sweet Clover for Bottom Lands.

WM. BOLLING.

Bees in this part of the country are not in as good a condition to go into winter as they might be. The fall flow of honey was very small; the blossoms of goldenrod and aster dried up before they had fairly opened, and bees worked very little on them; this stopped late breeding, and but little brood was found in the hives by the end of September.

I packed my 42 colonies of bees for winter on their summer stands, in the same manner as described in BEE JOURNAL for Aug. 3, page 241. I had some 200 lbs. of honey in frames ready to extract, but while the drouth continued, I kept it for future necessity, and when I packed my bees, it was just the thing I needed to let my bees have plenty of honey to winter on.

Honey has been sold here from 15 to 18 cts. for comb, and 10 to 14 cts. for extracted. I have sold all my extracted honey to the laboring class of people for 14 cts. per lb., who want to put the honey on bread for their children on going to school. Two lbs. of honey will cost no more than 1 lb. of butter, and the former will go much further than the later.

As soon as we have educated the laboring classes in this country to use honey in this way, and that honey is as wholesome and healthful for their children as butter, honey producers will never see the market glutted with extracted honey.

Allow me to say to Mr. E. Doty, Macksburg, Iowa, that he can plant nothing better on his 8 acres of bottom lands than sweet clover to answer every purpose. Sweet clover will grow on bottom lands, even if the point of the roots will touch the water.

One of my neighbors had about 2 acres on the bottom of the Big Canadaway Creek, thickly grown with sweet clover; he mowed it in June, but when in August and September the sun had burnt up every green thing in the pastures, and farmers had to feed their cows from the hay-mow, his cows had plenty of green clover to eat, and could make butter without extra cost for grain; and last, though not least, my bees gathered the honey and worked on it from early morning until late at night.

Dunkirk, N. Y., Dec. 15, 1881.

For the American Bee Journal.

The Apiary Register Book.

M. L. TRESTER.

I like Mr. Thomas' suggestions about the form of this book. I would like a book ruled as follows: First column, number of stand or location, which is always permanent; then, number of hive, which is liable to be changed from one stand to another; age of colony; age of queen; race of bees from which the queen came; estimated number of bees in a colony, estimated amount of honey in the hive; when the honey was last taken away; date of last observation; two or three blank columns for apiarists to place a heading to suit themselves, and a wide column for remarks, simply a good book or none.

One year ago I packed straw all around and over the hives, two or three feet thick, leaving open the small entrance, and I lost them all. I bought two Italian colonies in the spring and started anew; increased to 14 colonies by division, and extracted 230 lbs. of honey, leaving them plenty for winter. If I have ten colonies in the spring I will feel positive that I have made over four hundred per cent. I like the BEE JOURNAL and my bees very much, but if I had a cast iron nose and upper lip I would like the bees better.

Lincoln, Neb., Dec. 17, 1881.

For the American Bee Journal.

Consumption of Honey in Winter.

REV. DR. M. MAHIN.

In the AMERICAN BEE JOURNAL December 28, W. Williamson, Lexington, Kentucky, says of bees flying out in such weather as we have had during the winter so far, "Of course they consume more honey." I am well satisfied from my observation during the last twelve years that this is a mistake, though a very common one. Two and four years ago the bees flew out almost every week, and sometimes almost every day for weeks at a time, and the consumption of honey was much less than in cold winters. If breeding were carried on abundantly the consumption of food would be large; but it is not, and with a moderate supply of honey I apprehend no danger from starvation. So far my bees, which are on the summer stands, have consumed but little honey, as in-

licated by the particles of comb dropped on the bottom boards. I do not know, of course, how much warmer the weather is in Kentucky than it is here; but I do know that in this part of the country the prospect for safe and successful wintering could not be better.

I am very much pleased, so far, with the Syrian bees. Mine are easily handled, and they are much more quiet in warm fall and winter weather than either blacks or Italians. And yet they will put dead bees outside of the hive when the temperature is below freezing. I will, if I live, give them a more thorough trial next year. I have but one purely mated queen, and I procured her from D. A. Jones, and of course she is pure and purely mated. I have three queens raised from her, but they were so late that I have not seen very many of their progeny. I think they mated with black drones. I have never seen bees fill themselves with honey, when the hive is opened, more eagerly than do the Syrians. They are somewhat excitable, and threaten to sting, but they seldom do it. If they prove equal to my expectations, I will Syrianize a large part of my apiary.

Of course, I want the BEE JOURNAL for next year, and all the rest of the years while I live and keep bees. Logansport, Ind.

For the American Bee Journal.

Bee-Keeping in Kansas.

E. M. LEWIS.

July 1, 1880, I purchased 11 nuclei, consisting of 1 queen and 1 lb. of bees each—put them at work in movable frames filled with comb foundation, but the season was so dry that even buckwheat and the fall flowers secreted but very little honey, consequently my bees did not have sufficient honey for such a winter as followed; therefore, I, like many others, lost most of my bees. But, having the combs and hives, I thought I would try it again. This time I sent for the same number at \$3 per nuclei, to be delivered the 1st of March, 1881, thinking this time I should succeed. They worked well up till June 9, then we got a great storm of wind, rain and hail, which destroyed and cut to the ground everything but timber and fences.

Now came the question what shall I do with my bees. They must all be fed for an indefinite time or die. I procured syrup, and fed them regularly every day for six weeks; then I had the bees in good condition, if there had been anything for them to gather. But the drouth following the wet spring continued, and I gave up in disgust with Kansas as a bee state, discontinued feeding, and said they might go; I would spend no more time or money on them. The result was some 3 or 4 colonies flew away, and then came a nice rain, and then another and so on.

There being some buckwheat and late flowers, they have laid up enough, I think, to go through until spring. I packed 5 in straw and buried 9 in a

clamp as recommended by D. B. Boomhower of N. Y., who published his success in wintering in the JOURNAL.

Hanover, Kan.

For the American Bee Journal.

Bee and Honey Shows.

A. C. INNIS.

In attending the State Fair, held at Fond du Lac, I was very much disappointed at the limited show of the products of the apiary as well as bee-keepers' supplies. Being an amateur, I went there with the intention of learning something of a practical nature, but I had the good fortune to make the acquaintance of Mr. A. A. Winslow, of New Holstein, a thorough apiarist, and from him obtained much information, and also a good honey extractor.

I began the season of 1880 with one colony, increased to 3, and obtained 17 lbs. of honey, wintered without loss, in the cellar, but owing to ignorance, lost 1 by robbing. Last spring I purchased 2 more colonies increased to 8, which are in the best possible condition, and obtained 220 lbs. honey—17 lbs. being extracted.

My expenditures amount to \$38.70; the honey obtained amounts to \$42.75 and the 8 colonies, I value at \$48.

I am satisfied that it will pay to keep bees if done intelligently. Count me as a life subscriber to the JOURNAL, for without it I should be like a ship at sea without a rudder. I am laughed at here as a fanatic, but so long as I feel that I am on the right track I can sit in my apiary and laugh in return at those who are trying to make bees pay in the old slipshod way.

West Rosendale, Wis., Dec. 22, 1881.

For the American Bee Journal.

Good Pasturage for Bees.

PHILIP P. NELSON.

If I should compute, in dollars, the benefit the BEE JOURNAL has been to me during the past two years, it would cause the subscription price to look exceedingly reasonable.

The 10 colonies that I had left in the spring increased to 27, which are now in first class condition. I did not keep account of the pounds but have sold \$125.00 worth of honey in one and 2 lb. sections. The income from my best colony, in honey and bees at present prices, amounts to \$56.00. My bees are mostly hybrids. I have had one Italian queen. Most of the native bees here are a sort of a brown German kind, but very good bees. The Italian blood crosses on them with excellent results; producing fine workers, gentle to handle.

I have no trouble to sell honey; the great difficulty is to produce enough to meet the demand.

I am a farmer and stock raiser, and cannot give my bees the attention that I would like to, and yet I cannot

get all the good from the land unless I have the honey gathered. This year from one pasture I had an income at one time of milk, honey, butter, beef, pork and mutton, and I might add horseflesh. I am greatly interested in planting for honey; buckwheat does not seem to do much good here. Turner raspberries and eatnup are the most eagerly sought after of any plants that grow here. Sweet clover grows in great profusion along many of the lanes; the bees always work on it, but I have never seen them go for it very lively; it is pretty sure to yield some honey, and I have noticed that bees that had sweet clover to work on, wintered better last winter than those that had none. We often get a big yield of heartsease honey. I consider it about the worst for wintering purposes, and yet it is fine honey to sell.

Manteno, Ill., Dec. 28, 1881.

Farmers' Home Journal.

Purity of Honey Guaranteed.

W. WILLIAMSON.

At the last annual Convention of the State Bee-Keepers' Association, the question of adulteration of honey was discussed with great earnestness, and a unanimous resolution passed and a committee appointed to prepare a new act and endeavor to have it passed at the present session of the Legislature. The law at present reads as follows:

Sec. 1. Be it enacted by the General Assembly of the Commonwealth of Kentucky, that any person or persons who shall sell or cause to be sold any manufactured honey, unless such honey is so represented and designated as manufactured honey, shall for the first offense, be fined in any sum not less than ten nor more than one hundred dollars; and for each repeated offense shall be fined not less than fifty dollars nor more than two hundred and fifty dollars.

Sec. 2. That any person or persons who shall sell or cause to be sold any such manufactured honey which contains any substance injurious to health, shall, for the first offense, be fined in any sum not less than ten nor more than one hundred dollars, and for each repeated offense shall be fined not less than fifty nor more than two hundred and fifty dollars; and such adulterated articles, by order of court, shall be destroyed.

Sec. 3. This act shall take effect from its passage.

The adulteration of honey is carried on to such an extent that people in large cities cannot tell where to purchase pure honey. Hence the necessity of a stringent law that cannot be evaded (if it is possible to make such a law). Such an act would not only protect the bee-keepers, but protect the public from fraud and deception, such as the adulteration of food. It is also detrimental to the public health, and if a law can be made that will guarantee the purity of the food we eat, it ought to be made at once.

Lexington, Ky.

SELECTIONS FROM OUR LETTER BOX

Recipe for Making Honey Pop-Corn Balls.—Take one pint of extracted honey, put in an iron frying pan and boil until very thick, then stir in freshly parched corn, and when cool mold into balls. These will especially delight the children, and the older ones will not refuse them. Try them.

MRS. A. M. SANDERS.

Interested.—As a bee-keeper I cannot do without the JOURNAL, and even if I did not keep bees I should take it for the interesting information it contains on scientific matters.

L. JOHNSON.

Walton, Ky., Dec. 26, 1881.

A Correction.—In the BEE JOURNAL of Dec. 14, page 397, H. P. Sayles is reported saying that "the Italians required more care and attention than the blacks, and he believed, taking the season through, that he could get more box honey from the blacks than the Italians, and a better quality of extracted honey." It was Mr. John Hodgson that expressed himself in that way respecting the two races of bees, and not Mr. Sayles. Mr. Sayles was emphatic in expressing his preference for Italians to black bees, and Mr. Hodgson for blacks in preference to Italian bees. Further on in the report of the Northeastern Wisconsin Convention, on "the Yield and Increase of the Present Year," Mr. Sayles' increase in stock is omitted entirely. He had increased to 38 full colonies. His yield and increase was regarded as the largest of any one present, but leaving out his increase of stock, it would not be as large as some others. Will you, Mr. Editor, make this correction for the benefit of all concerned.

T. E. TURNER, *Sec. pro tem.*

State Society for New Jersey.—In BEE JOURNAL for Dec. 7, I see Mr. G. W. Thompson sounds a bugle-note for a State Society for New Jersey. That is what we want. It is high time New Jersey was on her feet in this matter.

CHAS. H. RUE.

Manalapan, N. J., Dec. 23, 1881.

Bees Wintering Well.—Bees are wintering nicely so far; they had a good flight on Nov. 30, and again Dec. 18 and 19. They went into winter with plenty of good stores, and we hope will come out much better next spring than they did last. The past season was rather poor here, the bees gathering but little surplus honey.

C. A. GRAVES.

Birmingham, O., Dec. 22, 1881.

Bees On The Wing.—The season has been mild, so far, and my bees celebrated Christmas while on the wing, on Dec. 24 and 25, 1881.

WM. STOLLEY.

Grand Island, Neb., Dec. 27, 1881.

Mild Winter.—Will the continued warm sunshine we now have, and have had all the fall and winter, cause bees to consume more honey than if it were colder? Up to this time we have had no snow, except, perhaps, $\frac{1}{2}$ an inch observable on sidewalks and fences one morning late in November. We have not had ice to exceed one inch in thickness and not more than ten mornings; days generally are clear and warm; bees fly almost every day; there is no danger of dysentery. A few days ago I heard a farmer say that he had some cherry blossoms; there is quite a difference between this and last winter, up to this time. We had 30 to 40 snows and everything froze up solid, and remained so until Feb. 1. Possibly our winter is yet to come. Bees are in good condition, and do not appear to be consuming but little honey.

D. W. BELLEMEY.

Vienna, Ill., Dec. 25, 1881.

[Yes; if the weather is cold enough to require artificial heat, and yet not so intense as to produce the semi-dormant state incident to extreme winter.—ED.]

That Cough Medicine.—Many people are probably not aware that much of the linseed oil, especially that termed boiled, is adulterated with poisoned drugs. Therefore, when doctors recommend it for medicine, as Dr. Tinker has, they should caution the public.

P. F. TWITCHELL.

Andover, O., Dec. 27, 1881.

Questions.—1. Can honey extractors be made so as to accommodate two different sized frames—Langstroth on one side of the comb basket, and a frame 11x12 on the other?

2. Where quills are entirely covered with propolis, should they be used for winter coverings?

3. Where natural swarms repeatedly fly up from the alighting-board and settle again upon a limb, what is the best course to pursue? Nearly all my swarms troubled me in this way last summer, and sometimes they would go to the woods.

A. M. SANDERS.

[Yes; the Excelsior extractor, Nos. 3, 4 and 5, will accommodate Langstroth and American frames at the same time. Nearly all the approved patterns can be manufactured to carry combs of two sizes.

2. We would not advise their use.

3. Probably the best course to pursue is to clip off about half of one wing of the queen, and, if increase is wanted, hive them on a new stand; if no increase is desired, destroy the queen cells in the parent hive, clip the queen's wing, and return them.—ED.]

Bees in N. W. Michigan.—In accordance with Mr. Demaree's suggestion, I will say for northwestern Michigan, that bees went into winter quarters about the middle of November; had

splendid flights Dec. 18, 25 and 26, and carried in water both days. The loss from my 19 colonies will not exceed a pint, while last year each colony had lost more than that. I have no fears for their safety.

GEO. E. HILTON.
Fremont Center, Mich., Dec. 30, 1881.

Mignonette.—I would like information on the following points: 1. What can I plant in my yard that my bees can feed on? I have $\frac{3}{4}$ of an acre of a black loam, rich and dry. I want something that will bloom the same season sown, and be ornamental at the same time. 2. What is the proper space between the bottom-bar of a frame and the bottom-board of the hive? 3. Will the distance make any difference in wintering? I am a beginner. I bought 4 colonies of black bees last spring, which have increased to 9, besides giving me 350 lbs. of extracted honey. All are in good shape for wintering, and have at least 20 lbs. of sealed honey each. I am the only one keeping bees in this town, and have no trouble in mating my queens. I cannot discuss bee matters with the scientists, but I have the comfort of reading the BEE JOURNAL weekly, and anxiously await each number.

A. MONTREVIL.

Walkerville, Ont.

[1. You can plant mammoth mignonette, sweet basil, and many other annuals with good ornamental effect and remunerative profit. This will also give opportunity for planting to advantage during the season with biennials and perennials.

2. Three-eighths of an inch is the proper space to allow between the bottom of the frame and the bottom board of the hive.

3. The space in the bottom will make no perceptible difference in wintering, unless, indeed, it should run to an extreme.—ED.]

Bees in Georgia.—DEAR EDITOR: Permit me to congratulate you for the successful accomplishment of the great task you have ventured upon—the establishing of a Weekly bee-paper. Now that you have conquered the initial difficulties, I trust that the path before you will be smooth. The past year has not been a prosperous one for the bee-keepers in this latitude. Indeed, the past summer and fall have been even more disastrous to them than the winter had been to the Northern bee-keepers; for, during the unprecedented drouth of 4 or 5 months' duration, the bee-forage absolutely failed, the queens stopped to lay, the colonies dwindled down, the invasions of the moths could not be checked, and thus most of the bee-keepers I know lost all their bees. I saved mine (kept in my garden in the city), only by the closest attention and watchfulness; but the colonies are now extremely weak. They, of course, did not afford any surplus honey during the past season.

L. KNORR.

Savanna, Ga., Dec. 23, 1881.

Poor Honey Season.—I was nearly discouraged last spring when I found 18 out of 20 colonies of bees had died. But I determined to try again and I bought 10 colonies, which I increased to 28, in good condition for winter. I got 335 lbs. of clover honey in 2 lb. sections. The season was a very poor one for honey in this county, the long drought cut the season very short. I sold all my honey at 25 cents per lb.

W. M. B. McCORMICK.

Uniontown, Pa., Dec. 5, 1881.

Sixty Colonies on Summer Stands.—I am pleased to know that the BEE JOURNAL is to have smaller pages in 1882. They are more convenient to preserve and handle. Every one who has 5 colonies should take the BEE JOURNAL. I have 60 colonies on the summer stands all in good condition. They had a flight on Dec. 14.

THOS. PIERCE.

Gansevoort, N. Y., Dec. 19, 1881.

Making Comb Foundation.—I had 30 colonies of bees in the fall of 1880 packed in chaff; all came out alive in the spring, 2 were queenless and I left the hive in April. They had no flight from Nov. 9 till March 6. I increased to 61, and extracted 2,500 lbs. of honey. All have plenty of good honey for winter and are in good condition, packed the same as last winter. I have tried all kinds of soap to make comb foundation with, but had little satisfaction. Last summer I used 1 lb. of honey mixed with one-fourth of water; it worked like a charm and needs no washing. We have a machine to even the sheets and roll them out 5 and 6 feet long. DAVID BYER.

Markham, Ont., Dec. 21, 1881.

Clock-Work.—Success to the BEE JOURNAL. After reading it for the past year, I have concluded that the editor is like the pendulum of a clock, steady, but right on the mark every time. While you conduct the BEE JOURNAL, Mr. Editor, and I keep-bees, send it right along to

GEO. WILLIAMS.

Nashua, N. H., Dec. 17, 1881.

Packed in Chaff.—Last spring I had 23 colonies; I increased them to 52, and extracted 2,900 lbs. of honey, and took 100 lbs. of comb honey, leaving them plenty of stores for winter. They are packed in chaff. I believe upward ventilation kills more bees than anything else. I always put the cap down tight with a sheet of paper under it, and put the hives under the chaff in a bin, with a heavy weight on the top of the chaff. The lightest one always winter the best

ARTHUR J. RUSSELL

Millbrook, Ont., Nov. 22, 1881.

Successful.—I cannot keep house without the BEE JOURNAL; put me down for a subscriber as long as I keep bees. I began taking the BEE JOURNAL with the first colony of bees, three years ago. I have had good success, which I owe in a great measure to the BEE JOURNAL.

A. G. RYKERT.

Attica, N. Y. Dec. 24, 1881.

The New Races of Bees.—My bees are wintering well so far. I have not tried the new races, and unless I hear better reports about them, I think I shall let them alone. I can sell extracted honey at home for nearly as much as I can comb honey.

ISAAC SHARP.

Waveland, Ind., Dec. 29, 1881.

Poor Bee Pasturage.—This is rather a poor location for bees; we depend on white clover, and that has failed for three seasons. I lost all my bees last winter except eight colonies, and they were very weak. I obtained no surplus, but increased to 31, and fed about 200 lbs. of granulated sugar, which gives them plenty for winter, but some are rather weak in bees.

W. M. H. RAFFERTY.

Pittsfield, Ill., Dec. 26, 1881.

Bees in Florida.—Perhaps a line from one of your readers, formerly of Salem, Ind., but now a sojourner in this land of flowers, would be of interest to your many readers. Bees can be kept here in any kind of a shell that will keep out the rain and sunshine, and feed them on anything sweet, except glucose—that curse to honey-producers. It is no trouble to winter bees here, if you leave them enough to eat, or will feed them sugar cane syrup, if they have not enough honey. Those keeping bees here say the orange is the best and first plentiful bloom giving them honey and building up their bees to swarming in March; but I think that for successful honey gathering here I would feed up my bees strong, so that I could get the surplus honey from orange bloom, which can be done, for it would be no task to have the colonies strong by the middle of February. Should I ever stop any season here I would try my hand at bee-keeping for our Northern trade. The weather is warm as our June is usually. We have had but one frost here this winter yet, and it is thought there will be no more. The thermometer on Christmas was 80° at noon.

JOHN CRAYCRAFT.

Waldo, Fla., Dec. 26, 1881.

Worth \$50 a Year to Me.—Please send me the JOURNAL as long as you and I live. I have received it for 1881, and it was worth 25 times its subscription price to me.

SAMSON J. HOPKINS.

Evansville, Wis., Dec. 30, 1881.

Hybrids as Honey Gatherers.—I have 12 colonies of bees in winter quarters. I have kept bees for 10 years, and, seeing so many bad reports last winter from all over the country, I thought it my duty to report my success in wintering. During all my experience in bee-keeping I have lost only 1 colony, and that was 9 years ago. Last winter I had 7 colonies; all came through strong; they never were in better condition than last spring. My bees and myself were ready for the honey harvest. Apples and cherries yielded abundantly; next came white clover, but, to my disappointment, only for a few days. Dry weather set

in and there was no more honey for us. My average crop per colony was about 30 lbs., all in 2 lb. sections. I have 3 colonies of Italians, but like my hybrids best, not for beauty, but for honey gathering. I sold all my honey at 25 cts. per lb.

C. H. NAGLE.

Allentown, Penn., Dec. 18, 1881.

Enthusiastic Appreciation.—I consider the BEE JOURNAL indispensable. I should be lost without its timely hints. Its Convention notes, containing the views of the master minds of the apiarian world, is enough to make the heart of the smaller apiarist leap for joy. Long live its editor, who fights so valiantly against glucose and adulterations generally. I have 28 colonies with blankets over the tops and ½ inch strips under. I will give the results in the spring. I keep feed in dry places for them every warm day, of which we have had many. The weather is warm and rainy.

G. W. ASHEY.

Valley Station, Ky., Dec. 28, 1881.

Home Market for Honey.—The weather is remarkably warm for the time of year. My bees are in cellar, and, to all appearance, are doing well. I leave the entrance below open, keep the room perfectly dark, and they are as still as mice. I have no fear as long as they have plenty of air below. I sell all my honey at 25 cents per lb. at Galva. It is in pound boxes with label on top of each section, as follows: "One pound of pure, unadulterated comb honey from the apiary of J. M. A. Miller." I find no trouble to sell all I have to spare at a good price with the above guarantee, and those who attempt to use my name to sell an inferior article at a reduced figure, are cut off.

J. M. A. MILLER.

Galva, Ill., Dec. 23, 1881.

[Yes; the way to succeed is to develop the home markets.—ED.]

What a Contrast.—A year ago, at a corresponding date, the earth was covered with deep snow; every stream and rivulet was frozen over, and the merry jingle of sleigh bells resounded over hill and dale. To-day the weather is as warm as a pleasant May day, and in place of the musical jingle of bells we had more animated and much sweeter music (to our ears) the humming of countless numbers of bees. So far this winter we have scarcely had ten days in succession when our bees were not flying one or more days. We feel quite safe now, should we get a cold snap for even six weeks. Our bees carried pollen to-day from rye and oats, chopped, placed in the yard for them.

W. H. SROUT.

Pine Grove, Pa., Dec. 28, 1881.

Wintering Nicely.—I have 80 colonies of bees in chaff hives. They are wintering nicely, and had a flight every few days during the winter, so far.

F. E. TOWNSEND.

Hubbardston, Mich., Dec. 29, 1881.

ESTABLISHED 1861
THE AMERICAN BEE JOURNAL
 COLLECTED IN AMERICA

RATES FOR ADVERTISING.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space.

Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements for the Weekly as follows, if paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 ".....	20 " " "
" 13 " (3 months)....	30 " " "
" 26 " (6 months)....	50 " " "
" 39 " (9 months)....	60 " " "
" 52 " (1 year).....	75 " " "

Discount, for 1 year, in the Monthly alone, 25 per cent., payable in advance.

Discount, for 1 year, in the Semi-Monthly alone, 40 per cent., payable in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

Transient Advertisements payable in advance. —Yearly Contracts payable quarterly, in advance.

THOMAS G. NEWMAN,

974 West Madison Street., Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the *best* advertising medium, but the lowest rates on yearly contracts.

How to get the Weekly Bee Journal free of cost for 1882.—Until further notice, any subscriber who desires to obtain a good book on apiculture, can have either Cook's Manual, Quinby's New Bee-Keeping, or Novice's A B C, bound in cloth, postpaid, and the Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, or Blessed Bees (a romance), bound in cloth, for \$2.75. The JOURNAL and all five books for \$6.00. This is a rare chance to get a good library on bee-keeping. A person can sell the books for their published price, \$6.00, and get the Weekly BEE JOURNAL free for his trouble.

Those having already paid for the Weekly BEE JOURNAL for 1882 may send for the books alone and deduct the \$2 already sent for the JOURNAL.

This offer will be withdrawn on January 10th.

Special Notice.—We send this number of the BEE JOURNAL to those of our subscribers for last year who have not yet sent on the money for 1882. Many of the renewals will be in transit in the mails, and those who have not yet started the money are hereby cordially invited to do so at once, or they will receive no more, unless we hear from them immediately.

We invite ALL to promptly renew, and save the unnecessary trouble of taking the names from our mail list, and having to replace them again in a few days. Promptness in this will save us much valuable time and perplexity.

Once in a while we receive a rather un courteous letter because the BEE JOURNAL is discontinued when the time is out that has been paid for. We try to please all our subscribers, but it is not an easy task for us to determine who does and who does not want it so continued; so we must ask to be informed on the subject.

Now, if all who desire it continued would drop us a postal card, or mention it when they are sending a remittance, it would save us much trouble and themselves the annoyance of having the JOURNAL stopped.

Thousands have used Kendall's Spavin Cure for rheumatism after all other remedies had failed, and have experienced instant relief. 1w4t

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Articles for publication must be written on a separate piece of paper from items of business.

To Promote a Vigorous Growth of the hair, use Parker's Hair Balsam. It restores the youthful color to gray hair, removes dandruff, and cures itching of the scalp. 1w4t

When changing a postoffice address, mention the *old* as well as the new address.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

"How do You Manage," said a lady to her friend, "to appear so happy all the time?" "I always have Parker's Ginger Tonic handy," was the reply, and thus keep myself and family in good health. When I am well I always feel good-natured." See other column. 1w4t

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—	a copy of "Bees and Honey."
" 3,—	an Emerson Binder for 1882.
" 4,—	Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper, cloth.
" 5,—	" " " "
" 6.—	Weekly Bee Journal for 1 Year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise of less weight than 8 ounces. Canadians will please remember this when ordering Binders.

Look at the wrapper label and see that proper credit is given for money sent us, within 2 weeks. If it does not then appear, please send us a Postal Card, and we shall with pleasure make the correction, for an error may occur during the rush at this season, though we endeavor to be careful to always give proper credit.

The Apiary Register will be ready to send out next week.

It devotes 2 pages to each colony, embracing between twenty and thirty headings, neatly ruled and printed, with space at bottom for remarks, and so arranged that a single glance will give a complete history of the colony. Each book will also contain printed rules for the apiary, and twelve pages ruled and printed for an apiary cash account. As each book is intended for a several years' record, it is gotten up on first class paper, and strongly bound in full leather covers. There will be three sizes, sent postpaid, at the following prices:

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start. We have added these to our new Premium List for getting up Clubs for the JOURNAL.

TERMS OF SUBSCRIPTION:

WEEKLY—(52 numbers) \$2 a year, in advance. Three or Six Months at the same rate.

SEMI-MONTHLY—The first and third numbers of each month, at \$1.00 a year, in advance.

MONTHLY—The first number of each month, at 50 cents a year, in advance.

Any person sending a club of six is entitled to an extra copy (like the club) sent to any address desired. Sample copies furnished free.

CHICAGO, ILL., JAN. 11.

The Honey Crop for 1881.

Respecting the Table we gave in the BEE JOURNAL for Oct. 12, of the Honey Crop of last season, Mr. W. Z. Hutchinson remarks as follows:

Mr. C. N. Wilson, in the *Semi-Tropic California*, is certainly unfair in his criticisms of you and your "table of the honey harvest of 1881," but are not you a trifle mistaken, when you say that friend Hasty bases his argument, in the *Bee-Keepers' Exchange*, on an error made by a compositor? Please read his criticism once more, and I think you will notice that he says: "Of course there is an arithmetical slip here, and the colossal sum is really the number of cents instead of the number of dollars." Friend Hasty then says: "The question herein raised is this: Is not 100,000,000 (lbs.) much too large an amount to claim for this year's honey crop?" And in this I must say that I agree with friend Hasty, as you will see by the following article of mine in the *Country Gentleman*:

Last September, the editor of the American BEE JOURNAL requested his readers to send in reports of their honey crop. They responded promptly, and reports were received, showing the yield of honey from nearly a quarter of a million of colonies, or about 8 per cent. of all the bees in America. The average amount of surplus was about 69 pounds per colony, and the increase was about 71 per cent. In rare instances, as much as 400 pounds of comb honey were taken from a single colony. In the production of honey, New York took the lead, followed by Pennsylvania, Canada, Ohio, Michigan, Wisconsin, Illinois and Louisiana, in order named. California, so famous for its large yields, produced a very light crop. The editor remarked that, "if the one-twelfth that reported are a fair average of the whole, then the crop of American honey for 1881 amounts to

120,000,000 pounds! If we call it only 100,000,000, it is worth \$15,000,000. Surely the industry is of sufficient magnitude to satisfy the most enthusiastic of its devotees."

In estimating the entire honey crop, from the reports received from 8 per cent. of the bees, the editor makes a reduction of one-sixth. In his enthusiasm, I fear that he did not sufficiently take into consideration the fact that the reports received were from the best educated and most progressive and successful apiarists of the country, and that a far different showing would have been made, had he received reports from an equal number of colonies kept in box-hives and log gums, and owned by ignorant bee-keepers. I do not consider myself competent to say just how much reduction should have been made, but I do certainly think that Mr. Newman has placed his estimate at too high a figure.

That we were not mistaken is fully proved by the following taken from the article in question by Mr. Hasty, as published in the *Exchange* for November:

The finality of the report is that this year's honey crop is \$1,500,000,000—three-quarters of the amount of the national debt! To consume it all in the United States each family of five persons would have to eat \$150.00 worth. Of course, there is an arithmetical slip here, and the colossal sum is really the number of cents instead of the number of dollars. The number of pounds figured is but 120,000,000, and the 20,000,000 are thrown off to cover shortage.

If additional proof is required, we have it in Mr. Hasty's subsequent letter, in the *Exchange* for December, which is but just published:

In my criticism on the BEE JOURNAL's honey report, I mentioned, among other errors, the one by which the total value of the honey crop was made a hundred times more than its own figures would allow. I was not at the time aware, that the next issue of the JOURNAL had contained a correction. Criticising typographical errors, already editorially corrected, would be rather petty business. Fortunately no argument was directed against these retracted figures, but whatever strictures the article contained, fell on the figures the JOURNAL intended to give. E. E. HASTY.

Richards, O., Dec. 21, 1881.

Now let us examine the argument against our editorial on the Honey Crop, which is as follows:

The question herein raised is this: Is not 100,000,000 much too large an amount to claim for this year's honey crop? What we have sold and sure is the 9,467,622 pounds which are reported. The 100,000,000 are estimated from the smaller sum. Is it not building a pretty large structure on a comparatively small foundation?

The estimate begins with putting the number of colonies in the country at 3,000,000. In the absence of data I will not dispute, but surely 10,000 hives to each congressional district looks a little large. The grand error is in making no adequate distinction between frame hives and box hives. The great majority of the bees in the country—say 2,000,000 colonies are still in primitive housings, and kept in let-alone style. To estimate the yield of these at about the same, hive for hive, as the yield of colonies in well kept apiaries is a flagrant inaccuracy.

Sufficient reply to this criticism is simply to repeat the exact words of the editorial in the BEE JOURNAL for Oct. 12, page 321 which are as follows:

There are in America about 3,000,000 colonies of bees, but our reports are from less than a quarter of a million, or one-twelfth of the whole. If the one-twelfth that are reported are a fair average of the whole, then the crop of American honey for 1881 amounts to 120,000,000 of pounds. If we call it only a hundred millions, it is worth \$15,000,000. Surely the industry is of sufficient magnitude to satisfy the most enthusiastic of its devotees.

It should be remembered that this is but a closing paragraph, having no particular bearing on the "Table of the Honey Crop of 1881," except to show that if the one-twelfth who had reported are a fair average of the whole, (which are roughly estimated at "about three millions of colonies of bees"), then the crop of American honey for 1881 amounts to 120,000,000 pounds.

It will be readily seen that we asserted nothing, basing all the calculation upon an "if"—and then to show that we did not regard the figures as at all definite, we threw off the small amount of twenty million pounds of honey, estimating the balance as worth fifteen millions of dollars. It would seem that we could hardly have been more indefinite in these casual remarks about the estimate of the whole Honey Crop of America.

If anyone thinks that twenty millions of pounds are not enough to "throw off to cover shortage" for the inexperienced and box hive men—(and very likely it should be more)—they are perfectly welcome to "throw off" twenty millions more, or two or three times that amount, and still the only point we made is sufficiently maintained; which was, that bee-keeping was an industry of sufficient magnitude to command attention!

Surely neither Mr. Hasty nor Mr. Hutchinson will dispute the latter and only point we made! In the light of these facts, have they not been criti-

cising "a man of straw"—a creature of their own fancy?

Both of these gentlemen have our thanks for the courteous manner in which they have criticised; it is just what we like. Let the argument be as hard as possible, and driven closely. All we ask is politeness and courtesy, and a desire to arrive at the truth. This should be the object of all discussion.

Changes among Bee Papers.

The *Bee-Keepers' Instructor* has been moved from Adelphi, O., to Somerset, Ky., and Mr. Thomas is making it one of the best of the monthlies. We are glad to notice this. It is the only bee-paper now published in the South, and it should receive a very liberal patronage, for it richly deserves it.

Mr. Nellis has sold the *Bee-Keepers' Exchange* to Houck & Peet, of Canajoharie, N. Y., who have improved it in many ways, and we hope will not only issue a good paper, but publish it on time.

The *American Bee-Keeper*, published in Missouri, has not put in an appearance since October. Has it ceased to exist?

The *New England Bee Journal* has not been received since November, and we fear has also succumbed to the inevitable.

The *Kansas Bee-Keeper* is to be enlarged to 20 pages, and the price changed to 60 cents a year, but it has not yet come to hand.

The *Patron's Guide*, published at Boyd, Ky., has been enlarged, and the editor thus speaks of its prosperity: "Regardless of short crops, rain or winter's icy blasts, every mail is bringing renewals of subscriptions to the *Guide*, and many new names to be enrolled as members of our rapidly growing family."

The *Western Rural* says: "Lizzie Cotton is again advertising his bee knowledge in some of the agricultural papers. Lizzie is a fraud of the male gender, and a newspaper office that does not know it, holds a great deal of stupidity."

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Glucose-Grape Sugar.

Novice, in *Gleanings in Bee-Culture* for January, says:

May I suggest to friend Newman, that glucose contains a little larger per cent. of dextrine than does grape sugar, to preserve it in a liquid state. Instead of "chemicals" being added to the latter to make it solid? We shall get at the truth after awhile, if we are only patient.

The truth was gotten at long ago—and this is its sum and substance: Novice has been driven *volens volens* from every position he has taken advocating the use of the vile trash for feeding bees, etc., and all that is left for him now, is—*jeu de mots*—a play upon words. We have neither the time nor disposition to follow up a mere quibble, and "for the present" we leave him to extricate himself from the "web" he has himself woven, as quoted in the BEE JOURNAL for Nov. 16. It would have saved him much trouble, had he confessed the truth at first, and not tried to cover up his record, by asserting that we had come over to his position.

Competitive Apiaries.—The British Bee-Keepers' Society intend to offer a \$100 prize "for the best managed and most profitable apiary, to be worked with a limited number of hives, upon any principle or combination of principles." England is waking up to the importance of the industry, and is doing good work in the line of progress.

It would save us much trouble, if all would be particular to give their post office address and name, when writing to this office. We have letters (some inclosing money) that have no name, post-office, County or State.—Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

We are sometimes asked who our authorized agents are? Every subscriber is such an agent; we have no others, and greatly desire that each one would at least send in one new subscriber with his own renewal for 1882. The next few weeks are the time to do this. We hope every subscriber will do his or her best to double our list for 1882.

Single copies of the JOURNAL sent postage paid for 5 cents each.

Sweet Clover in Colorado.—By reference to the minutes of the Colorado Bee-Keepers' Convention, on page 27, it will be observed that President D. S. Grimes made the most satisfactory report given in the Convention—one which will bear comparison with the most flattering reports anywhere. Mr. G. commenced the season with 15 colonies, obtained 2,000 lbs. of surplus honey, increased to 33 colonies all in good condition, and has 1,000 lbs. of honey in combs put away for spring use. As an explanation of his good success, Mr. Grimes said he had 75 acres of sweet clover pasture on which his bees foraged, and which we presume had been planted solely in view of its value for cattle pasturage. Sweet clover will undoubtedly become as great a favorite with stockmen as it is destined to become with apiarists, not only on account of its adaptability to all soils and latitudes, even where other clovers will not thrive, but also because of its superior nutritive qualities and ability to withstand water or drouth.

Mortality in Winter.—In reference to this subject we have received the following letter, just as the BEE JOURNAL is ready for the press:

FRIEND NEWMAN:—Since writing my last, I am convinced that it will pay any bee-keeper to go hundreds of miles to hear Mr. Betsinger on what he has to say about "the cause and prevention of the great mortality with our bees during winter." Mr. B. has devoted a large share of the past season, besides spending much time and money in his investigations and researches, and I trust we shall have a large attendance of our principal apiarists which would help to settle this perplexing question. Our Association will be pleased, and under obligations to your JOURNAL, if you will call special attention to the above fact.

GEO. W. HOUSE.

Fayetteville, N. Y., Jan. 6, 1882.

We have received the programme of the above Convention. There will be 7 sessions, covering 3 days. We have a special invitation to be present, but cannot then leave the office, or we should be glad to again meet the bee-keepers of New York.

Notes from Sunland, on the Manatee River, Gulf Coast of Southern Florida.—This is the title of a neat pamphlet of 84 pages by S. C. Upham, Braidentown, Fla. Anyone desiring to know anything of the climate, soil and productions of that region should send him 25 cents for this little book.

MISCELLANEOUS.

Wax Boiling in England.—Mr. A. Pettigrew, in the *London Journal of Horticulture*, gives the following details:

Boiling wax and preparing it for the market is very disagreeable work. All bee-keepers with their wives and servants dislike this work exceedingly, and none dislike it more than we do. Melted wax is easily cooled, and when cooling cleaves to everything it touches, and it is difficult to remove. Combs before being melted are bulky, and therefore have to be compressed before they are placed into a copper to be boiled. When the wax begins melting the pollen of the combs is liberated and mixes with the water in the copper or boiler. There is great difficulty in separating the melted wax from the pollen. Our plan has been to place the compressed combs in a bag of cheese-cloth and boil them, skim off the melted wax and run it through a strainer or a piece of muslin. But we have never been satisfied with this mode of melting wax. It is troublesome work. After the cakes of wax have cooled some pollen slightly mixed with wax adheres to their under sides, which is scraped off, the cakes being again boiled in clean water and run through a cloth into dishes half filled with clean cold water. We obtain thus wax as pure as it is possible to take it. By running the wax into cold water at the last time of boiling the bottom of the cakes appear to advantage, and look as if they had been moulded. The bottom of our cakes of wax look better than the upper surface, owing to the cold water freezing the wax into various forms as soon as they meet.

Some years ago a bee-keeper at Wigan told the readers of this journal that this plan of taking wax is too slow and troublesome, and that he had invented another which is easier and better. His plan or mode commended itself to me at the time, but owing to the smallness of our kitchen oven I have never put it to the test of experiment. His plan, if I remember rightly, is to melt the combs in a dry heat by putting them into a wire sieve or strainer or colander, and placing this in an oven sufficiently warm to melt the wax, and over a dish to receive the melted wax as it escapes from the pollen. This appears to me to be a very feasible mode of melting wax, and easier than the one we have followed for so many years.

Another mode of taking wax—probably the best invented—was carried into execution in Bowdon a short time ago. A lady obtained a great boxful of honeycombs; she first took the honey cleanly from the combs, then commenced in a novel manner to manufacture the wax. Instead of taking the wax from the pollen and rubbish, she took the pollen from the wax by

washing it in clean water. Then she boiled the wax and poured it into a dish without using a filter. She brought the wax to me to sell for her, which I did at 2s. per lb., and I have never seen better or cleaner wax. This plan makes wax-taking comparatively easy and pleasant.

Glucose and the Michigan State Bee-Keepers' Convention.—The *Dowagiac Times* gives the following account of Dr Kellogg's lecture on Honey Adulteration with Glucose:

An excellent dessert to the general feast was dished up by Dr. Kellogg, of the Sanitarium. Doctor K. is a young man of far more than ordinary natural abilities, in addition to having a finished medical and chemical education. His subject was "Honey as Food." The Doctor dwelt at length upon the use of sweets to the human system; spoke very highly of honey as one of those sweets.

The subject of adulteration of sweets naturally came up, and was discussed at length, many questions being asked by the audience. Glucose (a syrup or sugar made from starch, by a sulphuric acid treatment) he had found to be the one adulterant used in the honey, syrup, and sugars of commerce. Glucose is made from corn (that being the cheapest starchy substance), though it can be, and has been, made of potatoes, grapes, wheat, rye, saw dust, old rags, or anything that will produce starch. He told how much had been made from an old shirt, but had no fears of any contact with shirt glucose, as the great bulk was, from economy, made of corn. Thousands of bushels of corn is used daily by the Buffalo factory. Other factories are springing up all over the United States. France and Germany are parents of the manufacture. Much is used in making beer.

Grape sugar is glucose granulated by a secret process unknown to classical chemistry, and kept secret by the manufacturers. On being asked of the prevalence and effect of adulteration by glucose and grape sugar, Dr. K. said it was almost impossible to find a sample of syrup that was not a large proportion glucose; that soft sugars were also badly mixed. He recommended the purchase of granulated or confectioners' sugar as the only ones safe against adulteration. They had trouble in getting pure syrups at the Sanitarium. The dealers were unable to get it. Samples of liquid honey that he had analyzed was found badly mixed. They had all been put up by dealers in the large cities. He had no idea that producers adulterated honey, though he had read that a mixture could be put into combs and capped over artificially. This caused hearty and prolonged laughter.

Prof. Cook (professor of entomology, of our State agricultural college), arose and said that he had read the same thing, but every man of any experience with bees or honey of course knew better; that no human being could fabricate even the most bungling imitation of honey comb filled and capped over.

Dr. Kellogg then said that he had no fears of comb honey being adulterated by any one, nor of any honey being adulterated by the producers. These producers have got a state law enacted making the adulteration of honey a fine of \$100. He gave it as his opinion that sufficient quantities of free sulphuric acid, or lime, or oxide of iron, or all, were to be found in glucose, or syrups mixed with it, to be unwholesome to the human system. Besides, it was a great cheat, because the sweet was only about $\frac{1}{4}$ or $\frac{1}{2}$ as great as that of cane sugar.

An elderly physician in the audience (Dr. Whiting) arose and said we are finding new and dangerous symptoms with our patients, that by inquiry and the symptomatology point directly to the free use of commercial syrups."

Signing Notes.—In the *Dowagiac, Mich., Times*, "J. H." (eddon) gives the following advice on this subject:

"Say, John, I want to ask a favor of an old friend, I need one thousand dollars bad just now, and the bank wants a signer. I can pay it easily enough in 30 days. It wont even trouble you."

"Well Harry, I would like to do you a favor any time, but read this," (taking a paper from his wallet that reads as follows):

TO MY BEST FRIENDS.—The following is a copy of a "pledge" I have given to my wife:

"Whereas, you have practiced industry, economy and self-denial, to aid in the accumulation of the little we now possess, making your interest and rightful ownership the same as my own, therefore, I promise you that I will not so far usurp your rights and those of your children, as to hazzard our accumulations by signing any obligations with any person whomsoever."

"I trust your reason will approve of, and your friendship excuse my necessary refusal."

How strange it is that bankers with their vast experience can't trust John's "30 days," when they "can pay it sure" so easily? Readers cut out this "pledge," sign it, and when a friend asks you to sign an obligation that you do not wish to, show it to him, and after he reads it, if he is a friend worth having, he will be a friend still.

Survival of the Fittest.—The *Canadian Farmer*, says:

The bee-keeper who seeks to grasp the ideal bee by his own culture, must take no stock in the absurd doctrine of the "survival of the fittest." What has been done by stock-breeders has been accomplished by a most careful system of selection and management, backed up by untiring industry and perseverance.

☞ It will pay to devote a few hours in getting up a club for the BEE JOURNAL. Read the list of premiums on another page.

CORRESPONDENCE

For the American Bee Journal.

Yellow and Leather-Colored Bees.

CHAS. DADANT.

In the BEE JOURNAL for Nov. 23, Mr. Demaree is yet arguing his favorite plea in favor of the yellow bee.

The first Italian queen that I introduced in my apiary was yellow to the tip of her abdomen. Her workers were as yellow as could be desired. This queen was the daughter of a queen imported from the apiary of the celebrated German, Dzierzon, whose strain of bees will never be excelled as to color; Dr. Dzierzon, for more than 20 years previous, having bred in view of improvement in color.

The progeny of this queen produced workers which had, most of them, the three yellow bands perfectly visible; most of their colonies had not a single black bee. Yet these workers were but half Italian, for, at that time, there was not another Italian queen within fifty miles of Hamilton, and, as I had worried my colony by rearing queens, I had not a single drone, and my young queens had all mated with black drones.

The following year I received three queens from Italy. Of course, I was far from being satisfied with these queens. They were dark, and their progeny was also darker even than the ill-mated queens.

Then I began to think that the color was not a sure test of purity, and, after a careful study, I proclaimed that the quietness of the bees on the combs, when they are taken out of the hives, is the surest test; this quietness being in direct ratio with the purity of the Italian bees.

Several bee-keepers pretend that the Italian bee is not a pure race; others, that it is the result of a mixture of Cyprian and black bees. If such be the case, let me ask, how is it that such an union has produced, in the offspring, a behavior so different from that of both the parents?

The Cyprian queens, when you open their hives, flee out of sight; their workers are disturbed and run everywhere, ready to fight. The black queens and bees act about the same, with the exception that the workers gather under the combs, and fall to the ground. The Italian queens, on the contrary, remain quiet, and every worker sticks to the combs undisturbed.

In writing of me, and of my bees, Mr. Demaree says that "some people" may suspect that the wonderful power of selfishness can move the best of men. Several times I have argued for the leather-colored Italian bee. My preference was based on facts, observed by myself and by perhaps 100 or more customers, who had made, as I did, the comparison between both races, and who prefer, as I do, the leather to the light-colored bee. After

reading the article of Mr. Demaree, James Heddon sent me the letter given hereafter. Mr. Heddon cannot be accused of being moved by selfishness:

"Dowagiac, Mich., Nov. 23, 1881.

"FRIEND DADANT: I have just read the ably written article of Mr. Demaree, and while I admire his outspoken, earnest manner, I must say that all my experience with different races and strains of bees convince me that he is wrong. I bought many queens (over 70 in all) of Grimm, Alley, W. J. Davis, and others, of the "pure" golden, three-banded bees, and yet I wrote "the Italian bees are not superior to the Germans" of my apiary, all things considered. Finally, Mr. Oatman asked me if I had ever tried the leather-colored Italians. He evidently thought them a distinct strain, and said they would change my views upon the subject. I thought then, as I do now, that Mr. O., having been an extensive breeder, held opinions of worth, and I, then starting a second apiary, purchased 25 colonies and some queens from him, and put them in my new apiary, with some colonies of bright golden Italians. Their marked superiority over any bees I had ever seen induced me to supersede all my bright queens with those reared from the long leather-colored ones. I found no trouble in discovering traces of blood from the bright Italians, both by looks and actions, for the next 2 or 3 years. That fact convinced me that they were, to say the least, a separate strain. I wrote to Mr. Davis (who stood then as now high in my estimation), telling him all about the superiority of these Oatman bees over those purchased of him and others. I have reason to believe that this letter found him in a position to welcome something different in the line of blood, and though he had at that time one of the purest apiaries in America, I think that he superseded it with something he considers, after years of use, much better. I should not be much surprised if that is not the leather-colored Italians, or them and some other blood carefully handled. I hope to hear from Mr. Davis upon the subject. I write you because I am quite positive that Mr. Oatman told me that he obtained his leather-colored strain of bees from you, out of one of your importations. That I have so handled this strain of bees that they are better, rather than poorer, than when I obtained them, I have no doubt. That you, Mr. W. J. Davis, and numerous others are doing the same thing I have also no doubt. My opinion is, if we breed for color, we shall move backward; if for traits, forward; if for both at the same time, our movements will be slow in any direction."

Mr. Demaree, who says that he takes a broader view of the subject than I can comprehend, makes sport of my remark that, as he never bought a queen from me, he cannot know how our bees are. If I made such a remark, it is because Mr. D., in the BEE JOURNAL for Sept. 14th, wrote about my "gentle dark Italians," saying that if he wanted to breed a game race of

bees, he would commence by crossing the Cyprian with "Mr. Dadant's dark Italians," the robust Cyprian mixed with "these ferocious dark hybrids," etc. Now, unable to sustain his position about the ferocious temper of the leather-colored bees, Mr. Demaree says that in writing this article his intention was to joke and worry me. If so, the joking power of Mr. Demaree is not very varied, for, on several occasions, he made thrusts against the dark Italians, accusing them of being full of vindictiveness, and always ready to fight. Such accusations only show that he never has seen the worker progeny of a queen imported from Italy.

With Mr. Heddon, I think that it will be very difficult to produce a uniform type of bees, with all the best qualities, and worthy of the name of the "American bee." There are several sides to this question, the color of the bees being only one of them, and not, to my mind, the most important.

Hamilton, Ill.

For the American Bee Journal.

The Coming Bee, again.

H. L. JEFFREY.

The above heading seems to have been talked of at every convenient gathering of apiarists. It has been used for the subject of articles from the ablest apicultural writers of the day, and how much nearer the goal are we, either in the attainment of our wished-for bee, or in the elucidation of the *modus operandi* for obtaining her? One gives one method, another, or I might say all the rest, differ with the first and each other in the majority of points of working to attain the desired results, and yet all agree on the point that we must breed from our best queens, or in other words, from the queens of the colonies giving us the best results. Then follows what we may expect to get by working in such a channel, or perhaps the *modus operandi* of work or management according to A, B, C or D's ideas, and we follow it up, but we must not in-breed at all, and still we must keep getting queens from our most successful honey producing apiarists, and next, or first, we must have only pure drones, or must raise drones from our best stock, then comes a diverge. "There is the uncontrollable drone" to mate with.

Now, and first, if we are to get our drones from our best queens, or if we are to raise our queens from our best queen, it makes but little difference which way (on paper without trial), but one thing is sure, our breeding colonies have got to be the best to be obtained, either at home or abroad, if success is ever expected in the shape of perfection of the bee of the future. But when A, B, C or D claim it is to come from this or that hybrid stock, they are talking a great deal lumpy; it may be a commingling of races, but it will be a thoroughbred bee and cannot be a chance hybrid. It has been proved by hundreds of thousands of experiments that hybridism is a sure

road to dissatisfaction, and I know of a number that have tried to work from a hybrid-stock starting-point, and they have always given up with evidence that they would result in a strong tendency to show apparent purity in offspring of both the original parents, and that after several successive generations. And like results will positively settle the hybrid starting-point.

That bees cannot be manipulated like other kinds of stock is an error. That they are not governed by the same laws as other stock is an error; and that there are not governing laws that are particularly their own is positively true and beyond question, as every observing, practical bee-keeper knows, and those laws are, without doubt, elastic enough to be manipulative to a practicable extent.

One question right here is, who is going to give us the perfect bee? How are they going to obtain it? When are we to have it? And where from will we get it?

I have been reading all that I could get hold of that has been written, and, like many others, have gained but a dim light on the subject, except that some think it will be a three or four banded bee.

Friend Newman (I say friend because you are a friend to us all), cannot you possibly sift this subject out so as to give us the fine flour and positive and concise rules to work by, and report results to you for a summing-up or comparison?

I do not know what others are doing, or just how they are working, or in what points they are succeeding; but one thing I feel very sure of, they are either succeeding blindly without knowing how, or they don't and won't tell us the whole in plain language.

Another point I am sure of, we may think we know what to expect from the queen, but we expect more than we get, and we get some things that are accounted for most mistakably, or else apiculture, as it is, is a wrongly taught and practiced science.

When Mr. Theo. Peet wrote some time ago that the drone was an important factor, he wrote a good deal of overlooked truth and no foolish poetry.

At the present day, we are obliged to swallow that detestable Dzierzon theory, or disbelieve our own eyes. Now we will acknowledge it true, and on that ground ask some questions: If we have an extra good colony for honey qualities, which is to have the credit, the queen or the drone she mated with? If the queen, why don't we get the same from her daughter's progeny? If from the drone, why not from the workers of the queen he mates with (the queens and drones coming from the same stock)?

Will some one answer the following questions fully in the BEE JOURNAL, and give us a chance to sift out the fine flour?

What relation is a drone raised by a queen to the drone her mother mated with?

What relation to the drone she mates with?

What relation to her princess?

What relation is he to her (the queen laying the eggs)?

And what relation is the mating drone to the queen's princesses and workers?

I am sure all of the above questions, or their correct answers, are of just as much need to be considered as the qualities of prolificness, gentleness, great honey gathering propensities, or any amount of color or bands, and, by a thorough understanding of their proper answers, rules will be seen, which, if followed, will give all the graces called for.

Perhaps some of the readers of the BEE JOURNAL think I had better finish up that foul brood and the desicated brood question. I will, but I wish to wait till spring and know for sure if my past experiments prove true. I shall send specimens of it to Prof. A. J. Cook again as early as practical, and to the editor, with condensed report of observations at the earliest opportunity.

Woodbury, Conn.

[Referring to the above suggestion relative to laying down concise rules to be observed in breeding for the "coming bee," we certainly cannot arrogate to ourselves the wisdom to do so. If Mr. Jeffrey will reflect, that thousands of intelligent bee-keepers in America are deeply interested in the improvement of their bees, it would seem inexcusable egotism for us to make suggestions, especially when decided and perceptible improvements have already been accomplished. While one may be slowly, but surely, approaching the summit in a round-about course, another, with more comprehension but less patience, may reach it by a shorter route. We can hardly guess when the result will be reached, but that it will be attained we cannot doubt; and perhaps sooner than many anticipate.—ED.]

For the American Bee Journal.

A Talk on Sundry Bee Matters.

WM. F. CLARKE.

I often feel disposed to write on a variety of bee-keeping topics in a free-and-easy, chit-chaty sort of way, dispensing with all the formalities of a set article or editorial. Whether this sort of thing will interest the readers of the AMERICAN BEE JOURNAL, or be voted a bore, I do not know, but shall probably find out after the present lucubration sees the light. We are constantly trying experiments with bees, and it may not be amiss now and then to try one with bee-keepers. "So, here goes."

A BEE COMPANY.

We have organized a company in this town, and started an apiary as a tentative business venture. Money is plenty at six per cent. and some of us think we can pay all expenses and de-

clare a dividend of 10 per cent. every six months. If this can be done in connection with a legitimate industry, will it not be preferable to shaving notes and squeezing debtors? Thus far, we have only bought 44 hives of bees, being the sum total of that nice little apiary at Kincairdine, with which I fell so desperately in love last July, and of which I wrote a brief account for the BEE JOURNAL. Mr. Sturgeon, the owner of it, had either to give up his business or part with his apiary, and very reluctantly concluded to do the latter. He, however, reserved 2 or 3 colonies, having come to such a pass that he cannot live without bees. Twenty-seven of our colonies are in double chaff hives, made after a pattern obtained from A. I. Root. The remaining 17 are in the common Simplicity hive. We had outside cases made for these of plained lumber, at a cost of 65 cents each. They look nearly, if not quite as well as the others, and don't cost one-fourth the amount. The cases are six inches larger every way than the Simplicity hive, and the space is filled in with chaff. I never handled a double chaff hive until last summer, and found one serious objection to it: The permanent upper story is very inconvenient for the elbows in taking out and putting in frames. It also necessitates a great deal of stooping, whereas with the single hive, you can sit down on a stool or box, and take solid comfort while exploring the condition of a colony.

JONES' NEW DEPARTURE.

Jones has become an editor. He is conducting a bee department for the *Montreal Witness*, a paper I have long written for, but from which I retire January 1, in order to give my best attention to the *Rural Canadian*, which has been kindly noticed in the BEE JOURNAL, and will, of course, have a bee department of its own. Jones makes a very good list of it as a beginner, and it strikes me that many practical bee-keepers might do good service to the cause of apiculture, and help their own business, by running bee departments in their local newspapers.

DOOLITTLE'S CATALOGUE.

"I arise" to state that I have received the above, and like it very much. It is the neatest and most tasty thing of the kind in my collection of bee-keepers' catalogues. For the most part, it is well written. But friend D., like the majority of those who write on apiculture, uses "the plural of majesty," and it sometimes reads queerly. "We had desired to have a little friendly talk with you about bees and bee-keeping, etc., etc., but owing to sickness * * * I shall have to be brief." "We hold ourselves personally responsible," etc. I think we had better, all of us, give up this form of expression, and come down from our majestic stilts to Quaker plainness of speech. Only the "big man" who really fills the editorial chair, has a right to use the magnificent "We, Us & Company," anyhow. Correspondents and advertisers, unless a firm, should use the singular,

and indeed, as will be seen by the above quotations, cannot write good grammar unless they do. I am particularly pleased with that part of Doolittle's circular which relates to the culture of small fruits. Being an enthusiast in that line myself, I cordially second the advice to bee-keepers that they combine apiculture and small fruit culture.

ARE THERE TOO MANY BEE PAPERS?

I am inclined to think so. Doolittle's club list enumerates "NINE in the United States for 1882." I didn't know there were so many, and I am sure I cannot find time to read them all. It's a delicate matter to touch upon, and reminds me of a question once put to a graduating theological student, "which are the minor prophets?" He replied that "he didn't like to say as the answer might seem invidious." Mrs. Partington, says, "comparisons are odorous," but really, some of the bee publications in quality of paper, typographical execution, and editorial ability, are no credit to us. They are like weak colonies of bees,—haven't honey enough to winter well, and ought to be united to stronger colonies. Whether we can be overstocked with bees or not is a question much discussed. I raise the inquiry, whether it is not possible to be over-stocked with bee papers. I think it is.

BEE STINGS.

There have been a number of references to the above subject in the bee publications during the past few months. Professor Cook, very high authority, maintains that by successive inoculations with bee poison, it becomes a matter of indifference whether you get stung or not. Mrs. Harrison, our queen bee-keeper, eulogizes bee-stinging as a cure for rheumatism and the dropsy. I am sorry to be obliged to take issue with such eminent persons, but my experience contradicts them both. The older I get, the worse I suffer from a bee-sting. It has never done my rheumatism a mite of good, but on the contrary, gives me the worst kind of rheumatism, and as for dropsy, it always makes me very dropsical, especially about the eyes. In the September, 1873, BEE JOURNAL, I gave an account of "a curious and painful experience," with a bee-sting in the center of the upper lip. Well, strange to say, during the past summer, everything I got in any part of the body, centered both as to pain and swelling in the upper lip. A hard lump, the size of a marble, invariably formed in the center of that upper lip, and from it the pain and inflammation radiated all over my body, and specially affected the head. Mentioning these facts to the editor of the BEE JOURNAL in October last, all the comfort I got was that I ought to let bees alone. That is morally impossible.

BEE GLOVES.

I had great satisfaction last summer in the use of a pair of bee gloves, which I cannot claim to have invented, for they grew out of some sug-

gestions I read in one of the BEE JOURNALS. They were made of canton flannel, or rather a species of soft crash towelling, covered with a very fine quality of brown linen. Gauntlets would be a more proper name for them than gloves, as they are long enough to lap over the coat cuff, which they grasp with a bit of elastic. After putting them on, I soaked them with cold water, which rendered them cool and pleasant to the hands, and made the bees, even when somewhat excited, indisposed to settle on them, for they are dainty little creatures, and don't like to damp their feet. They couldn't sting through them, and being wet, didn't want to. After trying rubber gloves, woolen mits with a forefinger in them, and sheepskin thistle mits of the same shape, I give these the decided preference. They were nicely made at our glove factory here, and only cost, material and workmanship, about 75c.

L. C. ROOT & BRO.'S REPORT.

This is a very interesting document, and should be carefully studied by all bee-keepers. I do not remember to have seen it in the BEE JOURNAL,* but it is well worthy of a place there, and indeed, in all the bee papers.

BEE-KEEPERS' SUPPLIES.

We, here in Canada, labor under serious disadvantages in regard to the above. Duty and express charges come so high as practically to banish us from the United States market, and this may explain to dealers why they get so few orders from this side of the lines. Many of our bee-keepers worry along with rude appliances, because they cannot afford to import better. Our people are not so ingenious and enterprising as the Americans, nor is there a brisk enough competition here to give us a choice of the best articles. D. A. Jones is doing something to supply this lack, and I just received a nice sample section-box from M. Ramer, of Cedar Grove. We shall doubtless get over this difficulty in time, but there are many things we should order if it were not for custom-house dues, post-office regulations, and express charges. I hope our brother and sister bee-keepers, will "to a man" use their influence to bring about Reciprocity between Canada and the United States. The bars and restrictions that now exist, are too oppressive to be tolerated much longer. Nor will dry jokes about annexation help the matter, for the more that is said on that subject, the less will our Government be disposed to relax. We want free commercial and social intercourse and interchange, let our political relations be what they may.

Listowel, Dec. 15, 1880.

[*Published Dec. 17, p. 388, BEE JOURNAL.—ED.]

Translated by A. R. Kohnke.

Peccadillos of Bee-Keepers.

The following is an abstract of a lecture delivered by Mr. Kaestner, as found in the *Deutscher Bienenfreund*. Peccadillos of the bee-keeper. What

a terrible word. But let us classify them according to the degree of knowledge a man may have of the science of bee-keeping, as peccadillos of the apprentice, of the journeyman and of the master.

Enthusiasm in apiculture may in certain cases be considered as a very contagious disease. Let any person wholly unacquainted with bees and their care, get into the company of enthusiastic bee-keepers, and he will be most likely to catch it. For the sake of brevity we will assume Mr. Roe is the infected person. He forthwith concludes to become a bee-keeper,—no, not that, but an—apiculturist, who will manage his bee on the most approved plans, because honey tastes pleasant, and he has an imaginary sight of a bursting pocketbook, stuffed with the proceeds of honey sold. Hives are cheap and easy to be had, but whether they are of the best style, face toward a proper direction on the surrounding country, is especially favorable to bee-keeping, are minor considerations. This would-be bee-keeper thinks the bee must get the honey. The advice of an experienced bee-master would be very valuable to him and save trouble and expense. But never mind the expense; our friend Roe knows how to hold a saw and handle a plane. His cleverness and economy will produce a hive exceeding every other, except probably in accuracy.

The bees must be bought, but "cheap" is the watchword. In spring one or more colonies are bought; they will, they *must*, swarm; if not, he can "divide" them. Sure enough, spring favors his expectations; his bees swarm; some are large, some rather small swarms, but he accepts them all, hiving each one by itself; other colonies he divides; for his apiary must be stocked; his hives must be filled.

If the season is not a very favorable one, what will be the consequences of such thoughtless work for increase? Colonies will be weak and light in stores in the fall, starve during the winter and next spring finds Mr. Roe minus bees, who blames the "new fangled notion" of frame hives and "other traps;" his grandfather had bees, too, as he remembers, but had them in gums and old nail kegs, and he had always plenty of honey.

He finally comforts himself with the idea that "everybody must pay his apprentice" and he begins anew. This time he is a little more careful. But a visit to his apiary, to observe how he handles his bees, how he wants to induce swarming bees to settle by gun-shots and the drumming of tin pans, will prove that he always will remain an apprentice; his faults and peccadillos are on the increase. To inform himself of the subject of apiculture by reading standard authors or the BEE JOURNAL, he considers time and money thrown away. And, after a year or two, his hives are as empty as before, and mice and spiders have taken their abode in them.

But supposing it is not quite so bad; if Mr. Roe manages to avoid many mistakes, he wants to become a journeyman bee-keeper; he is a mem-

ber of a bee-keepers' association, attends the meetings, reads books and papers on apiculture, and observes how masters in the business manage their bees. Very soon he thinks he knows it all, and is ready to prove it. He has yet some colonies in box hives, which are no ornament in his apiary; these must be transferred; he had read in a bee book that that may be done at any time in the year, provided it is warm enough for the bees to fly. So he goes to work at the end of April or in May and transfers; how he cuts and slashes; it is fun to look on; by much patching and propping he manages to fill 5 or 6 frames; the remainder of the old comb does not fit anywhere; especially those having honey are too thick. After a few days the weather turns cold, brood gets chilled, not being put compactly in the frames and convenient enough for the bees to cover; stores are scanty, forage not yet very plenty; result—weak or starving colonies.

Suppose, Mr. Roe has avoided all this; he has managed to winter his bees without the loss of one colony. He will henceforth consider himself a master, because he has read somewhere, that only a master is able to winter bees without loss. Spring looks very propitious; his colonies have used very little of their stores; they are full of bees and brood, and everything looks well. But, all of a sudden, the weather turns cold and remains so for some time; the stores of the colonies are exhausted in double-quick time, and starvation and death threatens his bees. He would like to give them full frames of capped honey, but has none; his honey was sold in the fall, hence he will buy to feed, and he may consider himself lucky, if he is able to obtain pure honey or first class white sugar; but woe unto his bees if he thinks anything will do, if it is only sweet, stuffing his bees with poor syrup, sugar or glucose, or spoiled infected honey, forgetting all about dysentery and foul brood.

All this being the consequence of avarice which made him sell his last drop of honey, probably extracting in the fall more than the bees could spare instead of saving some in case of emergency. But next year Mr. Roe will manage things differently. He now feeds his bees, whether they are in need of it or not; besides he had read about stimulative feeding, and wants to push his colonies now in that way; his colonies get diseased with dysentery, and commence to rob. He does not feed in time, is careless in doing it, and uses no judgment in general. Beside these he makes many other mistakes. He bothers with weak, queenless colonies, imports or buys costly queens from Italy, Egypt, Syria, Carniola, etc. His night's rest is even disturbed by dreaming of that big *Apis dorsata*.

But, we will cover all these shortcomings with the cloak of brotherly charity, and see how he manages his bees through the summer. We find him in the apiary, extracting. He looks rather pleased, for his pets have been very industrious. Everything is

full and crowded. He must extract, put on sections and remove those finished. But, on closer observation, we notice that he works too hasty. Now, this section does not fit; that honey-board does not suit; he has mislaid his knife; cannot find another instrument he wants; the bees he shakes off in front of the hive, which may incur the loss of a queen; he cannot immediately replace full frames by empty ones, because the worms and moths have ruined them; he throws out some of the uncapped brood into the extracted honey; his extractor is a miserable clap-trap affair; in short, he lacks order and neatness. Such are peccadillos of a would-be bee-master in summer.

But what about fall management? Will he improve upon his former mistakes. It has been a poor honey year, but he has had lots of swarms. How does he act now? Very dilatory indeed. He did not feed his light colonies early in September; little of the stores consist of capped honey; colonies rob one another without the least anxiety on his part. To our expostulations he answers: "Oh, well, one cannot be so very particular; if I do lose one colony, that does not make much difference; I will unite some; others I intend to bury and a few I will put into the cellar; I hope to get along nicely, and there is time enough to do all this yet."

We are rather surprised at his answer, but have resolved to let him alone. But winter sets in early and his preparations are not yet finished; whether or not his cellar and ditches are fit to put bees in has not entered his mind. Next spring, when he puts his bees on their summer stand, he finds dead bees by the quart, some of them molded and decayed, suffocated, drowned and starved. Still, he is contented, because others fared no better and you cannot winter bees without having some dead ones in spring! Poor consolation!

A few more points which I shall mention before I close. Instead of leaving costly experiments to masters, some, who have not the time nor money nor knowledge, engage in extravagances. They have read about giant colonies, American honey-racks, artificial fertilization, etc., etc., and our friend Roe goes to work with a vengeance, tries everything new, spends and loses time and money to find in the end, that he paid too dear for his whistle.

Rural New Yorker.

Pollen in the Hive in Winter.

PROF. A. J. COOK.

In articles written for other journals, and in my "Manual of the Apiary," I have stated that the old bee could live for long periods without pollen. As honey, however, is a hydrocarbon, and so contains no nitrogen, it is to be presumed that the old bees need and do eat some pollen during the active season, to supply the waste of tissue, consequent upon all physical activity.

I have further stated that pollen was an indispensable requisite to brood-rearing; that it is an essential element in the food of the larval bees. As a scholium under this last proposition, I have expressed the opinion that in some conditions the presence of pollen in the hive in winter is a positive injury, and that in all cases it is unnecessary. But I would remark, and with emphasis, that this pollen is more valuable as soon as the bees commence to fly the following spring, and then any frames that contain it should be given to the bees.

These facts have lately been called in question by several writers. I think most of the critics object, simply because they do not understand my position. One writer, however, who, whatever else may be said of him, puts forth very original ideas, and contradicts nearly every well grounded fact in apiculture, calls for proofs.

1. I have wintered bees on food which was made wholly of cane sugar, and which I had analyzed, and which gave no trace of nitrogen. This was fed on clean combs which, so far as we could see, contained not a trace of bee-bread. New combs are so transparent that they cannot contain more than the faintest trace of pollen, at least without showing it. I have fed bees, right in the busy season of the year, this same kind of food and have had them so shut up that they could get at no other, and they have lived in this way for weeks and have built large combs, and when given liberty were in good condition. It is impossible to prove that bees need and must have nitrogenous food when they are actively storing, but this position is sustained by all analogy.

2. In the last experiments the bees would have enough pollen in their stomachs and on their pollen baskets, so that they would put quite a little in the cells after first building the comb, and so would commence rearing brood, but the brood-rearing would soon be discontinued. After the brood-rearing had ceased, I could set it to going at once, by giving the bees a frame of bee-bread. In such cases we must not feed honey, as there is often quite a little pollen in the nectar which the bees have brought to the hive. Some honey, as basswood, often contains quite a trace of this. This would give enough pollen to rear a little brood. Again, for several winters I have practiced giving half our bees pollen, and the other half, frames with no pollen. In all cases we have noticed that those without pollen would always be without brood in the spring, while in the other hives we almost always found brood. Those without pollen would go to gathering very fast as they could get pollen the first of April and would then, or as soon as we would supply the lack of pollen in the hive, go rapidly to breeding.

These last experiments have satisfied me that bees are often better off with no pollen in winter. In the best condition they will eat little or no pollen, as they breed very little, and in these circumstances he presence

of pollen would do no harm. So in just the best cellar or in any condition where the bees are kept just right, no harm will result from the presence of pollen. In the South, too, where the bees fly out often, there is no danger from the presence of pollen in the hive. Here in the North, on the other hand, we often have a warm time in January, and the bees, unless so protected that they do not feel the warmth, will commence breeding if they have pollen. They may get a large area of brood. Now if there is no chance for them to fly, or if the weather becomes cold they are injured by this activity which came, we may say, as the result of the presence of pollen. The next Spring they are in feeble condition, and there is more of a tendency to dwindle away as the warm days incite them to fly forth.

If bees can be kept perfectly quiet in winter, they eat nothing but honey, and do not need to void their feces. With activity comes more food-taking, perhaps, too, they take some of the nitrogenous food, and as a result they become diseased and die. I have never found any support of the theory of the late Mr. Quinby, that bees excrete a dry powder in winter. The facts that I observed in our colonies wintered with and without pollen have led me to the above theory. The theory may not be correct, but the facts are still to be explained. I am so much convinced that I remove all of the pollen if I can as I prepare the bees for winter.

For the American Bee Journal.

Drones and Drone-Workers.

S. S. BUTLER, M. D.

How can we get our queens fertilized by the best drones? Every bee-keeper has a few colonies that are much superior to the rest. Why? I claim that they have better queens that have mated with good drones—the result is—*best* colonies. I use the word “best” to distinguish them from others which are all the way from “poor” up to “very good.”

What kind of drones do those *best* queens give? Fine large ones, fully one-third larger than drones from those small active queens, which are degenerates; for all the imported queens that were produced in natural swarming, are of medium size. Queens that have given me the most industrious workers were of medium size; abnormal queens are very prolific, giving great quantities of what I, for want of a better name, shall call drone workers; also quantities of small, active, swift-flying drones, for our large, clumsy and slow *best* drones to compete with. The consequence is, that supposing there are as many of the fine as of the poor drones, the poor ones being so much swifter, nearly all of our queens mate with the poor ones, thus keeping our apiary full of queens that, although they are prolific enough, their eggs are so poorly vitalized that the workers are short-lived, make short flights, can stand

but little labor, and amongst them are great quantities of drone-workers, amounting sometimes to fully one-half. I am satisfied that they do no work outside, among them are no ragged-winged ones.

That there are large quantities of them in almost every apiary, I am certain. How can you tell them? In this way: When honey is scarce, the bees first kill off the drones, and towards the last of drone killing, you will see the workers in front of the hive licking and pulling certain ones about, keeping them outside, and persecuting them nearly the same as they do drones. I have seen it stated in such cases that bees were robbing and used to think it was so, but it is not; and you can prove it in this way: Anyone who has blacks, hybrids and marked Italians, will find, in front of the different hives, the same kind of bees that are in the hives (which would not be the case if they were robbers) that were killed off, for blacks and hybrids are great robbers. They would be in front of Italians and hybrids, and Italians in front of the blacks.

These drone-workers, I am satisfied, are the cause of the small amount of honey obtained by some colonies that keep full of bees, in comparatively good seasons, for it takes a large amount of honey to keep the hive full of those poor good-for-nothings, which all has to be brought in by those bees that have stamina enough to make out-door workers.

The remedy is to keep an abundance of drones from the best queens, and not to let any of the others rear any, or, if they do get some, trap them off.

Here is the history of two of my colonies the past season, Nos. 2 and 37; it has been a poor year. No. 2, a pure Italian queen, medium size, quite an ordinary layer, keeping only 5 or 6 Gallup frames full of brood during the best of the season; the workers were perceptibly larger than any others. No doubt they were longer lived, as the hive was full of bees and gave, before they swarmed, fully 100 lbs. of extracted honey, while the average was but 42 lbs. There never was any great stir about the hive, few standing around the entrance, while there were quantities about No. 37, and others, that gave but very little honey; they were bringing in stores while others were consuming what they had brought in, during the early part of the season, and her daughter's bees had filled up the hive.

The queen in No. 37 was of the same age as the other, a very prolific layer, had mated with a hybrid drone, giving some black and a good many two-banded bees; the drone was no doubt one of those poor ones; she laid nearly twice as many eggs as No. 2, was full of bees, but I extracted but once, only 18 lbs.; at the close of the season they killed off nearly one-half of the workers, while none were killed in No. 2. Why this difference? One of these two reasons made the difference: Either it is not a benefit, but rather a detriment for a queen to be what is called very prolific (we would

not expect as good colts from a stallion that had sired 20 colts in a season as if he had sired but 10); why should we expect as good workers from a queen that lays 4,000 eggs, as from one that lays but 1,500 or 2,000. 2. Or else supposing the queens were equally good, the quality of the eggs of No. 37 were spoiled by the poor drone s mated with.

I have had, and no doubt every old bee-keeper has had many such cases; in a good year they do not kill off those drone workers (see Mr. Heddon's article, page 481, Oct., 1881, *Gleanings*).

W. F. Clarke, in Oct. *Gleanings*, page 494, says: “Mr. Jones says he got 62 queens in one lot, only 2 or 3 imperfect ones.” I claim that the only test of a perfect queen, and that she has mated with a perfect drone, is the worker progeny, which must be very industrious, strong and long-lived. I would as soon expect to get 60 No. 1 colts from a fine stallion in one season, as 60 fine queens at one time from a colony. Horsemen wishing to get tip-top colts from extra stallions, let him get but very few.

H. Alley, in the BEE JOURNAL, May number, 1880, page 237 (one who has had more experience than any other person living raising queens), says: “Where too many are reared in one hive, even though they are 16 days from the egg, do not live so long as queens that are reared in hives where only a small number are reared at one time.”

P. L. Viallon (a young queen breeder but a very observing man), says in Nov. *Gleanings*, page 525: “I have experimented on this subject several years, and have come to the conclusion that it is an easy matter to degenerate bees, and there is no improvement to be made on the daughters of imported mothers.” Further on he says: “I have found my bees a little less energetic after 2 or 3 generations.” A frank acknowledgment that by his management in rearing them, they do degenerate, and he says that he shall breed only from imported mothers.

I think the system of breeding is radically wrong somewhere, that has to send to Italy to get queens to keep up his stock. Why does not the Italian stock run out? Any one that will procure his stock from some locality in Italy, say 10 miles away from any one that is rearing forced queens, and after getting them, raise all his queens by natural swarming, keeping only those cells that are perfected before they swarm out, always breeding up, need not, and will not have his bees degenerate.

It is a principle running through all nature, that in propagating, the less in quantity, the more perfect in quality. Then who can say that the most prolific queens are the most profitable?

Greiner Bros., in the BEE JOURNAL of Sept. 21, seem to have the idea that “I think that a common hive is better than a frame hive.” If they have followed me in all I have said, they will recollect that I said that it was not the hive that made the quality of the

bee. I spoke of dividing, as practiced by almost every one; it is only the few that give the divided part a queen or cell. I would like to see all of our friends rear such perfect, hardy bees, that they would all winter without loss, no matter how they were kept, only seeing that they had plenty of good stores. I would not call any system "safe and harmless" that cost me nearly one-half my bees.

Damage Done by Skunks to Bees.

N. LEVERING.

Aside from bruin, there is no animal so detrimental to an apiary as that highly perfumed creature wearing the euphonious name of "skunk." Many apiarists are not aware of the extent of damage done their bees at this season of the year by these pestiferous creatures, who hang about the apiary like hungry office-seekers about the public crib and with as great yearning for its contents.

The evidence of their nocturnal visits are very discernible about the hive—marks of their claws about the entrance and the earth pawed out in front, and not unfrequently effecting a passage under the hive and tipping it over upon its side—their object being that of bees and honey. The ingenuity displayed by these sagacious animals is somewhat amusing. They scratch upon the front of the hive or knock at the door, as much as to say, are you at home? The bees hearing the alarm rush out to ascertain the cause, when his skunkship receives them on his bushy tail, which, when well filled, he slashes about in the dirt for the purpose of disabling the little defenders, and when he accomplishes this he turns and devours them, when another and like experiment is made, and thus by repeated tail manipulations the colony is soon reduced in number until it becomes an easy prey to the bee moth or dies for want of sufficient numbers to keep up the requisite heat in the hive.

A friend recently informed me that on visiting his apiary, he found several hives tipped over on the sides, and some of the frames containing honey drawn out and the honey devoured, which was evidently the work of his skunkship's undermining operations.

I am often asked, "What is the remedy?" I know of nothing better than to kill the skunk—to wage a war of extermination upon the invaders with a little "cold pizen," which may be administered in small pieces of fresh meat placed near the entrance of the hives, especially those bearing the evidence of their depredations.

At this season of the year bees are often weak in stores, especially so this season, and when weakened in numbers, will soon pass in their checks.

Los Angeles County Convention.

The Los Angeles County, Cal., Bee-keepers' Association held their regular monthly meeting at the office of C. N. Wilson, Los Angeles, on Dec. 17, 1881.

The President appointed F. E. L. Marsh, Secretary *pro tem*.

The minutes of the last meeting were read and approved.

The committee to take measures to organize a State society reported progress, and further time was given to report on constitution and by-laws for the State Association.

On motion, Mr. D. S. Given, of Illinois, inventor of the Given foundation press, and Mr. J. McIntyre, of Canada, were elected honorary members of the Los Angeles County Bee-keepers' Association. The above-named gentlemen being present, stated that they were both here looking for suitable places to go into the bee business.

C. N. Wilson was re-elected President, Robert Hall and Jesse Sutton Vice-Presidents, F. E. L. Marsh, Secretary, and J. E. Pleasants, Treasurer.

On motion, the committee on State association was increased to seven, and the President appointed Wm. Rathmussen, D. S. Given, J. H. Book additional members of said committee.

The question of bees destroying fruit was discussed at some length, and the subject of disease amongst bees, its cause and cure, was considered by F. E. Marsh and J. W. Wilson.

Adjourned to meet at the same place on January 21, 1882.

F. E. L. MARSH, Sec.

From Colorado Farmer.

Colorado State Convention.

Colorado is fast taking rank with the older States of the Union in the matter of bee culture, and before another decade there is no doubt of the fact that this will be the most important industry in the State.

This is especially gratifying, the more so because of the fact that it has only been a few years since there was no bee culture of any consequence in the borders of the State. To have accomplished the results as at present existing, in so short a space of time, is a magnificent tribute to the energy and progressive spirit of the people of Colorado. Bee culture is fast becoming recognized as an important factor in the commerce of the country, and if properly fostered and encouraged in the West, will soon grow to large proportions. Heretofore there has been no organized effort to promote the interests of bee culture in Colorado, and this fact has tended to retard its growth and expansion. In spite of this drawback, however, great strides have been made in the way of advancement, but those more directly interested have been seriously considering, for some time past, the organization of a State Society, like those in existence in older States in the East, so that, by concerted action, there might be more rapid advancement and progress. This feeling at last assumed definite shape, which resulted in a call for all those interested in bee culture in Colorado, to meet at Denver on December 15, for the purpose of perfecting a State organization.

Valentine Devinney was chosen as temporary Chairman and Robert L. James as temporary Secretary. The constitution of the National Bee-keepers' Association was adopted to govern the State society. The name, "Colorado Bee-keepers' Association" was adopted.

D. S. Grimes was elected President by acclamation. Mr. Grimes made a brief speech, thanking the Association for the honor conferred upon him. He said that Colorado had long been noted for having the best bread and butter, now the State is to take a forward step and have the best honey.

The following Vice-Presidents were then elected: Arapahoe county—J. L. Peabody; Jefferson county—V. Devinney; Douglas county—G. Stoner. The election of other Vice-Presidents was postponed until the last day of the meeting.

Robert L. James was chosen as Secretary by acclamation.

Mrs. Olive Wright was elected Treasurer by acclamation.

V. Devinney, of Jefferson county, and G. Stoner, of Douglas county, were elected as an Executive committee, which, with the President, Treasurer and Secretary, constitute the full board.

The Secretary was instructed to secure articles of incorporation, under the laws of the State of Colorado.

Met in the evening at 8 o'clock.

A discussion arose about the value of charcoal and sawdust in the hive, and charcoal seemed to be the favor-

ite. A slanted board was recommended to be placed in the bottom of the hive which would enable the bees to work out the dead bees and moths.

The question arose, "was it better to let them swarm, or divide them," and there seemed to be a division of opinion. If a man undertakes to divide, and does not know how, he is likely to lose them. Several instances were related of persons losing bees when they knew nothing of the process of dividing.

Mr. Estlake related how he had cut the wings of the queen to prevent the swarm from leaving, and even then they would go away and leave the queen there.

Louis Broek bought 40 colonies three years ago. He had 68 in the fall and in the spring he had only 2 left. He fed them all summer and mice then destroyed the queen. The 2 mice were found in the hive dead and covered with wax. He let them work along and swarm naturally. He has 6 hives in good condition and took 138 pounds of honey.

It was claimed that honey was the best food. James Haviland recommended corn meal and New Orleans molasses.

Mr. Chilcot has 20 colonies now; had 4 in the fall, and took away about 40 pounds of honey.

D. S. Grimes had 15 colonies last spring, and has taken away about a ton of honey, and now has 33 colonies. He has 1,000 pounds of comb honey in frames that he intends using in the spring. Have 75 acres of sweet clover pasture. He uses the Thomas live. If a colony is weak coming on to the close of the season, destroy the queen and get a good one.

The opinion was approved that there are only certain localities in Colorado adapted to bee culture. Bees will not go more than $1\frac{1}{2}$ miles for pasturage without being tired and worn out. Adjourned.

SECOND DAY'S SESSION.

At 1 p. m., a tempting array of honey, in frames, jars, bottles and table, while specimens of hives and jelly glasses, were spread upon the various tools useful in the apiary were scattered about the apartment. The attendance was as good as that of the first day and a much livelier interest was manifested by those present.

J. L. Peabody spoke on the subject of "artificial swarming," and did not advocate its usage in extensive apiaries where the sole business was honey. He referred to city bee-keeping, and recommended a tight fence, eight feet high, about the hives, as the bees at that height on leaving, would soar away above the neighbors, and so avoid any ground of complaint being made against them. Two colonies of bees during the last season, by increase and product, have netted this gentleman \$100 each, a success which he ascribes to the fact of his care in preventing waste.

Dr. King, of Boulder, gave his experience from one colony as a start, to a collection of about 125 stunds. The doctor advocated wintering bees in the cellar, giving them no exercise

and allowing no ventilation from the top of the hive. He had noticed his Italian bees going 14 miles for pasturage, in following up the blossoming raspberries, which mature more slowly toward the range. Since July 7 one colony had produced 400 pounds, which, with the rest, was wholesaled to Boulder merchants at 25 cents per pound. He bived by means of the queen-cage, letting the swarm go, but holding the queen captive, which always brought them back. Comparing drone and worker comb, the worker whiter and more regular, more salable, but the drone would be preferred on account of its being lighter, by those versed in honey matters, wishing it for their own use. Dr. King recommended the American hive.

John McBroom wintered by banking the hives with dirt, and, contrary to Dr. King, believed in ventilation from the top of the hive—leaving a small space below for the passage of bees. Last winter he saved by this method 64 out of 66 colonies.

Jesse Eastlake spoke of the honey plants, one of which he had with him. Willow, gooseberry, cotton wood, wild cherry, and plum, ashberry, and strawberry plants, are all utilized either for honey or pollen. Wheat blooms are used in season, and clover of different kinds with milkweed, are visited by little workers with excellent results.

H. M. Richards, of Arvada, had obtained his start from one colony given him by a disgusted neighbor in 1877, and now had over 100. He exhibited some fine honey of different kinds made by bees from milkweed, being pure white throughout.

After one or two more short addresses the association, by its President, Mr. Grimes, was invited to meet jointly with the Horticultural Society, on the second Tuesday in January, and it was so decided. The annual meetings of the association will be held the second Tuesday in December next.

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.
G. W. DEMAREE, Sec.
Christiansburg, Ky.

The Northeastern Ohio and Northwestern Pennsylvania Bee-Keepers' Association, will meet at Jamestown, Penn., Feb. 1, 2, 1882.
W. D. HOWELLS, Sec.

The annual meeting of the N. W. Illinois and S. W. Wisconsin Bee-Keepers' Association, will be held in Temperance Hall, Freeport, Stephenson Co., Ill., on Jan. 17 and 18, 1882.
JONATHAN STEWART, Sec.

The Indiana State Bee-Keepers Association is called to meet in annual session, Wednesday and Thursday, Jan. 24 and 25, 1882, in the rooms of the State Board of Agriculture. By order of EXECUTIVE COMMITTEE.

The Northeastern Bee-Keepers' Association will hold their twelfth annual convention in the Common Council Halls, at Utica, N. Y., on the 25th, 26th, and 27th days of January, 1882. The executive committee are determined to maintain the high standing and enviable reputation the association has justly gained in the past, and propose to outdo all former efforts on this occasion. From present indications the coming convention promises to be the largest and most interesting ever held in America. New features will be introduced, and business of vital importance will be brought before the convention that makes it the duty of every member and bee-keeper to attend. Essays and addresses are expected from Capt. J. E. Hetherington, W. L. Tennant, L. C. Root, James Heddon, Chas. Dadant, T. G. Newman, N. N. Betsinger, Dr. A. H. Marks, and others of America's renowned apiarists, on the most interesting topics of the day. If you wish to enjoy the benefits to be derived from the good work already in progress by this association, you will surely attend. All are invited; none can afford to remain at home. Articles and implements of the apiary for exhibition, etc., should be sent to the Secretary, at Utica, N. Y., who will take personal charge of the same and arrange all articles so as to compare favorably with others on exhibition.

DR. A. H. MARKS, Pres.

GEO. W. HOUSE, Sec.

The Nebraska State Bee-Keepers' Association will hold its annual meeting in Ashland, Neb., on the 12th and 13th of January, 1882. A cordial invitation is extended to all who are interested in bee-culture. Members will be returned to their homes by the railroad companies at 1 cent per mile.
T. L. VONDORN, Pres., Omaha.

G. M. HAWLEY, Sec., Lincoln.

The Texas State Bee-Keepers' Convention will be held at McKinney, Texas, on Tuesday, April 25, 1882.

CLUBBING LIST FOR 1882.

We supply the Weekly *American Bee Journal* and any of the following periodicals, for 1882 at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

	Regular Price	Club Price
The Weekly Bee Journal (T. G. Newman)	\$2 00	..
and Cleanings in Bee-Culture (A. J. Root)	3 00	.. 2 75
Bee-Keepers' Magazine (A. J. King)	3 00	.. 2 60
Bee-Keepers' Instructor (W. Thomas)	2 50	.. 2 35
The 4 above-named papers	4 50	.. 4 00
Bee-Keepers' Exchange (Houck & Peet)	3 00	.. 2 80
Bee-Keepers' Guide (A. G. Hill)	2 50	.. 2 35
Kansas Bee-Keeper	2 60	.. 2 40
The 7 above-named papers	6 50	.. 5 50
Prof. Cook's Manual (bound in cloth)	3 25	.. 3 00
Bees and Honey, (T. G. Newman)	2 40	.. 2 25
Binder for Weekly, 1881	2 85	.. 2 75
Binder for Weekly for 1882	2 75	.. 2 50

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

**SELECTIONS FROM
OUR LETTER BOX**

Questions.—Last season was so wet and cold the flowers did not yield any honey; at any rate they did not get but very little honey. I am wintering 80 colonies. I am going to move my bees (most of them) further out in the country, about 30 miles. Is it best to take them on snow? Will the disturbance be any injury to them? There is no way to take them but on wagon or sled; the road is so rough that I do not think it possible to take them on wagon in warm weather (unless in an express wagon). What time is best, the first of the winter or toward spring? I intend making bee-culture my business, and am giving my whole attention to it, therefore I need your highly esteemed JOURNAL.

A. L. ETHERINGTON.

Milton, Nova Scotia, Dec. 29, 1881.

[We cannot advise the removal of bees in any manner, during a season when they cannot have a good flight immediately afterward, and would sooner run the risk of breaking down combs, in early spring, over rough roads, than the risk of disturbance in winter. It *might* be safe to move them on the snow, but all the chances are against it.—Ed.]

Packed in Sawdust.—I have 40 colonies of bees packed in sawdust. I have always packed them so, with success. In the winter of 1880-81, I lost 2 out of 53 colonies. I keep them because I like to work with them. I have the American hive, or rather the Hill hive.

S. B. BRILLHART.

Kendallville, Ind., Jan. 6, 1882.

Poor Summer for Bees.—I started last spring with 16 weak colonies. We had 10 days honey harvest early in July. I obtained 500 lbs. of honey from alsike and sweet clover. I had to feed for winter. I increased to 31—doubled back to 17, and fed coffee A sugar; I think it the best for bees to winter on. I have wintered on it and foundation; no other comb and no pollen. The bees bred in the fall and early in spring when they could get no pollen at all, and did well. I sold all my honey at 25 cts. per lb. at wholesale and retail. I do not see why extracted honey should be classed with glucose and rag-syrup, and sold at from 7 to 10 cts. I have no trouble in getting 25 cts. for my honey, all extracted. I now winter out-of-doors in double-walled hive, with air-space all around and underneath.

H. RICHEY.

Sing Sing, N. Y., Jan. 3, 1882.

Has Taken a Notion to Bees.—I am old, have the rheumatism, and have taken a notion to bees, but have not succeeded very well. I lost 23 colonies out of 30 last winter. I take 2

other papers, and when I get my mail, I read the BEE JOURNAL first. I would rather miss my supper than to miss a copy of the BEE JOURNAL.

M. WHEELER.

Colesburg, Iowa, Jan. 6, 1882.

Bees and Grapes.—A neighbor called on me in the spring, and saw my hives (the Langstroth), and concluded he had begun wrong. He asked me to call and see his bees, to transfer them. On seeing his arrangements, I left, after giving such advice as I thought necessary and I think it was appreciated. Later in the season, when bees were working on grapes and golden rod, I took an empty hive to transfer the bees into, and found the party had brimstoned his bees, as "they had spoiled his grapes." I examined the grapes and tried to convince him that the yellow-jackets and quail had been there first, assisted by the linnets and wild canaries, as they are called, but he had his mind made up. I thought, before I left him, that he felt a little sore, but wouldn't acknowledge, as some body's bees visited the grapes occasionally. I have often watched to see my bees, spoiling my fruit, but have never succeeded; but in grape picking time in filling the boxes a great many get more or less broken, and one can see the difference at once. We put 50 and 60 lbs. in a box, and a ton or more in at a load, before loading they stand at the end of the rows 4 or 5 high, and thus many get broken. You can then see thousands at work sipping the juices that would run to waste. I have distributed the copies you sent, where I think you may receive a benefit in time. I have more or less callers all the time, and always try to keep the BEE JOURNAL and Cook's Manual to the front.

J. D. ENAS.

Napa, Cal., Dec. 25, 1881.

Remedy for Ants.—In the BEE JOURNAL for Oct. 5, J. L. Wolcott says he has used fine salt as a remedy for ants, for 20 years. Will he please tell us how he uses it?

JOSEPH BEATH.

Corning, Iowa, Jan. 1, 1882.

My Report.—I would not be without the JOURNAL for much more than its cost. I could not send my report in time for your table, as our harvest did not end till October. I commenced with 17 colonies and increased to 34. I obtained 800 lbs. of surplus honey (one-half being comb), and sold it at from 15 to 20 cts. per lb. The past season's crop was short in this locality.

R. C. AIKIN.

Shamburgh, Iowa, Jan. 5, 1882.

Will Try Again.—In the winter of 1879-80, I lost 126 colonies of bees out of 144, by dysentery. In the winter of 1880-81, I had 81 colonies on summer stands, with a box outside filled in with chaff all around. Last spring I had 12 colonies left; I increased to 24 by natural swarming. Last summer was a poor season for honey; we had no rain for 4 months, and in the fall

every flower was burnt up. My hives are the Langstroth, except one, which is a box hive and has stood the test for 9 years. If I could winter safely I should be satisfied. I shall try again.

JOSEPH LEE.

Farmers, Mich., Jan. 3, 1882.

Cold Spell.—We have a cold spell. For two mornings it has been 2 degrees below zero—and this is one of them. Bees in this locality seem essentially right, so far.

T. F. BINGHAM.

Abronia, Mich., Jan. 5, 1882.

Favorable Winter.—So far, the winter has been very favorable for bees in our section. T. L. VON DORN.

Omaha, Neb., Jan. 4, 1882.

Worth \$5.00.—I would not miss a number of the BEE JOURNAL for a year's subscription. It has been more than \$5.00 benefit to me during the past year. As long as I keep bees I want the BEE JOURNAL.

E. HUTCHINSON.

East Avon, N. Y., Dec. 29, 1881.

A Good Showing.—Bees are rather scarce here yet, on account of the severe winter and great loss last year. Many lost their entire stock. I, however, managed to get through with 15 colonies (in a reduced and feeble condition) out of 67 that I had in the fall. My account stands thus at present. My financial showing is, as I think, somewhat encouraging. I sold 856 lbs. of honey (397½ extracted and 458½ in section boxes), for which I received \$200.79; sold 1 colony during the early part of the season for \$15.00; received premiums on honey at our State Fair, \$12.00, and at County Fair, \$6.00.

Total cash received.....	\$233.79
Increase of 42 new colonies by artificial swarming at \$10.00 each.....	420 00

Entire gain..... \$653.79

Divide this by 15, the number of colonies in the spring and we have \$43.50 per colony; or, if we say nothing of increase, premiums, etc., and take the cash received for honey only, we have \$13.38 per colony. In the above account I have not counted my own time, as I consider this a pleasant pastime. My extracted honey was put up in neat tin-topped tumblers, and my comb honey in neat 1½ lb. dove-tailed sections, without glass. My honey averaged a little over 23 cts. per lb. The past season has been the best that I have seen for many years; the yield was principally from white clover.

H. BESSE.

Delaware, O., Dec. 29, 1881.

Thymy.—Please explain the word "thymy" which is used on page 25 of Bee-Culture, written by the editor of the BEE JOURNAL. J. S. DUNCAN.

Browning, Mo., Jan. 1, 1882.

[Webster defines it thus: "abounding with thyme; fragrant." We used it in the latter sense.—Ed.]

Questions.—Last spring I kept my queens laying very profusely by feeding cheap syrup. This fall, as soon as the honey flow began to shrink, I fed double the amount of pure heartsease honey. About Oct. 5, they stopped laying. Why did they not keep on laying? Will cutting out drone-comb discourage bees? How far will a queen go from her hive to find a mate? Why do queens not lay in the second story of a hive as readily as in the first story? How can two strains of bees be kept pure in the same apiary.

M. L. TRESTER.

[They stopped breeding because of the cold nights; and the impossibility of properly caring for the young. Bees will not become discouraged from cutting out drone comb, if honey is coming in good with which to patch up, or if good worker combs or foundation be furnished to replace the drone comb. Queens are supposed to go a distance of $1\frac{1}{2}$ to 2 miles, if necessary. Queens, as a rule, accept the lower story as a home, because they are nearer the bulk of the brood-nest, and pollen and honey are first stored there. Two strains cannot well be kept pure in the same yard, with queen-breeding going on in both strains.]

Remedy for Whooping Cough, Colds, etc.—The following is one which I consider unsurpassed: Mix of good whisky, 1 pt., pure extracted honey, 1 pt., and 2 tablespoonfuls of pine tar. Dose for children, from 15 to 20 drops and increase. For adults, teaspoonful—given when the cough is troublesome, 3 to 10 times a day.

This is a lovely day. The thermometer indicated 62 F. in a cool, shady place at 3 o'clock p. m. Bees are actually gathering honey from a small patch of mammoth mignonette. Queens are laying as if spring was near at hand. I never saw a better prospect for a large increase, 3 months hence. Our queens stopped laying last year about Nov. 5, and began Jan. 15; but this is a year when you may record bees laying uninterruptedly, for a whole year—a thing I have never seen before in Texas. Our prospects for a wheat crop is good; oats, rye and barley all look well. One more week and then comes the busy season with us—oats to sow, and corn-land to prepare.

B. F. CARROLL.

Dresden, Tex., Dec. 25, 1881.

A Beginner.—I kept bees for 6 years on the old plan, till 1881. In the fall of 1880, I had 11 colonies of black bees on the summer stands, and in the spring of 1881 they all died except 1 queen and 72 bees. I had no honey but what we used in the house. Last spring I bought 3 colonies (2 Italians and 1 black), caught one wild hybrid swarm, and I paid \$5 for learning to handle bees, and never was sorry for it. This fall I put 19 colonies in winter quarters in good condition. Suc-

cess to the BEE JOURNAL. 1. What seed will be best to sow with sweet clover? Will white clover do? 2. Where can I get Simpson honey plant seed? Answer through the BEE JOURNAL. J. C. MISLER. Ligonier, Ind., Jan 1, 1882.

[Yes, white clover will do to plant with sweet clover; but, if sown in the fall, wheat is the best, or as good as anything to mix with it; if in the spring, oats or anything of a summer crop will answer. 2. We do not know just at present, but presume dealers having it for sale will advertise the fact in the BEE JOURNAL, long before planting time arrives.—ED.]

Repairing Losses.—The spring of 1881 found me, like many others, with few bees, and as I wished to build up again, I bought 5 colonies of Geo. Grimm, for \$30.00. The express charges, caps and sugar for feeding cost \$10 more, making \$40 in all. These gave me 8 swarms and 517 lbs. of comb honey, which I sold at 15 cents per lb.—\$76.55; the 8 swarms are worth \$36. After deducting the cost of the 5 colonies, I have \$72.55 for my labor. E. PICKUP. Limerick, Ill.

Linseed Oil as a Medicine.—Mr. Twitchel's caution in regard to the use of linseed oil as a medicine, on page 12 of the last number of the JOURNAL, I think hardly necessary, since the druggist would be hard to find who would sell "boiled" linseed oil for that purpose, and few would go to the paint-shop for it. The article used as a medicine and kept in stock by druggists, is *cold-pressed*, and often prescribed by physicians, on account of the mucilage it contains, instead of castor oil. G. L. TINKER. New Philadelphia, O., Jan. 7, 1882.

Bees Doing Well.—My bees are all in good condition now. They have had a flight about once a week all winter. I owe my success to the BEE JOURNAL. Long may it live and continue as good as it has been in the last year. S. C. SMITH. Wheeler's Grove, Iowa, Jan. 3, 1882.

Preparing Bees for Winter.—I am 64 years old, but not too old to enjoy the company of my blessed bees. I bought two colonies last May, and increased to eight, (4 natural swarms and two nuclei,) but got no surplus honey. White clover was almost a total failure. June was wet and cold and bees hardly gathered enough to live on, until the golden rod, of which there is two varieties here, and asters, several kinds also blossomed, and then my bees gathered their winter stores. Had there not been a large flow of honey from these, they would not have had enough to winter on. I built a small house 19x6 feet, one roof, double boarded and packed with saw-dust on the North side and ends, with double door and double floor, and two thickness of paper between floor,

all shingled, except about 20 inches in width on the South side, which is of matched boards in two sections the length of the building, made so as to open at any time the weather may be warm enough to give them a flight, or to warm them up if desired. My plan of preparing them is to tack a piece of coffee-sacking over the frames after I have placed two or more $\frac{3}{4}$ by $\frac{5}{8}$ inch strips of boards across the frames. I then put quite a thick quilt; on the top of that I put two dry blocks, resting on the cross-pieces and put on the cap. I cover them up with old quilts, carpets, etc. I have two small ventilators in the roof; a two-inch pipe near the ends of the building. O. B. SCOFIELD. York, Maine, Dec. 19, 1881.

A Good Honey Crop.—I wintered all my bees without loss, and they came out very strong in the spring, and the yield of honey was as large as we ever had—from 100 to 150 lbs. to the colony, besides a fine increase of stock. Success to the BEE JOURNAL.

Sunbury, Pa. MARTIN KINNEY.

Production and Sale of Honey.—I began the last season with 15 colonies which had survived the fearful winter, but they were by no means strong. Most of them were the dark Italians. Not having enough to occupy my time, I prepared my hives and went to work on my farm. When a swarm issued, my wife hived them if I was not at home. On April 17, they began to bring in pollen; the weather at once became warm and balmy. The last half of April and all of May, the weather was warm and clear; there was hardly a day that the bees could not fly. The spring bloom was in abundance; the later part of May they began to swarm. My best colonies swarmed 3 times in 10 days, for which I refused to take \$25.00 as soon as hived. By the last of June I had 32 colonies; I sold one, and 2 left for parts unknown. I returned 10 of them to the parent colonies, after taking away the queens. I took 850 lbs. of comb honey. This was a small yield. I can sell all my honey at my door at 20 cts. per lb. We have an abundance of soft maples and willows, which gives our bees early pollen. The soil is very rich, and we have an abundance of linden, some trees growing 3 feet in diameter. A good colony will store 100 lbs. in 10 days. I have sown since last March, alsike clover, sweet clover, motherwort, catnip and Rocky Mountain bee plant. It is to the interest of every one to plant and sow as much as possible for the bees.

H. CLARK.

Palmyra, Iowa, Dec. 26, 1881.

Queen Excluders.—Prof. Cook, in his address before the Michigan Convention, refers to a plan mentioned by Mr. Jones at the National Convention, "of preventing flight of queens and drones by means of perforated zinc over the entrance of the hive." Please give the plan more fully. H. Z. S.

[It is described in the JOURNAL for March 30, 1881, page 98.—ED.]

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII. Chicago, Ill., January 18, 1882. No. 3.

Published every Wednesday by
THOMAS C. NEWMAN,
 EDITOR AND PROPRIETOR.
 974 WEST MADISON ST., CHICAGO, ILL.
 At \$2.00 a Year, in Advance.

Remit by money-order, or by letter, express or bank draft on Chicago, or New York, payable to our order. Such orders cost 2 cents for collection on local banks.

Free of postage in the United States or Canada. Postage to Europe 50 cents extra.

Entered at Chicago post office as second-class matter.

Glucose Manufacturers in Conclave.

Pursuant to a call for that purpose, the glucose manufacturers of the United States met at the Grand Pacific Hotel, in Chicago, on the 10th inst, for the purpose of devising means for self-protection by the organization of a National Association. Referring to the second day's proceedings, the Chicago Tribune of Jan. 12th says:

The glucose manufacturers continued their sessions at the Grand Pacific yesterday with closed doors. The meeting decided to refuse the publication of the names of those present. There were fifteen factories represented, which embraces all but two of those in the country. An organization was formed, to be styled the "National Glucose and Grape-Sugar Association." Officers were elected as follows: President, J. A. Cunningham, of Danville, Ill.; Vice President, J. Firmenich, of Buffalo, N. Y.; Secretary and Treasurer, J. M. Jones, of Leavenworth, Kan.; Executive Committee, P. B. Veiller, of Chicago; W. P. Coast, of Iowa City, Iowa, and A. Woolner, of Peoria, Ill. The meeting adjourned subject to call. The Executive Committee will meet to-day to deliberate on the future action of the association.

We expect next to hear of the but-terine, suine, oleomargarine and slush-ine manufacturers forming a National Association for the purpose of protecting themselves against honest dealers who refuse to handle their stuff under any other than its proper name. Recently, at a meeting of the Chicago Retail Grocers' Association, we have been told, a resolution was proposed and adopted by a large majority, not to handle any of the above stuff in any manner whatever, and we think the time is approaching when glucose will be equally as abhorrent.

A Kind Suggestion.

We are always pleased to receive suggestions or criticisms concerning the BEE JOURNAL, and hence give place to the following:

I like the new size of the BEE JOURNAL much better than the old, but do not like the advertisements on the first page. We have become accustomed to look on the first page for the valuable editorials, and think the BEE JOURNAL would look much neater with all the advertisements at the back. We only suggest the change as an improvement—not as a complaint. Bees are wintering well, and have used but little honey.

Fairland, Ind. L. R. JACKSON.

The reason for devoting the two first and last pages to advertisements, was to form a cover to keep the reading matter from being soiled, and preserved for binding; this was suggested by several of our correspondents, but, as we much prefer to commence the editorial matter on the first page, we will do so hereafter, and place all advertisements at the end. Those who want to preserve them for binding, should either have a Binder and place them in it as fast as received, or else carefully put them away out of the dirt and dust, after reading, until the volume is complete, for binding.

A correspondent in Canada wants us to say in the BEE JOURNAL whether the Apiary Register Book can be sent to Canada by mail, and without "duty." It can; it is a "book," and such go to Canada from the United States free of duty, and, as we prepay the postage, there is nothing extra for Canadians to pay more than for those living in the States.

By an oversight of a clerk in the paper warehouse, one of the bundles of paper that was sent to the printer was much thinner than the rest, and it was used before we knew it. We have scolded them and hope it will not occur again.

Prohibiting Importations of Queens.

Our attention has been drawn to the following paragraph, published in a late number of the Detroit (Mich.) *Evening News*:

The suggestion of a Michigan bee-keeper, that Gov. Jerome take action to prevent the Canadians from flooding our "infant industry" with queen bees produced by the pauper labor of Palestine, Java, Ceylon and elsewhere, is timely and appropriate. These foreign insects may be superior to ours, and may result in the production of more and better honey at less cost, but that argument would hold quite as well in the case of foreign iron and steel and cotton and woolen goods. It is not more or better honey that our American industries are after; what they want is more work, and from all accounts the native American queen bees will give the drones ten times more labor than the foreign ones.

We think it hardly possible that, among all the bee-keepers in the State of Michigan, one can be found thoughtless enough to give utterance to a sentiment so illiberal as that attributed to them above; and had one done so, even in a jocular manner, we wonder that the *News* should seize upon it as a text for a ludicrous burlesque. There are so many incongruities in the article, short as it is, that no intelligent bee-keeper can be persuaded to view it in any light but that of badinage, though stamped with the impress of serious argument. Let us candidly consider the inconsistencies in the article quoted:

1st. There is not a bee-keeper, in the State of Michigan, so stupid as not to know that Gov. Jerome can take no action to prevent the importation of queen bees, or any other stock, from Canada, or anywhere else, which is intended as an improvement upon our present stock. This is regulated by the general government.

2d. Bee-keeping is not an "infant industry," but is coeval with history itself. It is only its scientific management which is comparatively young; but it is developing with astonishing rapidity.

3d. Canadians have had no queen bees produced in Java or Ceylon with which to flood our country, and the imported Palestine queens they have sent us, were produced by an American citizen in Cyprus, and who, we believe, still holds his residence and right of suffrage in the State of Michigan.

4th. It is not yet a settled point that these "foreign insects" are superior to ours, except as bred upon or from

our stock. There is no analogy between them and "foreign iron and steel, and cotton and woolen goods." Instead of being imported to enter into competition with American products, the reverse is the case; they are desired for the purpose of stimulating a fixed occupation, and giving remunerative employment to thousands of our citizens who are now scarcely self-supporting, besides developing a source of national wealth and foreign traffic now comparatively neglected, and only awaiting intelligent and improved application, with the best facilities to accomplish it.

5th. It is "more and better honey that our American industries are after." In order to obtain the best bees to secure these results, enterprising Americans have chilled in the bleak winds of Russia, thirsted on the burning sands of Arabia, smoked the friendly pipe in Germany, bearded the lion in the jungle of India, endured malaria on the Nile, climbed the walls of China, scaled the rugged mountains of Caucasus, scorched under the Cyprian sun, dreamed 'neath the sunny skies of Italy, ascended the steppes of South America, and waded the swamps of Africa. No climate has been too distant, and no obstacle too difficult, to discourage the American in his efforts to secure bees that would gather "more and better honey." At the present time, thousands of our countrymen are cultivating the soil to insure a certainty of "more and better honey," and the science of botany has been made to contribute of its lore to assist the apiarist in his purpose.

6th. As drones are not supposed to be laborers, we cannot imagine how the "native American queen bees will give the drones ten times more labor than the foreign ones." This is doubtless a joke, or sarcasm, on the poor drones.

All in all, the article quoted above is too illiberal and selfish to be regarded in any light but that of a joke, and with such a spirit prevailing, our boasted progression in bee-keeping, or any other science, would soon retrograde, and but a few decades would be required to return us to the foggy styles and superstitious notions of a century ago, and perhaps return us to a level with the barbaric ages, for we could adopt no improvements, for fear of patronizing the "pauper labor" of some country whose civilization ante-dates our own by thousands of years.

Honey Shows at Fairs.

The time is now at hand when the Vice Presidents of the National Society, for the various States, should use all their influence to get a good List of Premiums offered by the Managers of Fairs, for Bees, Honey, Wax, etc., and we hope they will each one see to it, that no stone is left unturned which may prove advantageous to the general good of the bee-keepers and honey producers of America.

Dr. W. W. Hipolite, Vice President for Arkansas, is already at work with the managers of the Arkansas State Fair, and has drawn up the following list of Premiums:

1. Best package of comb honey in the most marketable shape, 5 pounds or more.
2. Best crate of comb honey in the best shipping and most marketable shape, 20 pounds or more.
3. Best package of extracted honey in the most marketable shape, one pound or more.
4. Largest and best display of honey, both comb and extracted, in the most marketable shape.
5. Best display of honey, both comb and extracted, in the most marketable shape, by a lady.
6. Best colony of black bees, in movable-comb hive.
7. Best colony of Italian bees, in movable-comb hive.
8. Best Italian queen bee.
9. Best display of beeswax, 3 pounds or more.
10. Best machine for extracting honey.
11. Best wax extractor.
12. Best bee-hive for all purposes.

Exhibitors must satisfy the superintendent that the honey entered for these premiums is the product of his or her apiary, or of one under their control.

Dr. Hipolite, in his letter to the Managers of the State Fair Association, with his suggestions concerning the "honey department" makes the following remarks, as we see by the *Arkansas State Gazette*:

I would further suggest that larger premiums should be offered for the products of the apiary, to secure a larger display of these products from different portions of the State. The State fair is a great educator of the people, and bee-keeping is an industry which should be developed as one of the industries of our State; for the honey crop may be made an important item of material wealth to the State. In other States the production of honey has assumed large proportions, and there is no good reason why it should not with us. On the first day of March, 1881, the assessor of Los Angeles county, California, reported 16,613 colonies of bees for that county, and the same county shipped, in a single season, 1,500,000 pounds of honey, while in Arkansas, with honey

resources nearly if not quite as great, less honey is produced than is consumed. Merchants in Little Rock will tell you that while their customers prefer the honey produced here, even at a higher price, the supply is not equal to the demand, and they sell California honey over their counters.

There is a ready foreign demand for every pound of pure honey this country has to spare. A commercial exchange says that "The American honey trade with Great Britain is growing rapidly. A recent English order calls for 58,000 one-pound cans of pure extracted honey." The same is true of other nations; even Japan is now buying largely of American honey. This country takes the lead of all others in the production of this commodity. In other States, with natural advantages inferior to our own, there are men who produce honey by the tons, and if we would but turn our attention to it, we could produce tons where we now produce pounds. The State Fair Association could do much to encourage the development of this industry in our State by the offer of liberal premiums on the products of the apiary.

The labors of Dr. Hipolite have been rewarded. It was but a few years ago that no notice whatever was taken of bees and honey in the Premium List of the State Fair; but now they are assigned a place as a separate class, with a Superintendent, and liberal premiums are offered, and through his exertions, we have no doubt, it will increase and grow in importance yearly.

We have no authority to call upon the Vice Presidents everywhere to act—but in the interest of the pursuit of bee-keeping we would urge them to attend to the matter without another week's delay—"for the time is at hand."

Approbation.—Mr. James Heddon, Dowagiac, Mich., writes as follows:

"The Weekly in its present form is just what we need, and no one will ever drop it for any other paper. The Weekly was a long-felt want, and the form it now is in is A No. 1. I think I am as free to tell you what I do not like, so that gives the above its deserved weight."

Like all who have expressed their opinion of the present form, we much prefer it—but, as the Weekly for last year was an experiment, we were obliged to take the most economical form. The change for this year adds a thousand dollars a year to the expense account. An item we now feel warranted in assuming on account of our large increase of subscribers for 1882. The Weekly is no longer an experiment, it is a fixed fact.

Sundry Questions and Answers.

Comb Foundation.—I intend going to Florida soon to engage in bee-keeping, and find I can buy my bees (if I am on hand when they swarm) for \$1 per swarm. It would be my intention to build them up rapidly by the use of comb foundation in movable frames, but there are still some points which books throw no light upon, such as: 1. Should foundation be full size of the frames? 2. Will such a method yield any returns the first season? 3. Would it be more profitable to buy the old colony, hive and combs for \$5? Boston, Mass. GEO. E. DUPEE.

1. Much depends on the make and weight of the foundation. With Dunham foundation, about 5 feet to the pound, the most satisfaction and the greatest profit will be derived from using full frames—that is, so the foundation will hang about $\frac{1}{2}$ or $\frac{3}{4}$ of an inch from the bottom-bar, and within $\frac{3}{8}$ of an inch from the end-bars.

2. Yes; quite as satisfactory as the parent colony, if the swarm be a strong one, and foundation is used in all the frames.

3. If the colonies and combs you buy for \$5 each are in box hives, it would be much cheaper to buy the first swarms and foundation. Let us figure it up (taking two as the basis, for you would probably buy your box hive before a swarm had issued): 2 first swarms, \$2; 4 lbs. (20 sheets) foundation and freight, \$1.88; 2 hives, \$2—total, \$5.88; against, 1 box hive and contents, \$5; 2 new hives, \$2; labor in transferring, \$1—total, \$8; making a difference of \$2.12 in favor of first swarms and foundation, and straight new combs.

Florida as a Bee State.—I would like to know something about Florida for the bee business. 1. Is it a good country for honey, and is the honey of good quality? 2. What are the principal honey plants of that State? 3. What part of the State is the best for honey? Please answer these questions in the Semi-Monthly BEE JOURNAL. The winter here has been very mild; I think the bees will winter well. The honey crop has been light for the last two years, I hope the coming season will make up for lost time. I have 28 colonies, all packed in chaff, and they are doing well. I wish the BEE JOURNAL a happy and prosperous New Year. B. M. LINGLE. Paoli, Ill., Jan. 7, 1882.

We cannot answer your questions with the precision and accuracy they deserve, but presume if you will address a letter to Mr. W. S. Hart, New Smyrna, Fla., who is Vice President for that State of the North American Bee-Keepers' Society, or to Messrs.

Alderman & Roberts, Wewahitchka, Fla., enclosing stamps for reply, they will take pleasure in giving you full and reliable information upon everything pertaining to the industry. They are all practical men.

Basswood and Sweet Clover.—Where can I get about 100 basswood trees two years old? What method shall I pursue to get basswood seed to grow? I want to put out a nursery. How old must the trees be before blooming? Where can I get sweet clover seed, and what is the price? I have 60 colonies of bees. My yield was light last year; but they paid expenses. My bees are in good condition up to this time. THOMAS PRATT.

Carlisle, Iowa, Jan. 6, 1882.

You can obtain young basswood trees from nearly all nurserymen, and they will bloom when six to eight years old. The seeds should be sown in drills, as are plums, cherries, etc., and carefully cultivated till about one year old, then transplant; it will be well to partially shade them the first summer after transplanting. Select soil, if possible, in proximity to water-courses, bottom-lands, or on gravelly soils in which water lies near the surface through the hot months of summer. As it makes a rich, luxuriant shade tree, it is a great favorite in all our northern cities in the parks and along the avenues. Sweet clover seed can be bought from most dealers in apiarian supplies, at about 30 cents per pound. See our advertising columns.

Winter Feeding.—I must have the BEE JOURNAL. I cannot afford to lose a number; it is too precious. I commenced the season with 3 colonies, increased to 9 by natural swarming, and took 268 lbs. comb honey in 2 lb. sections. I fear some have not stores enough below for winter use. 1. At how low a temperature will it do to open a hive. 2. At how low a temperature will they take food at the entrance? 3. At this time of the year, is it best to feed at entrance, or under chaff cushion? Bees are flying a little to-day, temperature 52°.

F. S. WILLIAMS.

Jackson, Pa., Dec. 27, 1881.

1. When the bees can fly freely.

2. They will take feed from the entrance, if they are short, whenever they can fly from the entrance with safety.

3. We would prefer to feed under the chaff cushion, as the syrup or candy is kept at a better temperature, and the bees are more comfortably fixed to take it.

Photographs of prominent Apiarists—Langstroth, Dzierzon, and the Baron of Berlepsch.—Price 25 cents each.

SAMPLE PAGES OF THE APIARY REGISTER BOOK.

By particular request of several subscribers we give below the two "Sample" pages of the "Apiary Register," the blanks filled up with imaginary entries, and the Remarks, below, such as would be useful, etc. Of course, it is

FILL UP THE BLANKS IN THIS BOOK.]

COLONY No. 19.				HONEY.		QUEEN		CHARACTERISTICS.					
PRINCIPAL EVENTS IN THE HISTORY OF THIS COLONY.				Pounds of Comb Honey.	Pounds of Extracted.	Bloom from.	From	(Standard, 100 Points.)					
Year.	Month.	Day.					WHEN THE QUEEN WAS HATCHED.	Removed to.	Industry.	Docility.	Hardness.	Prolificness.	Color.
1879	5	6	Bought of John Doe, or Swarmed from No. 8, or Divided from No. 17.	30	64	Sw. clo., Linden, Sp. N.	Year Mth. Day. 1878 7 5	Fertilized by.	70	60	65	70	yel.
1879	6	20	Divided—made colony 30.	48	29	Linden, nig. & alstike.		Size.	90	50	75	95	br't.
1879	10	18	Total honey for 1879.	25	96	W. clo., Linden, sw. clo.	1879 5 20	Strain.					
1880	5	14	Swarmed—new colony 42.					Race.					
1880	6	20	Swarmed—returned the swarm.										
1880	9	16	Total honey for 1880.										
1880	10	4	Swarmed—new colony 84.										
1881	5	4	Gave ripe queen cell from col. 3.										
1881	5	12	Divided—made colony 96.										
1881	6	20	Queen removed for breeding.										
1881	8	2	Introduced Cyp. Q. from R. Roe.										
1881	9	25	Total honey for 1881.										

REMARKS.—1881—Nov. 1, put in cellar; strong in bees; about 25 lbs. honey, mostly tall, two-thirds sealed. 1880, April 5—Took out of cellar; weak; some dysentery. April 25—Dwindled; breeding finely; fed diluted honey. June 1—Fed sugar syrup and honey during May; fruit bloom abundant, but northeast winds and rain. July 1—White clover was a failure, owing to wet weather; sweet clover abundant, colony strong, honey coming in fast. Aug. 1—July was dry and hot; linden yielded well; sweet clover still doing nicely; extracted July 15. Sept. 4—Golden rod is plentiful and yielding well; sweet clover mowed, July 20, is white with bloom and covered with bees; extracted 30 lbs. to give queen room; still storing. Nov. 8—Took off sections Sept. 20, all full; plenty of honey left for winter; strong in bees; put in cellar to-day.

REMARKS.—1881—March 15, put on summer stand; strong and healthy, with considerable brood. April 15—Weather very cold, and the bees have diminished. May 15—Weaker still; weather wet and cold. June 20—Bees becoming very strong; weather hot; white and sweet clovers abundant; honey coming in rapidly. July 10—Droath has set in; bees have abandoned white clover, but very busy on sweet clover, motherwort and man-moth mignonette. Aug. 10—Droath continues; sweet clover in first seeding; that mowed and cropped in July again in bloom. Sept. 20—Bees consuming stores; droath continues; honey coming in from sweet clover and heartsease. Nov. 5—Packed by placing in a box 6 inches larger than the hive, and filling in all around with chaff, on summer stand.

quite impossible to imagine all the contingencies which might arise requiring special mention, and to provide for this we have devoted a liberal portion of each page to remarks, leaving space enough, however, to give a history of the colony for three years. Two pages like the above, facing each other, are devoted to each colony.

AMONG OUR EXCHANGES.

MISCELLANEOUS.

Honey as Food.—The London (England) *Horticultural Journal*, gives the following extract from an address on the above subject, by Mr. T. W. Cowan, F. G. S., of Horsham, at the Brighton Health Congress:

Mr. Cowan said that bees in olden time were extensively cultivated for their honey and wax, and it was remarkable how frequently allusion was made to these products by ancient writers. We read that the land where Abraham dwelt was one "flowing with milk and honey," and that in the Mosaic law there were many statutes regulating the ownership of bees. Solomon recommended the use of honey in the words, "My son, eat honey for it is good." About 600 years B. C., bees seem to have been regularly cultivated, for Solon made a law requiring bee hives to be placed 300 feet apart in cultivated fields. The Persians, Grecians and Romans made use of honey extensively, and it was used for sweetening their beverages. It was mixed with wine, and to this day it is used by the Spaniards in sweetening "Malaga wine." It was used up to the seventeenth century when sugar was introduced, and as the use of this increased, the use of honey decreased. On the continent of Europe, bee-keeping had been carried on more extensively in former times than in England, and for a long time we had been depending on foreign supplies.

In the olden times, when bees were destroyed by brimstone, different ways were adopted for separating the different qualities of honey. The light-colored combs were pressed and strained to get the best quality, and the inferior honey was used to make "pain d'épices," a sort of ginger bread sold in every town in France. Large quantities were imported into this country from Cuba, Chili, and, lately, extracted honey from California. It was not until the formation of the British Bee-Keepers' Association, in 1874, that really much progress was made in developing the honey resources of this country. Bees are no longer destroyed to obtain their honey, but are induced to build straight combs in frames, and these are taken out, and, having the cells uncapped, are placed in an extractor, by which means the honey is obtained in a pure state, and very different to the heterogeneous mass of honey, pollen and crushed brood which was formerly known by the name of honey. He stated that there was great economy in being able to return the combs to be re-filled, inasmuch as it took 20 lbs. of honey to make 1 lb. of comb. He wished it to be understood that bees did not make honey, but that they collected it from the nectaries of

flowers, and that each flower yielded honey of its own peculiar flavor.

The climate of England was particularly suited for the purpose of bee-keeping, and there was no country where it could be produced better in flavor than in this. He said pure honey should be used by every family. It was no longer a luxury only to be enjoyed by few, but was sufficiently cheap to be within the reach of all. It had properties which made it a valuable food. It differed from alcoholic stimulants, which dull the intellect, as it produces a bright intellect. Children were very fond of honey, and one pound of it went further than a pound of butter. It had the peculiarity of keeping good, whilst butter would become rancid, and thus is injurious to health.

Importance of the Pursuit.—The Springfield, Mass., *Republican* gives its views on this subject as follows:

Bee-keeping is an interest of considerable importance. It has an extensive literature of its own and men enter into it with the true enthusiasm of science. At a recent convention of bee-keepers in Chicago, one of these enthusiasts in apiculture gave an interesting sketch of his pursuit in foreign countries of new races of bees. He set up an apiary on the Island of Cyprus to test the merits of the Cyprian bees; he visited Palestine and obtained colonies of Syrian bees, and after a deal of trouble succeeded in transplanting both varieties to this country. It is only within a few years that Italian bees have been introduced here and proved superior to the common black bees. These new races are claimed to be superior to the Italians. The Syrian bees, especially, are remarkable for their superior prolificness, swift flight and the long distances they are able to cover in quest of honey. The study of bees has a fascination for some people and it is often rendered a source of considerable profit. There is quite a library of books attainable on the subject, besides magazines, while at Chicago there is published by Thomas G. Newman a weekly devoted to apiculture called the AMERICAN BEE JOURNAL. This is an exceedingly neat little paper of 16 pages and is a complete cyclopedia of everything relating to bees.

Food Adulteration.—In noticing this book, the *Bee-Keepers' Magazine* remarks as follows:

It shows that much of what we eat and drink is so badly mixed up with foreign matter, that one who is compelled to do much of his eating away from home naturally wishes he had never read this book, for he need not be surprised to find himself imagining dried horse liver in his coffee, iron and indigo in his tea, minute tape worms in his butter (oleomargarine), trichina in his pork, terra-alba, alum, etc., incorporated in the bread, flavored glucose for honey, syrup, etc., etc. The above and hundreds of

other dirty and poisonous substances actually are incorporated into much that we eat and drink, and the adulterators are growing rich at the expense of the public health, and we hope that just such books as this one may be widely circulated, until a public sentiment will be created against those enemies of the human race that will finally crush them out.

Are Eggs Laid in Queen Cells?—Dr. A. B. Mason, in the *Bee-Keepers' Instructor*, remarks as follows:

A writer in the December number of the BEE JOURNAL, under the heading of "Do Queens Lay Eggs in Queen Cells?" in relating some of his experience, says: "I do not dare, at present, directly to advocate what would, from the above, seem to be true, against the theories of experienced apiculturists. But here is my experience for what it is worth, and I confess to some few pinches of doubt about a number of things pertaining to bees, which are pretty generally taken for granted after reading them in a book or paper." The same correspondent refers to an offer of \$50 having been made "to anyone who could prove that the bees ever removed an egg from a worker to a queen cell." It seems to me, from my own and this correspondent's experience, that it would be better to offer the \$50 to any person who would prove that the queen ever laid an egg in the queen cell. The experience that this correspondent gives is worth more than all the "theories of learned and experienced apiculturists." There are good reasons for believing that a queen does not deposit eggs in queen cells; and if I have the inclination in the future, I will ask some of our experienced bee-keepers in "convention assembled," some questions, the answers to which will either overturn some generally accepted theories, or be directly contrary to all experience.

Bee Government in the Hive.—The St. Albans *Messenger*, says, that at the meeting of the Vermont State Board of Agriculture, Mr. O. C. Wait, of Georgia, gave an interesting lecture in which he said:

Though the bee is not made in God's image, yet many of their habits—neatness, industry, economy and government—may profitably be imitated by some men. It has been supposed that their government is an absolute monarchy, but on the contrary, it is a more perfect monarchy than the world has ever seen among men, and the females have their equal share. Mr. Wait here drew an amusing comparison between their government and our own, not only in a political but in a social sense. Every fruit-grower and farmer should keep a few colonies of bees for the more perfect growth of his crops. They carry the pollen from flower to flower, and thus, while gathering honey they spread the seeds of growth and multiply the fruit.

CORRESPONDENCE

For the American Bee Journal.

Reply to Mr. Dadant on Wintering.

JAMES HEDDON.

My experience and observation proves that Mr. Dadant is correct in his judgment that the space above is the incentive which draws the bees to the top of the combs, and to the quilt. I think that I, perhaps, fell into the common error of imagining that Mr. Dadant's fixtures above were similar to my own, the same as he had in conceiving the shape of the space, and size of the same.

I use only 8 Langstroth frames, hence my hive is only 11 $\frac{1}{2}$ inches wide, instead of 14, as Mr. D. figures it. Perhaps, from the little I said in regard to the 2 inch space, on page 275 of BEE JOURNAL, he had a right to suppose that I used a space 2 inches deep all over the entire top of my hive. Such is not the case, as former descriptions of my method will show. I have used 2 bent pieces, thus —, about 6 inches apart in about the center of the hive. You will see that the ends of the bent pieces come down to no space at all, for what keeps them bowing is the fact that they are cut enough longer than the inside measure of the hive to give any bow desired, by slipping the ends inside the side-boards of the hive. You will now see that the ends of the quilt lay upon the frames flat from the ends of the hive toward the center, for about 4 inches, when it begins to rise gradually to the 2 inch height near the center of the hive. The whole space made amounts to about 108 cubic inches of space opened up above the bees, instead of 566 inches, as Mr. D. supposes it to be (and so puts it on page 354 of Weekly BEE JOURNAL).

This season I have used but 1 bent piece, which cuts the space down to about $\frac{1}{3}$ of what I figure and describe above. I did not make the change because I saw anything detrimental about the former space, but because from what I had seen I thought that the space made by one piece would accomplish the object, viz: of making a perfect winter passage cross-wise of the combs, and one stick requires less lumber and manipulation, than two.

I shall never comply with the "instincts" of my bees, where I think my reason is a better guide, nor with the instincts of my cows, horses, sheep, swine, etc. My bees have an instinctive hatred of having their hives opened, but I shall continue to open them whenever my reason dictates so to do. We should follow their instincts only, when our reason fails to grasp the case. I reason that if it is a rule that all bees in box-hives, split open from top to bottom, winter better than those that are tight, and that Mr. Jerome Wiltse, in an extended observation found that bees

that contained a large space above them were almost the only ones that survived, and Mr. Vandervort reports the same thing, that mine will bear a winter passage above the frames, notwithstanding the fact that it is their instinct to glue up every little crevice about the top of the hive, as we are told.

I have never yet been able to demonstrate that any thin, or other quality that the honey might take on, had anything to do with the safe wintering of our bees.

I believe this. The great losses that apiarists suffer, by the death of their colonies, has one common cause, viz: dysentery. I do not believe that thin honey will cause that disease. I know that bees will have it in its most aggravated form when their honey is thick and in perfect condition every way, as far as the eye can detect.

In regard to small colonies, there is little to support a belief that they will not survive any of our severest winters as safely as large ones. It seems to me that it has been amply proven, that cold does not directly damage bees. I can bring more witnesses than you could print the names of in a whole column, to give testimony of the successful wintering of very weak colonies, during cold winters, when many strong ones died (not with cold, but dysentery). There is something about large colonies that seems to engender dysentery, I think because of a higher degree of heat they keep up in the center of the larger cluster, and greater consumption of stores, both tending to the use of pollen.

Some years ago Mr. Hosmer, of Minnesota, adopted and advocated the plan of reducing every colony to only one quart of bees, for winter. That movement, and its discontinuance, simply proves that the catholicion does not rest in the size of the colony.

One spring, after a good snug winter, I was buying some colonies of a farmer, when he pointed to a hive (box) that I had supposed empty, and said "I'll present you with that one," when I turned it up, and found three pieces of comb, all not aggregating three-fourths of a square foot, and thereon about a tea-cup full of bees. This hive had stood out under a "beehed," warmed by its shadow, and above the snow level. I took them home, and let them alone, as an experiment. They survived and made a colony, unaided, except by a little feeding.

I have no evidence that cider, stored in combs, causes dysentery—I don't know. I know that during the fall of 1879 my colonies worked so lively on a large cider mill here that they came near taking possession of it, during the hot weather of October. Though the following winter was very mild, they were confined more than 6 weeks at one time (if I remember right), and yet they had no dysentery. I believe that when the exact cause of the disease is known, it will be seen that it is not cold, acids, nor thin liquids that cause it, but solids, in the shape of pollen.

Because I "lost two-thirds of my colonies," it will not do to say that the

strongest survived, for such was not the case, only the fittest survived; and why the fittest I defy anyone to tell.

I now have just 222 colonies in one apiary, put up in 5 or 6 different ways (some in a cellar), and does anyone suppose that Mr. Dadant or any other man can, by a complete over-hauling, "spot" the ones that the coming winter is going to condemn? I am a "doubting Thomas."

An old ignorant farmer, some 15 miles away, wintered all of his 30 colonies which were almost entirely neglected. Does anyone believe that all his sudden increase, to these 30 colonies, were all strong?

I admit that very frequent and extensive flights completely prevent or cure dysentery in its first symptoms, but I also admit and assert that there are other conditions over which we may hope to get control that also prevent it, though the bees do not see the light for 6 months of the coldest weather. I know of many such cases, and I also know of the disease raging so badly in Kentucky and Missouri, where the flights were frequent, that thousands of colonies succumbed.

As long as we depend upon "flights," whether caused by the rising temperature alone, or that combined with our efforts to arouse our slumberers, in this locality, we shall be at the mercy of the blind forces, as of old. When I said semi-dormant state, I meant that quiet state which they rest in through the winter, even when crossing combs or exercising to keep up the temperature. I might have called it the "quiet state," for no shifts in the hive or degree of cold outside causes the physical and mental excitement, that jarring or opening the hive does.

The main reason why putting bees in the cellar with some accumulation, is bad, is because of the disturbance by the removal.

Mr. Dadant wishes to know upon what I base my idea that brood-rearing causes dysentery. It is this: Experience and observation have shown me that of all the colonies that die with it, a vast majority leave brood. Of all those that are healthy at the same time, a large majority have no brood. Reasoning has forced me to conclude that brood-rearing demands the use and manipulation of pollen and in the course of such manipulation the bees partake of it, during this early period in the season, when they cannot fly to void their feces, and that pollen is a substance that possesses a residue that cannot be passed from the system by sensible and insensible perspiration, as could the excess of water contained in thin or cider honey. Dysentery is the result. I do not claim to be just right in this matter. I only claim to give my honest opinion, formed from my experience and observation.

I presume that in many of the points at issue, Mr. Dadant and myself are both correct. Soil and climate make great differences, and educate us in very different directions. It seems to me that such honest and friendly controversies cannot fail to

lead to some thoughts and discoveries that will help us on to the control of this important branch of our industry. The more so, with such a man as Chas. Dadant at one end of it.

Dowagiac, Mich.

For the American Bee Journal.

Upward Ventilation in Winter.

JOHN A. BUCHANAN.

Just so long as success is attained in wintering bees by both methods—ventilation and non-ventilation, there will be earnest advocates of both systems. It cannot be that both systems are equally successful. There is no use to deny the fact that bees have been wintered by both methods, but which plan has been proven the best?

I advocate upward ventilation as the safest plan for general adoption.

Are we any more successful in wintering bees at present with all the modern appliances and knowledge of the science of bee-keeping, than we were 20 years ago? The general answer is "not a bit." Then, we ask, in what condition for the most part were bees then left for winter? Without entering into a description of that condition it will be understood when we say, winter found them as summer left them. No contraction of entrances, surplus boxes left on with entrance holes to them all open, and, as often as otherwise, glass in boxes broken out and doors open, thereby ventilating the hive most thoroughly, but still the bees were all right, and the winters then were just as cold as they are now. Why do we so often see in some of the bee periodicals modern bee-keepers say:

"I guess I shall be a candidate for 'blasted hopes,' as my bees have died during the past severe winter, notwithstanding my great care in packing so thoroughly, and those that have survived are so weak it will require the most of the season for them to get in good condition again, but I am not altogether discouraged as I have purchased a lot of black bees in box-hives from an old foggy bee-keeper and will transfer and Italianize them, and try again."

Now this is a little too funny; but it proves what? That bees are safer whether in box or frame hives, left in their summer condition, without packing, than they would be with packing as generally adopted by the would-be cautious apiarist of to-day. Judging from reports given in the papers from time to time, and from my own extensive observations, last spring, of a great number of apiaries, I have arrived at the conclusion that more colonies survived the winter of 1880-81 that were left to themselves with thorough ventilation, and unprepared by packing, than the number saved that were packed for protection. During a severe winter there is a great amount of moisture arising from a colony of bees, which will condense on walls of the hive, or in the packing materials, which will have so filled them with moisture that the tempera-

ture of the hive is brought down so low that it is impossible for the bees to generate sufficient warmth to be able to change their position when the stores in reach of them are exhausted. This cold, damp condition of the hive and packing soon exhausts the vitality and reduces the temperature so low that the colony becomes unhealthy and diseased. All of this trouble can be avoided by means of a proper condition of hive, and providing means for escape of this sweat or moisture.

In nearly every case, last spring, where I found hives that had been placed on blocks raising them up from bottom-board from $\frac{1}{2}$ to 1 inch all around, the bees survived and so where hives were much open from season cracks, which provided thorough ventilation and circulation of air, thereby keeping cluster, combs and hive dry. Again, hives, regardless of size or depth of frames, were packed with chaff, straw, etc., ample means provided for free circulation of air through the packing, keeping all perfectly dry, with sheltered eastern or southern exposure, colonies so arranged lived and came through with less consumption of honey than where unprotected. Again, in hives of very large size, without upward ventilation, but large entrance openings and sheltered exposure, were saved. But limited success was attained with bees in cellars where the temperature remained much below 45.

One fall, I placed quilts, well tucked down over frames and over these thick chaff cushion, and contracted the entrances to $\frac{3}{8} \times 2$ inches, and flattered myself I had them in better condition than some of my neighbors' bees that were left with entrances full width of hive open, and also several large holes open into honey boxes. But, imagine my surprise at the beginning of the next season, upon examination, to find those terribly neglected, badly managed bees working in boxes and swarming a week or ten days sooner than my own.

Is it not a fact that the first swarm of bees you hear of in the season, has come from some old foggy's bees, cared for as above described; and don't it bore you, too?

On the 28th of last May, a gentleman passing my apiary asked me if I had had any swarms yet. No; the best of them are only occupying, with all my nice quilts and chaff cushions, about two-thirds of the usual number of frames. "Well," said he, "I had a nice swarm this morning." And without further talking I got on my horse and rode out (5 miles) to his place to see the hive that had so early cast a swarm. He had but 1 colony and that was standing in the corner of his garden with a few boards over it to shelter it from rain, and had not been touched or opened since the honey was taken from boxes the fall previous.

The hive was a Langstroth; 10 frames 8 inches deep; honey-board, with $\frac{1}{2}$ inch space between it and frames; one large honey-box on, holes open and two $1\frac{1}{2}$ inch holes opened

into the cap, where moisture passed off into the cap, which was fitted loosely and open at the joints. The entrance was nearly the full width of the hive, $\frac{1}{2}$ inch, and was open all winter and spring. A slight dash of Italian blood was in the bees. I have occupied this space to prove the position taken at the start, and cases similar to these have no doubt been observed by all.

Pack your bees as well as you wish, but see to it that said packing is kept perfectly dry by upward ventilation.

Holliday's Cove, W. Va.

For the American Bee Journal.

The "Coming Bee Hive."

W. T. STEWART.

In the BEE JOURNAL of Dec. 21, 1881, we have an article from Dr. L. C. Whiting, on "The coming bee hive," in which he very forcibly illustrates some of the advantages of a reversible frame over any other frame. Any practical bee-keeper that will read his article thoroughly, will at once see that every advantage that he claims for a reversible frame, is true beyond a doubt. He further says that the frame alluded to was originated by Mr. Van Deusen, and that some of the best bee-keepers are using them, all of which is true. Now let me predict something and have it recorded in the AMERICAN BEE JOURNAL, for future reference, that in less than 10 years' time all the best bee-keepers in this country will use a reversible frame, and that the coming frame will not be the frame that Mr. Van Deusen has invented, be they ever so good. I have some of his style of frames, and they are good.

I have a reversible frame and hive of my own invention that totally eclipses his, for convenience. In mine, no wedges or following board is needed; there is nothing about it that the bees can glue fast; no place about it for one single moth worm of one-eighth of an inch long to hide from the bee. Every frame is exactly $\frac{3}{8}$ of an inch from side, top and bottom of hive; every frame the proper distance apart—no two frames touch each other. I can remove a frame from any part of the hive, without even shaking any other frame. I can turn the hive on the side, on the end, or even bottom-side-up, and every frame will remain in its proper place; I can put them in a wagon and move them anywhere, without any preparation whatever, and not a bee will be hurt. I need not kill a bee in taking out or putting frames back in the hive. There are no projections anywhere about frame, to interfere when extracting.

It is suited equally well for extracting or section comb honey; is changed in a minute from a large to a small hive, and *vice versa*—either of the four sides of the frame can be instantly reversed from top to bottom, from side to top, and any bar is top, or bottom, or side, as desired; everything about it is simple, practical and cheap; no other hive or frame like it

has ever been described in any of the bee papers. It is, I think, "the coming frame" or hive. It can be used for any size or shape frame, and soon I hope to give all a chance to adopt it. I have experimented a great deal, and studied hard to get the best hive that could be made for all purposes, and I think now that I have it.

The best implements for the apiary are just as necessary as the best bees, and in a very short time Americans will have the best bee house, the best hive, the best pasturage and best sale for our products of any people in the world. Each of our leading bee-keepers have some particular fact for some one thing, and when all pull together we are mighty in bee-culture.

As this is the season of the year when we should be getting our hives ready for the coming season's work, I think we should discuss the hive subject. Persons that have never used but one style of hive, cannot imagine the difference there is in working them. Don't let us say this or that hive is good enough. While some are improving the bee in order to get the very best, let others try to improve the hive, so as to have the best bee in the best hive, and then we can do wonders in apiculture.

Eminence, Ky.

For the American Bee Journal.

Troubles of a Beginner, etc.

A. P. FLETCHER.

Some 2 years ago, I became interested in bee-culture (having previously known but very little about bees), by a circular from Mrs. Lizzie E. Cotton, West Gorham, Me., and about the same time (*Gleanings in Bee-Culture*, by A. I. Root, Medina, O., fell into my hands, which I subscribed for, also Root's A. B. C. together with Langstroth, Quinby, Cook, and Mrs. Lizzie Cotton's book on bee-culture, all of which I have pretty thoroughly read during the past two years. I have had a little experience in transferring, and introducing queens, hiving, etc.

MRS. COTTON'S FRAUDS.

I very much admire all the above works, *except* Mrs. Cotton's. She is a contemptible swindler. Her book contains only 125 pages, for which she asks \$1.00. Mrs. C. says, in her circular, "send me four dollars and I will send you one sample Controllable bee hive, one sample glass honey box, one sample feeder, receipt for feed, with complete printed directions how to manage bees on my plan." I sent \$4 and received nothing but a roughly made model of what she termed her controllable bee hive—a thing of no practical use. Express charges 95c.

A lady, in this neighborhood, bought a colony of Italian bees of her, Mrs. C., for which she paid \$20, and they are all dead. The hive contained only 5 frames, which I suppose is properly termed a nucleus. I was informed there were only a handful of bees in the hive when received.

In addition to the \$20, the express charges were \$3.52. A practical bee-

keeper in this neighborhood, called on the lady soon after her purchase, and ascertained that the queen was worthless, and advised her to send immediately for another queen, which Mrs. Cotton promised should be shipped about the 25th of July, but it has not made its appearance. Now that the bees have all died, the poor woman has nothing left for her \$23.52, but one "controllable bee-hive" and Mrs. C.'s famous book on bee-culture, with her photograph inserted on the first fly leaf. What a boon! The lady referred to is Miss Lovina Ewing, West Berkshire, Vt.

CHANGING SEX OF THE DRONE.

Mr. Gordon Bishop, a bee-keeper of Woodville, Wis., informed me that "when bees are in want of a queen, and have no other means of obtaining one, they make a queen out of a drone." I know, by reading, of only two kinds of layers, viz: a queen and a fertile worker. Mr. B., when asked how they did it, said he "did not know; but they did it!" Can you tell me how they do it?

In a certain village in Michigan, a notice for school meeting was posted on the district school house door, one of the articles of which read, "To see if the district will vote to *change the sex of the teacher*." The real meaning of the article was, to see if the district would vote to hire the man who had taught the winter term, to teach the following summer term also, instead of hiring a lady. Is there any way to "change the sex" of the drone to that of the queen? Mr. B. is a pupil of one Mitchell, who, according to Root, does not always furnish all that is ordered from him, after receiving the money.

Do bees make comb exclusively from honey? And if so, do they elaborate the wax scales while in the field?

Franklin, Vt.

[We do not think there is any way to change the sex of a drone or male larva to that of a queen or female, and this conclusion was arrived at after several experiments, when the transformation would have been likely to take place if it had been possible. Bees undoubtedly make wax from honey or its equivalent, such as sugar, syrup, and, perhaps crude juices or saps, which first, however, are rendered into honey, and its elaboration in scales from the wax-segments takes place in the hive, hence the hanging clusters always found in empty frames when comb building is in progress.

Since the foregoing article was received we have the following, sent for publication, which gives the other side of the question, and in order to do exact justice we will give it entire.—ED.]

West Winsted, Conn., Dec. 9, 1881.

I am a constant reader of the Weekly BEE JOURNAL, and like it very much. I think it is a little the best bee paper out, and I have seen some others. I

notice that you are still severe on Mrs. Lizzie E. Cotton, and give you credit for being honestly impressed with the belief that you are doing the public a good turn by your articles about her. I, nevertheless, believe you are mistaken. I am indebted to her for my first lessons in bee-keeping, and have found her to be honest and reliable so far. I know that she is not a brilliant business woman, but I believe she does the best she knows how, and does not swindle anyone.

I have written you before about her. I offered through *Gleanings* (A. I. Root's) \$5 for proof that any person had ever sent her money for goods and had neither received the goods nor the return of the money. Mr. Root sent me the names of two or three persons who had claimed such a state of facts. Mrs. Cotton sent me letters from the same parties acknowledging the receipt of the same goods. I have investigated her very carefully, both among her neighbors, and among those who have dealt with her, have seen a number who have ordered goods and bees of her and have got what they ordered of her. I have corresponded with those who have been there, and have been shown what there was to be seen by Mrs. Cotton herself. I am not paid for writing this article, but I think you have no right to say what you do about her unless you are ready to prove several instances of what you claim. I make the same offer to you. I will give \$5 for proof of money sent to her, and received, without return being made. If she is a swindler I want to know it, and will then denounce her. I do not claim that her husband has always been solvent or honest. But I do claim that since the business has been done in Mrs. Cotton's name that it has been done straight. I believe Mrs. Cotton to be trying to get an honest living in a legitimate business, doing it in an honest way, and that she is trying with the help of her husband to bring up a large family of children in the best way she knows how. I don't think you have any right to advertise her as a swindler unless you are ready to prove it, and I assert you cannot.

Some time I may want to offer to the bee-keeping fraternity free, through the BEE JOURNAL, a new kind of hive, not to sell it, but to give the fraternity the benefit of my experience. I built last fall four hives of brick. They bid fair now to winter bees on about 10 lbs. of honey, out-doors, and to keep dry and bring the bees out finely in the spring. I never heard of a brick hive, I have thought several large volumes about bees and bee-keeping, and the brick hive is a part of the results. They cost a little more, yes, quite a little more, but if they will save 10 to 15 lbs. a year, of honey, and be warm and dry in winter, and cool and dry in summer, and save putting in the cellar, they will be a good thing. I think bees will be much less likely to swarm from them than from the ordinary hive. I am only an amateur, and only have 20 colonies of bees. If after trying my brick hives through a season

I think them a success, I will write you again about them. I do not expect to trouble you often this way.

R. E. HOLMES.

[We have published many "complaints" about Mrs. Cotton's business transactions, and there seems to be a good chance now for some one to get \$5 back, by sending the proofs required by Mr. Holmes. Mr. H. admits that it is a man who has not "always been solvent or honest" that is carrying on business in a woman's name, and while persons have sent money to him (or her) for articles advertised, and have not received anything of value for the money, they are sometimes swindled even more than they would have been to have received nothing, having heavy express charges to pay on useless "traps."—ED.]

For the American Bee Journal.

Bee Houses; Are They Profitable?

A. R. KOHNKE.

Now and then some one will inquire whether or not bee houses are profitable. Advocates of houses claim absolute protection from changes of weather, which appears to be their main object; besides that, it is claimed that they are quite secure from thieves. But the construction of a frost and burglar-proof bee house costs a little more than some may believe; its cost will, of course, be governed by its size, and, being double-walled, would cost about as much as a one-story house of the same dimension. That would be an extra outlay, for the bees would have to be in hives all the same. In Germany, bee houses are much in vogue, and an observant reader cannot help but notice the disadvantages. I will enumerate some of them, gathered from different German bee periodicals of late:

First, Mr. Hilbert lost his bees lately, by fire; his bee house burned down, and to move the colonies, was out of the question. This is a common occurrence in Germany.

Second, Colonies infected with foul brood infect the whole house; in single hives, out-of-doors, they may be cured, and the hive disinfected; not so a house, where it is well nigh impossible.

Third, Houses are wax-moth harbors. Such a frost-proof house is the best place imaginable for them to breed to their hearts' content, if I may be allowed that expression.

A celebrated bee-keeper in Germany advises bee-keepers to use hard wood for frames, because if made of soft lumber, the wax-moth larva gnaw and eat them, according to his experience. Now imagine such an army of worms, that they even attack the wood of the frames, being hatched, of course, in all the cracks and crevices of a bee house.

Now, those reports of destruction of bees by fire, foul brood and wax-

moth, I found in different papers; not one of them alluded to the disadvantage of bee houses, but by putting the above statements together, one can easily see that these are results of bee houses which are a nuisance, and to be shunned by every thoughtful apiarist. If I remember correctly, Mr. A. I Root lost some of his bees by his bee house getting on fire.

Mr. Heddon built a bee house, but discarded its use, as such, some years ago.

To sum up, bee houses are not desirable on account of expenses, danger from fire, increased danger of contagion of foul brood, when once present, and the increased protection the wax-moth enjoys, especially as the inside of a house will not be frequented by birds to eat them.

Youngstown, O.

For the American Bee Journal.

Best Summer and Winter Hive.

J. A. WILLIAMSON.

Nearly all admit that a hive with a deep frame will winter bees better than with a shallow frame. This is absolutely true, because the honey is mostly above the cluster, where the heat from the cluster warms and permits them to ascend as they may, from time to time, require more food; but for surplus comb honey, a shallow frame is better so that the surplus arrangement may be near the brood and above the cluster. How shall one manage so that the hive will conform to both of these requirements? I will try to describe one that I have in use that fills the bill exactly. It consists of 2 kinds of frames, one for the brood and the other for surplus. The latter holds 6 $4\frac{1}{2} \times 4\frac{1}{4}$ 1-lb. sections and the brood frame is of the same dimensions, outside measure, so as to be used interchangeable.

The brood-frames hold a comb about 8x13 inches; 16 of these frames are used in the brood-chamber, and 12 of the wide frames filled with sections above, for surplus, and, if desired, two or more below, in each end. The brood-frames have tight ends, $1\frac{1}{5}$ inches wide, and, when clamped together make the brood-chamber 24 inches long. Twelve of the wide frames are clamped together for surplus and put on top, holding 72 1-lb. sections on top and, if we wish, 12 or more in the lower story. Each outside frame is covered with glass or a thin board. In making up our hive for winter, we take away all the wide surplus frames, which hold the sections, below as well as above; we have now left 16 brood-frames in the lower story; take 4 from each end, clamp them together, put them over the 8 left in the lower story.

Our hive now is about 13 inches each way (nearly square), and about 18 inches high, we have them now double, which equals a rack, the combs of which are 17 inches deep. We always find more and better honey at the ends or sides, on the top, or over the cluster. The real brood-chamber is undisturbed which is very

important in making up for winter. I have a box or case 4 inches larger than the brood-chamber for packing, for winter. In making up, or dividing in the spring, take 4, 5, or more, brood frames, clamp them together and put them on the bottom board; cover the top of the rack with cloth, or honey-board, if you like.

The above is a description of my notion of a hive for winter combined with large surplus room, etc.

Argenta, Ill.

For the American Bee Journal.

Foul Brood and other Matters.

J. H. TOWNLEY.

"The difference of opinion as to the probability or possibility of curing foul brood, as stated in the proceedings of the Michigan State Convention, I consider very damaging to the bee-keeping public at large; the more so, when noted bee-keepers disagree on the subject. Mr. C. F. Muth says it can be cured by the use of salicylic acid, while Mr. D. A. Jones asserts he has thoroughly tested it, and found it of no use, indirectly hinting that he has another and surer remedy. From the nature of the disease, I doubt Mr. Jones having had a case of genuine foul brood. Nor will Mr. Townley's remedy stay the progress of the disease among his remaining bees, if it has attacked as many as 60 or 70 colonies, for he could not possibly know what colonies of the remainder had caught the contagion before the disease makes its appearance among the brood."

The above, taken from the BEE JOURNAL, vol. 18, page 8, has induced me to give briefly some of my own experience with this malady. When it first appeared in my apiary, 5 years ago, there was no known case of the disease, neither has there been since, nearer than 10 miles. Its first appearance was in a colony that had been wintered in a snow-bank. (Digression—After having lost nearly \$200. worth of bees by trying to winter them under snow, I know of but one place I would prefer a snow-bank to, and that is a mill-pond.) One end of the hive was elevated, perhaps two-thirds of the bees were dead and laid in a mass in the opposite end, wet and rotten; not more than one cell in 10 of the brood would hatch; the remaining cells containing brood, had been capped, the capping was depressed, usually with a hole through it; the brood was dead and lay in the cells a stinking, sickening, disgusting mass, which, if one attempted to remove, would "spin" out in strings several inches in length. This I think was in April. In two or three months several more colonies were found slightly affected.

At first I tried to save what I could of the affected colonies, by putting the bees into clean, empty hives, extracting the honey, melting the combs into wax, and cleansing the hives, covers and stands with fire, as soon as they were found. The bees were first put into an empty box, and after be-

ing left there two days they were shaken into clean hives, and what comb they had made was melted into wax. In no case did the disease appear again in the colonies so treated. The objection to it was the liability to spread the disease (it being contagious) to healthy colonies, especially so, if the work was done when bees were flying and were not gathering honey. After my experience with this malady, I think one who has no experience with it would be more than likely to lose by fooling with it in his own apiary, in any way, shape or manner whatever.

I seldom found more than 4 or 5 affected colonies at any one time, but in a few weeks after treating them, as above described, more would be found, so that at the end of the season I was no better off so far as getting rid of the malady is concerned than at its commencement. The next season I made short work of it by either burning, or burying every diseased colony, with all that belonged to it, as soon as it was found. The third year I found only one colony diseased in my apiary of more than 100 colonies. Since then (July, 1879), during the breeding season every colony in my apiary has been overhauled as often as once in from 3 to 6 weeks, the bees shaken from the combs, and the brood carefully looked over without finding a diseased "cell," so that I think I am now entirely rid of foul brood notwithstanding the assertion of Mr. Kohnke to the contrary.

I was very much gratified with meeting Mr. Jones at the Michigan Convention, and listened to his remarks there with a great deal of pleasure. I think he gave us much valuable information and hope he will attend the future meetings of the Association. But, if salicylic acid will cure foul brood, and he has diseased brood in his apiary so much worse than foul brood that the acid will not cure it, I hope he will leave it in Canada; we don't want it in the United States?

In conclusion, although foreign to the subject, we are apt to be too positive in our assertions; to make assertions that we would not make if we knew all the facts. Even the best and most experienced apiarists sometimes make not only assertions that they have no facts to prove, but also inconsiderate assertions, that are disproved by the experience of others. Although numerous instances of this kind might be referred to, I will refer to only one—that of Mr. Langstroth, in his letter to Mr. A. I. Root, as published in *Gleanings*, vol. 14, page 319, and afterwards published in the *BEE JOURNAL*; viz: "In the very cold winter of 1872-73, I wintered in the open air in hives only $\frac{2}{3}$ thick, until February, a number of colonies which were estimated not to have over two quarts of bees per hive. All the bees of a hive were placed between two combs full of honey, which were kept nearly three inches apart, and they formed a single cluster, shaped like a ball. If the combs of these colonies had been left in their summer position, no amount of chaff used

in any fashion could have saved them." If Mr. Langstroth had visited my apiary about March 20th, in 1873, and seen me open hive after hive of very much such colonies as he mentions, that had been used for queen-rearing, in 1872, and in which the combs were left in their summer position—colonies so small that they occupied only a small part of two spaces between the combs—only one comb running through the cluster of bees; and all of them successfully wintered on their summer stands packed in chaff, he never would have made the above assertion.

For the American Bee Journal.

Is Parthenogenesis Proven?

J. W. K. SHAW.

While awaiting the arrival of the "*Apis Americana*," permit a *puer Americana* to dissect an article by Dr. W. R. Howard, in the *BEE JOURNAL* for Sept. 14, 1881.

I also deny (with Mr. Robinson) that parthenogenesis is a fact proven in nature. All admit that the queen bee is not bi-sexual; therefore all her eggs must be fertilized by the spermatozoa of a male to produce fruitfulness. This is the rule in nature, whether in human, animal or insect life. When once they are bi-sexual, they ever remain so. No embryo can start into existence without the interposition of the spermatozoa of the male, even in bi-sexual insects. Asexual, *i. e.*, without sex, is not a law of nature. Agamic, *i. e.*, without marriage, or agamous, is applied only to vegetable life, as having no visible organs of fructification. There is, and can be, no budding process in the re-production of animal or insect life; all are furnished with the organs of re-production, bi-sexual and sexual, for the preservation and procreation of their species.

A budding process in jelly fish, is only the development of a bi-sexual, and not of an agamic process, or asexual, if you will. Asexual is contrary to all laws of nature, in insects, animals or fish, and is confined to botany alone. Asexual, having no visible organs of generation.

He also says "it is impossible to draw any absolute lines of demarcation between ova and buds." Such a line is not necessary; nature in all its workings, points with an unerring finger, as absolute and unchangeable as the hand which directs the movement with unerring wisdom, and provides for all, through and by general laws, established to germ productive nature. Again he says: "Eggs that you wish to hatch must be left to the care of the bees." No egg in our apiary will hatch if they do not care for it. To produce a perfect female, or queen bee, they build a special cell for it, and feed it with royal food; they build for the drone, or male, a special cell also. Can any one say they have no especial food for the male bee? Neuter cannot be applied to the worker bee, for they are undeveloped females; they, too, have a different cell, and who is able to prove

that the bees do not feed the workers with a special worker food. When it is so hard to prove where truth lies hidden, it is easy to say: "We pin our faith to the skirts of scientists." But are they not human? Being human, they are fallible! And since parthenogenesis is a myth, and in no conclusive manner a reality, and since reproduction of the species is the production of living individuals by actual congress of the species, I wish that "good common sense," common to all "enlightened, intelligent apiarists," may seek for a solution of the mystery in that well "where truth lies hidden," and be not astonished if you find at the well—the *puer Americana*!
Loreauville, La.

For the American Bee Journal.

Bee-Keeping as an Occupation.

WM. CAMM.

It seems not only possible, but practicable, to meet bad seasons by judicious sowing and planting for honey. An attempt to examine colonies with a view of transmitting you a report, last September, was frustrated by robbers. I commenced the winter with 29 colonies, 3 being Cyprians, and 2 Syrians. The little experience I had with these bees was favorable, especially with Syrians.

Bee-keepers have no more reason to be discouraged than those following other rural occupations. Wheat was comparatively a failure; corn was badly injured by drouth, and on clay lands, where the juices contained more sugar, the chinch-bug played havoc with it. Many, to save what they did raise cut up all their corn, and then came the soaking warm rains and spoiled that. Where corn was good the cholera has killed hundreds of hogs to which it was being fed. Bugs, insects and drouth, so injured the vegetables and fruit, that one is hardly surprised to hear of cabbages being imported from Holland, potatoes from Ireland and beans from Italy.

Had I been able to Italianize in 1879 I should, in spite of the season, have gotten about 100 lbs. per colony. The drouth had continued so long that I felt sure of copious rains in summer and destroyed my black queens just as white clover came in, and the drouth stopping the secretion of nectar suddenly, bees were very perverse in raising queens and in receiving those bought, so that several were destroyed after laying one or two weeks; this made it necessary to draw upon my few Italians continually. Started with 21 colonies; took no honey but changed all black for yellow queens and increased 8 colonies.
Murrayville, Ill.

The Indiana State Bee-Keepers Association is called to meet in annual session, Wednesday and Thursday, Jan. 24 and 25, 1882, in the rooms of the State Board of Agriculture. By order of EXECUTIVE COMMITTEE.

Local Convention Directory.

1882.	Time and Place of Meeting.
Jan. 24, 25—	Indiana State, at Indianapolis, Ind.
25—	Northenstern, at Utica, N. Y. Geo. W. House, Sec., Fayetteville, N. Y.
Feb. 1, 2—	N. E. O. & N. W. P., at Jamestown, Pa. W. D. Howells, Sec., Ashtabula, Ohio.
April 11—	Eastern Michigan, at Detroit, Mich. A. B. Weed, Sec., Detroit, Mich.
25—	Texas State, at McKinney, Texas. Wm. R. Howard, Sec.
26, 27—	Western Michigan, at Grand Rapids. Wm. M. S. Dodge, Sec., Coopersville, Mich.
27—	Kentucky Union, at Eminence, Ky. G. W. Demaree, Sec., Christiansburg, Ky.
May —	Champlain Valley, at Bristol, Vt. T. Brookins, Sec.
25—	Iowa Central, at Winterset, Iowa. Henry Wallace, Sec.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings. —ED.

N. W. Wisconsin Convention.

The Northwestern Wisconsin Bee-Keepers' Association, met at La Crosse, Wis., on January 2, 1882. In the absence of the President the Vice President called the meeting to order at 2 p.m. The Secretary then made a verbal report of which he was to furnish a copy, for the next meeting. The Treasurer's report was read and ordered filed.

The following were elected officers for the ensuing year:

President, Emanuel Markle; Vice Presidents, J. Petty and Wm. Lossing; Secretary, G. J. Pammel; Treasurer, John A. Salzer.

A motion was made to amend Art. 3 of the Constitution so that it shall read as follows: The officers of this Society shall consist of President, two Vice Presidents, Secretary and Treasurer, whose duties shall be those usually assigned such officers, and their term of office shall be one year or until their successors shall be elected. Carried. Mr. Wm. Lossing was then elected 2d Vice President.

Upon motion, the President appointed a committee of five to try and get a good attendance at the next meeting, viz: W. Lossing, H. Sanders, E. A. Morgan, E. Markle and L. Peters.

Mr. Salzer said he did not know why the bees killed his queens (bought in the Harris mailing queen cages), after being released.

Mr. Markle said that 44 hours before he had introduced the new queen, he killed the old one and put the cage with the new queen on top of the frames in the hive, and in 48 hours the new queen was accepted, and that he had not yet lost a single queen in that way.

Mr. L. H. Pammel explained how to introduce queens with the Harris mailing queen cage; it was substantially the same as the instructions on the cage, and said that he believed it

to be the cheapest and best in use. Considerable discussion followed.

Mr. Markle said that queens can become imperfect by rearing too many from one mother, and referred to some cases. After debate it was decided in the negative, and that the fault was in the method of introducing and handling the queens.

Question: "Are the cells that are lengthened to form queen-cells, after the eggs are deposited made expressly for that purpose, before the eggs are deposited by queen, or is it simply a worker cell lengthened?" Those present came to no conclusion, although four-fifths of them believed them to be lengthened worker-cells.

Upon the question: "Do worker bees lay eggs?" the members came to no conclusion.

An article was read from the BEE JOURNAL on the subject "How to get rid of fertile workers" by E. A. Thomas, to throw light on the above subject, and a great deal of interest was manifested.

L. H. Pammel read a paper on "Bee-keeping as it was."

The following resolution was then adopted:

Resolved. That we the members of the N. W. B. K. Association tender a vote of thanks to the City Council for the use of City Hall and to the papers that published a free notice of the meeting. Adjourned.

G. J. PAMMEL, Sec.

S. W. Iowa Association.—Every man who ever contemplates keeping one colony of bees should take the BEE JOURNAL, to know what his brethren are doing, and do likewise. There are several important factors in bee-culture; the first and most important of these is the man himself; 2. The queen; 3. The extractor; 4. Comb foundation; 5. A convenient hive. I will not take your time and valuable space in commenting upon each one of these points, only that of the man, because if the man who contemplates keeping bees will only take one or more of the bee papers, and read it, he will soon learn the importance of the other improvements. A man, to be successful in bee-culture, must accept of the improvements, take and read the papers, and never neglect his bees any more than he would his horses, cows, hogs or sheep; and then there is less risk with bees than either of the others, and a much greater percentage of profit. You have not had a report from the Southwestern Iowa Bee-Keepers' Association. It rained all day Sept. 29. My wife was taken suddenly sick, consequently all discussion was abandoned, and but little business transacted. A committee was appointed to award prizes, consisting of Messrs. Leonard, of Taylor County, and Round and Nichols of Adams. L. E. Mercer, of Taylor County, was awarded a premium of one colony of Italian bees, and Frederick Redinger, of Adams County, one colony of Italian bees. The old officers were all re-elected. The President is to give notice through the BEE JOURNAL of the time and place of the next meet-

ing. A few reports were handed in as follows: The Rev. James M. Rees, of Lenox, reported he bought 2 colonies of bees of L. E. Mercer, in the spring; increased to 7; took 50 lbs. of comb and 77 lbs. of extracted honey, and left plenty for the bees to winter on. Fife's apiary about the same; Mercer's about the same. Season was poor, but all who used the extractor done well.

JAMES T. FIFE,

Corning, Iowa, Dec. 31, 1881.

The Northeastern Bee-Keepers' Association will hold their twelfth annual convention in the Common Council Halls, at Utica, N. Y., on the 25th, 26th, and 27th days of January, 1882. The executive committee are determined to maintain the high standing and enviable reputation the association has justly gained in the past, and propose to outdo all former efforts on this occasion. From present indications the coming convention promises to be the largest and most interesting ever held in America. New features will be introduced, and business of vital importance will be brought before the convention that makes it the duty of every member and bee-keeper to attend. Essays and addresses are expected from Capt. J. E. Uetherington, W. L. Tennant, L. C. Root, James Heddon, Chas. Dabant, T. G. Newman, N. N. Betsinger, Dr. A. H. Marks, and others of America's renowned apiarists, on the most interesting topics of the day. If you wish to enjoy the benefits to be derived from the good work already in progress by this association, you will surely attend. All are invited; none can afford to remain at home. Articles and implements of the apiary for exhibition, etc., should be sent to the Secretary, at Utica, N. Y., who will take personal charge of the same and arrange all articles so as to compare favorably with others on exhibition.

DR. A. H. MARKS, Pres.

GEO. W. HOUSE, Sec.

The N. E. Convention.—"The Great Light on Wintering Bees, Cause and Prevention of Dysentery." was the subject chosen by me on which to deliver an address before the Northeastern Bee-Keepers' Association. Unintentionally the last half of the title of the subject was omitted in the notice. Those desiring to attend this Convention should remember that a thousand miles is a short distance, compared with the knowledge that they will gain upon this subject alone. I shall try to be present, with samples of excrement from colonies in a healthful state, and also those affected with dysentery, which will be fully illustrated, giving cause and prevention.

N. N. BETSINGER,

Marcellus, N. Y., Jan. 10, 1882.

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.

G. W. DEMAREE, Sec.

Christiansburg, Ky.

SELECTIONS FROM OUR LETTER BOX

Wiring Foundation.—What weight of comb foundation will do to use with wires, and how large should the wires be? Will Olm's No. 4 machine make foundation that will do for brood comb?
E. F. TAYLOR.

Canton, N. Y., Dec. 20, 1881.

[About five feet to the pound is best for wiring, or without. Use No. 36 tinned wire. We suppose Olm's No. 4 machine will make foundation suitable for brood chamber, if your frames are not too large. You can correspond with him and learn full particulars as to size of sheets made.—ED.]

Wintering Bees in Texas.—We have had no cold weather this winter. Mustard, turnips, lettuce, garden peas, radishes, cabbage, and in fact nearly all kinds of garden vegetables, are growing here now from seeds scattered in autumn. Mustard and peas are commencing to bloom, though I think a little freeze would put an end to some of them. This is the first winter that I have had to feed my bees. I am feeding about 20 colonies, some of my strongest colonies that I am feeding have brood in all stages, though only on one or two combs. There are no signs of disease, as they have had an opportunity for flight every few days. I wish the WEEKLY BEE JOURNAL success.

WM. R. HOWARD.

Kingston, Tex., Jan. 6, 1882.

Italianizing and Transferring.—I have 9 colonies of Italians and 3 colonies of hybrids, if they live until spring. Would you advise me to Italianize my hybrids? How is best to transfer from a large frame to a smaller one? I want them all in one sized hive.
A. L. BAKER.

Lansing, Mich., Dec. 25, 1881.

[Yes; Italianize all of them. Any time in early spring will do to transfer them, and the job will be easily performed, as you have only to cut down larger combs to fill smaller frames. Trimming will be done at ends and bottoms to save the brood, and the pieces can be fitted in frames and thrown to the outside, where they will not interfere so much with brood-rearing, and soon as filled with honey can be lifted out for winter stores; or the pieces can be thrown in the waste box, and melted up for wax.—ED.]

Bees Prosperous.—My bees wintered well. I lost only 4 colonies out of 30; I increased them to 50 and obtained over 1,000 lbs. of honey in sections, which I sold at 20 and 25 cents per pound.
M. E. MASON.

Andover, O., Jan. 2, 1882.

Extracting.—Please answer the following questions in the BEE JOURNAL: 1. I have 11 colonies in Langstroth hives, half of them blacks, and half of them pure Italians. I wish to run 4 colonies for the extractor, and the rest for sections. Which bees will do the best in the section boxes, the blacks or Italians? 2. How shall I proceed in fitting my double-story hives for extracting? Fill each upper story with 10 frames of foundation, and put them on when it is time to put on surplus boxes, or shall I "hook" out two or three empty combs from each of my hives, in apple blossom time, replacing with foundation, and thus get empty combs to fill the upper story? 3. Shall I put on the upper story full of combs at the time when I put on sections?
D. D. MARSH.

Georgetown, Mass., Dec. 27, 1881.

[1. Run the blacks for box honey; they will do nearly or quite as much work in the boxes as the Italians, while the latter are better to handle around the extractor, and not so easily discouraged by being robbed so frequently. 2. Fill your second stories with straight combs, selected from the brood chambers of the other hives, for extracting, supplying their place with foundation. 3. Put on the upper story full of combs soon as honey begins to come in freely from any source.—ED.]

A Good Showing.—In the spring of 1881, I had left only 18 colonies; I sold 3, leaving me 15 to begin the summer with, and some of them were very weak. I increased them by natural swarming to 44, after selling 5 first swarms.

To bees sold,	\$60 00
Comb honey, sold at 20c.....	284 20
Extracted, at 15c.....	25 00
Increase, 29 colonies, at \$7....	203 00

Total.....\$572 20

My bees are in good condition for winter. They had a good fly on Christmas. They are wintered on the summer stands, packed in fine hay. Allow me to congratulate you, Mr. Editor, upon your success with the WEEKLY BEE JOURNAL. I hope you may still prosper, and keep the old reliable AMERICAN BEE JOURNAL at the head of all bee papers of the World.
JOHN BAXTER.

Pickering, Ontario.

A Good Investment.—Bees are flying to-day. I bought 3 colonies in the spring of 1881; increased to 5; sold comb honey for \$6.50. I think my two extra colonies are worth \$8.00, and this with the \$6.50, makes \$14.50, clearing myself in one season, which I think pretty good for a green hand.

F. B. MCQUEEN.

Brownhelm, O., Jan. 7, 1882.

Cold.—The mercury stood at 18 below zero here yesterday morning.

G. M. DOOLITTLE.

Borodino, N. Y., Jan. 6, 1882.

The Pollen Theory.—I went into winter quarters in the fall of 1880, with 19 colonies of bees; put in cellar 15 hives, left 4 on summer stands, well protected; 2 of them were movable comb hives and 2 box hives. The bees in 2 movable comb hives and one box hive died with dysentery. Two of those in the cellar died with dysentery, 1 with mice, and 3 of them died after setting them out; 1 was robbed, and 1 dwindled. So you see I came out with 8 colonies. There was about 2 quarts of pollen in the box hive where the bees died. I think too much pollen killed the bees; my reason is this: I had 5 or 6 colonies in the cellar with little or no pollen in the combs, and they came through all right and clean. Those that had no pollen were second and third swarms, and one first. Some of these were among my best colonies. One of these third swarms gave 115 lbs. of honey, all basswood, so I cannot see what is the good of so much pollen in the hives. If bees can get much pollen in the fall, they will gather more than is good for them. My bees gathered a great quantity of pollen in the fall of 1880; this fall they have gathered very little. Some localities produce more pollen than others, just as some localities produce more honey than others. I am one of the number that stands 10 to 1 on Mr. Heddon's theory. I will give the result of the season's work: Obtained 400 lbs. of extracted honey, and 300 lbs. of comb honey in 2 lb. sections, and could have obtained 100 lbs. more if I had had time to attend to them. The fall wheat harvest began before the basswood was over, and I had to attend to it. I sold the comb honey for 20 cts. per lb., and the extracted for 15 cts. Send along the BEE JOURNAL, as I cannot get along without it, for it is a very welcome visitor.
WILLIAM COLEMAN, JR.

Devizes, Ont., Canada, Dec. 12, 1881.

Deserted by the Queen.—My 37 colonies of bees were put into winter-quarters Nov. 1st, all strong with bees, plenty of honey, and all right with young queens. Yesterday evening I found one of my queens in front of the hive with a few bees around her, about dead. I examined the colony, and found them in good condition minus the queen. Would like to know the cause of the queen coming out at this time of year.

W. R. THOMSON.

New Iberia, La., Jan. 4, 1882.

[We cannot give a reason for the queen deserting the hive with so few bees attending her, unless she was driven out by robbers, or, not having been fertilized, took advantage of a fine day to fly out to mate.—ED.]

The Wrong Man.—I notice in the BEE JOURNAL, page 21, remarks quoted as coming from me, which should have been credited to some one else. If I remember rightly it was Dr. Ashley, of Ann Arbor.

L. C. WHITING.

East Saginaw, Mich., Jan. 11, 1882.

Unprolific Queen.—I have been greatly benefitted by the BEE JOURNAL in the past and expect much profit from it in the future. I have 21 colonies of bees in my cellar, packed with quilts around the brood chamber and straw over the quilts. Bees have not done very well this summer, owing to cold and cloudy weather in the spring. I tried to Italianize my bees this summer but failed. I bought a queen which was introduced to a colony, and was accepted, but she did not lay. I gave them a frame of brood and fed them 8 or 10 days, but she did not lay an egg. What do you think was the cause? Do you think she will do better next spring? Please answer through the BEE JOURNAL.

CHARLIE W. BRADISH.
Glendale, N. Y., Dec. 24, 1881.

[It was probably quite late when you introduced her, and she did not recover from her imprisonment and change in location in time to lay last fall—though she should have done so, even if but little. If she does not show early signs of prolificacy in the spring, you will find it profitable to supersede her; we think she does not amount to much.—ED.]

Mild Winter.—The winter so far has been very mild, just cold enough so that bees would not venture out of their hives; the lowest dip was 12°, highest 40°; on Christmas day the mercury ran to 45°, and the bees flew some at noon. Monday and Tuesday it rained continually; Wednesday was warm as summer, and the bees had a splendid fly, and are now in nice condition for the remainder of the winter. I commenced the season with 20 weak colonies and bought 9 the last of June—4 old and 5 new swarms; lost one in getting them home; have 50 now, 45 of which are in chaff hives on their summer stands, 5 in single-wall hives in the cellar, all in good order. Have obtained 2,000 lbs. of comb and 250 lbs. of extracted honey, which is nearly all sold at home at 16 to 20c. for extracted. I have reared 40 Italian queens. I have taken the BEE JOURNAL for the last 10 years, and think it is cheaper now than ever before. It is indispensable to beekeepers.

J. H. KENNEDY.
Little York, N. Y., Dec. 31, 1881.

In the Cellar.—Last winter I put 29 colonies in the cellar, Dec. 9; I did not bother them through the winter. The cellar was ventilated with 4-inch pipes, one running through the ground to carry in fresh air, and one running up through the center of the floor to carry out foul air, both running down within 3 inches of the bottom; had slaked lime scattered all over the bottom to absorb the moisture. The cellar was perfectly dark. I took the bees out the 15th of April; all dead but 13 colonies, and they were weak and moldy. The 20th of June I divided them all once; I built up all of them with the combs of the dead bees, which had lots of honey in them. About the 1st of August I had 3 nat-

ural swarms, which made me 29 in all. They did not get much honey until about the 15th of August, when we had a splendid flow; then I put on 2-lb. section boxes on part of the hives, and second stories on 8 hives, with 10 frames in the second story, full of foundation. The rest of them I extracted. I got 1,000 lbs. of extracted honey, and 600 lbs. of comb honey. I have sold nearly all of it for 20 and 25 cts. per lb. My bees are in good condition for winter, on their summer stands.

GEO. W. STARK.
Holmesville, Neb., Dec. 25, 1881.

Production of Comb Honey.—I want to know what frame and section to use to get the largest amount of comb honey.

C. A. PONTUS.
Canton, O., Jan. 10, 1882.

[A shallow frame is considered much the best for comb honey, because of giving the bees less labor to climb up to the sections, and giving larger section surface above the frames. As much honey can be obtained in 1 and 2 lb. sections as in a larger box, but, of course, the smaller the section, the more attention will be required in taking away or tiering up promptly during a plentiful honey flow.—ED.]

All that Could be Desired.—The first number of the JOURNAL for 1882 is at hand, and has been perused with usual interest. I am much pleased with its present form. It is surely all that could be desired. I was a little fearful one year ago that the Weekly would not receive the patronage that it deserved, and sufficient to make it pay. I now predict for it a very bright future. You have labored faithfully to make it what it is to-day. Success to your efforts.

F. A. SNELL.
Milledgeville, Ill., Jan. 11, 1882.

Dwindling.—I think the bees are wintering quite well, so far. We have had plenty of warm days and the bees have had quite a number of good flights. This necessarily implies some dwindling, as I have found quite a number clinging to fences, etc., which are certainly lost. I did not have time to attend to my bees the past season; they did well early in the season, at which time I missed the golden opportunity to extract. I had 16 colonies left out of 32, in a very poor condition. I transferred 8 into Langstroth hives, increased 3 by natural swarming, lost 1 entirely by excessive heat melting down combs, had 4 or 5 queenless, and a bad time generally to build up. I now have 18 colonies, 13 of which are in good condition, all on the summer stands, with blankets over the frames—plenty of honey for stores, and about 100 lbs. of surplus honey in 4 $\frac{1}{2}$ x 4 $\frac{1}{2}$ sections. I had poor success in either side or top storing. I expect to lose some of my colonies in the spring, because I have too many old queens and cannot prevent spring dwindling, unless I can get early

brood. I intend to Italianize all my colonies if possible, and be better prepared for the coming year. I am trying to introduce bee pasturage, and hope to succeed. I am well pleased with the new style of the BEE JOURNAL. It is just the thing for convenience; although not intending any flattery, yet I must say each successive change improves it in every sense. You have indeed struck the key-note, if I am any judge of bee journalism. I wish you a happy and prosperous year.

P. A. GROVE.
Kirkville, Mo., Jan. 12, 1882.

Is there Danger of Smothering?—I have the hives with my 12 colonies of bees set in a row, with 12 inches straw on the sides, and 6 or 8 inches of sough grass on top, some ventilation at the top, and an air space 2 inches high in front, at the bottom. I have been told that they would smother; is there danger of it, and should I remove part of the covering? There are no dead bees at the entrance.

A. HODGES.
Shenandoah, Iowa, Jan. 10, 1882.

[If you have even a slight upper ventilation, with the air-space you mention below, they cannot smother; but they may become so warm as to create uneasiness. Should this occur they will gather around the entrance in great numbers; until then, let them alone.—ED.]

The Last Prize Queen.—It is due to Mr. Charles H. Lake, of Baltimore, Md., to say that after the prize was awarded to Dr. L. P. Wilson, of Burlington, Iowa, I received the sixth and last queen bee, that became a contestant for the prize from Mr. Lake in a nucleus hive, with two full-sized frames, and about a quart of bees, the progeny of the queen which he forwarded. The queen herself was not as large as the Wilson queen, nor perhaps as bright a yellow color; but the bees were very large and brightly colored, and the gentlest which I ever handled. Not one even threatened war upon me, though I took them out of the hive on two or three occasions. At the same time, if a stranger bee came sneaking about, he was instantly seized and treated without mercy. The queen filled 3 frames about $\frac{2}{3}$ full of brood after she was inserted in a larger hive, and went into winter quarters in first-rate order.

E. L. BRIGGS.
Wilton, Iowa, Nov. 28, 1881.

Canadian Opinion.—As one of your Canadian readers I write to express my high appreciation of the change made this year in the JOURNAL. For present reading as well as future preservation the size, stitching, and cutting the leaves is a very great convenience, and very much enhances its worth.

J. CARSWELL.
Adelaide, Ont., Jan. 10, 1882.

The Northeastern Ohio and Northwestern Pennsylvania Beekeepers' Association, will meet at Jamestown, Penn., Feb. 1, 2, 1882.

W. D. HOWELLS, Sec.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII. Chicago, Ill., January 25, 1882. No. 4.

ESTABLISHED IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

Published every Wednesday by
THOMAS C. NEWMAN,
 EDITOR AND PROPRIETOR,
 974 WEST MADISON ST., CHICAGO, ILL.
 At \$2.00 a Year, in Advance.

Remit by money-order, registered letter, express or bank draft on Chicago or New York, payable to our order. Such only are at our risk. Checks on local banks cost us 25 cents for collecting.

Free of postage in the United States or Canada. Postage to Europe 50 cents extra.
 Entered at Chicago post office as second class matter.

Vernal.—Mr. J. W. Winder, Thibodeaux, La., under date of Dec. 30, 1881, sent us his "New Year's greeting," accompanied with a small package of green peas and blossoms, magnolia, orange and oak leaves, and rose buds and flowers, all gathered from open grounds. He writes they had ice two November mornings—none since. Truly, in that land of sunshine,
 "December is pleasant as May."

It will be remembered, in February last Mr. Winder sent us white clover and other blossoms and foliage, while we yet remained snow and ice-bound in this Northern climate for several long, discouraging weeks.

New Price Lists Received.—The following New Price Lists of Bees, Apian Supplies, etc., are received:

- Honck & Peet, Canajoharie, N. Y.
- J. V. Caldwell, Cambridge, Ill.
- James Heddon, Dowagiac, Mich.
- C. H. Deane, Mortonsville, Ky.
- Wm. W. Cary & Son, Coleraine, Mass.

Also the following Catalogues of field, garden and flower seeds:

- Joseph Harris, Rochester, N. Y.
- Cole & Brother, Pella, Iowa.
- E. R. Roe, Cornwall-on-the-Hudson, N. Y.

Vick's Floral Guide, by James Vick, Rochester, N. Y., which is one of the most handsomely illustrated and printed pamphlets in the world. Send for them all, they are well worth possessing.

The *Bee-Keepers' Guide* was enlarged with the December number and presents a neat appearance. Mr. A. G. Hill, its editor and proprietor, is getting up quite a spiey paper. It is published at Kendallville, Ind.

The Tardy Bee Papers.—We have just received the Nov. number of the *American Bee Keeper*. Its editor, Mr. E. M. Harrison, explains the delay in its issue, and promises the December and January number in a week. The tone of the paper has improved during the past few months, and we hope that inasmuch as it is to have a "new dress" of type, it may enter upon a new career of usefulness, and devote itself to the promotion of scientific apiculture.

The *New England Bee Journal* has been suspended, but the editor promises to start it again as a monthly in March, at 60 cents a year.

The British Bee-Keepers' Association demand that all honey in the comb shall be put up in American "Prize Sections," and shown in a Prize Crate, containing 12 sections and the crate glassed. We are glad to see this. It will pay to study uniformity in marketing honey.

Bees in Sweetwater Valley, Cal., settled on a rattlesnake 6 feet long, 12 inches in girth, with 22 rattles, and stung it so that it was blinded, and afterwards easily killed with a spade.

Mrs. L. Groves, Arvada, Col., has an apiary of 103 colonies. For a lady and Colorado, this is quite a large affair. But then, Colorado is one of the best of States for bees, and, with its salubrious climate, it is no wonder that a lady is robust and healthy enough to care for such a large apiary.

The *Bee-Keepers' Instructor* and *Bee-Keepers' Exchange* have our thanks for kind mention of the Weekly BEE JOURNAL in its new dress for 1882. Both of these papers have materially improved for 1882, and we wish them success.

Suggestions About Conventions.

It is self-evident that there should be a reform in the methods of conducting Bee-Keepers' Conventions.

Last November, when giving the report of the Chicago District Convention, we stated that it was in many respects a model Convention. There were no essays read; it consisted wholly of discussion. The points of interest were all covered, by the excellent programme devised by the President, Dr. C. C. Miller.

In that Convention, the interest was kept up, unabated, to the end, and it was even difficult to get a motion to adjourn when the time arrived to do so. We have sent the following suggestions to the North-Eastern Convention, held this week in Utica, N. Y., on this subject, hoping that they may draw out a full discussion:

1. Some plan should be devised to make a more perfect organization, and *knit* together, more closely, all the apiarists of our country. County Societies should be auxiliary to the State Society (for such is yours, except in name), and all the members of the county organizations should thereby become members of the State Society, entitled to all its benefits and privileges, and proportionately bear the expenses of holding such. The Presidents of State Societies should become *ex-officio*, the Vice Presidents of the National Society, and thus cooperate unitedly for the general good—and delegates should be sent from the Counties to the State—and from the States to the National Society. This can easily be accomplished, and would contribute to the general welfare. Organization is *life*; in union there is strength. Disorganization is *weakness*, and leads to dissolution—*death!*

2. The present method of conducting conventions, by so many and such long essays, is killing in its influence, and often works positive damage to all concerned. To illustrate:

A long essay is read, and before it is ended, those who listen to it are tired out, and forget or do not quite comprehend the points, and so it passes, without being sufficiently understood or discussed—goes into the minutes, and under the sanction of the Society, is published to the world as its views, when, perhaps, it represents the opinions or feelings of but a moiety of those present, thereby doing positive *damage*, because it misrepresents the society in general. If

essays are admitted, but one should be thrust upon a session, and if possible that one should be printed, and placed in the hands of the members to be discussed at the next session. In this way some of the difficulty could be overcome, and the detrimental effects avoided.

3. If such organization was obtained it would facilitate correct statistics, and the united power of the apiarists of the Nation could be exerted to demand legislation against fraud and adulteration; obtain redress for injurious rulings of the Postal Department, such as denying the admission of bees to the mails, etc., and correct the unjust discrimination of railroads in classing honey at exorbitant rates when they carry *similar* staple articles at one-fourth the freight demanded for honey.

Again, a *brotherly* tie would be formed—helping one another—not only in the matter of marketing our crops, but perhaps in helping the unfortunate, succoring the families of deceased members, and possibly providing for those overtaken by calamities, etc.

These are but a *few* of the things that could be accomplished by united effort, but we only wish to throw out these suggestions, and leave it with others to discuss the matter, and devise a scheme for carrying it to a successful issue.

Honey-Making in the United States.

The following paragraph is part of an article which we have clipped from an exchange, and is credited to the *Popular Science Monthly*:

The annual production of honey in this country is estimated at about 35,000,000 pounds, and the business of bee-keeping is becoming rapidly systematized. One firm of wholesale grocers in New York keeps as many as 12,000 swarms; other keepers have often from 3,500 to 5,000 swarms. Arrangements are made with farmers and owners of orchards to allow an apiary of a certain number of swarms to be placed on their grounds. At the distance of three or four miles another apiary is placed with another farmer, and so on. For this accommodation, the bee-keepers pay either in money or in shares. It is estimated that, on an average, an acre will support twenty-five swarms, yielding fifty pounds of honey each. The apiaries are cared for by men in the employ of the bee-owners. Many ingenious contrivances have been introduced for the purpose of saving the labor of the bees and the keepers.

We were surprised to see a paragraph containing such gross errors

emanating from so high an authority as the *Science Monthly*, and cannot pass it by without making some corrections, as it is not only calculated to mislead statisticians, but may eventually work serious injury to the bee-keeping interest. It illustrates, also, the ease with which standard publications can be mistaken in matters with which they are not perfectly familiar.

The production of honey in the country amounts to about 100,000,000 pounds annually, instead of 35,000,000 pounds, as given above.

The allusion to a firm of wholesale grocers probably has reference to the Messrs. Thurber, who may have handled the product of 12,000 colonies, but it was the combined production of scores of bee-keepers in all parts of America. But few, if any bee-keepers in the country, have more than 3,000 colonies. Capt. Hetherington, we think, is the most extensive bee-keeper in the United States, and 3,000 colonies is the maximum of his operations.

But when it is asserted that "on an average, an acre will support twenty-five swarms, yielding fifty pounds of honey each," the most incredulous disbeliever in over-stocking will smile with doubt, and, with pencil in hand, will figure it up as follows: Twenty-five colonies, each gathering fifty pounds of honey, would give a total average per acre of 1,250 pounds, and, assuming the bee's flight in each direction to be two miles from the apiary, would give 2,560 "average" acres within reach, capable of sustaining an apiary of 64,000 colonies, which, averaging 50 lbs. of honey each, would foot up a total yield of 3,200,000 pounds. Prodigious! Truly, "there's millions in it!"

Honey Wine.—Mr. C. J. Quimby, says the *Bee-Keepers' Magazine*, "has succeeded in producing a wine from pure honey *vivalling*, if not excelling, in all desirable qualities the imported wines. This wine has been submitted to experts, druggists, physicians and wholesale importers, and all, so far as we know have expressed themselves as surprised and gratified, and predict that this discovery is destined to work a complete revolution in the bee-business, greatly in favor of the honey producer, as it turns much of his produce into an entirely different substance, and hence necessitates a larger supply."

Glucose Syrups and Honey.

We have expressed the opinion several times, that it was an impossibility to manufacture complete honey combs by machinery, then fill them with glucose and cap them artificially; but when Dr. Nichols asserts so positively (as he is charged below with having done) that it can and is being accomplished, it is time to investigate the subject. With this object in view we have instigated a series of inquiries, and will give our readers the result when it shall be reached. Following is an article from the *New England Farmer* on this subject. The Dr. Nichols spoken of is, we suppose, Prof. Nichols, of the Boston *Journal of Chemistry*, in whom we recognize a stalwart and fearless opponent of food adulterations, and an advocate of honest goods under proper names:

Dr. Nichols, in his lecture on sweets, delivered before the Massachusetts Board of Agriculture at Bridgewater, brought out some facts which are probably not generally known by the public at large. The syrups sold in our stores, he said, are doubtless all made up of mixtures, in which glucose or grape sugar, made from western corn plays a prominent part. As from ten to twenty-five per cent. of grape sugar can be mixed with cane sugar, and seventy-five per cent. of corn syrup can be added to sugar-house syrup without being detected by the taste, it is not to be wondered at that glucose is largely used in this age of adulteration.

The product of the western corn-fields now finds a ready market in New Orleans at the sugar and molasses factories, and it is believed that Cuba is becoming a good market for the product. If this is the case, why not take our glucose from first hand at a fair price, instead of paying transportation to New Orleans, Havana or Porto Rico and back, before we can bring our appetites up, or down, to the regulation standard of sweetness?

But perhaps the most startling statement made by the doctor was, that glucose is really taking away the occupation of the honey-bee. It has long been used for feeding bees, and an inferior quality of honey is made from such feeding, but this is too slow and uncertain a practice for this ingenious race of Yankees. The glucose sometimes affects the health of the bees unfavorably, so a short cut is made by the manufacturing of a perfect comb from beeswax, and filling the cells with the glucose, direct from the syrup mills. The comb is made by machinery, and after filling is sealed over like bees' comb, and then sold in the markets of the world, perhaps as California honey or such other trade mark as the dealer may fancy. Verily this is an age of inventions.

It is undoubtedly true as the *Farmer* says, that much of our glucose

finds a ready sale in New Orleans and Cuba, where it is mixed with sugars and syrups, and sent back to the North and West and sold as a pure cane product; and why this is done, is because the deception would not be complete without the expensive transportation, and Southern brand. The time is not far distant, if it has not already arrived, when glucose will be shipped to foreign ports in large quantities and returned to us as a genuine article of cane sugar, and this, too, after paying an import duty at foreign ports and another at our home ports, as was formerly said to be the case with American wines and liquors.

The BEE JOURNAL has long urged upon bee-keepers that the food adulteration question was one of vital importance to them, as not only working to their detriment in the home market, but liable to lead to a damaging prejudice in markets abroad. By reference to the proceedings of the Austro-German Convention, on pages 59 and 60, this week, it will be seen our fears were too well grounded. It was resolved to petition their government to increase the duties on honey and wax to such an extent as to virtually exclude them from their markets, and, moreover, the American proclivities for indiscriminate adulteration are also made the pretext for attributing the propagation of foul-brood to our exports. We have too much confidence in their intelligence to place any great amount of confidence in the latter bug-bear; but there may be room for complaint in regard to mixing glucose with the honey sent there, and if, instead of increasing the duty on honey and wax, they would make it a civil and penal offense to import or sell the adulterated article, we could rejoice with them in their progressive step.

A late number of the *Chicago West End Advocate*, says: "Recently three prominent citizens of Atlanta, Ga., died of paralysis, caused by the ingredients used to adulterate fancy brands of sugar and syrups." And it is insidiously working mischief all the time. If bee-keepers, or dairymen, or any other class of producers were alone the sufferers, there would not be so much cause for alarm; but when a whole nation, supposed to be composed of intelligent, thinking, charitable people, can supinely and inertly allow dishonesty and fraud, in the guise of food adulterations, to usurp the channels of honest trade, poison-

ing our whole people and imposing upon foreign confidence, it is time to examine the criminal code of foreign governments to find a remedy. We are almost persuaded that semi-barbarous China has taken a step in advance of the United States in civilization, in making death the penalty of food adulteration. Here, if one person kills another with firearms, or other violent means, it is "murder," but if whole communities are slowly poisoned with adulterated food, it is a matter of "business." There, if a whole people be slowly poisoned or diseased, it is as much a crime and punishable as if but a single victim suffers a speedy and comparatively happy death.

New Bee Feeders.—We have one from U. E. Dodge, Fredonia, N. Y., one of his bee-feeders, reference to which is made on page 61, this number. The feeder is made with two wooden strips 10 inches long, nailed on two others 6¼ inches long, making an open box about 10x7 inches; a 1½ inch strip is nailed crosswise inside 1¼ inches from one end, and a piece of cheap cotton cloth is nailed over the bottom from this strip to the furthest end, leaving the narrow open space for the bees to come up from below. The top of the box is covered with a 7x9 pane of glass. A slanting ¾ inch hole through one of the ends, to the inside, through which to pour liquid feed, completes the feeder. When more upward ventilation is wanted, this feed hole is covered with wire-cloth, instead of a tin slide.

From Scovell & Anderson, Columbus, Kan., we also have a new feeder. This is 9 inches long by 5½ wide and 2 inches deep. There are two outer 1-inch slots cut down into a block, something like the Novice feeder, in which to pour the feed, then two inner 1-inch slots, covered with wire-cloth, from which the bees take the feed, and between these a mortise is cut clear through, to allow the bees to come up. A ¾-inch strip passes around the edges underneath, which bears up the feeder from the tops of the frames. This is for a top feeder, over the frames, and underneath the quilt.

Several correspondents ask for the best method of making paste for putting labels on tin pails of honey. Will some one please give a recipe for making such as will stick well to tin, and oblige many inquirers.

MISCELLANEOUS.

Small Packages for Honey.—The *Bee-Keepers' Instructor*, makes the following very sensible remarks on this subject :

"Extracted honey, 8@8½ cts. in round lots, to 12½ cts. in small packages." That is the way the St. Louis market report reads this month, and to the observant bee-keeper it speaks volumes. A difference of fully ½ in price for probably exactly the same quality of honey, and allowing simply to the manner of putting up. It is very plain that the day has gone by (if it ever existed), when honey in barrels, or large packages, will command anything like the price it will if put up in smaller, more attractive packages, and those apiarists who appreciate this fact, and cater to the popular demand, are not slow in reaping their reward. In this world appearances go a great way, and he who puts up his honey in the best manner—in small tin pails, glass fruit jars or kegs, if extracted, or small sections, packed in medium-sized crates, if comb—neatly labeled and scrupulously clean, is sure to realize top prices.

Poor Management of the Apiary.—Dr. J. P. H. Brown, Augusta, Ga., gives advice and reasonable hints to apiarists as follows in the *Bee-Keepers' Magazine*:

During the last of the month examine all your colonies as some might need feeding; if so, lose no time in attending to it. If the weather is cold at the time, the feed should be placed immediately over the cluster, or where the bees can get at it without crawling from the cluster.

For this sort of feeding the "pepper box" feeder, or the Van Deusen feeder is the one I prefer. Sticks of candy laid across the frames under the quilt is said to be good, but as my bees may be different from those of the parties who recommend it, they are prone to cut it up and carry it out of the hive as a nuisance. Ten pounds of granulated sugar to a gallon of water makes a feed that is always reliable.

Suffer no trash to collect on the bottom of your hives—sweep them out clean. Such debris usually contains the eggs of the bee moth or its larvae, which will mature as soon as the weather gets a little warmer and commence to cut and web the combs of your weak stocks. In the latter part of the month there will be brood started in nearly all your normal colonies. This will particularly be the case if the month should be warm and open. When bees are raising brood they consume their stores rapidly; hence when you feed, either give it so fast as they will take it up until they

get enough to last them till they can gather from the flowers, or feed in small quantities every other day until the middle of March. I have tried both plans of feeding and find the results about the same. The first plan is less laborious. There is to be no "half way station" in this "feed business." To feed for a while and then quit, and allow the bees to starve at last is indicative of unpardonable carelessness and bad management.

One of the great sources of failure in bee-keeping is in not having things ready at the right time. We wait till our actual need is upon us, then we send off for bees, queens, hives, sections, extractors, etc., and expect them right away. Some hardly wait till the order has reached its destination but write a "postal." "Why don't you send right along those things?" Those people do not think that there are other bee-keepers besides themselves that have sent orders—many orders may be ahead of theirs. In getting off goods there may at times be some unavoidable delay over which the manufacturer may have no control. Sometimes delays occur by parties giving improper shipping directions, or may improperly direct their letter, or may fail to give their signature. I have often received orders from parties who wrote their names with so many flourishes and hieroglyphics that no experts within my reach could decipher them, and my only resource was, to cut the unknown signature off the letter, paste it on an envelope, and direct it to the post office address indicated by the post-mark, with the hope that the postmaster might be able to identify the writer.

It is not the intent of this article to be any apology for that class of supply dealers who are constitutionally slow coaches, and are dilatory in filling orders, but to urge bee-keepers to order before they need the goods.

It is the duty of every supply dealer to fill the orders he receives with the utmost dispatch, and we believe all those who have an eye to business do it; at least they endeavor to.

Organization.—The *Indiana Farmer* contains the following information to bee-keepers in Indiana:

At the last meeting of the State Bee-keepers' Society, the association was changed to a delegate organization and one vice-president was appointed for each county in the State. It was thought this would place the association on a more firm basis, and facilitate business. Each member of the county societies being also a member of the State Association and entitled to all benefits, copies of proceedings, etc. Some provision will be made for persons in counties where no organization exists, and the question will again come up as to the form of the association. In a communication to us last spring, Dr. N. P. Allen, then president of the National Association, says: "I notice in the address of your former president, Mr. Belman, that he recommends the organization of county societies in every

part of the State. I was glad to see the recommendation, as I consider organization the life of bee culture, and the best thing that can be done to spread a knowledge of scientific bee culture among the people. If every state would organize a State association, and every county a county society, the honey resources of each state and county would be developed, and valuable statistics of the honey and wax productions of the United States obtained.

Bee Literature.—The *Eagle*, Union City, Indiana, gives its opinion of the necessity of bee literature, as follows:

A bee-keeper, without bee literature, is like a mechanic without studying architecture, or a farmer who will take any kind of stock on his farm, and not try to improve it.

What good will it do for you to have a colony of bees with a hive that will allow them to store away a hundred pounds of honey, if they can consume only 30 lbs., and leave 70 lbs. in their hive; the following year they can gather only 30 lbs., and the remainder of the year they will be idle for want of room? They fill up the brood combs with honey, and the consequence is they will not raise brood in the after part of the season, and they go into winter quarters with old bees, and if they live through the winter they will come out weak in the spring, when they should be strong, so as to commence storing for the coming season.

There are a great many good bee hives. One to be available must be a frame hive, easy to manipulate, so that, if your bees have more honey than they need, you can take it, without daubing your bees, and without making your honey mussy. Hence the most profitable thing that a man who has bees can do is to take a bee paper. The *Weekly BEE JOURNAL* is, I think, the best.

Driven off by Bees.—"The little busy bee" was once used in a naval fight in the Mediterranean. A gentleman recently wrote to the San Francisco Social Science Association, giving the story as he heard it from an eye witness. It seems that a small vessel, which was suspected of belonging to pirates, was chased by a Turkish man-of-war, on board of which were 500 seamen and soldiers. As soon as the man-of-war came up to the privateer, several hundred men were sent in small boats to take possession of her. When the small boats got alongside the privateer, the latter's crew mounted the rigging, taking with them a dozen hives of bees, which they had stolen to sell on the Italian coast. At the word of command the bees were thrown into the boats among the Turks. The terrible time that followed was beyond description. Some of the soldiers jumped overboard to escape the furious insects, and in the excitement the privateer escaped. The scene was witnessed from the deck of an approaching English ship, which picked up two of the Turkish boats.

The Dzierzon Theory.

DR. G. L. TINKER.

That the questions arising out of this theory may be generally understood, I will preface this article with a few explanations. The Dzierzon theory, as now understood, is simply the doctrine of parthenogenesis or agamic reproduction applied to the honey bee. The Baron of Berlepsch's admirable treatise with the above title embraces thirteen propositions relating to the scientific knowledge of the honey bee. The eighth and ninth, setting forth the doctrine of parthenogenesis alone out of the thirteen remain unconfirmed. These comprise the salient points of the theory and are very ably discussed. Parthenogenesis is defined as "the production of young by a female without intercourse with a male." Agamogenesis, as "reproduction without the union of the whole or parts of two organisms for the formation of offspring." These terms are therefore nearly synonymous.

With many of the lower order of insects parthenogenesis is an established fact, since the virgin females in many instances produce female as well as male offspring. Going farther down the scale of life and we have simply dimorphism or alternate generation in which the female is parent only to the male, and the male only to the female. But such is the relation between the lower and the higher forms of life that the alternate generation may be traced as a preponderating influence in the generation of the higher forms of life; or in other words, the female, ordinarily, exerts a prepotent influence over the male offspring and the male the same over the female offspring.

Ascending in the scale of life, we find in hymenopterous insects a well defined exception to the complete operation of the laws of dimorphic and agamic reproduction. In the queen bee, no females can be produced without a union with the drone, parthenogenesis is so far true that the virgin queen can produce drones only. The only point in question, therefore, is whether the drone progeny of a fecundated queen may be affected by the mating drone. I think that it may be, and deny that the fact a virgin queen may produce drones is evidence that the vivifying fluid of the drone may not affect the ovaries of a queen so as to modify her drone offspring.

It has been said that a black queen mated with an Italian drone produces a drone progeny that cannot be distinguished from the drone progeny of purely mated black queens. So, too, it has been stated, that a pure Italian queen mating with a German drone may produce a royal and worker progeny that cannot be distinguished

from that of a purely mated Italian queen. In the latter case, the fact of the impure mating cannot be positively determined except in the second generation. In the former case, the third generation would be required to determine perceptible effects, as follows: Mating a pure black queen with an Italian drone, one of her drones to be mated with a pure black queen, the royal offspring of the latter to be mated with an Italian drone. The drone progeny of the latter queen should show some of the markings of the Italian drone. A better test, to my mind, would be to begin with a pure Syrian queen to be mated with a pure German drone, etc. This would be a very difficult experiment to carry out, yet almost every other test must be attended with negative results. For instance, a Syrian queen may be mated with a German drone. The prepotency of the queen over her male offspring may obliterate all perceptible effects of the first cross, as with a black queen. Still the light colors of the Italian and Syrian bees are without doubt more easily affected by crossing than the dark color of the German bees, since the workers of a black queen fecundated with an Italian drone are only about one-third marked with one or more yellow bands, while in an Italian queen mated with a black drone at least one-half and often two-thirds of the workers will be without yellow bands.

I should not regard the mating of a Syrian or Cyprian queen with an Italian drone as affording a reliable test, owing to the three races being evidently nearly related.

A test having some reliability is where a lot of pure sister Italian queens have been mated, some with German, and some with Italian drones, as indicated by their worker progeny. The drones of the impurely mated queens will show an admixture of black blood in their form, size, growth of hair at the end of abdomen, and color, while the drones of the purely mated queens will be quite similar in all respects and well marked Italians.

Having repeatedly observed these results with great care, led me at length to doubt that part of the Dzierzon theory relating to parthenogenesis, except in so far as it applied to virgin queens and laying workers.

There are, however, other considerations bearing against the theory worthy of notice. As will be seen from the anatomy of the generative organs of the queen bee, there are a large number of ovarian tubes (according to Prof. A. J. Cook not less than one hundred) opening into the oviduct. In the act of copulation there is nothing to prevent the spermatozoa of the drone from migrating, as is there wont, through all of these tubes. That their presence in a queen's ovaries could have no effect upon them, seems to me quite improbable. Indeed, we find the abdomen of the queen to begin to enlarge at once preparatory to the depositing of eggs, demonstrating that their (the spermatozoa) presence has had a decided effect.

Again, it may be found that the in-

gress of only one spermatozoon into the micropyle of an ovum may not be sufficient to alter the sex, which has been shown to be constantly male in the eggs of the virgin queen, but the entrance of several spermatozoa into an ovum, in passing by the spermatheca, may cause the male elements to be prepotent and so change the sex of the ovum. In this manner it is possible to account for the variously marked worker bees of an impurely mated queen by supposing some ovi to be impregnated with a few, and others with many spermatozoa.

In concluding, it may be well to note, that since agamic reproduction in the honey bee has been left an open question by so excellent an authority as Prof. A. J. Cook in his "Manual of the Apiary" (see page 89), no more fruitful field for experimentation is now open to the scientific bee-keeper or the practical scientist.

Another Bee Enemy.

E. T. FLANAGAN.

I find the following in the *Bee-Keepers' Magazine* for December, 1881: "Mondovi, Wis., Oct. 12, 1881—Mr. Editor: There has been a worm in these parts, that has destroyed a good share of the brood; it seems to be different to the moth worm, and works wholly in the bottom of the cell, and kills the brood before it is ready to hatch. It does not look to be affected until the bees uncup it, and it is all dead. I cannot find any way to get rid of them, they eat from one cell to another, and through the center of the comb. The worm is not like the miller moth worm, but is much smaller and seems to hatch in the bottom of the cells. I have found some of the worms not larger than a worker egg, all the way up to as large as a small sized knitting needle, and about $\frac{1}{2}$ inch long. I find them in every one's bees that I have looked at; if they continue, they will ruin all the bees. Have you been troubled with any such thing, and if so, is there any remedy?"—N. H. FISHER."

To which Professor Hasbrouck responded: "The worm you describe seems to be something new, I have never before heard of anything like this."

In an article in *Harpers' Magazine* for Dec., by W. H. Gibson, entitled "Among our foot prints." I find the following which may throw some light on the subject:

"There is still another beetle which is met with in our rambles *** known as the meloe. In color the meloe is of a deep indigo blue, rotund in form—when touched it exudes from every joint a yellowish liquid, from which habit it is commonly known as the "oil beetle." or oil bug, and by which it may be easily recognized * * clumsy and unattractive as this beetle is, it is nevertheless much more interesting than one would imagine * * * Briefly told, the history of this common blue beetle is as

follows: It feeds upon the leaves of butter cups and other plants, on the ground beneath which the female deposits her eggs, several hundred in number. These hatch into very minute, but surprisingly active larvae, scarcely larger than a hyphen on this page. They immediately crawl up the stems of neighboring plants, and nestle among the blossoms. I have seen large numbers of them in a single flower. Beneath the magnifying-glass this tiny creature is seen to possess six long legs. They are given to the grub only at this stage of its existence and for a special and remarkable purpose. It is not in quest of honey that this little atom seeks the blossom, but merely as its hair, in which to lie in wait for its victim. Presently it comes in the shape of a bee that alights on the flower. In an instant the agile meloe jumps upon the body of the intruder, to which it clutches tightly, with those six clasping legs. Thus clinging it is carried into the hive, and when the bee reaches its cell, the meloe releases its hold, and creeps into its new home, where it finds the plump, white bee grub a ready breakfast. By the time the young bee is devoured or several of them, the meloe casts its skin and assumes the form common to the larva of many beetles, in which those long legs are no longer seen. Henceforth, it feeds on the pollen or bee-bread stored by its duped foster-mother, until when fully grown it passes into the pupa state and soon appears again as that guileless innocent in our foot-path."

Is not the connection between the two accounts quite marked, and is not this worth looking into, during the coming season, by our sharp, quick, wide-awake apiarists? especially in that section of our country where the loss of bees in the manner described by Mr. Fisher occurs?

For the American Bee Journal.

Moving Bees in Winter.

O. P. CODDING.

I bought in Jan. 1868, two colonies in box hives; they were to remain in the cellar where they were until spring, but sometime in March I got uneasy about my bees and brought them home, put them in the cellar and they remained there until the last of April, when I put them out. They were all right, gave two swarms each, and gathered some box honey.

Again, in Nov., 1880, I went to St. Albans, a distance of about 28 miles, and purchased 10 colonies of hybrids, but the roads were so rough that I did not dare to move them. About the middle of Dec., when it was good sleighing I brought them home safely, starting about day-light, and arriving home about dark. I stopped about one hour at noon, to feed my team and for dinner. I opened the entrance of all the hives, to give the bees fresh air; they were all as quiet as they would have been in the cellar. I then closed the entrances and drove home,

and put them into the cellar next morning. They remained in the cellar until April 20, 1881, when I put them out, and found live bees in every hive, although one was queenless, and had but few bees, but this was not caused by moving, I do not know but they wintered just as well as 10 others, put in about the middle of Nov. None of the 10 purchased had any dysentery. The best colony cast 4 natural swarms; the first gathered 92 lbs. of honey which I extracted, and cast a swarm, making 5 swarms and 92 lbs. of honey. All are alive at present.

I would not have you think that I advocated moving bees in winter when you cannot give them a flight afterwards, but it worked all right in my case, and I should try it again if I wanted to move bees under similar circumstances. I also know of two other trials at moving bees in winter; both came out well excepting one tip-over which smashed up some of the combs.

The colonies I moved last winter were in Langstroth hives, which, by the way, I do not like very well.

Johnson, Vt., Jan. 14, 1882.

For the American Bee Journal.

Section Honey Boxes.

E. A. THOMAS.

This is an old subject, and one that has been thoroughly discussed in the JOURNAL, but for the benefit of the hundreds of new subscribers I will express my views in regard to the various sections now on the market.

I will first divide sections into two classes, those holding about one pound, and those holding two pounds. In regard to the relative value of these two classes, much depends upon the state of the market. The sooner bee-keepers realize this necessity of producing honey in good packages as the market demands, the better it will be for them.

At the present time the tendency of the market is towards pound packages, not only for honey, but for all light groceries. A careful examination of the honey markets for the past year should convince every one that honey in one pound boxes brings a higher price and quicker sales, than any other package. It has been my experience that bees will not store as much honey in one pound boxes as in two pound, as it takes them just as long to finish up a pound box as it does a larger, and in the honey season, time is honey with bees. But the deficiency in the amount of honey stored in these boxes is more than balanced by the difference in the price of such packages and those holding two pounds or more; so we have the advantage of quicker sales in favor of the one pound sections.

Of the two pound boxes, I prefer the "prize box," which makes a very attractive package for the market.

In regard to the dovetailed *vs.* one piece section controversy, I will say that I have not fallen in love with the one-piece section; it may be the best, but I fail to see it. Perhaps it is owing

to my obtuseness that I am unable to appreciate its value. I have found the box faulty in the following respects:

1. They cannot be bent into shape, without cracking the corners, as rapidly as the dovetailed boxes can be driven together. That they can be bent into shape all right, I do not question; but it takes time and care to do it. Skillful workman may after long practice bend them very rapidly; but it must be remembered that the bee-keeper who only uses a thousand or two does not get the requisite practice to enable him to do it rapidly and without cracking the corners.

2. They do not make as strong a box as the dovetailed. Do not pass over this point as one of minor importance, for it is of great importance to the bee-keeper, the grocer and the consumer. I do not doubt but that if handled with care they will cause no trouble, and the bee-keeper, who understands how they should be handled and packed for market may have no trouble with them. But when the honey falls into the hands of the grocer, what then? A customer comes in and calls for some honey; he takes out a section from the crate and puts it into his scales, not as gently as he might, weighs it, and sets it in a decisive way on the counter in front of his customer, perhaps hitting one corner on the counter first and thus racking the box. The customer pays for the honey and goes to pick it up, and says: "Here, this honey is looking all over me." The grocer looks, and sure enough, it is; he has cracked the comb in racking the box. He has to give him another box, and either consume the broken honey himself, or sell it at a discount. The lesson teaches him to be more careful for a time, but by-and-by he gets in a hurry and cracks another.

The result is that when the producer or commission man comes around again, a conversation something like the following will take place:

"Good morning, Mr. Blank; is that honey all sold?"

"Yes, sir."

"Well, how did you like it?"

"I don't like it; the boxes are so weak that every now and then I crack a comb, which spoils the sale of the box, and honey daubs my counter, floor and myself."

"Is that so?"

"Yes."

"Well, now *we* never have any trouble with it, suppose you try another crate?"

"Don't want it. If you have got any honey in boxes strong enough to hold it, I will take some; but I don't want to handle any more like the last at any price."

Those who favor using the one-piece section may say that if the grocer would use proper care, there would be no trouble. Now, friends, please remember that "if" is the biggest word of its size in the whole English vocabulary, and that grocers *do not* always use proper care. They are not, as a general rule, bee-keepers, and do not know all about the one-piece sec-

tion and how to handle it; consequently, they handle them as they would any other box, and the result is that they now and then crack out a comb or set the honey to leaking, become disgusted, and refuse to handle honey. Every one should appreciate the fact that, in order to create a steady and uniform market, it is necessary to put honey on the market in such packages as will cause the grocerymen the least trouble in retailing. We should make it for their interest to handle it, when they will take pains to increase the demand.

But suppose the honey gets into the hands of the consumer in good shape, what then? Perhaps he steps into several stores on his way home, and in setting his box down he is very liable to hit one corner first; before he gets home, he may find his honey leaking all over him. Put yourself in his place and see how you would like it. Do you think you would want to buy any more in such a box? I am sure I should not.

In regard to the appearance of the all-in-one-piece sections, I must say that if accurately made they are very handsome. If the corners are glued, the second objection is done away with, but as this will require a great deal of time and care, it will only serve to strengthen the first objection.

Coleraine, Mass.

For the American Bee Journal.

Extracted Honey—No. 2.

JAMES HEDDON.

The question is frequently asked, "which class of honey production pays best—comb or extracted?" In reply, one writer argues in favor of comb, and another in favor of extracted honey. Each produces some arguments that are valid, and make us wish we were devoted exclusively to his choice.

Answering that question, from a stand-point of the present, I would say that the difference in the nature of the production, and present market value of each class, is so slight, that greater reasons for a choice lie in the adaptability of your climate, flora, market, and your natural choice in the different styles of labor connected with them.

Owing to the successful employment of our best comb foundation, I think that I prefer comb honey production; however, if I start another apiary, which I shall do ere many seasons, instead of dealing in supplies (if my trouble of poisoning from the bees improves as it is now doing), I shall devote it exclusively to extracted honey. I will tell you the reason why, and this will touch the third part of the subject—marketing.

From the length of time that I have been engaged in the business, and the amount of shipping and jobbing of honey I have done, I am continually receiving orders from abroad, and some of these are for extracted honey. To hold this trade, it is really necessary to keep an assortment of styles

on hand. But I am not going to mix the two classes of production together in one apiary. I see little good, and a great deal of damage, in such a course. The extractor (a thing no man should be without), used in the comb honey apiary, will be used only in cases of emergency, as a mechanical necessity, and to empty the partly filled sections in the fall.

If all my honey crop was to be sold at wholesale, I should choose which class I would produce, and become a specialist in that class, were I running a dozen apiaries.

Comparing the profits of the two classes of production, in the near future, I have no reasons for any choice, in the probable prices. Both will be levelled to the cost of production with our necessary margin added, if such is not already the case. For the production of extracted honey, as for both kinds, I should start in an unoccupied field, or not at all. I should try to form some sort of an estimate of the amount of nectar annually secreted on an average, within my area of say six miles diameter. Next, of about how many colonies working in this field would give me the most surplus honey.

Both of the above problems are very knotty, and there is no doubt but that less has been learned, for the amount that has been said about them, than about any and all others, the wintering problem thrown in. All I can say is, notice that nearly all the large percentages of increase and surplus that are reported are from small numbers of colonies. We often see "from 10 to 70 colonies and 1,200 lbs. of surplus and how I did it," but we never see from 100 to 700 colonies and 12,000 lbs. of surplus, unless it ends with, "how I didn't do it."

The one who looks over the field must form the conclusion as to the best number of colonies to keep, for the best results, and then "cut and try" till he is satisfied.

Lay out a yard large enough to hold the maximum number of colonies you expect ever to keep in that locality, and put a tight board fence around it, 6 or 8 feet high, and if in an exposed position to thieves or meddlesome boys, run 2 strands of sharp barbed wire all around over the fence, about 8 inches above the fence, and the upper one 10 inches above the lower one. Make at least four gates, and one capacious building on the south side of the apiary. This will give you a cool front, and you can see the bees fly, when swarming or otherwise, plainer against the northern sky. Have a well close to this building, and keep two extra pails and a Whitman fountain pump always in readiness, for any straggling swarms that come along, or any of yours that might attempt to abscond. The pump is *par excellence* to keep two swarms from mixing, that might come out together. With this pump, we one year caught two swarms that came along, that no other device could have arrested, besides stopping 4 of our own that attempted to leave us—all that tried to go that season.

Have the floor of your building of

dressed lumber, if you can afford it, matched, and of hard wood, at least under, around and about your extractor. Have that extractor fastened solid to the floor, and to the wall at one side. I much prefer the overhand motion of turning gear, and like the Excelsior the best of any machine I have ever seen on the market. Have a broad shelf, about 3 feet high handy to the extractor, and a drip pan for cappings. We have used one on the same principle, though smaller, as the one described by Chas. Dadant & Son, in back number of the BEE JOURNAL, with wire-cloth middle, and pan below to catch drips.

Many other details might be mentioned, but I will pass on to the hive for extracted honey. I know the hive question is one about which there is much prejudice, so I will "touch lightly" and simply give you my preferences. I would use the same hive (and have used it for taking honey in the extracted form) that I do for comb honey, viz: the 8-frame Langstroth. I have tried the 10-frame extensively for extracted, as well as comb honey, as I have also the one-story hive, and while I am aware that there are some strong points in favor of the one-story, yet there is, I think, more in favor of the 8-frame Langstroth hive. With the upper story for combs of the same size out of which to take all of the honey that we extract. It will be found unnecessary to go down into the brood-chamber, or hive proper, for surplus, if the arrangement is right. I have discarded metal rabbets for the hive, but for the super out of which we extract, I always use them, in conjunction with flat, wood top-bars, but never metal corners.

I think no sounder advice can ever be given than to say, use only the standard Langstroth frame, have all combs built on full sheets of worker foundation on wires. If you have all worker combs below you surely must have, or the queen will present you a lot of up-stairs drone brood. I always use a thoroughly perforated honey board (of a peculiar construction, which cannot well be described here), that is adapted to a super that is suited to the hive, without any honey board, as well as with. At first I sometimes, on some colonies, adjust the super without the board, but adjust the board the first time round to extract. The presence of this board also facilitates the handling of the frames wonderfully, and at the same time has a tendency to dissuade the queen from going aloft. In the hive I use 8 combs, within the space of $11\frac{1}{2}$ inches. In the supers of the same space (after the foundation is drawn out into comb) I use seven.

We now have the super ready, and supposing that some of the colonies and the field are ready for surplus storing, we lift the hive cover and adjust the second story or super; place the same cover on the super, and turn your pins in the surplus honey register, one to the date, and the other to "empty," and then wait patiently till time to examine it.

For the American Bee Journal.

The Foul Brood Disease—A Review.

A. R. KOHNKE.

For the last three years or so, I have been watching with great interest the discussions as published in the BEE JOURNAL, with reference to foul brood. Most or all of our knowledge how to cure this disease has come from Germany, based on unrefutable testimony, experiment and experience of bee-keepers in that country who took a special interest in this subject, not only as apiarists but as scientists, until after a protracted trial of several years, salicylic acid was pronounced the specific. Through the instrumentality of Mr. Muth, of Cincinnati, this knowledge has partly been disseminated in a general way, but his success in eradicating the disease in his apiary has thus far not supported his faith in the reliability of the remedy. For in reviewing the BEE JOURNAL of the last three years, we find him having one or more cases of foul brood on hand every year. This he attributes to contagion from outside sources. How far Mr. Muth may be correct in his supposition I have no means of knowing, but it is evidently based on the reappearance of the disease, after he had, as he thought, cured the diseased colonies.

I proceed rather reluctantly upon what I have further to say on this subject, because in the first place I am comparatively little known, certainly not as extensively as Mr. Muth is; second, the latter gentleman is a personal friend of mine, with whom I very much dislike to disagree, when I know that this may possibly rob me of his friendship. For this reason I have abstained from criticising his articles, hoping he would in time correct himself, for the benefit of all concerned.

But now to the prescriptions Mr. Muth gives: I quote from BEE JOURNAL of 1879, vol. 15, page 503, where he states that E. Hilbert used 50 grammes of salicylic acid and 400 grammes of pure spirits, which reduced by 50 gives 1 gr. of the acid to 8 of spirits, this he discarded, because he found it killed the larvæ and he had made up a different solution by his druggist, viz: 128 grains of acid, 128 grs of soda borax and 16 ounces of water, or reduced by 16—8 grs. acid, 8 grs. borax and 1 ounce of water. But in BEE JOURNAL of 1880, vol. 16, page 535, it is stated 16 grs. acid, 16 grs. borax and 1 oz. water.

Now it is evident that Mr. Muth has made some grave mistakes and the reappearance of the disease in his apiary may be caused as much from that as by contagion from outside sources, as I shall presently show.

1. The first solution of the acid in alcohol is too strong and his larvæ did not die from the effects of the alcohol but from an overdose of the acid; he states "1 drop of that solution into 1 gramme of water," as used by E. Hilbert, and in the next column "a small portion." What signifies a drop? Of alcohol it takes 138 drops to fill a fluid drachm, but only 45 drops

of water to do it. How much is "a small portion?" Is a physician warranted to use that expression in his prescriptions? Will it do for him to say take of arsenic or laudanum a small portion? The difference in size of a dose of calomel makes all the difference in the world as to the effects of it. Nobody need suppose that salicylic acid is as harmless to bees as some are inclined to believe. If used too strong in the feed for the bees, they will not take it, if weak enough so that they do not object to it, it may still be strong enough to kill the brood, as Mr. Muth found out, though drawing wrong conclusions. But let us proceed to his mistake number two.

2. In vol. 15 of BEE JOURNAL, the proportions are as 1 oz. water to 8 grs. of acid. In vol. 16 of the same paper they are as 1 oz. of water to 16 grs. of acid or double that of the first; in the first it is in the proportion of about 1 gr. of the acid to 57 grs. of water in the second 2 grs. of the acid to the same amount of water. As Mr. Muth refers to those in his other articles and essays on foul brood, which is the right one? I answer: Neither! This leads me to mistake number three.

3. Borax is borate of soda or two equivalents of boracic acid combined with one of soda. Now it is known that in liquid solution boracic like carbonic acid is a very weak acid and easily driven from its base, the soda, by others even such as acetic acid. To illustrate the process I subjoin the following diagram:

But sallylate of soda is entirely useless as a disinfectant, in fact any soda salt interferes with the disinfecting properties of salicylic acid.

If Mr. Muth had told the druggist for what purpose he wanted the solution, he would, perhaps, have been told the merits of that composition; but if he did, I am rather inclined to believe that it is an oversight of the druggist, forgetting that some remedies or medicines are incompatible.

If anyone should doubt my statements, I refer them to the article on salicylic acid, in the United States Dispensatory, 14th edition, 1877, page 1749 and 1750, where it plainly states that soda salts must be avoided to aid in dissolving salicylic acid if used as a disinfectant.

But what about the cure he effected? some will ask. I reply, a cure has never been effected, but Mr. Muth treated his diseased colonies to pure comb or foundation, and pure honey, by which a suppression of the disease was effected only for a shorter or longer period, after which a renewed outbreak made its appearance, as abundantly proven by Mr. Muth's admissions.

This explains also, why some claim not to have been successful with salicylic acid, as they probably used the method Mr. Muth recommended.

Besides the points taken above, there are others of as much importance, for instance the temperature of the solution to be used in sprinkling

the bees and brood; "lukewarm" is a vague expression, but 70 or 80° Fahr. everybody can find out what that means. This article is longer than I intended it to be and I will close it for the present.

Youngstown, O.

For the American Bee Journal.

The One-Piece Sections.

JAMES FORNCROOK.

MR. EDITOR.—In *Gleanings* for January the following editorial paragraph appeared. It reflects upon me, and classes me with N. C. Mitchell, and I would ask space in the BEE JOURNAL to reply thereto, and to set myself right. Mr. Root says:

FORNCROOK'S PATENT ONE-PIECE SECTIONS.—Out of respect to friend Forncrook we have permitted the advertisement to go in as you see it, although it does seem as if he were getting very close to our friend Mitchell, in claiming all section boxes made of one piece of wood. I have pointed him to a letter in *Gleanings*, describing one-piece sections, made and used several years ago; but his reply was to the effect, that sections made of strawberry-box stuff are quite another thing. This amounts to saying, as I see it, that a rough box is not patented; but if you plane it, or sandpaper it, you are infringing. Do you say that a patent has been granted him? Very likely; but so has a patent been granted on the foundation we are using; on putting it on to wires; on division-boards for bee-hives, and also on the very tin separators we are using, and have been using for years. The Patent-Office supposed all these things were new, and are doubtless honest; but, friends, is it in anyway likely they have a man in the whole Patent-Office corps who has an idea of modern bee-culture? A proposal was started, at the convention, to raise a fund for mutual protection, if any of our number should be subjected to expense; but I trust nothing of this kind may be ever necessary. Mr. Forncrook proposes to make all bee-keepers pay \$6.00 per thousand, instead of the established price of \$4.50.

The letter Mr. Root refers to is in *Gleanings* for April, 1876, and is as follows:

SECTION FRAMES AND HONEY BOXES—Friend Root: I see by *Gleanings* for March, that J. I. Johnson, Palmyra, N. Y., asks a preventive of bees running the combs together in section boxes. I will tell you what I did last summer, and it worked to a charm. I had 8 colonies of bees in double hives, my own make, Quinby suspended frame, 20 frames in hive. I made 100 lbs. box, 150 in sections, and 50 extracted honey. I live on a public road, and people constantly passing wanted a few pounds of honey; of course they had nothing to hold it. Well, I thought about a section box; I could get nothing to make them of easily, so I got some peach box covers and some strawberry box stuff, and ripped them up in one-inch strips (I

suppose you know how a strawberry box is, cut half through at each corner and nailed at one side, but the *veneer* must be wet over night before *bending*; it then works nicely). I then put a piece of comb in the top, 1 inch square (would prefer drone comb if white) in some I struck little bits of wax along the under side of top. When filled they weighed from one to two pounds each. Only two sections out of the 150 lbs. were connected. I sold all my honey at the house, for cash, comb honey 25c., extracted 20c. I had more demand for the little sections than any other. I put the sections in the frames both front and back of the hive. I think the comb foundation for the sections, a grand hit. One colony made 90 lbs. comb honey. Besides the 300 lbs. honey, I had 6 swarms from the 8 colonies, making 24 all in good order, to start with this spring. ALEX. FIDDES.

Centralia, Ill., Mar. 8, 1876.

Mr. Root sent us the above extract, and stated that the one-piece section was mentioned in the first edition of Cook's Manual, but when pressed, he could not find it. At the Convention at Battle Creek, Mich., last December, Prof. Cook admitted that the berry box section was not of practical use for shipping honey in.

Three years ago Lewis & Parks sent a sample of our one-piece section to Mr. Root, and in *Gleanings* for February, 1879, he remarked as follows, concerning it:

"Their new section box will not come under this criticism for although it is more work to make than ours, it is a most decidedly neat and finished job when done. They apply the same idea to making boxes, and if any want these in place of sections, they are most decidedly the handsomest honey box for the money which I ever saw. As the principle is evidently no secret, I will give it here. I made a few sections on nearly the same plan, as much as 3 years ago but discarded the plan as being too much work."

In the above extract Mr. Root admits that it is new, when he calls it their "new section box," and says "I made a few sections on nearly the same plan, as much as 3 years ago, but discarded the plan as being too much work." He discarded it, probably, because he had not the ingenuity to perfect it, and now it has been perfected, he would like to claim it as his idea, when, it is safe to say, he never thought it *could* be perfected.

His discarding or abandoning the section shows that he did not consider it practical. All the Patent Office wants to know about any invention is: "has it been in public use two years prior to the date of the application?" Because a man or a half-dozen men put some strawberry boxes on their hive, and had them filled with honey, does not prove that sections made of "one-piece" were in public use. Mr. Root's assertion that because we have planned our section, we have patented it, is too silly to reply to.

He says we propose to make bee-keepers pay \$6 per thousand instead of the established price of \$4.50. Who

established this price? Mr. Root did not. He never reduced the price until he was compelled to by others coming down. We reduced the price of sections and there was a good living profit then; but, as everybody knows, basswood has since advanced at least one-third.

In *Gleanings* of December, 1877, Mr. Root advertises thus: "Section boxes in the flat by the quantity \$9.50 per thousand and upwards, according to size." Why did he not then have interest enough in bee-keepers, to reduce the price to \$4.50? They could be made as cheap then as now.

The true reason of Mr. Root's opposition is this: He has been manufacturing one-piece sections, and selling machines to make them, which our patent now prohibits him from doing.

Mr. Root is the wrong man to class anyone else with N. C. Mitchell. He said he inserted our advertisement "out of respect to Mr. Fornerook." Why should he *respect* a man whom he publishes as a swindler and classes with Mitchell?

Watertown, Wis., Jan. 16, 1882.

[We give place to the above communication, simply to let Mr. Fornerook define his position, and that he may be understood aright, having been publicly classed with Mitchell, etc.]

When the Commissioner of Patents ordered the taking of testimony in the case of interference, the editor of the BEE JOURNAL was summoned as a witness against Mr. Fornerook, and in testimony gave a history of the use of section boxes for honey, and produced the first efforts of quite a number of inventions—the berry box, the section of Mr. T. T. Delzell and some others—and the Commissioner of Patents decided that none of them were competent to debar the issuance of the patent—and accordingly ruled them out. These points were then thoroughly tested, and we can see no use now of bringing up a point already decided, especially as, so far as we can see, the patentees do not intend to use their patent to defraud bee-keepers, or make them unnecessary trouble.—ED.]

The Cultivator.

Report from my Apiary.

W. Z. HUTCHINSON.

Perhaps some of your bee-keeping readers would be interested in a report from my own humble apiary. I was not one of the fortunate ones, as, during last winter, I lost nearly all my bees. It was with difficulty that I obtained money with which to buy more bees; while to find bees to buy, unless at exorbitant prices, was an equally difficult task. All the colonies purchased were either in box

hives or else in movable comb hives having frames that differed in size from mine; hence all had to be transferred. June 1st, I found myself the possessor of 18 fair colonies. The weather continued so cold, that queen-rearing operations were not commenced until nearly a month later than usual. White clover began opening its blossoms about the first of June, and although it was so abundant that many fields reminded one of a snow-drift, yet the weather remained so cool that but little surplus was gathered until the latter part of the month. The yield was quite fair from about June 27th until about July 8th, when the white clover was deserted for the fragrant, bounteous basswood. The yield from basswood was fair, but that from fall flowers was cut short by the drouth. I reared and sold 263 queens, doubled the number of my colonies, and obtained 1,100 pounds of extracted honey. I keep an exact account with my apiary, and estimating the colonies that I now have on hand (28) at \$5 each, my profits have been \$15.43 per colony.

To help solve the wintering problem, I am trying several experiments. Some of my colonies have been deprived of their natural stores, and have been fed A coffee sugar. Others have been given early-gathered honey, while others have been left wholly undisturbed. Eleven colonies were protected, by different methods, and left upon their summer stands, ten were buried in clumps, and seven were placed in the cellar. Next spring I will tell your readers how my bees wintered, and which method gave the best results. I am glad to add, in conclusion, that, although the production of honey is steadily increasing, it is no longer a drug in the market. It never could be so readily disposed of as at the present time. Large quantities have already been sent to Europe, while the indications are that the foreign demand will largely increase, and that honey will eventually become nearly as staple a product as the biscuit and butter with which it is eaten.

Genesee County, Mich.

Prairie Farmer.

Preparing Bees for Winter.

MRS. L. HARRISON.

There are some things, with reference to wintering bees, upon which bee-keepers differ; but all agree upon these two points, that in order to be successful, young bees should be raised late in the fall, and plenty of well ripened sealed honey, accessible to them at all times. In this locality last year, the flow of honey lasted until the middle of October, and was so abundant that the brood chamber was filled with it, to the exclusion of brood. Consequently the bees forming the colonies at the commencement of cold weather, were old and feeble, and had worn themselves out, gathering the heavy fall harvest.

By reason of the long continued drouth, we find that honey is not en-

croaching upon the brood chamber at the present time, but it is filled with young of all sizes. Therefore, there will be plenty of young, vigorous bees, with meager stores. Late swarms, either natural or artificial, should be examined, in order to see if they are gathering sufficient to keep up breeding, and if they are not, they should be fed. The value of bees have very much increased, by reason of the heavy losses of last winter, and even should the coming season prove to be a mild, and successful one, they will be in demand, as the past summer was not favorable for their increase. We have often noticed that the small colonies, that we were petting all the fall, were our very best the following summer.

In order to rear brood, food should be given sparingly, so as not to have it stored in the brood apartment, but when feeding stores for winter, it should be given abundantly, as fast as bees will store and seal it. A person must be governed by his locality, as to the time when winter stores are given—some feed as soon as frost kills the flowers, and recommend throwing out all unsealed honey, and feeding a syrup of granulated sugar.

We have been strengthening our weaker colonies, by taking two or three frames of brood from the strongest, and giving it to them. In place of the removed brood, good worker comb was placed, and the colony fed at night with extracted honey. When we first attempted to remove these brood frames, we were compelled to beat a retreat, but after feeding for a night or two, they were on their good behavior, and as civil and polite as a dancing master.

Before opening a hive, when honey is scarce, it is well to take the precaution of feeding a little for a few nights, and opening it early in the morning or late in the evening, when few robbers are on the wing. As we had not feeders enough to go round, we followed the advice lately given by a bee-keeper, of using small tin pans covered with thin muslin, and tied under the rim, so bees cannot get under it. These feeders are a success, when the muslin is tied loosely, it will settle down as the bees remove the feed, and no bees get drowned.

Peoria, Ill.

For the American Bee Journal.

Prof. Cook on Pollen and Fæces.

WM. F. CLARKE.

If I tackled Mr. Heddon with diffidence, it is with fear and trembling that I presume to break a lance with Prof. Cook. But, high authority as he is, justly, among bee-keepers, he is not infallible, and I am sure does not wish to be so regarded and treated.

I have read with considerable astonishment the Professor's article copied from the *Rural New Yorker* into the BEE JOURNAL of Jan. 11th, and headed, "Pollen in the hive in winter," and beg, with all due modesty, to set forth the points of my astonishment. At the outset, the

Professor specifies a few statements made by him in the bee periodicals, and in his "Manual of the Apiary." They are as follows:

1. "That the old bee could live for long periods without pollen."

2. "It is to be presumed that the old bees need, and do eat some pollen during the active season."

3. "That pollen is an indispensable requisite to brood-rearing; that it is an essential element in the food of larval bees."

As a "scholium" under this last proposition, the Professor tells us he has "expressed the opinion that in some conditions, the presence of pollen in the hive in winter is a positive injury, and that, in all cases, it is unnecessary." An emphatic remark is then added, "that this pollen is more valuable as soon as the bees commence to fly the following spring, and then any frames that contain it should be given to the bees."

My astonishment began to burst forth when I read the next sentence, which I take the liberty of italicising: "*These facts have lately been called in question by several writers.*"

Now, I am not aware that any of the above stated positions have been lately called in question, except the one styled by the Professor "a scholium." By the way, it is hardly "a scholium," which means, according to the dictionary, "annotation, an explanatory note." I think it is an independent proposition. As I am one of the "several writers" referred to, let me say, I call in question only the "scholium." Nay, I have hardly called that in question. I have represented it as "not proven." I have certainly called in question Mr. Heddon's position that pollen is the cause of dysentery, but that is a far more sweeping statement than the one made by Prof. Cook.

My astonishment was considerably increased when I read a little further on the following allusion to *somebody*. "One writer, however, who, whatever else may be said of him, puts forth very original ideas, and contradicts nearly every well-grounded fact in apiculture, calls for proofs." I said to myself, as I read that over and over again, "can he mean me?" "Puts forth very original ideas." Well, that's highly complimentary, but I can't claim any originality; I'm but a humble disciple of Langstroth, Quinby, Cook, and other great authorities in apiculture. "Contradicts nearly every well-grounded fact in apiculture." That isn't me; "sartin, sure." If I contradict *any* "well-grounded fact in apiculture," I don't know it. Neither do I know any writer in the bee periodicals of whom his sweeping assertion is true. Who is it? "Calls for proofs." Well, that's me. I am in the habit of doing that on every subject, even the subject of religion. And, surely, Prof. Cook will not make it a ground of complaint against any man, that he "calls for proofs."

I have called for proofs that pollen is the cause of dysentery, and that it is injurious to adult bees. I am calling for these proofs yet, after carefully reading Prof. Cook's article. All

that the Professor undertakes to show, is "that bees are often better off with no pollen in winter." He adds, "*Perhaps, too, they take some of the nitrogenous food, and as a result, become diseased and die.*" So long as that "perhaps" sticks there, I shall keep calling for proofs.

It may be "that bees are often better off with no pollen in winter." This is probably true as "often" as there is an unusually mild spell in mid winter, such as the Professor describes, leading to premature breeding.

I can assure the Professor and all others, that I never write for the mere sake of controversy. My aim is to elicit facts—to come at the truth. In order to do this, I want not theories or opinions, but proofs. I propose to keep on calling for these, until they put in an appearance.

Prof. Cook tells us he has for several winters given one-half his bees pollen, and the other half none. In all cases, it has happened that the bees without pollen had no brood in the spring, while in the rest he says, "we almost always found brood." Is it considered a detriment to a colony to have brood started at the end of winter? I ask for information. I may be an old fogey and all behind the times, but I have always regarded it as one proof of a colony being in "good order and condition," and having wintered well, when there is more or less brood in it, especially *more*, at the opening of spring. It may be, I have never denied it, but only called for proofs—that it is better to deprive colonies of combs containing pollen, when preparing them for winter, but if so, it will add considerably to the labors, quite abundant enough, of beekeepers who have large apiaries.

I am not a chemist, and cannot pretend to discuss "hydro-carbon," "nitrogen," etc., with the Professor, yet I may venture to remind him that pollen is not only nitrogenous, but carbonaceous, albuminous, etc. It is good for young bees, like "milk for babes," and as milk isn't bad for adult men and women, perhaps pollen may not be bad for mature bees. Who knows? The fact that they *can* do without it, does not prove that they are better without it. Bees *can* do without honey, and live on sugar syrup, but most of us would rather see our hives well stocked with honey in the fall, than be under the necessity of feeding artificially for winter supplies.

There is yet another sentence in Prof. Cook's article which I read with astonishment. It occurs toward the close. He says, "I have never found any support of the theory of the late Mr. Quinby, that bees secrete a dry powder in winter." I am greatly surprised to find the Professor calling this idea into question. But, stop; perhaps like the original and heterodox individual he refers to in the former part of the article, he only "calls for proofs." Well, L. C. Root, p. 254, "Quinby's New Bee-Keeping" adduces proofs, and says, "Careful observations by others, as well as myself, confirm the truth and importance of his (Mr. Quinby's) conclusion." Has Prof. Cook tested this matter by

the little experiment suggested by Mr. Root, or by chemical analysis?

Searching for what information I could in regard to the excreta of bees, I find that Dr. Donhoff's analysis gives "one-third uric and hippuric acid, and the residue of indigestible portions of pollen." Has this analysis ever been corrected? If not, how does the no-pollen theory square with it? I don't know whether the excreta analyzed were summer or winter, normal or abnormal, but, anyhow, here is a doctor of no mean repute, who states that these excreta contain two-thirds "of indigestible portions of pollen."

My library is not extensive; I am not a professor either of entomology or chemistry; the study of apiculture can only be with me a species of knitting-work, filling up the interstices of leisure woven into a very busy life; and I assure "my learned friend," that I write these things as a docile disciple, rather than as a dogmatic teacher. I am one of a very big class, gathered every week in the school of the AMERICAN BEE JOURNAL. We are not much past "the A. B. C. of bee-keeping," and if this article moves the Professor to give us a lecture, many others will be thankful for it as well as myself.

Listowel, Ont., Jan. 14, 1882.

Local Convention Directory.

1882. *Time and Place of Meeting.*
- Jan. 24, 25—Indiana State, at Indianapolis, Ind.
- 25—Northeastern, at Utica, N. Y.
Geo. W. House, Sec., Fayetteville, N. Y.
- Feb. 8, 9—N. E. O. & N. W. Pa., at Jamestown, Pa.
W. D. Howells, Sec., Ashtabula, Ohio.
- 9—Northeastern Maine, at Dexter, Maine.
- April 11—Eastern Michigan, at Detroit, Mich.
A. B. Weed, Sec., Detroit, Mich.
- 25—Texas State, at McKinney, Texas.
Wm. R. Howard, Sec.
- 26, 27—Western Michigan, at Grand Rapids.
Wm. M. S. Dodge, Sec., Coopersville, Mich.
- 27—Kentucky Union, at Eminence, Ky.
G. W. Demaree, Sec., Christiansburg, Ky.
- May — Champlain Valley, at Bristol, Vt.
T. Brookins, Sec.
- 25—Iowa Central, at Winterset, Iowa.
Henry Wallace, Sec.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

The Northeastern Bee-Keepers' Association of Maine, will hold its second annual meeting at Grange Hall, Dexter, Me., Feb. 9, 1882. An invitation is extended to all persons interested in bees and honey, to attend, and bring their pet bee hives, smokers, extractors, etc., that we may compare the merits of each different kind. The President will give an address, and we shall hear the Secretary's report, and elect officers for the ensuing year. Wm. Hoyt, Sec.

Translated by A. R. Kohnke.

Austro-German Convention.

The Austro-German Convention met at Erfurt, Sept. 5-8, 1881, and was probably the largest in the world, being attended by more than 700 beekeepers from all parts of Europe.

One of the first actions of the Convention was to elect Mr. Vogel, of Lehmannshoefel, near Cnestrin, Permanent Vice President of the Association. Having paid due homage to their deceased members, especially, their former Vice President, A. Schmid, Von Berlepseh and others, and disposed of other matters of minor importance, the debate was opened by Dr. Dzierzon, who remarked that the practical part of bee-keeping had made wonderful progress since the days of Aristotle and Virgil, as also the theories or natural history with reference to the bee, but there were still some mysteries left unexplained, for instance, What is it that transforms a worker bee larva into a queen? Does it depend on the quantity or quality of the food? He supposed it to be the latter;* for, whenever royal jelly was transferred from a queen cell to a worker cell containing a larva, the bees would invariably enlarge that cell to rear a queen.

Another question to be answered was: When and how are workers qualified to lay eggs sometimes, even in colonies having a good queen? A third point was to the speaker not yet perfectly clear, viz: The preparation of royal jelly to feed larva and queen.

Mr. Vogel answered this last question, referring to Dr. Leuckart's and V. Siebold's investigations,† stating also that royal jelly stood in the same relation to the bee, as the milk to mammals, viz: being a secretion of certain glands. Queen larva got this exclusively as food, while worker bee larva obtained that only during the first 5 or 6 days, and before sealing the cell containing the same they are provided with a store of honey and pollen.

Rev. Rabbow mentioned another point not yet explained, viz: What is the cause that on crossing two different races of bees, for instance, German drone bee and Italian queen, the progeny of such a queen is at the beginning purely Italian, then purely German, and finally mixed?

Mr. Ilgen mentioned another mystery, viz: Why do young queens suddenly become barren, after having been very prolific? Exhaustion by over-exertion and exhaustion of sperm in the seminal sack were given as reasons, and concurred in by Hilbert and others, who also said that instead of sending money to foreign countries for bees and queens, the latter of which arrived very often in an injured condition by rough handling during transportation, over which the shipper had no control, the beekeepers should aim to improve the

stock they had, by selecting first-class colonies to breed from, and if beekeepers in Germany had to buy queens, to get them of bee-keepers or queen-breeders of Germany who were reliable, and were known for the purity of their strain of bees.

Messrs. Lehzen, Gravenhorst and others concurred with reference to using perforated zinc to confine the queen to a limited number of brood-combs, their experience being that the use of the same was injurious—1st. Because loaded bees on coming home would with their load go to the brood-combs first, trying to find room in or near there to deposit the gathered stores, and only after a vain effort would return to the honey department; this consumed some time and tired the bees, hence proved to be a loss instead of gain. 2nd. Bees or colonies, where the queen is thus confined, are not as industrious as others where that is not done.

The next question considered was "the value of the different races of bees." Those considered were the Cyprian, Syrian, Egyptian, and especially the Caucasian bee. Mr. Hilbert opened the discussion by saying that with reference to the Caucasian, their character ran to extremes. The pure race, as imported, could hardly be induced to sting being very docile, 2d. They were extremely lazy. 3d. Very poor breeders, beginning later in the spring and stopping sooner in the fall, than any other race. (Mr. H. experimented with 5 Caucasian colonies). But on rearing queens from such an one, this second generation, or cross between them and any other proved to be indefatigable fighters, excelling in this respect the Cyprians by far; besides that, the pure race, as lazy as they are, are born robbers, attacking the strongest colonies. As to Cyprians, he said they were very prolific, good honey gatherers, but when he wanted to take the honey from such a colony, they would most of the time get the better of him, stinging everything coming within their reach.

Mr. Vogel, in stating his experience with 12 pure Caucasian colonies, said that his colonies in the spring of 1879 built up very well, in fact, better than any others, and were his strongest colonies in July, but—no honey. Could not be induced to sting on the hottest day, or when queenless. They wintered very well from 1879 to 1880; in the spring of 1880 developed the same as before—hives being choked full of bees and brood in July, but no honey.‡

Getting rid of those he had, he sent for 4 others, from the same source, 2 of which proved to be the very opposite of what he had had before. In the fall they were very populous and heavy with honey. In color they were almost identical with the Italians.

Mr. Dathe, Jr., said that a cross between the Caucasian and German bees produced very irascible bees.

* It is rather surprising to observe a doubt about this matter with an old, experienced bee-keeper, as Dr. Dzierzon is, after the investigations of V. Siebold in 1872.—TRANSLATOR.

† The salivary glands of the bee by Siebold, 1872.—TRANSLATOR.

‡ There seems to be a limit to prolificness, as stated in my article on "coming bee" sent to the AMERICAN BEE JOURNAL. Those bees probably used up all their honey they gathered, to rear brood.

Mr. Haas, St. Petersburg, Russia, from whom all these queens and colonies had been obtained, admitted the robbing propensities, docility, excessive breeding, and consequently, little honey. His bees were confined 218 days during the cold winter weather.

Mr. Hilbert remarked that the color of the pure Caucasian was a dark gray, and not like the Italian, to which he did not get an opposing reply.

Mr. Vogel claimed that a race or strain of bees may be pure without preserving the color of the queen or colony bred from because such a constancy did not exist in nature; nature was not encased in an iron jacket, but changeable.

Mr. Walther substantially admitted the points Mr. Hilbert stated.

Dr. Dzierzon said that he was the first who imported Italian bees into Germany, and wherever the purity of the race had been preserved, they had always been observed to be more serviceable than any other, being more docile, prolific and good honey gatherers; as a criterion, on first sight, he would consider the color. To this last remark Mr. Hilbert objected, as Cyprians were better colored, but worse to handle.

Rev. Deidreht claimed that there was no constancy of color with Cyprians.

The next question considered was, how to insure successful and profitable bee-keeping in Germany. Beekeepers there claiming, that on account of the large importation of adulterated honey [I suppose, glucose—Translator.] they could not sell their honey at a reasonable figure, and it was resolved to petition the government to raise the duty on all imported honey and wax, from 33 cents per 100 pounds, as it has heretofore been, to \$2.25 per 100 pounds for honey, and for wax, from 88 cents to \$4.50 per 100 pounds. United States money and weights. Several bee-keepers claimed to have traced foul brood to American honey, where bees had had access to empty honey barrels, the contents of which had been used by confectioners. Having discussed this question in all its bearings, the Convention adjourned to meet next year in Wiener, Austria.

[It seems to me our German bee-keeping friends are very unreasonable as to prices obtainable for wax and honey, for one bee-keeper says, five years ago he got \$1 per pound for wax, and now he cannot get more than 22 cents. That is still more than we can get here, leaving out of consideration that one dollar goes much further in Germany than in this country. So also for honey, they ask for buckwheat, in comb, 18 cents, can any bee-keeper in this country ever get such a price for such honey? When they object to adulterated honey they are perfectly right, and it seems to me to be within the jurisdiction of Congress to forbid the exportation, sale or manufacture of any sweet under any other but its real name, as it injures a large trade in honey and wax. The beekeepers of this country will soon feel

the duty imposed upon honey by the German government. The attention of the Imperial health office in Germany has been called to this fraud, after having it forbidden in Germany, they will next likely forbid importation of that stuff called glucose or manufactured grape sugar, and adulterated honey in any shape, especially if they regard foul brood as having been imported from this country.—TRANSLATOR.]

SELECTIONS FROM OUR LETTER BOX

Flights in Winter.—Is it indicative of the normal condition of a colony of bees in the cellar, with mercury at 40°, to continue a humming sound? 2. Is it better to give them a fly in the open air, if the temperature is right, once or twice during the winter? I have thought they might become so thoroughly aroused as to consume a large amount of honey, also cause the queen to commence rearing brood, which must perish before maturity.

W. WAKEFIELD.

St. Paul, Minn., Jan. 13, 1882.

[1. The humming noise should be almost inaudible; but we doubt if they are ever perfectly quiet when in a normal condition.

2. We would, by all means, give them one or two good cleansing flights, if the temperature is suitable, allowing them to remain outside until they become quieted from chilling, when they can be put back in the cellar without damaging results. During the few days in winter when they can fly, the queen cannot be induced to deposit eggs enough to work any harm, or to cause an unusual consumption of honey.—ED.]

Syrian Bees.—Please give a description of the Syrian bee in the JOURNAL, and address of some one who has them for sale. OTTO S. DERRY.

Portland, Mich., Dec. 31, 1881.

[The Syrian has been several times described in back numbers of the BEE JOURNAL. For names of dealers, see our advertising columns.—ED.]

What Ails my Bees?—Last winter my bees nearly all died, with plenty of honey; this winter, they come out of the hives and do not go back. Every morning I find numbers of them lying in front of their hives. They are on the summer stands, raised up $\frac{1}{2}$ inch, with small blocks. Last night about five inches of snow fell, and this morning you could see dead bees lying all around on the snow. The hives feel heavy, and they certainly must have honey, as they were all fed until very late in the fall. What is wrong? and how can I remedy it? They never acted this way before.

They seem to come out of all; I have 14. SAMUEL M. LILLEY.
Montgomery Sta., Pa.

[Those are old bees, most or all of which come out of the hives to die. It is better they should come out and perish, than remain to die in the hives before spring.—ED.]

Timber for Sections.—Will you please state whether honey in one-lb. sections, made of basswood lumber, sells as readily and at as high a price as the same quality of honey in the same size sections made of poplar. It is claimed by those having the poplar sections for sale, that honey in them will sell for 2 cents a pound more than if in basswood. W. N. HOWARD.

St. Johnsbury, Vt., Dec. 30, 1881.

[It is certainly a mistake; basswood makes quite as pretty and durable a section as poplar, when nicely dressed and sand-papered.—ED.]

My First Year's Experience.—One year ago I put 10 good colonies of bees in the cellar; 8 of them came out in good condition last spring; 2 were weak in numbers, but plenty in stores. I increased to 20, bought 3, and one came to me. I took 1,500 lbs. of extracted and 30 lbs. of comb honey. I put in the cellar 24 good colonies in good condition on Nov. 5.

SAMUEL SANDERSON.

Glenallan, Ont.

Box-Hive Men not Progressive.—There are but few who keep bees in this section; which are kept mostly in box hives, and it seems almost impossible for such persons to change their opinion in regard to hives and management of bees. At our county fair I exhibited honey, and distributed copies of the BEE JOURNAL among those who were interested in bee-keeping. I hope that I may derive as much information from the BEE JOURNAL during the coming year as I have the past.

THEO. D. THOMAS.

Pleasant Valley, N. Y., Jan. 16, 1882.

Well Satisfied.—I have kept bees for 13 years, beginning with 3 colonies, and have had varied success. I now have 130 colonies. Last year was a famous season for honey, the white clover being simply immense. I do not get as much honey as some of whom we read in the BEE JOURNAL, but I assure you I had a large quantity last fall. I am satisfied if I get 40 lbs. of box honey per colony. I have so much farm-work to do that I cannot run my bees just as I would like to, but you never saw a nicer bee-yard than mine. ABRAHAM HUNT.

Rodman, N. Y., Jan. 9, 1882.

Fall Honey for Winter.—Bees are wintering well, so far, in this locality. The weather has been mild, and the prospect is good for an early spring. The bees gathered enough honey last fall to winter on, from buckwheat and wild flowers, which was rather

better than was supposed, being so dry last fall.

GEORGE COLE.
Freeport, Ind., Jan. 14, 1882.

Moving Bees over Rough Roads.—In the BEE JOURNAL for Jan. 11, page 29, I notice A. L. Etherington inquires in regard to moving bees over rough roads. I have had some experience in that line, and will give my views of it. Wait until warm weather, remove all combs containing honey, fasten the remaining combs securely so that they cannot jam against each other and mash the bees, remove the top of the hive and cover at least $\frac{1}{2}$ of the hive with wire screen, giving them all the fresh air they need (and that is a good deal,) load then into a wagon that has springs enough to ease off the hard jolts, put some straw under them, place them so that the frames will be *cross-wise* of the wagon, and wedge the hives in tightly, so that they cannot bump against each other, and they can be moved with perfect safety. If the heavy combs of honey are left in the hives they may break down and nearly ruin the bees. The combs of honey can be packed in empty hives (close together) and there will be but little danger of their breaking down. CHAS. E. MCRAY.
Canon City, Colo., Jan. 14, 1882.

Bees in Sawdust Cellar.—I have 47 colonies in a sawdust cellar with chaff cushions over the frames. The entrance is left open—should it ever be stopped with wire cloth? The honey season was good in this part of New York.
A. BURRILL.
Cuba, N. Y., Jan. 12, 1882.

[Do not stop the entrance with wire-cloth; but few contingencies can arise when it will be an advantage—never when everything is in proper condition. Often serious damage may be done by closing it entirely.—ED.]

White and Sweet Clovers.—I sowed twenty pounds of sweet clover seed last November, and am thinking of sowing some more in the spring, on ground that I will seed to oats. How would it do to sow white or Dutch clover with the sweet clover, for early summer pasture, for the bees, or would the sweet clover be likely to kill the other clover? If both would thrive on the same ground we could have bloom from the middle of May until frost.
W. H. RAFTERY.
Pittsfield, Ill., Jan. 19, 1881.

[But little, if anything, will be gained by sowing white and sweet clover together. The latter will yield a more abundant stock pasture than the former, will bloom almost or quite as early, will yield triple the honey bloom, and will last the season through. The honey is quite equal to that from white clover, and bees will neglect the white clover to gather it. Again, neither will bloom till the second season to any extent, so there will be no advantage gained on that

score. We think eventually, with the least encouragement, the sweet clover would take full possession of the field, and the bees would rejoice with you over the "survival of the fittest."—ED.]

Bees in Maryland.—My bees went into winter quarters on their summer stands, with quilts over the frames, early in October, in very good condition. They flew on twenty days in December; their last flight being on the 28th, since which the ground has been frozen. It was snowing last night, and also to-day. I am greatly pleased with the JOURNAL and think it worth very much more as a weekly than its relative cost.

A. DREVAR.
Annapolis, Md., Jan. 6, 1882.

Bricks as Absorbents.—In my letter published in the BEE JOURNAL for Jan. 11, 1882, I wish to make this correction: where it speaks of two dry "blocks" it should have read, *two dry bricks*. These I put in to absorb the moisture in the hives, in connection with the quilts.

O. B. SCOFIELD.
York, Maine, Jan. 16, 1882.

How to get Dead Bees out of Combs.—Stand them, one in a place, where mice can get at them, and where nothing else will bother them. As fast as the mice clean them, take them away and put others in their place until you get all your combs cleaned up. I think mice are the best machine for this purpose.
M. H. MILSTER.
Frohna, Mo., Jan. 19, 1882.

Doing Nicely.—I have 30 colonies of bees in the cellar since Nov. 15 last, and they appear to be wintering well. I ventilate my cellar with a 6-inch pipe running under ground about 25 feet to the outside, and from the bottom of my cellar I have a 4-inch pipe leading into a chimney, so that I can regulate the temperature reasonably well; also have 15 colonies of D. Daninher's in the same cellar. I wish the BEE JOURNAL abundant success.

JOHN CORSCOT.
Madison, Wis., Jan. 20, 1882.

Merits of Hives for Wintering.—In August, 1880, I bought 1 colony of Italians which I wintered in the cellar; in 1881, I increased to 5, took 20 pounds of honey, and got the bees in good shape for winter. In September I bought 4 colonies more. In October I put the quilts on top of the frames. In November I put the hives in rough boxes, gave them entrance through the rough boxes, packed all around the hives with chaff, giving them ventilation by putting blocks under the lids or tops. Last week I examined them to see if they had enough ventilation. The bees were stepping around on the upper edge of the combs most beautifully indeed. On December 28, I bought and brought home 6 colonies of black bees which I

packed the same way, but they have taken no flight yet; the weather turned cold the next day and has been too cold for bees to fly ever since. Please answer the following questions. Is there any difference in wintering, better or safer, on the Langstroth or the American frame—that is, will they cluster nicer and in better shape in real cold weather, if the hives are packed, ventilated, and a quilt over the frames, all just alike, the colonies being about equal? Is there a patent on the N. C. Mitchell hive? Please excuse all mistakes. A. F. YODER.
Goshen, Ind., Jan. 14, 1882.

[You will probably observe no difference in the wintering of the bees, whether in Langstroth or American hives, provided, as you say, all are "packed, ventilated and a quilt over the frames just alike, the colonies being about equal." Last winter, which was cold and long enough to furnish a test for almost any reasonable man, demonstrated that there was but a trifling percentage of difference in the two styles as to success in wintering. The only feature patented about the so-called Mitchell hive was the peculiar construction of his division-board, which consisted of cloth, rubber or paper binding on the ends.—ED.]

Dodge's New Feeder.—I have, by a long series of experiments and close observation, become satisfied that but a small portion of the colonies lost in wintering freeze to death, but starve, on account of their stores becoming inaccessible in cold and frosty weather. As the heat naturally rises above the cluster, it often happens that a colony starves to death with plenty of honey within a few inches, but inaccessible on account of frost and cold in the remoter portions of the hive. I think that thousands of colonies might be saved annually from this cruel fate, and loss to their owners, were the proper means provided that would enable them to reach a proper amount of food at all times, and in a temperature corresponding with that of the cluster. In presenting my feeder to the bee-keepers of America, I claim to have accomplished the following objects: 1. I place the feed directly over the cluster, and accessible at all times, in a temperature corresponding with that of the interior of the hive; 2. It feeds equally well summer or winter; 3. It feeds with equal facility, syrup, candy, sugar, comb honey or extracted, or any suitable bee-feed; 4. It feeds without disturbing the bees; 5. It can be covered and nicely tucked in with the quilts or chaff cushions without any escape of heat; 6. It is a perfect upward ventilator, and consequently an absorbent of moisture, keeping the cluster dry at all times, and when not required for top feeding and ventilation, is equally as effective for entrance feeding. U. E. DODGE.
Fredonia, N. Y.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII. Chicago, Ill., February 1, 1882. No. 5.

THE AMERICAN BEE JOURNAL

Published every Wednesday by
THOMAS C. NEWMAN,
 EDITOR AND PROPRIETOR,
 974 WEST MADISON ST., CHICAGO, ILL.
 At \$2.00 a Year, in Advance.

Remit by money-order, registered letter, express or bank draft on Chicago or New York, payable to our order. Such only are at our risk. Checks on local banks cost us 25 cents for collecting.

Free of postage in the United States or Canada.
 Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

The Future Prospect.—The editor of the *Bee-Keepers' Magazine*, says:

In nature, as well as in almost all things, one extreme is apt to be followed by another in the opposite direction, and judging from this standpoint we may expect nature to favor bee-keepers in 1882.

Unfair Copying.—We are always glad to have our Exchanges copy articles from the BEE JOURNAL; still more to have them endorsed by those who copy them; but when they get so enthusiastic as to copy them without giving the BEE JOURNAL due credit—thus palming them off for their own production—it is a little "too thin." We have noticed scores of our articles thus copied, going the rounds of the agricultural papers, credited to some other periodical, because some one desiring honestly to give credit, mentioned the paper from whom it was last taken, after being stolen from the BEE JOURNAL. An Indiana paper copied our editorial article on "Sweet Clover in Colorado," from page 20, but failed to give any credit. A Baltimore paper, a few weeks ago, had a column article, copied, word for word, from an editorial in the BEE JOURNAL, with the name of a "correspondent" signed to it. A Louisiana paper copied our experiments with comb foundation, under its editorial heading, appropriating our experiments, arguments and conclusions, without as much as saying—"By your leave."

Since the above paragraph was put in type, we are advised that the official report, as first published in the *Colorado Farmer*, was incorrect, and our editorial was predicated upon that report. Mr. Grimes had but a single acre of sweet clover. Will our Indiana contemporary please modify that editorial on "sweet clover in Colorado" by making the correction?

Wood Separators.—Mr. C. R. Isham, Peoria, N. Y., remarks that the apiarists in that part of New York, will for the future use wood separators, in place of tin, for surplus sections. He thinks they are preferable in many respects. So far as our observation is concerned, their use has not been a success, but perhaps the difficulties of the past may be overcome, and we shall await, with interest, reports from those using them the coming season.

New Price Lists.—Catalogues and Price Lists for 1882 are on our desk from the following dealers in apianian supplies:

A. H. Newman, Chicago, Ill.
 Dr. Wm. R. Howard, Kingston, Texas.
 T. F. Bingham, Abromia, Mich.
 Paul L. Viallon, Bayou Goula, La.
 Jas. Forncrook & Co., Watertown, Wis.

To any one sending a club of two new subscribers for 1882, we will present a volume of the BEE JOURNAL for 1880, bound in paper covers. It contains much valuable information, and it will pay any one who does not already possess it, to obtain a copy. Many of our new subscribers will be pleased to learn that they can get it for \$1.00, by sending for it at once, before they are all gone.

We will send Cook's Manual bound in cloth, postpaid, and the Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Method for Granulating Glucose.

Through a recent extract from the Philadelphia *Dispatch*, published in the Chautauque (N. Y.) *Farmer*, and forwarded to us by Mr. William Bolling, we learn a company is now being organized in Philadelphia for the manufacture of Glucose from cassava or manioc plant, which grows luxuriantly in our most Southern States, in Mexico, Cuba, and, in fact, in all tropical and semi-tropical countries. The roots or tubes of the plant are used. From the best authorities we learn "the juices of the root are poisonous, but by treatment with pressure, heat and water, the poisonous qualities are removed, and the root yields a starchy substance called *cassava*, which is much employed as food. Tapioca is purified cassava." It is also used in making a fermented and highly intoxicating liquor. Since Glucose production has reached the enormous amount of 200,000 tons annually, in this country alone, the manufacturers have left no means untried to discover a substitute for corn, which has so advanced in price, owing to drouth and other causes, as to make glucose a trifle less profitable. The prospectus of the company now being formed to make glucose gives some comparisons as to the cost of raising corn and cassava. "The average production of corn in the States of Pennsylvania, New York, Ohio, Michigan and Illinois is 35 bushels to the acre. The amount of glucose produced from one bushel is 30 pounds or 1,050 pounds to the acre. Well authenticated evidence is at hand to the effect that 20 tons of cassava to the acre is no unusual crop in Florida. This, at 56 pounds to the bushel, would give a yield of over 700 bushels per acre, or at the rate of 30 pounds of glucose per bushel, would produce over 21,000 pounds of glucose per acre. A comparison of the yield of glucose from corn and cassava shows that 1,000 acres of corn yields about 500 tons of glucose; 1,000 acres of cassava yields about 10,000 tons of glucose."

Heretofore we have felt tolerably safe in the selection of our table sugars, as the coffee A and granulated grades were regarded as quite pure, owing to the supposed impracticability of granulating the glucose products; but all this security has been removed by the reference made by Dr. Kellogg, in the Michigan State Bee-Keepers' Convention, to the feasibility of granulating glucose as perfectly as cane

sugar can be done, and which is confirmed (if confirmation was required) by the following startling publication in the *Chicago Tribune*, giving the meager details of a discovery to remove from us our only dependence in sugars and their purity:

Dr. William Robinson, of this city, has discovered a process for converting glucose, or grape sugar, into the pulverized, granulated, or loaf forms—a process which, judged from the work it does, is apt to play an important part in the refining of this class of sugars. The Doctor's secret combines both chemical and mechanical action for the removal of the gum, acids, and all other impurities from the lump of crude sugar and the transformation of the purified article into either the granulated, pulverized, or loaf form. Dr. Robinson showed several samples of the crude and the purified sugar to a *Tribune* reporter yesterday, and the results accomplished by his process were something wonderful. The crude sugar itself comes in hard lumps of various sizes, slightly yellow as to color, and decidedly "waxy" as to touch. After undergoing the purifying process, it is perfectly white, dissolves readily in water, and is about half as sweet as cane sugar, the rank taste of the crude product having been entirely removed. The purified sugar can be readily mixed with the cane, but, whether alone or mixed, makes a very palatable article.

The Doctor claims that he can convert crude grape sugar into the refined article, either granulated or pulverized, at a cost not to exceed a quarter of a cent per pound. When thus converted and purified, he claims that it will not cost four cents a pound at wholesale, which is considerably less than the wholesale price of other sugars. He has demonstrated that it is as feasible to convert 100 barrels a day as it is to convert half a pound at a time, though his experiments as yet have not proceeded upon a large scale. It is understood that two or three heavy glucose manufacturers, impressed with the importance of a process which promises to do so much for the future of grape sugar, have offered to furnish the necessary capital to refine the crude product on a large scale, while others are reported to be anxious to buy the secret outright.

Thus it will be seen, an almost illimitable field is opened up for the production of inferior sweets indistinguishable from the wholesome and genuine article, except as our sense of taste may prefer the better and reject the poorer. Without the intervention of legislative action on the part of Congress, a sample of genuine cane sugar will become as rare in our grocery stores and on our breakfast tables as Guinea gold now is in the jewelers'. As regards the detection of the inferior or artificial article by

chemical means, it is wholly impracticable, as every infallible means so far published requires an expert, and much experience and comparison to arrive at a correct and definite conclusion.

However, disguise their manufactured products as they may, and call them what they please, they are all much inferior to the genuine article they are intended to counterfeit. Dr. Robinson, it will be seen, admits his granulated glucose is only half as sweet as the cane product, and perhaps that estimate will be considerably discounted when all the facts are known.

In view of the various devices resorted to by unprincipled persons to counterfeit sugars, syrups, etc., it is a consolation to know that, instead of the outlook being dark and gloomy for bee-keepers, the reverse is true. Honey is steadily and surely becoming a greater favorite with the public, and where properly put up, and ordinary diligence is used in marketing it, ready sales can be made at remunerative prices, and speedy returns received; and finally, when pure cane sweets shall have been exiled from our markets, the enterprising bee-keeper will have a market at his door for what he can spare from the neighborhood demand, because there will still be consumers in abundance for natural sweets—and what can be sweeter than honey?

The Apiary Register.

We have now filled all the orders for the Apiary Register, after vexing delays in the Bindery, and hope all will be pleased with them. The following are some of the opinions of those who have received and examined them:

The Apiary Register is received, and, to my mind, it just fills the bill. I am sure that to all who wish to keep an accurate apiary record, it will be invaluable. On Nov. 24, I put in the cellar under lime cushions 56 colonies. They are in fine condition, so far.

A. J. HATFIELD.
South Bend, Ind., Jan. 23, 1882.

I received the Apiary Register; am much pleased with it; it is just what every bee-keeper needs.

M. SORRICK.
Des Moines, Iowa, Jan. 24, 1882.

The Apiary Register is at hand and will supply a long-felt want. It will save a great deal of labor, as you can sit in your office and look over your Register, and plan out your work. You can see what colonies are likely to need attention, and will not have to trust to memory.

L. C. WHITING.
East Saginaw, Mich., Jan. 21, 1882.

Another Reform Needed.

"Hardly ever"—that is to say, very seldom, do we find in the "calls" issued for conventions, the name of the hall or place of meeting mentioned. It is but a short time ago that a bee-keeper who went to a certain town to attend a bee convention, became so exasperated at finding no notice of the place of meeting in the local papers, or anywhere else, in fact, that he telegraphed to the editor of the BEE JOURNAL at Chicago, thus: "Where is the Bee Convention?" We have had similar experience. We were sent for to attend a convention, and expected to find some one at the depot to inform us where to go, but found none. We then inquired of the station agent, at the nearest hotel, but could get no information of any bee convention. We then tried to find a bee-keeper who received his BEE JOURNAL at that post office, and were directed first this way, and then that way to find him. After spending half a day and paying over a dollar for hack fare, etc., we finally found that the bee man lived some miles out in the country. The Secretary had been derelict in duty—had made no arrangements for a hall, but finally one was obtained, and a few bee-keepers gathered in, and the result was a failure of realizing the object of the meeting.

These thoughts were drawn out by receiving a copy of the *Journal*, published in Berlin, Wis., dated Jan. 17, where the Northeastern Wisconsin Bee-Keepers' Convention was advertised to meet on the 17th and 18th of January. The following is what the Berlin *Journal* had to say about it, and will explain itself:

A SWEET MEETING THAT DIDN'T OCCUR.—For several days past the following item has appeared in the *Journal*:

The Northeastern Wisconsin Bee-Keepers' Convention will meet in Berlin, Jan. 17 and 18. A cordial invitation is extended to all who are interested in bee-culture.

The above notice was sent us on a postal card which was postmarked Ripon, but read as follows:

Berlin, Jan. 10, 1882.

CHAS. STARKS—Dear Sir: Please insert the following notice in your paper this week if possible. (Then followed the notice.) Please arrange this as you like, but *stir* the bee-keepers up.

C. H. GREEN.

On Monday one or two of the Berlin bee men applied to us for information as to the Convention announced. We gave them all we knew about it as above stated. They were entirely ig-

norant of the matter, and Mr. Beckwith stated that the Convention at the last meeting was appointed at Packwaukee.

To-day (Tuesday) was the day announced for the opening of the Convention. Several bee-keepers from the surrounding country have been in. They could find no convention and applied to the *Journal* for information. Our reporters could find no convention either, and the matter is a profound mystery.

Since the above was written another bee-keeper, from Aurora, has called to inquire about the Convention, and says it has been advertised in the AMERICAN BEE JOURNAL, Chicago, for some weeks past.

It is possible that the non-arrival of the train from the east this afternoon prevented the arrival of the head and front of the affair, although who the said "head and front" is does not appear.

At all events the Convention that was to "bee" has not bee-n, and those who came to the city to attend, had their journey for naught....

Burnett Davenport, of Aurora, has had his trained bees in training for several days for the bee Convention which was to have taken place in Berlin to-day. Geo. Smith intended to bring up the question of Spawmed Bees, from which he has suffered so severely, and also intended to exhibit his fine swarm, branded across the backs, "G. H. S.," and which he keeps blanketed. E. W. Daniels, of Auroraville, was going to discuss the proper way to lead bees out to water, while Mr. Beckwith, of this city, proposed giving his views of pulling of their shoes and turning them out to pasture, in the summer. Mr. A. Young, of Eureka, was to have exhibited some buff cochin bees of his own invention, and an unknown gentleman, from Waushara county, proposed introducing some bees whose business end had been treated with sand-paper to remove the stinging qualities. The treatment of bees while moulting, the profit in keeping farrow bees, and the teaching of American bees Italian, were subjects to be discussed. If the Convention fails to occur to-morrow, the bee-keepers of this section should administer a stinging rebuke to the instigator of the brand.

Hereafter, to prevent such exasperating experiences, let us have the name of the Hall or place of meeting, mentioned in the notice.

We know nothing of the circumstances connected with the "hitch" at Berlin, but it would be very proper for the Secretary to "arise and explain."

☞ We understand that California is to have a Dollar bee paper. It is to be edited by Mr. N. Levering, published at Oakland, called *The California Apiculturist*, and the first number is promised next week. When received we will notice it further.

Glucose Tests.—We are frequently in receipt of inquiries for some reliable, simple method to detect the presence of glucose, and have experimented much with this object in view; but so far, we have been unable to find anything satisfactory and fully reliable, that would not require an expert chemist or microscopist to manipulate it. Green tea, alcohol, tincture of iron, and many other articles have been suggested, but none of these have we found infallible. Of course, unless the inquirer be a scientist, there will be no reason to suggest an analysis, and such an one is already familiar enough with chemistry to require no suggestions from us.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

MISCELLANEOUS.

A Warning Voice.—The Cincinnati *Grange Bulletin* gives its opinion of breeding the best queens, etc., and concludes with its warning to bee-keepers in the following language:

It is strange to see so many bee-keepers' conventions and societies, for the good and mutual benefit to be derived from such meetings, in the interchange of thought and practical management of bees; and after all to find that prices for bees, queens, and even comb foundation are so low, that nearly all the special breeders now complain that they handle too much stock and goods for the little or no profit there is in the trade. Why this state of affairs? Surely the laborer is worthy of his hire, and should be paid for all time and trouble in furnishing a good and acceptable article for the market, let it be bees, queens, honey, or anything in the line of apian supplies. It is a well known fact to at least one-half of our best queen-breeders that every queen taken from a full colony of bees will retard it more in its progress and prosperity, than it would to take 25 pounds of honey from them; and yet, we say, how strange it is that bee-keepers do not establish a uniform price for all our supplies and live up to it. No wonder we hear so many complaints of poor queens and irregularly marked bees, from the queens

so abundantly furnished by these nucleus-hive queen breeders which as a rule give such poor satisfaction, for there is not more than one in every five of such queens worth the time and trouble of introducing them. We have tried and tested the queens thus raised to our full and entire satisfaction. It is this nucleus system which has both ruined the quality of queens and overthrown just and fair prices for good stock. Therefore, we raise a warning voice against all such frauds, no matter whether in queens thus raised, glucose, or any other dishonorable commodity produced by dishonest vendors to deceive the unsuspecting.

Sentiment and Bee-Keeping.—"Hail Columbia" in the *Western Agriculturist*, gives apiarists a bit of her experience, as follows:

"Of all the hobby folks that I ever saw, bee-keepers are the hobbiest. They all have new inventions, each one so much better than the last, and by the time that half of us get this last new thing, and get used to the hang of it, or the slide of it, or the lay of it, as the case may be, behold, it is old and out of date, rejected by all leading bee-keepers. Get the best, get the best, and we go flying from one invention to another with a rapidity distracting to sober-minded people.

When I first began bee-keeping I had the Langstroth hive, with a honey box the size of the hive, and matters seemed easy and simple enough; but that was too much box, it discouraged the bees, and those boxes were cut down to half size, and that lasted one season. Then came the one-pound frames, the prize box, and the section boxes, following each other in quick succession. When I took in honey to sell in small frames, the grocery men wanted prize boxes; when the next month I took them the prize box, they wanted section boxes, and now I have the section boxes, but by next season there will be something new.

"These forty thousand bee-keepers won't let anything alone. As for me, I'm worn out. There seems to be no end to the rabbets and sections, and Cyprian queens. Italians! was the cry, and now when we all had them and had got used to their ways, they must hatch up a new kind of queen, fresh from the isle of Cyprus. Mr. C. was patient with me for several years, but when he saw there was no end to it, he declares he'll have to build another house to hold the bee fixings; he says it takes more clap-trap and bang-ups to run a hive than it does to run a sawmill. "Why," says he, "my father used to get more honey out of his old bee gums than you do with all your regalia."

"Then there is another side to bee-keeping that I never can get on—that is the sentimental side. It is the fashion for bee-keepers to say: 'I love my bees, I hate to sell them, I think they recognize me,' etc. I like my bees well enough when they behave themselves, but just as soon as

one stings me I get mad, and every additional sting makes me madder and madder; repeating the ten commandments or the multiplication table don't prevent—the mad will come."

What Hive to Use.—The Hon. L. Wallbridge, in the *Canadian Farmer*, gives the following advice concerning the hives to be used for comb and extracted honey:

This is the season of the year in which the bee-keeper should get ready his hives for next summer's campaign. To those who have not yet decided upon any particular hive, I would say, have only hives of one pattern in your apiary.

As to what the proportions of the hive should be depends very much upon the manner in which you intend to manage your bees, or rather in what way you desire your honey product to go to market. If you desire box honey or honey in sections, I do not know of a better hive than the Langstroth. As this hive left the hands of the inventor, its size was 18 $\frac{3}{8}$ inches long, 14 $\frac{1}{8}$ inches wide and 7 $\frac{1}{8}$ inches deep, all inside measurements, and contained ten frames, cubic contents 2563 inches. Many use this hive with nine frames, 12 $\frac{1}{2}$ inches wide, and are well satisfied with it. The contents cubic of this hive would be 2268 inches inside measurement. The Langstroth hive affords more honey surface, and the section frames will contain eight one pound sections each. This is a very convenient form in which to send honey in the comb to market.

A section 4 $\frac{1}{4}$ x 4 $\frac{1}{4}$, and two inches broad, will contain just one pound of

Case of 8 sections, 4 $\frac{1}{4}$ x 4 $\frac{1}{4}$ inches, for Langstroth Hive.

honey. Much depends on neatness in commanding ready sales.

If, however, you intend to extract your honey, and market it in that way, you will find a hive of the following proportions very convenient, both as containing combs well proportioned for the extractors, and the hive itself easy to handle—16 inches long, 12 $\frac{1}{2}$ inches wide, 12 inches deep, cubic contents 2400 inches. The frame adapted to this hive will be found to be nearly square, and very convenient in the extractor.

Many bee-keepers neglect to get their hives ready until swarming time commences. Such persons, instead of having the bees in one kind of hive (as I strongly recommend) will find at the end of the season their bees will be in boxes, kegs, barrels, and in all conceivable shaped things. You must give up this method, or quit bee-keeping.

Does it Pay?—Mr. George Grimm, in *Gleanings*, says it does. His report is as follows:

Though my report is not a very brilliant one, yet I am well satisfied with my season's work. About 200 per cent. net on the capital invested is not a bad gain. Last winter left me 392 colonies; but though my loss was less than 10 per cent., the remainder after the ordeal they had passed through, could not all be in good condition. The demand for bees was so great and so urgent, that almost before I knew it I had sold 248 of my best colonies. This left me but 144—and, of course, the poorest of the lot.

The season opened up with the best prospects for a honey crop, and I began to wish that I had back the good strong colonies that I had sold. Finding several parties not far distant, whom the past poor season and the trouble of last winter had entirely disgusted with the business, eager to sell out, I bought the weak, half-starved, and partly queenless remnant of the colonies at a bargain, and was enabled to face the new season with about 190 colonies; or, perhaps, I had better say, nuclei and colonies. Anticipating a good demand for bees next spring, and having a large number of hives and about 2000 combs on hand, I determined to increase as much as possible. I divided them up into five apiaries. At home I started some 80 small nuclei to rear queens. Myself with one assistant did all the work. Nov. 18th to 21st, my bees were put into cellars—610 colonies. Two were left outdoors. Nine-tenths were supplied with young queens during the season, and all have a good supply of honey. Oct. 1st I returned from a trip to northern Dakota. Not a cell of brood was to be found in any of the hives. What feeding I did was done after that time. The colonies are, as a rule, of medium strength, and present a good appearance. I believe they will winter well.

Does it pay? Well, I should say so! 200 good swarms can be bought for \$1,400. In a poorer year than this, an average surplus of 50 to 100 lbs. per hive, and an increase of 50 per cent, would not be extraordinary. The increase would easily pay for expenses, and 10,000 to 20,000 lbs. honey at 20 cents would be better than 4 per cent on U. S. bonds. Or take my case this year; 190 not good colonies; increase, 422; prospective loss during next winter, 10 per cent, or 61 colonies (but I am certain 5 per cent to 8 per cent will be the limit), leaves a balance of 361 in spring at \$7.00 per colony is \$2,527, and honey \$300, gives total gross gain, \$2,827. My expenses were between \$500 and \$600; leaves balance of at least \$2,227. If I estimate good colonies worth \$7.00, my 190 were worth on an average not more than \$5.00. It is not hard to do twice or three times as much with good colonies as with poor ones. I think we'll stick to the business a few years more, even though every winter should equal the last.

Jefferson, Wisconsin.

CORRESPONDENCE

Gleanings in Bee-Culture.

American Apiary in Cyprus.

FRANK BENTON.

The photograph, the best and largest that could be obtained here, shows only a small part of the apiary, whose foreground is cut off, and which extends some distance to the right, and a part of which is the large inclosure back of the house.

Most of the hives shown in the picture are plain boxes, of about 2000 cubic inches capacity; designed to hold medium-sized colonies for queen-rearing—all queens being reared in full colonies. The whole apiary is devoted to this branch of bee culture, and of course movable combs are used exclusively, the loose-fitting Langstroth being employed to the exclusion of all other styles. The size, however, is 9 inches deep by 10 long outside. Twelve of these are placed in one story, but sometimes twelve more are put into a second story, placed above the other. But even on four of these combs, a queen with plenty of young bees and a good supply of honey will winter here.

the same size as the others, but the walls are generally a little over twice as thick as those made of burnt clay, being quite two inches. Of course, they are very heavy, unwieldy things; yet (since there are few trees in Cyprus) these thick clay walls protect the combs from the sun even better than do the thinner burnt clay ones. In winter, too, they keep the bees warmer. The diameter of those cylinders is greater at the rear end than in front, in order to facilitate the removal of combs of honey; for from these, as well as from the other kind of hives, the natives take such an amount of honey as they think the bees can spare, by cutting the combs out from the back end, after the re-

Frank Benton's Apiary, Larnaca, Island of Cyprus, Mediterranean Sea.

The costumes of Greeks, Arabs, and Turks, with the group of camels, give to the view a decidedly Oriental air. The camels have just arrived from the interior of the island, and the attendants are busy removing their loads of clay cylinders—the native bee-hives. A Turkish woman belonging to the caravan stands near.

In the group at the left is a priest of the Greek church, with a Greek citizen, and a Greek porter, the latter being about to start for the steamer landing, with a case of bees for shipment, while the two former are watching "Amerikanos" manipulate a hive of bees. "But, can they be handled thus with so many people and animals?" asks some one. Certainly they can, if one knows how to manage them, and has a bit of patience.

At the extreme left of the porch are some twenty clay cylinders piled up like drain-tiles. These are some of the bee-hives of the natives, and this shows exactly the manner in which their apiaries are arranged—is, in fact, a model of a Cyprus apiary. The cylinders are made of clay, and burnt, and each is about a yard long and 9 or 10 inches in diameter, except each end, which is a little larger. A stone disc is fitted into each end, and the crevices, except an entrance-hole, filled with puddled clay.

On the roof is another model (!) apiary, such as may be seen at many a Cypriote's home. The cylinders of this collection are made of clay, into which short straw has been incorporated, and they have been merely dried in the sun. Inside they are of about

removal of the rear disc, and after the bees have been driven forward with smoke. But brood and some dirt often get mixed with the combs taken out, which are then crushed, and the honey strained out; hence the quality is very poor; yet 13 cents per pound (14 piastres per oke) is the price commonly asked for it in the bazaars. It often happens that the poor bees find their winter stores have been stolen from them, and that, after a hard year's toil in the hot, scorching hot, summer sun, they must starve in the cold. Surely, I hope there are no Cypriotes in America, and that all of the beautiful little workers I send over there will fare better than would have been the case if they had been left to the not very tender mercies of Greek or Turkish Cypriotes.

The house is one of those old rambling adobe and stone structures so characteristic of Cyprus. Its walls are two feet thick, floors of stone, and roofs of beaten clay six or eight inches thick, and supported by great arches of massive masonry. Some idea of its size may be gained from the following facts: The front court is 60 by 100 feet, and is nearly inclosed on three sides by parts of the house, which contains 14 rooms. The front porch is 12 feet wide and 65 feet long. A hall at the right leads through the house 50 feet to the back court, which is about 30 feet by something over 60, and is inclosed by the house on two sides.

When our little "prize queen," who first "piped" Sept. 5th, 1881, can trot from room to room, it will be a task to hunt her up in this old mansion—our home in Cyprus.

For the American Bee Journal.

Pure Bees—A Short Review.

G. W. DEMAREE.

The several articles over my signature, which have appeared in print from time to time, discussing the question of purity of the Italian race of bees, were penned for no other purpose than to call attention to what careful experiment has demonstrated to my entire satisfaction to be true, viz: that the Italian is not a pure blood race of bees. In discussing this and other subjects, I have thought it the square thing to give the name of the writer whose views I thought proper to controvert. I do not think it the fair thing to quote the language of a writer and proceed to wallop him soundly, without saying "I mean you?" and thus give him a fair chance to "arise and explain" if he chooses to do so. Viewed from this standpoint, my articles have not been so very controversial, and certainly have not taken the form of a "favorite plea," as Mr. Dadant says they have.

If I mistake not the reader will be able to discriminate between the main issue and the side issues that have been raised as the discussion progressed. In my paper read before the National Convention at Cincinnati, I took the ground that the imported Italian is not a pure blood race of bees. And in my attempt to prove the proposition I cited the fact that there are two so-called strains of the Italians, which fact makes it impossible that the race as a whole can be pure.

In due time Mr. Dadant and Mr. A. I. Root confronted me with the "three band test." If the reader will take the pains to scan the pages of the back volumes of the bee papers, and examine the standard works on bee-culture, he will see that the three band test and its twin brother—Huxley's doctrine of the "survival of the fittest," has been the rallying point of the venders of queens and bees. It would now seem that I have demolished the citadel of strength, by showing that the three bands do actually

exist however obscurely, on the body of the hybrid or American cross, as well as on the hybrid imported from Italy.

In discussing this subject I have said that the progeny of some queens imported from Italy do not show the three bands. Of course I meant that the bands were not visible to common observation. If you are willing to accept of the fact that the Italian race is a cross between a yellow and one or more black races of bees, you will have no trouble to understand why that if you breed out the black blood by selection, the yellow will gain the ascendancy as you progress, and the bands will become distinct and well defined. While on the other hand if you breed out the yellow blood, or let your stock run down by a preponderance of black blood, the bands will grow fainter and fainter, till artificial means must be resorted to if you would know they exist at all.

If I understand Mr. Doolittle (whose opinion I value highly) he corroborates these statements. Mr. Dadant's experience with his first Italian queen as related by him on page 22, BEE JOURNAL, Jan. 11, "gives him away" without lien or incumbrance. According to his statement, that finely bred queen from Dr. Dzierzon contained sufficient yellow blood in her make-up to transmit the yellow bands to the progeny of her daughters mated with black drones. The statement further shows that these bees after being hybridized in this country contained more yellow blood than the three imported queens whose progeny were "darker even than the ill-mated queens."

Mr. Dadant now gives up the three band test and falls back on "good behavior," as a reliable test. I would gladly spare him this last "ditch" if the facts and sound philosophy would suffer me to do so. But I have had colonies of hybrids—a cross between a selected yellow queen but a black drone, that behaved precisely like the well bred Italians. While other colonies of a like cross would behave just like the black bees. This is no uncommon thing. It is precisely in accordance with the laws of transmission of traits from the parent to the offspring.

One single exception will destroy Mr. Dadant's new rule for test of purity. There is really no reliable test of purity, simply because the Italian is not a pure race. It is very kind in Mr. Heddon to come to the rescue of Mr. Dadant. His letters are always interesting, but he fails to help Mr. Dadant out of trouble. He does not touch the main question. He only gives his opinion, which though valuable is not conclusive. Others differ from Mr. Heddon's opinion.

In a late article Mr. Heddon intimates pretty strongly that the opinion of those who make "large reports" is more valuable than that of those who make small, or no reports at all. It seems to me that Mr. Heddon failed to look all around the subject before he wrote that. A good location abounding with bee forage is essen-

tially necessary to a big report. If Mr. Heddon will set down one of his apiaries in the best portions of the blue grass region of Kentucky, where corn, hemp, wheat, oats and tobacco, cover the fields as far as the eye can see, and where the red clover grows too luxurious for the "bill" of any bee, and white clover struggles for existence at the side of the prince of grasses (Kentucky blue grass), and where the basswood has disappeared long ago, and eternal war is made on "woods" every where, he would begin to conclude at the end of one or two seasons' experience that his opinion is not very weighty judged by the rule he has laid down. In just such a closely cultivated country I have demonstrated that bees can be made to pay. The truth is, in a good location such as may be found in many parts of Kentucky, and such as Mr. Heddon is blessed with, any kind of bees will give good results without a very high order of skill on the part of the apiarist. Christiansburg, Ky.

For the American Bee Journal.

Bee-Keeping for Ministers.

WM. F. CLARKE.

Ever since the appearance of Rev. O. Clute's report for 1881, in the AMERICAN BEE JOURNAL of Dec. 7, I have wanted to write a few lines on the above topic. It is a good showing, worthy the author of "The Blessed Bees." By the way, I hope that book paid. It richly deserved to be a financial success, whether it was or no. Every bee-keeper should read it. A romance at present, it bids fair, at no distant day to be a reality. Mr. Clute has gone far toward the realization of his own ideal, and I metaphorically pat his broad back, and congratulate him.

But—bee-keeping for ministers—that's my theme. One of the ablest of their class who ever lived, eked out an insufficient support by tent-making, and I don't see why modern ministers should not try their hands at bee-keeping.

The inadequate salaries of the great majority of ministers, is a great evil in many ways. Their helplessness and inaptitude in supplementing their scanty incomes, is a worse evil, because, in too many cases, their conscious dependence makes them timid, and fearful of the results of any departure from the beaten track of so-called orthodoxy. To be voted heretical, means beggary. "'Tis pity, but pity 'tis, 'tis true." Whether a minister gets a liberal or meagre salary, he should be free as air to declare whatever he conscientiously believes to be truth. Alas! poverty "makes cowards of us all"—or not to be too uncharitable—some of us. To be possessed of some resource, on which to fall back, would give ministers back-bone, and a sense of manly independence.

If bees persecuted all ministers as they do me, it might be questionable kindness for me to advise their going into apiculture. But there is some-

thing "peskey" about me, which I am charitable enough to think is not usual among my "reverend" brethren. And, as they are usually too much cloistered, take too little fresh air, and, like one of old, "cannot dig, and to 'beg are ashamed," as they ought to be, I recommend bee-keeping, as a light, pleasant employment (if you don't get stung too often), and eminently favorable to good health.

Let me tell a little story which, I think has never appeared in the BEE JOURNAL. A rural parish clergyman in England, one of the class of whom Goldsmith tells, as passing rich on forty pounds a year" received a diocesan visit from a newly-appointed bishop, who had been a former class-mate of his. The bishop expected to find his old friend in straitened circumstances, and was greatly surprised to find him surrounded by all the indications of comfort and competence. After a good dinner, served with some style, his lordship began to enquire into his friend's circumstances. "Married a rich wife?" "No, my lord." "Got a legacy?" "No, my lord." "What, then?" "My lord" was the reply, "I am a manufacturer, and employ a large number of operatives from whose labors I reap a good profit. If your lordship will step into the garden, I will show you the factory." So, he led him out-doors, and showed him a well-kept apiary. It made a great impression on the bishop, and whenever afterwards any of his clergy complained of poverty he was wont to say, "Keep bees! KEEP BEES!"
Listowel, Jan. 14, 1882.

For the American Bee Journal.

Keeping Bees on Stilts—No. 2.

BY W. G. PHELPS.

The curtain now arises on the scene of Mr. Hopeful's summer operations in bee-keeping. He had, you doubtless remember, previously procured 100 boxes supposed to contain bees, and after the few trifling incidents—narrated in my last article, had landed them on his ancestral estate. Now Mr. Hopeful had given the subject of apiculture much profound and searching thought. An unknown but considerate friend had kindly sent to his address a copy of the BEE JOURNAL. This paper after scanning its pages, our enterprising friend pronounced too matter-of-fact for him. He concluded he would not subscribe. He was positive that bees could be managed with far less of what he termed "tom-foolery" and with absolute certainty of heavier profit than the JOURNAL asserted. All the talk about half crops of honey for 1880 was just nonsense, or the result of mismanagement on the part of the bee men. If bees wouldn't gather honey, why just manage them so they would. What if the flowers didn't secrete honey, surely the bees could be made to "lick it up" around the stores and cider-mills, if rightly managed. Among Mr. Hopeful's bee purchases were quite a number of what are termed

"lucky bees" upon which he particularly prided himself. It is possible that some of your readers may be resting in blissful ignorance of what constitutes a "lucky" stand of bees. Mr. Hopeful knew though, and informed me, and as I am in duty bound to give all the details of his interesting experiences, here it goes. It is a fact that bee-keepers are mortal, notwithstanding the other fact that some of them sing in sirenian strains, (Mrs. Lizzie Cotton for instance). They fail "to winter" well and are oft times affected with fatal "spring dwindling." In other words, they sometimes die. It therefore remains a solemn and very important duty, Mr. Hopeful says, for the nearest surviving relative to inform each colony of bees of their late owner's decease, accompanied with sundry knocks upon the side of said hive. After this ceremony is performed they become pre-eminently "lucky bees." Such bees could not fail to be profitable stock to operate. What cared Mr. Hopeful if some of these colonies did feel extremely light, were they not under the spell of their late owner's enchantment—and bound by the mystic power of the incantation? Pshaw! said Hopeful, science is no where after that. However, our Mr. Hopeful in truly scientific styles delighted to study the nature and watch the movements of his "pets." He would seat himself as he said in the "remotely immediate vicinity of his apiary," and while drinking in the spring-time fragrance of the opening bud, through the medium of his highly sensitive nasal organ, would likewise indulge in rose-colored visions of the prospective prosperity that was to attend his bee-keeping operations when, well—when his bees came in. Such, almost daily, were the meditations of our esteemed friend. One day after indulging a more than wonted flight of fancy, he caught one of the little insects and holding it dexterously between two straws, proceeded to descend upon some of the anatomical features prominent in its formation, in the hearing of the wondering Mrs. Hopeful. "Observe (says he) these delicate *antillars* with which the beautiful creature, prognosticates as it searcheth for its ambrosial sweets."

And oh, observe! says he, the seraph like formation of its incomparable "throatax!" "Did you ever behold aught like it?" "Notice also my dear, the matchless symmetry of its posterior parts." (Here Mr. Hopeful brought the object of his observations close up under his eye-glasses). "Mark the beauty of that unrivalled encasement, the loveliness of that artistic color, but most wonderful of all, behold the perfection of that polished shaft which, ever and anon"—here unfortunately for future observation and remark, the beautiful bee unexpectedly escaped from its captor's grasp, and taking a true "bee-line," came immediately in contact with the prominent nasal appendage, the property of our esteemed friend. Hereupon, it gave a practical demonstration of the adaptability of the "polished shaft" for business, by inserting it

well into that integument of said organ. "Ouch!" shrieked the investigating Mr. Hopeful, "Dear me!" piped dear Mrs. Hopeful, while she followed the retreating figure of her liege lord into the house. As he nervously rubbed the tomato leaves upon the punctured part and fumbled distractedly for the salts, was it simply the sighing of the wild wind among the leaves of the luxuriant trees, or was it the melodious cheering voice of sweet Mrs. Hopeful simply remarking, "bee stings you know you told me dearie were excellent for *rheumatiz*."

Galena, Md., Nov. 3, 1881.

Is the Problem of Wintering Settled?

JAMES HEDDON.

From reading the able article of Mr. F. Della Torre, on page 387, I must say that I believe he may be nearer the facts in the case than any other man that has ever written upon the subject.

Is it possible that bacteria and pollen are both the causes of bee dysentery? It seems so. If Mr. Della Torre is correct, it is so.

Mr. Dadant thinks that bacteria is the cause. I once thought so. Then I thought pollen was independent of bacteria, that is, I saw signs that said "eating pollen did this." I did not think to see if the pollen was bacterious or fermenting.*

In our late State Convention, Mr. Harrington, of Medina, Ohio, stated that a weed (vulgarly called "tremble weed") growing about his locality produced bacterious or fermenting honey, that when bees stored it to any extent, death by dysentery was sure to result. Bees working upon this "tremble weed" and upon cider mills, are truly "bacteria-laden bees." Where else they may get bacterious honey we know not. Honey is so full of floating pollen, that bees succeed in rearing brood with that, and no other. Perhaps that pollen may ferment and produce dysentery. Again, it may be that bee-bread may ferment, owing to the kind of pollen it is made from, or from the kind or amount of honey and water that is used in its composition, or both.

If all the above points were unfavorable, it may be that the bee-bread fermented in my 47 hives in my large dry cellar, in 1869, even though they had plenty of upward ventilation; while in Mr. Balch's damp cellar, 35 miles away, where his hives had no upward ventilation, and the combs came out moldy and wet, and the bees strong and healthy, they either had no accessible bee-bread, as for some reason it did not ferment, or the bees did not eat it.

Yet, it may be that Mr. Della Torre

* All fermentation (the first stages of decomposition) is bacterious. These bacterious terms have been considered by many as animal (myself among the number), but Prof. Cook who is excellent authority, considers them vegetable. I now have no doubt that he is correct; however, as regards the wintering problem, it makes no difference, as they are a living growth, in either case, dependent upon the air currents or assistance from higher forms of life for their transportation.

is incorrect in his reasoning (having had no experience with dysentery except what he purchased), and that my first convictions were correct, viz: that older bees, when by adverse circumstances are induced to eat any pollen during confinement, will have dysentery as the result. Those whom I have looked up to as authority have taught that bee-bread was essentially a larval food. We know that the food that young babes, calves, and colts live on exclusively would, if used to the same extent by the adults of their species, produce dysentery and death.

This illustrates why pollen may be "ever ready to produce life" at one time and under certain conditions, while at other times it kills. The dinner that strengthens you to-day may kill you if duplicated one week hence, under other conditions.

I have but little doubt but that moisture is a great aggravator or producer of bad effects from its favorable influence toward the production of bacteria. Whether chaff, cellars, houses with stoves in them, hives lined with lime cushions, will prevent this fermentation when the pollen and honey are most unfavorable within themselves, we cannot yet reasonably decide; but I, for one, have fears as to the practical and ready means of prevention, just as soon as we get a clear understanding of the cause, and causes of the cause. I believe we are coming at it, slowly but surely. I believe that my first conception of the cause will turn out to be true. Some other form of life is working for the ascendancy over the life of our bees.

If it would not be asking too much of Prof. Cook, I would ask him in behalf of the science-loving apiarists of the world to give us through these columns as elaborate an account of the late French experiments with that low form of life so destructive to stock, as his valuable time will afford. When relating the experiments in our State Convention, we felt a tingling sensation run over the brain, and thought surely these scientists are the saviors of men.

Those Fine Bees in Canada.

W. P. HENDERSON.

THE AMERICAN BEE JOURNAL, of the 11th inst. reached me the 12th inst., and in looking over it I find from the pen of W. F. Clarke, the following: "We have organized a company in this town, and started an apiary as a tentative business venture. * * * * Thus far we have only bought 44 hives of bees, being the sum total of that nice little apiary at Kincardine, with which I fell so desperately in love last July."

In looking at his communication in No. 29, July 20th, which I noticed at the time, that Mr. Clarke, visited "an excellent Canadian apiary," and found, as he says, "a uniform, nicely marked, even-tempered lot of Italian bees." * * * * "We opened some 20 hives to inspect the queens. In sev-

eral cases we had no need for a puff of smoke, so quiet were the bees."

Now, if Mr. Clarke's company intend to rear queens for sale in Canada, I know of no better stock than the Sturgeon stock to rear from. There are many queens, however, of the same stock in different apiaries of the Dominion.

But the funny part to me, Mr. Editor, in the different articles of Mr. Clarke, published in the BEE JOURNAL and elsewhere, is his recollection of all those islands in Canada, covered with nothing but bees, and his remembering all those Syrian, Cyprian, Parry Sound, *Apis dorsata* and *Apis Canadensis*, hard names, but failing to remember that of little Tennessee, or the name of that little Tennessean who furnished Mr. Sturgeon with those fine queens.

When the tentative Canadian queen apiary advertises, I will, with pleasure, extend the right hand of welcome to them upon the platform for public patronage, with a wish that *Apis Americana* the coming bee, may be produced in a much shorter period than many are predicting.

Murfreesboro, Tenn., Jan. 12, 1882.

For the American Bee Journal.

Exact Reports of Honey Crop.

E. L. B.

I have before me a report of a honey crop from a very honest man, of a very superior strain of bees, resulting from a hybrid cross, which gathered just 40 lbs. of honey per colony, from red clover, when ordinary Italians did not get one pound. These bees understood themselves, and put in just that convenient multiple of pounds, that would not puzzle the brain of buyer or seller. Five colonies equals 200 lbs.; 10 colonies equals 400 lbs. How convenient? Then again, three swarms from one old colony, last summer. These together make four colonies, all in splendid order for winter, except they have about 15 lbs. of honey per colony too much, for wintering. Four times 15 lbs., are 60 lbs. It is so easy to count the surplus inside the hive! Then these four united give just 400 lbs. of white comb honey, and exactly 300 lbs. of dark comb honey; all nearly built in two pound sections. Just 175 lbs. to the hive; 87½ sections per colony—22 sections per month, in box honey; besides the extra 15 lbs. inside of brood-chamber—just two pounds per working day (these bees don't work on Sunday) all summer, wet or dry, cold or hot, blossoms or no blossoms; besides filling the brood chamber.

There was one colony that far excelled these. It stored just 400 lbs. It didn't go into fractions at all. Just 400 lbs., 200 boxes or sections; 50 sections per month—a whole crate and four sections over, every 15 days.

Brothers of the bee-keeping fraternity, "That coming bee have ariv in another State," and the breeder has written a letter announcing this to an apiarist of Michigan.

Wilton, Iowa.

For the American Bee Journal.

Foul Brood and its Cure.

A. R. KOHNKE.

As some bee-keepers may be led to believe, by Mr. Townley's assertion, that he cured foul broody colonies, by simply putting them into a clean hive, that they also may succeed by the same procedure, I wish to say that I consider such a thing impossible.

Foul brood means bacteria of putrefaction which do not only pervade brood but also honey, pollen, and the body of the old living bees. A patient having small-pox cannot be cured by moving him into another house, not by starving him. Wherever he is taken he carries the contagion with him, in his body, until he is cured. It is the same with bees. If Mr. Townley's bees got well after being removed to other quarters, it would simply prove that there was no contagious disease about. Mr. Townley admits of having had no faith in nor success with that method and resorted to cremation, also substantially admitting what he seems to deny, viz: that he cannot tell whether or not he has eradicated the disease, for when it takes a bee-keeper three years of repeatedly burning his infected bees, hives, and all, at a loss of \$200, he may rest assured, that by that method he has not yet burnt his last hive and colony, which are as liable to catch the contagion as those before them which were burned before the last ones showed signs of the disease.

Youngstown, O., Jan., 1882.

For the American Bee Journal.

Foundation for Sections.

H. C. FARWELL.

In Mr. Doolittle's article on page 6 of the BEE JOURNAL for this year, I was sorry to see that the Given foundation, made on the Given press, should be left out of his test. The great trouble with the thin foundation for sections is that it does not contain scarcely any wax in the wall. It is plain enough that foundation as thin as 10 square feet to the pound cannot contain much wax in the wall. You would not think of putting such foundation in the brood-chamber because there is not enough wax in the wall to much more than give the cell a fair start. Then why put it in the sections? The reason is that all the heavy foundation made on the roller mills has so thick a base or septum that the bees leave the so-called "fish bone" in the center of the comb.

This difficulty has been overcome by the Given press. The great pressure brought to bear on the sheets of wax makes the septum exceedingly thin and at the same time making a heavy wall. The septum of this foundation is as thin in that which measures 6 square feet to the pound, as in that which measures 10 square feet to the pound, if properly made, and fully as thin if not thinner than natural comb. Mr. Doolittle says:

"At a time when honey is coming in moderately, say when a good colony is bringing in from 3 to 5 lbs. per day of extracted honey, comb foundation is a success in the surplus arrangement, but at a time when honey comes in with a rush, the same colony gathering from 12 to 20 pounds per day, it does not pay the cost, for my bees will fill a box having a starter of natural comb, and finish it as quickly as they will one full of foundation by its side."

I can see no way to account for this statement only in this way, that when the bees brought in only 3 to 5 lbs. of extracted honey per day they could supply the amount needed to complete the full length of the cell; but when they brought in 12 to 20 lbs. of extracted honey per day they had to secrete from 2 to 4 times as much as those bringing in 3 to 5 lbs. per day. Thus putting those which brought in from 12 to 20 lbs. of extracted honey almost on a footing with the bees which had simply a starter.

Now if this wax had been supplied in the wall of the foundation the bees would not have had to furnish it, and I think Mr. Doolittle would have had to give a decided preference in favor of the sections filled with sheets of foundation. Mr. D. may say that some of the foundation was heavy, measuring 6 square feet to the pound, so it was, but his test shows that the septum of the same was very thick, and had their extra wax been in the wall, instead of the septum, it would have been just what we want. If we would have foundation a perfect success in the sections we must have a heavy wall and thin septum; such we have in the Given foundation. If we are going to furnish wax for the bees to build comb with let us furnish it, and not give them thin foundation with one-third or one-half enough wax, and making them furnish the rest.

Dorset, Vt.

For the American Bee Journal.

The Effect of Bee Stings.

T. C. MACE.

I stated in the BEE JOURNAL a short time ago the fact that the sting of the honey bee affects me dangerously; seeing Wm. F. Clarke's experience in the last number of Weekly BEE JOURNAL, I will give mine.

Soon after being stung (it matters not on what part) I feel the effects in my eyes, ears, lips, nostrils and throat, particularly the latter, and generally more or less all over my body; swelling begins to progress at a fearful rate; breathing through my nostrils soon becomes impossible and breathing at all becomes very difficult, so much so at times that I am nearly suffocated for want of breath.

On two occasions during the past season, my tongue swelled so that I could scarcely speak so as to be understood.

A few years ago some doctors advised me to try drinking spirits. I did so and still use it for that purpose. I imagine that it does good as the

sooner I take it after being stung the more mild the effect of the sting seems to be, and during the swelling a swallow of spirits seems to slightly relieve the difficulty of breathing, for a few minutes, but sometimes it is almost impossible to swallow the spirits or anything else.

I have some faith in "inoculation" notwithstanding the fact that the more I am inoculated the worse the effect. If it were not that each sting is fraught with danger, I would try the experiment in about this way: After being stung I would take spirits after the effect of the sting had considerably passed off (but not entirely), and while the system was somewhat under the influence of the spirits I would be stung again, then take more spirits and after the effect of the sting had sufficiently passed off another sting, and so on indefinitely until the sting had little or no effect, taking just spirits enough to neutralize the poison to a considerable extent, but not entirely. As soon as the indications justify (if they should justify) diminish the amount of spirits taken, but continue the stinging for sometime after the spirits has left the system. The experiment might result thus, or it might not. If it should, I have an idea the system would be effectually inoculated.

I should be encouraged to try the experiment by the fact that some years ago, after the effect of a sting had passed off sufficiently to render it possible for me to get among the bees again, I immediately received another sting which seemed to affect me but little, if any; but my wife and father-in-law think it would be too much like suicide for me to try it. I wish, however, that some one else would. If Mr. Clarke does not seem to think the sting really dangerous, will he try it? Now, please don't plead temperance, for I am a temperance man (except on occasion of bee stings). We have heard and read of well authenticated cases (both accidental and experimental), of the human system being effectually inoculated so as to become venom proof. I have seen such accounts in the BEE JOURNAL. I formerly knew a man in an adjoining county who told me that the sting of the honey bee effected him very painfully, but on one occasion (on cutting a bee tree I believe) he was so severely stung by several bees that he had to be carried home by his companions; since which he has been venom proof. Cameron, Mo., Jan. 16, 1882.

For the American Bee Journal.

Is this all Fiction?

L. W. VANKIRK.

I must have a chat with Mr. Doolittle, and I guess the best way will be to run over to his ranch. *Wie gates*, Mr. D.? I see you are busy. Yes, very; last winter was hard on my little pets; I will have to do a great deal of doubling up. Why do you have to do this? Well, it will take me some time to tell. You know I use a small hive. Last season I united, and stimulated

my colonies until the queens had every comb filled with brood, so when the harvest came they were forced to store all their honey in the surplus chamber. I obtained a good crop, but the season closed sooner than I expected, and I found my colonies scarce of honey and full of bees. After I had weighed my surplus, I fed back all that was not salable, and not having enough of this, I drew largely on the sugar barrel. Well, didn't you get them in good shape for winter in this way? No; somehow, the queens wouldn't do any good laying, there being such a horde of old bees on hand, etc. After a great deal of fussing, I was forced to let them go into winter quarters, and my cellar was too cold for them, the thermometer ranging from 30° to 35° all winter, and that temperature is far more destructive to bees than a higher or lower temperature. What temperature should a cellar be kept? About 46°, but it is a good plan to give them a gradual cooling off once or twice a month. I agree with you there, but your bees have wintered badly; how will you be able to hand in your big report this fall? Well, I'm going to unite and get the number just as small as possible (I won't count those nuclei over there), and feed liberally to get the queens to lay, and by the time the honey season comes, I will have lots of queens on hand, and I can divide up and have all those empty combs occupied by the time the season is in full blast. You see it will be easy to get a good average, and that is all I care for. By the way, stranger, how many bees do you keep and how are they doing? Well, I went into winter quarters with 96, including a few that were united, and came out with 87. Well, stranger, were they good and strong? No, sir; they resembled yours in some respects; they had plenty of honey and few bees. Well, did you double up? No; I had sixty-odd that didn't need anything; the balance had their honey uncapped from time to time, but I didn't get all strong enough till the honey season had come. What did you do then? Why, the strong ones were swarming by this time, and I used up about 20 or 30 swarms strengthening these weak ones and stocking my nuclei.

How many have you now, stranger, and what were your profits from them last season? I have 90 colonies, and my profits were about \$800.00. How about your outlays? Twenty dollars will cover all, including 7 bee papers. Do you give the bees all your time? No, sir; bee-keeping is a "sort of side issue" with me. I do a hand's work on the farm most of the time, and let "the girls" preside over the apiary. Why don't you give it your whole time? I would, if I could get any one else to take the same interest in the other work that I do. I can get along pretty well by taking a day now and then, and making good use of my "spare moments." I have made bee-keeping pay in this way for 8 years, and have not lost as many, or half as many, in all this time, as you did last winter. But my time may be coming. How is it; is this all fiction? Washington, Pa., Jan. 18, 1882.

SELECTIONS FROM OUR LETTER BOX

Unfortunate.—I subscribed for the BEE JOURNAL the beginning of the year, and I think I began the year well. I am 65 years old, and have had bees 4 years. I began with 2 colonies; 1 died, the other sent out three swarms. One took to the woods, which left me 3 to winter. They came out all right in the spring and increased to 15, which gave me 256 pounds of honey, and I sold it at 25c. per pound, netting me \$64. This was all in box honey. In the winter of 1880-81 they all died, and left lots of honey, some of which I sold. Last June I bought 1 colony in an observatory hive. Last spring I sent to H. A. Burch, South Haven, Mich., for 6 colonies of Italian bees. They were to be delivered the 1st of May, but no bees came; I wrote a number of times, and he said he would send them as soon as he reached my order, and he kept promising from time to time, but neither sent the bees nor refunded the money. At last I brought suit against him for money or bees, and he sent the bees in poor condition the latter part of September, with hardly anything to keep them through winter. I have had to feed them ever since. I cannot tell whether they will pull through or not. I bought 12 colonies of black bees this fall; they are all in good condition. I am going to Italianize them.

S. T. WOOLWORTH.

Gratiot, Wis., Jan. 24, 1882.

Bees in Kentucky.—I am glad to acknowledge that I am a more enthusiastic apiarist since my attendance of the National Society, at Lexington, Ky., and believe my success in the past can be greatly excelled during coming season. We all hail with delight the improved appearance and increasing value of our favorite, the BEE JOURNAL, and hope its Editor and staff may be blessed with the great prosperity ever due to industry and true merit. Bees are wintering well in Kentucky and the prospect for 1882 is flattering when we consider the mild winter, hives stored with the greatest abundance of rich stores to induce early breeding; then we have had a copious rainfall for 3 months past which will bring us a profusion of early blossoms and rich verdure of clover and grasses for our little pets to revel in.

JOHN T. CONNLEY.

Walnut Lick, Ky., Jan. 20, 1882.

Honey Pop-Corn Balls.—Allow me to thank Mrs. A. M. Sanders for her recipe for making honey pop-corn balls. We have tried it and think they are very nice. Bees are wintering well, so far, in this vicinity. I have 45 colonies; 25 in cellar and 20 on the summer stands, packed in chaff. Being in attendance at the Michigan State Bee-Keepers' Convention, I say you are right in regard to the glucose question.

J. T. SMITH.

Bellevue, Mich., Jan. 23, 1882.

Bee-Culture in D. C.—There is not much intelligent acquaintance with bees in the D. C. and parts adjacent, and I do not know what can be done to create a proper interest. Maryland and Virginia ought both to be great bee States, and I hope soon will be. Washington City, I believe will, in the near future, beat the world for its honey flow, for its flora, and especially for basswood and white clover it will, as a city, be unequalled. The tide-water regions of both States ought to be admirable for honey, but it is almost entirely neglected. I am going to see what I can do through the clergy. If we can interest them, they can soon interest their people. I have now 42 colonies, which I hope will winter safely—all hybrids and Italians. I hope to do well next year. I read the Weekly BEE JOURNAL right through.

J. A. BUCK.

Washington, D. C., Jan. 23, 1882.

Kentucky Bee-Keeping.—There are not a great many who have bees near me; at least those who have bees have but few colonies; scarcely any within 3 miles of this point, have more than 10 or 12 colonies. I began the winter with 40 colonies in Langstroth hives, mostly Italians, and as far as I know, they are all alive. Some of them were weak in the fall, but I have fed considerable, as the weather was favorable. We had rather a poor honey season last year on account of the severe drouth, but a very favorable winter so far, the weather being so open that they have had several flights. We have not had much severe cold weather, and little snow, but plenty of rain and mud. As far as my observation has extended, the bees seem to be consuming but little of their winter stores, rather less, I think, than usual. Success to the BEE JOURNAL.

J. F. ELLIS.

Fiskburg, Ky., Jan. 26, 1882.

Artificial Comb Honey.—Do people in large cities buy and use our beautiful section honey, and at the same time think they are using or eating artificial comb honey? I am frequently told by well-informed men that section honey is manufactured in Chicago, and none but experts could tell it from our natural section honey, except by its flavor. One man told me, in traveling through New York State he saw wagon loads of full comb shipped from the factory. I told him it was perhaps near Canajoharie, and was foundation filled in frames ready for the bees; but he insisted it was full-size comb, and added that in New York city they manufactured large quantities of section honey, and that it sold 2 cents higher, per lb., than natural honey, and yet did not contain a drop of honey. I have so far always denied the possibility of any such honey in sections. If the questions are worthy of any notice, please give us light. A few words in explanation: A friend of mine tells me that he has frequently eaten artificial section honey at his sister's table, in Chicago, that could not be told, until cut, when it would show plainly from the absence of the natural cells.

Question—Could a sheet of wax be made resembling capped honey, fastened into a section, the section filled with glucose of the proper consistency, and then the other side sealed up with a similar sheet of wax? I say no; but these are well-informed men.

H. S. JACKMAN.

Peru, Ill., Jan. 19, 1882.

[We have expressed the opinion that the manufacture of artificial comb honey was not only impracticable, but utterly impossible. However, we have a series of investigations under way, as stated last week, to ascertain how the impression originated, and will give publicity to the result when fully learned. Undoubtedly, the whole story has originated from a mistaken impression, probably from the use of too thick foundation in the sections, or some one not thoroughly familiar with apiculture, has seen some bee-keeper using combs which were built the previous season and saved over for spring or summer use, then a fertile brain has suggested that they were artificially filled with glucose and capped over. Once imagining how it might be done, it is easy to give out the impression that it was so done, and a story or prejudice never loses by traveling. Persons in large cities might buy artificial comb honey, even though they knew it to be such; but they would prefer the genuine. We know they buy sugars and syrups, and yet no one is so ignorant as not to know that the majority of the latter is glucosed. Some are even so demoralized that they buy butterine, knowing it to be such, and the reason assigned is "it looks as well as most of the butter."—ED.]

Bee-Culture in Tennessee.—I read the BEE JOURNAL with a great deal of interest and profit. I would be more interested if you had more correspondence from Tennessee and the South. I would like to see our people more interested in the production of honey. From your correspondents in the north, and northwest, you seem to labor under many more difficulties incident to your rigorous winters, than we do in the south. It is a rare circumstance that our bees perish from cold, and we never winter in houses or cellars, or pits, but on their summer stands. Your reports, however, indicate that your annual yield, per hive, is greater than ours. Perhaps it is owing to your superior care, manipulation and skill. It seems to me, that, taking everything into consideration, the south must be a better location for an apiarist than the north; when we take into the account the rigorous winters of the north, involving so much loss, so much care and labor. We would like to see some of your enterprising bee-keepers in this

country. In my opinion, a lucrative field awaits such here. We have had an exceedingly mild winter so far, and our bees are in prime condition. They are now gathering pollen from the American *arba vitæ*. I see that Wm. F. Clarke, in his article, in your last issue, "goes for" Mr. Doolittle for using "we" when speaking of himself. Will you allow me to ask Mr. Clarke to say, in his next, whether it is in good taste for Doctors and Divines, when writing for bee papers, or advertising bee productions, to sign themselves Rev.—Dr.—? If so, would it be in good taste for a general to sign himself Gen.— or a lawyer to sign himself Lawyer—?

JOHN FOX.

Columbia, Tenn., Jan. 16, 1882.

Keep the Ball Rolling.—I see that Mr. G. W. Thompson has made the motion for a Bee-Keepers' Society, in New Jersey (see BEE JOURNAL Dec. 7), and it has been seconded by Mr. Chas. H. Rue (see JOURNAL Jan. 3). Now, Mr. Editor, it only remains for you to put the question, and in doing so, be sure to record my vote in the affirmative. Let some one arrange for the meeting to organize and circulate the notice, and New Jersey will no longer be counted out of Beeing; but will take her stand with other progressive bee-keeping States.

J. H. B. COOK.

Caldwell, N. J., Jan. 16, 1882.

California Prospects.—It would please many of us California bee-keepers to attend the National Conventions, but the distance intervenes depriving us of that pleasure, and this is the penalty we pay for living in the land which may truly be said to "flow with milk and honey," although there are years here when the flow of honey is very light; but the flow of milk continues, and such was the case last year. Judging from present appearances, the prospect for 1882 is not very encouraging, although this is something which is beyond human wisdom, to say what the future will bring, especially in the way of honey. But this I can say, that even when there is a deficiency in the honey crop here, the mortality of the bees need not necessarily follow. All of our good honey is produced in the mountains or foot hills, but there are seasons, when from different causes there is no secretion of nectar in the mountain plants, consequently, the bees can gather no honey; but they can be saved by moving them to the valleys where there is a succession of bloom, especially on lands that are irrigated, and on such lands you can grow whatever you wish to plant, enabling their owners to sow feed for them any time of year. Rape and mustard will bloom the year round. There are also in these low lands hundreds of acres of different varieties of the willow, which blooms from December until May. The eucalyptus, acacia, and pepper tree have been extensively planted here, and they afford both honey and pollen. I could enumerate many other honey plants which we could cultivate for

the bees, but my letter is already too long. You will ask, "Why, then, does not California have a surplus of honey every year?" It is because the Californian has had his palate so pampered with good mountain honey that he cannot descend to eat strong, mixed, valley honey, which is much darker, and of a very inferior quality. I heartily approve of the action of the National Convention in choosing Wm. Muth-Rasmussen as their Vice President for California. I think the mantle could not well have fallen on more worthy shoulders.

J. E. PLEASANTS.

Anaheim, Cal., Jan. 13, 1882.

A Missing Bee Man.—In the spring of 1874, Abraham Krider, who claimed to be from Bucyrus, O., was dividing and transferring bees in our section of country. He introduced a new hive, which was simply a square box with cross-sticks and slats one-inch square, and one-inch apart, on top of the hives, to give the bees free access to the honey apartment. His mode of dividing was as follows: Drum one-half of the bees with the queen out of the "gum," put them in the new hive, which he put in the place of the old gum, removing the latter to one side to rear a new queen or die. In transferring, he removed all of the bees, and saved all the combs and honey. In the spring of 1875, I was employed by Mr. Krider to furnish conveyance and tools for manufacturing hives. In the following November we went to Kosciusko and Wabash counties, taking orders for dividing and transferring bees the following spring. Our orders amounted to nearly \$1,000. Mr. Krider, who was about 32 years old, 6 feet tall, weight 180 lbs., wore a mustache generally blacked, and spoke the German language naturally, suddenly disappeared. He was a great cigar smoker, and had a craving appetite for strong drink. A postal giving his whereabouts since that date, will be thankfully received. Being left in a dilemma, I then employed Mr. I. R. Good to assist me, since which time he has devoted his time to the business of bee-keeping and queen-rearing, and has been quite successful.

AMOS P. BLOSSER.

Goshen, Ind., Jan. 18, 1882.

Can it Be?—I think I have made a discovery, without the means to demonstrate it, *i. e.*, that the worker-bee has an opening in the pollen baskets on the posterior legs, through which moisture can escape to hold the pollen in place in the baskets. I obtained this impression last spring when feeding rye-meal. The bees would buzz over it for a few moments, then I could see pellets in the basket, and they would not touch the meal, only stir it with their wings, while others would get in the meal and wallow like pigs. I have no microscope to test the matter, and request the scientific readers of the BEE JOURNAL to investigate the subject. Among other things which convince me this is so, I have seen bees laden with pollen come from the fields, on some the pollen

was comparatively dry, and on others, apparently from the same source, it was so wet that it would almost drop off. Will some of the scientists give their opinions? Bees are apparently doing well. They had a good flight on the 28th of December.

ABE HOKE.

Union City, Ind., Jan. 23, 1882.

Persimmon Bloom for Honey.—Bees done poorly here last season. I went through the winter with 36 colonies, but had no swarms, and only about 300 lbs. of honey. Bees seem to be wintering well now. I wish to say to those who are planting trees for honey, that the persimmon is one of the best. It comes in bloom about the same time that linden does, and bees work upon it in a perfect swarm. What kind of seed can I scatter upon a tract of land that was once heavily timbered, but is now cleared, and used as commons, generally as a cattle range? It is a heavy clay soil; water stands upon it in winter, but dries off in summer, making fine pasture. There are still logs and stumps on it. It would produce fine crops if cleared. Is the Emerson Binder the same kind that has the spring-steel back, and is used for music?

JOHN H. CHRISTIE.

Dyersburg, Tenn., Jan. 17, 1882.

[Sweet clover is the best you can plant, as it requires no cultivation after being once covered; a light harrowing will be sufficient to cover it, and it will hold its own against everything else. The Emerson Binder has cloth back, and no still springs. It is much cheaper and quite as durable as the music binders.—ED.]

Labeling Tin Cans of Honey.—I have found out what is the reason labels (no matter what kind of paste is used) will not stick to tin. There is a thin film of grease on all new tin ware, which must be removed, washing the place where the label goes on with a solution of caustic soda or potash, and drying with a cloth will obviate the difficulty, and common flour paste will then stick.

H. K. BEECHAM.

Acme, Mich., Jan. 25, 1882.

A Peculiar Case.—I have a colony of bees in my honey house, up stairs, with entrance on the outside, so they can fly at leisure. We use the room 3 times a week for band purposes. There are 15 members, and of course, we make quite a noise with 13 horns and 2 drums; the result is, the bees are about $\frac{1}{2}$ or $\frac{2}{3}$ dead, and they have eaten 25 or 30 lbs. of honey since Nov. 10. I think from the smell, on opening the hive, they have dysentery. Well what I started to say is this, on examination, the 21st inst., I find drones in all stages, from eggs to flying drones, no worker larvae in the hive. The mother hatched June 10, 1881. She was as prolific as any queen I had up to the time of putting away for winter. She is a well-marked Italian queen, but her progeny is rather dark, but pure, if three-banded

is pure. Did you ever hear of a queen laying drone-eggs only in winter. I have had bees quite a while, and this beats me, what do you think about it? J. F. KIGHT.

Poseyville, Ind., Jan. 23, 1882.

[We think you have no queen in the hive now; if there is one, she has been reared since the fall set in, and has not been mated. It often happens that queens become what are called drone-layers, but not a young, properly-mated, prolific queen.—ED.]

From a "four-year-old" Apiarist.—Permit me to say your JOURNAL for 1882 "just fills the bill," is both magazine and paper, is weekly but not weak, and is just the shape to bind for future use. For two years I leaned on the capacious breast of Novice, but after leaving the infantile stage of bee-culture, I naturally struck to the more solid food in the BEE JOURNAL. I am only four years old yet (in the sweet industry), but I read your JOURNAL with great pleasure. I have a vacation every week from my pastoral cares when I get hold of that.

D. D. MARSH.

Georgetown, Mass., Jan. 17, 1882.

Terribly Severe.—Yesterday we had the worst day of the season. The mercury was below zero, with the wind blowing a perfect gale from the northwest, and the air was filled with whirling snow. It has cleared off now, but the mercury stands at 26 degrees below zero, while I write. This is the coldest that we have had in Borodino since I have kept bees. At such times as this, I can but think bees are far better off in a cellar of even temperature, standing at 45 degrees, or above.

G. M. DOOLITTLE.

Borodino, N. Y., Jan. 24, 1882.

Bees Have Devoured Little Honey.—Bees, so far, have wintered well, with but little consumption of honey, considering the mild weather and the many flights they have had.

JOHN C. PEDEN.

Lawrenceburgh, Ky., Jan., 25, 1882.

Feed the Bees.—Look at your bees the first warm day, and if they have not sufficient honey, at once get some coffee A sugar and take 4 measures of sugar and 1 of water (hot), put it on the stove and cook about 3 minutes, and feed the bees. If you have no feeder, make one; if your cushions are wet dry them; if you take no bee paper send for the BEE JOURNAL for 3 months at least, it may save you a colony of bees. G. N. PHARES.

Kempton, Ind., Jan. 26, 1882.

The First Blood.—On Jan. 7 and 15, 1882, my bees were bringing in pollen and honey from mustard, which was sown in September last. Continuous rain for thirteen days past, except those named, when the sun shone out near noon. A. B. McLAVY.

Bastrop, Tex., Jan. 16, 1882.

Ants in the Apiary.—In answer to Mr. Beath's inquiry I would say: Sprinkle the salt wherever the ants are; which is generally on the honey-board and under the edges of the cap. As it is not offensive to bees, it may be put on the bottom-board or anywhere about the hive.

J. L. WOLCOTT.

Bloomington, Ill., Jan. 24, 1882.

Bees Doing Well.—My bees are wintering finely, so far; even the small two-frame nuclei are doing splendidly. They are all in the cellar, with thermometer at 50° most of the time.

D. G. WEBSTER.

Blaine, Ill., Jan. 27, 1882.

Dreadful, Whew!—It is 20° below zero here. I think some of my bees must be dead, or else I have a tough lot. I dare not look at them till the weather is warmer. The JOURNAL now ought to suit everybody, with the improvement on last year's style. Somehow, I think the first number, for 1882, was the best I have seen for a year. I like the idea of putting all the advertisements at the back end, they appear more at home then.

H. ALLEY.

Wenham, Mass., Jan. 25, 1882.

Local Convention Directory.

1882.	Time and Place of Meeting.
Feb. 8, 9—	N. E. O. & N. W. Ps., at Jamestown, Pa. W. D. Howells, Sec., Ashtabula, Ohio.
9—	Northeastern Maine, at Dexter, Maine.
April 11—	Eastern Michigan, at Detroit, Mich. A. B. Weed, Sec., Detroit, Mich.
25—	Texas State, at McKinney, Texas. Wm. K. Howard, Sec.
26, 27—	Western Michigan, at Grand Rapids. Wm. M. S. Dodge, Sec., Coopersville, Mich.
27—	Kentucky Union, at Eminence, Ky. G. W. Demaree, Sec., Christiansburg, Ky.
May —	Champlain Valley, at Bristol, Vt. T. Brookins, Sec.
16—	N. W. Ill. and S. W. Wis., at Rock City, Ill. Jonathan Stewart, Sec., Rock City, Ill.
25—	Iowa Central, at Winterset, Iowa. Henry Wallace, Sec.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

The Northeastern Bee-Keepers' Association of Maine, will hold its second annual meeting at Grange Hall, Dexter, Me., Feb. 9, 1882. An invitation is extended to all persons interested in bees and honey, to attend, and bring their pet bee hives, smokers, extractors, etc., that we may compare the merits of each different kind. The President will give an address, and we shall hear the Secretary's report, and elect officers for the ensuing year. WM. HOYT, Sec.

The Texas State Bee-Keepers' Convention will be held at McKinney, Texas, on Tuesday, April 25, 1882.

N. W. Illinois and S. W. Wisconsin.

The Sixth Annual Meeting of the Northwestern Illinois and Southwestern Wisconsin Bee-Keepers' Association, was held at Freeport, on Jan. 17, 18. There was a pretty good attendance, and a very interesting time. Several new members were admitted, and many questions discussed; one being the best means of discriminating information that is to be obtained from the experience of different persons in the way of handling and caring for bees, and procuring the best results.

Mr. Pratt, of Dixon, gave quite graphic descriptions upon several questions which were very interesting. The objects of these Associations is to help and be helped by the experience of practical men, and we had men there with us who are doing the best to make bee-keeping a success that they can, and are willing to tell of their mistakes and failures as well as to tell of their success. You may rest assured that when such persons assemble together in Convention it makes an interesting meeting.

The Association has 98 members. The attendance was small considering the membership, there only being at any one time during the meeting 42 members, but what were there seemed to be enthusiastic. The following persons were chosen as officers for the year 1882 or until their successors are elected: R. M. Milliken, President; Levi Keister, Vice President; Phares Kleckner, Treasurer; Jonathan Stewart, Secretary. The number of colonies of bees represented was 845 that were prepared for winter; all of them were reported to be doing nicely, having plenty of good honey, and they will no doubt come out all right in the spring in good condition to gather the best of sweets for the owner and those who love honey—not *glucose*.

The next meeting will be held in Rock City, on May 16, 1882. The next Annual Meeting will be held on the third Tuesday in January 1883, at Freeport, Illinois. J. STEWART, Sec.

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted. G. W. DEMAREE, Sec.

Christiansburg, Ky.

Change of Time.—So as not to conflict with other meetings, the time of holding the Bee-Keepers' Convention at Jamestown, Pa., has been changed from Feb. 1st and 2d, to Feb. 8th and 9th. This promises to be one of the most interesting meetings yet held. A good programme has been made out, and all interested in bee-keeping will find it to their advantage to attend. M. E. MASON, Pres.

W. D. HOWELLS, Sec.

When changing a postoffice address, mention the *old* as well as the new address.

The Northeastern Convention.

Much of the space of this week's BEE JOURNAL is devoted to the proceedings of the Northeastern Convention, of New York, to the exclusion of considerable matter in other departments. We give the report of the Convention in its entirety, as published in the Utica daily papers, sent us by the Secretary, and have inserted all of the essays upon which discussions were reported. Others will be published as we can give them space.

It is hardly necessary for us to say that we deplore the action of the Convention in allowing itself to be drawn into a belligerent attitude toward, and unkind criticism of, the National Society (see page 88). Being a "life member" (not an officer) of the latter, and an "honorary member" of the former, we feel somewhat compromised by the action taken at Utica. We were not present when the "essay" referred to was read and the vote taken, at Lexington, and knew nothing of either till we saw the report of the proceedings—though it might easily be construed that we were, by reading the published report. We were unwell after arriving at the Convention, on the evening of the second day, and several times had to leave the Hall for a short time to get fresh air, and such might have occurred on one of these occasions. In justice, we should not be held the least responsible for anything done in our absence—which we neither indorsed, opposed, nor even heard read—as was our case with all the matters complained of.

The criticisms of Mr. House on the National Convention are:

1. Its manner of electing its officers by instructing the Secretary to cast

the ballot of the Convention for those reported by the nominating committee. Of this we disapprove, but we do not believe any injustice was ever done—it being an expedient to save time, there being no other nominations.

2. That its sessions should be held at the East, West, North and South, but that "during the past few years there is seemingly little or no regard paid to custom and privileges." Well, let us see. In 1877 and 1878, it was held in New York—that was the only time in its history when sessions were held in the same place two successive years! The year previous it was held in Philadelphia; all in the East. In 1879 it was held in Chicago (call that West); in 1880 in Cincinnati, and in 1881 in Lexington—both towards the South. It is certainly in vain to try to find any cause for complaint in this.

We suggested that the session of 1881 should be held in New York, but a New Yorker present responded that New York had not asked for it; we suggested Atlanta, Ga., but was met by the same objection. If New York wants it, let her send an invitation to the next meeting.

3. Its indorsement of Mr. Langstroth is called by Mr. House a "farce"—an "injustice"—"unjust discrimination"—a "stain upon its record, never to be blotted out"—"and enough to make the very blood chill."

To say that such epithets are foolish, ridiculous and unjustifiable, is putting it exceedingly mild.

The gentlemen who so unanimously voted to indorse the sentiments, as the views of the Convention, evidently intended only to show their appreciation of the labors of Mr. Langstroth, without the least disparagement to the late lamented Quinby, Wagner, Weiss, etc. It is, we feel certain, exceedingly unjust to attribute any other motive to them.

The National Convention was a very harmonious body, and we are fully persuaded never thought of being thus stretched upon a "rack" of torture.

On page 86, it will be seen that a malcontent sent a letter to the Utica Convention "making complaint that the AMERICAN BEE JOURNAL continually misquotes and endeavors to weaken the honey market." Having spared neither time nor money in our endeavors to *develop* the honey market, and just as honey is being made a staple article commanding a cash price at our very doors, to have such a *foolish* complaint entertained by the Convention and a "committee appointed to investigate the matter and report next year"—is supremely ridiculous!

The same individual sent his complaints to us with a threatening letter, a few weeks ago—intimating that a new bee paper would be started to "take the place of the BEE JOURNAL," etc.,—to which we replied in full, and added:

"As you think best to impugn my motives and use threatening language hostile to me and the JOURNAL—please let this close the correspondence. I have no time to attend to such, nor relish for it. I have done the best I could to get up a good Bee Paper, and shall continue to do so, regardless of consequences. You or anyone else have the same privilege, without consulting me or my interests."

As we own the BEE JOURNAL and have to take the full responsibility of its prosperity or adversity, we don't see what any individual or Convention has to do or say concerning its management. We cheerfully receive "suggestions" from anyone, but cannot submit to any *dictation*. If the BEE JOURNAL does not suit bee-keepers they are under no obligation to take it. This is a *free* country, and there are seven or eight bee papers, and he must be hard indeed to please who can find none to suit him.

Let bee-keepers try to cultivate generous feelings towards one another—encourage brotherly love, and practice charity—then they will neither find time, occasion, nor inclination to pick a quarrel with their fellow laborers. This is to be deplored every where, but no where more than among bee-keepers.

Conventions conducted in the interests of the pursuit of bee-keeping will ever receive the cordial attention and support of honey producers—but if such are to be *prostituted* to a

display of personal animosities, and the jealousies of the discontented—then it is far better to never more hold a Convention—the pursuit, now being on a firm basis, will prosper, and honey become popular with the masses, even though there be no concerted action among bee-keepers. The pursuit will be "wounded in the house of its friends"—but it will *not* be destroyed. Its professed friends will alone be the losers.

Artificial Comb Honey.

Much has been said about the manufacture and sale of artificial comb honey, and so numerous and apparently well authenticated have been some of the rumors regarding its accomplishment, that many thoughtless persons have accepted it as a fixed fact. One story even goes so far as to advance the price of such bogus stuff two cents per pound above the genuine article, in the Eastern retail markets.

We have been unable to surmise how the hoax originated, and after much inquiry and investigation have come to attribute its start to the same cause as that assigned by Prof. Cook, on page 85 of this number—a joke. A. R. Kolnke, on page 93, this issue, referring to this matter, says that after the comb is built out by the bees, the bee-keeper may fill it with anything he pleases, and seal it himself, too. He adds:

"The *modus operandi* I have known for several years, but, considering there is enough cheating and adulteration going on, as it is, I deem it not advisable to give vent to this invention"....

In a matter like this, or any other, we think the real fact, fully and plainly told, is most beneficial. The method referred to, we presume, is that exhibited at a German Bee-Keepers' Convention, where an ingenious member present sealed over a comb of honey by a process of spraying on hot wax; but the work was slow and tedious, and instead of suppressing the fact as prejudicial to the bee-keeping public, the affair was given publicity as a triumph of patience and skill. Notwithstanding our abiding faith in the ingenuity of humanity at this day, we do not believe it possible to artificially seal honey combs at a cost to compete with the labor of the bees; nor do we believe it practicable to fill the combs with anything, by hand or mechanical means, and then depend upon the bees to complete the work profitably and satisfactorily. And as

to the making of artificial combs, with cells built out to natural length, and in close imitation of the wonderful work of nature's little drudges, *it has not been done*. The genius who shall accomplish this may next turn his attention to the discovery of a perpetual motion, or prepare his crucible for the transformation of the baser metals into gold.

Honey as Food and Medicine.

We have just issued a new edition of our pamphlet bearing the above title. It has been revised and enlarged from 24 pages to 32, the new pages being devoted to *new* Recipes for Honey Medicines, as well as all kinds of cooking in which honey is used.

It is undeniable that *pure honey* is the simplest, the healthiest, the most natural, and the most strengthening article of food for healthy persons, as well as the best remedy for the sick; and for the convalescent it is the true balsam of life, to restore them to their wonted strength and health.

What is needed is to educate the community up to this idea, and in no way can that be done so well as by directing their attention to the merits of honey.

This little pamphlet should be scattered by thousands all over the country, by honey producers. In this way it will *create* a home market in almost any locality.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

When 100 or more copies are wanted, they will be sent by express, at the expense of the purchaser.

The present seems to be an unusually mild winter all over the world. An English correspondent, at Derby, writes on the 12th of December, "I have plenty of sunflowers in bloom in the garden, and primroses. Some of my daisies are in bud. The season is a remarkably open one." During January they had a "cold wave," as did nearly the whole Northern World. Still on the whole the winter has been a delightful one in America as well as in Europe.

CORRESPONDENCE

For the American Bee Journal.

Producing Comb Honey—No. 1.

G. M. DOOLITTLE.

By referring to the Weekly BEE JOURNAL for Dec. 7th, I find that notice was then given that Doolittle "will write a series of articles during 1882 on the production, care and sale of comb honey." Upon looking the field all over, I believe I can please the readers of the BEE JOURNAL no better than by telling them first what I do in my own bee-yard, and how I do it, thus writing from a practical standpoint rather than trying to theorize, by telling you what might be done. In order to write understandingly, I will take up the text under the different heads: Production, Care and Sale, separately, and give my mode of treating each one.

First, then, we have production: In order to produce good results in comb honey the first requisite is plenty of bees when the honey harvest arrives, for whatever else we may have, success cannot be obtained without plenty of bees. Again, as I said before, these bees must be on hand in time for the honey harvest, else they become merely consumers instead of producers. How often we find men keeping bees on this (consuming) plan, getting nothing from them in the line of surplus honey, unless it is some little buckwheat honey, or that gathered from fall flowers, which is generally of inferior quality, for the reason that they do not have anything but colonies weak in bees at the time the harvest of white honey occurs. Such bee-keeping does not pay, and for this reason I have dwelt thus long on this part to enable all to see that, of all others, this is the most important item in the production of comb honey.

Our first step, then, is to produce plenty of bees in time for the honey harvest. With most of us white clover is the main honey producing plant, which blooms about June 15th to 20th, and by June 25th is at the best; hence, our bees must be in readiness at that time if we wish to succeed. From practical experience I find that it takes about 6 weeks to build up an ordinary colony in the spring, to where they are ready to produce honey to the best advantage; so I commence to stimulate brood-rearing about the first of May. I have tried many plans of feeding, both in the open air and in the hive, to stimulate brood-rearing, but finally gave them all up for the following: When I have decided it is time to commence active operations for the season I go to each colony and look them over, clipping all queens' wings that were not clipped the previous season, and equalizing stores so that I know each colony has enough honey to carry them at least two weeks without any fear of starvation. At this time I find, as a rule, each good colony

will have brood in four or five combs, the two center combs containing the largest amount. I now reverse the position of these combs of brood by placing those on the outside in the center of the brood-nest, which brings the combs having the most brood in them on the outside. Thus, while the colony has no more brood than it had before, the queen finds plenty of empty cells in the center of the brood-nest, in combs having some brood in them, and she at once fills these combs with eggs, so that in a few days they will contain more brood than those that were moved to the outside, while the bees have fed and taken care of this as well as though its position had not been changed. Thus quite a gain has been made in regard to increasing the brood.

In about 8 days, if the weather is favorable, the whole yard is gone over again, and this time a frame of honey is taken from the outside of the cluster and the cappings to the cells broken by passing a knife flatwise over them, when the brood-nest is separated in the center and this frame of honey, thus prepared, placed therein. As I go over the yard each time I am careful to know that each colony has abundant honey to last them at least two weeks, for if we wish to obtain the largest amount of brood possible, the bees must never feel the necessity of feeding the brood sparingly on account of scanty stores. It is also necessary to know that there are no cracks or open places at the top of the hive to let the warm air pass out of the hive, but tuck all up as nicely as you would fix your bed on a cold winter's night.

After 7 days more have elapsed, I again go over the whole yard and insert another frame of honey in the center of the brood-nest prepared as before. If at any time I am short of honey, I use sugar-syrup made by taking confectioners' A sugar and dissolving it in hot water (at the rate of one pound of water to two pounds of sugar), by placing the two in an extractor can, which should be placed some three or more feet from the floor. Stir well till all is dissolved. Now, procure an old pan of the ordinary size and punch the bottom full of holes about 1-16 of an inch in diameter, punching the holes from the inside of the pan, when it should be placed under the faucet to the can containing the syrup. Immediately under the pan place another can if you have it (if not a wash tub will answer), and you are ready for business. Take an empty comb and lay it down flat under the pan and on the bottom of the can, when you will open the faucet letting the syrup out in the pan till enough has run out to fill one side of your comb, when you will shut it again. Turn over your comb and fill the other side, and after hanging in your tin comb bucket (wash boiler, or some convenient tin thing which is most always at hand) a little while to drain, it is ready to be used in any spot or place, the same as a frame of honey. I prefer this way of feeding to any feeder in existence. If you wish to make quick work of filling

these combs, have an assistant to hand you the empty combs and take the filled ones; roll up your sleeves and hold the combs near the bottom of the can, or low enough down so the falling syrup will force the air out of the cells so they will be filled; turn your faucet so the required amount of syrup will be in the pan all the time, and you can fill them (the combs) almost as fast as he (the assistant) can hand them to you. The sides of the can keep the syrup from spattering about the room, and what is caught therein can be turned into the upper can again. Well, I have taken some time to tell you how to do this, but as I do not expect to tell it again, I thought I would try to make it plain.

The next time I go over the yard I generally reverse the brood as at first, as well as to put a frame of honey in the center. By this time the bees will have hatched out of the combs which were placed on the outside, and as the queen does not lay as readily on the outside of the cluster, these combs will not be as well filled as the center ones.

After about a week more, the yard is gone over again in like manner, and if but 9 frames are used to the hive, *this* time will conclude the stimulating process, for at the end of about 5 days more, or about the 10th of June, all our frames are full of brood, and our colonies in good condition for receiving the surplus boxes.

My next will be about how I manage the weak colonies, and also how I would manage if I wished to keep only a limited number of colonies in an apiary.

Borodino, N. Y.

For the American Bee Journal.

Yellow or Leather-Colored Bees.

W. J. DAVIS.

In the BEE JOURNAL of Jan. 11th, page 22, Mr. Chas. Dadant publishes a letter from Mr. Heddon, in which he expresses the opinion that I have found something better than the yellow Italians, that is the leather-colored Italians. As Mr. Heddon's letter has been published, it follows that what I have to say, in reply, should have the same publicity.

I take pleasure in saying that I consider Mr. Heddon a close observer of everything pertaining to the apiary, and when he takes a position in "good earnest," and not merely for the sake of provoking discussion, he is oftener right than wrong, but to say that he is always right, is what I cannot concede to any one whose writings I have ever read on bees or their management.

Before discussing points upon which we do not agree, I will mention one upon which we do agree, viz: that we aim to keep bees for the honey they can store for our benefit. I suppose it matters but little whether the color be yellow, black, green, blue or leather, or that they vary in size from that of the house-fly to the humble bee, if they bring in plenty of good honey, and do not endanger human

life by having them in our gardens, and at the same time please the eye. I have heard men say that they preferred the color of the black bee to the yellow Italians, while I confess I prefer the yellow, and others prefer a mixture of the two.

It is evident to my mind, that the bee of the future (if not of the present) will have some other color. Messrs. Dadant and Heddon say give no more leather, while I and others say give us more gold. I would not be understood to advocate the production of yellow bees at the expense of honey-storing qualities. Can these gentlemen assign any reason why leather-colored Italians can amass any larger stores than the yellow Italians? I verily believe that it is more difficult to keep the latter up to the proper standard in any locality where black bees exist, or even a mixed breed, where the mother bee is from an objectionable race.

I am still breeding the yellow Italians. I presume Mr. Heddon did not intend his letter for publication, but if he desires to compare notes on the relative value of the "leather and the gold" through the pages of the AMERICAN BEE JOURNAL, here am I. We have taken sweet counsel together by way of the silent pen in the years gone by, and I will promise that we will not come to blows.

Youngsville, Pa., Jan. 28, 1882.

For the American Bee Journal.

Honest and Kind Criticism.

A. J. COOK.

I am more than pleased with the BEE JOURNAL for Jan. 25. It shows that even bee-keepers can criticize in a fair and amiable spirit. In reading the able papers by Messrs. Tinker and Clarke, I was reminded of something I have read about our late lamented President: "In the debates in Congress, Garfield never insulted his opponents; he was always just to them. He never cultivated the cheap notoriety of sneering retort, and he was respected and liked by those with whom he radically differed."

Mr. Langstroth once said to me that he wondered if being stung did not make bee-keepers cross, uncharitable and selfish? I suggested that Satan had more to do with it. Mr. W. F. Clarke, if I remember rightly, has been stung, and so he is a living refutation of Mr. Langstroth's proposition. Let me suggest to Mr. Kolnke that he need have no fear that Mr. Muth will take serious umbrage at fair, candid criticism; that is what we all like and crave.

I am very busy and only have time to say to my good friend, Rev. W. F. Clarke, that my article was written before his criticisms on Mr. Heddon appeared, though published later, so I never thought of him. I could never say that he contradicted well-grounded facts, for I not only don't believe such to be the case—I positively know it not to be true.

In the future I hope to explain more fully in regard to the pollen matter.

Mr. Prentiss, of Sandusky, says he knows that pollen killed nearly 100 colonies of bees for him last winter.

Let me add, Mr. Editor, that the canard about the manufacture of comb honey has outlived its usefulness. It is no longer good, even as "a joke."

Cornell, N. Y., Jan. 27, 1882.

Northeastern New York Convention.

The 12th annual Convention of the Northeastern Bee-Keepers' Association, was held at Utica, N. Y., Jan. 25-27, 1882.

On account of the absence of the President, W. E. Marks, and Vice President Doolittle, because of sickness in their families, W. E. Clark, of Oriskany, was chosen President *pro tem*.

After the calling of the roll and the reading of the minutes of the last meeting, the reports of the Secretary, Treasurer and standing committees were read and accepted.

There remains in the treasury, according to the report, \$63.65. The Society is in a prosperous condition, both financially and numerically.

Secretary House read the following address from Mr. Thomas G. Newman, editor of the AMERICAN BEE JOURNAL:

Suggestions About Conventions.

BROTHER APIARISTS:—New York has several organizations of bee-keepers, but the "Northeastern Bee-Keepers' Association" is the father of them all, and of right, is, and should be, looked up to as the State Society. So long presided over by that illustrious, but lamented bee-master, father Quinby, its fame is world-wide, and its influence not exceeded by any Society on the American Continent. Its members include some of the most progressive and successful apiarists of the age.

It would, therefore, be eminently proper for the Northeastern Convention to take advance ground, and inaugurate some of the many reforms necessary to the well-being and permanent good of American apiarists. Allow me to make a few suggestions. I seldom write essays for Conventions, and had it not been the special request of your excellent secretary, I should not have written this, and now content myself with simply throwing out a few "hints," and trust that you will give them your best attention.

1. Some plan should be devised to make a more perfect organization, and knit together, more closely, all the apiarists of our country. County Societies should be auxiliary to the State Society (for such is yours, except in name), and all the members of the county organizations should thereby become members of the State Society, entitled to all its benefits and privileges, and proportionately bear

the expenses of holding such. The Presidents of State Societies should become *ex-officio*, the Vice Presidents of the National Society, and thus cooperate unitedly for the general good—and delegates should be sent from the Counties to the State—and from the States to the National Society. This can easily be accomplished, and would contribute to the general welfare. Organization is *life*; in union there is strength. Disorganization is *weakness*, and leads to dissolution—*death!*

2. The present method of conducting conventions, by so many and such long essays, is killing in its influence, and often works positive damage to all concerned. To illustrate:

A long essay is read, and before it is ended, those who listen to it are tired out, and forget or do not quite comprehend the points, and so it passes, without being sufficiently understood or discussed—goes into the minutes, and under the sanction of the Society, is published to the world as its views, when, perhaps, it represents the opinions or feelings of but a moiety of those present, thereby doing positive *damage*, because it misrepresents the society in general. If essays are admitted, but one should be thrust upon a session, and if possible that one should be printed, and placed in the hands of the members to be discussed at the next session. In this way some of the difficulty could be overcome, and the detrimental effects avoided.

3. If such organization was obtained it would facilitate correct statistics, and the united power of the apiarists of the Nation could be exerted to demand legislation against fraud and adulteration; obtain redress for injurious rulings of the Postal Department, such as denying the admission of bees to the mails, etc., and correct the unjust discrimination of railroads in classing honey at exorbitant rates when they carry *similar* staple articles at one-fourth the freight demanded for honey.

Again, a *brotherly* tie would be formed—helping one another—not only in the matter of marketing our crops, but perhaps in helping the unfortunate, succoring the families of deceased members, and possibly providing for those overtaken by calamities, etc.

These are but a *few* of the things that could be accomplished by united effort, but we only wish to throw out these suggestions, and leave it with others to discuss the matter, and devise a scheme for carrying it to a successful issue.

But I will not weary your patience by further particularizing—while I am absent in body, I shall be present in spirit, and sincerely hope your meeting will be a success, and beneficial not only to yourselves but apiarists everywhere.

Chicago, Ill.

The essay was discussed by Messrs. Bacon, of Verona, Snow, of Fayetteville, Clark, of Oriskany, and Dickinson, of South Oxford. The remarks of these gentlemen were generally in accord with the spirit of the essay.

The next essay, read by the Secretary, was by James Heddon, and was entitled the

Improvement of the American Italians.

How to obtain the best bees is an absorbing theme among our fraternity just now. Well may it be, for, as you all know from experience how varied has been the results from different colonies, supposed to be equal in all respects. You well know that in this lies a large portion of the cause of success. We have experimented with the Italian bees, the German bees, the Cyprian bees, Syrian bees, etc., and yet it remains an open question which are the best.

True, a majority prefer the Italians to the Germans, but a considerable minority yet prefer the German. A fact worthy of our careful consideration, is that among those who, by theory and practice, adhere closely to the German, are men who have had large experience with both races, and who are extensive and successful honey producers. Many of these men have preferred hybrids to either race in its purity; others have not liked them. In my judgment, both classes arrived at their conclusions through their experiences, and both drew logical deductions from their different standpoints. Among each of these races we notice strains that differ widely from each other. Our success with hybrids depends upon two facts, the skill possessed in obtaining good strains of each race to start the crossing with, and the judgment and strains used by the master in superintending these crossings.

My experience has forced me to know that individual colonies of a strain differ from each other more widely in their virtues, than do different strains; further, that strains differ more widely than races, so far as I have used them, my use being confined to German and Italian bees.

I have no doubts, after 5 years of experimenting, that virtuous traits of character in the bee are as surely transmissible as are qualities in other animals. I believe I am yearly demonstrating and reaping benefits from the fact. No bee will ever satisfy me that does not possess qualities that are identified with the German bees alone. The same with the Italians alone.

I would that I was at liberty to give to you the verbatim contents of several letters I have from intelligent and experienced breeders, who are yearly filling the demand for thrice-emerged Italians. It has been found far more profitable to fill a present demand in a wrong direction, than to create a demand in a right one.

From what I can learn I do not, at present, think that the Cyprian or Syrians possess any special trait of character, not embodied in the virtues of the two older races, worth bringing into our breeding. A few vital points in all that we can afford to work with at once. We have about the same number of propensities to guard against, of course, viz.: the opposites of those for which we are breeding.

The older members will recollect

that during the early days of the Italians in America, from among the reports of the leaders of the present, came words like these: "I like the Italians better than the blacks, and the hybrids better than either, if they were not so cross. They beat all I ever saw as honey gatherers." Another, "My pure Italians go ahead of my hybrids and blacks; my hybrids are good, peaceable bees, but not as good gatherers as the pure Italians."

It is neither just nor logical to say that such statements were false, but we have reason to believe that from variations and sportings, came these different experiences.

These variations, I think, invite us all to improve our stock.

We have the enormous advantage of rapid generation. We have had the disadvantage of no control over the males, but now I find, in my present conditions, that I have almost perfect control over them. I have the only bees (222 colonies) kept within 3 or 4 miles. I have used selected combs, and those built on full sheets of foundation on wires, and find that by a little care, I can stock the air with about such drones as I wish.

As natural as the ebb and flow of the tide, has come up the cry of "hold on," "don't import any more bees," "we have got bees here now better than those we import." "why, they are buying and carrying back to Italy our American Italians."

These statements and acts are not the result of theory, but of practice, giving us demonstrations of facts. I think the desire for Cyprians and Syrians came from the facts that there was no longer any cause to import Italians. How came this change?

In the business of breeding off black and on yellow rings, our attention was called to the wisdom of breeding in some qualities. Almost every breeder bethought himself to choose the best business colonies when picking out his yellowest bees. Those who have closely watched the results of their labors, are seeing that nearly all the improvements they have made have come, not from change in race or color, but from breeding from the best acting colonies; that, instead of saying, "I will pick out my best acting colonies from among my yellowest to breed from," they should have said, "I will pick out my yellowest from among my best acting colonies, if I must supply yellow bees in order to satisfy my patrons." Now, I think that no experienced and observing breeder will differ from me, unless on the point of whether he should start with pure yellow bees alone, or both the races.

Whoever takes issue with me upon this point, I think will be forced to admit that the German or black bees possess some very valuable qualities, that the Italians do not. All the room left for argument then, is as to whether we can add to our "coming bee" these superior qualities, without necessarily taking with them some poor qualities possessed by the same race. I am forced to say that I know that I can, and have done it. I will state here and now, that I, as a comb honey pro-

ducer, would, were I confined to one race or the other in its purity, choose the German bee.

I firmly believe that the lauded leather-colored Italians were shaded by a dash of black blood, which has become fixed. I also believe that far better bees than these can be produced by the same process under the direction of reason.

Why, I, like many other special apiarists (of whom New York has a large share) prefer the production of comb honey. I will leave for another paper, but such being the case, am I not justified in refusing to give up the speedy and white comb-building propensities of the German bees, also their superior disposition to store in the surplus department rather than the brood combs, and their consequent reluctance to swarm? Are not these admitted peculiarities of the black bees? No, the yellow ones; and are they not vital points?

Dowagiac, Mich.

This essay called forth a discussion of the nature of the different kinds of bees, which was participated in by very many. The discussion was general, interesting and profitable.

The question of puncturing grapes was brought up. This is important among bee-keepers, and it is one over which legal difficulties have often been threatened. It was the unanimous opinion of all present that honey-bees never under any circumstances puncture the skin of a grape. Tests have been repeatedly made, and in no case has any bee ever been known to touch a grape that was not punctured. Black ants are the enemies of the grapes. Two bills were introduced in the California legislature to do away with all bees on this account. A careful examination and an extended debate proved that there was not a single case of bees puncturing grapes. The society placed itself on record on the matter by adopting the following resolution introduced by C. R. Dickinson, of South Oxford, and amended by Mr. King, of New York:

Resolved, After due investigation of well known and numerous cases, the Convention unanimously asserts that the honey-bee never punctures the skin of a perfect grape or any other fruit. But that the sucking of juices from fruits is only from that which has been punctured by other insects, birds or natural causes.

A motion was carried that the Secretary cause to be printed 200 copies of the above resolution and that these copies be distributed among the members and various publications.

During the day 28 persons were enrolled as members of the Association; the total membership is now about 160. A. J. King, editor of the *Bee-Keepers' Magazine*, was made an honorary member.

At 5 p.m. the Convention adjourned to meet at 7 p.m.

EVENING SESSION.

At the appointed hour the Convention was called to order by Mr. Clark, President *pro tem*. The Secretary read a communication from Messrs.

Bingham & Hetherington, asking that their smoker and honey knife should not be entered for premiums or competition. The request will be complied with.

Secretary House also read a communication from James Nipe, of Spring Prairie, Wis., making a complaint that the AMERICAN BEE JOURNAL continually misquotes, and endeavors to weaken the honey market.

After some discussion, Mr. House moved that the matter be laid on the table, to be called up at the next annual meeting, and that a committee be appointed to investigate the matter and report next year. Mr. Dickinson was appointed as that committee.

L. E. St. John then read a paper by Chas. Dadant, on "dysentery, its causes, effects and prevention."

The next topic for discussion was the "Disposal of Products."

Under this head, there was a talk on temperance and glucose. The question of using extracted honey in the manufacture of beer and wines was also ably discussed, and the feasibility and probability of such a use were shown. It seemed to be the opinion of the Convention that honey should be sold only to recognized, upright dealers, and the adulteration of honey with glucose would not then take place. Better prices would as a consequence be realized.

The Convention adjourned until 9 a.m.

SECOND DAY.

The Convention was called to order at 9:15 a.m., by acting president, W. E. Clark, of Oriskany. The reading of the minutes followed, after which several persons were admitted to membership.

The following committees were appointed: On implements, L. E. St. John, N. N. Betsinger and W. A. House; on question drawer, J. C. Schofield, S. M. Locke and A. J. King.

The topic for discussion, "Experiences with comb foundation," was then taken up. The remarks of Mr. Root seemed to open a very profitable discussion. He claimed that the use of comb foundation was necessary to the thorough bee-keeper. He admitted that much of the foundation sold was adulterated, and the object must be to get that which was the most free from adulterating substances.

Mr. Bacon agreed with the remarks of Mr. Root, but did not think that a heavy foundation was advisable.

Mr. Dickinson argued in favor of a heavy foundation for the brood-chamber, and a light foundation for surplus boxes.

Mr. Locke stated that a foundation for the brood-chamber should measure 6 feet to the pound.

In reply to a question of Mr. Betsinger as to whether one could detect the adulteration of wax with ceresin or paraffine, Mr. Van Deusen said that unless there was considerable adulteration, he could not. That gentleman also stated that foundation 10 or 11 feet to the pound was advisable for surplus boxes. He exhibited specimens of foundation, partly drawn out, on flat-bottoms.

Secretary House also exhibited samples of pure foundation, wax mixed with paraffine and ceresin. The discussion was further continued, and the following resolution, offered by Mr. Dickinson, was adopted:

Resolved, That the adulteration of comb foundation in any manner is to and is denounced by this Convention as much as the use of glucose should be.

The Secretary read the following essay by W. J. Davis, on

The Best Method of Rearing Queens.

I have not egotism enough to suppose that I can instruct the members of so intelligent a body of apiarists of the old Empire State, in any department of our fascinating pursuit, especially the one assigned me (by your affable Secretary) which lies at the foundation of successful bee-culture, and any effort so to do would be but reflecting back a glimmer of the light received from that pioneer of practical and scientific bee-culture, Mr. Quinby, of your State. Your large and prosperous Association is, to my mind, an evidence of the enthusiasm he labored to awaken in a long-neglected industry. His pen enriched the pages of the agricultural press of your State in ante bee journal days, and led many a groping novice from darkness into light. May the names of Langstroth and Quinby never be forgotten while a flower blooms and a bee's wing cuts the summer air in this fair land of ours.

In the consideration of our subject, we shall go beyond the mere mechanical part of queen rearing, for I address a convention of bee masters, not novices, and first consider the object to be attained. That the queen bee is the "main spring" of the hive, there will probably be none to question, and to produce her ladyship in that way that shall develop the highest excellence, such as vigor, beauty, longevity, gentleness, etc., should be the aim of every bee-keeper, whether he rear queens beyond the wants of his own colonies or not.

When we look into the laws that govern the production of animal life, we find that one law obtains, from man down through all the grades of lower animal life, viz: "The animal after his kind."

While climate, food and surroundings have their influence, man is still man, whether barbarous or enlightened, and his domestic animals when bred with any special peculiarity or trait in view, have developed the traits desired. While there are many desirable traits in our present strain of Italian bees that should be fostered in breeding, I have named but four, deeming that further enumeration would make my essay undesirably long.

The first trait, vigor, strength, power of endurance. As bee-keepers, we do not want all our hopes blasted by the occurrence of unusually severe winters, which are liable to occur in our variable climate. That one colony of bees lives, and another by its side dies under precisely the same conditions, is evidence of different powers of endurance.

I have at different times exposed a number of laying queens, confined without workers, in cages, to a low temperature for bees singly, and watched the result. All were supplied with the same kind of food, some would become dormant in a short time, while others would live several days.

I know no better term than to say the latter possessed more vigor, or power of endurance, and, as the queen, so would be bee worker progeny, easily chilled in summer or winter, or possessing power to resist unfavorable surroundings.

2. Beauty. Men love the beautiful wherever seen. "Beautiful women," beautiful landscapes, beautiful homes, beautiful flowers, beautiful honey and beautiful bees. Some men may profess a contempt for the beautiful, but we don't believe their professions, and if forced to take them at their word, we sorrowfully admit them to be moral monsters. But we hope there are none such in our fraternity. The dimsy assertion of some, that we sacrifice productive industry as the price of beauty in our bees, is not sustained by analogy, or unprejudiced experience. To possess the highest type of stock of any kind, is a source of pleasure. To have our customers say, "The queen you sent me is the handsomest one I ever saw," is certainly pleasant, to say the least.

3. Longevity. It is a fact that some queens die after having laid eggs but a few weeks, while others live and prosper 4 or 5 years. All life insurance companies are particular to inquire as to the longevity of the parents of the applicant for a policy of insurance, claiming to calculate the risk with much certainty. I shall assume that the same rule holds good in the breeding of bees, and that a long-lived queen will be more likely to produce long-lived queens and workers than one that lived to be only 1 year old. It will readily be seen that if we can add but one week to the average life of the working force of the hive, we have added largely to the profits of the apiary. A week of added life to the worker bees would be a week of active out-door labor. To rear bees that die off quickly (comparatively) is a profitless pursuit.

I deem it a very great mistake to suppose that the queen that can lay the greatest amount of eggs in a given time is therefore a desirable queen. If we assume that the queen bee is capable of laying 500,000 eggs during her life, shall we have them laid in 2 years or 4? In my early experience with the Italians, I had queens that would keep 10 Langstroth frames and all the surplus capacity I could give them full of brood, the bees during the clover harvest working for dear life to feed the baby bees, which, in a short time, were to be only useless consumers. If there be any spot on earth where the honey flow is abundant and perpetual, my argument would not apply, but that place is not Western Pennsylvania.

I found that such colonies, while they yielded an undesirable increase, never gave me any surplus honey, or

even provided themselves with sufficient winter stores, while other colonies with far less brood would give a good yield of surplus honey, and well-filled combs of winter stores; and subsequent years of experience have fully satisfied me that excessive breeding is not a trait to be desired in the "coming bee," but longevity is.

4. Gentleness or amiability of temper.—The sting of the bee is bad enough, even to professional apiarists, but they are not the only ones affected by the presence of vicious bees. We claim the right to keep bees in villages, in incorporated towns and cities, and if we, as bee-keepers, tolerate cross bees, they and we must grow more and more in disfavor with the people, and ordinances for their removal from such places will become more frequent. In short, every consideration of wisdom, peace and comfort, dictates the suppression of the vicious type of our honey bees.

Having thus defined some of the qualities to be kept in view in rearing queens, we will next consider briefly when and how to proceed. 1. Vigorous, long-lived queens cannot be reared much outside the swarming season, and no interference of man can produce better queens than the old fashioned way of natural swarming, provided the swarming colonies are of the type above indicated. But when the supply of queen mothers is very limited, the process is quite too slow. Hence we must resort to the removal of the queen mother from one colony to another at intervals of about 10 days, or the removal of brood from the hive of said queen mother. In my own practice, I prefer to remove the queen, and queens produced by the removal of the queen mother at any time when a good degree of activity exists in the hive with plenty of bees, brood and eggs, and increasing stores. I have never been able to discover that they were in any way inferior to those produced by natural swarming, while those reared out of season, certainly are inferior. 2. At what age shall the queen mother be? I take it that, with the queen bee, as with man and all our domestic animals, there is a period of greatest vigor, and there are times, whether perceptible or imperceptible, of gaining or declining strength. Hence, in selecting queen mothers, I would alike avoid the extremes of life; I would not breed from a queen less than one, or more than 3 years old—probably the best age is the summer that the mother bee is 2 years old. About 10 or 11 years since I purchased an Italian queen from, at that time a prominent breeder, who professed to have reared 6 generations of queens in one season, and I guess he had. Without assuming it as a fact in beeology, I would submit it as an hypothesis that the continued breeding of queens from young queens, will stimulate too excessive breeding at the expense of vigor, longevity and honey storing qualities.

As to how to produce the greatest number of queens, shall form no part of this essay, as bee-keeping has suffered enough from that source. If queen breeders would kill at sight

every objectionable queen, and sell less in numbers at a better price, it would be quite as well for the breeder, and much better for the purchaser. Allow me to wish you a happy and successful session of your Association, and a prosperous year for the blessed bees and their owners.

Youngsville, Pa.

Mr. Root thought that the essay was a most important one, and proper action should be taken with regard to the selling of queens.

Are Bees A Nuisance?

Question—Is there any law against keeping bees in incorporated towns or cities?

In reply to this question, Mr. Hoose gave an instance of a man keeping bees in Syracuse, who was driven from the city by the authorities on account of his bees being a public nuisance.

Mr. King, of New York, ridiculed that idea, and gave instances of his bees, which are kept on a building in Park Place, New York, swarming on an Italian's stand at the corner of Park Place and Broadway. It was an object of curiosity, and not only was it not considered a nuisance, but he received the best advertisement that he ever obtained. The papers took up the matter and the incident was circulated widely.

Adjourned for one hour and a half.

AFTERNOON SESSION.

The Convention reassembled at 1:45 p.m. Secretary Hoose appointed L. E. St. John assistant secretary. Several new members were elected.

The following officers were elected: President, W. Clark, Oriskany; Vice President, L. E. St. John, Greene; Secretary, George W. Hoose, Fayetteville, Treasurer, R. Bacon.

The Convention then balloted for next place of meeting, with the following result: Syracuse 16, Utica 11, Albany 12. Syracuse was chosen, and the third Tuesday of January, 1883, the session to continue for three days.

The Secretary read the President's annual address on

Wintering Bees.

As soon as possible after the honey season has closed, I examine my bees thoroughly and see what condition they are in for the coming winter. I am particularly careful to see that they are strong in bees, for I consider that very essential to success. I find that it is poor policy to attempt to winter weak colonies. If they are too weak I make them strong by uniting early, until they are all strong. If any are queenless, now is the time to supply them, as we can use the surplus queens for that purpose. There is no difficulty in uniting at this time of year if we give them a thorough smoking, so that they may all have the same scent and fill themselves with honey. In uniting, the hive that is left empty should be removed from the stand, and then bees will not return.

My next care is to see that they are well supplied with stores for winter. They should have from 20 to 25 lbs. of good capped honey to be safe. I feed

the light by taking frames of honey from those that have more than they need, as it is a very easy matter to make them all safe in this respect. If they are short of stores feed 7 parts loaf sugar to 4 of water, putting it into tin dishes, oblong in shape. They may be made to hold 6 or 8 lbs. Put a float of wood in the dish. Feed on top of brood chamber, until they have sufficient stores for winter use. My next care is to remove combs from the brood-chamber until the bees fill all the combs that are left.

I use the new Quinby hive, and winter them in from 5 to 6 frames. Colonies that do not fill 5 frames I do not consider strong enough for winter. I unhook the frames from the bottom-board, and hook them on a frame that raises them just an inch from bottom of the hive. I put them at right angles to the position they occupy in summer, as this allows me to completely surround them with the packing; which consists of dry pine planing mill shavings. I then cover the frames with pieces of heavy hop baling, which is the best and cheapest cover I can find. I also fill the space over the frames with the same packing, and leave an air chamber of two inches under top board for the moisture from the bees to collect and pass out at a wire screen near top of hive.

I have the entrance of hive open to give the bees a chance to fly whenever an opportunity presents itself. When the weather is stormy, cold or windy, I put a board in front of entrance, against the hive to prevent a direct draft. When bees are thus cared for, they will winter very safely on their summer stands. I have usually wintered in this way without the loss of a colony. Last winter my loss was about 25 per cent., but was owing to the fact that they were moved and packed after cold weather set in. I could not get the shavings to pack them with until then. Most of my bees last winter were wintered in a cellar, and my loss was 75 per cent. I have tried very hard to winter in-doors successfully, but have not succeeded very well and have become disgusted with it, as my experience has been very sad. When wintered on their summer stands as I have described and prepared early for winter, I feel perfectly safe, for I know they will winter well. When thus prepared, they will not fly in winter unless it is warm enough for them to return safely to their hives. But what is best of all, they do not dwindle in the spring. I have used the Quinby hive since 1872, and do not believe there is as good a hive made for wintering and carrying bees safely through the spring.

I cannot close without referring to spring. The winter packing is very essential in spring, and it prevents the bees from flying when they should not. It also retains the heat which is so necessary to successful brood-rearing. The packing should not be removed until we have settled warm weather. I usually leave it until the bees are nearly ready to swarm. When brood-rearing begins in earnest the cloth cover should be removed from top of

brood-chamber, and be replaced by enamel cloth, in order to retain the moisture which the bees need so much at this time of year. If they cannot obtain it in the hive they will leave many times when the weather is too cold for them to return. This brings me to spring management, which I will reserve for a future occasion.

N. N. Betsinger, Marcellus, addressed the Convention on "Wintering bees, and the cause and prevention of dysentery." His remarks were applauded.

Mr. Barber, of St. Lawrence county, next spoke, corroborating Mr. Betsinger's ideas in regard to heat. Bees should not be removed from the cellar before willow bloom in the spring. He allowed no cold air in the cellar.

Mr. Root related the experience of Mr. Hoffman in wintering, which substantiated the arguments of Mr. Betsinger and Mr. Barber. He thought that bees which wintered best consumed the least honey, and advocated a high temperature.

Mr. Barber said: I have 193 colonies in a cellar, 16x19 feet.

Mr. Betsinger said the temperature and the atmosphere should be changed every two hours if necessary. To do this the house should be under perfect control. If the bees are easy, they will make no noise. Bees should never make a noise. When bees fly in the spring and spot the snow, it is a sign of dysentery.

Mr. Bacon said he found his bees all right and he believed them healthy when they made a low murmur, like distant roar of wind in distant woods.

Mr. Barber said bees should not be set out when there was snow on the ground. He had found that the colder the day the greater the deposit of excrement.

A. J. King said he thought heat was good for bees.

Mr. Barber said last year he had wintered 200 colonies with a loss of 8, 4 by mice and 4 by starvation. He had wintered as many as 160 colonies without losing any. The farmers in his section all wintered bees according to his plan, and did so successfully. To ventilate he used a 3-inch tin pipe, 24 feet long, going from the cellar to the outside. He did not ventilate the hives at all, but left them open at the top. He thought more bees were killed by ventilation than by any other method. There was no way in which fresh air could get in, except through cracks and crevices, as no cellar was perfectly air-tight. L. M. Barber and D. Barber each wintered over 100 colonies last winter, and lost none, either by wintering or springing. In his own cellar he found some dead bees in the spring. There were about 3 bushels to a hundred colonies.

Mr. Bacon said he covered the top of his hives with straw to prevent a current of air going through.

In reply to a question, Mr. Barber said he would not think of wintering 15 or 20 colonies in the same manner as he did 100. There would not be heat enough in the ordinary cellar. He found excrement only in the shape of dust. The bees did not besmear the hives.

Mr. Betsinger said the latter statement showed that his statement that feeding honey causes dysentery, to be correct. He had not finished his experiments, but should continue. He had been at school, and should continue to go to school. The late mortality among his bees had proved very valuable by giving him experience.

Mr. Bacon asked what kind of foundation comb was best for surplus honey? The question was not answered.

Mr. Vrooman gave the Scholastic county method of wintering, which he said was the best of all. Box hives were placed on strips in the cellar, and a temperature of 48°. These bees wintered dry and without consuming any honey. In the spring, out of 85 colonies, about a peck of bees were swept up. The tops of the hive were entirely tight.

Mr. Bosworth moved that a vote of thanks be tendered to Mr. Betsinger for his able essay. Carried.

L. C. Root, of Mohawk, gave an address on "The Most Successful Method for the Prevention of Swarming."

Under the head of miscellaneous, the subject of "Wintering" was taken up again. In reply to a question, Mr. Barber said from 15 to 20 per cent. of his bees were found breeding in the spring.

One delegate said he had had very good success, but he was compelled to put an absorbent in top of the hive to prevent comb mold from moisture.

Mr. Betsinger said he kept such a high temperature as to drive moisture out of the hives through the pores of the wood.

Several delegates said this could not be done, because the inside of the hive was covered with propolis, and the outside was painted with two coats of paint.

Mr. King said moisture would accumulate during the breeding. This contained a certain amount of carbonic acid gas, which was deadly poison. He opposed upward ventilation, except as afforded through chaff or other loose material.

Mr. Dickinson said a colony would consume about 25 lbs. of honey during the winter. About 75 per cent. of this was moisture, or about 3 quarts of water. He would like to know how this amount of water would pass off?

Mr. Betsinger said the amount of water would pass off through a hole as large as a knitting-needle in 35 minutes, and no one would know it.

Mr. Barber said the cellar he wintered in was moist, and sometimes very moist. He thought the moisture was beneficial. His bees were certainly not injured by it. He thought it not half as dangerous as wintering out doors.

Mr. Barber said he even had 6 inches of water in his cellar many winters. He set every hive on the bottom-board except the lower tier of hives.

On motion of Mr. Dickinson, a vote of thanks was tendered to Mr. Barber for his ready and clear replies. Adjourned.

The evening session was devoted to the exhibition of hives and implements used by bee-keepers. Mr. Stod-

dard, an inventor, who was present, exhibited a model of a lift bridge, which is quite ingenious.

THIRD DAY.

The morning session was called to order at 9:15 a.m. by Vice President L. E. St. John. After listening to the reading of the minutes by the Secretary, A. J. King, of New York, read his essay on "Failures," which was adapted especially for beginners in the art of bee-keeping.

The National Convention.

Secretary House read a letter from Professor A. J. Cook, President of the North American Bee-Keepers' Society, asking that the present Convention consider the three following points: First, the desirability of appointing committees from different sections to secure local associations, either county or district; second, the importance of a separate building and a grand display of honey, beeswax and implements at the State Fair, and thirdly, the question of adulteration. This should be properly denounced.

The following criticism, by Geo. W. House, on the National Convention, published in the *Bee-Keepers' Instructor*, by request of several members was then read by Mr. Locke:

In regard to the National Convention. We wish to speak of the manner of electing officers. We think it in bad taste, and that it has too much the odium of ringism about it to be even palatable. Every member *should* have the privilege of a free ballot. No gag law.

When that society was organized, the constitution and by-laws were in accordance with American custom and principles. It was organized with the intention of holding its sessions North, South, East and West. But during the past few years there is seemingly little or no regard paid to custom and privileges.

Much was said by certain persons about the resolutions passed at the Northeastern Convention less than 2 years ago. Yet where is the earnest and honest thinking bee-keeper, that has the best interests of the fraternity at heart, that will not admit that those resolutions have been the means of doing *more real good* than any similar action in the American apicultural history.

But where is the honest apiarist that can truthfully say the same in regard to the action taken by the last National Convention. I refer directly to the address of Mr. T. F. Bingham, entitled "A Partial Review," and the action taken by the Convention concerning it.

While I wish it distinctly understood that I fully appreciate the noble and earnest work put forth by the illustrious Rev. L. L. Langstroth in his inventions, improvements and writings, and while I am to-day in full sympathy with his conditions, etc., yet I claim that that body has caused to be placed upon its record a stain, never to be blotted out. Yes; not only a stain, but they have perpetrated the greatest outrage ever recorded in the history of American

apiculture. We refer to the attempt to "lionize" a few at the expense of others, and still they proclaim: "Honor to whom honor is due." Was there ever a Quinby? or a Wagner?

Fellow apiarists, when I read that address and the action taken upon it, it makes the very blood chill, as it courses through my veins. O! *where* is the true American apiarist that can digest that action and withhold the emotions caused by honest inward feelings? Does it not bring you face to face with the discoveries, the inventions, the practical teachings, the benevolence and the immortal fame of our beloved and lamented M. Quinby, the father of American apiculture?

As Friend Hetherington has truthfully said, "Thousands are to-day enjoying a delicious and wholesome article of food that would have remained ungathered, except for his earnest advocacy of the business as a source of revenue to the Nation, and profit to the bee-keeper," and thousands of bee-keepers will blush with shame to think of the injustice done him at Lexington, Ky.

Gentlemen of the North American Society; you that were participants of that farce; can *you*, upon taking a sober, second thought, say to your fellow apiarists that your considerations were fairly and impartially rendered, with justice indiscernible?

Allow me to quote from Mr. Bingham's address. He says: "The system I have denominated the American, is the substitution of absolute control, for the 'happy-go-lucky' methods previously pursued. The early writings of the lamented M. Quinby, called the 'Mysteries of Bee-Keeping,' which were among the most conspicuous of the closing era, may be appropriately called its closing chapters; while the writings of the Rev. L. L. Langstroth, and the invention of the movable-comb hive, may be justly called the opening chapter in improved bee-culture, and the foundation of the American system."

Reader, pause, and ponder well, lest you render an unjust decision. Where is the intelligent bee-keeper that can endorse this taking from one and giving to another? I for *one* am willing to go on record as denouncing this heinous offense. The sun may cease to give us light. The diurnal revolution of the earth may stop; but *never* will the bee-keepers of America submit to such an unjust discrimination.

But further on Mr. Bingham says: "Is it of any value to bee-keepers of to-day, or the bee-keepers of the future, that the memory of the inventor of the movable-comb bee hive, and the honey extractor, and comb foundation, should be revered and perpetuated?"

O! Father of the Heavens! Is this "Honor to whom honor is due"? Is there no Frederick Weiss? Can it be there was never a Herr Hruschka? Brother apiarists, shall we submit to such an injustice? No, *never!* but we *appeal* from the action of that body to the apiarists of the world, remembering that "Truth crushed to earth shall rise again."

I wish to call the reader's attention to the last three paragraphs of that address as published in the AMERICAN BEE JOURNAL, page 335. Can you not discover the shadowing of the "Patented Smoker?" Can you fail to notice the plea for protection to that implement? and the attempt to wrest *that* invention from its inventor? Every one of common sense knows that if he had a valid patent, infringements could be abolished by lawful proceedings. Perhaps they will be, for we read that we must use no other, if we wish to be exempt from prosecution in using them. This may have its effect with the ignorant, but we don't believe, at this enlightened age, that "bull-dosing" will work.

Notwithstanding all this, the North American Society in convention assembled at Lexington, Ky., and the 7th day of October, 1881, did there and then cause to be recorded the following motion, which, according to the minutes, was passed with great unanimity:

"Moved, that the sentiments expressed by Mr. Bingham be endorsed as the views of this Convention."

Verily, verily, if such a course is allowed to obtain without notice, our National Association will surely die, a disgrace to American apiculture.

Fayetteville, N. Y.

This called forth much discussion upon the subject of smokers, for Mr. House had criticised the action of the National Convention in indorsing the smokers of Mr. Bingham, and claimed that the entire merits of that smoker was due entirely to M. Quinby.

Mr. Clark, who had just entered, thought the Convention should not fritter away its time by trying to decide as to whom invented the smoker. He said, however, that he would not use the Bingham smoker under any consideration. He did not think that Bingham should be upheld in using the inventions of Quinby. Because the true inventor, Mr. Quinby, did not get a patent and Bingham did, we are obliged to pay for it.

Mr. King—I have carefully examined the Bingham patent and I have found that his patent covers everything and nothing. I have manufactured smokers right along and I have not infringed on any patent. I do not hesitate to say that Quinby was the first inventor.

Mr. Locke—I believe in right and justice every time. M. Quinby is revered and loved by all apiarists. We ought to denounce any injustice that has been done to Mr. Quinby.

On motion of Mr. Betsinger, a committee was appointed to draft resolutions condemning the unjust resolutions passed by the National Convention. The President appointed as such committee Messrs. Van Deusen, Clark and Bacon.

Secretary House then read the following address on

Co-Operation:

Mr. President and Gentlemen:—When we look about us we cannot fail to notice the wonderful achievements accomplished by associated

action. At this enlightened age no branch of business can successfully compete with its adversaries without a combination of interests. Co-operation and concerted action have wrought wondrous changes in every conceivable branch of industry. Think of the vast strides and the great improvements as they have advanced during the past twenty years; not alone in invention, mechanism, agriculture and the press, but also in apiculture. To-day we see associated system of dairying, in manufacturing and marketing their products, and in breeding the various kinds of stock.

We see a combination of interest in mining, in transportation, and in buying and selling stocks, grain and all the leading staple products. We see combined action in manufacturing, on the part of the tradesmen as well as the capitalists. We have "Boards of Trade," Protective Unions, Mutual Life Assurance Associates, and so on through the category. *Co-operation* is the key to all.

It is true we have kept pace with kindred pursuits, as far as knowledge, invention and production are concerned. But it is also a fact that the protectives of our interests have been sadly neglected. Seemingly but a comparatively few recognize the value of the contemplated action, I see no reason why we should not put business into our Association. Many benefits may be derived from such action. Not alone in keeping pace with other industries, but in the advancement of our science and the protection of our interests. The lumber we buy for our necessary buildings, hives and boxes, the tools we use in making them, the nails used for putting them together, and the glass we use in preparing our honey for the market, are all protected in their prices by strong combinations. Then why should we hesitate in adopting anything that may prove an advantage and a protection to our business. By purchasing our supplies, such as hives, boxes, crates, glass, foundation, implements, literature, etc., at wholesale or in job lots, we can obtain manufacturers' prices, and secure to the average producer a saving of from fifty to one hundred dollars annually. This is no small item when we take into consideration the competing elements that now seem to be damaging to a certain extent.

By careful investigation from actual transactions, I can authoritatively say, that under efficient management the contemplated associated action will prove a clear gain of one per cent. for every pound of comb honey produced. Therefore, during such seasons as was 1878, or at any time when our larger markets are crowded, we can sell our products for the one cent per pound *under* the market, and at the same time realize as *much* as those who do not enjoy such privileges. Many are the ways in which we might be benefited by *co-operation* and a unity of action. We should remember in all our transactions that "A dollar saved is a dollar earned."

With a unity of action we can bring into use a uniform style of package;

a uniform system in grading and marketing. A world-wide reputation can be established for our grades of honey protected by any appropriate trade mark we think advisable to adopt.

With co-operative effort, we can place apiculture on a footing second to none of the many national industries; and command a power that will force a recognition of our products as a staple commodity, and command respect from all foreign countries. In fact co-operation and a combination of interests, are the powerful main-springs that have revolutionized the business portion of the world; and judging from the advancement made in the past 20 years, who can venture to predict the position we shall occupy 20 years hence?

I would submit for your earnest consideration the feasibility of incorporating a Mutual Benefit Association for Life Assurance, consisting entirely of bee-keepers. Common prudence ought to prompt every man to seek reliable insurance. Where families would now be left in debt for their homes (or perhaps without a home), with a certificate in a properly managed assurance society, many bee-keepers would be comforted in knowing that their loved ones would be left in a condition where they could help themselves. With little effort on the part of each of us, such a society can be organized and sustained with but little expense to the beneficiaries.

Our deliberations should be in truth and earnestness, remembering that in the past our "Northeastern Association" has been the first to rebuke injustice; the first to correct evils and protect the interests of our fraternity; the first and always on the alert to sustain a good cause when the interests of the fraternity were at stake.

It is acknowledged that our Association stands at the head of any of its kind in America.

It is conceded that our deliberations and conclusions are the highest known authority. Thousands are to-day anxiously awaiting the publication of our proceedings. Then let us hold fast to that which we have gained in the past; strike while the iron is hot, and place our far-famed Association on a higher and a grander footing, until we can proclaim to the world, *Sans Pareil*.

Fayetteville, N. Y.

This essay elicited the warmest discussion of the Convention, especially the question of the feasibility of adopting a uniform package.

Mr. Betsinger thought the position of the essayist was well taken, and his suggestions should be considered carefully. We can sell to each other as well as a jobber can sell to a dealer.

Mr. Root was particularly interested in that portion of the essay that called for a uniform box for honey. The important thing for us to consider is, what is the greatest amount that we can get for our goods. If honey is put up in small, uniform boxes by us, we can dispose of our honey to a better advantage. That at least is the opinion of the dealers.

Mr. Dickinson was interested in the

matter, but he thought that it was a game of every man for himself. As a matter of convenience in packing car lots, Mr. Root's idea was a good one, but if I can put my honey through any ingenuity in better shape than my neighbor, and therefore get a better price, I do not care to have my neighbor adopt my plan.

Mr. Root said that it was for the interest of all that a certain standard in market honey should be adopted. We can educate the people to this standard.

Mr. Clark said: I do not believe in the doctrine of every man for himself. I think that if one puts up honey in 1-lb. boxes and he gets a good price, others will follow, and the price will return to its old level. But if we have uniform, one and three-quarter pound boxes, the expense will not be so great, and the price will always be good.

Mr. Locke agreed with Messrs. Root and Clark, that the time has come when we should adopt a uniform box.

Mr. King said this ought to have been agitated some time ago. This diversity of boxes has gone so far that it is almost impossible to crush out now. We can put a stop to the agitation of one-half pound boxes, which is now making, by prompt, decided action.

The discussion took a wide latitude, every one relating his particular experience in selling his goods. Many told what jobbers had advised, and all agreed to disagree upon certain points. In the midst of the talk, which was exciting, yet good natured,

Mr. Betsinger stamped the Convention by offering a resolution to the effect that a uniform box be adopted. He also threatened in the event of the resolution passing, to press another one that should compel the members to use the box adopted.

Mr. King offered an amendment to Mr. Betsinger's motion that more than one size box should be used. This again carried the members on "the sea of troubles," until Secretary House mercilessly cut all short by a motion to adjourn. This last motion was carried.

AFTERNOON SESSION.

In the afternoon session the resolution in regard to the size of boxes was discussed at length.

Mr. Dickinson moved to lay on the table; lost, ayes 10, noes 19. A resolution making the weight of the box not less than a pound and three-quarters when filled with honey was then adopted.

Mr. Betsinger moved that the Association adopt some kind of a seal to be used on everything passing from the Association. Carried.

Mr. Betsinger moved that a committee of three be appointed to select a seal. Carried.

The Convention selected Mr. Betsinger, George W. House and Mr. Peet.

The Secretary read an interesting paper on "What per cent. of increase is most profitable," written by W. L. Tennant, of Schoharie.

J. Van Deusen, from the committee

on resolutions in regard to bee smokers, reported the following which was unanimously adopted:

Whereas, At the late National Convention held at Lexington, Ky., a resolution was passed which partially ignored the instructions and inventions as affecting modern bee-keeping of our friend, the late lamented Mr. Quinby, and particularly the bellows smoker, denouncing them as belonging to an era now passed away, etc., and in his place exalting others far above him, and denigrating them as belonging to the modern era of practical and advanced bee-culture.

Resolved, That the action above stated is entirely inconsistent with the facts, and that we denounce the same as nothing less than a slander on the fair name of Mr. Quinby, and a seeking to impose on the intelligence of American bee-keepers.

Mr. Roof, from the committee appointed last year to secure the passage of a law to prevent the adulteration of honey and other sweets, with glucose, said the bill against adulteration of sweets in general, was too broad and too sweeping in its provisions to receive the sanction of the Governor. The adulterators of honey buy pure honey in one place and glucose in another, and do the mixing themselves. He thought the law against adulteration now in force was strong enough to cover the adulteration of honey. He did not know how to effect a remedy.

Mr. King said the members of the Association should put up its honey in packages ready for market. The package should then be stamped with the seal. There was a strong law against obliterating or counterfeiting a seal. There is a brand of beeswax, each piece of which is stamped. This wax, though no better than other wax in the market, brought 5 cts. per lb. more, because the purchasers knew it to be genuine.

Mr. Locke said comb honey shipped from the country was shipped to New York, and there cut up and adulterated with glucose.

Mr. Dickinson said the action of the Convention was silly and foolish.

Mr. Barber said he was of the same opinion. The Convention had passed a resolution to use no boxes weighing less than 1 $\frac{3}{4}$ lbs., while many of the members had a large number of boxes ranging from 1 to 2 lbs. These boxes would be used at least for 2 years to come. The market demanded boxes of various sizes, and so long producers would be compelled to furnish it.

There was some discussion as to whether it should be placed on the documents of the Association, or on the honey produced by its members. The President decided that the seal would only be on the documents of the Association.

Mr. Betsinger moved that the Association furnish its members rubber stamps with which to stamp its goods.

Mr. Root thought each producer should stamp his goods individually.

Mr. Bacon favored the stamp or seal. All the members would be interested in keeping the product pure, like the patrons of a cheese factory.

If any one was found adulterating honey, the other members would see that he was punished. In unity is strength, and the members of the Association have a common interest in keeping their product pure.

The resolution was amended so that members shall buy their own stamps, and adopted.

Mr. Dickinson, from the committee on implements, presented its report, which was adopted.

Mr. Baum asked that all who intend to use the Vandervoort foundation next season, to arise. Eighteen members out of 31 present, rose.

The following resolutions were adopted:

Resolved, That the thanks of this Association are due and are hereby tendered to the representatives of the *Utica Morning Herald*, and *Observer*, for the very complete report of our proceedings as published in their respective papers, and for other courtesies shown us.

Resolved, That the thanks of this Association are due, and are hereby tendered to all the essay writers.

MISCELLANEOUS.

There being no report from the committee on question box, because no box had been provided, Mr. Root moved that a standing committee of three be appointed, to which questions can be sent during the year to be answered at the next annual Convention. Carried. The chair appointed L. C. Root, I. L. Scofield and E. D. Clark.

Mr. Locke exhibited several races of bees preserved in alcohol, including the pure Syrian, pure Italian, pure Cyprian, Syrian hybrid, Cyprian hybrid and Italian mated with both Syrian and Cyprian, all from D. A. Jones, Beeton, Ont.

Mr. Barber said his plan of keeping honey was to place it in a room thoroughly aired, every day, until it is to be shipped. He left it unglassed. He found spiders around in the corners, and he believed the spiders killed off the millers if any hatched. He stored his honey on the ground floor, and, by leaving it open continually, kept the temperature of the room the same as the outside air.

Mr. Peet, from the committee on seal, presented a design, which was adopted.

The roll was called, and 13 members answered that they intended to use the rubber stamps; 9 were undecided, and 3 answered no.

Speaking of the different woods of which the honey boxes are made, most of the members favored basswood. This is even preferable to white poplar, which warps very much when it becomes wet. Mr. Bacon said he had used white spruce and found it very good. It did not warp or split, nor did it stain as easily as poplar or basswood. The President, Mr. Baum, and others, also favored white spruce.

After further discussion, the Convention adjourned.

The Texas State Bee-Keepers' Convention will be held at McKinney, Texas, on Tuesday, April 25, 1882.

Local Convention Directory.

1882. *Time and Place of Meeting.*

April 11—Eastern Michigan, at Detroit, Mich.
A. B. Weed, Sec., Detroit, Mich.

25—Texas State, at McKinney, Texas.
Wm. K. Howard, Sec.

26, 27—Western Michigan, at Grand Rapids.
Wm. M. S. Dodge, Sec., Coopersville, Mich.

27—Kentucky Union, at Eminence, Ky.
G. W. Demaree, Sec., Christiansburg, Ky.

May — Champlain Valley, at Bristol, Vt.
T. Brookins, Sec.

16—N. W. Ill. and S. W. Wis., at Rock City, Ill.
Jonathan Stewart, Sec., Rock City, Ill.

25—Iowa Central, at Winterset, Iowa.
Henry Wallace, Sec.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.
G. W. DEMAREE, Sec.
Christiansburg, Ky.

SELECTIONS FROM OUR LETTER BOX

Building Straight Combs.—Please tell the readers of the BEE JOURNAL how to extract honey from the combs where built irregular; also, if there is any method to cause bees to build their combs uniform on the frames without using foundation?

JOHN SHERRETTS.

Norfolk, Ore., Jan. 14, 1882.

[It is better to shave the combs down as near a straight surface as possible with the uncapping knife; though any of the extractors in general use will throw the honey from crooked or uneven combs when uncapped. The best method we know of to get uniform combs without the use of foundation, is to level the hives perfectly, then use frames with triangular or V shaped top-bars, having the apex or point hang downward; rub comb or beeswax along this lower edge, but not far up on the level or slope, spread the frames evenly in the hive, and as fast as an objectionable comb is built out and filled, remove it, extract the honey, and melt up into wax.—ED.]

Fall and Spring Record.—I have been prepared in four different ways for wintering on the summer stands. I made a record of the condition of each colony Oct. 28, since which time they have not been disturbed. This record is very minute in detail. I shall make a like record in the spring, and I will then send it for publication. My idea is that some might draw conclusions that would benefit them.

HENRY JONES.

Chesaning, Mich., Jan. 27, 1882.

Cotton Frauds.—On page 40 of the BEE JOURNAL for this year, Mr. R. E. Holmes comes to the defense of Mrs. Cotton, and among other things says: "I do claim that since the business has been done in Mrs. Cotton's name, that it has been done straight." I would ask Mr. Holmes if he regards the transaction described by Mr. Fletcher in the preceding article, "straight." To be sure he received something for his money, but not the goods he ordered as described in her circular. My mother has had an experience with Mrs. Cotton exactly parallel with Mr. F.'s, with the exception that she refused to pay 95 cts. express charges, and the box was sent back to Mrs. C. It was nothing but a small, roughly-made model of a bee hive, not nearly large enough for a hen's nest. The circular which induced my mother to send Mrs. C. \$4, is the same as the one quoted by Mr. F. In both cases, instead of sending a "sample hive," as advertised, there was sent a poor model not worth the express charges. Is that fraud? I do not, any more than Mr. Holmes, desire to injure Mrs. C. in "trying to get an honest living," but until she returns the \$4 we sent her, and Mr. Holmes reconciles these facts with his statements, I must continue to think her a swindler.

J. W. MERRIFIELD.

Penn Yan, N. Y., Jan. 26, 1882.

Advice Without Reasons.—In the BEE JOURNAL Mr. Heddon says "I think no sounder advice can ever be given than to say use the standard Langstroth frame." I will say I think there can be no more unsound advice given, than that. There you have Mr. Heddon's say and you have my say. No reasons on either side; which is the heaviest? I think neither is of any more account than a feather in a gale of wind. A man that gives his advice without his reasons, insults (unless the reasons are apparent with the advice, as "I advise you to experiment and learn for yourself") those to whom the advice is given, for he indirectly says I know, you don't. I do not say that is the intent, for I believe Mr. Heddon, and all others that write for the JOURNAL, do so with the desire to benefit its readers. I will state some of the reasons given for using the Langstroth frame, "everybody uses it, everybody admits that it is the handiest frame to use." A. I. Root's reason to me, was, that he must make the hind wheels of wagons track with the fore ones. These are all strong reasons, but they will apply just as well to the use of whisky and tobacco. Some may use the Langstroth frame so long that they get used to it, think it is handy, and perhaps like it. Women may clean up tobacco-spit, empty spittoons, help drunken husbands to bed, until they get so used to it that they do not mind it, but I hardly think they get to like it unless they have acquired a taste for the stuff and occasionally find a half emptied bottle or a paper of tobacco and appropriate it.

E. B. SOUTHWICK.

Mendon, Mich., Jan. 25, 1882.

Using Old Combs.—I read the BEE JOURNAL and am much pleased with it, especially as it now is a Weekly. I am learning to be a bee-keeper. Have bought 10 colonies of black bees—3 in frame hives and 7 in box hives; aim to transfer the 7 to simplicity hives in the spring. One, however, died from being robbed (by bees) some days ago. The comb is straight, and I have put it away carefully. It is somewhat soiled by a few dead bees and larvæ, and is dark. Will it pay to put it in frames for use, and for what purpose?
J. S. KERR.

McKinney, Tex., Jan. 15, 1882.

[It will answer to transfer the combs, even though soiled, and put in your stronger colonies to clean up, and will be very useful for either brood-rearing or extracting from.—Ed.]

Bees require Care.—A number of apiarists in our locality have become almost discouraged because of the ill success they attained in wintering their bees during the severe winter of 1880-81. A few of the industrious insects survived the extreme cold, and those that came through in good condition seemed to put forth an extra exertion after the appearance of the sunshine of spring. Because of the excessive flow of nectar and the limited number of colonies, the increase was exceedingly rapid, and the beautiful honey which was stored up during the season of 1881, aroused the enthusiasm and caused the dispirited hopes of some bee-keepers to vanish away, as the mist before the morning sun. By giving the necessary attention to the "little fellows" we shall bring them safely through the present winter, and our watch-word *success* be inscribed on our banners which shall remain "waving" in the balmy breezes so long as we give our "little pets" the requisite attention.

E. J. HINSHAW.

Lynn, Ind., Jan. 26, 1882.

A Correction.—Besides a few mistakes of minor importance, there is one or two which should not be left incorrect with reference to the report of the Erfurt Convention in Germany. The Convention will meet next year, not in Wiener, Austria, but in Wiener-Newstadt, Austria, Wiener-Newstadt being about an hour's ride from Vienna. Referring to an editorial remark, as quoted from translated report of the proceedings of the Convention, it should not be understood as if German bee-keepers are of the opinion that all or any of the imported American honey contained the germs of foul brood. But they are informed that most or all extracted honey imported from this country, is largely composed of glucose. Many of them having experimented with that stuff to convince themselves it would kill bees and brood, thus furnishing a hot-bed for the disease, or perhaps being the first cause of it. To such importations under the name of honey, they object. And, as they have no means of preventing adulteration of the pure article in this country, they propose

to put a heavy duty on everything bearing the name honey. As to the statement of a certain Professor in the Boston *Journal of Chemistry*, I would say that the gentleman is correct in so far, that, after the bees have drawn out thin foundation, the bee-keeper may fill the empty comb with any thing he pleases, and seal it himself too. The *modus operandi* I have known for several years, but, considering there is enough cheating and adulteration going on, as it is, I deem it not advisable to give vent to this invention, though it would be a good thing for some apiarists to know how to seal open honey in the brood chamber in fall.
A. R. KOHNKE.

Youngstown, O., Jan. 28, 1882.

From Northern Pennsylvania.—The past honey season was very good in Northern Pennsylvania. I wintered 48 colonies in chaff hives, with a loss of only 5, increased to 93, and took 3,200 lbs. of comb honey, besides some extracted, and expect to take 1,000 lbs. more in the spring, the hives being too full for brood rearing. Bees are wintering splendidly this winter, there being no dead bees and no signs of any disease.
C. J. HAIGHT.

Rush, Pa., Jan. 29, 1882.

The Meloe.—This is mentioned by E. T. Flanagan, on page 53. The "meloe" is not among the honey bees here, but it troubled the bumble bees badly last summer. "Among our foot-prints," as quoted by him, is a solid article; "small" bee-keepers had better read, think, watch "among our foot-prints," and wake up.

W. J. WILLARD.

Jonesboro, Ill., Jan. 29, 1882.

Recipe for Sticking Labels on Tin Pails.—Take laundry starch, dissolve in a little cold water then add boiling water, or boil the starch until it is as thick as is used in starching clothes. Apply the starch to the back of the label with a flat brush; put the label in place, then smooth the face of the label with the brush and starch, as starch adds looks to the face of the label.
T. S. BULL.

Valparaiso, Ind., Jan. 31, 1882.

Under Sized Bees.—I had a bit of experience last season which was quite novel, and somewhat interesting to me at least, and desire to know if any others have had a similar experience. Seven colonies were put to rearing cells, and given brood from an Italian queen. Strips of comb were used fastened to tins; these, put in frames were all the brood colonies had. The 9th day, all the frames with cells were introduced to hatchers, with the temperature at 96° to 100°. In 12 days the queen cells begun to hatch at a lively rate; about 15 days afterwards the few worker cells, sealed up while rearing the queen cells, began to hatch. They were one-half the usual size of worker bees, lively, well-marked, and ran about the hatcher 3 or more days before they died. Mr. Quinby thought a high temperature matured the bees early,

but will some one of the more scientific bee-keepers tell us why they hatched only one-half the usual size?

W. H. MALLORY.

Worcester, N. Y., Jan. 30, 1882.

Blizzards! Whew!—I see G. M. Doolittle reports 18° below zero Jan. 6th. I will report for the information of all winter-packing bee-keepers that we have not had one frost this year, and do not expect any now until next winter. White clover has been in bloom since Jan. 1st, as well as many other things in garden and field. Some trees that were bare of foliage in December, have leaves now as large as one's hand. I send you a bouquet of roses, peas, yellow jasmine, orange, white clover, magnolia, willow, dew-berry, and several other blossoms I am not able to name; also grass, sugarcane, fern leaves; also Japan plums, and mulberry leaves and fruit, with fig leaves as large as your hand, etc. Of course, bees are having a buzzing time of it, carrying in loads of pollen, if not honey, from every opening flower. They generally commence working on white clover here about the 10th of February. Last year clover opened later than usual, and the season proved better than the average.

J. W. WINDER.

Thibodeaux, La., Jan. 31, 1882.

[The bouquet came safely to hand, and is a forcible reminder of the magnificent extent of our proud country. While its more northern portions are now (Feb. 4) swept with a frigid temperature and the silvery sleigh bells make continual music; in Louisiana and other southern States the air is redolent with the perfume of fragrant flowers, the busy hum of bees and happy birds making nature joyous; here, though the nights are sharp and frosty, the days are bright with sunshine, and our bees sporting around their hives at mid-day remind us that we, too, have glorious weather to be thankful for. We congratulate our readers at each extreme, but envy neither.—Ed.]

Bingham's Bees.—Yesterday Bingham's bees flew if they pleased. They did not seem to care much for the chance, but a few flew from all the hives. With this evidence that they did not need a fly, I believe there is safety in saying "they will keep." I am glad to see the critics at work. Still I think time is the best critic.

T. F. BINGHAM.

Abronia, Mich., Jan. 28, 1882.

Report for 1881.—I had 48 colonies in the fall of 1880, and but 7 were left in the spring. I bought 4, making 11 in all. I have obtained from these 1,825 pounds of comb honey, and have extracted 250 lbs. What I have sold, so far, amounts to \$266.55.

FRANCIS CULLEN.

Mottville, N. Y., Jan. 31, 1882.

ESTABLISHED 1872
 THE AMERICAN
BEE JOURNAL

RATES FOR ADVERTISING,

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space.

Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements for the Weekly as follows, if paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 "	20 "
" 13 " (3 months).....	30 "
" 26 " (6 months).....	40 "
" 39 " (9 months).....	50 "
" 52 " (1 year).....	60 "

Discount, for 1 year, in the Monthly alone, **25 per cent.**, payable in advance.

Discount, for 1 year, in the Semi-Monthly alone, **40 per cent.**, payable in advance.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

Transient Advertisements payable in advance. —Yearly Contracts payable quarterly, in advance.

THOMAS G. NEWMAN,

974 West Madison Street., Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the *best* advertising medium, but the lowest rates on yearly contracts.

The *Apiary Register* devotes 2 pages to each colony, ruled and printed, and is so arranged that a single glance will give a complete history of the colony. For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

We will send Cook's Manual bound in cloth, postpaid, and the Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

New Publications.—The following Catalogues and Price Lists for 1882 have been received:

- J. T. Wilson, Mortonsville, Ky.
- L. E. McFatridge, Carroll, Ind.
- Dougherty & McKee, Indianapolis, Ind.
- W. P. Henderson, Murfreesboro, Tenn.
- U. E. Dodge, Fredonia, N. Y.
- F. A. Snell, Milledgeville, Ill.
- A. W. Livingston's Sons, Columbus, Ohio.

Mr. H. S. Hackman has sent us the circular of Mrs. Cotton—who bids for "dupes" for the coming season.

The *Kansas Bee-Keeper* for January is received in its new form. It is much improved, and the BEE JOURNAL extends its congratulations to the enterprising publishers.

The *Bee-Keepers' Exchange* for February is also at hand. The new editors seem to be improving, and are making a good paper. They speak thus of the "Apiary Register," a copy of which we sent to the editor of every bee paper:

This is something new, and fills a needed want in every bee yard. The one we have is calculated for 100 colonies, and is so complete in its systematic and condensed arrangement that the whole story of each is told on one leaf about 4x6 inches—which makes a book for 100 colonies 3/4 inch thick. Can be carried in the bee-keepers' pocket without any inconvenience. Thus he can know the exact condition of any colony in a moment. We predict for this book a large sale, as it has only to be seen to be appreciated. We propose to order some at once.

To any one sending a club of two *new* subscribers for 1882, we will present a volume of the BEE JOURNAL for 1880, bound in paper covers. It contains much valuable information, and it will pay any one who does not already possess it, to obtain a copy. Many of our *new* subscribers will be pleased to learn that they can get it for \$1.00, by sending for it *at once*, before they are all gone.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

CLUBBING LIST FOR 1882.

We supply the Weekly *American Bee Journal* and any of the following periodicals, for 1882 at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

	Publishers' Price.	Club.
The Weekly Bee Journal.....	\$2 00..	2 75
and Gleanings in Bee-Culture (A. J. Root).....	3 00..	2 60

Binder for Weekly for 1882.....	2 75..	2 50

We are sometimes asked who our authorized agents are? Every subscriber is such an agent; we have no others, and greatly desire that each one would at least send in one new subscriber with his own renewal for 1882. The next few weeks are the time to do this. We hope every subscriber will do his or her best to double our list for 1882.

A Sample Copy of the Weekly BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

When changing a postoffice address, mention the *old* as well as the new address.

Articles for publication must be written on a separate piece of paper from items of business.

H. A. Burch's residence and nearly all its contents were burned up, Sunday, Jan. 29th. Well insured.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

When you have got an old horse that has passed the market period, apply a bottle of Kendall's Spavin Cure and the result will be marvelous. Read advertisement. 5w4t

BEESWAX.

I wish to buy a quantity of good yellow Beeswax. I am paying 22c. per pound, delivered here, Cash on arrival. Shipments collected.

ALFRED H. NEWMAN,

972 West Madison Street, CHICAGO, ILL.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL,
Monday, 10 a. m., Feb. 6, 1882.

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—The market has an upward tendency, and I am now paying the following prices in cash: Light comb honey, in single comb sections, 17@21 cents; in larger boxes 2c. less. Extracted, 8@10c. **BEE SWAX**—Prime quality, 18@22c.

AL. H. NEWMAN, 972 W. Madison St.

CINCINNATI.

I pay 8@11c. for extracted honey on arrival, and 16@18c., for choice comb honey.

BEE SWAX—18@22c., on arrival. I have paid 25c. per lb. for choice lots.

C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—Choice white comb, in 1 to 1½ lb. sections, 20@22c.; same in 2 to 3 lb. boxes, 17@20c.; dark and mixed, in 1 to 3 lb. boxes, 12½@15c. Extracted, white, 10@11c.; dark, 9c.

R. A. BURNETT, 165 South Water St.

SAN FRANCISCO.

HONEY—Buyers are more inclined to operate, but sellers are less anxious. A lot of dark extracted was seeking a buyer a few weeks ago at 8c., but has since been withdrawn, and now for the same lot 8c. is bid.

We quote white comb, 16@20c.; dark to good, 10@14c. Extracted, choice to extra white, 8½@10c.; dark and candied, 7@8c. **BEE SWAX**—23@25c.

STEARNS & SMITH, 423 Front Street.

NEW YORK.

HONEY—There is a liberal supply of honey here for which trade is very little demand, and prices are weak and irregular.

We quote as follows: White comb, in small boxes, 18@19c.; dark, in small boxes, 12@14c. Extracted, white, 10@11c.; dark, 7@9c.

BEE SWAX—Prime quality, 21@23c.

THORN & Co., 11 and 13 Devoe avenue.

ST. LOUIS.

HONEY—Plentiful and slow for all save choice bright comb—this sold readily; comb at 18@23c.; strained and extracted 9@11c. to 12½c.—top rates for choice bright in prime packages.

BEE SWAX—Steady at 20c. for prime.

R. C. GREER & Co., 117 N. Main Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.

BEE SWAX—Prime quality, 25c.

CROCKER & BLAKE, 57 Chatham Street.

CLEVELAND.

HONEY—The market continues very steady; best white, in 1 and 2 lb. sections, sell a quick on arrival at 21@22c.; No. 2 at 19@20c. but buckwheat honey we find difficult to sell—holding it at 17c. Extracted, is in fair demand at 12c. in small packages, and 11c. in large packages.

BEE SWAX—25c., and very scarce.

A. C. KENDEL, 115 Ontario Street.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

- For a Club of 2, — a copy of "Bees and Honey."
- " " 3, — an Emerson Binder for 1882.
- " " 4, — Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
- " " 5, — " " cloth.
- " " 6, — Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

A HAPPY NEW YEAR TO ALL

29th Year. 1882. 29th Year.

CHARLES H. LAKE, Manager.

VOLUME FOR 1880,
Bound in paper covers. A few copies for sale at \$1.00, postpaid to any address.
THOMAS G. NEWMAN,
974 West Madison Street, Chicago, Ill.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., February 15, 1882.

No. 7.

Published every Wednesday by
THOMAS C. NEWMAN,
 EDITOR AND PROPRIETOR,
 974 WEST MADISON ST., CHICAGO, ILL.
 At \$2.00 a Year, in Advance.

Remit by money-order, registered letter, express or bank draft on Chicago or New York, payable to our order. Such only are at our risk. Checks on local banks cost us 25 cents for collecting.

Free of postage in the United States or Canada.
 Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

Improvement of the Race of Bees.

The principal queen breeders of Italy have addressed a communication to *L'Apicoltore*, the Italian bee paper published at Milan, Italy, in which they discuss the matter of queen rearing, and promise to profit by the addresses of our friend, Mons. Ed. Bertrand, editor of *L'Apiculteur*, published at Nyon, Switzerland, and the editor of the AMERICAN BEE JOURNAL. We extract the following paragraphs :

"The learned addresses of Messrs. Ed. Bertrand, of Switzerland, and Thomas G. Newman, of America, at the International Apicultural Congress last July, have had a wide publicity through the bee periodicals of Europe, and we desire to practice the recommendations made by these gentlemen at that Congress."

"We heartily endorse the recommendations of Mr. Thos. G. Newman, and assure him that we will give the rearing of queens for exportation to America and elsewhere the greatest of care, and as he advises, we will do all in our power to improve the race of bees, putting into practice the methods advised by our friend in America, but the illustrious ex-president of the North American Bee-Keepers' Society, and honorary member of so many subordinate societies on the other side of the Atlantic, should remember the great extra expense consequent upon an incessant and progressive selection, and we hope that he will be our advocate in America, and inform his countrymen that low prices and the best quality of merchandise are in our case absolutely incompatible."

The communication was signed by Signors Pietro Pilati, Lucio Paglia and Carlo Bianconcini, and indorsed most fully the recommendations and advice we offered to the Congress for the rearing of the best bees. We are fully aware that the last sentence, quoted above, is the key to the situa-

tion. To obtain something for nothing has been carried to such a length that it has threatened us with disaster. The very poor policy of getting cheap queens, at the expense of quality, has had its day, and now the sober-thinking and wise apiarists are setting their faces against such a dangerous policy.

If we expect to get a queen worth having from Italy, it is in vain to expect it at the price of \$3 or \$4, to which price they came down in our country last year.

This heap-by-cheap policy is ruinous when applied to any business, and should be discountenanced by bee-keepers generally, as too dangerous in its results to be practiced by them, and wholly incompatible with the idea of improving the race of bees. Who, but a lunatic, would think of buying a cheap Durham bull, or full blooded horse, or pig, for the purpose of breeding the best stock, horses or swine? and yet it would be just as reasonable as to buy an imported Italian queen for the same purpose for three or four dollars.

We can assure our Italian contemporary and the queen breeders of Italy, that a more reasonable era is dawning upon our people, and hereafter they will buy queens for their merits, and pay fair prices for them, instead of obtaining scrub stock at poverty-stricken prices. We only ask them to apply the most rigid rules of selection and progression, ask a fair price, and breed *the best*.

The bee-keepers of Philadelphia and vicinity have formed an Association, with Dr. Henry Townsend, President; C. H. Beeler, Jr., Vice President, and F. Hahman, Jr., Secretary. The object of the society is the "promotion of scientific bee-culture, by forming a strong bond of union among the bee-keepers."

A Sweet Meeting that Did Not Occur.

In the BEE JOURNAL for Feb. 1, 1882, we mentioned the fact that a Bee-Keepers' Convention appointed to be held at Berlin, Wis., could not be found by those who were looking for it. We said we knew nothing of the circumstances, but invited the Secretary to "arise and explain." The following explanation is received:

In regard to the meeting of the Northeastern Wisconsin Bee-Keepers' Society, I am the Secretary, and suppose I ought to explain. The Convention in Oshkosh, in Jan., 1881, in view of the small attendance and cold weather, decided to amend the by-laws and hold but one meeting a year, and that in October; but at the meeting in Pewaukee, this was forgotten, and I was prevented from attending, at the last moment, by the illness of my child. Had I been there, the mistake of appointing a meeting in January would not have been made. I wrote to the Secretary *pro tem*, telling him of the change, and asking him to see the different persons who were present, and get their permission to change the meeting to October, but received no answer from him till a few days before the time appointed for the Convention to take place, he having been very busy, and unable to devote the time to it, but said no one would be able to go from that part of the country, or not more than one person. It was too late to postpone the Convention then, and I did not know what to do, not feeling I had any authority in the matter, but I wrote to Mr. Chas. Green, of Berlin, from whom I had received a card a few days before, sending the card to him and telling him it would explain the matter. I send you leaf from my letter-copying book with the letter. Mr. Green has undoubtedly explained the matter to the bee-keepers in his vicinity, and I hope there is no harm done, and that the meeting will be held in October in Berlin, Wis.

My regret in the matter is sincere; it was simply impossible for me to leave home, so that I could not be there to explain it myself.

[As we expected, the matter was caused by a train of unavoidable circumstances. Let us hope that a little more care will be exercised, and that hereafter the "sweetness" supposed to be flowing around bee-conventions, may be so definitely located that the "busy bees" will all find it.

☞ It would save us much trouble, if all would be particular to give their post office address and name, when writing to this office. We have letters (some inclosing money) that have no name, post-office, County or State.—Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

Incorporating Bee-Keepers' Societies.

Hon. L. Wallbridge, President of the Ontario Bee-Keepers' Society, has our thanks for calling attention to a typographical error in the BEE JOURNAL of Feb. 1st., page 68, where the depth of the Langstroth frame is erroneously given as $7\frac{3}{8}$ inches; it should have read $9\frac{1}{8}$ inches. The standard Langstroth frame is $9\frac{1}{8} \times 17\frac{3}{8}$ inches, outside. Mr. Wallbridge adds:

I use this hive $12\frac{1}{2}$ inches wide, with 9 frames $9\frac{3}{8}$ inches deep. Bees *invariably* (a strong word) leave $\frac{1}{8}$ of an inch between combs when they are allowed to choose their own distances. Should not this be the proper space between and at the ends of comb frames, and between the frames and honey boxes? I am now about to make my hives for next year, and wish to be accurate. You will confer a favor on others besides the writer, if you will give your views.

I would ask: Are the bee-keepers' associations in your State incorporated by legislative enactment, or are yours simply voluntary associations? The Ontario bee-keepers desire to be created an incorporation by law. Do you feel the want of being incorporated? I know there are inconveniences attending incorporation which I fear the Ontario bee-keepers do not see. I think we might dispense with it if you do.

After many years of observation and experimental study, three-eighths of an inch has been fixed upon with great unanimity, by experimental bee-keepers, as the proper bee-space. The difference between three-eighths and one-third of an inch is so very slight, however, that but little if any difference will be perceptible in the result.

Our bee-keepers' associations are all voluntary organizations, to join upon the payment of a light membership fee, and withdraw from at will. Holding no realty in common, and transacting no business requiring a seal or bonded officers, no necessity exists for, and no advantage would be gained by being incorporated. If it were intended to transact a general business requiring the acquisition or ownership of real or personal property, or other transactions whereby legal proceedings in law or equity might be resorted to, it would be necessary to file a declaration, take out a charter, and organize under the general law regulating incorporated bodies.

☞ We will send Cook's Manual bound in cloth, postpaid, and the Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75.

A Correction.—In the BEE JOURNAL for August 24, 1881, page 270, Mrs. A. M. Sanders gave her report—and about the middle of the letter this sentence occurred: "I had one chaff-hive, but that one did not lose a pint of bees; I like those hives," etc. By an oversight our printer thought the word lose was "have" (it looked much like it), and it was so set up and printed. As this completely changed the meaning of the sentence we learn that Mrs. Sanders felt aggrieved and wrote to the maker of that hive complaining of the matter, and intimating that it was purposely done, to injure it, etc. Her letter was a few days since forwarded to us for explanation and correction. We are sorry that the error was not observed and corrected *at once*—but must ask our correspondents NEVER to think for a moment that we intentionally change any idea. Sometimes it is very difficult to read a word and we often change the sentence to make it grammatical, but never knowingly change the idea. And we regret that any one should be ungenerous enough to intimate any such thing.

Horticulture and Bees.—The *Fredonia, N. Y., Censor*, of Jan. 26, 1882, speaking of the Horticultural Society's meeting at Brocton, says:

An "Improved Bee Feeder" was exhibited by the inventor, U. E. Dodge, of this village, which good judges pronounce of superior merit as it is certainly practical and cheap. Mr. Dodge also had specimens of evaporated apples in boxes with glass sides, which were very perfect.

The way to bring honey to public notice is to lose no opportunity of exhibiting honey, bees, apiarian implements, etc., at fairs and shows of all kinds. Persistent labor will always win. Keep the ball rolling.

☞ The *California Apiculturist*, is the name of a new bee paper published in Oakland, Cal. It contains 8 pages of the size of the BEE JOURNAL, and is to be published monthly at \$1 a year. It is edited by Mr. N. Levering, who is known to our readers as a practical bee-keeper, and it is published by the Apicultural Publishing Co. It is well filled with good reading matter, and we wish it success.

Recipe for Paste.—To make ordinary flour paste adhere well to tin or glass, add a small quantity of honey or brown sugar—say a tablespoonfull of honey to a pint of paste. Glue size is better than honey for pasting on wood.

WM. C. PELHAM.

MISCELLANEOUS.

Prepare for Spring Work.—Under this caption Wm. M. Kellogg writes thus to the *Prairie Farmer*:

Right now is the time to get ready our season's work in the apiary. By-and-by our bees will be coming out from their winter quarters, and we shall then be so busy attending to their wants that the little items, which have a vast bearing on the success or failure of the honey crop, will be neglected or entirely omitted. And say what we will about the pleasures of bee-keeping, the stubborn facts of the case are, that we are after the dollars and cents of the business, with very few exceptions, and they who expect to make a success of bee-keeping, to get large yields of honey, or increase in swarms, without attending to the little things of the business, need expect naught else but a failure in their efforts. Let us begin now to get our "house in order," these long winter evenings; let us spend a part of the time in discussing what we need to do to help our little pets when the time comes for them to work. Most of us have but little to do during the winter season, and the busiest ones can spare now and then a day to the bees.

Last fall, in the hurry of getting our honey ready for market and the bees packed away nice and snug for winter, many of our tools and fixtures were set to one side, tucked away into the handiest place at hand "for now," meaning to clean them up by-and-by. That by-and-by has come now; here go it with a vim.

First, that pile of unfinished sections that we extracted the honey from last fall, and put away in a hurry, get them all together and with an old broken stub knife scrape off every bit of propolis, smooth and nice, so that they will go together like new ones without any bother. There, see what a nice lot of them we have, will not the bees fairly laugh to get at them? The mice have got at a few of them, we cut out their nibbling, unless soiled too much, if so, cut out all of it and replace with a good piece of comb foundation.

Now we will estimate about how many cases of sections we will need to use this season, and use our partly-filled sections accordingly. We ought to put in one or two of them to each row of sections to give the bees something to climb up on, which seems to help them very much.

Then there are the honey boards, or cases, to hold the sections on the hive; clean them all up too, then put in the sections, tin separators, and wedge all up firmly, and set upon the shelf ready for use. It is not always best to put on a full complement of sections at the first, so when the time comes we

can only put on so many as we judge the colony can take care of.

Now for the hives and extra combs; we look them all over, dig out a mud dauber's nest here, a patch of propolis there, clean them all out. Our frames of empty combs need pruning some, a bit of drone comb here, another spot where the moth may have spoiled it, and fill up the vacancies with a piece of foundation. This work you will need to do in a warm room, for foundation and comb are brittle things in cold weather, but propolis comes off the best where it is cool.

Then there is our old smoker, look how it is "stuck up," not with pride, but honey and soot, do not forget to clean that up too, and set the old shop to rights generally, and we will find plenty to do, I will warrant you.

Now lets see, have we as many sections, and as much comb foundation as we will need this season? I do not believe we have; and now we have been pretty busy and got rather tired, to-night we will write out an order to send off to-morrow to the dealer for the needed supplies. If we order now, he can get our goods ready at his leisure, but after awhile he will be so busy filling orders that we may have to wait, and lose precious time, for when the honey is coming in fast, time is honey and honey is money. "In times of peace prepare for war," go now, get ye ready for spring work!

A Cat's Experience with Bees.—The Virginia City, Nevada, *Enterprise*, gives the following amusing anecdote:

Charles Kaisey, who has the only hive of bees in town, says that when he first got his colony his old cat's curiosity was much excited in regard to the doings of the little insects, the like of which she had never before seen. At first she watched their comings and goings at a distance. She then flattened herself on the ground and crept along toward the hive, with tail horizontal and quivering. It was clearly evident that she thought the bees some new kind of game. Finally she took up a position at the entrance to the hive, and when a bee came in or started out, made a dab at it with her paws. This went on for a time without attracting the attention of the inhabitants of the hive. Presently, however, Old Tabby struck and crushed a bee on the edge of the opening to the hive. The smell of the crushed bee alarmed and enraged the whole colony. Bees by the score poured forth and darted into the fur of the astonished cat. Tabby rolled herself in the grass, spitting, spluttering, biting, clawing, and squalling as a cat never squalled before. She appeared a mere ball of fur and bees as she rolled and tumbled about. She was at length hauled away from the hive with a garden rake, at the cost of several stings to her rescuer. Even after she had been taken to a distant part of the grounds the bees stuck to Tabby's fur, and about once in two minutes she would utter an unearthly "yowl!" and bounce a full yard into the air. On coming

down she would try to scratch her ear, when a sting on the back would cause her to turn a succession of somersaults, and give vent to a running fire of squalls. Like the parrot that was left alone with the monkey, Old Tabby had a dreadful time. Two or three days after the adventure Tabby was caught by the owner, who took her by the neck and threw her down near the bee hive. No sooner did she strike the ground than she gave a dreadful squall, and at a single bound reached the top of the fence, full six feet in height. There she clung for a moment, with a tail as big as a rolling-pin, when, with another bound and squall, she was out of sight, and did not again put it an appearance for over a week.

Plant for Honey.—The Chicago *Herald* remarks as follows on this important topic:

Our pleasant and useful cotemporary, the AMERICAN BEE JOURNAL, of this city, is quite emphatic in its recommendation that it is a wise thing to grow both trees and plants which afford a supply of honey for the bees. Among plants it recommends the well-known sweet clover, which will give them continuous pasturage from June until it is too cold for the bees to fly. So far as trees are concerned, there is none of such value as the basswood or linden, though its season is quite short. It is a very beautiful and healthy tree in all parts of the country, and once established is easily grown. We understand that it may be raised from cuttings, though they will require considerable care the first year. The linden is a very beautiful tree, especially when full of fragrant blossoms in early July. The quality of the honey from this tree is very superior, having a flavor almost equal to the wild sage honey of Lower California. Certainly it will pay to grow both trees and plants for honey, and so far as the trees are concerned, the sooner they are planted the better.

The Longevity of Bees.

E. A. THOMAS.

It seems to me that this subject is of vital importance to the successful cultivation of the honey bee, and I wonder that it has not received more attention at the hands of prominent beekeepers.

Every one has doubtless noticed the difference in the length of life in the human family; how, in some families generation after generation will live to a ripe old age, unless prematurely shortened, while in others each generation grows old much earlier in life, and die of old age at an age when others would be in their prime. You will also notice, in examining the records of families, that the average length of life of each successive generation, many times either increases or diminishes. This has also been noticed in many of the lower animals, and it is only reasonable to suppose that there is also a great difference in the length of insect life.

As there is no effect without a cause, we must endeavor to ascertain the causes which tend to lengthen or shorten the life of *apis mellifica*. I have conducted many experiments for the purpose of determining these causes, the result of which I give below:

First, in regard to the longevity of queens, I have found that those reared from the egg live to a greater age, and their offspring are capable of greater endurance and of longer life, than those reared from old larvae. This is demonstrated by noting the condition of colonies having such queens, at intervals through the season. Those containing queens reared from the egg will be found to steadily increase in numbers until the hives cannot hold their teeming population, while colonies having queens reared from old larvae, never become very strong even though the hives are crowded at all times with brood. While the latter may increase as rapidly as the former early in the season, they will fall far behind later on, when the places of the fast dying bees must be supplied by the hatching brood. It is reasonable to suppose that a queen reared from the egg will receive a more full and perfect development, than where the development is forced, as is the case with queens reared from old larvae.

Thus I have found that the longevity of each succeeding generation from any queen can be greatly augmented by breeding from the egg and every queen I rear in future will be bred in this way. By breeding from bees that are long lived, considering both the life of the queen and her offspring, we may greatly improve our bees in this direction. I will speak of the value of long lived race further on.

There are certain unnatural causes which tend to shorten the life of a queen and of her offspring. Queens that are balled and hugged by the bees when introduced, until they have a greasy appearance, will be found to be very short lived. I consider such queens as utterly worthless and destroy them at once. There are other causes which time and space will not permit me to speak of.

Second, the longevity of drones must have more or less influence upon the length of life of the queen's offspring. As we cannot wholly control the mating of our queens, we must depend a good deal upon chance for their mating with long lived drones; but we may considerably lessen the chances of poor mating, by stimulating the colony that produces the finest drones to rear a large number, keeping all others cut off or trapped. It is very difficult to ascertain the age of drones, and almost impossible to determine their average length of life in different colonies. I once induced a colony to retain their drones all the winter, by stimulative feeding, and allowed them to rear none the next spring. In June I found many drones in the hive, which had every appearance of being very aged, and I have no doubt that they were the ones reared in the colony the fall previous. I induced this colony to rear a large number.

Third, the longevity of the workers must depend upon that of the queens and drones. This is a self evident truth, and does not need to be demonstrated by experiments. If we find the workers in a colony very long lived, we must conclude that either the stock from which they sprang or the drone with which the queen mated, or both, were long lived. While we have no means of knowing where the drone came from, we can trace the stock back on the side of the queen, if a careful record has been kept—and here is where the "Apiary Register" proves of value.

If the reader will pardon the digression, I will say here that all who understand the value of a fine strain of bees, and who wish to improve their stock, will do well to send to the Editor of the BEE JOURNAL and get an *Apiary Register*. He has gotten up a neat and well bound book which is cheap at the price, and it should be in the hands of every bee-keeper. In my next article I will give a few hints about keeping the Register, marking the queen, etc.

But to continue: In determining the longevity of bees, you should note their condition in spring; in the case of short lived bees, the colony will dwindle badly in spring; do not understand me to say that all bees that dwindle in spring are short lived, for there are many other causes which produce dwindling. The bee-keeper who is troubled with spring dwindling should investigate the matter, and if he cannot find any abnormal condition of the bees that would cause the trouble, it is safe to conclude that they are short lived or weakly. The remedy is to introduce new blood into the apiary from some long lived race,

breed from that stock and keep the drones of the other cut off or trapped.

The importance of this subject must impress itself upon the minds of all after a careful consideration of the question. It is as important in breeding a fine strain of bees to endeavor to augment the longevity of the race, as it is to breed for hardiness. Long lived bees will endure more, and consequently will store more honey in summer; the colonies will throw off larger swarms, which will not dwindle from the effects of hard work before the new brood begins to hatch; and last but not least, they will live long enough in spring to recuperate their strength of numbers, and rear sufficient brood to take their places when they shall "give up the ghost."

I can see a marked improvement in my own bees since I gave attention to this subject, and I am not troubled in the least with spring dwindling or with weak colonies; they always keep strong and vigorous.

Coleraine, Mass.

For the American Bee Journal.

My Very Strange Visitor.

G. M. DOOLITTLE.

A stranger by the name of L. W. Vankirk called, a few days since, to have a friendly chat with Doolittle (see page 63, BEE JOURNAL). As I am always "chatty" the time passed off pleasantly. Upon departing the stranger found Doolittle was more a fact than fiction, for, somehow, Doolittle's talk was of about the same tenor as his articles in the bee papers—thus the stranger was satisfied that a *chat* only developed the truth that Doolittle was the same matter-of-fact man which he had read about. However, I learned some new things which *might be of great advantage* to me and as I am always free to give the readers of the BEE JOURNAL all that I learn, I will tell you about it.

Bee-keeping to be *most* profitable should become a "side issue," for in this way with the help of "the girls" and a dayspent "now and then," by a busy farmer, \$800 can be easily made in a season. Also, if you wish to make a big report, let your bees become weak by keeping them in a cellar ranging from 30° to 35°, cooling them off gradually once or twice a month (many may not wish to try this plan, but my strange friend would) so that you can double them down to a small number. Now, do not feed back any unsalable honey in getting the bees ready winter, nor any of that taken from the nucleus in uniting in the fall, till after all is weighed and thus you can make a big report, and "do one hand's work on the farm" besides.

I had heretofore supposed to make an *honest report* that no honey should be counted but that *actually* sold, but my strange friend has put me on the road, so that I can swell the amount largely; therefore look out for a "magnificent" report next fall.

Then again I learned how to "draw largely on the sugar barrel" and thus

get a large return from this, as a part of the side issue. I have used no sugar heretofore, except in the spring of 1878 to keep my bees from starving, so right here I can score another point toward that "grand" report, next fall.

Surely such a "side issue" can be made a great source of wealth, for, if an L. W. Vankirk can make \$800, therefrom, by spending a few days' time from his more profitable farm, a specialist who can devote his whole time to the business can make his thousands. I presume we shall hear no more about specialists as honey producers, after this.

Borodino, N. Y.

For the American Bee Journal.

Reply to A. R. Kohnke's Review.

CHAS. F. MUTH.

In reply to Mr. Kohnke's review on page 56 of the BEE JOURNAL, I must say, a review, as the name implies, is the view of a party on a subject of former date. It may show the character of both parties, whether they are practical men, or whether the knowledge of one or the other is merely of a theoretical character.

Nothing improves our knowledge more than a free discussion, and a difference of opinion serves generally to throw light on a subject. I do not often indulge in literary attempts, and when I do, other business does not permit me to dwell too long on any one subject. I must make my articles short, and avoid repeating. For instance, when an article like the above mentioned review requires an answer, I must not postpone it until next day, because by that time, something else is occupying my brains and time, and the reply would never be made.

I have read some bee books and had some practical experience with bees, and whenever I wrote about them, I gave facts as they appeared to me. If I have been wrong at any time, I am willing to be corrected, and if convinced, shall acknowledge it like a man, and no hard feeling will be created thereby against any body.

However, in the "review" of Mr. Kohnke, I fail entirely to see where I have erred, although he counts up "three mistakes," as he states, which sound just as plausible to the uninitiated, as the great discovery of the application of electricity on a swarm of bees, which was published in the BEE JOURNAL in March, 1880.

Mr. Kohnke states that, according to my statement, Hilbert's foul brood recipe was 50 grs. of Salicylic acid, and 400 grs. of pure spirits (or alcohol), which I suppose is correct. If it was not, I suppose he would have given the proper proportions, as he read, like myself, the German bee papers giving the details.

He next says that in 1879, my recipe was 8 grs. of Salicylic acid, 8 grs. of borax, and 1 ounce of water, and that in 1880 I recommended just double that strength, that he waited to see me correct it, and he concludes that I made some grave mistakes, and that he will show that the re-appear-

ance of the disease in my apiary may have been caused by the effect of the medicine—that is rich! If I do not make another grave mistake, Mr. Kohnke has kept 5 colonies of bees during one summer (from spring to fall), while living in the suburbs of our city, and if he ever kept bees before, I was unable to observe it. He was certainly no bee-keeper, and he has kept no bees since, which his last letter tells me. In the meantime, however, he was in some manner connected with Mr. Heddon, who, I venture the assertion, can tell us that Mr. Kohnke is not even able to open a hive of bees like a practical bee-keeper does it. His knowledge is theoretical, and as such is the fact, he should not have overlooked important points, as follows: My remedy to use with the atomizer, was and is now 8 grs. of Salicylic acid, 8 grs. of borax, and 1 ounce of water. But since I have cured the disease by the means of feeding, I have used the medicine of double strength, and one ounce of this mixture is answering for a quart of food. If the mixture were single strength, I should have to use 2 ounces. All of these matters have been duly reported every season, and every other matter of importance that came under my observation. Mr. Kohnke may improve his knowledge by looking that matter up. It is not worth my time to do so.

In my (alleged) mistake No. 2, as he calls it, Mr. Kohnke gives those two mixtures single and double strength, and says: "As Mr. Muth refers to those in his other articles and essays on foul brood, which is the right one? I (Kohnke), answer neither." This leads me to mistake No. 3, etc. This is not rich, but—well, I leave it to the reader to say what it is. Had I as much time to spare as Mr. Kohnke, perhaps I would repeat every time when occasion offers; but, as stated above, whenever I am through with one thing, I have something else to do and think about.

I have nothing to say about the chemical composition of my remedy, but that it is effective and does all I claim for it.

The matter may soon be sifted by parties better posted in chemistry than I am. My druggist, whom Mr. Kohnke, I think, knows, is a good chemist, says that Kohnke's statement is nonsensical.

No beginners should expect to meet with the same success as old hands. But, if anybody fails to cure foul brood when employing my remedy given at our Cincinnati Convention in 1880, and recorded in the BEE JOURNAL, and in my "Practical Hints to Bee-Keepers," it is because only the minority of men are successful in any undertaking. If they would take the same pains I did, they would be more fortunate.

"But," says Mr. Kohnke, "what about the cure he effected? some will ask. I (Kohnke) reply: A cure has never been effected, but Mr. Muth treated his diseased colonies to pure comb or foundation, and pure honey, by which a suppression of the disease has been effected," etc.

This is not rich, either, but it shows plainly that Mr. Kohnke never treated a colony of bees diseased with foul brood, and he, very likely, never saw one. It is, therefore, an assumption, so say the least of it.

There is no better authority than Emil Hilbert, whose articles on foul brood appeared in our German bee papers, and are the basis of my treatment, but which appear to have been carelessly read by Mr. Kohnke, or were misunderstood by him, because of his lack of practical knowledge. I have simplified Hilbert's arrangement very successfully, and I leave it to those who know me if I am guilty of assumption.

I am so little alarmed about the disease that I, last spring, bought out a neighbor's bees affected with foul brood for a number of years, and who used my remedy all along. I had told my old friend that he would not be man enough for the emergency, but he had to satisfy himself first, before he gave up the bees. His 8 colonies were placed in my apiary, and all his goods pertaining to bee-culture which I did not take along were burned before I left the place. Three of the colonies were still affected with the disease and cured during the first few months of spring. From my friend's apiary, very likely, dated a number of occasional cases of foul brood in my apiary, where, however, they could not do much harm, because I know how to cure foul brood, and I am not afraid to prove it.

Cincinnati, O.

For the American Bee Journal.

Fresh-Made Comb Foundation.

J. W. PORTER.

Permit an old friend to congratulate the BEE JOURNAL on its improved appearance. It is becoming more and more valuable, since the change.

I can indorse Mr. Isham's remarks in favor of wood separators for I have long used them. The smoother and harder they are the better, I think. They take up little more room than tin.

As I have seen nothing published in regard to the superior advantages and value of fresh made foundation I wish to ask why it is, for it must have come to the observation of many who are in the habit of using it. To me it seems that freshly made, or at least that which has not been allowed to become hard, is worth very much more, and there are times when I would prefer even to melt into wax that which is hardened by age and pay for fresh foundation. Is not there some way in which seasoned sheets may be made acceptable and pliable? I shall try a warm bath in slightly sweetened water and laying them damp in piles together, and only cut as wanted in the hives. Can any one speak from experience in this matter?

This is a question of great importance, for every one who uses foundation must at times carry over quantities of it. It is, in my opinion, something that has an important bearing

upon the tests made as to the relative value of that made from different machines—its *mechanical condition* at the time of insertion. I would call the attention of Mr. Doolittle to this point for his experiments were of great interest.

Last year I tried, side by side, in several different hives, three different kinds made on as many different machines, by well known makers, and invariably found that the sheets that were freshest and most pliable were the best. All I suppose were freshly made but some of it was pressed too hard. Especially I found this the case with the thin "flat bottom." There is no doubt but the chemical condition is affected by the presence of impurities, and over-heating affects the value greatly.

Having used foundation since its first introduction and fully realizing early the importance of its perfection, to honey producers, it is a matter of congratulation that invention has been so active in supplying our needs. Let us have all the light possible. In a suitable temperature sheets can be kept, if closely packed, a long time fresh, but the aim should be to give the most perfect work possible with the least pressure of the sheets. Such is my experience.

Since writing the above, I have a letter from a gentleman, who well deserves the name of bee master, for he last year produced from one colony more than 700 lbs. of honey. He goes so far as to say, that if he had to cut out and melt up starters that had been in the sections two months and put in new in the busiest season, he would do it. Are not others observing a difference of the kind named?

Charlottesville, Va.

For the American Bee Journal.

How to Detect Glucose.

W. C. PRESTON.

Having noticed in your excellent JOURNAL an inquiry for some simple method of detecting glucose, allow me to give your readers the test in common use in chemical laboratories.

The test is sufficiently simple and at the same time very delicate—and may, I think, be stated so plainly that the non-professional reader will find no difficulty in its practical application. It is based on the fact that if to a boiling alkaline solution of blue vitriol a solution containing glucose be added, a red precipitate of cuprous oxide will be immediately thrown down; while cane sugar will give the red precipitate only after protracted boiling. It will be necessary to prepare the following solutions, which may be bottled up and kept for use as required:

1. One-half ounce blue vitriol dissolved in one pint of rain water.

2. Three ounces caustic potassa dissolved in one pint of rain water.

Also procure a test tube about 6 inches long, such as may be found at most any drug store. Pour into this tube about a tablespoonful of the blue vitriol solution and add about an equal amount of the solution of potassa—a

light blue precipitate will be formed—now add a small quantity of the sweet substance to be tested (it is better to be in solution), and heat to boiling. If even a trace of glucose is present it will be revealed by the reddish tint immediately imparted to the liquor, best seen by looking down through the tube lengthwise. If there is much glucose a red precipitate will sink to the bottom of the tube.

It may be well to add that this test does not enable us to detect the adulteration of honey by manufactured glucose, inasmuch as all honey contains a large percentage of the same saccharine substance—but pure, as formed in Nature's laboratory—the nectaries of flowers.

State University, Iowa City, Iowa.

For the American Bee Journal.

Bee-Keeping in Australia.

S. MACDONNELL.

DEAR EDITOR.—The notice that appeared in a late number of your JOURNAL regarding the death of the late President Garfield, was one fitting any publication whatever its general object, and as, perhaps, I am the only citizen of this country who writes to the BEE JOURNAL, I shall not like the event to pass without an acknowledgment of the high esteem and respect entertained in all classes here, for one known to us only by his fame and noble character, and of the deep regret which was universally felt at the tragic end of your late President.

My Italian bees have progressed satisfactorily. At one time I was afraid that one colony had sent a swarm to the woods, whereby I should have lost one of my imported queens, but my fears have proved unfounded. I have but little time to try the Kabler or other process for securing the pure impregnation of queens, but have contented myself with giving Italian cells to queenless black colonies, after having removed the queen cells from all their own brood. I have treated about 15 in this manner, and an examination this week found about 12 with yellow queens, some showing an admixture of black. The number of Italian drones which I shall be able to rear next season, and the absence of black drones in my apiary, will, I trust, then give me a better chance of securing pure impregnation for a fresh batch of queens.

An enterprising German bee-keeper lately arrived, and was sent to me by the German Consul for advice. He showed himself to be a thorough master of the science, and I considered his proposal to run a farm of 400 colonies, but, as I was to find all the capital, and he to receive one-half profits, in addition to an allowance of £3 (\$15) per week, my estimates showed but a pittance for myself. The hives which he proposed using were to have dovetailed joints, to contain 10 frames, 8 inches wide, 13 deep in brood chamber, and 10 frames half the size in surplus gear, the surplus separated from the brood by excluder-zinc. The hive was to have a door at back, and

the frames to hang from a groove into which they slide. The matter, for the reason of cost without adequate returns, has been abandoned by me. I was much amused at his ingenious smoker, consisting of a deep-bowled pipe; the cap fitted with a muzzle, allowing the tobacco smoked to be puffed on to the bees, while the hands were free for operation. How would this suit Mr. Root's "tobacco column?"

I have determined to run a farm of about 100 colonies for a commencement, on a friend's orchard in the vicinity of Parramatta, about 15 miles west of Sydney. Oranges and other fruit trees are largely cultivated there, and in addition, there are many hills and valleys yielding an abundance of our native honey-producing plants. My present stock, at Homebush, where bee fodder is not sufficient to keep more than a small number of colonies, I intend to reserve as a queen breeding station, to supply Italian queens to the farm. Langstroth hives will be adopted throughout. Foreseeing the possibility of the venture assuming larger proportions, in course of time, when it would pay to employ an expert, I should much like to know the rate at which a man able to manage a large bee farm, could be procured from America on a 3 year's engagement, passage paid? Ordinary farm laborers get 25 shillings per week (\$6), and find their own board and lodging. Ours is a delightful climate, no winter, and bees thrive amazingly.

I wish you the compliments of the season, and a prosperous year for the AMERICAN BEE JOURNAL.

Sydney, Australia, Dec. 28, 1882.

[It is very doubtful if a skillful apiarist, such as would prove satisfactory and profitable, could be obtained for less than \$75 per month, for a three years' engagement. Good apiarists, seeking employment, are exceedingly few.]

Accompanying the above communication was the following list of articles exhibited by Mr. MacDonnell, at the Balmain Industrial Exhibition of 1881. As it will interest our readers to learn the progress of bee-keeping in Australia, we give it a place.—Ed.]:

1. Diagrams of the Anatomy and Physiology of the Honey Bee—Published by the British Bee-Keepers' Association.

2. Langstroth Frame Hive, containing 3 stories, the first story having 10 frames for brood-rearing, the second having 10 frames for storing honey for extracting, and the third having 18 section boxes, each to hold 2 lbs. of comb honey.

3. Langstroth Single Frame Observatory Hive, allowing the whole economy of the hive to be brought under inspection.

4. Honey Extractor, by the use of which honey is extracted by centrifugal force from the comb, and the comb is returned to the hive, thus enabling

the bees to re-fill the same comb, time after time, without troubling them to build it afresh.

5. Comb Foundation—For compelling the bees to build straight combs for rearing worker bees, and preventing them from rearing drones.

6. Honey Knives, for uncapping frames of sealed honey preparatory to placing them in the extractor.

7. Syringe for washing drone brood out of cells.

8. Queen Cage, for introducing fresh queens into the hives.

9. The Cheshire Bee Trap, enabling bees to leave a box but not to re-enter.

10. Bee Smoker, for puffing small quantities of smoke into hives, whereby the bees, fearing that they are to be driven from their home, are induced to fill their honey sacs with honey; the consequence being that, like a man after a good dinner, they are not inclined to be quarrelsome, and the hive may be opened without fear of the operator being stung.

Mr. A. R. Kohnke and Foul Brood.

D. A. JONES.

In reply to Mr. A. R. Kohnke, on foul brood, page 8 of the BEE JOURNAL for 1882, I would say that I am sorry his cure is too expensive, and requires too much time for me; besides, I do not know of a case of foul brood in Canada now, although I suppose there are some. A bee-keeper, a friend of mine, told me he knew of a case not far from him, which is about 40 miles from me. I told him how to cure it; he promised me to do so, last fall. I suppose he did.

Mr. Kohnke makes a proposition to cure in six weeks; why, bless his soul, I would not give him a cent to fool six weeks with a case of foul brood that can be cured with one or two hours' labor without the use of salicylic acid, or any other medicine. Twenty degrees below zero will not kill foul brood. Take honey from a badly-diseased foul brood colony, mix it with acid as strong as the bees can take it, and feed a clean colony; it will become diseased. The same honey boiled for fifteen minutes may be fed with impunity. But bad foul-broody combs sprayed with acid for days, then soaked in a strong solution of it, completely immersed, when given to a colony starts the disease. I will make the following offer to Mr. K.: if he will bring me a colony of foul brood that I cannot cure with a few minutes or hours of labor, I will give him one hundred dollars for it; I to use no drugs. Or, if he will bring me five very bad foul-broody colonies, and take an equal number himself, equally bad, if I cannot cure mine, without the use of the acid or any drugs, in less time than he can by the use of the acid safely, then I will forfeit five hundred dollars. We have no salicylic acid in Canada that cures foul brood, but we have plenty of men that can do it. But we have no means of curing it without melting up the

combs into wax; we return the wax to the bees made into foundation.

At some seasons of the year bees may first be shook into a clean hive, prepared with foundation; combs rendered into wax, honey extracted, boiled and fed back to the colony, and the hive and rack scalded for fifteen minutes. Dr. Duncan, of Embro, Canada, did this last spring (see *Gleanings in Bee-Culture*, page 32 for this year). If bees are removed from the diseased hive and made to consume all the honey in their abdomens before they commence breeding, no disease will appear.

Some recommend burning all. A gentleman in California wrote me some time ago that he had just burned 178 colonies, hives, combs, honey and all. Now this is bee murder, and a useless destruction of property. It reminds me of the bed-bug recipe that was being sold and guaranteed a sure cure. It read as follows: "If your house is infested with bed-bugs, just burn it and it will kill every one without fail." I used to fear the moth miller more than I now do foul brood. The curing of foul brood is less labor with me than transferring from log-gums, and when I hear of any in this part of Canada, I see that it is cured.

Now some may think from the above that foul brood is not the dangerous disease that it is represented to be, and if they just shake off the bees from the combs of a diseased colony into a clean hive of combs, and whistle Yankee Doodle, that the job is done and the disease is cured. Such, however, is far from being the case. If bees are placed on empty combs immediately from a diseased colony, some will carry their sacs full of the diseased honey and empty it into the cells of the clean combs, then, perhaps, go to the fields, gather more honey, and store it on the top of the diseased honey. Now, that honey might remain there for a long time, but when fed to larvæ it would bring on the disease. The great danger in treating the disease is in bees from clean colonies getting a drop of the affected honey, as all the honey in a diseased hive is affected, and one drop of honey from the affected hive will start it in a clean colony. So all operations should be performed when bees are not flying, or under a wire tent, or some other device that prevents any other bees from getting one drop of the diseased honey. An old saying is, "An ounce of prevention is better than a pound of cure," and this is doubly true in this case, for 100 colonies may all become affected by the careless handling of one colony. When honey is scarce you should make your bee-yard a quarantine as far as possible.

I will give the following mode of curing: Suppose a person has a large apiary affected with the disease. I would first remove all the combs not containing brood, extract the honey and boil it, then it is ready to feed back. Render the combs into wax and make it into foundation; boil the frames 15 minutes, and fill in the foundation again, placing them in clean hives. I next drum and smoke the

bees until they all fill themselves with honey (this is very important, for if some are not filled, they will die when others have plenty); then shake off as many bees from the colony as can be spared, always taking the queen from the colony, leaving enough to nurse the brood; place them in a box, cover it with wire cloth, carry it to a dark, cool cellar or bee house, lay it on its side, and allow the bees to remain there from 60 to 80 hours, until you see them beginning to drop down and show signs of starvation; then shake them into the clean hives with foundation, feed them, and put them into a new location at least 1 or 2 miles away from the diseased yard. Queenless colonies will not last as long when left to starve as those with queens, and should be doubled with others, or watched more closely, as they are sometimes so restless that they exhaust their food in 2 days or less. It will not do to put bees in a light, warm place to starve, as some run around and get excited, consuming all the honey in their sacs, and starve, when others more quiet have plenty. A dark, cool, quiet place, where they remain clustered quietly, is the proper place.

It will not do to remove the affected colonies and keep the purified at home, unless they are taken 3 or more miles away, as sometimes bees return to their old location, and might bring the disease with them; while if any of the purified ones return, they remain and are treated with the others again when the brood hatches. As soon as the queen and bees are removed for starving, the hatching brood and bees should be doubled up so as to have all colonies full of combs of hatching brood. The empty hives thus secured should be scalded for future use. As soon as all the brood hatches, the bees may be brushed off the combs after being made to fill themselves with honey, same as the first, placed in some boxes as the first were, and treated in the same way. While they are starving, scald the hives and frames, render the combs into wax, make it into foundation, return it to frames again, place them in the purified hives, and put your starved bees into them again. The honey that was in the combs, of course, should be extracted before cutting the combs out of the frames, and boiled to feed them. Now bring the first lot purified back to the yard again, and you have all your bees and hives purified and free from disease, if you have done it as it should be done, without any loss except your time.

Now, if it is done when there is no brood in the hives, or if you do not care to save the brood, the entire yard can be purified in about 3 days, as you remove all the bees from every hive to starve, while they are starving the hives are boiled, honey extracted and boiled for feeding back, combs rendered into wax, made into foundation, returned to the frames after they are boiled to disinfect them, return the frames with foundation to the purified hives, and the bees when starved may be shaken back in the hives on the original stands, and fed back their

purified honey. The honey should be kept at the boiling heat for 15 minutes.

I know of many other plans and ways of doing it, some less trouble and quicker done than the above, but do not wish to give any that could not be carried out by a novice.

There is no more need of losing a colony by foul brood than by queenlessness, and it is so simple and easy to cure when thoroughly understood, that I hope it may be completely wiped out in America. I am sorry to have to trespass so much on your valuable space, but trust there may be no more burning or destroying bees from the above disease.

For the American Bee Journal.

Prohibiting Imported Bees.

JULIUS TOMLINSON.

The BEE JOURNAL arrives regular, full of good things. In looking over No. 3, when I came to page 34, I had a hearty laugh over the editorial, in relation to an extract from the Detroit *Evening News*. As I am the Michigan bee-keeper referred to, perhaps I ought to "rise and explain."

There are some things in this State, a little peculiar and different probably from some things in other States: 1st. The *Evening News*, with an immense daily issue, wide awake and enterprising, and which advocates free trade, with a zeal that "no lawyer knows," in which advocacy I am free to say, I heartily concur.

2d. A very worthy Governor, but who lives in Saginaw, and believes that salt, if not king ought to be.

3d. The action of Governor Jerome in appointing delegates to the high tariff convention in New York last autumn; and

4th. The coming State Bee-Keepers' Convention, at Battle Creek.

It was in reference to the above situation that the following was written, and published in the *Evening News* of same issue, as the extract quoted in the BEE JOURNAL:

"There is to be held in Battle Creek, Dec. 9th, an important industrial convention. It is the annual meeting of the Michigan Bee-Keepers' Association. The production of honey has become a very important industry, and many thousands of dollars are received annually by the bee-keepers of the State. As this is to be a very important meeting I would respectfully suggest to our most excellent Governor, that he appoint delegates from different parts of the State to attend that Convention.

"I would also remind the Governor that a certain Mr. Jones, of Canada, is largely engaged in bee-keeping, and is selling large numbers of queens to bee-keepers on this side of the line. His queens are very superior stock; they are endorsed and recommended by Prof. Cook and most of our leading bee-keepers. Mr. Jones has spent many thousand dollars to procure this stock. He has himself visited Palestine and Cyprus on purpose to procure superior queen bees. He has also em-

ployed Mr. Frank Benton, a citizen of this State, to visit Ceylon and Java, where amid untold perils he searched for that wonder of the insect world, the *Apis dorsata*.

"Now, Mr. Jones, being a foreigner, I would respectfully implore the Governor, in his next message, to recommend that Michigan bee-keepers be protected against these Canadian queens. If it be said that this is no part of the Governor's business, I would say that this is in exact accordance with the Governor's action in other matters. Has he not recently appointed citizens of this State to attend the high tariff convention in New York, and did he not in his first message recommend that Michigan Salt be protected from "the Canadian article?" This is very important and I hope the Governor will seriously consider these matters. Canadian queens should not be tolerated in this State.

J. TOMLINSON."

Of course the *News* made a blunder when they talked about the drones being laborers, otherwise I see no great incongruity in the comments of the *News*. Doubtless, if you had had all the points, your editorial would have been somewhat different.

Allegan, Mich.

[The above article has somewhat of a political cast, with which the BEE JOURNAL has nothing to do; but as it is rather necessary to explain the curious article copied from the Detroit *News*, and commented upon on page 34, we give it a place.—ED.]

For the American Bee Journal.

Potatoes as Bee Enemies.

A. R. KOHNKE.

The writer of a prize essay in a German bee paper, attempts to prove that the potato may be considered as a bee enemy. After going into a lengthy discussion of the comparative nutritive value of potatoes and honey, he comes to the conclusion that it would be far more profitable, especially for people being in possession of only a few acres of land, to devote that to the cultivation of honey plants, to the exclusion of potatoes, inasmuch as all available ground is taken up to raise that vegetable, and not a single weed is allowed to grow which might furnish the bees honey.

Though it must be admitted that potatoes are very poor in nutritive qualities and honey rather rich, it would not be good policy for any one having one or two acres, to plant for the bees, and buy his vegetables with the proceeds of his apiary.

The main object of the article above mentioned was to induce bee-keepers to provide a better pasturage for bees. To this fact the bee-keepers in Germany seem to be as alive as some are in this country. Whether it will or will not pay to sow exclusively for bees, I intend to prove myself next summer. Bee-keepers or others who have seeds of supposed honey plants, not for sale anywhere, and have not

the time or land for experimenting, may send some to me, free of charge (say enough to cover at least an acre of ground), name of plant and time of bloom should be noted. Results will be reported in due time through the BEE JOURNAL.

Youngstown, O.

Does it Pay to Rear Dollar Queens?

REV. A. SALISBURY.

I frequently notice articles in the bee papers stating the profits of rearing and selling untested queens; but these advocates of Dollar Queens present nothing new to inspire the confidence of bee-keepers, of long experience, in their assertions. It may do, where one owns a bee paper in which to do his "puffing," and who buys queens at from 50 cents to \$1 and sells them at \$1.50; but the one who rears them—does he make money in doing so?

There seem to be many who look upon the proceeds of a queen-rearing apiary as largely profit. But let us see if we cannot do better than to continue to sell fine queens at \$1. After awhile we may want something for our labor, besides bare expenses.

Let us examine the matter a little and try to find the profits, if any. We will suppose that an expert can rear, fertilize and sell 500 queens and receive therefor \$500. That looks like good pay for 4 month's work; but let us examine further. The expenses for circulars, advertising and correspondence are \$90; 500 cages \$50; say 50 queens lost in the mails, \$50; syrup for feeding 100 nuclei, \$100; for feed for colonies after consolidating in the fall, \$35; lamp nursery and oil, \$7; postage on queens, \$10; wages for an expert, at \$40 per month, for 4 months, \$160. Total, \$512, or \$12 more than the queens sold for.

In the above I have said nothing about how many good colonies must be robbed of cell builders to rear the 500 queens, for royal cells must be built in good colonies, to produce the best queens. Neither have I taken into account the capital invested in nucleus hives, feeders, etc.; nor the number of queens to be replaced to make all satisfactory when complaints are made; nor have I mentioned the many combs cut up for eggs to rear queens from, for the colonies containing the finest breeding queens get no surplus honey, as they must be handled all the time.

Mr. Hutchinson tells us that a breeder cannot rear "dollar queens" at a profit, if he allows some of his nuclei to stand queenless several days, for lack of queen cells. All, of course, will subscribe to this statement, but all will not agree that they can be reared at a profit when cells are constantly on hand. And more than that, in this latitude, we have, as a rule, about two months in the 4 that the flow of honey is very light, during which time the bees largely refuse to take either a cell or young queen at once, and say by their actions, we pre-

fer to be without a fertile queen 25 or 30 days, rather than to take the strange task you want to impose upon us. And in running 100 nuclei it is out of the question for one hand always to keep them filled with queens against their will. If others can do it, they can do what I never have done, in the past 20 years, and I fear I am too old now to learn that art.

If any should ask why I rear dollar queens, I answer, that the course pursued by others, sometimes leads us to do things we do not approve.
Camargo, Ill.

For the American Bee Journal.

More About the Best Bees.

JAMES HEDDON.

The reason why I am so anxious to get at the cause of bee dysentery, is because I hope that to know the cause will aid in stopping the effect. But in regard to the birth-place of Italians, Cyprians, and Holy Landers, and the number of original rings, these points have as little to do with our success in the pursuit, as a knowledge of the rings of Saturn, and they are of far less interest to me. There is sublimity about the rings of Saturn, but almost a quarrel about the rings of bees. All we need to know is, which are the best bees, and which is the best way to produce better ones. Why then should we spend time theorizing about origin, color, parthenogenesis, and "tweedle-dee and tweedle-dum," when the whole matter is practically one capable of full demonstration.

When we have produced *apis Americana*—that is a fixed type of the best bee on earth—then will be time enough to count the spots and hairs sufficiently to know them wherever seen. When that time comes these bees will sell for their qualities, and the spots will be thrown in.

Mr. Demaree says it was kind in me to try to help Mr. Dadant out of his trouble. That is the first intimation I had that Mr. Dadant was in any trouble. I hardly think anyone except Mr. Demaree has made any such discovery. Perhaps it is so, and it may be quite natural that Mr. Demaree should be the first to discover it. If Mr. Demaree has got him into this trouble, he should have had more respect for age, and priority of position. Mr. Dadant is "old" in the bee business, and especially the importing trade; he has been through these far-off birth-places of our imported stock; he has fooled the best judges and most experienced American apiarists so long, that to trap him now, makes me feel as though the stores of honey we have obtained from bees of his importing and breeding, may be only a myth—a dream!

Mr. Demaree says that in a late article I intimate that the opinion of those who make large reports, is of more worth than those who make small ones, or none at all. Were Mr. Demaree not a lawyer, he would never have thought of borrowing that "none at all" to strengthen his position with.

If I have my eye on the remark that Mr. Demaree alludes to, I said substantially this: That a friend got a perfectly enormous yield of honey and increase; that he had been some years breeding a cross between the Italians and Germans to get it with; that he got much of it from red clover; that these "hybrids" stored 40 lbs. of surplus comb honey from red clover alone, when the "golden Italians of the period," did not obtain one pound; that another friend obtained 200 lbs. of surplus comb honey per colony, from 150 colonies, and from some of the best 400 lbs. each; he also had mixed bees of careful breeding. The reason the names of the parties was not given is because they wish it so, to the end that they would not be written to for queens, which they do not have to sell, surplus is their main business. I thought these reports which I knew I could depend on, presented a strong argument of the demonstrative order.

Does Mr. Demaree expect to wash away this proof by giving the credit to location entirely? Suppose the location to be the best this side of the Rocky Mountains (which I know is not the case), would not good bees get such a yield? Mr. Demaree fails to explain why the Italians, of rings and royal pedigree, in this same splendid location got nothing. But I shall not ask him to wade where the water is over his head.

Whether just or not, it is exceedingly handy to cut down the merits of others' successes by saying "grand location," and excuse the failures of your "ringed, striped and speckled" bees by charging it all up to a large honey crop. Upon this very subject, hangs much of our future success or failure.

It seems to me that whoever makes a convert to rings, hairs and down on the hind leg, without practical qualities, does him great harm. For that reason I am earnest in the discussion of the subject. I respect Mr. Demaree's opposite opinions, and admire his vigor of putting them, but I doubt his ever having had the right sort, or right amount of experience in the matter.

Dowagiac, Mich., Feb. 3, 1882.

For the American Bee Journal.

The Controversy about Pure Bees.

CHAS. DADANT.

Mr. Demaree, of Kentucky, says he has overthrown all my arguments. If so, he must have proved the assertion he made, which was the subject of this controversy: that the Cyprian race is gentle and peaceable, and that the dark Italians, which I have imported for 15 years past, are ferocious hybrids. He has also proved (as he says), that the Italian race is not a pure race. If all this is satisfactorily proven, by Mr. Demaree, I will leave the field to the victor, and allow the reader to judge for himself. It were idle to argue with so good a lawyer.

Hamilton, Ill., Feb. 6, 1882.

Indiana Bee-Keepers' Convention.

The annual meeting of the Indiana State Bee-Keepers' Association, was held in Indianapolis, Jan. 24. The meeting was called to order with President J. H. Orear in the chair, all the officers being present. But a small amount of routine business was transacted when the meeting adjourned for dinner.

The attendance after dinner was considerably increased by the arrival of belated members.

Shortly after 2 o'clock, Gov. A. G. Porter arrived, and entertained the Society with a very neat address. In the course of his remarks he said:

The value of the honey produced in this State in 1881 is reported by our Bureau of Statistics to have been \$207,042. In 1880 the value of this product was \$239,525. The reduction of value in 1881 was occasioned by a short production which happened on account of the extreme severity of the winter, which was very destructive to bees, and from the drouth of the summer, which diminished largely the supply of "nectar" from which the honey is produced. This reduction was general throughout the country.

The production of honey is not one of the great industries of the State, though the business when skillfully pursued, is, I am informed, quite a profitable one, and the climate and "pasturage" of the State are favorable to the bee and to a large product from its labor. It will probably not for many years to come be pursued singly, to a large extent, as an industry; but as a by-business of the farm, to amuse the leisure of the farmer's household, and at the same time add to the receipts of the year, it may be largely and most usefully increased. There is nothing about which more has been written than upon the bee and its habits, and the more these are studied the more entertaining and engaging they become.

Aristomachus, we are told, spent 60 years in the study; Lord Brougham, the busiest statesman of his generation, took time to make chemical analyses of the honey comb under various conditions. The interest shown by this Association in bee-culture and in the product of the hive, shows that the industry is likely to excite more and more attention. Like the butter-maker, however, you are met by competition. It takes an extremely delicate palate to distinguish between oleomargarine and any other than the very best quality of butter. Oleomargarine is eaten every day, on perhaps $\frac{1}{4}$ of the tables in our cities, without a suspicion that it is not butter. The artificial honey is hardly less deceptive, and unless honey is eaten from the comb, there is little assurance to the ordinary palate of its purity. It is said, however, although the bee is now assisted in its work by manufac-

turing for it the base of the honey comb, that human skill has not reached the point of manufacturing cells which will pass for genuine cells of the comb. So far, your industry is protected from the ingenuity of imposters.

By resolution of Mr. Scholl, a vote of thanks was tendered the Governor for his address, and the interest which he had shown in the Convention.

The larger part of the afternoon was taken up in the discussion of suggestions brought out by the Governor's speech. After the transaction of some unimportant business, it was decided to hold a night session, the meeting adjourning until that time.

Promptly at 7:30 the meeting was called to order, when the President proceeded to deliver his annual address. After reviewing the history and the object of the Society, the President said: "I hold it the duty of every apiarist, young or old, to be always ready when called upon, to give a reason for the hope there is in him. And since I hold myself second to none in fealty and devotion to the cause, I make bold to bring my humble tribute, and lay it beside many brighter garlands on the shrine of our Society. Since our last meeting, many of our brightest hopes and fond anticipations have been blighted. The death angel has been in our way, and many of us who failed to have our hives in proper condition, found in the early spring "*articulo mortis*" written over the doors of many of our most beautiful colonies—even whole apiaries have been depopulated. The complaint is not confined to one locality, but is universal through all the northern states, especially so in the more improved portions of the country. In the unimproved portion, away from large orchards and sorghum factories, they suffered the least. The course of this wide spread disaster should claim our most particular attention at this time, and if there is any way by which we can avoid another visit of this, the worst disaster that has befallen apiculture, we should improve it.

We find that no manner of wintering had anything to do as a preventive, that is so far as packing was concerned, for we find that those who had their bees in the cosiest nooks did not escape, while in some cases those occupying most exposed places came through all right.

While acknowledging that many prominent bee-keepers did not agree with him, the President attributed the principal cause of disaster to allowing the bees to go into winter quarters with uncapped honey, which, by fermentation, is formed into carbonic acid and alcohol. He advised the removal of this uncapped honey, in his opinion, the rock on which we had stranded.

He said bee-keepers of to-day must improve on what they have learned, be open to conviction, and learn from any and all sources, for it is by gathering a little here and more there that we have arrived at our present state of apicultural knowledge, and by looking back over the past we can see

what grand strides we have made in the last few years.

The President's address was discussed at some length.

Mr. C. F. Muth, of Cincinnati, did not believe it necessary to remove the uncapped honey; thought very much more depended on the proper ventilation of the hive. He gave his plan for preparing hives for winter. He removes the second story, Langstroth hives, lays 2 or 3 slats across the frames, under the cloth, to give room for the bees to pass over the top of the frames. On top of the cloth he places a straw mat about one and a half inches thick, a sample of which he had present. On top of this mat he places two additional slats of which he lays the cover of the hive, allowing a free circulation of air between the mat and cover.

The subject of wintering was discussed to a late hour, when the meeting adjourned to the next morning.

The first business on reassembling was the election of officers for the ensuing year. The nominating committee recommended the following names: President, L. A. Cotton, Traders Point, Marion County; Vice President, Jonas Scholl, Lyons Station, Fayette County; Secretary, Frank L. Dougherty, Indianapolis; Treasurer, Mrs. Lizzie Stout, Indianapolis.

There being no other candidates, on motion of Sylvester Johnson, Mr. Davis was instructed to cast the vote of the Convention for said nominees.

On taking the chair, President Cotton made a few pleasant remarks; thought the Association could not do too much in furthering the interests of apiculture. He did not contemplate extensive bee-keeping himself, but was satisfied beyond a doubt that, as Gov. Porter had expressed it, it was a by-business which would pay equally as well, if not better, considering the amount of capital invested, than poultry raising, sheep husbandry, or the various other kinds of by-business, to which the average farmer must resort for success.

The next thing in order being the election of delegates to the National Convention. Messrs. Cotton, Scholl and Dougherty were elected as such delegates, and were instructed to ask the Convention to come to Indianapolis for their next meeting.

Considerable time was given to the subject of the care of honey, especially to extracted honey.

Mr. Muth wished to impress it on the minds of bee-keepers, that honey should be thoroughly ripe before being placed upon the market, that freshly extracted honey should never be closed up, but should stand in open vessels for at least from 4 to 6 weeks, and in a warm place before being closed up.

Other equally important subjects to bee-keepers were discussed at great length, such as "Progressive Bee-Keeping," by Dr. H. Peachee; "Preparing Bees for Winter," by Jonas Scholl; "Wintering Bees," by L. R. Jackson; "Statistical Report," for Spencer County, W. F. Ranzler, all of which were fully commented on.

After returning a vote of thanks to Secretary Herron, of the Board of Agriculture, for favors shown, and to Mr. C. F. Muth, of Cincinnati, for his kind assistance, the Society adjourned subject to the call of the executive for the next annual meeting.—*Indiana Farmer*.

Read before the N. E. Convention.

Failures in Apiculture.

A. J. KING.

Just in proportion that knowledge has increased in relation to any given pursuit, the number of failures have diminished, and the profits increased. But the field of practical knowledge is now so wide, and the number of avocations in which one may engage for a life work are so various, that it is impossible for one mind to master the details of all, or even any considerable portion of them. Yet if what is undertaken is not thoroughly understood and one's knowledge practically applied, mistakes and failures will continually occur, and a business which might have been pleasant and profitable, degenerates into one of hazardous drudgery. In short, one must realize that what is termed "good luck" is only the result of carrying out intelligent plans with a strong heart and willing hands, and that "bad luck" is the reverse of this.

After the general introduction of movable-frame hives in this country, the average of honey production greatly increased. Still, 50 lbs. of surplus honey to the colony was regarded as a wonderful yield. Now, from 100 to 300 lbs. per colony is often realized, and we have instances where 500 and 700 lbs. have been taken. Permit me to predict that the time is not far distant when under a combination of the most favorable circumstances, 1,000 lbs. from a single colony will yet be realized. And I will further state that I believe most of the circumstances themselves will yet be under the control of the apiarist.

Twenty years ago, when the maximum yield was about 50 lbs., many believed that the bee-keeping industry had reached its meridian, and that further substantial advances were impossible. To-day multitudes hold the same opinion regarding our present status. As the former class did not anticipate the scores of new methods and appliances now in use, so the latter see nothing more in the womb of the future to be brought out and developed. It is a well known fact by practical apiarists that the great bulk of honey taken in a season is gathered by the bees in a comparatively brief period, and that if the sources of supply would continue to yield as long as the weather would permit the bees to fly; that the total amount of honey at the close of the season would be more than trebled.

Add to this the significant fact that the cultivation of honey crops is yet in its infancy, that very many plants require for honey secretion very different conditions of the atmosphere and soil, and we have the conditions

for a constant honey-flow, for in a large tract covered with these plants of varying dispositions, some would be continually under the proper condition no matter how often the shifting of the weather should occur.

Through the influence of conventions and publications on bee-keeping, the ideas and devices of our best and most experienced apiarists relating to all the different phases of the subject, from the rearing of the bees to the disposition of their products have been widely disseminated, and the causes of failure have been constantly lessening, until now it may be truthfully said that he who embarks in the bee business and fails to realize a fair compensation for the time and capital invested will very generally find the causes of his ill-success within himself. He has most probably gone into the business under the popular delusion that bees not only "work for nothing and board themselves" but they clothe their owner in "purple and fine linen," and enable him to "fare sumptuously every day."

Success is the product of a great many factors in the bee-keeper's arithmetic, multiplication, subtraction and division may be profitably resorted to at times, but if addition (feeding) be neglected, the result will surely reveal neither quotient nor remainder, and the answer of the season will be a product of blasted hopes. Judicious and timely feeding, both stimulative and otherwise, is a positive prerequisite to success, and he who is too lazy or stingy to supply this requirement had better not embark in the business. In short, the man or the woman who expects to realize all the possibilities of fortune in apiculture, must acquire an ardent love for the pursuit, by a faithful and student-like perusal of all the best books and papers devoted to the subject, and this should be supplemented by practical lessons among the bees, involving all the operations referred to in the previous lessons, and this under the eye and supervision of an experienced apiarist.

The intending bee-keeper must realize that he is entering on a pursuit which requires much hard labor, both physical and mental. That to secure the best results he must inwardly digest the fact that if a good workman requires good tools in order to do a well finished job, it is doubly true in regard to himself. That attempting to make his own bee-fixtures, and depending on his agricultural paper for instruction, is but poor economy, if indeed it deserves the name at all. That a month or more spent with a practical and therefore scientific bee-keeper in the busiest part of the season, would be of incalculable benefit to him, even though he pay for the privilege.

Apiarists as a class, are men of large hearts and genuine sympathies, and seldom refuse to advise beginners, if solicited in the proper spirit, but if approached by one who, upon a hasty reading of the "Blessed Bees," or some other fictitious production, has become suddenly wise in his own conceit, he is usually left to find out by a sad experience that a "little

knowledge is a dangerous thing," as well in bee-keeping as theology.
New York.

SELECTIONS FROM OUR LETTER BOX

The Hive for Beginners.—Would you advise beginners to use brood frames with close-end top bars instead of open top bars.
G. H. D.

[No; we offer no such advice. But few persons approve of such, and many object to them. We advise the use of one of the popular hives, with frames of ordinary size and regular shape. Nearly every beginner, during the first year, fancies he could invent a hive that would "beat the world," but, after more experience, finds one of the standard type of hives to be good enough for him. Beginners should be content to learn from experience of others—to follow and not expect to lead.—Ed.]

How to make Paste or Glue with Flour.—Make a dough with water and flour, then dilute the dough with more water. Use about one tablespoonful of flour for one-half glass of water, or a little more. Put on the oven in a tin stew pan, stirring constantly to prevent burning; as soon as it boils it is done. If the labels come off with this glue, they are made with paper too thick. If you want a glue which lasts without rotting, mix in the flour before wetting it, some powdered alum.
CHAS. DADANT.
Hamilton, Ill., Jan. 31, 1882.

Golden Honey Plant.—I have 8 colonies, some Italians, but mostly blacks; they had two flights in January, and seem to be in good condition. Snow fell last night about 7 inches deep, yet the weather seems warm; about 30 degrees. Some time since I sent Dr. G. L. Tinker, New Philadelphia, O., some seeds of the golden honey plant. The seed he sent back to me were larger than those I sent him, but are the same kind. I find for 2 miles up and down our creek a few stalks of the golden honey plant growing. I observed closely the working of the bees on different kinds of plants, but the golden honey plant seems to have more bees at work than any other. We have some 5 or 6 varieties of golden rod here, but no basswood.
E. M. COOMBS.
Memphis, Ind., Jan. 31, 1882.

Bees Doing Well.—In this locality, bees had a good flight on Jan. 27, and Feb. 6. I have 23 colonies; 15 packed on the summer stands; 6 being packed in boxes with chaff and 2 in chaff hives.
NORMAN V. GOODNOE.
North Lansing, Mich., Feb. 7, 1882.

Superseding Queens.—Permit me to ask: 1. Are there any bee-keepers who make a practice of replacing old queens with young ones, for fear the old ones will not live through winter?

2. If so, what disposition do they make of the old ones?

3. Would two years old be the right time to make the change?

4. Would not perforated zinc partitions for confining the queen to a limited portion of the hive, be good for controlling the bees till you wished to divide them? I am thinking of those bee-keepers who have only a few colonies and want to increase, and have not time to wait for natural swarms.
WALTER HARMER.
Manistee, Mich., Feb. 3, 1882.

[1. Yes; all successful bee-keepers make a practice of superseding old queens in the fall, or during summer when they have good young queens on hand.

2. The old queens are, or should be, destroyed.

3. As a rule, two years is the right age to supersede them, though some are good and prolific the third season.

4. We are not partial to the use of perforated zinc. If the bee-keeper cannot spare time to give his bees close attention, he should divide the colonies when they begin making preparations for swarming. If the frames are uniform, the division can be made about as quickly as the perforated zinc can be applied.—Ed.]

Adhesive Paste.—The *American Cultivator* gives this recipe for such paste as is used on the backs of postage stamps: Dextrine, 2 ounces; acetic acid, 4 drachms; water, 2½ ounces. Mix the dextrine, acetic acid and water, stirring until thoroughly mixed, and add alcohol. For attaching labels to tin, rub the surface with a mixture of muriatic acid and alcohol; apply the label with a thin coating of the paste.
J. W. WINDER.
Thibodeaux, La.

Bees are in Satisfactory Condition.—The indications this morning were good for a pleasant day, so I thought I would ride down to my apiary for the first time since October. I was taken sick in October, but I am now about as well as ever. I examined every colony, and can say that I have been keeping bees for 14 years and never had them to winter as well and on so little honey as they have this winter.
J. T. WILSON.
Mortonsville, Ky., Feb. 6, 1882.

A Query.—Will the JOURNAL please ask Dr. W. R. Howard to tell your thousands of appreciative readers, whether he thinks the Dzierzon theory necessarily follows from the establishment of the much-cherished idea of parthenogenesis?

W. H. ANDREWS.
McKinney, Tex., Feb. 2, 1882.

Maple and Sorghum Syrups.—Advise through the BEE JOURNAL: 1. Will it do to feed a good quality of maple syrup to bees in the last of February or first of March, when it is known to be pure, having made it myself? 2. Is sorghum fit to feed bees in April, when they can fly every few days? 3. When a person doubles up the bees in the spring, is it best to try and save the surplus queens, or destroy them?

R. P. WILLIAMS.

Goldsmith, Ind., Feb. 4, 1882.

[1. Maple syrup will answer when bees are getting occasional flights.

2. If bees are not confined to the hive for long periods, we do not know why a good, or even poor article of sorghum should be more detrimental to their health than fruit and cane juices and timber sap, all of which are more or less consumed by bees when the honey flow is light.

3. By all means destroy them. Most of the queens taken out are in some way defective, or the necessity would not exist for uniting the bees.—ED.]

Wintering Well.—Bees have wintered nicely so far; they have been flying lively for the last two days. I never saw bees in better condition than they are now; some are breeding. If the good weather continues there will be but little loss this winter. 1. I have 60 brood combs full of honey out of which I would like to take the honey. I have tried it with the extractor, but it breaks the combs. How can I get it out? 2. Will bees make any drone comb if supplied with worker foundation? I am well pleased with the BEE JOURNAL; I could not do without it so long as I keep bees.

H. J. SMITH.

Burlington, Wis., Feb. 8, 1882.

[1. Remove the combs with honey to a warm room, and let them get completely warmed through. This toughens the combs and thins the honey, and you will have no trouble in throwing it out while kept in that state.

2. To a great extent drone comb can be restricted by the use of worker foundation; but it is not a positive preventive.—ED.]

Cellar Wintering With Success.—I commenced the season of 1881 with 28 colonies, only one being a strong colony. They increased to 73; all but one had plenty of good honey to last them till May. They gathered 2,000 lbs. of extracted honey, and 200 lbs. of comb honey. My home market has taken the most of it. I have had no trouble in wintering in the cellar for the last 15 years, when they have had good honey enough to last them through. My cellar is not a dry one, and I have no ventilation, except when the doors are open. We keep our vegetables in the same room with the bees, and have to go down several times a day. FRANK SEARLES.

Marley, Ill., Feb 7, 1882.

Honey Granulation.—1. Will honey granulate if excluded from the air? I know of one case where extracted honey was put in a glass self-sealing can, and when opened the other day, after standing one year, was in the same condition as when sealed.

2. What causes my bees to be eaten in the hive, the bottom-boards of some hives being covered with the fragments of dead bees?

3. The bees in this vicinity are all blacks; I wish to introduce either the Italian or Cyprian bees next season—which would you advise, and how early can I purchase queens?

A. E. FISHER.

North Hatley, Quebec, Feb. 2, 1882.

[1. Ordinarily, honey will granulate if chilled, even though excluded from the air.

2. The bees you suppose to have been eaten, are those which have decomposed from the action of moisture, leaving the harder portions, such as the part between the wings and the scales of the abdomen, dried up.

3. The relative merits of the Cyprians, as against the Italians, are not yet sufficiently demonstrated to warrant us in recommending their preference. Good queens can be obtained from northern and central breeders in June, and from the south in April and May.—ED.]

Buckwheat and Sweet Clover.—Will sweet clover do well, sown the last of June with buckwheat, and will it make a good crop of bloom the next year? Will it bloom the next year, if sown in the fall, after buckwheat is harvested? We have plenty of linden here yet, but timber is scarce and it is used very fast for fuel. Bee-keepers will have to plant to fill its place.

E. DOTY,

Macksburg, Iowa, Feb. 1, 1882.

[We think it will do to sow sweet clover with buckwheat in June, and with satisfactory results in bloom, much more so than if sown in the fall when buckwheat is harvested.—ED.]

Wintering in Cellar.—Last Tuesday the thermometer registered 22° below zero. Bees are in excellent condition, the temperature in the cellar has not varied much since they were put in, while outside it has ranged from 60; above to 22° below zero. That is the right kind of a cellar to winter bees in. We expect that every colony will not only come out alive, but strong.

E. A. THOMAS.

Coletaine, Mass., Feb. 1, 1882.

Reversible Frame Hives.—I cannot do without the BEE JOURNAL; can hardly wait after I read one number, until the next arrives. The present size suits me 75 per cent. better than volume 17, because if bound, will make it handy to handle. My bees are in splendid condition. They have had, up to this, a fly once in 8 or 9 days.

If the weather continues as it has been so far, I expect to have strong colonies by May 1st, ready for work. In the JOURNAL, Vol. 18, No. 3, page 39, Mr. W. T. Stewart, of Eminence, Ky., mentions his reversible frame hive. I read it with interest and like the idea. Please give a description in detail in the BEE JOURNAL. Has he them for sale, or is it patented?

JOHN W. STURWOLD.

Haymond, Ind., Feb. 3, 1882.

Reversible Frames.—In the BEE JOURNAL of Jan. 18, 1882, I find an article by Mr. W. T. Stewart on the coming bee hive, and the advantages of a reversible frame. I am pleased to see the matter of reversible frames discussed. More than two years ago I became convinced a frame of that description would possess decided advantages over the ordinary frame, and after much thought on the subject invented metal corners for my frames which would admit of their being reversed at pleasure. A description of my metal corners was published in the BEE JOURNAL of March, 1881. I was not aware there was a reversible frame in use similar to my own, but inferred from the remarks of Dr. L. C. Whiting in the BEE JOURNAL, of Dec. 21, 1881, on the Van Deusen reversible frame, that it was similar. I have been awaiting a description from Mr. Van Deusen of his hive in response to the Doctor's call, and hope he will give a description of it in the BEE JOURNAL. As Mr. Stewart claims a reversible frame hive of his own invention which he thinks totally eclipses Mr. Van Deusen's, I think a description of it would also be appreciated by all advocates of the reversible frame hive.

W. B. ANDERSON, M. D.

Bloomington, Mich.

[We believe Mr. Stewart intends to patent it, and will, of course, have it for sale in due time.—ED.]

Every Colony Answered the Roll Call.—Yesterday we had a beautiful and warm day, and the bees had a good fly. Every one of my 147 colonies answered the roll call, and I am happy as a lark. I expect a lively time of it next season. The money I pay the BEE JOURNAL for advertising is, I think, well spent. It must have a large number of subscribers, for within one week after my advertisement first appeared in it, I received quite a number of orders, where the parties said: "as per advertisement in BEE JOURNAL." I. R. GOOD.

Nappanee, Ind., Feb. 9, 1882.

☞ The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted. G. W. DEMAREE, Sec. Christiansburg, Ky.

☞ The Texas State Bee-Keepers' Convention will be held at McKinney, Texas, on Tuesday, April 25, 1882.

THE AMERICAN BEE JOURNAL

RATES FOR ADVERTISING.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space.

Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements for the Weekly as follows, if paid in advance:

For 4 weeks.....	10 per cent.	discount.
" 8 ".....	20 " " "	
" 12 " (3 months)....	30 " " "	
" 24 " (6 months)....	40 " " "	
" 36 " (9 months)....	50 " " "	
" 52 " (1 year).....	60 " " "	

Discount, for 1 year, in the Monthly alone, 25 per cent., 6 months, 10 per cent.

Discount, for 1 year, in the Semi-Monthly alone, 40 per cent., 6 months, 20 per cent.

Advertisements with drawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

Transient Advertisements payable in advance. Yearly Contracts payable quarterly, in advance.

THOMAS G. NEWMAN,

974 West Madison Street., Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the *best* advertising medium, but the lowest rates on yearly contracts.

The *Apiary Register* devotes 2 pages to each colony, ruled and printed, and is so arranged that a single glance will give a complete history of the colony. For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Articles for publication must be written on a separate piece of paper from items of business.

A Sample Copy of the Weekly *BEE JOURNAL* will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

New Publications.

The *Oriental Casket*, is the title of a new literary monthly, of which we have received two numbers. It is elegantly printed on line paper, and devoted to literature and science. It is published at \$2 a year, at 912 Arch st., Philadelphia, Pa., by L. Lum Smith, and edited by Emerson Bennett. Those who want a literary *gem* should send for the *Oriental Casket*.

The *British Bee-Keeper's Guide Book*, is the title of a manual of 136 pages, by Thos. Wm. Cowan, Esq., the Chairman of the British Bee-Keepers' Association. As the author of this little work is one of the most progressive among the English apiarists, of course it is a valuable and yet simple manual, and will do a vast amount of good in the way of disseminating light on rational bee-culture in Great Britain. We acknowledge the receipt of a copy of the second edition, sent to us "with the author's compliments." It is nicely printed and fully illustrated; all the newest American inventions are given a prominent place and thorough description and approval. Price 1s. 6d.

"Rational Apiculture;" the habits of the bees, fertilization of queens, etc. This is the title of a new work of 110 pages, translated from the Italian into French, by M. L. Gortier, and published by the Apicultural Society of Somme, France. We are in receipt of a copy of the above mentioned work. It is a critical examination of the theory of parthenogenesis of bees, by L'Abbe Giotto Ulivi, of Tuscany, a province of Italy.

Mr. J. A. Everitt, Seedsman, of Watsonstown, Pa., met with a serious loss on the night of Jan. 25, by having his entire edition of catalogues, together with all the plates, electrotypes, etc., destroyed by fire. The catalogues were almost completed at the time. Mr. Everitt will have another edition ready soon, which is to be more elegant than any before published. Send for it.

We have received new Catalogues and Price Lists of Apiarian Supplies from

- Dr. J. P. H. Brown, Augusta, Ga.
- J. A. Hopkins, South Oxford, N. Y.
- A. E. Mamm, Bristol, Vt.
- Dr. Nugent, Strathroy, Ont.

Elwanger & Barry's Catalogue of Fruit Trees, Shrubs, Roses, etc., is received, from Rochester, N. Y.

CLUBBING LIST FOR 1882.

We supply the Weekly *American Bee Journal* and any of the following periodicals, for 1882 at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

	Publishers' Price.	Club.
The Weekly Bee Journal.....	\$2 00.	
and Gleanings in Bee-Culture (A. I. Root).....	3 00.	2 75
Bee-Keepers' Magazine (A. J. King).....	3 00.	2 90
Bee-Keepers' Instructor (W. Thomas).....	2 50.	2 35
The 4 above-named papers.....	4 50.	4 00
Bee-Keepers' Exchange (Hook & Peet).....	3 00.	2 80
Bee-Keepers' Guide (A. G. Hill).....	2 50.	2 35
Kansas Bee-Keeper.....	2 00.	2 40
The 7 above-named papers.....	6 30.	5 50
The Weekly Bee Journal one year and Prof. Cook's Manual (bound in cloth).....	3 25.	3 00
Bees and Honey, (T. G. Newman) ..	2 40.	2 25
Binder for Weekly, 1881.....	2 50.	2 75
Binder for Weekly for 1882.....	2 75.	2 50

O. H. Townsend has moved from Hubbardston to Kalamazoo, Mich.—the latter now being his address.

We are sometimes asked who our authorized agents are? Every subscriber is such an agent; we have no others, and greatly desire that each one would at least send in one new subscriber with his own renewal.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

To any one sending two *new* Weekly subscribers for a year, we will present a volume of the BEE JOURNAL for 1880, bound in paper covers. It contains much valuable information, and it will pay any one who does not already possess it, to obtain a copy. Many of our *new* subscribers will be pleased to learn that they can get it for \$1.00, by sending for it *at once*, before they are all gone.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

When changing a postoffice address, mention the *old* as well as the new address.

When you have got an old horse that has passed the market period, apply a bottle of Kendall's Spavin Cure and the result will be marvelous. Read advertisement. 5w4t

Sweet Clover for the South.

We are more than pleased to observe the deep interest awakening in regard to planting to secure a continuous honey flow, and the general favor which the much abused, but very worthy, sweet clover (*Melilotus alba*) is gaining. Mr. J. L. Edwards, of Wadesboro, N. C., in a letter dated Feb. 6, 1882, writes as follows:

I have had poor success with bees, owing to the fact that there are but few honey-producing plants or trees on my plantation, or in my section of the country; but your remarks on sweet clover, in the BEE JOURNAL for Jan. 11, encourages me to give it a trial; I am anxious to raise enough honey for my own family. Now, I wish to know if sweet clover will do well as far South as this—latitude 33°? If it will make good hay and pasture, I will plant it instead of red clover. What kind of land does it grow best on? I have about 50 acres of creek bottom, part sandy loam and a part clay loam; I have also a variety of uplands, sandy, clay and gravelly. Some of my bottom lands are too wet for red clover, some are too sandy; all of my uplands are too dry for red clover to stand our long hot summers. Please answer the above questions, and give me all the information you can. I feel deeply interested in sweet clover. Hay is worth \$25.00 a ton with us, and if sweet clover will succeed here, as well as it does in the Northern States, I will go into it quite extensively.

Try the sweet clover on your bottom lands, especially on the sand and clay loams; also on the uplands. It will stand any amount of water, and on gravel soil the tap-root will run down till it finds moisture. Your climate, we think, is well adapted for its growth, as it will withstand any degree of summer heat or winter cold, and its deep-penetrating, wide-spread-

ing roots, admirably adapt it to any variety of soil, whether wet or dry, sand or clay, loam or gravel. Being remarkably thrifty in growth, it will be found equal to red clover for soiling, and can be successfully grown in localities where the latter will prove a failure. Prof. C. E. Thorne, of the Ohio State University, thus testifies regarding its value as a field plant: "It will grow quite luxuriantly in hard, poor clay, where even white clover will scarcely live at all, and grows much more rapidly than red clover in any soil, while in the soils that are, as is said, 'clover-sick,' it thrives as well as anywhere. It is a good forage plant for bees and for cattle, and is well adapted for soiling, as it makes a growth of 4 to 6 feet during the season, and is said to bear 2 or 3 cuttings. A German analysis gives its hay a feeding value of \$15 per ton as against \$16.28 for very good red clover hay. While red clover, upon which our farming in many sections, and especially in clay lands, depends so essentially for crops of grain, is becoming more and more uncertain. It would seem to be worth while to try this 'fast weed' as a resource for recuperative green manuring, in heavy soils especially."

But its greatest recommendation for the general bee-keeper is the fact that it requires no especial cultivation, thus making it especially desirable for roadsides and commons. Being a biennial, the seeds possess great vitality, and may be kept over for a long time, and scattered a handful at a time, as opportunity offers, or a bare place develops itself.

Mr. Vennor says: "We are going to have a very stormy and cold March in western and southwestern sections chiefly." But he has signally failed in his prognostications for December and January, for this locality.

Fastening Foundation in Frames.

Mr. S. F. Miller, of North Manchester, Ind., addressed us for a method of increasing by dividing, which was published in the BEE JOURNAL, together with instructions for doing so successfully. The following letter from him gives the result of his practice:

In the BEE JOURNAL for 1881, page 100, you instructed me how to increase by dividing, in answer to a letter on that subject, and I will now report my success. I had two colonies, one of 6 frames and the other of 7, but I had so little experience I did not know the difference between nuclei and full colonies. First, I had to build the two up to strong colonies, and then I followed your instructions for increasing, and now have 7 colonies in excellent condition. To-day they had an excellent flight, and made everything hum. They have plenty of honey. Now, did I not do well for a beginner? I had only a plug-hat full of bees and 2 queens, to commence with. I must express my gratitude for that editorial instructing me and thousands of others, and which I shall forever deem as the foundation of my success. I suppose I must go ahead this spring and increase on the same plan, as before, only that I must use foundation instead of old combs, as I have none. I do not rightly understand Prof. Cook, in his "Manual," how to fasten foundation in the frames. I have never seen any foundation. I use the standard Langstroth hive. All I know about bees is what I have learned from the BEE JOURNAL. I have a good chance for success. This is a good location for honey, and very few bees. Which do you think the best, the 8, 9 or 10 frame Langstroth? Mr. J. T. Smith, on page 74, thanks Mrs. A. M. Sanders for her recipe for making honey pop-corn balls. Why not publish the recipe for us in the BEE JOURNAL?

If you intend running for increase this season, then adopt the same course you did the last. There are several methods of fastening comb foundation in frames, as follows: If you use flat top-bars, then double over about one-fourth of an inch along the upper edge of the sheet, with a blunt knife press this lapped portion firmly along the under side of the bar, so the sheet will hang from the center. A machine has recently been invented for the purpose of rapidly fastening foundation in frames, where flat top-bars are used, and for firmly fastening thin foundation in the section boxes. Many use wax and rosin melted together, and glue the foundation on. If you use a top-bar with an inset strip (as many do), you can easily press the foundation to the strip, without the use of melted wax and rosin. If a

triangular or V-shaped top-bar be used, then cut four slits at equal distances along one edge of the foundation, one-half an inch deep—this will give five sub-divisions of the edge—now press up the center and two end portions of the edge, and bend down the other two; lay down the sheet on a table, place the frame with the lower

Triangular Top-Bar with Foundation.

sharp edge of the top to the sheet, and press, with the fingers or a blunt knife, the foundation on the top-bar. These flaps will alternate on each side of the top-bar, and the foundation will hang from the center.

We prefer the standard Langstroth hive, holding 10 frames. Sometimes a good queen will nearly occupy 10 frames in brood-rearing, and then they are invaluable in strengthening up the weaker colonies. They are also very desirable, as giving the largest surface for section boxes to be placed on top. Should an especial occasion demand less room, or a necessity arise for contracting the brood chamber in order to drive the bees into the supers, it is an easy matter to lift out a frame or two, and insert a division-board at the side. We think a queen is not so liable to take advantage of a slight cessation in the honey flow, and cease laying, where there are ten frames and the consequent more or less honey around the edges, as where there are fewer frames. We are aware there are several practical bee-keepers who differ with us regarding the style of hive, as well as the number of frames; but our correspondent asks which we think the best.

The recipe for making honey pop-corn balls, to which reference is made, was published in the BEE JOURNAL of Jan. 4, on page 12.

Syrian Bees.—Please say through BEE JOURNAL who is a reliable person to procure a colony of pure Syrian bees from. L. G. HALLEY.

New Hamburg, Canada, Feb. 10, '82.

By consulting our advertising columns you will see who have bees for sale. We think they are all reliable persons.

Mild Winter in Europe.

Not only has the present winter been an unusually mild and pleasant one in most portions of the United States, but in Europe they have been similarly blessed. The following letter from Mr. J. D. Hutchison, Glasgow, Scotland, breathes of encouragement:

As proof of the mild weather which we have enjoyed in this country during the winter, I may mention that a gentleman in Dundee, on looking over his apiary a few days ago, found that 5 of his colonies had a large amount of brood in all stages. He was fortunate in procuring a colony of hybrids about 3 years ago, which were then distributed through most of his other hives, and have much improved the working power of the bees. In 1880 this hybrid colony gave 3 swarms, and from the 4 he had over 150 lbs. of fine comb honey, besides leaving his bees sufficient winter stores.

The flowers which have been grown here in the open air are beginning to bud, and in some places full-blown flowers can be had. Butterflies, etc., have been seen several times of late.

The Caledonian Apian Society has had no meeting yet this year, but I expect one will be held at an early date to make arrangements for the annual exhibition, which takes place in Glasgow next July, and which I think will be the largest held as yet.

By the above, it will be seen that 150 pounds of fine comb honey, from four colonies, is regarded as an extraordinary yield, and to be accomplished only by bees which have been much improved. We have published several reports, the past season, where whole apiaries in America have given nearly double that amount as an average for each colony, and there are instances on record where triple that amount have been realized from a single colony in one season; and when bee-keepers have fully realized the importance and profitableness of planting bee pastures (which all eventually will), the fabulous *one thousand pounds per colony* may be among the triumphs frequently realized.

The above letter however suggests, or rather, sustains, one most important fact: that, with improved bees, the honey yield is not commensurate with their home demand, except at such exorbitant prices as to make it an extravagant luxury. Those who have bewailed the intelligence disseminated throughout Europe by the BEE JOURNAL and American apicultural books, can learn an important lesson from the letter, and rejoice with the more intelligent that we are rapidly and surely developing an insatiable and remunerative foreign market.

Foul Brood; Its Origin, Development and Cure.—We have received from A. R. Kohnke, Youngstown, O., a copy of his pamphlet bearing the above title. In his preface the author says:

"I have ventured to offer the bee-keeping public a concise method, delineated in these pages, by which they will be enabled successfully to combat this dreadful malady. I have drawn on the experience and experiments of the most noted scientists and apiarists of Germany, such as Professors Kolbe, Cech, Fisher, Preuss and Lamprecht, but especially Hilbert and Schoenfeld, to whom the bee-keeping fraternity of the whole world is indebted for their efforts and final success in curing foul brood, and to whom I offer my sincerest thanks." Price, 25 cents.

Goodrich's Foundation Fastener.—Mr. S. Goodrich, of Urbana, Ill., has recently invented a very ingenious contrivance for fastening foundation securely and rapidly in frames with flat top-bars, and in sections. He has deposited one in the BEE JOURNAL Museum, and explained the manner of using. We will give, next week, a full description of the machine, with a cut, which cannot be engraved in time for this issue.

L'Abbe L. DuBois, President of "the Society d'Apiculteur de la Somme," writes: "The AMERICAN BEE JOURNAL grows better and better every year. It is the first of all French and foreign periodicals that I know of. If I had to choose between them all, I should without hesitancy choose the AMERICAN BEE JOURNAL." This is high endorsement, for l'Abbe L. DuBois is one of the most learned and progressive apiculturists in the World.

An error occurred last week on page 105, 2d column, 3d paragraph, in Mr. Heddon's article. For "honey" substitute the word *hay*. We republish the paragraph properly corrected:

Whether just or not, it is exceedingly handy to cut down the merits of others' successes by saying "grand location," and excuse the failures of your "ringed, striped and speckled" bees by charging it all up to a large *hay* crop. Upon this very subject, hangs much of our future success or failure.

The semi-annual meeting of the Tuscarawas and Muskingum Valley Bee-Keepers' Convention, will be held in the Town Hall at Coshocton, O., on April 19 and 20, commencing at 10 a. m. A cordial invitation is extended to bee-keepers everywhere.

J. A. BUCKLEW, Sec., Clarks, O.

AMONG OUR EXCHANGES.

MISCELLANEOUS.

Introduction of Bees Into America.—Mr. J. M. Hicks, in the *Grange Bulletin*, remarks as follows on the subject:

As near as we can learn, bees were introduced into this country in the latter part of the 15th century, by the Puritan fathers. I have often heard my grandfather, Dempsey Hicks, say that his father, James Hicks, who came from England, brought bees with him when he emigrated to this country, then a perfect wilderness, and there were no bees to be found in any part of the country. He also said, that the red men of this country often told him there were no bees to be found in the forest previous to the coming of the pale-faces (meaning the white men).

Encouraging Outlook.—Mrs. L. Harrison, in the *Prairie Farmer*, remarks as follows on the honey prospect:

The last two honey seasons have been partial failures in most localities, and this, together with the unprecedented losses in bees during the winter of 1880-81, has thinned out the ranks of bee-keepers. The faint-hearted fled in disgust, throwing their hives and fixtures to the moles and bats, and crying "humbug" at the top of their voices. The brave buried the dead, and gathered up the remnant of the lost nation and encouraged the mothers in the production of young, furnishing candy for the babies, flour, honey, and "coffee A." Under the fostering care of their owner, each mother did her best, and sent off colonies to occupy the deserted homes of their unfortunate predecessors, until the bee village was again populous. The rearing of so many bees consumed large quantities of honey, consequently little surplus was left, therefore the honey product of 1882 will find very little old honey in the market to come in competition with it.

This winter, so far, has been favorable for bees on their summer stands. January 26th was rainy, but a little past noon the clouds broke away, and the sun shone, the thermometer indicating 64° in the shade. Out rushed the bees from their hives, like pent-up school children at recess, and a merry sport they had. They cleaned house, but carried out few dead; every colony was living and in fine condition.

The skies are brightening for bee-keepers, and the outlook is favorable. Honey will no longer go begging for a market, as the demand for it is constantly increasing. The large crop of 1879, and consequently low price, caused it to be introduced into many

families where it had previously been a stranger. Many persons who had formerly been of the opinion that honey disagreed with them, and always made them sick, were tempted, by its low price and beautiful appearance, to partake of it, and were agreeably surprised that no sickness followed the indulgence. They found out that the honey of to-day, produced by scientific bee-culture, is very different from the black mixture of bee-bread, old comb, and honey, formerly offered in the markets.

Catalogues.—We have received new catalogues and price lists from the following persons:

- J. H. Robertson, Pewamo, Mich.
L. E. Welch, Linden, Mich.
W. S. Cauthen, Pleasant Hill, S. C.
G. B. Lewis, Watertown, Wis.
Wm. Ballantine & Son, Sago, O.
C. G. Dickinson, South Oxford, N. Y.
W. C. R. Kemp, Orleans, Ind.
S. D. McLean, Columbia, Tenn.

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.
G. W. DEMAREE, Sec.
Christiansburg, Ky.

To any one sending two new Weekly subscribers for a year, we will present a volume of the BEE JOURNAL for 1880, bound in paper covers. It contains much valuable information, and it will pay any one who does not already possess it, to obtain a copy. Many of our new subscribers will be pleased to learn that they can get it for \$1.00, by sending for it *at once*, before they are all gone.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 8oz.

Nebraska State Convention.

The third annual session of the Nebraska State Bee-Keepers' Association, was called to order by the President, Mr. T. L. Vondorn, at Ashland, on Jan. 12, 1882. The minutes of the previous meeting were read and approved.

The Treasurer presented his report, showing the total receipts to be \$20.25 and expenditures \$11.25, leaving a balance of \$9.00 in the treasury. It was accepted and placed on file:

The committee on constitution and by-laws failed to report, owing to the illness of one of the members. A new committee was appointed, consisting of Messrs. Myers, Culbertson and Hildebrandt. Vice Presidents and others from the different counties in the State, reported as follows:

Prof. Culbertson, for Lancaster County, reported but a small flow of honey in the middle and southern parts, owing to severe drouths, while in the northern, the yield was much larger, and a greater increase of bees. By request, he gave his last year's experiments in wintering, both out-door and cellar. Those out-doors were placed close together, protected by a shed on the north, and covered with several feet of hay. A cloth was put over the frames, and the story filled with dry cobs. He lost 5 of the 6 treated in this way. He put 21 in the cellar, putting several thicknesses of cotton cloth over the frames, and a paper on top of these, on which he put unslacked lime to absorb all moisture. The back end of the hive was raised higher than the front, that all water might run out. He lost 5 of these.

Mr. Decker, of Wahoo, reported large yields of honey and great increase of bees.

P. P. Hayes started with 1 colony, increased to 5, and obtained 400 lbs. of honey.

Mr. Dodder, of same place, increased from 15 to 60.

Mr. Vondorn, of Omaha, gave report for Douglas, who started with 14 colonies, increased to 41, and got 1,900 lbs. of honey.

Mr. Yager increased from 1 to 8.

J. F. Sawyer from 22 to 60.

Mr. Edwards from 92 to 204, and received 2,000 lbs. of honey; the location was overstocked.

The Secretary gave reports received from Gage, Jefferson, Butler, Hall, and others, which indicated a large yield of honey, and almost unprecedented increase of colonies.

It was moved that a question box be opened, in which any one could put questions they wished discussed. Messrs. Culbertson, Rouse and Trestler were appointed a committee to answer the questions.

On motion, Messrs. B. E. Kennedy, of Omaha, and D. H. Wheeler, of Plattsmouth, were made honorary members.

The Secretary was instructed to notify members to pay delinquent dues, or their names would be dropped. Adjourned to meet at 7 p. m.

The evening session was opened by the reading of the President's address. Messrs. Culbertson, Caldwell and Trestler were appointed a committee to report upon this.

The first question selected from the question box was: "How to Winter Bees Successfully?"

Prof. Culbertson opened the discussion. He would remove some of the combs, and spread the others, so the bees would have a chance to cluster in large bodies; would make holes through the combs, so they could pass from one to the other without being chilled. These, with thorough ventilation, dryness, and an even temperature of from 40 to 45 degrees, he considered the requisites. These conditions he thought more easily attained, taken one year with another, by means of a cellar especially prepared for that purpose. In regard to what he considered the requisites, nearly all agreed with him, yet the methods used to obtain them, were nearly as many as there were persons present.

Mr. Rouse wished his bees to be in a healthy condition, and to keep breeding until Oct. 10, if possible. Yet the young bee should have a flight to bear long confinement. He puts the bees on as few combs as they will cover, by putting in a chaff division board; puts a box with a cloth bottom filled with chaff on top; this gives thorough ventilation. He then packed hay around his hives, covering them up entirely, leaving no place for the bees to get out. He had colonies come through all right, with top ventilation, when the entrance was filled with ice. Others have the same experience.

Mr. Caldwell thought what would do one year would not another. He considered a good cellar the best place to winter in, but a poor one the worst place. He put husk mats on top of his frames, and chaff over that, and tried to obtain as nearly an even temperature as possible.

Mr. Vondorn crowds his bees on as few combs as they will cover, spreading these that they may cluster. Packs with chaff, and puts woolen cloths over the top; thinks it not necessary to have all young bees late in the fall to winter successfully. He thought the Langstroth frame as good as any for wintering.

Mr. Hawley had wintered his successfully in a cellar, and preferred that way.

The committee on revision of the constitution and by-laws made their report, which was adopted as read.

In the morning session, the election of officers resulted in the re-election of the old officers.

A paper, by Mr. Vondorn, on practical bee-culture, was read.

From the question box, the subject of "the best honey plants," was discussed.

Mr. Myer preferred rape to all others he had tried. He had 4 acres, and while in bloom, the bees worked on it both late and early, and during

all kinds of weather. They would not work on buckwheat that was in bloom at the same time. Buckwheat was not recommended as worthy of cultivation. Sweet clover and matrimony vine were recommended to sow in all waste places. The President had applied to the department of agriculture for mellilot and white clover seed, also motherwort seed to distribute among the Nebraska bee-keepers.

Mrs. Thomas recommended motherwort as one of the best. It was conceded that the most of our honey was gathered from heartsease and golden-rod; some thought sunflower secreted honey, but most thought not. Wild cucumber was spoken of highly.

The subject of "feeding bees" was discussed. The question was asked, why bees fed late in the fall do not breed as fast as when fed in the spring?

Mr. Vondorn said that cold nights were the cause, and also that bees seem to understand that it is the last of the season. He feeds a syrup, made by boiling 2½ lbs. of best sugar in 2 lbs. of water. The use of glucose for feeding was discouraged.

The next question was, "of what importance to the apiarist is selection in queen rearing?"

Mr. Ashland thought as much depended upon the selection of queens from which to rear our colonies, as with any other stock.

Mr. Vondorn thought more attention should be given to the rearing of choice drones, and to accomplish the desired purpose, we would have to establish our queen-rearing apiary several miles from any other colonies. He thought choice queens could not be reared for less than \$3 each.

Queen cells should not be allowed to become chilled, as it is apt to make the wings defective.

In hatching 20 in a queen nursery, he found their wings and bodies defective. Upon examination with a strong microscope, he found them infested with small worms. The Cyprians were not so gentle and easy to manage as the Italians, but equally as good honey gatherers and for increase.

Read before the N. E. Convention.

Prevention of Swarming.

L. C. ROOT.

I am asked by the Executive Committee of this Association to give my experience as to the most successful method of preventing swarming. Much has been written and said upon this subject by many bee-keepers of the day, yet a successful method of controlling the desire to swarm in all cases has not yet been given us. It is therefore one of the hidden mysteries of bee-keeping upon which more light must be shed. As this can only be accomplished by continued study and the adding of our mites to the general fund, I will offer a few facts as they have been developed by a somewhat extended experience. In considering this question we must keep it closely by the side of the thought of our de-

sire to keep our bees fully and constantly at work. It will be generally acknowledged that bees seldom swarm unless honey is being gathered to some extent.

The great question is: how can we keep our bees all at work storing surplus honey without the interruptions occasioned by the desire to swarm and its results. Let it be borne in mind that the conditions which hinder our bees from storing the greatest amount of surplus honey are the same as will create the desire to swarm. We have been told that the size of the hive has little to do with this desire. In contradiction to this I wish to say that, in my experience, it has much to do with it. When you pass through an apiary, during a flow of honey, and see from one to eight quarts of bees lying upon the hives, it indicates not only that the conditions are such as to induce swarms, but also that the bees are not as fully occupied in gathering honey as they should and might be if proper precautions were observed.

Let us notice some of the conditions necessary. I shall indicate as the first requisite a good prolific queen; second, sufficient room for the queen to deposit eggs; third, plenty of room for the bees to store honey; fourth, suitable ventilation; fifth, the proper shading of hives.

While I do not assert that in anything bees never deviate from the general rule, I have ample reason for believing that if the rules I lay down are observed, fair success may be obtained. While my conclusions here reached are based largely upon experience of past years, they are more largely the result of that of the past season, during which time we have had more than ordinary opportunities for observation. It is generally known that our yield of honey for 1881 was very large. In fact, I believe that our yield from one apiary of 40 colonies, of a little over 243 lbs. average per colony, is the largest yield from an entire apiary of the size, ever obtained. I speak of this to mark the fact that this was an apiary where the colonies were the most populous of any I had ever known, and yet we had not the slightest trouble in preventing swarming where the requirements named were supplied.

I may be asked what the first mentioned essential of a good prolific queen has to do with the desire to swarm. I shall not be questioned as to the desirability of such a queen, in other respects. My answer is: that when other conditions have been complied with, our troubles with swarming have been with such colonies as have contained queens that the bees desired to supersede. When the queen cells were sufficiently advanced, such old queens would leave the hive with the swarm, or they would be destroyed and the first young queen hatched would lead the swarm. It should be remembered that our surplus honey, the past season, was nearly all taken with the extractor.

Our second and third points of furnishing sufficient room for both queen and bees to be fully occupied may easily be attained, when the combs

are extracted and interchanged, as may readily be done; but when box honey is desired, more difficulties arise. We may, by the most approved methods, add boxes which will afford sufficient room to store all the honey the bees would gather, but we find that the combs in the brood-nest must be kept so thoroughly occupied with brood and honey to induce the bees to work freely in the boxes, that often the desire to swarm is produced.

The fourth and fifth requisites, which are in the direction of preventing the hive from becoming overheated are very important. In a hive which is very populous, the necessary labor performed creates a great amount of heat. If the weather is very warm, and the hives are sheltered from such breeze as might be afforded, work will be almost entirely discontinued. This is one of the greatest reasons why bees on high ground, where there is a better circulation of air, and where it is generally cooler, gather most honey, other things being equal.

Our home apiary is in a very warm location. During the past season, as the colonies became populous and the weather warm, I noticed the bees lying out upon the front of several hives. I sent an assistant to draw the slide in the bottom board which closed an opening 5x10 inches. The next day in passing through the yard, I observed the bees all busily at work except in two hives. Upon examination, I found these two had been missed, and the ventilators were yet closed.

My conclusions, then, are that in securing extracted honey, with proper management, swarming may in most instances be easily controlled; but when box honey is produced, it is much more difficult. Surplus boxes filled with starters of choicest combination, with free and immediate access, may be supplied as soon as the bees will occupy them. It is very important that this be not delayed until the bees have already the disposition to swarm. Proper ventilation and shade may be given; and combs of brood may be taken from the brood-chamber, and empty ones supplied. Yet during some seasons, and with some colonies, it will fail to prevent swarming. If we continue to investigate and unite our experiences, we shall yet attain the desired end.

☞ The Texas State Bee-Keepers' Convention will hold its meeting at Judge W. H. Andrews' Apiary, at McKinney, Texas, April 25, 1882.

W. M. R. HOWARD, Sec.

☞ A meeting of the bee-keepers of New Jersey will be held at Hall No. 25, Albany street, New Brunswick, N. J., March 15, 1882, at 10 a. m., to organize a State Bee-Keepers' Association. All interested are cordially invited. G. W. Thompson, Stelton; C. H. Rue, Manalapan; J. H. M. Cook, Caldwell, Committee on Call.

☞ The Texas State Bee-Keepers' Convention will be held at McKinney, Texas, on Tuesday, April 25, 1882.

For the American Bee Journal.

The New Races of Bees.

S. VALENTINE.

Bees are wintering well here, both out and in-doors. I have some on their summer stands and some in my cellar. I have just been down in the cellar where I have some 80-odd colonies, and they are all quiet and I think in good condition, except three, which are a little "fussy." The one that has the most "growing" about it is the colony that had my imported Syrian queen in. It is a strong colony, and there are a great many old Syrian bees in it; they are old, for I sent Mr. Root my imported queen last August.

As I have not reported on the Syrian bees for 1881, I will do so now. A year ago I wintered some six or eight Syrian queens. Early in the spring they were slower in breeding up than my albinos, but about the time clover began to bloom, they went to brood-rearing in earnest, and by the last of June they had so many bees I thought they hardly knew where to get lodging, and as I had some frames of honey, thought I would help them out of the trouble. I made some nuclei, and it insulted them so much that they would not receive a queen nor queen-cell, and a whole lot of workers went to laying at a wholesale rate, until they would pile twenty-odd eggs in one cell, and they continued to carry on this kind of work, until I called in a regiment of albinos and cleaned up things. I will give the facts on both sides as I observed them, and all can compare and decide for themselves.

The Syrian bees are not as large as the albinos or Italians, but are very active, and I think they guard the entrance better in cool weather. They fly swifter and light at the entrance and pass in quickly, but they do not carry as heavy loads of honey as the albinos or Italians, which adds to their quickness. The queens are very prolific and the workers not so apt to fill the brood-chamber with honey and crowd out the queen as the Italians and albinos, but the queens are more apt to lay in the sections. The workers are irritable, but if properly managed, can be handled on the comb without much trouble; but they desire to see what is going on and want to be right on or under your fingers, and if one gets pinched a little, is quick to give the signal and in a moment a thousand are running to see what is the matter; they laugh at a little smoke, until they shake all over. When you wish to shake or brush them off the combs, then comes the fun; they generally go in the air and then you find out you are dealing with Holy Land bees. I can take the sections from 5 or 6 strong albino colonies with as little bother, and in the same time, that I can take them from

one strong Syrian colony. The Syrians did not equal the albinos in surplus honey.

When Syrian colonies are made queenless they build a great many cells, but generally destroy a goodly number of them before the queens emerge. When I sent Mr. Root my imported queen, her colony was very strong and I divided it, and I had concluded not to rear any more Syrian queens, but just then I received a letter from a customer at Fort Scott, Kansas, saying he would likely need a lot of Holy Land queens this fall and I let the divided colony (which was very strong, but queenless) build up 44 queen-cells, and after they were capped over they destroyed all but 8 or 9, which produced queens. They are also more difficult to introduce queens in.

I have therefore concluded to drop the Syrians. I have but two queens at present, which are mated with albino drones. I shall keep these for further experimenting, but will not rear any more for sale, unless they develop more favorably, hereafter.

I am preparing to run at least 150 colonies for honey the coming season, of which a large majority will be albinos. I prefer them to any I have yet seen. There will be a rush for early queens, the coming season; the orders that I have booked ahead will require over 100 nuclei.

Double Pipe Creek, Md.

For the American Bee Journal.

The Best Bees Controversy.

JAMES HEDDON.

In reply to my article in the BEE JOURNAL, Mr. Briggs made a man of straw and then knocked him down, to his evident satisfaction. When we cannot answer what our opponent says, we should not put words and ideas up to answer that he did *not* say. Mr. Briggs' way of getting at my meaning is not only quite ingenious, and favorable for a reply, but about like the little boy whose mother told him "never to despise a man because he wore a ragged coat." This little boy being obedient, commenced at once to despise all men who wore coats that were not ragged. It would seem impossible for anyone to misunderstand my meaning as Mr. Briggs seems to have done.

Many of our largest honey producers eschew the idea of purity of any special race of bees as a point in successful honey-producing, and many of those of less experience are foolish enough to think these men are as wise as those whose honey has never been seen in the markets, and if one of these men should order a queen from some equally foolish breeder, asking for one "tested for qualities and not color," there would likely be no questions arising afterward in regard to the "rings of purity."

A friend of mine (in whose words I have confidence), who has swapped "rings of purity" for bees that are producing immense yields of surplus comb honey, writes me that during

the past season he has taken 700 lbs. of surplus comb honey from one colony and its three swarms, and they are not three-banded bees at all; neither are they pure anythings; they are simply a strain that he has produced out of the best Italians and Germans that he could get. He says they work on red clover immensely. He has 75 colonies that doubled, and averaged over 200 lbs. per colony, and are 15 lbs. each too heavy now. One noteworthy difference between his bees and the "pure three-banded," is that he has no queens for sale, and does not wish his name given; he is not a queen vender, but a home breeder and honey producer.

Does Mr. Briggs really think that it is more difficult to test bees for bands than for business? If so, why not quit testing for bands, for all you can claim is that they indicate certain business qualities, and test for the qualities direct? Does he imagine that a honey producer will complain of the number of bands upon a queen or her progeny, if they fill the bill of his expectations for qualities. Every queen that I call "tested" will have to pass through a different crucible and a far greater period of time, than those of the prize test. By a tested queen, I mean one proven to be normal and healthy, and lays eggs that hatch out bees that (no matter where, how or what they work upon) store large amounts of honey, build comb readily and behave peaceably. A queen that does that is tested to my entire satisfaction, and if she produces bees having no bands or four, as large as kittens or as small as yellow jackets, or is herself dark or light, large or small, normally or excessively prolific, she is of value to me; and what I prize for myself, I prize for others, and *vice versa*. I could test queens for bands with less than one-fourth the labor and time that I can for the qualities named above.

My experience is that large workers are usually found keeping company with the test qualities above named, but quite often small queens. There are other minor points of preference; but if we add them to our test qualifications too soon, they may get in the way of the more vital ones mentioned. I deem such a course poor policy.

I think, just what Mr. Briggs and I believe in regard to breeding, is pretty well understood. We do not differ in regard to what we want, but only in the method of obtaining it. We both want a better bee. Neither of us are old fogey enough to say, "we have reached perfection." Mr. B. puts great stress on the 3 bands that we have had for hundreds of years. "Keep them pure, as they were," seems to me to be the idea, in fact.

I believe the German bee has some very excellent qualities that the Italians do not possess; I want these qualities to become a part and parcel of "the coming bee," and for 5 years I have advocated working for it. The main difference in opinion is, I want two races (and may be, by-and-by, more) and months and years of time to test them, while Mr. Briggs wants the three-banded race exclusively

and a few weeks of time, if I understand him correctly.

If a general outpouring of opinions upon this subject now under discussion could be had, I think that Mr. Briggs would be astonished. I have had private letters from many of our oldest queen breeders upon this subject, and every one of them substantially agrees with me. Thousands of the inexperienced, believe that this system is the only correct one.

Nothing will ever conclusively settle this problem except years of experience of those who are trying to support themselves and their families by means of the cash realized from surplus honey.

How to Use the Apiary Register.

E. A. THOMAS.

The Editor of the BEE JOURNAL has done it! He has gotten up a neat well bound Register, well adapted to the wants of all apiarists, and I believe it will pay every one who has a dozen colonies or more to send and get one. By its use you can improve your bees, developing their most valuable qualities and thus increase the products of your apiary. We all wish to secure the largest amount of surplus honey from our apiaries, this being the chief end of bee-culture now, therefore, any means that will tend to increase the surplus crop, either directly or indirectly, should be embraced by all progressive bee-keepers. A careful and correct use of the Register cannot fail to redound to your ultimate success.

Some one way back in the corner may say that it "don't pay," or, "it is too much trouble." The first objection I have already answered; in regard to the second I will say that after learning to keep the Register properly it takes but very little time, it being in convenient form for carrying in the pocket while at work in the apiary.

Perhaps a few hints about keeping a correct Apiary Register may be timely here, and assist many in filling up the blanks in their books.

The headings are all plain and easy to understand until we come to the characteristics. Perhaps if I tell you how I mark my own queens, you will better understand how to use this part of the Register, so important in breeding valuable strains of bees and in developing any particular quality which you desire your bees to possess.

1. Industry. I have kept a record of the industry of my colonies for years, and my success is due in part to this fact. At intervals during the early part of the season before the honey harvest opens, I note the exact condition of every colony under the head of Remarks. I have found that about as sure a way to test the industry of a colony is to note how they work on the first pollen in spring; if they are found indolent at that time they will not prove very valuable as honey gatherers. At the close of the

season I proceed to mark each colony, taking into consideration the amount of honey they have stored, making proper allowance if extracted; their condition at the opening of the honey season and at its close; the vigor with which they work on the early pollen in spring; the weight of the colony in the fall. In the case of a young swarm I estimate the weight of the swarm when hived, and proceed as before.

After a careful consideration of all these points, I mark all the colonies that have given the best results at 75; those next the best at 70 and so on down; 100 is supposed to be a standard to be sought for but not yet attained. I rear my queens from those which stand the highest, and allow no colony to rear any drones that is marked below 75. I change the queens of all colonies marked below 50, at once. The next season, if I find any colony that beats the best record of the previous year I mark them 80, and so on up. After raising the standard of the best to 85, I raise that of the poorest to 60; that is, I change the queens of all those that are marked below 60. By this method of culling the best for breeding purposes and destroying the poorest queens, I have improved my bees to that extent that, at the "annual marking" last fall the best stood at 95 and the lowest at 75. I am cognizant of the fact that, without the aid of an Apiary Register I never could have obtained such satisfactory results in breeding, which have exceeded my most sanguine expectations.

2. Docility. The next space in order is headed Docility. Although secondary to some others, this is a valuable trait in a good strain of bees, and it is well to develop it as much as possible without interfering with other and more important qualities. No one will probably have any trouble in filling up this space, but I would suggest that, in deciding on the relative docility of colonies, they be manipulated on the same day and at the same time of day, using an even quantity of smoke and equal care. Any deviation from this rule will result in an inaccurate marking, as the atmospheric changes exert a great influence on the temper of the bees.

3. Hardiness. This is one of the most important qualities which an improved strain of bees can possess, and I earnestly recommend a careful consideration of this point. I apprehend that the solution of the wintering problem depends in a measure on breeding hardy bees; I speak from experience, having lost only two colonies during the last ten years, a result which is attributable as much to my bees being of a strong, hardy race, as to any improved methods of wintering. In marking the hardiness of colonies, great care and judgment is required. I always take into consideration their exact condition in fall; their condition when taken from their winter-quarters; how they stand the first cold winds of spring, etc. As hardiness must have an indirect influence on the amount of honey which the bees will store, I presume the colonies giving the best results to be the most hardy as well as industrious, all other things

being equal. Any argument in regard to this point will be out of the limits of this article, but if my meaning is not sufficiently plain, I shall be pleased to make it more clear at some future time.

4. Prolificness. In filling up this space I give particular attention to the strength of the colony. It is not always the strongest colonies in spring that contain the most prolific queens. A colony, although strong in the fall, may become depopulated from some cause or causes entirely beyond the control of the apiarist; therefore, a small colony in spring is not a sure indication of an unprolific queen. It seems to me the only correct way to mark them is to consider the amount of brood in proportion to the strength of each colony.

5. Color. I select the largest, best shaped queens, having an abdomen all yellow, and that produces the largest, finest and most uniformly marked bees as a standard, and compare all others to her. In this way I can mark every queen very accurately.

In conclusion, I wish to again call your attention to the value, aye, the necessity of an Apiary Register in breeding an improved strain of bees. If bee-keepers in general will get a Register, and keep a careful and concise record of every queen and colony. It will not be long before our American Italians will have a World-wide reputation. It may not be improper for me to say here, that I have already had several calls for queens, from Scotland, Germany and other parts of Europe, to be shipped during the coming summer. I have kept a Register similar to the one Mr. Newman has just gotten up, for a great many years, and I believe my success in breeding the present princely strain of Italians is due in a great measure to this fact. Coleraine, Mass.

For the American Bee Journal.

Foundation for Surplus.

C. C. MILLER.

Instead of using small starters I practice filling the sections full of foundation. This makes me anxious to find and use that which is the very best for the purpose, and I am glad of any light I can get on the subject. I am inclined to believe that unnecessary ado has been made about the "fish-bone," and that in many cases more of a "fish-bone" than many suppose, can be found in the natural comb. Still, I think the utmost care should be taken to leave no room for objection, and our combs should equal as nearly as may be, or, if possible, excel the natural comb.

So rapid are the changes and improvements in foundation that it is difficult for anyone to keep track of them all. As yet I have only tried the Root, Dunham and Van Deusen, and can only give my experience for what it is worth. This season I shall try the Vandervort and Given. The flat bottomed or Van Deusen I do not like so well as the others, and although some think the Dunham is not suit-

able for surplus, I had a lot of 70 lbs. that pleased me well. It ran less than 6 feet to the pound, but the base or septum was very thin. Some Root foundation running 10 feet to the pound was nice, but was made in narrow pieces, was crooked, and did not cut to advantage.

In the present unsettled state of affairs I do not know that it is possible, but for those who use foundation by the 100 pounds it is certainly desirable that there should be some settled understanding as to what constitutes thin foundation, and the proper price therefor.

For one, I am not anxious to have foundation running so many feet to the pound provided the middle wall or base is thin, for if it has high side walls and the bees will thin it out, I think it will be a gain. But foundation 10 feet to the pound cannot be afforded for the same price as that running 6 feet to the pound, even if the base of each be exactly the same in thickness. The custom of charging 10 cents per pound extra for surplus foundation is well enough if that much difference is in the making, but when I am charged the same price for foundation running 7 feet to the pound with the wax mostly or altogether in the base, as is charged for 10 foot foundation, I feel that I am not getting the best end of the bargain. If any uniformity can be established, it will be a blessing.

Section Honey Boxes.

A. D. STOCKING.

Mr. E. A. Thomas, in the BEE JOURNAL for January 25th, objects to the one-piece sections, although my experience with sections has been limited, I think the one-piece section the strongest and quickest put together, and it certainly is the neatest; it will stand more jarring and careless handling without cracking the combs than either the dovetailed or nailed section. I have never seen any dovetailed sections that would not get loose in the joint after being put together, standing awhile and getting dry, and the least jar racks them out of shape. Propolis will not hold them when it is cold, they require the joints to be dipped in glue to be safe. This is my experience with dovetailed sections.

As to breaking in putting the one-piece section together, if they are made from good stuff there need not be one in a hundred broken; take a sponge dipped in water and draw across the joints and pack them close for a short time, and they will bend nicely, and if a small paint brush be dipped in hot glue and drawn across the joints, they will be perfectly secure. It will take but a few minutes' practice to get the knack of putting them together so that they can be done (even with the gluing) faster than the dove-tail can be put together. I have no interest in the manufacture or sale of any section.

The Theory of Parthenogenesis.

DR. WM. R. HOWARD.

As *puer Americana* has "dissected" my article in the AMERICAN BEE JOURNAL, vol. 17, page 290, and not tried to compare the parts, or advance any arguments to disprove them, I will simply answer his questions, while I examine his assertions. In BEE JOURNAL, vol. 18, page 42, he says:

"I also deny (with Mr. Robinson) that parthenogenesis is a fact proven in nature." I will call his attention to the last paragraph in the article above referred to, in which I said: "Now, since parthenogenesis or agamic reproduction is the production of living individuals, without the actual congress of the sexes, he is compelled to admit the production of drones by parthenogenesis." Now mark, it is a well known fact, that virgin queens and "fertile workers" do lay eggs which produce living individuals, and no one has ever shown that these workers had been fecundated by meeting the drones. Again, he says: "All admit that the queen bee is not bisexual, therefore all her eggs must be fertilized by the spermatozoa of the male to produce fruitfulness." If the queen bee is not bisexual then she must be asexual, or a hermaphrodite, so called. If she is not a bisexual insect what is the use of congress of the sexes? I stated that "fertilization of the female germ by means of the male sperm, through the congress of sexes, is the rule with bisexual animals, but there are exceptions among insects." He says: "asexual, i. e. without sex is not a law in nature." I plainly defined the meaning of the term as I used it, and there certainly was no cause for his misconstruing it, viz: "The individuals in whom this budding process takes place are called 'asexual,' because, though they may resemble the female sex outwardly, their sexual organs are only partially developed."

He denies the budding process altogether. I ask him to explain the reproduction of the *aphis*, taking Huxley's 8 conclusions for his text. He says that "asexual" and "agamic" are confined to "botanology" alone, or "applied only to vegetable life;" if so, why are these terms so often employed by the best authorities in connection with animal life. He quotes as if from my article, "eggs that you wish to hatch must be left to the care of the bees." I have read the article over and over, and have overlooked it, or it is not there. I find no such language; though it is a truthful assertion, there was no point under consideration that demanded its immediate presence.

Again he says that "neuter cannot be applied to workers, for they are undeveloped females." Neuter was formerly applied to those hymenopterous insects having females of dimorphic forms, in order to distinguish the sexual form, or those which produced true eggs, and capable of sexual semen and fecundation, from the "asexual"

form (neuter or worker ants and bees), some of which have been known to produce young without the interposition of the male.

In conclusion, I will say that, in the above, I have merely called attention to the "dissected" article to prove the points he refers to, and had he carefully read it, and thoroughly understood it, he would have been spared the pains of even referring to it, unless he could have advanced some arguments to disprove the points mentioned, or have given some evidence to establish his own assertions. Mere assertions, without any attempt toward proof, are puerile in the main. At "that well where truth lies hidden," we all hope to meet—*puer Americana*.

Wired Comb Foundation.

E. T. FLANAGAN.

The great advantage wired frames possess over the unwired is so obvious, that it is strange that the practice of wiring all frames used in the brood chamber, and for extracted honey, is not more generally practiced. I know that in many quarters there yet exists a prejudice against wired foundation and wired frames, but when the work is properly done, and a fair trial given, all prejudice vanishes. The great difficulty at first was to get wire, or rather use wire, small enough to be fully imbedded in the septum, and yet strong enough to resist considerable pressure, and, at the same time, free from corrosion or rust. After many trials, this was accomplished by the use of tinned wire (No. 30 being the best size). Yet, even with the advantage of proper wire success did not always follow, owing to the inaccurate manner the wire was placed in the frames.

When made by steam power, the holes in the frames are pierced before the bars are ripped out, and when done properly, are as correct as could be desired; but the majority of beekeepers make their own frames, and, consequently, the holes have to be made by hand, and it is almost an impossibility to do it correctly in that way; besides the labor and fatigue, the time taken to pierce, say, 6 holes in each bar, or 12 to a frame, is very great. After having pierced and wired a large number of frames, and finding the work not so accurate as I desired, I obtained from F. B. Chapman, of Scipioville, N. Y. (by the way a successful bee man), a little machine, worked by hand, that he calls a "bar piercer," and I must say that after my experience in making the holes by hand, that I would not be without this machine for double its cost, could I not get another. It is simple, accurate, easily worked, and quite rapid in execution. I pierced over 600 bars in an hour, and done much better work than was possible by hand. It can be arranged to pierce as many holes as are desired at one operation or stroke of the lever or handle. Any one pos-

sessing ordinary mechanical skill can make one, and Mr. Chapman deserves the good will of all who need such a machine, for generously giving it to the public.

For the American Bee Journal.

Wooden Separators for Sections.

C. R. ISHAM.

MR. EDITOR: In your comments on my remark that "the apiarists in this part of New York, in the future, would use wood separators in the place of tin for surplus sections," you say that, so far as your observation is concerned, their use had not been a success, and you should await with interest reports from those using them the coming season.

My greatest success in apiculture has been in getting comb honey for the city market, and dates back to the time I became a subscriber to the BEE JOURNAL, then edited and published in Washington by the lamented Samuel Wagner.

I persisted in producing comb honey when Mr. A. I. Root was proclaiming in *Gleanings*, that, with him, honey boxes were things of the past, but who afterward perfected machines for rolling out foundation which created a revolution in the profitable production of box honey.

My first experience with separators was in using thin, perforated boards. I afterward used glass boxes with tin corners, until a fire in June, 1879, destroyed my buildings and most of my machinery for manufacturing them. With honey harvest at hand I adopted the speediest method to secure surplus going to waste, necessity compelling me to use separators at an expense of some \$40 or \$50 for tin; but just as soon as I could get my machinery to work, I commenced replacing the tins with wood, and to-day could not be induced to use tin for new racks or frames, if it was furnished to me free of cost!

The facility in changing the size of our sections to meet the demands of trade is of no small consideration, as it enables us to do so at comparatively little expense. The one fact of its giving a wider entrance, saying nothing about warmth or cheapness, is enough to commend their use to every thinking, practical apiarist, who is engaged in producing honey for profit.

When I see my views so strongly confirmed by such successful honey producers as Messrs. Newman & Son, of Peoria; Messrs. Van Eaton & Rians, of York; Stanley & Bro., of Wyoming, and the Messrs. Benedicts, of Perry, who, for the past several years, have been producing box honey by car loads, I feel that my position is practicable, and that time and experience will confirm, as a grand reality, that which you now look upon as a doubtful success.

We took an advanced position in advocating and using foundation for surplus honey, when it was condemned by Messrs. Doolittle, Betsinger and others at the Northeastern Conven-

tion; also at the National Convention held in New York, when Messrs T. G. Newman and A. J. King complained so sadly; the first named, about the "fish bone" in the center of the comb, and the latter commented so severely upon a case of honey he had received from Mr. A. I. Root, in which foundation had been used full size for starters.

The next fall Mr. King, in the *Bee Keeper's Magazine*, spoke of a ear load of honey shipped to New York by Messrs. Newman & Son, of Peoria, N. Y., and myself, as it stood piled up on the sidewalk in front of Messrs. Thurber's store, as being the handsomest lot of honey ever brought to New York, yet this same pile of honey owed its fine appearance to having been built upon wax foundation whose use for surplus he had severely condemned only the fall before.

It was some of this lot of honey which found its way to the Queen's table, giving it a place in the menu of the titled aristocracy of Great Britain, thereby helping to open up a foreign market for the surplus product of our apiaries.

This wax foundation properly made, in the language of one of New York's foremost apiarists, is a "grand success," and I believe wooden separators are destined to supply the great desideratum for the cheap production of surplus honey.

Peoria, N. Y.

[Mr. Isham is a practical and progressive apiarist, and we hope that another year's experience with wooden separators will fully equal his expectations. We object to nothing that is progressive and practical, but must say that this needs some further demonstration.—ED.]

For the American Bee Journal.

A Plan for Wintering Bees.

J. E.

One of the desiderata in the successful wintering of bees, is pure honey, and the absence of pollen in the brood nest. An excess of pollen in the combs will lead to brood-rearing, during a warm spell in winter. This is an abnormal state, and, if followed by protracted cold weather, will result in dysentery.

To obviate this difficulty, I propose the following plan: Put away nice worker combs, well filled and sealed, containing pure honey gathered early in the season, as this will be found to contain the least pollen, in number equal to two combs for each colony. Then, after brood-rearing has ceased in the fall, go round to each colony; lift out all the combs, shaking the bees back into the hive, and place two of these reserved combs of honey, 1½ inches apart, in the center of the hive; place a division board on the outside of the combs, packing the outside empty spaces with some absorbing material; cover with a quilt and chaff cushion in top story, and leave them until pollen begins to come in freely

in the spring; then place an empty worker comb in the central open space; the queen will quickly fill it with brood, when one of the division boards may be moved back and another empty comb inserted in the brood-nest.

This operation may be repeated every 10 or 12 days, according to the weather and amount of the honey flow, until the hive is filled with combs.

The advantages claimed for this method of wintering, are that the bees are packed up snug and warm, the open space in center giving them opportunity to cluster together in a compact mass, thus enabling them to keep up a proper temperature, and prevent loss by small bodies of bees being caught between the outside combs during a cold spell. Also brood-rearing can be regulated in the spring, according to the judgment of the bee-keeper, as they will rear no brood of any consequence during an absence of pollen in the hive; and every bee-keeper knows that too early rearing of brood is detrimental to the welfare of the colony.

Gainsville, Ky.

For the American Bee Journal.

Location is an Important Matter.

J. A. BUCHANAN.

No doubt the kind of hive used, and skill in management, has much to do in making the pursuit of apiculture a success, but location plays the most important part. Perhaps one-half or more of the bee-keepers of the country have a location where nearly the entire crop of surplus honey is secured from white clover, and but little from other sources during the season. Now, as we can here only count on from 3 to 6 weeks' yield from clover bloom, it may be easily seen that ordinarily, not very large quantities of surplus can be obtained. And, indeed, taking into account the number of seasons clover bloom fails to secrete honey, save in limited quantities, it may be questioned whether in such localities, bee-keeping, as a specialty, can be made to pay? Where even fair yields of surplus are secured from apiaries so situated, much more credit should be given to the apiarist than to those favored with a location giving them a second opportunity to secure surplus from fall flowers.

The seasons following long, cold winters, bees are usually left in a weak condition, and do not become strong in numbers, and of proper age to take the field and secure the full benefits of this short yield, and the chances are that many will only get there in time to find the season ended, and no surplus secured. Bee-keepers so located as to be favored with both an early and a late bloom, in such abundance as to give good yields of surplus, have more than a double advantage, and for such, with almost any kind of hive, it would indicate a poor knowledge of the business, if reports of large yields of surplus honey could not be shown. There would be

for the fall yield, or for any yield after clover bloom, bees in such great abundance, and of the proper age, together with the favorable weather usual for that season of the year, to give the most satisfactory results.

Since the same form of hive and management will not give in all localities similar results, I am by the nature of the subject led to briefly consider the question of the hives best adapted to location. Why is it that there is such a diversity of opinion as to the best form of hive or depth of frame. I claim that location and time when bees store winter supplies, has much to do in bringing about these conflicting opinions.

Take a locality where the honey supply for winter is stored during the blooming season for white clover (June and the early part of July), when the season for storing is ended, and the hive well supplied, the honey, if in shallow frames, will be in good condition for the bees to winter well, but by the approach of cold weather, if no fall honey is to be had, it is found that the honey in the center combs is nearly all consumed, and the colony in poor condition to pass safely through a cold winter.

In this case we have a helpless condition of things, unless means are provided for a safe and ready passage for the bees over the frames to the stores in the outside combs; but this timely precaution is not always attended to, and here follows heavy losses, and a vehement condemnation of the shallow frame. But if the honey had been stored in the fall, the same as before described, and not being much drawn on for the support of the colony before winter, there would be no complaints about the shallow frame. I think this a reasonable explanation, founded on facts, which makes plain why such great differences of existing opinions as to best form of hive to adopt. "What is one's meat is another's poison." That form of hive most successful in our locality may be a failure in another. Hence to draw the inference that deep frames with large storing room in the breeding apartment, for localities where stores for the whole season are gathered during the early bloom, and shallow frames and smaller breeding apartment, if supplies are gathered during both early and later in the season. Taking this as a correct view of the matter, there is no necessity for so much controversy as to the best hive or best manner of manipulation.

Experiment a little and ascertain the kind of hive and management best suited to each peculiar location. Holliday's Cove, W. Va.

It would save us much trouble, if all would be particular to give their post office address and name, when writing to this office. We have letters (some inclosing money) that have no name, post-office, County or State.—Also, if you live near one postoffice and get your mail at another, be sure to give the address we have on our list.

SELECTIONS FROM OUR LETTER BOX

Much Honey Consumed.—I put 33 colonies of bees into the cellar about the 10th of December, most of them well supplied with honey, and in good condition. To-day I set them out, and I never saw them fly livelier in June, than they did from 10 until 3 o'clock. All in good condition except one late swarm, which had starved. Had I better return them to the cellar, or will they do as well out, if the weather continues moderate. They have consumed nearly double the honey, already, that they did all last winter, put away in the same room, and prepared in the same manner. Can you give a reason for it? I like the make-up of the BEE JOURNAL this year much better than last, and consider it A No. 1. REUBEN HAVENS, Chebanse, Ill., Feb. 8, 1882.

[Leave them out, unless the weather becomes extremely cold. With the probability of frequent flights from now until spring, they will suffer no harm. The excessive consumption of honey was owing to high temperature in the cellar, and the uneasiness caused thereby. We presume you will find more or less breeding has taken place, while last winter there was none.—ED.]

Bacterium.—I thought bacterium was gone and pollen had taken its place; but as it appears to be returning, a few words concerning it may not be amiss. Bacterium, or the plural bacteria, which is most commonly used, are minute forms of vegetable organism. They are found in the sap of trees and vegetables, in the fluids of all animals, and abundantly in decaying substance. They are so minute that they float in the air unnoticed. They appear to be the root or starting point of fermentation or decomposition. They have no effect on any part as long as vitality remains. To illustrate: If a growing apple receives a scratch on it, not enough to stop its growing, the scratch will heal over and become sound; but if the apple is fully ripe, bacteria get in and fermentation, rotting and decomposition is the result. Again, bacteria do not work much below temperate, and not at all below freezing. They work better the hotter it is, until it gets hot enough to destroy vegetable life. Let us compare this with bee dysentery. Bees are most apt to have the dysentery in long spells of severe, cold weather, when the bees are quiet and the hive at its lowest temperature—at a time when bacteria work but little if any. On the other hand, when it is warm and bacteria work the fastest, the bees (if they have enough to eat) are entirely free from dysentery. I write for the consideration of the considerate. E. B. SOUTHWICK, Mendon, Mich.

Bees Wintering in First Rate Order.—I received the "Apiary Register," and it just fills the bill. Every bee-keeper should have one, if he has not more than 10 colonies of bees, for he can by it tell, at a glance, the condition of every colony of bees in his apiary, and know what changes are necessary, without looking over the hives. My bees, so far, are wintering finely, and to-day they had a fine flight. But very few bees have died: I think a tea-cup would hold all the dead bees out of 30 colonies. Twenty-seven are on summer stands, packed in chaff and straw, and 3 are in the cellar. I am very sorry to hear of the misfortune of H. A. Burch, of South Haven, Mich.; he furnished me with some of the finest queens it has ever been my lot to get. The queens were very large and prolific. The bees are long, leather-colored, very gentle, and great honey gatherers. His dealings with me were very satisfactory and just what he agreed to do. I wish I could say as much for one other dealer and breeder that I have had the misfortune to have dealings with, and have written letter after letter to him, and cannot even get an answer. What size will it be necessary to put holes into zinc for entrances to hives to prevent drones from flying.

L. DENSMORE, Livonia, N. Y., Feb. 8, 1882.

[The holes or perforations in the zinc excluders are just $\frac{3}{8}$ of an inch. Some use them with round perforations, while others cut out strips $1\frac{1}{2}$ inches long by $\frac{3}{8}$ wide, and running horizontal with the entrance.—ED.]

Better than Ever.—When I say that I like the AMERICAN BEE JOURNAL better than ever, and I may add, better than all others, I mean just what I say. The first and most important improvement was the change from Monthly to Weekly; the form of the Weekly I did not like, but made no complaint, because I knew you would change it whenever it became our and your own interest to do so—I was not mistaken. Your disposition to accommodate your patrons I very much admire. With the editorial commencing on the first page and the advertisements on the last pages, I think it is all we could desire. Permit me, however, to make a suggestion—if it would not interfere in making up the form—would it not be better to place the date at the top of each page, as in Vols. 9 and 17, it would certainly be a great convenience in reading. I hope soon, if time permits, to send you a communication on the "Improvement of the Italian bee." I have cultivated it with great care for more than 20 years, and differ with some of our writers concerning it.

WM. S. BARCLAY, Beaver, Pa., Feb. 8, 1882.

[Thanks for the compliment. As to the running date on each page, we discarded it on account of its troublesome-ness. We shall be pleased to receive the communication.—ED.]

Tin Numbers for Hives.—I would suggest now that you get up a tin tag 3 or 4 inches square with the serial on them, to go with the Apiary Register. The numbers could be stenciled on or could be printed with gum stamps. The figures should be large enough to be plainly seen for some distance. In this case, if the queen is changed from one hive to another, the tag can be taken off and go with her, and no alteration would have to be made in the Register. JOHN C. PEDEN, Lawrenceburg, Ky., Feb. 9, 1882.

[The numbers could be put on very readily with a stencil-plate. We fear the tin tags would be too expensive, and too easily lost.—ED.]

Doing Nicely.—My 57 colonies are wintering nicely. I looked through them on the 6th, and found all alive, strong, and active, with plenty of stores with ordinary weather to take them through all right. We have had an exceedingly wet, changeable winter. I use A. G. Hill's winter hive on summer stands, without protection, with wire screen under the center of the bottom board. This is the winter for this mode of wintering, and has been a grand success. I have lost but two weak colonies in four years. The past season, on account of excessive drouth, was a poor one for honey with us. The early spring opened up finely, and late fall closed out nice. ASBURY MCKNIGHT, Bible Grove, Ill., Feb. 1882.

N. E. Wisconsin Convention.—In the BEE JOURNAL of Feb. 1, 1882, page 67, under the heading "Another reform needed," reference is made to the N. E. Wisconsin Bee-Keepers' Convention advertised to be held in Berlin, Wis., Jan. 17th and 18th, that was not held there and then. It is due those who were disappointed about that meeting that some explanation be made. The Secretary of the N. E. Wis. Association was unavoidably absent from the meeting at Pewaukee, in October, 1881, and it appears from her statement that last winter it was decided to hold but one meeting a year and that in October, which was known to but few that were at Pewaukee, and overlooked by those present who did know when Berlin was fixed as the place and Jan. 17th and 18th, 1882, as the time of the next meeting, being about the time it was held last winter. I sent you a report of the Convention at Pewaukee for publication, from which you took a notice of the meeting to be held at Berlin, Jan. 17 and 18, which was all right had the meeting gone on, and perhaps all right, any way. But after that report was sent, the Secretary wrote me, suggesting that the meeting be held the latter part of March, and requesting me to notify those at the Pewaukee meeting of the change, some of whom were notified, but no notice of this change was sent to the BEE JOURNAL, because the Secretary, after notification that a change would be agreeable, had not time to notify you before Jan. 17th. I failed, through the pressure of

other engagements, to give the Secretary the necessary information in time to have the matter set right, which I regret very much. The N. E. Wisconsin Convention will yet meet at Berlin, when it does meet again, and will probably do as well for the friends of the Association to make amends for this disappointment, as they did for the friends in the vicinity of Pewaukee at the meeting there.

T. E. TURNER.

Sussex, Wis., Feb. 10, 1882.

The Lewis Section.—1. Has any one tried to use the Lewis improved one-piece section? 2. Is it really an improvement? 3. How do the bees get into the sections without a side inset? Please answer through the BEE JOURNAL.

W. S. BUCHANAN.

[Having had no experience with the "Lewis improved one-piece section," we cannot say whether it is an improvement. Mr. Lewis' circular gives directions to use them in cases by spreading, allowing spaces between for the entrance of the bees. For use in the rack, they will, of course, require to be spread in the same manner, using wooden separators between them.—Ed.]

Irregular Combs.—To straighten irregular combs I have practiced the following plan: Warm the combs by placing them in the sun until they are soft and pliable, then lay them on a flat, smooth surface, as a hive cover, and another flat surface, as a piece of plank on them, to press them down level, and let them remain thus till cold. They are then ready to hang in the hive, nice, even, and straight as could be desired. This is my practice, and my hundreds of straight combs, without an irregular or crooked one, is the result. I never shave down, nor melt up good combs into wax.

S. D. McLEAN.

Columbia, Tenn., Feb. 10, 1882.

An Excellent Report.—Last winter I only saved 5 colonies out of 41 prepared for winter the fall previous. These 5 were in very weak condition and I had but little hopes of any surplus from them. I obtained 2 colonies from my neighbors, making 7 to begin with. When the warm weather came they built up beyond my expectations, and gathered a small surplus from white clover; basswood lasted but a short time; red clover did well for the first time in a number of years, and buckwheat yielded sparingly. To sum up: I obtained 1,650 lbs. of extracted honey from my 7 colonies, spring count, averaging 205.5-7 lbs. per colony. I increased to 19, which are in the cellar with sugar syrup and no pollen. The honey which would have been required to winter them, is not included in the 1,650 lbs. After reading Mr. Heddon's articles, it set me thinking about my losses last winter. I found, by examination, that the colonies I fed the syrup to, had only such combs in the hive as I had used for

extracting, and had no pollen, while those that died, with natural stores, had large quantities of it. I think I never had bees winter so far with the loss of so few, as the present, but the worst time is yet to come, of course.

A. A. E. WILBER.

Moravia, N. Y., Feb. 6, 1882.

Will Air-tight Jars prevent Honey from Candyng?—When extracting last August I filled a Muth two-pound glass jar and corked it. The rest of my honey I turned into a can. I drew off a portion of it into tumblers in the fall, and while the honey in these has candied solid, that in the jar remains as clear as when extracted, though it has stood in the light every day since. The honey remaining in the can is still liquid, though it shows signs of granulating. Will honey which is put in an air-tight jar immediately after extracting remain liquid? Or, how do you account for some of this honey candyng, and some not? Please answer through the JOURNAL.

JAS. McNEILL.

Hudson, N. Y., Feb. 9, 1882.

[We cannot account for it, except that it has remained where it did not become so thoroughly chilled as did that in the can. Perhaps the lack of evaporation had something to do with it. We have had many samples of extracted honey, which have candied in air-tight bottles; some, too, that was quite new when put up.—Ed.]

What Was It?—In May of last year 2 colonies of bees, in fair condition, were found to be idle and hanging listlessly around the entrances to the hives, while their neighbors were busily engaged in bringing in honey and pollen. An investigation revealed the fact that perhaps $\frac{1}{4}$ of their brood was dead and decayed in the cells—some of it unsealed and some sealed, but with perforations in the cappings. The bees could not, or would not, remove the sticky mass from the bottom of the cells, so I proceeded to do it for them with a bent pin, and I continued to do so for one of the colonies, at intervals, until they fully recovered and made a prosperous colony. With the other I adopted a more radical course, by removing all their combs and making them start a fresh lot of brood, which all proved to be healthy. What was it?

J. L. WOLFENDEN.

[It was brood which had become chilled, and the bees were disheartened and discouraged. Had it been foul brood there would have been a recurrence of it in the two hives, and would have extended to other colonies.—Ed.]

Bees in the Cellar doing Well.—I have 50 colonies in Langstroth hives in the cellar, doing finely. Last season was a very poor one for bees, in these parts, but little surplus honey was produced.

A. REYNOLDS.

Quaker Springs, N. Y., Feb. 6, 1882.

Climbers for Shade.—Can the BEE JOURNAL give the name of a good annual climber that will furnish shade for hives and pasture for bees? In view of the action of the N. E. Convention, I should be sorry to become famous for anything, in apiculture. If the National Association cannot honor every man, they had better not mention any, for fear some side affair will kick up a row about it. I have lost six colonies already. Direct cause, old bees; indirect cause, poor bee pasture.

WM. CAMM.

Murrayville, Ill., Feb. 11, 1882.

[We do not know what to recommend as the best annual climber for shade and bee pasture, too; but would try some of the better and more prolific varieties of cucumbers, thus realizing a shade, honey, and a profitable crop of cucumbers for market, which of itself would pay the cost of cultivation. In all attempts at planting for honey, we would advise a preference always to be given that which possesses a value aside from its honey yield—not that honey itself will be unremunerative, but because a double crop, and hence, a double profit, is more desirable than the single return. We are convinced the N. E. Convention will at some future time see the error of their way, in condemning so unmercifully the National Convention. A mild reproof will often carry stronger conviction than bitter denunciation.—Ed.]

All Right, So Far.—As long as I have one colony left and the BEE JOURNAL continues so far to excel all others, I shall take it. I put into winter quarters, the fall of 1880, 30 colonies, caps packed with rags, hives set under a shed boarded up tight on the west and north, and about 18 inches of straw packed between the wall and hives; came through with 20 colonies strong in honey, but weak in bees. They carried in pollen April 18th and built up rapidly from that time, but the drouth came just in time to find the hives crowded with young bees, which had nothing to do but consume what they had gathered from white clover. They swarmed but little, increased to 28 colonies, and went into winter quarters in the same manner that I packed last winter, and seem to be doing well so far.

G. W. PAGETT.

Oxford, Ind., Feb. 9, 1882.

Recipe for Making Paste.—Make a thin batter of best wheat flour, stir this into boiling water, on a slow fire; when cooked, or thick, take from over the fire, and to each quart stir in 2 ounces of New Orleans sugar or molasses, while hot. This paste will adhere as well to a non-porous surface as to a porous one. Keep in a cool place.

C. HAUCKE.

Greenup Co. II., Ky., Feb. 6, 1882.

Bees have had Frequent Flights.—I have been making very close observations in reference to color of bees and their qualities for honey gathering, disposition in handling, hardiness, prolificness and beauty. My bees are of the lightest strains, with but few exceptions. I keep the darker ones in my Southern apiary; the light ones at home. I will give the results of my investigations to the readers of the BEE JOURNAL soon. Bees are wintering finely. I have 135 colonies in good condition, on the summer stands. The weather has been fine, with mercury above zero all the winter. The bees have had flights nearly every week. The prospect is good for the coming season. L. J. DIEHL.
Butler, Ind., Feb. 8, 1882.

Bees Doing Well.—I put about 40 colonies of bees in my cellar on Christmas day, and left 6 colonies on their summer stands. All are in fine condition. Those left out-of-doors have had frequent flights, and for the last 2 or 3 days have been carrying in pollen from soft maple. The weather is warm, being more like May than February. I. P. WILSON.
Burlington, Iowa, Feb. 15, 1882.

Prospects Brighter.—Last winter was so disastrous to my bees that I was ashamed to report my losses, after pronouncing my bees all right in March. My bees did so well last season, however, that I am getting reconciled. My honey crop averaged 150 lbs. for each colony that I saved from the wreck, and the increase by division was 200 per cent. Now, with a bee house built on the plan described by Mr. Greening, in No. 29 of last year's BEE JOURNAL, and better preparation of each colony last fall, I hope to report all my colonies fit for duty at next spring's roll-call. I have never had time to attend any of the Conventions, but promise myself in the near future the pleasure of taking yourself, Prof. Cook, and other bee-masters by the hand, and thank you all for much instructive and valuable information I have received by the perusal of your communications.

F. T. BOUTELLER.
Belle River, Ont., Feb. 9, 1882.

Cold.—Bees all right so far. They are getting a good fly to-day. An 18 inch snow fell on Saturday last which is melting rapidly. The coldest here this winter was on Jan. 24—2° above zero. The BEE JOURNAL comes regularly and is appreciated. Generally reaches me on Friday of each week. J. W. CARTER.
Pleasant Dale, W. Va., Feb. 8, 1882.

The Langstroth Hive.—I have tried four different patent hives for many years. The first was the Langstroth. They were all tried side by side with the Langstroth, and I found that the Langstroth was the best for all purposes, so I transferred all of my bees to this hive; therefore, I think that Mr. Heddon's advice is perfect, sound and provable. WM. ROBERTS.
Vaughansville, O., Feb. 14, 1882.

Wintering Well in Chaff.—I put into winter quarters 60 colonies, packed in chaff. All had a depth of 6 inches of chaff over the bees and inside of the cap. Previous to Jan. 26th they were not out for 5 weeks, but on that date they had a good flight. I discovered then that one had starved by clustering in one end of the hive and leaving plenty of honey in the other, that they could not get to, on account of the cold. On Feb. 6th the mercury ran up to 62° in the shade. Taking advantage of this, I opened every hive and found all in fine order; there was capped brood in a good many of the hives. We are having remarkably fine warm weather for this time of year. C. W. MCKOWN.
Gilson, Ill., Feb. 9, 1882.

Packed in Chaff.—Bees are wintering here finely. They enjoyed a good fly on the 6th inst., and one Dec. 18th. I have 146 colonies packed in chaff; all but 2 are in good condition. I am surprised at the reports of the extreme cold East. Seven degrees above zero is the coldest we have had. H. D. BURRELL.
Bangor, Mich., Feb. 10, 1882.

Spring-Like.—I send herewith some sprigs of smilax with bloom. My bees have had some grand and glorious flights the last few days. Some got into my plant house and gathered honey and pollen from smilax, etc. Robin red-breasts and blue birds greeted me this morning, the first time this season. The weather is like spring. What a difference between this and last season. H. S. HACKMAN.
Peru, Ill., Feb. 14, 1882.

Dairy versus Apiary.—I write to draw out from some source how much the apiary detracts from the dairy. It is well known, by observing dairymen, that bees take from their pastures some of the richest and choicest elements of their milk and butter, and the savory sweet and nourishing qualities from their beef and mutton, and their cows give, so to speak, skimmed milk when pastured near large apiaries. We have all noticed a vast difference in the savory elements of milk, butter, beef and mutton, and think the scientists will attribute a part to the depredations of the honey bee. I should like to hear through the BEE JOURNAL from some one versed in agriculture, as well as the apiary, about our bees depredating on the dairy. I have 50 colonies of bees in the cellar in good condition. I lost 8 colonies last winter out of 35, leaving 27 last spring, some very weak. I increased to 50, and took off about 500 lbs. of section honey, and called it a very poor year. Our bee pasture is mainly white clover; the quality of honey is good, and sells at 20 and 25 cts. per lb. I am well pleased with the present form of the BEE JOURNAL. When Jan. 1, 1882, came, I had 52 numbers (none lost), making a large book. ALVAH REYNOLDS.
Oneida, Ill., Feb. 6, 1882.

Bee-Keeping in Georgia.—Bees have had a flight nearly every day during winter, and there were but few days that they have not carried in pollen. In examining a few colonies on the 10th inst., I found all of them breeding finely, some of them with brood in 5 frames. Should they get no set back, they will swarm in March. Drones are nearly developed. The present size of the BEE JOURNAL I admire, and also the manner in which it is edited. I have not sent anything for publication in it lately, seeing that you had plenty that was much better, but please do not think I have forgotten the old AMERICAN BEE JOURNAL—long may it and its editor live. A. F. MOON.
Rome, Ga., Feb. 10, 1882.

Mild Winter.—The winter has been a remarkably mild one, and well calculated to bring bees through in good shape. My bees were carrying in pollen last Monday. H. H. LITTELL.
Louisville, Ky., Feb. 17, 1882.

Bee-Keeping in Utah.—Cache valley is about 100 miles north of Salt Lake City, some colder, and subject to early and late frosts; much healthier. We have not many bees here yet, but what we have are doing and paying well. We use the Kidder hive as yet. A colony of Italian bees in the Kidder hive will sell for about \$14; extracted honey about 25 cts. per lb. My report from the county was 70 pounds to the colony—a little over 6,000 pounds. I am satisfied if we had more experience and your modern improvements, we could do better. We will keep working at it till we get them. I guess you can appreciate the feelings of a young bee-keeper. Our bee pasturage is good—plenty of sweet, red and Lucerne clovers, and about 2,000 acres of willows. I winter on the summer stand, using stable manure and some sawdust, piling them beneath, at the sides, back and on top, and leaving the entrance clear. On the 1st of May they are ready for swarming. We generally increase two from one. Some years past we have been troubled with foul brood. The County Courts have appointed Commissioners to inspect and destroy foul brood wherever found, and they are doing a good work. The Courts impose a heavy fine on any one who refuses to destroy the infected hive. Though new, our county realized \$20,000 from honey alone. GEORGE HIBBARD, Bee Com'r.
Logan, Utah, Jan. 22, 1882.

Young Bees.—To-day, Feb. 3, I looked over all of my bees, as it was warm, and they had a good flight. I found them in excellent condition, strong in bees, and several had commenced to rear brood; one having brood on two frames, and some were hatching out. Some had hatched. I have 28 colonies, all in chaff hives. I find a scarcity of pollen in all of my colonies. L. C. McFATRIDGE, M. D.
Carroll, Ind., Feb. 3, 1882.

RATES FOR ADVERTISING,

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space.

Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements for the Weekly as follows, if paid in advance:

For 4 weeks.....	10	per cent. discount.
“ 8 “.....	20	“ “ “
“ 13 “ (3 months).....	30	“ “ “
“ 26 “ (6 months).....	40	“ “ “
“ 39 “ (9 months).....	50	“ “ “
“ 52 “ (1 year).....	60	“ “ “

Discount, for 1 year, in the Monthly alone, 25 per cent., 6 months, 10 per cent.

Discount, for 1 year, in the Semi-Monthly alone, 40 per cent., 6 months, 20 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

Transient Advertisements payable in advance. —Yearly Contracts payable quarterly, in advance.

THOMAS G. NEWMAN,

774 West Madison Street., Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the best advertising medium, but the lowest rates on yearly contracts.

The Apiary Register devotes 2 pages to each colony, ruled and printed, and is so arranged that a single glance will give a complete history of the colony.

For 50 colonies (120 pages).....	\$1 00
“ 100 colonies (220 pages).....	1 50
“ 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Articles for publication must be written on a separate piece of paper from items of business.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

Honey as Food and Medicine.

We have just issued a new edition of our pamphlet bearing the above title. It has been revised and enlarged from 24 pages to 32, the new pages being devoted to new Recipes for Honey Medicines, as well as all kinds of cooking in which honey is used.

It is undeniable that pure honey is the simplest, the healthiest, the most natural, and the most strengthening article of food for healthy persons, as well as the best remedy for the sick; and for the convalescent it is the true balsam of life, to restore them to their wonted strength and health.

What is needed is to educate the community up to this idea, and in no way can that be done so well as by directing their attention to the merits of honey.

This little pamphlet should be scattered by thousands all over the country, by honey producers. In this way it will create a home market in almost any locality.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

When 100 or more copies are wanted, they will be sent by express, at the expense of the purchaser.

CLUBBING LIST FOR 1882.

We supply the Weekly American Bee Journal and any of the following periodicals, for 1882 at the prices quoted in the last column of figures. The first column gives the regular price of both All postage is prepaid by the publishers.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL. } Monday, 10 a. m., Feb. 20, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour :

Quotations of Cash Buyers.

CHICAGO.

HONEY—The market has an upward tendency, and I am now paying the following prices in cash : Light comb honey, in single comb sections, 17@21 cents ; in larger boxes 2c. less. Extracted, 8@10c.

BEESWAX—Prime quality, 18@22c. AL. H. NEWMAN, 972 W. Madison St.

CINCINNATI.

I pay 8@11c. for extracted honey on arrival, and 16@18c. for choice comb honey.

BEESWAX.—18@22c., on arrival. I have paid 25c. per lb. for choice lots. C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—Choice white comb, in 1 to 1 1/2 lb. sections, 20@22c.; same in 2 to 3 lb. boxes, 17@20c.; dark and mixed, in 1 to 3 lb. boxes, 12 1/2@15c. Extracted, white, 10@11c.; dark, 9c.

R. A. BURNETT, 165 South Water St.

NEW YORK.

HONEY—There is a liberal supply of honey here for which trade is very little demand, and prices rule weak and irregular.

We quote as follows : White comb, in small boxes, 18@19c.; dark, in small boxes, 12@14c. Extracted, white, 10@11c.; dark, 7@9c.

BEESWAX.—Prime quality, 21@23c. THORN & Co., 11 and 13 Devoe avenue.

SAN FRANCISCO.

HONEY—Market is dull ; not much offering, but there is an entire lack of inquiry at present.

We quote white comb, 16@20c.; dark to good, 10@14c. Extracted, choice to extra white, 8 1/2@10c.; dark and candied, 7@8c. BEESWAX—23@24c. STEARNS & SMITH, 423 Front Street.

ST. LOUIS.

HONEY—Quiet and slow for all save choice bright comb—this sold readily ; comb at 18@23c.; strained and extracted, 3@1 1/2c. to 12 1/2c.—top rates for choice bright in prime packages.

BEESWAX—Steady at 20@21c. for prime. R. C. GREER & Co., 117 N. Main Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.

BEESWAX—Prime quality, 25c. CROCKER & BLAKE, 57 Chatham Street.

CLEVELAND.

HONEY—The market continues very steady ; best white, in 1 and 2 lb. sections, sells quick on arrival at 21c@22c.; No. 2 at 19@20c., but buckwheat honey we find difficult to sell—holding it at 17c. Extracted, is in fair demand at 12c. in small packages, and 11c. in large packages.

BEESWAX—25c., and very scarce. A. C. KENDEL, 115 Ontario Street.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club :

- For a Club of 2,—a copy of "Bees and Honey."
" " 3,—an Emerson Binder for 1882.
" " 4,—Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
" " 5,— " " cloth.
" " 6,—Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Examine the Date following your name on the wrapper label of this paper ; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

The Original YES, SIR ; Bee Smoker

Patented, 1878. Our patents cover all the Smokers that burn sound stove-wood, or do not go out. If you buy our implements first you will have to buy no others.

PRICES:

Table listing prices for various Bingham Smoker models and accessories, including 'Large Bingham Smoker', 'Extra Bingham Smoker', 'Plain Bingham Smoker', 'Little Wonder Bingham Smoker', 'Bingham & Hetherington Honey Knife', and 'Honey Knife'.

Handled to By Mail, Customer. Postpaid. T. F. BINGHAM, or BINGHAM & HETHERINGTON, Aromia, Mich.

SEEDS FOR Honey Plants.

I keep at all times a full supply of Seeds for Honey Plants, including

- Golden Honey Plant.
Melilot Clover,
White Clover.
Alsike Clover,
Mammoth Mignonette, &c.

Send for my catalogue which gives prices and instructions for planting—sent free upon application.

ALFRED H. NEWMAN, 972 West Madison Street, Chicago, Ill.

Homes in Tennessee.

The KNOXVILLE TRIBUNE is a medium through which parties coming to Tennessee can obtain information of value in regard to climate, resources, productions, prices of land, and other points of interest to the stranger.

Inquiries about Tennessee answered by letter or through the paper, as requested. Address

THE TRIBUNE, Knoxville, Tenn.

WANTED AGENTS to take orders for the best selling book on FARM and HOME topics ever published. Sells at sight. Ladies can handle it. Has no superior in any language ; 1,050 pages, with nearly 2,000 illustrations. Terms free on application. 50 Per Cent. to Agents.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by **THOMAS G. NEWMAN,** 974 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide or Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quilby's New Bee-Keeping, by L. C. Root.— The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. J. Root.— This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.

King's Bee-Keepers' Text-Book, by A. J. King.— This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Honey-Bee.— This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.— A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, \$1.00.

Bees and Honey; or, successful management of the Apiary, by Thomas G. Newman.— This embraces the following subjects: Location of the Apiary— Honey Plants— Queen Rearing— Feeding— Swarming— Dividing— Transferring— Italianizing— Introducing Queens— Extracting— Queening and Handling Bees— Marketing Honey, etc. It is published in English and German.— Price for either edition, 40 cents, postpaid.

Dzierzon Theory— presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.— This pamphlet discourses upon the Ancient History of Bees and Honey; the nature, quality, sources, and preparation of Honey for the Market. Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foams, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.— This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold— was awarded to Prof. Cook's Essay, which is here given in full. Price, 10c.

The Hive Itself.— Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.— A 24-page pamphlet, by Ch. & C. P. Dabant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.— Price, 15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth: 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages. 50c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Golders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Kendall's Horse Book.— No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of diseases, and much valuable horse information. Paper, 25c.

Ropp's Easy Calculator.— These are handy tables for all kinds of merchandise and interest. It is really a lightning calculator, well bound, with slits and pocket. Cloth, \$1.; Morocco, \$1.50.

Chicken Cholera, by A. J. Hill.— A treatise on its cause, symptoms and cure. Price, 25c.

Address, **THOMAS G. NEWMAN,** 974 West Madison Street, CHICAGO, ILL.

Goodrich's Foundation Fastener.

We stated last week we had received one of the above machines for a place in the BEE JOURNAL Museum. The following is an account of its inception and completion, as furnished us by Mr. S. Goodrich. The cut will convey a very accurate impression of the appearance of the machine:

I have been looking in the columns of the JOURNAL for the last two years for some practical method of fastening foundation comb in the frames, but so far have seen nothing very satisfactory. Last spring I concluded there could be a machine made that would fasten it, and do it much more rapidly than by any of the old ways, of rubbing down with a stick, or fastening with hot wax. I had one machine made, but when I came to

Goodrich's Foundation Fastener.

put it to practical use, I found it defective in some points (as the first experiments generally are), yet it fully met my most sanguine expectations, as far as fastening to the top-bar, but I wanted the comb fast to the ends, as well as the top. This it would not do, so I took the old plan of fastening the comb to the end pieces by the rubbing-down-process. I found that I could put a full, large swarm upon these frames without any trouble from breaking or getting out of shape, not having one fall during the season out of about 65 colonies that I used them in.

Not being entirely satisfied with what I had, I took a model and called on Rev. Salisbury, and between us we have made a machine carrying out my plans for fastening the foundation to the top-bar and ends of the

frame with only two motions, and pressing the wax firmly to the frame. I cannot tell how many sheets can be put in per minute, from the fact of its being too cold to work wax, unless we have a very warm room, which we did not have; but judging from the machine I worked last summer, fastening only to the top-bar, I think I am safe in saying that when the wax is cut ready for the frame, that I can put in 3 or 4 per minute. We do not know whether there is anything of the kind in use or not.

The machine deposited in the BEE JOURNAL Museum, is without the attachment for fastening foundation in sections. Mr. Goodrich informs us by letter that the latter has been added, and works perfectly satisfactory.

New Publications.

The following new seed catalogues are received:

F. E. Fassett & Bro., Ashtabula, O.
 E. B. Underhill, Poughkeepsie, N. Y.
 Jas. J. H. Gregory, Marblehead, Mass.

Of apiarian price lists for 1882, we have the following:

Edward B. Beebe, Oneida, N. Y.
 J. A. Osborne, Rantoul, Ill.

Mr. G. T. Athern, Latrobe, Pa., has sent us the initial number of *The Reveille*, a semi-monthly devoted to the interests of the G. A. R.

A subscriber in Ontario, sends us a sample of iron wire, and inquires if it will answer for wiring frames for foundation? It will not; use only plated or tinned wire, No. 30 to 36. We have several samples of foundation with plain iron wire, and in every instance corrosion has taken place.

W. C. R. Kemp, Orleans, Ind., has sent us a new smoker. It has the usual bellows; the fire-pot is conical in shape, about 3½ inches diameter at the base, and a syphon connected with the bellows makes of it a cold-blast.

Bees and Fruit.

The New York *Tribune* of Feb. 15, contained the following item in an article headed "Keystone Horticulture," which briefly reported the doings of Pennsylvania fruit-growers in council:

"Many members expressed sentiments unfavorable to bees; one remarked that he saved \$500 worth of fruit in one year by dispensing with his honey-makers. Mr. Meehan said he had positive evidence that bees are most destructive to the grape-grower when the supply of flowers is insufficient for their needs. Others gave similar testimony, and also that they do great damage to the pear crop. Inclosing grape bunches in paper bags, as protection, had several warm advocates. Of this new system all seemed to agree as to its efficacy in preventing insects from puncturing the fruit, but especially for its absolute protection against rot and various forms of fungoid disease. The cost of the ordinary grocers' two pound paper bags, and placing them over the bunches, is trifling compared to the advantage of magnificent bloom, beautiful color and excellent flavor which the covering tends to secure."

This is altogether the most exaggerated indictment against the honey-gatherers that we remember to have met with. But we doubt if that grand jury, THE PEOPLE, will find a true bill against the bees, when the evidence comes to be sifted. Mr. Meehan is high authority on horticultural matters, but we are compelled to challenge his "positive evidence" as to the injury done by bees to grape blossoms. It has been pretty clearly demonstrated that the birds do the mischief to ripe fruit. They puncture the skin, and the economical bees only gather up the luscious juices that would otherwise go to waste. As to the bees harming blossoms, this is the first time we have known this charge laid against them. It is generally supposed that they do good in the fructification of fruit-blossoms; that, in fact, they marry the flowers, and make their nuptials prolific.

We hope the paper bags will be found an effective protection, but should they ever be ripped open, the blame will have to be attributed to the beaks of birds, and not to the mandibles of the bees.

It is rather remarkable that side by side with the forgoing indictment against the bees, thus presenting bane and antidote in parallel columns, the following paragraph appears:

"There is no one simpler or better way of fortifying a child's mind against evil allurements than to teach

him or her how to gather and plant seeds of those pure and lovely hardy flowers the phloxes, which are to be found everywhere in countless variations. They may be sown in a frame in March or in the open garden in April or early May, and if set thinly and kept clean will show their blossoms and the variations of pattern and color, but all bright and charming, the following September. Then will be the time to point out how the bees, by carrying the pollen from one plant to another, cause the mingling of varieties and origination of new ones, and how men-hybridizers of grapes, potatoes, wheat, flowers, fruits, etc., imitate them to great advantage. The child will see the bees dusted with pollen; can mark fingers or noses with the yellow dust; and if there is a microscope at hand can see how curiously the pollen grains of different sorts of plants differ."

Manum's Section Gluer.

This is a machine for gluing the dovetailed sections, which has just been made by Mr. A. E. Manum, of Bristol, Vt. It weighs only 35 lbs. when boxed. Strength in sections for marketing honey is a necessity, and

we are glad to know that "inventive genius" is at work endeavoring to produce a machine to accomplish this as cheaply and rapidly as possible. No matter how accomplished, we want a *strong* section to keep the comb honey intact and prevent leakage. Mr. Manum thus describes his invention:

"My lightning dovetail gluer works to my satisfaction. It is very simple, durable, and easy to operate. A person can put together from 1,200 to 2,000 sections per day with it, and glue them. One of my men has put together with this machine 5 sections in 1 minute. It is worked by the foot, the operator sitting astride the seat. The plunger, to which the glue-pad is attached, has an automatic motion, and makes a dip into the glue at every downward motion of the treadle."

Gone to the Land of Flowers.

Mr. A. T. Williams has moved from St. Charles, Mo., to Gretna, La. He is well-known to our readers as a successful and progressive apiarist. The St. Charles *Cosmos* says he "took with him 250 colonies of bees," and adds:

"He proposes to follow up his specialty of bee-raising in that land of flowers. He has resided in this county for six years, and has made an enviable record, not only as a thoroughly proficient apiarist, but also as a gentleman in his business and social relations. He will take his family with him to New Orleans and will make the Pelican State his home."

Since arriving in Louisiana he wrote as follows from Gretna, La., on Feb. 14, 1882.

I left St. Charles, Mo., and brought a part of my two apiaries to this state early in December. I brought over 200 colonies, and lost only 1 in shipping. My bees were closed up over 3 weeks. I shipped them by steamboat. I am located now, with my bees, about 10 miles above New Orleans, La., on the west bank of the Mississippi river, and about 2 miles from the river, in the edge of the swamp. The location is a good one, I think, orange groves and white clover in front, soft maple, willow, and a vine called Back Jack, in the rear. There is no end to the white clover here, but bees don't take to it as they do in the North; it has been blooming sparingly for a month. The willow, early variety, has been in bloom 10 days. About 100 colonies have commenced work in the boxes. I have 100 Cyprians, and about the same of Italians. I will try and give the two races a fair trial, and report in due time to the BEE JOURNAL.

CLUBBING LIST FOR 1882.

We supply the Weekly *American Bee Journal* and any of the following periodicals, for 1882 at the prices quoted in the last column of figures. The first column gives the regular price of both All postage is prepaid by the publishers.

	Publishers' Price.	Club.
The Weekly Bee Journal,	\$2 00.	
and Gleanings in Bee-Culture (A. J. Root) 3 00.	2 75	
Bee-Keepers' Magazine (A. J. King) 3 00.	2 60	
Bee-Keepers' Instructor (W. Thomas) 2 50.	2 35	
The 4 above-named papers,	4 50.	4 00
Bee-Keepers' Exchange (Houk & Peet) 3 00.	2 80	
Bee-Keepers' Guide (A. G. Hill) 2 50.	2 35	
Kansas Bee-keeper,	2 60.	2 40
The 7 above-named papers,	6 30.	5 50
The Weekly Bee Journal one year and Prof. Cook's Manual (bound in cloth) 3 25.	3 00	
Bees and Honey, (T. G. Newman) ..	2 40.	2 25
Binder for Weekly, 1881,	2 85.	2 75
Binder for Weekly for 1882,	2 75.	2 50

Several correspondents in Michigan, on Feb. 23, reported snow 6 inches deep, with more coming; the mercury being 20° above zero.

Gleanings says: Upon inquiry of one of our best physicians, I find that the poison from the sting of the bee is one of their most potent remedies for a certain class of diseases.

AMONG OUR EXCHANGES.

MISCELLANEOUS.

Bees as Fertilizers of Flowers.—The Chicago *Herald* very truthfully remarks as follows:

It is a well known fact that bees fertilize fruit blossoms by mixing the pollen, thereby making the fruit trees and shrubs produce more and much better fruit than they would without the visits of the bees.

Honey is the purest and most healthful sweet known to man, and should be used in every family in place of the great abundance of adulterated sugars and syrups. The management of bees improves the mind and enlarges the power of observation, and when properly cared for liberal returns are realized for the outlay. There has been great progress in apiculture in the past few years, so much so that an apiarist of 10 years ago would be decidedly behind the times if he has not kept pace with the progress that has been made.

The Use of Crowders.—Mr. E. E. Hasty, in the *Bee-Keepers' Exchange*, thus describes their use in his Gallup hives:

I just don't know whether crowders have ever been used by other folks or not. The general reader, at least, will want a definition at the outset. What is a crowder? A square bit of ordinary board inserted into the combs at the bottom of the frame, to prevent brood being reared there, i. e., to crowd the brood close up to the top bar. Why crowd the brood upward? To bring the brood nest and the sections closer together, that the workers may be more ready to commence storing surplus. The flat frames are an advantage over the square ones, in that the top sections can be placed much nearer the brood. By crowding the brood nest up, the square frames can be put on nearly an equality with the shallow ones in that respect, and that without sacrificing the advantage previously held.

I have only been using this innovation the present season, and not beginning their use very early in the season, I am not ready to make a decided report, as to whether or not they pay for the trouble of putting them in. I am favorably impressed with them, however, and purpose to use them in most of my Gallup hives next summer. Only three frames in the hive need be crowded. If brood is carried up to the top in one frame, the tendency is to carry it up into the adjoining one also. Thus three crowded frames, alternated with four ordinary ones, crowd up the brood for seven frames. Outside of these, brood is not very likely to be carried to the bottom any way, unless it is to get a place to rear drones.

Now as to the manner of insertion. From ordinary $\frac{3}{8}$ lumber saw out blocks 3x3 $\frac{3}{4}$ inches. Choosing frames that have some drone comb, or some badly made comb at the bottom, cut away the lower portion clear across, so as to leave an open space just a little scant of 3 $\frac{3}{4}$ inches. Into this vacancy press three of the blocks, spacing them equal distances apart. The design is to have the bottom as open as possible for the passage and clustering of bees, and yet to have just block enough in to prevent any pieces of comb being started there. To make all secure, draw a piece of fine wire around the bottom of the frame laterally, to keep the blocks from being moved out of place. When the bees have built the blocks fast to the edge of the combs, as they will soon do, the wire can be taken off. If one block 3 $\frac{3}{4}$ x5 was put in the center I presume that the comb in the lower corners of the frame might be left. Usually, however, there is some empty space in the corners which the bees are prone to use for building drone comb, and putting the crowders clear across stops that game. For other frames than the Gallup the size of the block must of course be varied. I am not sure but the Langstroth frame might be crowded up to five or six inches with good effect; but as yet I have made no experiments in that direction.

Seasonable Hints.—Mrs. L. Harrison, in the *Prairie Farmer* gives this "bee gossip":

Bees thus far have wintered well, and to-day, Jan. 11, were busy cleaning house. They are not like some housekeepers, who leave decayed fruit and vegetables until summer, before removing them; for if a mild day occurs, they carry out all the dead bees and debris, thus keeping their hives clean and sweet. Sometimes the entrances to the hives get closed with dry leaves or dead bees, and, if not removed, result in the destruction of the colony. It is a little thing to take a wire or little twig and clean out the entrance to a hive, yet even this small attention may save the life of a valuable colony.

A leaky roof should not be tolerated in any apiary. Paint well applied pays good interest in preserving hives from decay and dampness, and might be brushed into cracks and upon the surface during mild days. We once visited a prosperous apiary where each hive had an extra covering of sheet iron, and which was turned up at the lower side, forming a gutter to carry off the rain.

As bees are active during mild winters they consume much honey, and all those who neglected to feed their bees in the fall should see that they do not starve. In some localities the fall pasturage was abundant, and bees were able to secure ample stores, in others this failed. Some writers claim that syrup made of granulated sugar is the best winter feed, but if this is so, why did not their Creator teach them how to make it, instead of gathering honey from flowers?

The Little Pets.—The Rev. John Irving, Md., delivered a lecture in Kining Park, Scotland, lately. A Scotch paper remarks as follows concerning it:

After describing the history of the bees and their workings very minutely, Mr. Irving said that of all the creatures we are in the habit of making pets of he knew of none more interesting or whose acquaintance is better worth cultivating than the bee, and at the same time he knew of none which has received more ignorant treatment at the hand of man. After giving an interesting sketch of bees and their daily work, he described the use of a bar-frame hive, which he exhibited, also comb foundation, the honey extractor, and other appurtenances connected with apiculture. The lecture was illustrated by enlarged and colored microscopic views of bee anatomy.

Keeping Bees in Paris.—A telegram from Europe states as follows:

The practice of keeping hives of bees in the streets of Paris has spread so extensively that the Prefect of Police has issued an order forbidding it for the future, except in the case of persons who shall have received a special authorization. The preamble of the decree represents the great danger to the population of the existence of so large a number of bees in the neighborhood of the markets, schools and refineries, as well as the opinion of the Council of Public Health of the Department of the Seine condemning the practice.

☞ An exchange remarks: The use of honey should become so common and general that a honey store or depot would be found profitable in every large town. If every family in the land would make honey an article of daily use, in place of the unhealthy syrups, then all concerned would be benefited.

☞ A meeting of the bee-keepers of New Jersey will be held at Hall No. 25, Albany street, New Brunswick, N. J., March 15, 1882, at 10 a. m., to organize a State Bee-Keepers' Association. All interested are cordially invited. G. W. Thompson, Stelton; C. H. Rue, Manalapan; J. H. M. Cook, Caldwell, Committee on Call.

☞ The Texas State Bee-Keepers' Convention will be held at McKinney, Texas, on Tuesday, April 25, 1882.

☞ The Champlain Valley Bee-Keepers' Association will hold their semi-annual meeting at Middleburg, Vt., May 11, 1882. T. BROOKINS, Sec.

☞ The Marshall County Bee-Keepers' Association will meet at the court house in Marshallton, Iowa, on Saturday, March 4, 1882, at 10 a. m. J. W. SANDERS, Sec.

1882.	<i>Time and Place of Meeting.</i>
March 15—	New Jersey State, New Brunswick, N. J.
April 11—	Eastern Michigan, at Detroit, Mich. A. B. Weed, Sec., Detroit, Mich.
19, 20—	Tuscarawas and Muskingum Valley, at Coshocton, O. J. A. Bucklew, Sec., Clarks, O.
25—	Texas State, at McKinney, Texas. Wm. R. Howard, Sec.
26, 27—	Western Michigan, at Grand Rapids. Wm. M. S. Dodge, Sec., Coopersville, Mich.
27—	Kentucky Union, at Eminence, Ky. G. W. Demaree, Sec., Christiansburg, Ky.
May —	Champlain Valley, at Bristol, Vt. T. Brookins, Sec.
16—	N. W. Ill. and S. W. Wis., at Rock City, Ill. Jonathan Stewart, Sec., Rock City, Ill.
25—	Iowa Central, at Winterset, Iowa. Henry Wallace, Sec.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Eastern N. Y. Bee-Keepers' Union.

This Society held its ninth semi-annual Convention at Central Bridge, Schoharie county, N. Y., on the 10th and 11th of July, 1882. The meeting was called to order by President W. D. Wright, at 10:35 a. m. The Secretary's and Treasurer's reports were read and adopted.

The following officers were elected for the ensuing year: President, W. L. Tennant, Schoharie, C. H., N. Y.; Vice President, S. Vroman, Seward, N. Y.; Secretary, Chas. Quackenbush, Barnesville, N. Y.; Treasurer, Zadok Brown, Esperance, N. Y. Also the following honorary Vice Presidents: Benj. Van Wie, Cobleskill, N. Y.; Jas. Markle, New Salem, N. Y.; Isaac G. Quimby, Quaker Street, N. Y.; Theodore Houck, Canajoharie, N. Y.; J. W. Mallory, Worcester, N. Y.; I. Nickels, North Harpersfield, N. Y.

AFTERNOON SESSION.

A committee, appointed by the President, consisting of S. Vroman, W. D. Wright, and Theodore Houck, reported the following questions for discussion:

1. What size honey-box is the most profitable for the producer?
2. What kind of comb foundation is best for use in surplus boxes?
3. What is the best method of introducing queens?
4. Which is the most profitable; side and top boxing, or top boxing alone?

Discussion of the above subjects as follows:

W. D. Wright. I have been using the 2-lb. box, and do not want anything smaller; I think I can get more honey, with much less labor, than with the 1-lb. box. I have all the fixtures for the use of the 2-lb. box, and shall continue to use it.

S. Vroman. I have been using both 1 and 2-lb. boxes; use the 1-lb. box be-

cause they sell in market more readily and for a better price; but think I can get a little more honey using the 2-lb. box. I shall continue the use of both another season, and compare the two more closely as to the amount produced.

M. D. West. I have been using the 2-lb. box, and think it is the most profitable, as I can secure more honey by its use than by using smaller ones; but if I was going to change, I would change to the 1-lb. box.

President Tennant delivered quite a lengthy address on the different sizes of honey boxes, as to the difference in the cost of the 1 and 2-lb.; the cost being only about $\frac{1}{4}$ less for the 1-lb. than for the 2-lb. box. The extra amount of labor and expense it would require to prepare the 1-lb. box for use after being filled, taking just as long to clean and glass a 1-lb. box as it does a 2-lb. box, and many other remarks in favor of the 2-lb. box.

Theodore Houck thought there could be more honey disposed of, and at better prices, by using the 1 and 2-lb. boxes; that the working class of people in the large cities would often buy honey in the 1 lb. box, when they could not afford to buy 2-lbs, and, therefore, thought the 1-lb. box brought it within reach of the poorer class.

President Tennant then called on the balance of the members present to state the kind of box each used. A short experience from each member showed that there were many different sized boxes in use, but all held nearly the same amount of honey—from $1\frac{1}{2}$ to $2\frac{1}{4}$ lbs, averaging nearly 2 lbs, or what would be termed a 2-lb. box. After the conclusion of the discussion, a vote was taken to ascertain the sentiment of the Convention, which was unanimously in favor of the 2-lb. box.

Question No. 2 was next taken up, which showed quite a difference of opinion among members, as follows:

S. Vroman had at first used the Root, in three-cornered starters; but of late has used the VanDeusen flat-bottom in full sheets, to his entire satisfaction.

W. D. Wright had also used Root in small starters, but of late has used VanDeusen flat-bottom in full sheets.

W. L. Tennant had used Root foundation in small quantities, but has used mostly VanDeusen and Vandervort, and think these are among the best in use, and shall continue to use them the coming season, weighing about 10 square feet to the pound.

J. J. Bivens had used both kinds on one hive—the Vandervort and VanDeusen—and the bees would fill the boxes which contained the Vandervort, and leave the flat-bottomed untouched.

Zadok Brown said his bees would work quicker on foundation than they would on natural comb. The President again called on each member present to state the kind he used; there was quite a large number of beginners that had not used foundation of any kind, while those that had were the same as already mentioned.

SECOND DAY—MORNING SESSION.

The next question for discussion being, which is the best method of introducing queens? Vice President Vroman gave a short address on the subject. He had tried various methods, and favored introducing as soon as the colonies are deprived of a queen—has no particular method.

Theodore Houck had introduced about 1,000 queens during the last two years, with good success, and had in most cases introduced immediately after depriving the colony of their queen. Had used the Peet cage almost wholly, and thought the best time to introduce queens was just when the bees found out they were without a queen; and in order to do this successfully, would first cage the queen in the Peet cage and fasten it on the comb, according to directions, and pull the tin slide out, giving the bees a chance to release her by gnawing through the comb on the under side of the cage, and in most cases they will at once accept her.

Zadok Brown said he had some experience in introducing, and had partial success with the Peet cage.

It was universally conceded that the proper time was just after removing the old queen.

Question No. 4, opened by J. J. Banta. I have used side and top-boxes; but prefer top-boxing, and of late have used top-boxing alone; use 2-lb. boxes, 21 to the colony.

P. Palmatier. I have been using side and top-boxes, but shall discard side-boxes the coming season, and use top-boxes alone.

S. Vroman used broad frames and top-boxes; used them because he thought that top-boxes did not give surplus room enough for a good strong colony of bees; he did not like to discard the broad frame, as he was afraid he would not get as much honey.

A committee was appointed to act with the secretary to revise the constitution and by-laws of this Union, consisting of M. D. West, W. D. Wright, and J. J. Banta.

A vote of thanks was tendered to Theo. Houck for his display of apiarian supplies, such as smokers, honey-knives, bee-feeders, comb foundation, wire nails, queen cages, honey labels, etc.

The meeting then adjourned to meet again May 2d and 3d, 1882, at Cobleskill, Schoharie county, N. Y.

W. L. TENNANT, Pres.

C. QUACKENBUSH, Sec.

The semi-annual meeting of the Tuscarawas and Muskingum Valley Bee-Keepers' Convention, will be held in the Town Hall at Coshocton, O., on April 19 and 20, commencing at 10 a. m. A cordial invitation is extended to bee-keepers everywhere.

J. A. BUCKLEW, Sec., Clarks, O.

The Texas State Bee-Keepers' Convention will hold its meeting at Judge W. H. Andrews' Apiary, at McKinney, Texas, April 25, 1882.

WM. R. HOWARD, Sec.

CORRESPONDENCE

For the American Bee Journal.

Producing Comb Honey—No. 2.

G. M. DOOLITTLE.

In No. 1, I told you how I managed all the good, strong colonies I had in the spring, to get them in good working order for gathering honey by the time the harvest from white clover arrived. It often happens that all the colonies in an apiary are not thus strong, and as I am requested by several to give my method of treating the weaker ones, I will do so, although it will be somewhat of a repetition of what I have before written on the subject.

Several years ago, when I wished to unite weak colonies in the spring, I did so early in the season, for the "books" said that the time to unite was when it was discovered that two colonies were too weak to be of use alone, which generally happened in April. That uniting two weak colonies to make one strong one is profitable to the apiarist, no one will deny, (unless, perchance, we are obliged to use everything in the shape of bees, as we were last season, in order to get our former number back again after a heavy loss); still, that uniting must make the *one* better than each of the *two* would have been when the honey harvest arrives, or our labor of uniting is worse than useless. After practicing the plan given in the "books" for a year or two, I became convinced that colonies thus formed were no better, at the end of two or three weeks, than each one would have been had they been left separate. I have put as high as seven remnants of colonies together in April, the seven making a good large colony at the time, and in a month all were dead. After coming to the conclusion that I could not unite bees with profit in early spring, I adopted the following plan, which has proved successful so far:

About the middle of April, some cool evening, I look over all my bees by removing the cap and raising the quilt a little, so I can see how strong in bees the colonies are, and all that do not occupy five spaces between the combs are marked, and the first warm day are shut on to as many combs as they have brood in, and a division board placed in the hive so as to contract the hive to suit the size of the colony. Honey enough is provided to keep them amply for two weeks, and the rest of the combs I store away for safe keeping, unless some of the strongest of them are able to protect them from robbers, in which case I leave them outside the division board, so the bees can carry honey from them as they wish. The entrances are contracted so as to let but one bee pass at a time for the smallest colonies, while the larger ones do not have

more than an inch in length of entrance given them.

The next work is to increase the brood as fast as possible in these small colonies. I keep them shut on the combs first given them till they are filled with brood clear down to the bottom, before they are given more room. As soon as this is accomplished, I give them a comb of honey prepared as I told you in No. 1, placing it between two full combs of brood. In about a week this comb will be filled with brood as full as the others. I go over them once a week in this way till I have five frames of brood in the strongest, when I take a frame of brood just hatching out from those having five full frames, and give it to the next strongest, say, one that has four frames, putting a frame of honey in the place where it came from. Thus, I keep working till all of them contain five frames of brood, which should occur from the 10th to the 15th of June in this locality. I now go to No. 1 and open it, looking the frames over till I find the one the queen is in, when it is set outside and the four remaining frames and all the adhering bees are taken to No. 2; I then spread the five frames in No. 2 apart so as to set the four frames brought from No. 1 in each alternate space made by spreading the frames in No. 2; No. 2 is now closed up and in a few days it is ready for the boxes. It will eventually make as good a colony for storing in boxes as the best of the stronger ones; at least such has been my experience so far. I have never known bees to quarrel, nor a queen to be harmed by this plan of uniting, as the bees are so completely mixed up that they do not know what to fight about.

But to return to No. 1, where the queen and frame of brood were left standing outside the hive. I now place this frame of brood back in the hive and put an empty frame beside it, adjusting the division-board, and I have a nice nucleus from which to get a queen to be used in swarming, as given further on. Many of the old bees carried to No. 2 will return, thus making a strong nucleus, which will fill the empty frame with nice straight worker comb in a few days, and still another, if the queen is left long enough. By-the-way, let me say that such colonies will build comb at a less expense than is required to purchase and fill frames with comb from foundation, besides the bee-keeper keeps such amount to expend on something more necessary to him than foundation for the brood frames. Now, if I wish no increase of colonies during the season, I serve my whole apiary as I did Nos. 1 and 2, beginning early enough to be sure that none have brood in more than five frames. By putting boxes on the strongest just before apple blossoms, and a few boxes are often filled from this source, as the bees must work in boxes if at all, when shut on five frames. It will be seen that I use nine frames to the hive, but the plan is the same with any number of frames. This having every frame in a hive crowded to the fullest capacity with brood two weeks

before the height of the honey harvest, has much to do with a good yield of honey, I assure you. This is the condition I aim to have all my bees in, and I have tried to tell you how so you can do the same, if you wish to adopt the plan I follow. My next will be about preparing and putting on section boxes.

Borodino, N. Y.

Bee-Keepers' Compass.

H. T. COLLINS.

In order to reach the haven where he would be, every bee-keeper, like the mariner, should be guided by a compass, and I herewith send a few ideas concerning one, in hopes that it may induce others to add their quota and "to box the compass" in their own way.

To simplify matters, this compass will not have as many points as the mariner's.

NORTH.—A choice queen. This is the pole star leading to success. She should be not more than two or three years old, and whose offspring must have the following traits: Longevity, which includes hardihood, industry, docility, and let us add beauty, if for no other reason, because it is a sign of good stock.

NORTHEAST.—Keep no scrub stock but supersede it, otherwise there will not be the opportunity of selecting these choice queens above mentioned.

EAST.—Strong colonies. As nature cannot provide her stores of boundless wealth without the daily rising of the sun, and the visit of his countless rays, so the blessed bees cannot "make boot upon the summer's velvet buds" unless they are strong in numbers, and abounding in courage.

SOUTHEAST.—Know at all times the condition of the hives. Do not be satisfied by *thinking* that that colony is prosperous, but find out by inspection, and if it needs your help, give it without delay.

SOUTH.—A comfortable home. That is, let the hive be shaded from too much sunshine in hot weather, and yet be so situated as to have a good circulation of air. To be *comfortable*, the hive must not be so restricted in room as to compel the bees to "lay out," nor so roomy as to afford more space than they can well occupy and guard. The bee-master can easily furnish this condition by means of that wonderful trinity of helps, the movable frame, extractor, and foundation. Only with a comfortable hive, and everything ship-shape can

"The busy bee improve each shining hour,
And gather honey all the day from every opening flower."

SOUTHWEST.—Provide bee-pasture. When this is done, it seems to me that a good many of our present troubles will be over. Colonies will then be in an active and normal condition during all the working season, much robbing, ill-temper, and "general cussedness" will be done away with, and the stock will go into winter quarters strong in young bees, and well supplied with sealed stores.

WEST.—Early provide for winter quarters. As the setting sun betokens the time for and the need of rest, so when

"The melancholy days are come the saddest of the year,
Of waiting winds and naked woods, and meadows
brown and sere."

then the successful apiarist makes all snug and safe for winter according to his best knowledge and ability. He sees to it that the colony has a young and vigorous queen, great store of young bees, and suitable food, be it honey or sugar syrup. He puts them into winter quarters in the cellar, or on their summer stands according to his locality and experience.

NORTHWEST.—A good and quiet rest. Do not disturb the bees more than is actually needed, while in winter quarters. If on the summer stands, have no rabbits and dogs, or other stock fooling around, and do not awaken them out of their quiet sleep, by jarring the ground, which is too often done by walking or driving near them.

Jacksonville, Ill.

For the American Bee Journal.

Talk about Sundry Bee Matters.

WM. F. CLARKE.

In common with all who have expressed themselves on the subject, I think the present size and "get up" of the BEE JOURNAL all that can be desired. It will make a very handy volume for reference when bound, and is not too large for the shelf of an ordinary bookcase. The editorial management also deserves high praise.

"THOSE FINE BEES IN CANADA."

Mr. Henderson hardly does me justice in complaining of my "failing to remember little Tennessee, or the name of that little Tennessean who furnished Mr. Sturgeon with those fine queens," I saw in the Kincardine apiary. Yet he had refreshed his own memory by looking at my communication in No. 29, July 20th. How then came he to say I had failed to remember "little Tennessee?" These were my words: "Mr. S. procured a dozen queens from Tennessee, I forget how long since, and also imported a few from Italy." Since I have been pulled over the coals for it, I am compelled to state in self defense, that Mr. S., for reasons best known to himself, requested me not to name "that little Tennessean." So I am cleared. I surmised that the dollar-queen business might have had something to do with his reticence, but may have been wrong. However, if all goes well, I shall sample Mr. Henderson's queens for myself, and then I can "speak in meeting" without let or hindrance. Mr. H. seems to harp on the word "tentative," used by me. I thought it was very modest and suitable. See its dictionary meaning.

MR. MACE'S KIND PROPOSITION.

Mr. Mace wishes experiments made with alcohol as a remedy for bee-stings, and as his "wife and father-

in-law" think it would be "too much much like suicide" for him to try them, he kindly suggests that I make a martyr of myself in the cause of apiculture. This is considerably like Artemus Ward's disinterested willingness to have his wife's relations go to the war. I had thoughts of calling a family council in regard to the matter on first reading Mr. Mace's proposal, but fearing it might be decided that it was my bounden duty to suffer for the public good, I concluded to take the responsibility of acting for myself, I therefore beg to decline submitting to the proposed ordeal and would suggest that there are plenty of men fonder of whisky than I am, who would be quite willing to take a sting and a drink turn and turn-about, for the indefinite period indicated by Mr. Mace. I am not a rabid temperance man, still I think the remedy might prove worse than the disease. Alcohol has a sting as well as the honey-bee, and it would be a melancholy thing if any one were to begin using alcohol to antidote bee-stings, only to find out that, "at the last it biteth like a serpent, and stingeth like an adder." Let us ransack the entire pharmacopeia for remedial appliances, before we add another to the thousand and one excuses which people make for using spirits. For myself I get along passably well with veil and gloves, and after seeing a Cyprian colony sting Mr. Jones to their heart's content, and finally drive him into the bushes, I don't feel it any disgrace to wear them.

PROFESSOR COOK.

The Professor's nice little article on "Honest and kind criticism," in the BEE JOURNAL of Feb. 8, has taken quite a load of anxiety off my mind, but still, influenced by the curiosity which is natural to all the sons and daughters of Eve, I am aching to know who that apicultural ignoramus is. In Yankee phrase I would say, "du tell." The Professor promises to "explain more fully in regard to the pollen matter." There are other points that await explanation; that of "dry feces," for example.

N. A. BEE-KEEPERS' ASSOCIATION.

I thoroughly indorse your editorial remarks on the proceedings of the Northeastern Bee-keepers' in regard to the "National" organization, as you call it, but please remember, it is a continental body. Its name was given to it for the express purpose of including us Canadians, and though but few of us have ever attended its meetings, it must be remembered that Chicago is the nearest place to us at which it has ever been convened. We live in hope that some time it may be held at Detroit, Buffalo, or some border city, possibly in Toronto itself, and then you may look for a grand muster of bee-keepers from this side of the lines. Having assisted at the birth of the North American body, and watched its history closely ever since, I hardly think it is open to the charges made against it. At the outset there were little jealousies which it happily allayed, and all the meet-

ings I have attended, have been pleasant reunions of kindred spirits. It has certainly done much to form and strengthen "a brotherly tie," and I would earnestly say, "destroy it not, for a blessing is in it." Perhaps it was not wise for the convention to endorse Mr. Bingham's views quite so fully. Still, I am sure there was no intention of robbing Mr. Quinby's honored brow of any of its well-earned laurels. I do not concur in the representation of Mr. Quinby's labors as belonging to the closing chapters of old-time apiculture. They helped largely to usher in the new era, and the eminent services of Messrs. Langstroth and Quinby (I don't know which should be named first in order of time), will go down to history as the "twin-brothers' yeast" that has leavened the whole lump of modern bee-keeping. I had the pleasure of knowing Mr. Quinby personally, and can fully agree with the graceful tribute to his memory penned by Captain Hetherington as a preface to the new edition of the "Mysteries of Bee-keeping." Mr. Quinby was himself so modest, that those who knew him best do well to guard his fame, still I think Mr. House has been unduly excited. No "heinous offense" has been committed; no "unjust discrimination" perpetrated, and I hope the kind words penned by yourself and others may have the effect of "oil on the troubled waters."

THE PRESENT SEASON.

I fear the "cold dip" we had about a month since has proved very destructive to bees. Here the thermometer went down to 30° below zero, and in some parts of Canada it was even lower. On Tuesday last, Feb. 14, it was mild enough for bees to fly, and I saw evidence enough in my own little apiary of the havoc done by the Arctic wave. Having no cellar or bee-house, I am wintering out of doors in chaff hives, with the exception of a single colony, which is in a plastered hive. The "cold dip" seems to have caught the bees suddenly. One colony was much spread out on the combs, and had entirely succumbed. Another, partially scattered, was reduced to great weakness, and others appear to have had the outer circle of the cluster chilled to death. This is my first trial of chaff hives, and I must own, I have serious doubts as to its suitability for the climate of Canada, unless, indeed, we thicken the walls.

PARLOR WINTERING.

This is a failure for the present season, but I believe I know the reason. The bees were not housed soon enough. There had been some cold nights before they were taken indoors, and I think a mere handful of bees once chilled through is not apt to recover. My little colonies never seemed lively, they acted as if they had the rheumatism, or a bad cold. They never fed to please me, and gradually dwindled away. So, Mr. Heddon will not have the pleasure of crowning me as a great discoverer just yet. But I am not discouraged.

My bees lived until the "cold dip," and in my absence the room was fireless. But for that, they would have survived longer. As it was, they lived two months in their little prison. If, under unfavorable circumstances, they lived two months, I argue that, under better circumstances, they may survive four. I have learned some lessons by this little experiment, which will enable me to improve upon it hereafter. That we shall find a way of applying artificial heat for the wintering of small colonies, is a cherished dream of mine, though I am free to confess that it may prove "but a dream."

Listowel, Ont.

For the American Bee Journal.

Experience With Cyprians.

L. JOHNSON.

I purchased an imported Cyprian queen from D. A. Jones in October, 1880. During the summer of 1881, I reared quite a number of queens from her, 14 of which I placed in full colonies in order to thoroughly test them. Several others I placed in the hands of bee-keepers who were capable of judging of their qualities. From these, as well as my own experience, I am able to form a pretty fair estimate of their character, etc.

1. The prolificness of the queens is quite noted, the imported mother, as well as daughters, keeping a large amount of brood until late in the fall; but their progeny seemed short-lived. The increase of bees in the hive was not equal to the amount of brood—Italian colonies not having so much brood, but increased in bees much faster. All winter long, since brood-rearing ceased, the Cyprians have dwindled rapidly. The bottom-board of most of them is often covered with dead bees, while but few are dropping from Italians. This characteristic was especially noticeable during November and December. Whether this feature will continue until spring, remains to be seen; but if so, there will be but a handful of bees to begin operations; but, as brood-rearing is now commencing with us, we hope the worst is over.

2. Their honey-gathering qualities are not equal to the Italians; or, if it is the vast amount of brood that consumed it so rapidly, that the show for surplus was poor indeed.

3. The hard name some have given Cyprians for irritability, has not been verified in my experience. They are quite nervous on first opening the hive, but soon quiet down so as to be easily handled; but if a few robbers are searching around, they soon become so much excited that all operations must cease. In all other points I see no difference between them and Italians. Taking the two races together, I shall certainly prefer the "old reliable" Italians, as bred by such men as Salisbury, Brown, Alley, and others. While I deeply sympathize with Mr. Jones in his earnest and expensive efforts to improve our bees by introducing these new races, yet I

very much question the success attained. Undoubtedly, the bright color and beautiful form of the Cyprians will make them favorites with many, yet by carefully selecting our queen mothers among Italians, even this latter point may be rivaled if not excelled.

Each year I am more convinced that "that coming bee" will be the purest and best type of the Italian race.

Walton, Ky.

For the American Bee Journal.

Salicylic Acid and Foul Brood.

A. R. KOHNKE.

In reply to Mr. Jones' proposition, I must say that I am perfectly delighted with his article. We agree, it seems, on all but one or two points. Mr. Jones says salicylic acid does not cure foul brood, which cure I offered to prove. Mr. Jones did not accept my proposition, but has done the other thing, which I expected he would, to-wit: given us his remedy. I am very well pleased with that substitution; but having had no experience with the starvation cure, it will not do for me to say it can or cannot be done. Perhaps all contagious diseases can be cured by starving the subject infected. Bee-keepers have to choose now between three different remedies. 1st, starvation, 2d, borax and salicylic acid in water, 3d, salicylic acid in alcohol, proportion one to ten. If they wish to get wise by "experience," I would advise them to try in the above order, and report success.

As Mr. Jones has declined my proposition, he will certainly excuse me from accepting his; meanwhile, I shall hold on to disinfectants if my bees get the disease, for it is whispered that foul brood made its appearance in this county last summer.

In his reply to my review, Mr. Muth evidently wishes to overthrow the force of my argument by referring to my limited experience, as far as he has observed, which dates from the fall of 1877. It will probably avail very little when I state that I have handled bees from my very childhood, for, as Mr. Heddon says, "how can you prove the experience?" Besides, "experience is a dear school," and I prefer to get my knowledge some other way if I can, as Mr. Muth surmises. But my experience is not the question at issue.

If I have been obscure in my statements in that article, I will briefly state the several points I wished to make, once more: 1. That the solution of one part of acid in eight of alcohol is too strong. 2. That Mr. Muth on two different occasions gave solutions of different strength of a remedy of his own invention, which, if the remedy had any effect, shows inconsistency. 3. That the solution of borax and salicylic acid cannot be used with success in curing foul brood.

To prove the foregoing, I cannot assert my own experience, for Mr. Muth says I have none; so I must go to some higher authority and will in-

clude Mr. Muth himself. Mr. Muth claims to have used the solution recommended by Hilbert, thereby killing his bees. Why, if it was the same, did it not kill Hilbert's bees? Again, it has been found to kill bees, or rather brood, if used too strong; now, as Mr. Muth's bees did die, I infer he used it too strong, and he, not I, has misunderstood Hilbert's directions.

To prove the second point is, perhaps, not necessary, as he gives a little more precise directions how to use the different solutions, under different conditions, though he has not done so on former occasions; at least I am not able to find them.

To prove the third point, I referred, as authority to the dispensatory of the United States, which is certainly a higher one than the assertion of any druggist to the contrary. This is a standard work, published to guide and instruct druggists; and the article on salicylic acid is given in condensed form from Professor Kolbe's book "On the Effects of Salicylic Acid," this gentleman being the highest authority on the subject. Hence, the assertion of Mr. Muth being able to cure foul brood with a mixture of borax and salicylic acid, is contrary to the experiments and experience of Professor Kolbe, and Mr. Muth cannot deny assuming higher authority than the above named gentleman, if he persists in claiming to be correct. Of course, if that is the case, I must acknowledge to have been mistaken. If my bees get the disease next summer, I will call a convention of bee-keepers to show them how I open a hive and cure foul brood, to prove "experience."

Bee Items from Mississippi.

OSCAR F. BLEDSOE.

Having been for some time engaged in ginning my cotton crop, on my plantation in the Yazoo Valley, let me say that this Valley promises much for the intelligent apiarist. The bloom is very luxuriant and rich in honey, such as the ratan, tupelo gum, various climbing plants, maple, red-bud, etc.

I have thought of establishing a large apiary down there, if I could procure desirable help. Until I have fully verified it, I will not say that any Southern locality I know of would be a good place to produce honey in large quantities for shipment. I am sure, however, that there is no risk or extra trouble here in wintering; that bees will always get enough honey to live on and prosper, and that every Mississippi farmer, by managing intelligently a few hives of bees, using extractor, etc., could procure ample surplus honey for his own use, if not some for sale. I propose to persevere in my attention to bees, believing that there is remuneration in the business here.

Last year I sold honey and bees enough to pay me back all the cash I

have ever spent on bees, and 50 per cent. profit besides, so that my apiary, books, periodicals, implements, material for a large increase, in hives, etc., are all clear gain.

My bees are all doing well, only 3 nuclei having absconded during my absence. I use a shortened Langstroth frame which can be adjusted temporarily in any hive of that depth. A short Langstroth frame is the *ne plus ultra* of a frame for rearing queens, and nuclei, and for shipment; also, in this locality, is the hive for all purposes of an apiary.

One-Piece Section Boxes.

BYRON WALKER.

My attention has been called to articles in the BEE JOURNAL of Jan. 25, in relation to the section controversy.

The first of the articles in question is from the pen of E. A. Thomas, of Coleraine, Mass., the other from James Fornerook, of Watertown, Wis. Lest silence be taken for consent to the views and claims referred to in behalf of the friends of one-piece sections, I will attempt to reply:

While I heartily indorse the views of Mr. Thomas with regard to the relative merits of the 1 and 2-lb. section boxes, I cannot admit the correctness of his criticism on the one-piece section box, as compared with the dove-tailed box. Mr. Thomas tells us that one-piece sections cannot be bent into shape without cracking the corners, as rapidly as the dovetailed sections can be driven together; that it required skilled labor to do this quickly; and that only those that use a large number of sections can hope to acquire the requisite skill. These are important points, and deserve careful attention. There are many things to look at, if we would reach a right conclusion in attempting to decide this matter. Very much depends upon the timber used in making the one-piece sections. If they are made of material thoroughly seasoned, Mr. T. is correct about its being a nice job to bend them rapidly without cracking the corners, especially if the sections have not been first steamed. On the other hand, if the sections are made out of timber from small, tough basswood, recently seasoned and steamed immediately before bending, they can be put together at least twice as fast as it is possible to make dovetailed sections with a mallet—the steaming of the sections being reckoned as a part of the process of putting together the one-piece sections.

There is another point in this connection that should not be overlooked in determining the rapidity with which these sections can be safely bent and the kind of labor to be employed for the purpose, and that is, the kind of grooves that are used for the corners. If these grooves are triangular, the sections can be bent very quickly, other things being equal; but if the section should break while bending, it is perhaps more trouble than the sec-

tion is worth to repair the break. On the other hand, if sections having a square cut at the corners are to be bent, great care must be taken in folding, or the sections will be bent at the wrong points, and so make one or more of its dimensions too long or too short; but if correctly bent, and the section should break from any cause at a corner while bending, it can be readily mended with wire nails.

There is still another style of one-piece sections, that differs from the last mentioned, only in having the square grooves so modified that the section always bends at the right points without any coxing; and in having the extremities of the sections joined with wire nails instead of dovetailing. I prefer this style of section to any other that I have yet seen, as it requires very little practice to put them together rapidly, and when put together, they make much the strongest section.

The second objection urged by Mr. Thomas, is, that it is not as strong as the dove-tailed, and that when filled with honey, they are liable to become broken or leaky, unless very carefully handled, while in the hands of the grocer, or before it reaches the table of the consumer; and to give point to this objection, he gives the report of a conversation, as a witness to which I suppose Mr. T. was present, in imagination at least. Now, I submit, if Mr. T. has had any such practical experience with these sections as he calls on us to imagine, would it not have been in better taste to have given us the benefit of that instead of what he has given us? At any rate, I venture to say, if he or any one else has had any such experience, it was while handling sections made of poor material or flimsily put together, or both.

I have handled a large amount of honey in a great variety of packages, including dovetailed sections. I have never had any package give such general satisfaction to all concerned, as these same one-piece sections; in fact, I have yet to hear the first complaint against them, when made as above described. On the other hand, my experience in handling dovetailed sections, is somewhat similar to the imaginary one related by Mr. T., with the imaginary element left out. I remember one lot in particular, that I purchased of parties who get their sections from the most extensive manufacturer of dovetailed sections in the United States (he has since discarded them, and now makes the one-piece section only), so that they ought to be a fair sample of such sections.

Well, in handling this lot, I had occasion to scrape the propolis off the sections before offering them for sale; and although the utmost care was used to avoid breaking sections, or starting leakage, about one out of every twenty sections was rendered unfit for market before the process was completed, owing to lack of strength in the sections.

I do not wish to be understood to claim that it is impossible to obtain dovetailed sections sufficiently strong, but I do claim that such sections are not a fair sample of those offered for

sale. With regard to using glue to add strength to one-piece sections, I will say that I have never had occasion to make use of it for that purpose, but am assured by those that have tried it that it is a success, and that the time consumed in applying it, is hardly worth mentioning.

For the benefit of those who find it necessary to steam the sections before binding, and who have not the privilege of using a steam box for the purpose, I would suggest that the wax extractor placed over a kettle of boiling water, using a piece of a board nearly covering the top to confine the steam, will make an excellent substitute; or even a common tea-kettle with the top removed will do very well.

Mr. Fornerook claims, in the communication referred to, that he has been obliged to advance the price of sections, owing to basswood lumber having advanced one-third in value. Is it not a trifle strange, if Mr. F. is correct about this, that he is the only dealer in one-piece sections that seems to have found this out? Even Mr. Lewis, who resides in his own (Fornerook's) village, asks less for sections this year than he did last. The sections he advertises however, this year, are a trifle less costly than those he sold last year. But Mr. A. I. Root should reply to this article by Mr. F.; but, to my mind, we have sufficient reply in the following editorial in *Gleanings*, for February, which I quote verbatim: "Before us is a copy of a patent granted to H. W. Hutchins, of East Livermore, Maine, for a plan of making boxes of one piece of wood, precisely like the Fornerook sections, even to the V shaped groove, dovetailing in the ends, and all. The drawing makes it so plain, it is difficult to conceive that Fornerook's was not copied from it."

Do Swarms Pursue a Straight Line?

Q. C. JORDAN.

I have been keeping bees for 15 years, but never had a great many at once, neither did I ever derive much profit from them, for I never gave them the attention required to make them profitable. I have, of late, become more interested in trying to improve them than ever before. Some time ago I purchased a colony of Italians from Henry Alley. On the 17th day of April last, that colony gave a swarm, and continued to swarm every few days until they had increased to 9 good colonies. Two of them absconded, and I had heard it said that bees always went in a straight line when they swarmed until they stopped, noting particularly the direction they went. I took my compass and found they went N. 64° W.; so I put out and went over fences and ditches, woods and swamps, until I came to Broad River, a distance of 6 miles, and I saw nothing nor heard anything of them. I concluded I would go across and go up on top of the hill on the other side,

and inquire if any one had seen them? As I was crossing the bridge a few steps below where I struck the river, I met Mr. Patterson. He, seeing my compass, was curious to know my business. I told him I was pursuing some fugitives, and wanted to know if he had seen anything of any parties eloping? He said he had not. I told him they must have passed close by there, as that was in the direction they were going. After I had worried him awhile, I explained the matter to him. He then told me that my bees were up at the house, already hived, and at work, and that Mr. Jackson, the man that had hived them, was gone from home. I told Mr. Patterson that I must have my imported bees, and that I would come back some day after them, which I never have done.

This satisfied me that bees do go on an air-line when swarming and leaving. Another experiment with the compass with the other swarm that left, proved the same fact. I am of the opinion that bees do not go over 6 or 8 miles generally, when they abscond. The notion entertained by some, that they have a home selected before they leave, is certainly incorrect, as the swarm above referred to settled on a bush on Mr. Jackson's spring path, and his wife found them in the act of settling.

Franklin, Ga.

For the American Bee Journal.

The New Bees, Queen-Rearing, Etc.

D. A. PIKE.

Having had experience with the Syrian bees, I must say that my impressions are not favorable to them. They did not gather enough honey to last them till cold weather came. I gave them honey from my other bees twice, before putting them into winter quarters. I have only discovered one good trait about them: the queens are prolific. But what does that amount to, if the bees do not gather enough honey to live on? I never saw a Syrian bee come in with a heavy load of honey. If fertile workers are wanted, get the Syrian bees.

If mine live till next spring, I will keep them till the first of July, and if they do not prove better honey gatherers in the future than they have in the past, off goes their heads.

I shall not sell any more Syrian queens till I have tested them more myself. Mr. S. Valentine's experience in the last BEE JOURNAL is about the same as mine. We Marylanders claim to have better bees than the Syrians.

Much has been said about rearing good queens. Some claim that they should be reared from 3 or 4 colonies. I hold that a queen-breeder should have his queens bred up to such a standard of excellency, that he need not be afraid to rear queens or drones from any colony in his apiary. Then he is prepared to send out good queens to his customers, and not till then! What would be thought of a queen-breeder who says that he intends to rear all his queens this season from

one queen, and all his drones from one or two other queens, and then say that he had fifty or one hundred orders in for early tested queens, as is always the case with queen-breeders. Do you think his customers would get queens fit to rear queens and drones from? hardly; or he would not need to be so particular about rearing all his queens and drones from a few colonies.

Smithsburg, Md.

For the American Bee Journal.
Another Partial Review.

T. F. BINGHAM.

It seems to me that the resolutions passed at the Northeastern New York Convention are aimed at a man of straw. When they specify smokers in the resolution they design to censure.

I am sure there was no allusion in my poor short essay to smokers. It did not contain the word, neither did it refer disrespectfully to the late lamented M. Quinby. Is it disrespectful to say "The early writings of the lamented M. Quinby, called 'The Mysteries of Bee-Keeping,' which were among the most conspicuous of the closing era?"

Will the gentlemen please notice the quiet sarcasm implied in the titles: "Quinby's New Bee-Keeping," and "New Quinby Smoker." Would any one suppose the book or the smoker to be *original*, from the titles? Either the new gets a compliment or the old gets a slur.

I trust there will never be so little of my smoker left that it will have to be advertised as the "New Bingham Smoker."

I am sorry to mention matters which should be in an advertisement, but the Convention report, already published, has made it necessary. President Clark evinced a wonderful faculty for overlooking the facts when he said that he "would not use a Bingham smoker under any consideration; that because Quinby did not get a patent and Bingham did, we are obliged to pay for it." The facts are that Bingham sells for 65 cents, postage paid, a $\frac{1}{3}$ larger and much better smoker than Mr. Quinby did for \$1.50, which was his (Quinby's) regular price for the old and now obsolete Quinby smoker.

When Mr. A. J. King first began to make my smokers, he advertised them as the "New Bee-Smokers;" afterward he offered to pay me a cash royalty for a license to make them. At the Chicago National Convention he told me he gave me the credit of the invention, but thought he had a right to make them as he was then making.

Abronia, Mich., Feb. 8, 1882.

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.

G. W. DEMAREE, Sec.

Christiansburg, Ky.

SELECTIONS FROM OUR LETTER BOX

Sweet Clover.—The thermometer stands 66° above to-day; bees flying lively and carrying in pollen for the first this year, the earliest I ever knew. My 31 colonies, all in good condition, had flights about every week this winter. The lowest fall this winter was 18° below, ranging from 35° to 55° above, but weather was very wet. My bees are mostly blacks and hybrids, packed in wheat straw on summer stands. We have no sweet clover in this country. I sowed some last fall in my garden, but if it has ever come up I cannot see it. What does the plant look like. It seems from the reading of the BEE JOURNAL, that it grows spontaneous around Chicago. We do not have much here for bees, only white clover, and that lasts until about the 10th of July, and after that our honey season is over for surplus. I like the BEE JOURNAL, but would like it better if it was a daily or tri-weekly.

L. T. MOBBERLY.

Long Grove, Ky., Feb. 19, 1882.

[Your sweet clover planted last season will undoubtedly come out all right. Its germination is of very slow development, hence it is better to sow it in the fall, or very early in spring, while it will yet get several sharp, severe frosts, to assist in bursting the hulls.

Sweet clover was sown in the western part of this city some 12 or 15 years ago, and now prevails to quite a liberal extent in the suburbs, and along the railways and roadways running into the city. Many farmers and bee-keepers have assisted to spread and perpetuate it, for their bees and grazing animals. It is found very good to plant along newly made roads, as the deep and matting roots have a tendency to retard wash-outs and gullies. The young plant has much the appearance of white clover, excepting that they grow more erect from the seeds.—Ed.]

Successful Wintering.—I packed twenty-four colonies of bees last fall, in the improved Quinby hive, on the summer stands. All are now doing well, I never have lost a colony yet. I pack in chaff, in Quinby hives, just as described by Mr. Poppleton, at the Michigan State Bee-Keepers' Convention, at Battle Creek. I do not think any bee-keeper ought to "kick" on Mr. Jones for selling queens this side of the line. My bees came into the shop yesterday after honey in some combs I had sitting out. Success to the Weekly; I should be lost without it.

S. S. BRISTOL.

Galesburg, Mich., Feb. 21, 1882.

Bee-Keeping for Profit.—In order to make bee-keeping pay every year in succession, we need experience, because experience will teach us, as nothing else will, that it pays in the long run to let bees have all the honey in the hive they can possibly use, at all times, for with us what is a harvest one year may fail the next, and what fails the first year will give plentiful bloom the next, and if not a plentiful bloom, if bees are very strong, or rather have an abundance of honey in the hive, they seem much more inclined to gather it. In 1881, the year just passed, our bees paid well, although the early part of the season Mr. Axtell and myself were both very sick for some weeks, and our bees suffered for care; but as they had a great abundance of honey at all times of the year, they did not feel the neglect that they would have done if on scanty fare. We do not believe it pays to give bees very close attention if we have to hire inexperienced help to do it, unless we can be with them; or if they do have experience, if they are careless or neglectful they will injure the bees more than they will do them good. If bees have an abundance of honey in the brood nest abundance of bees and a large hive, they need but little care from spring until fall, except to see to them in swarming time, that they do not fill up too closely with honey, and to care for the swarm, if one issues. We think it pays, also, to have young queens, or cells just ready to hatch, to insert into the parent hive; but the idea some throw out, that each colony must be opened and examined every 10 days or 2 weeks, we think erroneous. If one has but a few colonies and will be very careful not to injure them, then no harm is done if opened every day, but it will not pay; better have more bees and less care. The above suggestions are where we run bees for honey, which we think pays ever so much better than queen rearing or selling bees. At least such has been our experience. In fact, we would not sell bees at all, if it was not we could not keep so many in two locations—one for Mr. Axtell to look after, and one for myself. We think from 75 to 125, or perhaps a less number, are all that should be kept in one location, unless it is an extra locality for bee forage. We believe it pays to rear our own queens, too; except to buy one occasionally to introduce fresh blood. Perhaps our hive has something to do with our success in getting honey, rather than bees and queens, at the present cheap price for queens and bees, while honey brings a good price and ready sale, makes honey gathering the most profitable. We use the Improved Quinby hive with our own improvement on it, which affords an abundance of room above as well as below, and without the tiering up process, having always plenty of room in the hive. When surplus frames for honey are removed, then ample room is given for chaff packing, which keeps the bees dry and warm whether in the cellar or out. Last winter, 1880-81, we lost but 1 colony out of

over 100 wintered in the cellar. Some have felt a little disposed to laugh at us for packing with chaff for cellar wintering, but we think it pays every time. We think it pays to keep them in the cellar until about the time they can get natural pollen; then, when set out, next day or so crowd, them down on to about $\frac{1}{2}$ their number of frames, add more as warm weather and brood increases. This cures dysentery and prevents spring dwindling.

Mrs. L. C. AXTELL.

Roseville, Ill.

A Bee Cellar.—Tiling is now laid in my cellar and grading going on around the sides of my dwelling. The tiling is about 6 inches bore, most of it; 50 feet next the house is a little short of 6 inches, and 4 inches fall to the rod. I also have a 6-inch stove-pipe connected with the chimney. The top of the chimney is 23 feet higher. Will this give sufficient ventilation? The cellar extends under about two-fifths of the ground floor. The whole ground floor is $22\frac{1}{2} \times 16$ feet. The smaller tiling comes about 30 feet from the house. There is a door between the two cellars or parts. It is about 7 feet from the sleepers to the ground floor above. Will not this arrangement give sufficient ventilation to keep the bees in a healthy condition, winter and summer, if put in? We put our bees in Jan. 5. They appear to be doing reasonably well. Some colonies were quite light, and we have been so busy they have not been cared for since. The mercury has stood in the cellar most of the time at 44° . The winter here has been very pleasant, so much so we have been hauling dirt and grading around the house. Heretofore the floor in the east part of the cellar has been laid right on the ground, and the atmosphere was quite musty; but now I think we have obviated this, if not, I will cement the whole floor soon as I get time. I had $\frac{1}{4}$ acre of sweet clover last year, which was cultivated the first year. It gave a tremendous bloom. It was drilled in long rows 4 feet apart, and the ground was wholly covered with bloom, clear above one's head, some growing over 8 feet high, and the bees were busy on it for weeks. I wish to put in 6 or 8 acres of it this and next month. Will it do enough better to drill and cultivate it, to justify the care, over broadcast sowing? I would like, also, to drill in 3 or 4 acres of mammoth mignonette seed. MOSES BAILEY.

Winterset, Iowa.

[Your drain tile, as described, ought to give sufficient ventilation to meet the requirements of the bees, especially with the stove-pipe connection with the chimney, to act as a draft to bring the air through the tiling. Undoubtedly, a partial cultivation of the sweet clover will pay, as you have already demonstrated with your eighth of an acre. Should you conclude to put in the mammoth mignonette, why not drill it in with the sweet clover, inasmuch as the latter does

not bloom the first season, and thereby make the one cultivation answer for both? The mignonette will bloom the first season, and also form a good protection for the sweet clover, and save extra ground room for one year, at least.—ED.]

Poultry in the Apiary.—I am not regularly in the bee business, but read the JOURNAL with much interest and no little profit, and venture, therefore, to ask for information in your columns on these two points: 1. Which is best for bees, for the hives to sit on the ground or in frames, or on benches? 2. May poultry be allowed to run among the bees without injury to either? W. P. HANCOCK.

Salado, Texas.

[1. Each method has its advantages. We prefer for the hives to sit on frames, as they give an opportunity for a free circulation of air underneath the hives in summer, are cheaper of construction than platforms, and are not so liable to rot the lumber in the bottom-boards.

2. We have watched for hours, in vain, to discover chickens destroying bees while running in the bee-yard; but they do work great destruction to moths, spider, ants, and other insects. So far as we know now, we certainly favor the plan of giving poultry, especially chickens, free range of the apiary. We know nothing about ducks, and will not express an opinion regarding them.—ED.]

Bees Breeding and Gathering Pollen.—My bees have wintered well so far, and were bringing in pollen on the 14th of this month. The colonies are all strong and in good condition. I have 12 colonies in all, 3 Italians, and 9 hybrid, in 11-frame Langstroth hives. It snowed here all last night, and is still snowing. Will this cold snap be a back set on the brood?

EDMUND DE LAIR.

Oketo, Kans., Feb. 20, 1882.

[No; if your colonies are very strong, as the cold will probably be of very short duration. Of course, brood-rearing will not progress so favorably as if the weather was milder, and with moderate nights; but you will undoubtedly get enough young bees to off-set spring dwindling, especially as natural pollen has been coming in, and will continue to do so.—ED.]

Hill's Winter Bee-Hive.—Is there a patent on Hill's winter bee-hive, having a cap to slip over the lower part for winter protection?

Salem, Ohio. A SUBSCRIBER.

[There is, and the cap, we believe is embraced in the patent.—ED.]

To Cleanse Wax.—Why do not some of the great bee-keepers tell us how they get so much honey, and what kind of hives they use, one-story or two, and whether they extract from the brood chamber or the upper story only, and how much the honey weighs to the gallon? Then we would know where these great yields of honey come from. A gets 25 lbs. and B gets 75 lbs. to the colony, side by side. This is my method: In the spring I get brood in all the combs by transferring the outside combs to the center one at a time; then I put on a half-story to give the bees room. I try to keep the hive and boxes full of bees. If they swarm before June 20th, I put them in a new hive, and after a while return them to the old hive. I use the American frame, 9 in a hive. My bees have averaged me 90 lbs. per colony, spring count, for 5 years; increase, double. I have 41 colonies in the cellar at a temperature of 46°, and they are quiet. Following is a good method to cleanse wax: Tie some wheat flour in a sack or cloth, then immerse it in water and squeeze it out until the water is about the color of skim-milk; put in your wax and melt it; the flour will take all of the dirt to the bottom. Twice melting this way, will cleanse the blackest wax you ever saw. Please answer: 1. Is it best to give bees a flight between November and April? 2. Which hive will give the best returns—a long one, or a two-story hive? FAYETTE LEE.

Cokato, Minn.

[1. Yes, by all means, if the weather is suitable.

2. A two-story hive; as the honey can be taken from it to much better advantage, and with less disturbance of the bees. The "long idea" hive was much in vogue at one time, but has been generally abandoned, even by those who were most sanguine of its success.—Ed.]

Marking Location Anew.—I have read the BEE JOURNAL with much pleasure for 3 years, and, although a bee-keeper for over 30 years, I have known but little about them except what I have learned from the JOURNAL, and through use of the moveable-frame hive. But I have much to learn yet. In the JOURNAL of Nov. 16, page 363, I read Rev. Mr. Briggs' description of an out-door packing box, and I built two such, each 16 feet long, and filled them with hives of bees, and packed them as he directed. I was so well pleased with them that I built two more, but before putting the bees in, a neighbor told me that if the bees fly out they will return to their old stand, and will be lost. If this is true, I will pack no more. They have not had a flight since I packed them. Please let me know if this is so. Last summer I had my hives standing 5x3 feet apart, but not straight in line. Next summer I would like to place them in a straight line, but not so close, as I have plenty of room. What distance apart should I place them to be handy to manipu-

late? I have 30 colonies, nearly all in good order. Last winter I lost 8 out of 15, and bought 4 in the spring in log-gums, which I transferred into frame hives, and increased to 30. How shall I manage those I have packed in the 16-foot boxes, in the spring, as I cannot put them back on the old stands? SAMUEL UTZ.

Kenton, O.

[You will have no trouble about those packed away in the 16-foot boxes. If there are no hives on the old stands, the bees will find their way to their own hives; but a safer way will be to stand up, or slant, a board in front of each hive, to partially obstruct their free egress and ingress. Put up these boards as soon as you set them out in the spring, before they have had an opportunity to fly. By this means, they will mark their location anew. We often adopt this plan in summer, when changing location of hives, and never have experienced any trouble, nor lost any bees. If we had plenty of space, we would prefer our hives to stand 5x8 feet apart—that is, rows 8 feet apart, and hives 5 feet apart in the rows.—Ed.]

Bees in West Tennessee.—This is a medium section of our country, as I judge from reading the items in the BEE JOURNAL from other States. We have here maples, willows, red-buds, wild plums, hazels, black and sweet gums, and most all kinds except linden or basswood, which is so highly prized in the Northern States, though we have the poplar (tulip tree), which is hard to beat, for quality as well as quantity. White clover covers the ground in many places. All clovers do well here that I have seen. Alsike does well, also the Japanese clover, which has very delicate looking stalks, of finer texture than the white clover, and which the leaves resemble a little; but it has a yellowish bloom. It grows spontaneously in the woods and fields where not cultivated. Last season it stood the drouth better than any of the grasses, and cattle are fond of it. I do not know whether it is a good bee plant. I have kept bees 8 or 10 years in a small way; had 14 colonies last spring of Italians, hybrids and German bees, in Langstroth hives, which I increased to 27 by dividing, all in good condition now. Our bees are not troubled with dysentery here, and we need no winter houses or chaff hives. Bees winter well on the summer stands if the cracks are stopped up. I obtained 600 lbs. of extracted and 80 lbs. of comb honey, which I sold at 10 cents per lb. Some sell at 8 cents per pound for 30 to 40 pound boxes. We will have to use the extractor to drive them out with their old boxes. 1. Would it be advisable to use some of the small sections for comb honey? 2. Are the recipes given in "Honey as Food and Medicine" all reliable? I wish to write off some of them for our county paper, to improve the bee

business and interest the Patrons. 3. Do those extractors that use 3 frames at one time, require the frames to be lifted out each time when you want to reverse them, or is there room inside of the extractor to turn them? 4. Which do you consider the best extractor for 3 frames? 5. How much better is a good honey knife than a good table knife? 6. What would bees be worth, after May, without queen, per pound? I have no use for my workers after that time. 7. Could they be utilized?

R. H. C. MITCHELL.

Humboldt, Tenn.

[1. Yes; your locality is no exception to the rule, that the more attractive merchandise finds the quickest sale at the best prices.

2. We believe they are. They were culled with great care, and from the best authorities.

3. The frames require to be lifted to turn them.

4. The Excelsior Extractor is the only one we are aware of that takes 3 frames.

5. A good honey knife is as much better than a good table knife, as a good steel-pointed plow is better than the old-time forked stick, or the steel-bladed axe is better than the stone one.

6. Bees would not be worth much per pound after having spent a season of labor in your honey harvest, as they would all be old ones. You might, however, find buyers for them.

7. They could be utilized for but few days; probably not long enough to remunerate for express charges in transportation. We never took kindly to the traffic in bees by the pound, and many who were quite enthusiastic over the plan have abandoned it in disgust.—Ed.]

Dysentery and Wintering.—The question of wintering seems to be the only one left of great importance. The following conclusions I have arrived at after 15 years' of experience: Either very great cold, which causes a consumption of honey and pollen; or poor fall honey, when stores are scarce; or warm weather, which produces flight or uneasiness, and a consumption of stores; or brood-rearing, which causes the manipulation of pollen, are hints as to the cause of dysentery, the ravages of which are greatest toward spring, when long, cold confinement, or changable weather and partial confinement furnish the conditions, as pollen is not got rid of by perspiration, and dysentery is the result. It may be urged that bees do not always die with these conditions—I answer, neither do men nor animals always die under conditions favorable to disease. Mortality is the exception, not the rule, and the same with disease. A prevention by artifi-

cial means is the remedy, for which witness the success of bees in cellars and chaff hives, under proper management, a few main points of which are: abundance of fresh air of a uniform temperature; having the hives well ventilated by leaving them open at the top and bottom, or, if protected at the top, they must be covered warm, or moisture will collect and disease them; a poor quality of stores, with little or no pollen, for when they are set out in the spring it should be only when they can be supplied with pollen, either naturally or artificially, as they will not usually breed in a bee-cellar. As to ventilation in chaff hives, it must be at the bottom and at the top through chaff coverings; but as to wintering without any top covering, and especially in thin hives, I should expect to take the usual chances, which will depend on the above-named conditions, which, in my opinion, and as proven by experience, it is impossible to prevent, looking at the nature of the bee. I have had a number of colonies freeze, with quarts of bees and plenty of honey right under them, and no disease.

Milan, O. G. H. MACKEY.

Dead Brood.—I send you by mail, to-day, a sample of some combs in our apiary, which we fear are infected with foul brood. If you can settle that question you will confer a great favor. We bought bees last year from different parties, in box hives, and transferred them, and now we find something like I send you in most of the hives of one lot, and none of it in any others.

Salinas, Cal.

S. N. WYCKOFF.

[We find, on close inspection, no dead brood except in cells sealed over; none of these are perforated. On removing the cappings, we find only a thin, black, dried-up skin, which is easily removed with the point of a pin. If there was unsealed dead brood at the time of taking from the hive, it has dried to an impalpable powder. The dead larvae from these cells has undoubtedly been removed by the bees. We do not think it is foul brood, but it may prove to be a disease quite obnoxious, and would advise close observation as to its cause, extent and effect.—Ed.]

Winter Feeding.—[I purchased several colonies last fall in Langstroth and Thomas hives; it was too late to feed and prepare the weak colonies for winter, so I placed them in a clamp. I find, on examining, the weak ones are still alive. We have still two months before bees will fly, and I am afraid the weak ones have not sufficient stores to keep them alive till spring—1. Would it do to take them out of the clamp and into a warm room, cover the entrance with wire-cloth, and feed them? 2. Would they commence breeding, or should they have a fly after being disturbed? 3. Should a fine day occur before

placing them out for spring, and they are taken out for a fly, would they return to the hives, if placed in the yard? Am much pleased with the BEE JOURNAL, and wish you every prosperity in the change; I think it invaluable for the bee-keeper.

J. M. KNOWLES.

Lynden, Ont.

[1. You might put them in a room just above the freezing temperature, and feed them. Do not cover the entrances, for if two or three should make an unsuccessful attempt to get out, they would alarm all the balance, then a flight would be necessary.

2. They will not commence breeding, but might contract dysentery. The better way would be to feed them hard candy, placed on top the frames, which can be done almost any moderately mild day, without disturbing them. For the candy, use good sugar, putting about 1 pint of water to 3 pounds of sugar; boil till it will harden when cooled, then make in flat sheets; after it has hardened, place it on top the frames with as little disturbance as possible.

3. Should you have a day warm enough for the bees to fly with safety, you had better set them all out, slightly obstruct the entrances with a slanting board, and overhaul and feed all that require it. You can then give them honey or candy, as is most convenient. The flying bees will all return to their respective hives, except the weak or debilitated ones, which would most likely die in the hives before spring.—Ed.]

Lots of Pollen, but No Brood.—Bees flew splendidly yesterday, which makes the third flight they have had since October. They all seemed to be in fine order. Those I examined had lots of pollen, but no brood—not even an egg. My experience goes to prove that pollen is only used as food for larval bees, and not as a diet for mature bees, as very many writers would have us believe.

G. M. DOOLITTLE.

Borodino, N. Y., Feb. 16, 1882.

Wintering Bees.—My bees are wintering finely. There are no dead bees about the hives nor in them; they are clean and lively. My bees are in Langstroth hives, covered with honey-board. I learn from the BEE JOURNAL that cloth is better; if so, what kind shall I use. The boards are $\frac{1}{4}$ inch above the tops of frames. Should the cloth lay closely on the frames.

PROF. S. J. ROBBINS.

Penfield, N. Y.

[Cloth is better. We use woolen, but many use cotton; others ducking, while most anything will answer. If you have passage holes through the

combs, then the cloths or blankets can lie on the frames; if there are no passage-ways through, then place half-inch square sticks crosswise of the frames, to give the bees a passage over.—Ed.]

The Patent on One-Piece Sections.

—I have 65 colonies of bees in good shape, on their summer stands, and they seem to be doing well. The past season was a very poor one with me for honey. I obtained but little surplus but a large increase. 1. What does Mr. Forncrook's patent cover on the "all-in-one-piece section box." I see that Mr. Lewis advertises a one-piece section, on which he says there is no patent—is it an infringement? 2. How is Lewis' section used, with no opening in the bottom for the passage of bees. The BEE JOURNAL, in its present form, is about as near perfect as it can be.

A. D. STOCKING.

Ligonier, Ind.

[1. Mr. Forncrook claims his patent covers all one-piece sections; also the machine for their manufacture. We cannot answer whether Mr. Lewis' one-piece section is an infringement.

2. You will find this question answered on page 123 of last week's BEE JOURNAL.—Ed.]

Superseding Queens.—Our bees are healthy and have an abundance of stores. The winter has been pre-eminently an open one. To use a common expression in use about here, "it has rained all winter," and is still pouring down. Our bees have been able to fly every few days. Everything being drenched with water, I fear that there will be considerable dwindling. But bountiful stores, and a favorable spring, will soon supply the loss. Do you not put it too broadly in your answer to R. P. Williams, page 108, No. 3? If the queens are young, and the weakness of the colony not their fault (facts for the apiarist to decide), why not give them a comb of brood and save them for future use?

G. W. DENAREE.

Christiansburg, Ky.

[Perhaps the easiest way to answer the question is by asking another: If you were buying good queens (and we know you do not buy any but those you think are the best), would you feel that you were fairly dealt with, if you was sent a lot which had been taken from colonies that had been doubled up on account of weakness? Of course, there might be exceptional cases, but, as a rule, where a number of colonies in the apiary are too weak in population to attain satisfactory results, while other colonies are quite the reverse, the difference most likely is attributable to the queens. If queens are not worth buying as first class, they are not worth keeping.—Ed.]

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., March 8, 1882.

No. 10.

The Cheap Queen Traffic.

In this issue will be found two articles on the subject of rearing cheap queens, which take opposite and extreme views regarding the profit derived by the breeder. The first is a criticism on the article recently from the pen of Rev. A. Salisbury, who took negative grounds, and whose balance-sheet brought him in as a debtor. However extravagant some of his items may appear to a closer economist, certainly, with his long experience and facilities for economizing, where his critic might cut under, scores of prudent breeders would far exceed his expenses. The second article, from Mr. Alley, is corroborative of the experience of Mr. S. We presume this has been the case with nearly all who have been engaged in that traffic as breeders, unless it be those who have made tested queens a specialty, and have availed themselves of the "untested" feature to work off worthless trash.

We have long been convinced that "warranted" or "untested" queens were not only worthless, but an actual damage to the bee-keeping interest. One breeder, who has had more experience with cheap-priced queens than any other in America, or the World, and has probably reared and sold nearly as many as all the others combined, since he engaged in the business, says that "my opinion is, that not one queen out of ten sent out, is worth one cent." Another, who was until recently a very extensive breeder, in Michigan, of so-called "dollar queens," quit the business in disgust because it was a fraud upon innocent

purchasers, and remarked that "such were usually not worth twenty-five cents a dozen."

That it does open a wide door for fraud no one can deny. It is not long since an extensive Western apiarist and queen-breeder remarked, in the BEE JOURNAL office, that he received an order from a dealer in Ohio for 100 queens; that the party ordering made no stipulation excepting that they were to be the daughters of pure Italian queens. So he examined through his several hundred colonies, and selected all the superannuated and worthless ones which he was intending to supersede, and for which he received 65 cents a piece. Of course, he remarked, it was so much saved. Many patrons must have been losers.

We know there are some, and may be many, honest, conscientious breeders of untested queens; but we do not believe, among them all, there is one who is reckless enough to expect to buy a single queen for \$1.00, or 100 queens for \$65.00, which would be fit to rear even untested queens from; and if not fit to rear third-rate breeders from, it would be a sarcastic compliment to any bee-keeper's stock to say they would be cheap to him at any price.

What bee-keepers in America want is better stock—not cheaper queens; more honey—not lighter yields; longer-lived bees—not greater disasters; certain profits—not doubtful results. We would be glad to know that all queen-breeders are doing a profitable business; but we certainly would dislike to learn that any are reaping a harvest at the expense of their customers. The fault is not with the breeder, let the stock be what it may, but with the purchaser, who demands and expects to get good stock at an unremunerative price, and generally pays dearly for what he buys.

Honey at our State Fair.

Mrs. L. Harrison, Vice President for Illinois of the North American Bee-Keepers' Society, has been laboring with the Executive Committee of the State Board of Agriculture, to get a liberal consideration of the importance of the bee-keeping interest in Illinois. She has met with some success, but not to the extent her persistent efforts have deserved. In a letter dated at Peoria, Ill., Feb. 27, 1882, to the BEE JOURNAL, she says:

You are aware of my endeavors to procure a large exhibit of honey products for the State Fair of 1882. As the result of this work I have to report, for the coming fair, an increase of double premiums over that of last year, and yet "I am not happy."

Best lot of comb honey, not less than 10 lbs.	\$ 5 00
Second best do.	3 00
Best lot of extracted honey....	5 00
Second best do	3 00
Best machine for extracting honey.....	5 00

The Secretary writes: "I will only add—and not to be repeated—that large bodies move slowly, and you must not be discouraged. You have gained a little. I have added to the questions in the blanks, for agricultural statistics to be collected this year by assessors: No. of colonies of bees on hand May 1st, 1882, and No. of pounds of honey produced in 1881. These figures will show the importance of the busy bee."

I wrote to a number of bee-keepers and to publishers of bee literature, with reference to "special premiums." With but one exception all responded generously. I was in high glee over my success in this direction, until I received the following from the Secretary of the State Board:

"The Board, several years since, closed the State Fair list against 'special premiums.' It was not for the purpose of excluding such as you propose, but the door to special premiums, the line could not be drawn very well between legitimate offerings and those for advertising purposes, and it was thought best to exclude all specials from the list."

But the beggarly premiums offered are not for a moment to be thought the best results of Mrs. Harrison's work. As the Secretary writes her, "large bodies move slowly," and once moved in the right direction, by persistent effort, they accelerate in speed. We think the secretary's instructions to the assessors will result in furnishing a resistless motive power to move that large body with greater velocity in 1883. Meantime, much praise is due Mrs. Harrison for the interest she has taken in the matter, and we congratulate her on the partial success she has met with. That she has not

met better success is not from want of effort on her part, but owing to the circumscribed material she had to work on.

Food Adulterations before Congress.

Our readers will rejoice with us in the fact that Congress is at last engaged in a work of reformation regarding food adulterations, and that a bill has been introduced having for its object the taxation of glucose and oleomargarine to such an extent as to greatly restrict their manufacture. The bill, after reference to the committee on ways and means, was by them submitted to Hon. Green B. Raum, Commissioner of Internal Revenue. His communication to the Secretary of the Treasury, accompanying the bill, will be found below, and will be read with deep interest, while his manly and undisguised condemnation of the glucose and oleomargarine traffic will command the admiration alike of all honest producers, consumers, and dealers.

It will be observed, Mr. Raum takes practically the ground assumed by the BEE JOURNAL more than two years ago, and which we have reiterated from time to time, that State and municipal laws were incompetent to cope with these bare-faced frauds, and that relief SHOULD and MUST come from Congress. In fact, so familiar is the language he employs, that, were his communication not of very recent date, we might fear that our articles had been more or less a reflex from him. While we surmised the inability of States and municipalities to cure the evil, he has learned by demonstration that we were correct, and that relief must come from Congress. It is so seldom we are called upon to express gratitude to officials high in power for unselfish acts of duty, that Mr. Raum's honorable communication is the more gratifying. The following is the document referred to, and we bespeak for it a careful perusal:

Treasury Department, }
Washington, Feb. 14, 1882. }

Hon. Chas. J. Folger, Sec'y Treas'y:

SIR—I have received, by reference from the honorable Committee of Ways and Means of the House of Representatives, H. R. 920, being a bill to amend section 3328 of the revised statutes of the United States, in relation to tax on native wines: H. R. 142, being a bill to tax the manufacture of oleomargarine, and H. R. 3170, being a bill to tax and regulate the manufacture and sale of glucose, with a request that I furnish the com-

mittee with the views of this office upon the merits of these respective bills.

The adulteration of food and drink is an evil which State and municipal laws and regulations appear unable to prevent under our multiform system of government, and it seems that if the people are to be protected against the frauds of manufacturers, who palm off wines charged artificially with carbonic acid gas as genuine champagne; prepared tallow, lard, or grease as genuine butter, and glucose produced from cornstarch by the use of sulphuric acid, and soda ash flavored with a small percentage of Louisiana molasses as the best of golden syrup, it will be necessary for Congress, in the exercise of its undoubted power of taxation, to make provision that these spurious and adulterated articles shall be sold upon the market for what they really are, and shall not be palmed off on a trusting public for what they are not, to the great enrichment of those engaged in their manufacture. Oleomargarine and glucose are manufactured almost exclusively for purposes of fraud and adulteration. It is safe to say that few householders would buy for their own consumption butter which they knew to be composed, wholly or in part, of oleomargarine, syrup which they knew to be nine-tenths glucose, and champagne which they knew to be spurious.

It is by deception only that such articles are sold, and it seems to me that Congress will perform a most acceptable service to the people of this country by passing the bill in question substantially as introduced. In connection with this subject the subjoined extracts from an article in Appleton's Annual Encyclopedia, for 1879, are deemed of interest.

I inclose herewith the bills referred to me, suggesting some slight amendments thereto.

Very respectfully,

GREEN B. RAUM, Com'r.

GLUCOSE.—The adulteration of syrups with glucose is a practice which has recently spread alarmingly. The extensive use of glucose, or the grape sugar of commerce, is held to be the main origin of Bright's disease of the kidneys, and the cause of the present prevalence of that fatal malady. The importations of glucose increased tenfold between 1875 and 1877, and at the same time extensive factories were established for its manufacture in the Western States. The article sold as grape sugar is manufactured by boiling cornstarch with sulphuric acid (oil of vitriol) and mixing the product with lime. A portion of the sulphuric acid and sometimes copperas, sulphate of lime, and other noxious principles remain in the glucose. In the analysis of seventeen samples of table syrup by Dr. Kedsie fifteen were found to be made of glucose, one of them containing 141 grains of oil of vitriol and 724 grains of lime to the gallon, and one from a lot which sickened a whole family contained 72 grains of vitriol, 28 of sulphate of iron (copperas), and 363 of lime to the gallon. The cheap sugars

sold in Michigan are stated on the same authority to be adulterated with poisonous substances. Analyses of the sugar sold in New York reveal the presence not only of glucose with its inherent poisons, but of muriate of tin, a formidable poison; which is employed in the bleaching process. Mr. Fuller, a retired importer of sugar, called the attention of the United States Board of Trade, in their meeting held in New York in November, 1878, to the dangerous adulterations practiced with sugar, honey and molasses. Glucose is largely used to adulterate maple sugar, candies, jellies, honey, and other sweet foods.

OLEOMARGARINE—Which is now extensively manufactured from animal fat as a substitute for butter, is dreaded as a vehicle for infecting the human system with trichinae and other internal parasites. The fat is not subjected to a higher temperature than 120° F. John Michels, a New York chemist, states that the refuse fat of one pork packing establishment is to his knowledge sent to the artificial butter factories, and Prof. Church found in oleomargarine horse fat, fat from bones, and waste fat, such as is ordinarily used in making candies.

It will be observed from the above, that the grape sugar of commerce and glucose are identified as one and the same product, and, as so often asserted by Prof. Kedsie, Dr. Kellogg, Prof. Newton, and all other chemical experts of any note, the difference in the two articles is only in name. Where a distinction is made, it is only as a technical quibble; but it has no foundation in fact. Glucose is no worse than commercial grape sugar, nor can it be any better, so long as it is the same thing, but in different shape.

Testing the New Races.

Mr. W. S. Blaisdell, Randolph, Vt., makes the following inquiry:

Please give in the JOURNAL the standard tests of purity for the three leading races of bees—the Italian, Syrian, and Cyprian? If you will do this, you will very much oblige me and others who are purchasing queens, and who wish to be able to indicate from the progeny what value there is specially in the class called "tested."

It will require great familiarity with the three races to be able to distinguish any difference readily. We have frequently been more than a little puzzled over the problem. Count Barbo, Vice President of the Italian National Society, in Milan, in alluding to the crescent on the corslet of the Cyprian bee, which is the only distinguishing mark, said that it was not uncommon for their Italian bees to show the same mark. At the Na-

tional Convention in Cincinnati, in 1880, we exhibited some Italian bees preserved in phials of alcohol, as also one phial which was filled with bees on the Island of Cyprus, and four of the lots of Italians were unhesitatingly pronounced Cyprians by an expert present, who is quite as familiar with the new races as any man in America.

Perhaps the best test with those accustomed to handling the better Italians, is in opening the hives. While the Italians on the combs are slow, deliberate, and dignified in their movements, the bees from Syria and Cyprus are quick, nervous, and angular, hurrying and scurrying back and forth, and making every demonstration of anger, which is not always a feint. They are, too, less tractable with smoke.

Do they Love It?—Speaking of the late Convention of glucose manufacturers in Chicago, the *Southern Cultivator* remarks as follows:

They were in session several days and evinced a determination to prosecute their enterprise without abatement. Fifteen establishments were represented, and a permanent organization was accomplished for the mutual advancement of those engaged in this branch of manufactures. Despite the warnings of the press of the country, showing the danger attending the use of glucose, the people seem to be fond of it, as is indicated by its general introduction and large consumption.

We do not think the large consumption of glucose is because the people are "fond of it," but because they have it palmed off on them for pure sweets. The vile trash has no legitimate end—its only use is to adulterate. Its very existence is but a sham, a fraud and a curse; bringing disease and premature death upon thousands.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Give Address.—Please, in the next issue of the BEE JOURNAL, give the name and address of the makers of the Vandervort foundation machine, and oblige,
A SUBSCRIBER.

Lucia, O.

It is J. Vandervort, Laceyville, Pa.

MISCELLANEOUS.

Telephone for the Apiary.—Mr. Jas. A. Nelson, Wyandott, Kas., describes his telephone, in *Gleanings*, thus:

Our telephone is sort of three concerned; has 3 ends—one at the house, one at the shop, and one at the barn. At either point I can hear the bees when they strike the wire; can hear a call to dinner while sitting at my desk in the office, and, in fact, have heard the hens cackle in the barn from the shop; so you see we know when to go after the eggs. It is a triangle, with a single wire running from each point, making 55 feet from house to shop; 60 feet from house to barn, and 80 feet from shop to barn. The house is brick, and I could not well cut a hole through, so I just raised the window about 5 inches and put a board in the opening; where the wire passes through the board is a one-inch hole, covered with soft sheep leather; the wire through the leather is in the center of the hole, so the cold air and the bees are kept out. I think Mr. Gallup is needlessly alarmed about the bees killing themselves on the wire. I have watched them, and all I have seen strike have been rising from the hives, and it merely turns them from their course a little. I have not seen one fall to the ground.

Adulterated Food.—The *Maine Farmer* reports as follows on this subject: It is a "burning shame" that such frauds have not been stopped by Congress long ago. Let us hope that it will now be done speedily. The *Farmer* says:

A citizen of Bath recently bought some granulated sugar in that city. On melting some of it for making preserves, a quantity of blue scum rose to the top which alarmed the family. It is supposed that some of the best refiners use blue clay, and some of the poisonous aniline blues to improve the color of their sugars. This led to the testing of cream of tartar, which was purchased from the same dealer, supposing it to be pure, and it was found that more than one-third was a sediment which would not dissolve. The substance used for coloring sugar is ultramarine, and is used for the purpose of covering up some defects in the product, and as for cream of tartar, not one pound in fifty sold by grocers is pure. The adulteration amounts to one-half.

It is terrible to think that little children should have to suffer for indulgence in sweets, but so it is. We grown people stand by and see the health of our little ones vitiated because we must not interfere with trade. But this is a nefarious trade which gives us foods that act inju-

riously upon our frame, and particularly when we are young. That trade should be done away with, and the trader should be forced to stop it, if his own conscience does not do so. A time will come when it will be scarcely credited, that in our advanced nineteenth century, it was possible in open day to sell to little children, things that would poison their blood.

Sweet Clover.—The editor of the *Bee-Keepers' Instructor* makes the following remarks on this honey producer :

This is destined, we think, to become the great honey plant of the future, its great adaptability to soil and climate, the ease with which it can be raised, the great length of time it continues in bloom, and the fact that it can be grown on waste places and barren land, all being points in its favor, that will recommend it to every bee-keeper.

Honey from Corn.—Will bees gather honey from corn? is answered by a correspondent of *Gleanings* as follows :

Yes, and lots of it, too, sometimes. They gather it from the tassels at the same time they gather that dark-green pollen. I always know what my bees are working on. It is not every year they get a large amount, say about as often as one year in four or five. I have had them average from 5 to 10 lbs. per colony of the nicest honey. It comes after basswood.

Continuous Honey Bloom.—One by one they come to the music, take up the refrain, and join the chorus concerning continuous honey bloom. This was begun by us as a "solo" 3 years ago, and we now feel certain that ere long its "swelling chorus" will fill the World. The *National Agriculturist* adds its note thus :

No topic is more worthy the earnest consideration of bee-keepers, than that of bee-forage. It often happens that our bees can find honey for not more than 5 or 6 weeks, and yet in that brief time they will often store 50 to 200 lbs. per colony. What might we expect if the nectar-secreting flowers were to bloom the entire season through? The September flow of honey, often exceeding the yield in spring, in some parts of the country, answers the question. How we may supplement the natural yield of honey by judicious planting of honey plants, may well receive earnest thought and consideration during the winter. We already know that by planting figwort, cleome, catnip, borage, mustard and alsike clover, we may bridge over the famine of honey bloom. Of these, alsike clover is good also as a forage plant for cattle, etc., and by cutting a portion of the crop as soon as it comes into bloom, we may secure a second crop of flowers, and so a continuous yield of honey-producing flowers. Figwort and cleome, though of no other use, furnish abundance of good

honey, and that too at a time of usual dearth. The thoughtful apiarist may with profit give to this subject much study during the leisure of his winter hours.

One-Pound Sections.—Mr. J. H. Martin, Hartford, N. Y., remarks as follows in *Gleanings* :

The recent action of the North-eastern New York Association in relation to the proper size for section boxes, is much like the "pope's bull against the comet." If the market demands pound sections, and they sell better, why not leave the bee-keeper free to use what size he desires? I think the pound section has been upon the market too long to be now withdrawn. It is safe to say, that over half of the crop of comb honey for the coming year will be stored in one-pound sections; furthermore, as far as I have read the proceedings, I should call it a comb-honey association. The production and sale of extracted honey has not received the attention it should.

Seasonable Hints.—Mr. Dougherty, in the *Indiana Farmer*, gives the following on stimulative brood rearing :

It is not necessary that an ordinary sized colony of bees should occupy the entire brood apartment of the hives. Indeed, it is much preferable that they be confined on as few combs as they will well cover. So long as the queen has room to lay, there is no danger from over crowding, care being taken that they do not run short of stores. With the reduced space to occupy, they can much better keep up the requisite heat for necessary brood rearing. After the combs which they occupy become well filled with brood, more room should be given them, by spreading the brood and inserting an empty comb in the center of the brood nest. If on examination the center combs are found quite full, while those on the side yet contain room, it is better to change position of the combs without adding more, until all the comb in the hive is filled very close up to the top-bar. Just here we wish to caution you about spreading the brood too fast. So long as the queen has room in which to lay, they do not require any more room. Brood rearing proceeds very slowly in the early part of the season, and it takes them quite a while to fill the first four or five combs which they occupy with brood, and the cluster increases very slowly, the old bees dying off quite as fast as the young ones increase. Confining the bees to a few combs necessitates the use of a division-board, and they should be kept covered up as warm as possible to assist them in retaining the necessary heat. It is very essential that all colonies be made good and strong by the time the honey harvest begins, and to do this, that operation should be commenced 5 or 6 weeks before that time. The first thing to be done is to give all colonies a thorough examination, ascertain the condition of the colony, and the

amount of stores on hand, remembering that as soon as brood rearing commences, the stores will be consumed very rapidly, and unless they have plenty, provision must be made to supply their needs, and when feeding is once commenced, it must be continued until such time as they can gather a sufficiency to keep going.

The "Square List."—Novice has started a list of dealers in apiarian supplies, which he calls a "square list." We notice that he does not put himself into that list; but in place of that, in *Gleanings* for March, he remarks as follows :

If you wish to deal with some one who always has everything right, every time, and never makes a mistake, don't send to us. If, however, being always ready to make good every error, the minute it is discovered, will do, send along your orders, and we will be glad to serve you.

And in the same paper, Mr. W. Z. Hutchinson gives the following good reasons for not being included in that "square list" :

I can subscribe to the declaration with which the "square list" is headed; yet there is something repugnant to me about the whole business—this advertising, in this manner, one's honesty and good name. Public opinion says, that the physician must not advertise his wonderful skill; it says: "Let his works speak for themselves;" and I say, let a man's works or dealings speak for themselves. Dealer after dealer has advertised to "guarantee satisfaction;" but, judging from the manner in which some of them deal, it must have been unto themselves, and not unto their customers, that they guarantee satisfaction. A bee-keeper once said to me, "When a man advertises, or boasts of his honesty, I think it advisable not to trust him too far." Please don't think that I am casting reflections upon those whose names have already appeared in the "square list"—far from it. I consider them the squarest of square dealers. Perhaps, though, if I had lost a good round sum through the dishonesty or negligence of some "scaly" dealer, I might feel differently about this matter.

☞ The Lancaster, Pa., *Farmer*, makes the following kind mention :

The AMERICAN BEE JOURNAL, the oldest and ablest paper devoted exclusively to progressive bee-culture, published in the country, is now issued in a royal octavo form, weekly, at \$2.00 a year, by Thomas G. Newman, at Chicago, Ill. This is a far better and more convenient form than that of a quarto, in which it was issued in 1881. But, whatever its form may have been, its substance is, and always has been, of the highest intellectual order, and we do not see how any one who makes bee-keeping a specialty, can afford to do without it.

For the American Bee Journal.

Does it Pay to Rear Dollar Queens.

W. Z. HUTCHINSON.

Mr. Salisbury, in any discussion that we may have as to whether it is profitable to rear dollar queens, would it not be better to say nothing as to whether it is profitable to *deal* in them? It is a subject about which *we* know nothing from actual experience, at least *I* do not, and I presume that you are equally ignorant. If a man owns a paper, and sees fit to advertise his wares in it, that is *his* business; and if he gives his subscribers a good paper, one worth the subscription price, no one ought to complain, had they? Please do not let us have any more discussion upon this point—unless in a separate article—but turn our attention to the question: does it pay to rear dollar queens, i. e., does it pay the ordinary queen breeder, one who does not own a bee-paper?

According to the figures that you gave, on page 104 of the BEE JOURNAL, it appears that it does not pay. But are those figures imaginary, or do they represent the results of an actual experiment? If the former, they prove nothing; if the latter, they either show bad management, or a poor location; perhaps both. You say: "For circulars, advertising, and correspondence, \$90." That \$40-a-month expert should print the circulars and price lists upon a cheirograph, and no circulars sent out unless called for. The majority of people have so many circulars shoved under their noses, that they are sick of the sight of them, and toss them, almost unnoticed, into the waste basket. And now in regard to advertising, Mr. S., I hope that you will not be offended if I ask, if *you* have not indulged in too many "spread-eagle" ads.? Do you suppose that cut of a nice, large, queen bee, with which so many of your ads. have been adorned, ever brought you any customers; if so, how many? Again you say: "500 cages, \$50." That \$40-a-month expert should make the cages. If he does not have time to make them, and attend to the bees, *I* will furnish them for $\frac{1}{2}$ the money, and can clear \$2 per day while making them. In regard to the loss of queens while in the mails, I do not know whether your estimate is too high or not; but it is a greater loss than I have ever experienced. "Syrup for feeding 100 nuclei, \$100." Three years ago, in August and September, I was obliged to feed, in order to keep things moving; but the entire expense was only about 15 cents for each nucleus, during the two months of feeding. It was grape sugar that I used for feeding. In all of my queen rearing this is the only time, with perhaps two or three slight exceptions, that I have found it necessary to feed,

my nuclei usually storing some surplus, and after consolidating them in the fall, they have always had plenty of honey without feeding. "Lamp nursery and oil, \$7." Mr. S., you ought only to charge, had you, for the interest upon the money invested in a lamp nursery, and for the oil burned? Which certainly would not amount to \$7. You speak of capital invested in nucleus hives, etc., to which I take no exceptions, unless it is to remark that many breeders go to the expense of making a small hive for each nucleus, when, by using division boards, and putting 2 nuclei in an ordinary hive, nearly $\frac{1}{2}$ the expense for hives could be avoided. You speak of "queens to be replaced when complaints are made." This is something that I know but little about, having had to use only two queens in this manner. Neither do I "cut up combs for eggs to rear queens from." I merely cut holes in the combs; cells are built around these holes, and, after the queens have hatched, the combs are given to some strong colony, and the bees immediately refill the holes with comb. You say that "in running 100 nuclei it is out of the question for one hand to keep them filled with queens against their will." I, at one time, had nuclei, and that was at a time when but little honey was coming in, and yet no nuclei ever remained queenless 1 week at a time, 2 days being the average; and when honey is coming in plentifully, a young queen is usually given to a nucleus at the same time that a laying queen is removed; and, 9 times out of 10, she is accepted. Please allow me to copy a leaf from my account book. Bee account, Dr. to interest on \$200, invested in 15 colonies of bees, and the necessary hives and implements, \$16; advertising, \$30; postage, \$20; stationery, \$1; materials for queen cages, \$3.75; oil for lamp nursery, \$1.25; queens lost in the mails, \$20.70; total, \$92.70. Bee account Cr. by an increase of four colonies, at \$7, \$28; 600 lbs. honey, at 15 cents, \$90; 375 queens, at an average price of 90 cents, \$337.50; total, \$455.50; profits, \$362.80.

The above is my bona fide account for the year 1880, which was my most prosperous year. Last year we had a late spring and I did not commence queen rearing until about a month later than usual, and my profits from 18 colonies, were only \$277.74. In making my reports I have never counted my time, simply because other bee-keepers have not done so in making their reports; but if I should deduct \$160 for my labor, do you not see that there would yet be a good profit? And the expert at our house not only cares for the bees, but he cares for a nice, large garden, a squash patch of a quarter of an acre, and a potato patch; he splits the wood, milks the cow, helps take care of the babies, and does other chores too numerous to mention.

Mr. S., you may have kept bees 20 years, and yet have to learn how to rear dollar queens at a profit. I know a bee-keeper who has kept bees 20 years, and kept them in large num-

bers part of the time, and yet he has never made the business very profitable; many of the years it was a bill of expense. Five years ago, I had never opened a bee-hive, although, from reading, and from visiting apiarists, I had a good theoretical knowledge of the business, yet in the five years that I have been engaged in the business, during four of which I have reared dollar queens, my average profits, per colony, have been about \$18 each year. If I deduct \$160 for my labor, my profit would average about \$10 per colony, each year.

Many men say that farming is not profitable; and, judging from the manner in which they conduct the business, and the results that they obtain, it certainly does not appear *very* profitable; while others amass small fortunes in following this occupation. A few have obtained great riches by engaging in mercantile pursuits, while thousands upon thousands have failed in the business. Some bee-keepers say that foul brood cannot be cured with salicylic acid, while others have cured the disease with the acid. Some bee-keepers assert that dollar queens cannot be reared at a profit, while others do rear them at a profit. If they do not, why do they continue in the business? It makes no difference to me what course others pursue, when I cannot rear dollar queens at a good fair profit, I shall drop the business so quickly that it will fairly make your head swim.

In a good honey season, I presume that the raising of honey would be nearly, if not quite, as profitable as queen rearing; but in a poor season, by a little judicious feeding, queen rearing can be made more profitable than the raising of honey.

The above criticisms are plain and out-spoken, but they are made with a kindly spirit, and I trust that they will be received in the same manner
Rogersville, Mich.

For the American Bee Journal.

Potatoes vs. Honey Production.

J. H. MARTIN.

It is very evident that our German friends, mentioned by A. R. Kohnke, on page 104, were not successful culturists of the potato, and it seems that Mr. K. agrees with them, and advises that our potato lands be sown to honey producing plants.

I am strongly inclined to think that it would not pay. I live in the midst of a great potato-growing region. This (Washington) county is the banner potato county in New York State, and our shipments reach about four millions of bushels annually. In this vicinity the farmers plant from 8 to 50 acres each. Suppose one farmer who plants only eight acres has also bees; his potatoes last fall yielded an average of 150 bushels per acre, and were sold for one dollar per bushel or \$1,200. Now, if he had planted the eight acres to the most approved honey plant, to make the value equal to the potato, each acre would have to yield

1,500 lbs., or a total of 12,000 lbs. of extracted honey, at 10 c. per lb., \$1,200. Who knows that 1 acre can be made to produce 1,500 lbs., or even 300 lbs., which would be equal to 100 bushels of potatoes per acre, at only 30 cents per bushel.

Our farmers, even though they keep bees, would scout the idea of giving up their potato land to honey plants. I think, for our location, I could advise a better plan: Sweet clover seems to grow very rank upon poor, hard, clay soil. I have in mind two fields of 30 acres each within range of my apiary, one is used for grazing and the other for a meadow. The pasture produces very scanty forage, while the whole meadow yields but about 5 tons of hay. If both of these fields could be sown to sweet clover I imagine that several thousand pounds of honey would be the result; the pasture forage would be greatly increased, and the land soon be in better condition to produce hay or grain. But as the land does not belong to me, I shall not have the pleasure of beholding it covered with the nectar-producing plants. I hope Mr. Kohnke will receive seeds to sow those acres, and will be enabled to give us some idea how much honey an acre will produce.

If the yield from one plant could be estimated, how it would aid us in determining the approximate yield from an acre, if the acre is planted in rows like corn, so like corn the yield could be quite correctly demonstrated.

Hartford, N. Y.

For the American Bee Journal.
Beginning With Bees.

W. F. CLARKE.

"A man up a tree" has been writing on the above subject in the *New York Tribune*. Some of his advices are wise, and some otherwise. The first suggestion to one determined to make bee-keeping his "life-work," but "entirely ignorant of the art," is, to "begin with a few colonies—from 2 to 6 is enough." The second is, to "procure some good, reliable work on bee-keeping, and study it with care."

These counsels should be reversed. A person who has serious thoughts of making apiculture his "life-work," should study a good bee-book first, that he may get some idea of the amount of knowledge to be acquired, and that he may judge of his own aptitudes for the business. Tyros, generally speaking, suppose that the principles of bee-keeping are few and simple, easily picked up, and require but little thought and application. One of this class attended a convention of bee-keepers, listened to a single evening's discussion, and went away convinced that it was useless for him to attempt to master the ins and outs of apiculture. He had not the requisite application. It has been said of Queen Victoria that she could never learn to sing, for three reasons: 1st, she had no voice; 2d, she had no ear; and 3d, she had no application. The latter was the true reason. With application, anyone can become a

singer of some sort; and with application, anyone can become a bee-keeper on a small scale. But application alone will not make a *prima donna*, nor will application alone make a man qualified to be an extensive bee-keeper. He must be possessed of certain natural qualifications. There must be quick perceptive powers, quiet and steady perseverance, self-control and coolness of nerve, business promptitude and sagacity; last, but not least, a degree of imperviousness to bee-stings. A person peculiarly sensitive to bee-poison, whose flesh swells enormously, and whose blood fevers quickly under its influence, may keep a hive or two for scientific investigation and interest, but would be courting martyrdom to make bee-keeping his "life-work."

One colony, generally speaking, is enough to start with. The probabilities are that the beginner will lose that, through some error of management. The loss of one colony will not be so discouraging as the loss of "two" or "six." If he does not lose his first colony his bees will probably increase quite as fast as his knowledge and experience. If they do not, he can buy more bees when he feels competent to take care of them. Localities need testing as well as bee-masters, and a few colonies will suffice for that.

This "man up a tree" advises a beginner to make himself familiar with his bees, in order that they may know him personally, and find out that he is their friend. Considering that during the honey season, when we have most occasion to handle bees, their average life is not over three months, there is little chance to cultivate friendship with them. Besides, the first smell of you they decide whether to treat you as a friend or a foe. No kind treatment that you can give them will ever change their dislike of you into love. Be gentle with them always; but gentleness will not conquer their aversion if they have taken a "scomer" at you. It is people who are bee-loved who should make a "life-work" of apiculture. The most that others can do is to let the little insects know from the start that they have their master.

This writer says, "care and prudence, with occasional mishap, will cause the beginner to lose all dread of the business and of his bees." Well, that depends on how much they *hurt* him. If he is thick-skinned, and his blood so cool that bee-virus cannot heat it up, he will soon come to care no more for a bee-sting than for the prick of a pin. But if he is thin-skinned, and bee-poison injected into his blood is like the mixing of seidlitz powders, his respect for the business end of a bee will continue unabated to the last day of his life.

Here is some good advice:

"He should indulge no hopes of suddenly becoming an expert, or rapidly accumulating a fortune at this business. There is no short cut to success here any more than anywhere else. If pursued rationally and perseveringly, he will, in the course of some years of faithful apprenticeship

at the business, gain ability to handle and manage from 100 to 1,000 colonies of bees. He cannot possibly manage this number at first successfully, any more than he could conduct large manufacturing industries without having previously studied and worked at the business.

"Unfortunately no one industry (except, perhaps, mining) has been brought into so much disrepute as bee-keeping, by all sorts of characters undertaking to carry it on, on a large scale, without adequate previous experience or study. The very ignorance of the many who keep a few bees has made the business a fruitful field for the operations of quacks and quack vendors of all kinds of so-called wonderful hives and queens. This is all the more unfortunate because bee-keeping can be made as legitimate and honorable and successful, and is so made by many, as any other avocation."

This writer advises beginners to pick out their own pathway to knowledge and success, rather than serve a "personal apprenticeship to a professional." He admits that "the latter has its advantages," but considers that the most successful bee-keepers have been self-made. This may be quite true, but has it not been because bee-keeping has only of late become one of the fixed or exact sciences? Apprenticeship to mere "professionals" may not be worth much, but there is no way in which an observant mind can so soon or so thoroughly acquire a mastery of this business as by spending a season or two with a thoroughly practical bee-keeper. In time, no doubt, apprenticeship to this business will be the usual thing, as in the case of any and every other. Perhaps in "the good time coming" this may rank among the learned professions, and B. M. (bee-master or bee-mistress) be as common and proper an affix to people's names as M. D. or M. A.

Listowel, Ont.

For the American Bee Journal.
Glucose, Foul Brood, etc.

CHAS. F. MUTH.

Allow me to forward you a slip from one of our dailies, giving Commissioner Raum's address to the Secretary of the Treasury, for fear you will overlook it. The opinion of an authority like Mr. Raum should be read by every bee-keeper. According to it, we are not aware yet of all the danger our health is subject to by the use of glucose. It is due to the representative of our (Hamilton) county, Ex-Governor Thos. L. Young, to state that it was him who introduced the bill to levy a high taxation on glucose manufactories, so as to make the manufacture of the vile stuff next to an impossibility. The purpose of the manufacturer being, in the first place, the "making of money" of course, but, secondly, the preparation of an article for adulterating purposes.

The reply of Mr. Jones to Mr. A. R. Kohnke's foul brood matter shows

that he went through real practical tests, just as we can expect of him. His article shows that he did not give us for facts matters of which he had read only. We know Mr. Jones to be a bee-keeper of sound sense and great experience, and I wonder why he did not succeed with my remedy, supposing salicylic used to be of the same properties in Canada as in the United States. I am certain he has blundered somewhere, otherwise his cure of foul brood would have been easier and surer than with the starving process, which I have tried to my satisfaction, and in which I had a first class ally, Mr. Joseph Savage. It appears to me that I am better posted on the foul brood question than Mr. Jones, and I shall try to convince him of that fact (if such it be) in the course of a week or two, when I may have more leisure than I have just now. I am not alarmed that I shall offend, because such controversies are generally accepted in the same spirit in which they are given. Besides, Mr. Jones and myself know that neither one of us knows all about it, and both of us are still willing to learn.

Cincinnati, O.

[The article referred to above, and for which Mr. Muth will please accept our thanks, will be found on page 146 of this issue.—Ed.]

Rural New Yorker.

Pollen Essential for Brood-Rearing.

G. M. DOOLITTLE.

Of late much has been said of the deleterious effects of bees eating pollen as a winter diet, and out of it there seems to have grown the opinion in the minds of some that pollen is a necessity when brood is being reared. In other words, it is claimed by some that no brood can be reared without pollen, for we find in a prominent work on apiculture these words: "We are interested about pollen because bees cannot rear brood without either it or some substitute for it." Again: "They (the bees) had no pollen and, of course, no brood-rearing could go on without it." Also we find these words coming from high authority: "I have further stated that pollen was an indispensable requisite to brood-rearing; that it is an essential element in the food of larval bees;" after which the writer goes on to give circumstantial evidence to substantiate his position, without giving any positive proof that such position was correct. As positive evidence in court is considered to be of greater value than negative, I desire to give some such proof that the above writers are mistaken.

Some years ago I learned that a neighbor, living about a mile away, was to kill his bees the next day by the method practiced by our forefathers called "brimstoning." Accordingly I went and saw him, and got permission to drive out the bees and save them from such a cruel death, if I would secure to him the combs and

honey. After obtaining the bees I carried them home and put them in a hive together with six frames of nice, new comb without pollen. They were then fed very thick sirup made from standard A sugar, until I considered they had sufficient stores for winter. As it was late in October, they had but two chances to fly after they had been brought home and placed in the cellar for winter. We have no flowers yielding pollen late in the fall, consequently no pollen was obtained. Along in the fore part of February I commenced to stimulate them by jarring the hive to arouse the bees into activity, so that they would feed their queen. This was repeated afterwards by way of experiment. About the middle of March a fine day occurred when these bees were set out for a fly, as was our custom at that time. After their first excitement at being out in the warm sunshine had somewhat subsided, the hive was opened and, much to my satisfaction, I found brood in two combs, amounting to nearly half a frameful, comprising eggs, larvæ and sealed brood, with now and then a hatching bee. At night they were returned to the cellar, where they remained till the middle of April, when I found their numbers had much increased and that they had doubled their brood. I then began to feed flour, which they worked on eagerly as bees generally do in early spring.

Here I wish to introduce another person giving positive evidence, for "in the mouths of two or three witnesses every word may be established." This person is no other than Mr. E. Gallup, for whose opinions on apiculture I have the highest respect, and who was considered high authority a decade of years ago as an apiarist. He tells us in the *Bee-Keepers' Journal* for October, 1870, of an experiment he had made by way of putting a small swarm of bees in a hive late in the season and feeding them till they had built thin, small pieces of comb, when they were placed in winter-quarters "without a particle of pollen." He then tells us how he began to stimulate this little colony about the first of February, and says: "The queen commenced breeding, and by the time the bees first flew out in the spring they had doubled their number," and this without a particle of pollen. Next we find on page 265 of the *Bee-Keepers' Magazine* for 1880, these words from the pen of Prof. Hasbrouck: "They are certainly wrong who say that pollen is indispensable to the raising of young bees, because I have had, as an experiment, abundant brood reared by bees shut up on new comb and fed on refined sugar sirup when they could not possibly get a grain of pollen from any source." This, coming from an apiarist of close observation, can be relied upon, which, with the testimony of others, proves conclusively that brood-rearing, to a considerable extent at least, can be carried on without any pollen whatever.

From many observations made during past years, I am of the opinion that the state of the surroundings,

such as warm or cool weather, plenty of honey being secreted in the flowers, or no honey at all, a desire to keep up a rapidly diminishing colony, or a perfectly healthy one, has more to do with brood-rearing than plenty of pollen. That the "scramble" for pollen in early spring excites brood-rearing no one will deny; but pollen may come in quite as freely in the latter part of September, and yet no brood-rearing at all be the result. Much depends upon whether the bees desire brood or not; if they do, they will rear it without pollen, as our experience proves. If they do not so desire, a hive full of pollen has no effect upon them. Anything exciting to activity has a tendency toward brood-rearing, while that tending to quietude gives a reverse result.

Borodino, N. Y.

For the American Bee Journal.

The Dollar Queen Business.

HENRY ALLEY.

I am glad to see the dollar queen question brought up again. I hope that those who purchase queens will be convinced that queens cannot be reared and sold by honest dealers at so low a figure, and give the producer a living. I think most of our customers are willing to pay a fair price for queens. I know, to my sorrow, that queens cannot be reared at such prices. I am not like some who write on this question, as I do not think the queens should be poorer for being sold at a low price. I have contended for a long time that the manner of rearing, and not the price, is the cause of poor queens. Last year was the only year that I did not lose money at the queen-rearing business. There is a call for about 12,000 queens each year. I cannot rear over 1,500 of that number, even in the most favorable season. It takes all my time from the first of May to the first of October. Then the expense of rearing them eats up a large sum here in this State, on account of the great amount of feeding to be done. Last season I fed out 1,400 lbs. of sugar, besides several hundred pounds of honey. Add to the above the large number of colonies of bees that must be destroyed to fill 250 nuclei and to keep them replenished with bees for 5 months; then comes the full colonies that we rear queens in; then the postage on the queens, letters, postal cards, circulars, and advertising bills. I find it pretty hard work to get money enough in the fall to pay my bills—I certainly cannot get it out of the queen-rearing business. Now, what do bee-keepers want queen-breeders to do—keep on losing money, or stop rearing queens? I have been rearing queens so many years that I cannot feel like giving it up; it is like a second-nature to me. I have kept at it for several years, hoping that something would turn up so that a fair living at it might be made, and know of others who have done the same. Nothing seems to have turned up that has helped the case any, and at this time

there are no indications that there will be anything done to help the queen-dealer.

When the word "purity" is left out, or when purity is made secondary matter in ordering queens, then, and not till then, will the "coming bee" be found. I will not say that pure bees of any race are not as good as hybrids, but purity should not be sought for at the expense of all other qualities. If bee-keepers will be satisfied with queens as pure, and no more so, than those sent us from across the water, I think they will be better satisfied that purity (strictly pure and handsome bees) is of no account whatever. Of course, we all like the beautiful orange color of the Italians, but are those beautiful bees any purer than those not quite as handsome?

Queens should be reared and tested for business, and not for purity. In ordering queens the purchaser should say, "please send me a queen that you know to be very prolific, active, and vigorous; let her be a pure Italian if possible, but send me a good one or none, as I want to obtain honey," etc.

Who will deny that a good home-bred queen is not worth \$2.00? One good queen is worth more than all the poor ones ever reared. My opinion is, that not one queen out of 10 sent out, is worth one cent. My advice to purchasers is to purchase good queens and pay a fair price for them, and not only have purity, but longevity and prolificness guaranteed.

I will make a suggestion: Let all the leading queen-breeders combine, and resolve not to sell queens less than \$2.00 each, and not sell any that are not thoroughly tested; then, if bee-keepers want a cheap article, let them purchase of those who have not had much experience at the business.

Wenham, Mass.

For the American Bee Journal.

Things I Do, and Do Not Believe.

E. B. SOUTHWICK, M. D.

There are some things that I believe, and some things I do not believe. I will give some of them, and my reasons for the same, and I wish the reasons considered and nothing more, for a belief or an opinion without a reason is of no use whatever:

1. I do not believe that the queen always lays her eggs where they remain until they hatch.

2. I do not believe the bees feed pollen to the larvæ in the cells.

3. I do not believe that in cold weather bees that are in the outside of the cluster work their way into the center and get to the honey; but I believe the bees from the inside of the cluster come out on to the outside, and by so doing crowd those on the outside in, so they can get to their food.

4. I believe that starvation is the direct cause of dysentery in bees.

These 4 are enough for one article. My reason for the first is, that I have seen on combs where the queen had lately commenced laying, eggs scat-

tered promiscuously through the combs; I have traced rows of them from one end of the comb to the other, and criss-cross in every direction, as irregular as rabbits' tracks on the snow. I have also seen 2 or 3 eggs in 1 cell, and cells by the side of these without any. But when they were hatched, I have always found them in regular circular form, no cell missed, and no cell with more than 1 larvæ in it. From this I conclude that the queen lays her eggs, and the workers place them where they ought to be.

My reason for the second is, on examining the cells after the bees have put in the feed for the larvæ, we find it consists of a milky substance not like pollen or honey, or a mixture of the two. I, therefore, conclude that the bees eat the pollen, which excites some gland to secrete this feed for the larvæ, the same as some medicine will produce an action on some gland in the human system. The bees may have some way of bringing this gland into action without pollen; if so, that would account for the rearing of brood without pollen, as we sometimes hear of their doing.

For the third, on opening a hive in cold weather we find the bees on top and outside of the cluster so stupid they can hardly crawl. I think it would be impossible for those bees to work their way down to the honey. The business bee that comes out to inquire into the cause of the intrusion, comes from the center of the cluster; from this I conclude that the bees in the middle, when they get their fill of honey come to the outside, and take a position over the stupid bees. A continuation of this brings the stupid bees in on to the honey, and when they have filled themselves they become lively and take their place on the outside again.

"Fourthly," as the minister says, the cause of dysentery is a subject that bee-keepers differ very much about, and certainly I do not wish to be deceived about it. Since I stated last spring in the BEE JOURNAL that I thought the cause was starvation, I have studied considerable to ascertain, if possible, the real cause. I have treated many cases of dysentery among human beings caused by bad air, bad food, or any other poisonous substance taken into the system, and have found that perfect quiet, proper medicine, and little or no food, was the most sure way of curing the disease. But that is not the case with bee-dysentery—it is right the opposite, a general stirring up, when they can fly without chilling, and plenty of good, rich food, is the remedy, and it seldom fails.

The question comes up, is it the same disease produced by the same causes, and cured by so opposite a treatment? The conclusion is inevitable that it is not, and that it is not caused by poisons taken into the system. After I came to this conclusion, I commenced to search for dysentery from some other cause. On reading Mr. Chassat's (of Paris) experimental investigation on the effects of starvation on the lower animals, there I found two effects that I think will

touch on our case. The one was that the muscular force lost only 42 per cent., and the nervous not quite 2 per cent. The other was "at first a scanty excretion of dry, bilious grass-green feces, and afterward diarrhea of liquid saline matter. Do not these effects show our case exactly? They have lost very little of their nervous power, and have six-tenths of their muscular strength. Our bees that have the dysentery when they fly out, show much nerve and strength, even if they are so far gone that they cannot get back to the hive; but if they get back and get their fill of honey, they are soon all right (notice how quick Tanner regained his strength after his 40 days' starving). The diarrhea needs very little comment; it is our bee-dysentery exactly. But, it will be asked, if starvation produces dysentery what produces starvation when there is plenty of honey in the hive? I answer, anything that will stop the evolution or the regular action of the bees, as mentioned in No. 3. In case of long confinement, the bees become less active the longer they remain in the hive, if nothing disturbs them, and they may get so the inside bees fail to come out and take the place of those on the outside, until they so far starve as to show the symptoms of starvation, and unless there is a change death will be the consequence.

Again, in case of dampness in the hive, the bees will get stupid much quicker in a damp atmosphere than in a dry one, and the bees that come out from the center, if they find the bees and comb wet outside, will crawl back again rather than crawl over their wet companions, and the outside ones are abandoned to their fate; but if the weather soon becomes warm, the bees by their activity will get up heat, and by using their wings will get up a breeze and dry off the combs, and all is right again.

Also the bees may have commenced rearing brood, and those inside bees may be employed eating pollen, secreting food, and caring for the young, and the outside ones entirely neglected, and if the cold continues long, starvation and dysentery will be the result with those outside, and spring dwindling of those inside. It may be asked by some one why one colony may have the dysentery and another, under the same circumstances, not have it?

I will answer that by asking another, why will one colony under the same circumstances gather more honey than another? My answer to both is, I do not know.

Mendon, Mich.

For the American Bee Journal.

The Pollen Theory—One Experiment.

JAMES HEDDON.

Last Thanksgiving day we put 40 colonies into an out-door cellar; 4 of them were occupying our nucleus-sized frames, and were nearly all out of honey. I wished to save them to aid me in early queen rearing. About one year ago now I caught the sugar-

brick candy fever, and made some 30 2-lb. bricks. One batch, of some 4 bricks, I made with the addition of flour, as directed in *Gleanings*. These 4, together with some of the pure sugar-bricks, were left over.

Soon after housing these colonies, I introduced to 3 of them 2 pure sugar-bricks each. To the fourth one, 1 pure brick, and one mixed with flour, "to stimulate breeding." We gave it to them to see if bees could eat it safely in confinement. About 6 weeks afterward I took a peep. In each of the 4 hives the bricks were as much as $\frac{1}{2}$ to $\frac{1}{3}$ gone.

In hive No. 4, containing the flour-brick, the bees were all dead, and the bricks, frames, and bees fearfully daubed with dysentery. So far as I can see this is the only colony among my 220 that shows any sign whatever of the disease. I have not taken out these 40 colonies, as I might have done, and given them a flight, for I want to keep them subjected to the same degree of cold and confinement that last winter's weather would have done, in order to put to the test some experiments I am making, even to the risk of possibly losing some of them.

I have just read Mr. Clarke's attack on Professor Cook, with much interest and instruction. I have re-read it, and re-re-read it, and to save my life, I can't see any argument in it. The instruction I gain is this, as near as I can draw correct inferences: First, he "trembles" a little more before Cook, than Heddon; second, that as long as he cries "more proofs," he does not know that he is beaten; third, that he recognizes no answer to his wordy sarcasms, in what I have said in my reply to his attack on the "Pollen Theory." He hands out proof to the Professor, in the line of an assertion on the part of L. C. Root, that certain undefined observations of his and others, proves that bees discharge dry pellets of excreta during winter, but when I told him that I had carefully examined several hundred dysentery-killed colonies, and saw evidence that pollen-eating caused the disease, that did not go down as any evidence. I wonder if the above experiment will convince Mr. Clarke any?

At last he brings forward Dr. Donhoff's analysis of bees' excreta, which goes far to prove that pollen-eating is at the bottom of the mischief, and then exultingly asks, "How does the no-pollen theory square with it?" It squares with it just like this: When so scientific and extensive an observer as Professor Cook has never seen the dry pellets, it argues that if there is such a thing, it is very rarely met with, and that Dr. Donhoff's subject for analysis was dysentery excreta, and his finding the "undigested pollen" in it is just what I should have expected.

WE 18. 1.—Some in writing use the "we" and "our," while others use "I" and "my." As I am among the former, I will give my reasons when I speak of "our bees," why I do not say "my bees." These bees have been earned by a good woman and

myself in a real partnership, if not a legal one. They really belong to my wife and myself together, and the children are really interested in them also. When I speak of "our" packing for winter, I mean my help and myself. "Our" opinion about the best cellar for bees, is the opinion of all of us. I hardly think the more egotistic "I" and "my" sounds any better.

Dowagiac, Mich.

Translated from *Bienenzeitung*, by A. R. Kohnke.

Temperature Required in Winter.

DR. DZIERZON.

As in nature in general, so in a bee-hive prevails absolute rest at present. Half-asleep they await patiently the time when the morning rays of the sun of approaching spring shall call them again to renew their work. But alas! not every colony will then respond to the roll-call. Many of them have gone to sleep to awake no more. Success depends mainly upon the bee-keeper, whether or not he has done his duty with understanding and care to insure wintering without loss.

Although bee-keepers are agreed as to the most necessary requisites to obtain the desired object, there is still a great diversity of opinion as to the temperature bees require during their winter's rest. One claims, for instance, that a bee-hive should be made in such a manner that the temperature of the interior is never at or below the freezing point, whilst another says he is surprised to find that, though bees are chilled at 9° above freezing outside the hive, they are able to stand a much lower temperature when in the hive. Both are perhaps of the erroneous opinion that the whole interior of a hive is warmed by bees, as a room by a stove.

When the bees cover all the combs, instead of clustering, the temperature in a hive may perhaps be the same in all its parts; but when bees, on account of a low temperature, have clustered in as small a space as possible, they will warm the hive no more than a well covered person lying in bed will warm a room, because in both cases the heat of the warm body is confined to a very limited space. After a protracted cold spell of not more than 6° below freezing, I always found, even in the best protected hives, the combs and walls of the same covered with hoary frost, when even those bees on the outside of the cluster would enjoy a temperature 10° above freezing; otherwise they would certainly have been chilled and died.

To save honey and prevent exhaustion, bees maintain no higher temperature than is absolutely necessary to their existence, but are just as well off if nature or man provides a much higher, as is proven by their well-being and doing in Brazil, where they enjoy a temperature of 30° above freezing during the time of rest. When we have done our day's work and retired to enjoy our night's rest, we do so no matter whether the temperature is 20° above or below the freezing

point; bees the same, their rest being entirely independent of degrees of temperature, but dependent on the rest of nature and vegetation. And it makes no difference whether an extraordinary degree of heat or cold causes vegetation to stop growing.

It is, therefore, a mistaken notion to suppose bees must be exposed to a certain degree of cold to winter well. Instinct (which may be called a habit inherited) it is which teaches the bees to abstain from useless flights, because there are no flowers, thus compelling them to absolute rest. During the season from 1833 to 1834 we had no winter in the sense generally accepted; on the coldest day, it being the 6th of January, 1834, we had but 6° R. (18° Fahr. above zero) below freezing. In that same month hazelnut bloomed; in February gooseberries; and bees wintered excellent. So also our last winter (1880 to 1881) was not a very severe one and bees wintered generally quite well. Has a bee-keeper ever found cause to complain of too mild a winter?

It is therefore beyond my comprehension and I find hardly words to express my surprise, to notice that as sensible a man as Dr. Krasicki in his paper the *Bee-Keeper*, published in Poland, ascribes our losses during our late severe winters to an excess of high temperature. For after enumerating the losses of which bee-keepers complained in the different bee-papers, he says: Such are the losses of the German bee-keepers, who follow the advice of their veteran bee-master, who claims that bee-hives can never be made to be too comfortable; bees never generating more heat than is necessary to their well-being. But Dr. Krasicki says: "I prefer 10° of cold to 1° of heat. The bees with which Dr. K. has made his observations must have the nature of a Polar bear, and the Polar region must have been their native country, if his observations and conclusions are correct. Our German bee cannot be classed with such; these winter the better the milder the temperature is during that season, and the better the more they are protected in a severe one.

Bees do not suffer in Syria, Africa, and Brazil from heat, nor do they here in hot summer and mild autumns; and they should be destroyed by being too warm in severe winter? Who can comprehend such inconsistencies? There are only two cases imaginable: 1st, when the whole atmosphere is heated to such a degree that the comb begins to melt and breaks down, which has been reported to be sometimes the case in regions about the Red Sea; 2d, when the entrance of a strong colony is closed without having any other ventilation or opening. In such a case, the temperature in the hive becomes very high in a very short time, so as to break down the comb. Many a bee-keeper, furnishing strong colonies for exhibition at conventions, has found that to be a fact, as also the one who closed the entrance to cause two swarms, which were about to issue at the same time, to fly together, the

contents of the closed hive looked like being boiled when opened a short time after. But that with an open entrance, a colony should perish or even suffer, on account of being too warm, I flatly deny, and declare it to be an impossibility. If, for instance, the entrance has been closed during transportation, on opening the same a part of the bees will come forth immediately and commence to ventilate to expel the warm and vitiated air, and in a little while the colony will be quiet again. But if ventilation is of no avail on account of the whole atmosphere having a high temperature, then the bees will leave the hive and cluster outside, which we may observe quite frequently on sultry days in summer; this outside clustering we may even observe in winter, by putting bees in a very warm room. In 1846, when my whole apiary of 60 colonies and many empty hives were destroyed by fire, I had a chance to observe the conduct of bees in a heat which was unbearable to man. They would leave the hive in larger and larger numbers on the approach of the fire and heat to their hives, but clustered quietly on the outside until devoured by the merciless element, by which it appears that bees very well know how to rid themselves of heat in the hive as long as the entrance is open, and are not quite as stupid as Dr. Krasicki wants us to believe.

But does Dr. Krasicki furnish us no proof for his theories? Certainly, but on closer examination they prove too weak to support his cause. Here he mentions a colony in a log gum with a door which had come off, still the bees, though entirely exposed, withstood a very severe winter; there another colony in a hollow tree with a very large entrance had existed for several years. Why, that is nothing extraordinary and proves nothing. I have had similar cases happen to me, and reported them. Just think, the bees clustered in a compact mass in the center of their nest and the combs around them all covered with hoar frost, which, being a very poor conductor of heat, acts as a very good envelope, preventing the escape of heat, like a heavy feather bed. As long as bees can get to honey, they are able to withstand the severest cold weather, may the hive be open or closed. In fact, an open door or large entrance is preferred, as in that case they are supplied with fresh air more readily than by having an air-tight door and a small entrance perhaps nearly closed by frost and snow.

How the interiors of hives look after a protracted cold I had occasion to observe in the winter of 1845. From the beginning of February until Easter, we had the severest winter known for a long time, without any interruption, and I had to take many a heavy and well protected colony into a warm room to save what could be saved. On opening such hives, I found them almost a solid lump of snow and ice, looking more like an ice house than a bee hive. If bees do not winter well in well-protected hives, the cause is certainly not in

having had too warm winter quarters, but most likely on account of not having had proper ventilation to carry off the vitiated air and noxious gasses, or for want of water to quench their thirst. As long as the atmosphere is not heated to a degree as high as it attains sometimes about the Red Sea, which is with us no natural phenomenon, excess of it cannot be taken into consideration in our latitudes. It is my conviction that the average temperature which the bees enjoy during their working season, which is from 15° to 20° (66° to 76° Fahr.) is most conducive to their well-being in winter also, as in that case they would perhaps consume less than in severe winter weather, when, to keep up the necessary temperature, they have to consume more honey. To protect them from cold, their worst enemy, should always be our point in view, in doing which we will prevent an excessive consumption of stores, which is certainly to our own as well as their interest.

Karlsruhe, Germany, Nov. 23, 1881

SELECTIONS FROM OUR LETTER BOX

Increase and Prospects.—I have 25 colonies of bees, and am working 25 more for my neighbors; have examined them and find all doing well, with plenty of sealed honey, and think all will winter safely. I expect to work my home apiary for section honey, as I can find sale for comb honey when I cannot extract. I have trouble to obtain straight combs without separators; am like Mr. Doolittle, do not like comb foundation in sections, unless I could obtain a better kind than I have had. Last season was a poor one for surplus, but the early part was splendid for building up. I made 11 colonies from 2, which were very weak in the spring, one having no more than 1 quart of bees, besides I reared all my queens from the same two colonies. White clover was a complete failure as to honey, but after the fall rains we had a splendid fall harvest for the bees, but not much surplus. Golden rod yielded, I think, the principal part. We are getting paid back for our drouth last summer, with compound interest, for it rains almost without ceasing. We have had an exceedingly warm winter to date, the thermometer reached as low as 14° above zero on the 24th of January, that being the coldest we have had, while Mr. Doolittle, of New York, writes Jan. 24th, 26° below. What a difference in a few hundred miles. I have 2 acres of melilot or sweet clover, sown last spring, which looks promising. I will report results next fall. I measured one single root, pulled up, which measured 20 inches in length. Drouth surely will not affect it much. White clover looks well and has been green all winter.

A. W. STITH.

Demossville, Ky., Feb. 17, 1882.

Undersized Bees.—On page 92 of the BEE JOURNAL for Feb. 8, there is an item from Mr. Mallory in regard to undersized bees. If I rightly understand the statement, he means that those small bees hatched in 15 days after the brood was given to the colonies. He also states that it was thought a high temperature matured the bees early. Now, it is a plain case that they were not "mature" bees, but forced, imperfect, immature bees, and what were the queens, reared by such an artificial, forcing process, the full sisters of these same lively little workers which lived only a few days? I do not make the sweeping assertion, as others have done, that they are all worthless; but I do most positively say, that the majority of queens so reared will not give satisfaction, and will be short-lived. But scores of bee-keepers are practicing this method of queen-rearing, and sending them broadcast over the country, is it any wonder that the cheap queen business is falling into disrepute. Although we may differ in opinion as to how to produce the best queens, let us be very careful and sure of what we are sending to our customers, and "do unto others as you would have others do unto you," by sending out only such queens as we would be willing to introduce to our own colonies. JONAS SCHOLL.

Lyons Station, Ind.

A Prospect.—We have had some rain here in the last month, and have hopes of getting honey yet; still the prospect is not very good at my place. The rainfall has been 6¼ inches this winter; 16 inches is our average for this country. G. E. PLEASANTS.

Anaheim, Cal., Feb. 20, 1882.

Bees in Excellent Condition.—It being warm yesterday, my bees had a good flight. Upon examination, I found that they had brood in a space as large over as my hand. They are in the best condition I ever had them at this season. I think these points are necessary in wintering, viz: a good, fertile queen, plenty of young bees, plenty of sealed honey without much pollen, and to keep them dry.

THOMAS CHANTRY.

Casey, Iowa, Feb. 27, 1882.

Much Food Consumed.—Thus far the winter has been very mild, and bees have a good fly every week or ten days at farthest. They have consumed a good deal of their stores, and many will have to be fed to enable them to see the next honey season. B. G. C.

Trumbull county, O., Feb. 25, 1882.

Wintering Nicely.—Yesterday and to-day our bees had a good flight. Colonies taken up and fed with sugar syrup last fall are wintering with the loss of but few bees, and do not mark the snow with excreta like others with natural stores and plenty of pollen. We lost one nucleus with a pint of bees, having 6 frames. If confined to 2 frames they would probably have survived.

W. H. STOUT.

Pine Grove, Pa., Feb. 15, 1882.

Bees in Nebraska.—My bees carried in natural pollen on the 14th and 15th inst., which is the earliest I have ever known them to gather pollen in this part of the country. I think they obtained it from the soft maple and the hazelnut; but it turned cold since, and the 20th was about the coldest day of the winter. To-day is nice, but not quite warm enough for my bees to fly. Last spring my bees gathered their first pollen April 17th. I had success in wintering on the summer stand last winter, and my bees appear to be doing all right so far this winter. Which bee, in your judgment, is the best—the Italian or Cyprian? Most of my bees are dark-colored. I have 2 Cyprian colonies. They are bad to sting, but I think are more prolific and better honey-gatherers than the common black bee. P. BOLINGER.
Salem, Neb., Feb. 23, 1882.

[In our judgment, the Italian bee has as many excellent points as the Cyprian. It is possible that an amalgamation of the two races may develop new and desirable traits.—ED.]

Sweet Clover.—I have a fine young orchard, set out last fall, and expect to put two rows of raspberries between the rows of trees, and sow the whole in some kind of honey producing clover. 1. Now, will sweet clover grow so rank that, if I fail to cut it each year, it will be a detriment to the trees by choking them? 2. Does this clover spread? 3. If I wish to eradicate it, would it be hard to do? 4. What amount must I sow to the acre? Please answer through the BEE JOURNAL. Bees in this section doing nicely, though right now they might use overcoats to an advantage.

L. W. WAINWRIGHT.
Noblesville, Ind.

[1. Yes, it would prove a detriment, unless cropped or mown. In rich soil it would grow 5 to 7 feet in height.

2. It would spread in consequence of seeds dropping the second year; but, in the common acceptance of the term, it does not spread, as the roots grow in clumps.

3. No harder than red clover.

4. From 4 to 6 pounds. If drilled, less will be required.—ED.]

Sure Cure for Bee Stings.—I have never seen my cure for bee-stings in the BEE JOURNAL. I charge nothing for the recipe, except to be recognized as its discoverer. It is as follows: Buy from any drug store a small phial of tincture of myrrh, as soon as you are stung apply a little to the puncture, when all pain and swelling ceases instantly. It is also excellent for bites of spiders and poisonous reptiles. I hope all will try it and report result in the JOURNAL. Bees here are in excellent condition. So far, mine are doing finely, with a less quantity of dead bees than I have ever had at this time of year. The coffee sacks over them, I think, are

just the things for winter, being warm, and very nice for the evaporation of moisture through them; they are also excellent ventilators to permit the escape of foul air. I have not lost a colony this winter, and all have been tlying for the last week.

R. L. AYLOR.

Waterloo, Ky., Feb. 16, 1882.

Metal Rabbets.—Would you advise the use of metal rabbets, where the hives are made to take frames with open top-bars, or would you let the ends of the top-bars rest on the wooden rabbets?

G. H. DENMAN.

Pittsford, Mich.

[We would advise the metal rabbets in all cases where the wooden lugs of the top-bars rest on the rabbets. If metal corners are used, then, of course, metal rabbets are unnecessary.—ED.]

My Balance Sheet.—I am not yet so far through the woods that I can halloo much louder than a whisper, yet these bright, sunny February days, and the cheerful hum of the busy bee, inspires me to venture at making my report for 1881, as follows: Put into winter quarters, fall of 1880, 50 colonies, worth, say, \$250; bought 1 Barnes saw and freight, \$41.52; lumber, \$19; 17 dead colonies for combs, etc., \$22.10; nails, postage, etc., \$25.16; lost 23 colonies in wintering, \$115; bee-books and papers, \$5.50; total apiary debtor, \$478.28. Cr.—58 colonies at date, \$290; 13 empty hives, \$19.50; 500 frames, \$20; fixtures, \$10; 1 Barnes saw, \$40; 1,623 lbs. comb honey sold at 20c., \$324.60; 123 partly filled sections on hand, \$12.30; 14½ lbs. wax, \$2.90; 32 queens sold for \$40; total credit, \$759.30; deduct apiary debtor, \$478.28, leaving balance for labor of \$271.02. This report has nothing to do with my bee-keepers' supply business, which is a separate account. The weather here is very mild, with bright sunshine; the air is full of bees; and all nature wears a smile.

U. E. DODGE.

Fredonia, N. Y., Feb. 15, 1882.

From Kentucky.—I am a constant reader of the BEE JOURNAL, and consider it a boon to bee-keepers who read, think, and act intelligently. There are not a great many bees kept in this (Mason) county, but the business is gradually looking up, and many are adopting the more improved hives, and some the more improved methods of manipulation. Although the winter of 1880-81 was unusually severe for this latitude, bees wintered well, and so far as I have been able to learn not 5 per cent. of loss was sustained. Last season was a poor honey crop owing to the protracted drouth which cut the white clover short. My colonies did not average 50 pounds surplus, and no swarms; in fact the bees here seem to have abandoned the old plan of increasing by swarming for the last three years. I had 7 colonies in the spring, increased to 9, and all are now in excellent condition, on the summer stands, in Lang-

stroth hives, with the upper story filled with coffee sack on frames, and an abundance of old clothes and carpets on top of the sacks. I take the packing out and dry it every warm sunny day. I have not lost a colony for 5 years from wintering.

Minerva, Ky. O. N. WEAVER.

Light Wanted.—I wish all who have any improvements in the form of hives, would let us hear from them through the BEE JOURNAL before we get our hives all complete for the season.

1. The sweet clover seed I bought some time ago I find is all in the hull yet; please tell us how much we should sow per acre when in that state?

2. Will it germinate soon enough in that condition?

3. I expect to sow it in an orchard in the spring with oats. Should I sow anything with it? I intend to let it lay for pasture and hay. I hope it is decided by this time that it is no pernicious weed, as has been stated.

I wish to state for the benefit of those to whom it may not be the most convenient to carry their bees from the cellar to the summer stand for winter flights, or where it is too much shaded so as to prevent them from flying (which is the condition with my summer stands), that I find it unnecessary to carry them to their respective places, but set them in the most convenient place in the sun, and I have not seen a bee light in the place where they are kept in the summer. I have but a few to experiment with, but shall do the same hereafter. Bees are doing well; all have more or less young brood; averaged, per hive, a little over 100 lbs. of extracted honey; selling at 15c. per lb.

H. G. HICKMAN.

Schoolcraft, Mich.

[1. All sweet clover seed we have seen is in the hull. If sown broadcast, 5 to 6 lbs. per acre; if in drills, less will answer.

2. Yes; almost as soon as if hulled. The imported Bokhara clover seed, which is virtually the same, is hulled, but we have discovered no difference in its germination.

3. If sown in the spring, you can sow any grain with it you please, and realize a crop of grain, as the sweet clover will not bloom till the succeeding summer. But we would not seed an orchard with it; its growth is too rank and tall to be beneficial to fruit. It is no more a pernicious weed than red clover.—ED.]

Early.—Bees are booming, and gathering honey rapidly. I shall extract some new honey on the first clear, warm day. Some colonies have ripe queen cells and are preparing to swarm; the drones are tlying; we have no winter down here.

J. S. TADLOCK.

Luling, Texas, Feb. 25, 1882.

Heddon's Honey-Board.—1. Can you give me any idea or description of the honey-board of "peculiar construction" that Heddon mentions, on page 55 of BEE JOURNAL? In tiering up regular Langstroth hives, we get a space of $\frac{3}{8}$ inch between the two stories; even where the space is only $\frac{3}{8}$, there is some difficulty in handling top frames; bees are very liable to build up the lower combs between the top ones if they chance to hang a little out of place. 2. Should honey kegs be bunged up tight, if honey is kept for a long while? 3. Should they be kept in the honey house, or in cellar, during very hot or cold weather. Last summer I had a half barrel of honey in the cellar—it was closed up tight—one day I examined it, took out the bung, and it was all right; I closed it up again. Half an hour thereafter the bung banged against the ceiling of the cellar, and the honey ran out at the top of the cask. 4. Did the air I let in cause the trouble? there was no gas in the cask when I opened it.

II. W. FUNK.

Bloomington, Ill.

[1. Heddon's honey-board of "peculiar construction" consists of strips just the width of the sections to be placed on them. These strips, about $\frac{3}{8}$ of an inch thick, are joined by a strip nailed at each end, and to reach the full width of the honey-board.

Heddon's Honey Board.

This honey-board rests on the top of the hive, so as to give $\frac{3}{8}$ of an inch between the top-bars of the frames and the bottom of the honey-board. Regular Langstroth hives should only allow $\frac{3}{8}$ of an inch between the lower or brood frames and the bottoms of the upper or surplus frames. If more space is given, the bees will invariably bridge them. With hives properly leveled, and accurately made, the frames should never "hang a little out of place."

2. Honey kegs should never be filled to their utmost capacity; for the variations from cold to heat, and *vice versa*, expand and contract the volume of honey, and will produce leakage in any wooden package.

3. The honey should be kept in some dry, cool place—either cellar or honey-house. If thoroughly ripened, keep it bunged tightly; if not, scald it.

4. There was a slight tendency to fermentation, and the admission of fresh air gave it activity.—ED.]

Moldy Combs.—On the 16th of November I put 6 colonies of bees in my cellar, and to all appearance they have done nicely since then. To-day being fine, I was anxious to examine one; so I took it out, weighed it, and found the loss to be just 3 lbs., or 1 lb. per month. They did not fly much, but acted very much as they do in summer when smoked. The queen was lively, bees very easy to handle, and not a bit cross, though I used no smoke, lots of stores and no dead bees, but I found mold on the lower half of the sealed honey where not covered with bees, giving the part affected a bluish color. Mold caused, I think, by the hive sitting down tight on the bottom board, leaving only the summer entrance open, 3 being left that way; the other 3 are raised up an inch from the bottom board with a sheet and chaff cushions over all of them. Will the bees open the moldy comb when they need it? I intend to examine them all the first fine day. Would it be well to pare off the caps, and would the bees recap it? When bees have plenty of stores, does it stimulate early breeding to feed? I was surprised at the small quantity of honey used. I was particular in weighing. I do not understand your description of U. E. Dodge's feeder—how deep is the box? Why put in cotton cloth bottom? If bees go into the box will they not drown in the feed?

JOHN YODER.

Springfield, Ont., Feb. 16, 1882.

[Let the moldy combs alone, as the bees will take care of them. Lift out all combs but those actually needed, then add as the queen may need room, and the bees will do all uncapping necessary, and the cleaning. When bees have plenty of honey, there is no object in feeding except to stimulate to brood-rearing; then a thin syrup of honey and water, or honey, sugar and water, is better than a thicker feed. It is impossible to describe Dodge's feeder intelligibly; better send to him for a sample.—ED.]

A Fair Record.—I commenced last spring with 29 colonies of Italians; increased to 96 by natural swarming; obtained 1,600 lbs. of extracted, and 200 lbs. of comb honey; sold at an average of 15 cents per lb; sold 6 colonies at \$10 each, and went into winter quarters with 90 colonies, mostly Italians. They are all right yet. My plan for wintering is to pack in chaff, on summer stands. I prefer this to any way I have yet tried. This has been a very favorable winter for the safe wintering of our little pets. The coldest we have had this winter registered 9° above zero. Brother bee-keepers, let us try and breed our bees up to a higher standard. I know that our bees can be improved by systematic breeding. I think we should breed for the greatest honey gatherers, most hardy, most prolific, and most amiable, all in one. Van Wert, O. FRANK MCCOY.

Bees Gathering Pollen.—I put 45 colonies in a cool, dry cellar in December, and in January the weather became so warm that the bees became uneasy, and I carried them out for a fly. I returned them to the cellar in a few days for fear of a cold spell. But there has been no cold weather at all worth mentioning, and for the two weeks last past, the weather has been very warm, and the bees became so uneasy again that I set them out on the 15th of February, and to-day (Feb. 15), it is as warm as May, and the bees are gathering pollen from soft maple and elm. This is unprecedented for this part of the country, and as the queens are laying finely, if we should get a cold spell of three or four weeks' duration, later in the season, will it not prove disastrous to the brood? At about what period is it best for brood rearing to commence actively? My colonies all have plenty of stores of a good quality. I had charge of Mrs. Wirt's apiary last season, and increased from 30 colonies to 74, by natural swarming, and harvested nearly 3,000 pounds of excellent comb honey, which we sold at home for 20 cents per pound. My bees are nearly all Italians and hybrids. The best result in my apiary last season was from hybrids. I am a close student of Professor Cook and read everything in the BEE JOURNAL every week, and to these two sources I am indebted for the pleasure and the profit I derive from my "blessed bees."

J. R. BAKER.

Keithsburg, Ill., Feb. 15, 1882.

[Yes; three or four weeks of cold weather would kill most of the brood. Brood-rearing is controlled much by circumstances, and when soft maples and elms are in bloom or furnish natural pollen, it will commence actively. You should, however, reduce the capacity of your brood-chambers to the minimum of frames necessary, and only add to them as they become well filled with brood, in order to prevent disastrous chilling, as the capped brood will do much in keeping up animal heat in the hive.—ED.]

An Early Start.—The maples are in full bloom here now; I send you a few blossoms. My bees commenced carrying in pollen on the 10th and honey on the 11th, making several pounds of honey during the past week, which continued very warm and pleasant till Saturday afternoon, when it commenced raining, and rained till Monday afternoon; then turned off colder. If the weather had kept warm a few days longer the peach trees here would have been in bloom. On the 12th the thermometer stood 71° in the shade, and 91° in the sun. I commenced with 3 colonies in 1881; now I have 7 all in good condition. I took about 60 pounds of comb honey from them which I sold at 25c. a pound; sold it at home.

PETER MOERLEIN.

Brussels, Ill., Feb. 22, 1882.

Local Convention Directory.

1882. *Time and Place of Meeting.*
 March 12—Anderson Co., Ky., at Lawrenceburg, Ky.
 J. M. Johnson, Sec.
 15—New Jersey State, New Brunswick, N. J.
 April 1—Barren Co., Ky., at Sinking Spring, Ky.
 11—Eastern Michigan, at Detroit, Mich.
 A. B. Weed, Sec., Detroit, Mich.
 19, 20—Tuscarawas and Muskingum Valley,
 at Coshocton, O.
 J. A. Bucklew, Sec., Clarks, O.
 25—Texas State, at McKinney, Texas.
 Wm. R. Howard, Sec.
 26, 27—Western Michigan, at Grand Rapids.

 25—Iowa Central, at Winterset, Iowa.
 Henry Wallace, Sec.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

A meeting of the bee-keepers of New Jersey will be held at 1111 No. 22, Albany street, New Brunswick, N. J., March 15, 1882, at 10 a. m., to organize a State Bee-Keepers' Association. All interested are cordially invited. G. W. Thompson, Stelton; C. H. Rue, Manalapan; J. H. M. Cook, Caldwell, Committee on Call.

The Texas State Bee-Keepers' Convention will be held at McKinney, Texas, on Tuesday, April 25, 1882.

The Champlain Valley Bee-Keepers' Association will hold their semi-annual meeting at Middlebury, Vt., May 11, 1882. T. BROOKINS, Sec.

The semi-annual meeting of the Tuscarawas and Muskingum Valley Bee-Keepers' Convention, will be held in the Town Hall at Coshocton, O., on April 19 and 20, commencing at 10 a. m. A cordial invitation is extended to bee-keepers everywhere.
 J. A. BUCKLEW, Sec., Clarks, O.

The Texas State Bee-Keepers' Convention will hold its meeting at Judge W. H. Andrews' Apiary, at McKinney, Texas, April 25, 1882.
 WM. R. HOWARD, Sec.

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.
 G. W. DEMAREE, Sec.
 Christiansburg, Ky.

The Barren County Bee-Keepers' Association meets at Sinking Spring school house, three miles west of Glasgow, Ky., on the first Saturday in April, 1882. All bee-keepers of the county are invited.
 I. N. GREER, President.

65 ENGRAVINGS
The Horse
 BY B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents.—Sent on receipt of price, by
THOMAS G. NEWMAN,
 974 West Madison Street, CHICAGO, ILL.

 At \$2.00 a Year, in Advance.

Round Section Boxes.—Mr. G. B. Lewis has sent us a honey rack of Round Section Boxes, made of berry-box material. They are placed in our museum; and we await a trial and report after using them. Mr. Lewis gives the following description:

If these sections are practicable, I claim many advantages over any other, much less work to make them, can get 3 or 4 from the same timber that makes one of the others, weigh only one-third as much, consequently two-thirds less freight. Of course, they are to be shipped in the flat. They can be put together as fast as the dovetailed sections. For these samples we took dry basswood and wet them in cold water and bent them around a frame. Although made of thin material they are much stronger than any other section. They can be thrown into a heap promiscuously and shoveled with a scoop shovel and not brake them. They can be made and sold for \$3 per 1,000, with a good profit. It will necessitate changes in honey racks, cases, etc., to use them. But if they are better and cheaper, they will come into use.

Bingham's Smoker.—We have received one of these as they are to be made for the coming season. Mr. Bingham takes considerable pride in his work, and hence everything that he does is well done. He constantly improves that important implement—the smoker—in every way that his ingenuity can suggest. He describes the improvements made in this smoker thus:

“While I have not made an absolutely water and mouse-proof smoker, I have made a water-proof valve and corners that will not readily soak out the nails, if it gets wet. Mice will not touch the corners or valve. The joint-lining is waterproof, and will not stretch if it gets wet, nor will the valve wrinkle up. The bellows is absolutely linen-proof, as you will see. All but the smallest size is thus made.”

Mr. James B. Mason, of Mechanic Falls, Maine, sends us a few samples of sections which he obtained of a man in Doon, Ontario, by the name of McKenzie, having seen his advertisement of “hives, section frames, etc., of superior pine lumber” cheap. We are glad to say the advertisement was not in the BEE JOURNAL. Mr. Mason says with freight and duty they cost him DOUBLE the amount advertised, and when received he made a bonfire of them. They are of all lengths and thicknesses, and the roughest that it is possible to imagine. We do not wonder at their being consigned to the flames. That is the only thing they were fit for—but it must have been dear kindling wood. It would be impossible to use them for comb honey; it is but another phase of fraudulent dealing.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

We have received the “Prize List” of the East Northumberland Agricultural Society, with very liberal premiums for bee and honey exhibits. We are sorry to say that there is nothing about it to show in what part of the World it is located. This illustrates the error of not putting the state, province or country upon everything. The “Bay of Quinte” Bee-Keepers' Association issues the List, which is so liberal as to be worthy of much commendation.

Just as we go to press we learn with regret that Mr. G. M. Doolittle is sick; threatened with brain fever.

Present Indications.

Bee-keepers all over the country are now confidently expecting a good crop of honey for the present year. Every indication now points to that result, and we have no doubt but that the yield may yet surprise even the most sanguine with its magnitude. The *Semi-Tropic California* remarks as follows :

The present outlook is fair for a good honey season; still the time at which the season can be prognosticated with any degree of certainty has not yet arrived. Our bee-men, however, express more confidence in the promises for the present than they did at this time last year. Nothing but good news reaches us from all bee quarters, and we earnestly hope that this industry will be doubly profitable the coming season.

Colton *Semi-Tropic* gives vent to its enthusiasm in the following item :

Our bee-men are jubilant and are confident of having heavy yields this season. The bees are reported to be in excellent condition and have stood the winter well. The late rains insure plenty of food, and everything promises we shall have an enormous lot of honey stored during the summer season.

The sagacious bee-keeper will now provide early for the coming honey flow, and be ready with his "tub right side up" to catch all that comes to his door. The sloven, slow-coach, and old fogey will not be ready, and in the fall will make wry faces over their luck, and be all ready for the dismal quarters provided in the prison of "blasted hopes," long before December's wintry storms shall visit the earth.

One-Piece Sections.

On page 140, Mr. Stocking asked what Mr. Forncrook's patent covered. We replied that Mr. F. claimed that it covered all one-piece sections and the machine for their manufacture. Mr. Lewis objects to this and sends a letter containing the following extracts from the Patent Examiner's decision :

The device in controversy, as will appear from a consideration of the issue defined, is a sectional transversely grooved blank in single piece, having two features which render it available as a honey frame, viz., the longitudinal guide groove for starting the comb, and the side insets for the entrance of the bees. The box blank without these two distinguishing features is admitted old, and is shown by the patent to H. W. Hutchins, cited in the record by the Primary Examiner.

Mr. Lewis also sent us the Patent Office drawings of the Hutchins' box described by the Examiner. This is the same that was mentioned in *Gleanings* for Feb., and quoted by Mr. Byron Walker in the *BEE JOURNAL* for March 1, page 136.

Mr. Stocking inquired if the Lewis one-piece section was an infringement of the Forncrook patent, and desired its description, which we gave on page 123. We replied that we could not say whether it was an infringement or not. Mr. Lewis now writes us as follows :

I did not know until your reply to Mr. Stocking that Mr. F. claimed to cover all one-piece sections, and all machines that make them. I supposed he only had reference to making his section and using his machine. Mr. F.'s patent claims and description are perfectly plain and show just what he has. Any section not made like that, is no infringement; at least so say some of the best Patent Attorneys in the country.

We suppose the matter of infringement is a legal one, and hence we stated that we did not know, when questioned on that point. We answered the queries propounded to the *BEE JOURNAL*, by stating what was "claimed" by the patentee. The only interest we, or our readers, have in the controversy is to know what is claimed, and with this explanation we hope all will be satisfied to leave the matter for time, law, or something else to decide.

MISCELLANEOUS.

Ekes and Nadirs.—In correspondence from Europe, these words are often met with, and as many may not understand them, we give the following explanation from Mr. Pettigrew's "Handy Book on Bees :

Can bees be prevented from swarming? Yes, by the use of ekes; and what are these? Additions or enlargements from below—that is to say, eked or lengthened. Hives are eked by riddle rims, or hoops made of four or five rolls of straw of the same description as those in a straw hive, the same width as the hives raised by them. These ekes are fastened to the hives by nails or staples going into both, and the junctions covered with any kind of cement or paste.

But eking hives does not always prevent their bees from swarming? Not always, but in ninety-nine cases

out of a hundred it does. In some hot seasons, and on rare occasions, bees have been known to square the ends of the combs before their hives were quite full, and swarm. This so seldom happens that it may be considered exceptional, and out of the usual run of events. When our hives are timely eked we have never the shadow of a fear that they will send off swarms. When ekes are used cross sticks must be put into them at the highest parts, so that the combs may be fastened.

Nadirs are the opposite of supers. Nadirs go beneath bee hives, and supers above them. If a hive which we wish to keep for stock becomes heavy in July we place a nadir beneath it—that is to say, we lift it off its board, place a hive with cross sticks and a large crown hole on the board, then place the full hive on the empty one, pin the two together, and cement the junction. The bees are soon found hanging in a large cluster like a swarm through the crown hole of the nadir. New combs are speedily built from the upper hive through the crown hole down to the board, and in process of time the nadir is filled with combs and brood, almost all the honey going to the upper story. At the end of the season the top one is taken off for honey, and its bees driven into the bottom hive, which is kept for stock.

Nadirs are most useful for early swarms that become heavy before the end of the season. By placing nadirs beneath them both honey and stock hives may be obtained.

One year our earliest swarm was taken off about the 10th of May. By the end of four weeks it was full, and nearly ready for swarming. Instead of taking off a virgin swarm we placed it on a nadir. At the end of the season we found that it weighed 70 lbs. All the bees were driven below, and the top one taken. It weighed 50 lbs., and the nadir 20 lbs. We thus got nearly 30 lbs. of honey, and a stock hive from a swarm of May. A few pounds of refuse honey were given to the nadir, which was a strong colony in the spring following.

Spring Dwindling.—W. M. Kellogg remarks as follows on this subject in the *Prairie Farmer* :

The time will soon be here when bees will have to be taken out of the cellar, as generally the weather gets too warm for them to be kept quiet any longer than about the last week in March, though one season I knew it to be as late as April 15. But it is better to keep them in as long as possible without their becoming uneasy, by cooling the cellar or bee-house, or opening doors and windows at night, closing them early in the morning.

Many times we are obliged to carry bees out owing to a continued warm spell of weather, in the middle or latter part of March. This may continue for several days, perhaps a couple of weeks. Maple buds will start, the bees get a little pollen, enough at least to start brood rearing in full vigor, which the bees endeavor

to cover by expanding the cluster. Now comes a cold wave sweeping over the country, very likely bobbing the thermometer down to freezing; the bees have to cluster compactly to keep from chilling to death, and leaving a large share of the new tender brood to perish with cold. All these young bees that should have been saved to keep the old stock strong are lost, leaving the colony in worse condition than if they had started on brood at all, for old bees die very fast in the spring; during the winter they lie dormant and very few die during those months. But when warm weather comes to quicken the bees into active life and work, the old ones drop very fast, and unless young bees are raised to fill their places the colony will dwindle and become weak. Such colonies have to be nursed pretty carefully if they are going to be gotten up strong enough to be of any profit to the bee-keeper during the season, for it is the colonies that are "chock full" of bees when the honey flow comes that are going to get us the best yield of honey.

Most colonies begin to rear brood in the cellar in February, more so than those out of doors, the temperature being more even and higher, making the chances for spring dwindling much stronger than those colonies wintered out doors, which have extended their brood as far as they could keep it warm. The bees in the cellar having had a warmer place, have spread their brood farther accordingly, and when placed on their summer stands are not in fit condition to withstand sudden changes of temperature, like a man who has been housed up for weeks. Hence we see that something ought to be done to help retain heat in the hive. With our common hives made of inch boards it is a good practice in the fall to confine the bees in the center of the hive, giving them well filled sealed frames of comb honey, judging of the amount needed by the number of spaces occupied by the bees on a cool morning; place a division board down each side close to the outside combs, cover the frames with a good quilt of duck or burlap with a stick or two on top of the frames so the bees can go over the top of them, and fill the cap of the hive and down both sides of the division boards with clean, dry oat chaff, or straw if the chaff cannot be had.

If you did not do this last fall, do it now when you take the bees out, and thus save very much if not all of the spring dwindling, and a consequent loss of honey by and by. Very often the hives and combs come out of the cellar quite damp, which is another cause of chilled bees, which the straw packing will absorb and carry off.

Healthfulness of Honey.—The *Texas Agricultural Journal* delivers itself of the following:

"If the people were properly impressed with the facts in regard to the healthfulness, economy and delicious comfort of the daily use of honey, there would be nothing heard of over stocked markets.

Should Fruit-Growers Encourage Bee-Keeping?—Mr. R. Sherfy, at the recent Pennsylvania State Fruit Growers' Association gave a lecture from which we extract the following:

Almost simultaneously with fruit-growing I associated bee-keeping, not, however, without doubt as to its propriety from what I had previously read. Believing, however, that our All-wise Creator made all things for a useful purpose, I at once concluded to investigate the question of fruit and bees. The first fact that we notice is the love the bee has for the nectar and pollen of all kinds of fruit blossoms; its assiduous visits, crawling over stigma and anthers, dipping in here and there for nectar, patting the pollen upon the thighs, passing swiftly from blossom to blossom, carrying pollen from anthers to stigma, and never visiting but one kind of blossoms on the same raid.

Are these assiduous visits intended to benefit the bee, or is it not one of the great designs to bring about fruitfulness? Is not this little insect filling a place for the benefit of man, both in fruitfulness and in the increase of the colony, to assist in gathering a richer harvest in midsummer? We do not claim that the bee is the only agent to assist in fertilization; there are many other agencies. There are two facts that we have noticed, viz: That a bee will never visit an open blossom that has been injured by frost or cold; and that fruit never fails to set well where bees have reaped a rich harvest from the blossoms.

After fruit blooming the bees turn their attention to other fields of pasturage until the fruit matures or rots. Here is where many fruit-growers complain. The cry is "the bees are eating my peaches, plums or grapes," as the case may be, and in one sense they are right. Countless numbers are "diving" into the fruit—and here we investigate. Hale's early peaches are swarming full, fruit not ripe but rotting. Every bee stops short at a rotten spot. Remove every peach that is not sound; the bees run over the balance of the fruit in a wild and apparently frantic manner, then off to another tree they go and alight upon the first defect they find. Early York comes in, fruit sound, no bees about; we pick for distant market; in two or three days some are quite ripe; the bees are feasting upon them; we take off all unsound ones as before, and the bees hunt frantically, never stopping to gnaw or make an entrance, but off to another tree they go. Several years ago, when the new very early varieties of peaches first ripened on my grounds, I had a very decided test with the bees on two early Alexander trees. I took off all apparently defective fruit. The bees had no other resort; they carefully examined every peach left, never stopping except where the skin was broken. Although I had some trouble in saving the fruit of this variety, I failed to detect a bee tear a solid skin. The tenderness of the rind and slight disposition to rot, coupled with the

depredations of other insects, were the first causes that gave me trouble with this variety.

Bees have eaten my grapes, but not in every season. Those seasons were not confined to scarcity of bee pasturage, nor the kind of bee, Italian, hybrid, black or German. I observed the same manner of seeking broken places in the skin of the grape as in the peach. I have never yet seen a bee sit sparrow-like upon any kind of fruit and tear a solid rind. I am convinced that ripe fruit, that the bees are so fond of, should have been disposed of in some manner before the rising of that day's sun. Grape skins that bees have emptied of the pulp are nearly all slit from end to end. If the bees slit the grape skins, why do they make a circular entrance into the peach? If they tear the grape, why do they not go at it at once, instead of running frantically over it? I have found when the bees were busy at the grades that most bunches had fermented berries distributed through them, which indicates unsoundness from some cause in the skin of the fruit.

The Uses of Honey.—Mr. C. F. Muth writes as follows to the *Patron's Guide* of Boyd's Station, Ky.

To show to what extent honey is used for manufacturing purposes, my sales during 2 weeks in October, 1881, amounted to 22,000 lbs. Twenty-eight (or 29) barrels (520 lbs. in a bbl.) of it were used for manufacturing purposes, principally by bakers and tobaccoists. These latter find quite a profitable sweetening in honey and promise to be great customers for our produce in the very near future.

Our retail trade for table honey was rather slow for the last two months; but our sales by the barrel, to manufacturers, has kept one of our wagons busy most of the time.

Trade changes in all branches of business. And it is interesting to every bee-keeper to notice the change which has taken place in the honey trade. It is not long since when we could hardly convince our customers that the extracted article was pure honey. The next obstacle was its granulation. The granulated honey would be suspicioned and sold for less than honey in its liquid state. This was made use of by eastern and western adulterators; as, viz., the country was overrun with beautiful glass jars filled with glucose (which would not granulate) in the middle of which was a piece of comb honey. These adulterators did and do now a flourishing business, but this branch of their business is entirely used up. Consumers, now, prefer the granulated honey and I saw an article not long since, that glucose manufacturers have almost accomplished making glucose which will granulate. So you see that these infernal adulterators try their best to keep up with honest men.

Articles for publication must be written on a separate piece of paper from items of business.

Read before the Northeastern Convention.

Dysentery, Its Causes, and Prevention.

CHAS. DADANT.

Dr. Angelo Dubini, an eminent physician of Milan, Italy, and learned bee-keeper, contests that the term dysentery be accurate, to designate the disease, which is the subject of this article. In a book, *L'Ape*, published in 1881, he uses the term diarrhea. In fact, if we consult Webster's unabridged dictionary, we find that dysentery means inflammation of the rectum, or colon, attended with griping pains, constant desire to evacuate the bowels, and discharges of mucus and blood; while diarrhea means a morbidly frequent evacuation of the intestines; a relax; a flux.

Such definitions show pertinately that the word diarrhea applies more accurately to the symptoms of this disease, than the term dysentery.

But is really the affection in question a malady? If we give, at evening, to a colony of bees some syrup, made with one or two pounds of honey dissolved in a quart of water, on the following morning, if warm, we will see the bees flying out to void their intestines. They will shed liquid drops all around of a matter as colored as the honey contained in the syrup given the day before, yet we cannot say that these bees have the diarrhea; for this discharge will be natural, although more copious than usual. But this abundance will be the result of the unusual quantity of water absorbed with the honey.

If, instead of diluted honey, such as white honey is in sealed combs, or if we give thick syrup, made with the granulated sugar, it will be impossible on the following morning to notice the least discharge of excremental matter; for the reason that the honey, or the sugar syrup given, being absolutely pure, has left very little, if any, residues in the intestines.

Let us suppose that, in both cases, we shut up the bees, after giving the food. The colony with pure honey will support, without great suffering, a seclusion of a whole week; or if fed with sugar syrup it will suffer even less; while the bees fed with diluted honey will suffer from the first day; and their sufferings will increase every day on account of the overload of their bowels, which is increased by the necessity for the bees to eat a great quantity of a meagre food, in which they can barely find a sufficient support. Then, some bees, unable to stand the overload of their bowels, will perish; while some will regretfully relieve their intestines in besmearing their combs and the other bees.

If we give those bees a chance to fly, during a warm day, those not too much weakened by their sufferings, and which were not soiled by their

sisters, will become again lively and active, ready to resume their daily work.

From the above we can truly say that the word malady cannot apply to such a condition. It is an accidental suffering which ceases as soon as the cause disappears.

Now that we know what happens in a colony, in which we have intentionally produced the diarrhea, it is an easy task to find the causes which produce such suffering in the colonies during winter. These causes are multiple.

1. Bad honey. Sometimes the honey gathered in July ferments before winter. Its particles of sugar, on account of their affinity for each other, have united, to form granulations, freeing the water which was combined with them. This water then has fermented and bursted open the cells of the combs. The bees in sucking this honey have suffered by the fermentation and by the large amount of water that they have absorbed, to draw from this water the small quantity of honey that it contained, while the bulk of honey, hardened in the cells, could not be used. Such effect is often seen in linden honey.

Unsealed honey although ripened is also a cause of diarrhea; for, honey being hygrometric, absorbs moisture, sometimes to such an extent as to drop from the cells.

At best honey is unwholesome for winter when it contains too much mellose, or uncrystallizable matter, as honey dew; honey from heath, which is gathered in several countries of Europe, and probably also honey from the very last flowers of the season.

2. A second cause of diarrhea is an insufficient population to warm the hive, then the dampness, generated by bees, is condensed around the group, and besides eating too much honey, this food contains an unusually great quantity of water.

3. A third cause of diarrhea is an excessive and prolonged cold, then the bees, to raise the temperature of their hive, eat more, and overload their bowels with feces. It is for that reason that a colony placed in a cellar, where the temperature is maintained at about 45°, can remain healthy for six months and more.

4. At last a too long seclusion in a place either too cold or too variable; this variation, in the temperature being insufficient to give to the bees the chance of flying outside.

None of the causes that I have described would injure the bees, if they were able to fly out and empty their bowels as soon as they experience the need of it.

To this day, the winter is very mild; our bees can enjoy a good flight every week at least, and we have not yet noticed in our apiary a single drop of the foul matter, which they drip around their hives after a few days of cold weather.

To sum up: To prevent diarrhea, it is necessary to see whether all the honey is sealed; and if the bees are left on their summer stands, they need space according to their number,

so as to make them able to warm it. It is necessary to cover the top of the frames with some matter that absorbs moisture; it is also necessary to surround the hive with some straw or other warm material, and after a few weeks of protracted cold when the temperature rises to about 45° in the shade, it is well to awaken the bees by some jarring, so as to compel them to profit by the opportunity which is offered to enjoy a good flight and void their intestines.

If the bees are wintered in a cellar or a special repository, it is as necessary to avoid the rising as the lowering of the temperature far from 45°. If the cellar is too warm open the windows at night, if the nights are cold. If the nights are warmer than 45°, procure some ice and put it in the cellar to melt.

If the temperature is under 45°, shut up all the openings; then, if the colonies are numerous, they will warm the cellar; of course I suppose that the repository is proportionate to the quantity of bees to be wintered in it.

I have never used a stove to warm my bees, and would not like to be compelled to use such an implement.

Hamilton, Ill.

Read before the N. E. Convention.

Wintering and Dysentery.

N. N. BETSINGER.

Mr. President, may it please your honor, Brother Bee-Keepers with both profit and pleasure, be it unto you, to listen for a few moments upon the subject I have chosen, on which to give you the great light, and that light which is just now beginning to draw upon us, is, "How shall we maintain the health and strength of our bees during the long rest in vegetation, here in our northern latitude," on every hand we are informed. "I am done with bee-keeping, the winters are too severe for us."

Thousands have theorized, and a few (seemingly at first) to give a little ray of light, to escape another such a calamity as the most of us the past winter had the misfortune to witness, in which many are, and will be misled with such pet theories.

Not that I think all will fail, for judging from the mildness of this winter thus far, almost any plan will succeed admirably; especially those left on their summer stands, but the great mystery is, why do bees with the same plan of preparing them, winter perfectly one season and the next almost all die entirely?

Some say they have been breeding too much, others say too old bees, or that they ate too much pollen, or the honey was poor. Not a few hold if they could fly every six weeks, perfect health would be maintained. Now it has been a great puzzle to me why this diversity of opinion, until of late, I am able to reconcile it all; the plan wintering in nearly every case has been imperfect.

However, as I propose to tell you the main and only cause of dysentery,

I will not dwell long on repeated theories. I know some of you are already beginning to smile and are saying within yourselves, another theory is to be added to our list. But I say unto you, I shall do what has never yet been done to this subject, and that is, prove every statement I make upon this question.

First, let me enquire, is there any one present who can detect (if any) the difference between honey gathered in 1879 and that of 1880, both being from the same kind of flowers, if not, be it then conceded, there is no difference, no matter what season it is gathered, and to the bee, when properly sealed, honey is honey, and no worker bee during her life, can consume more than seven grains thereof. The calculation is that a swarm of bees will average in November, not far from 15,000 bees, none of which will survive after consuming about 15 lbs. of honey. The quantity of honey taken into a bee's stomach at any one time, is very minute, and that of pollen, is much less, both of which are only consumed to supply the body with heat, while the cluster is in its semi-dormant state. A farmer houses his stock to save feed, but not so with the bee-keeper, for he is obliged to give his bees protection in order to save life, and when the conditions of the latter are perfect, the object of the former is obtained, but where such is insufficient, the bees find it necessary to consume food to prevent the cluster from becoming entirely dormant, the stomach in such cases is used as an organ for generating heat, and the body must sooner or later fall a victim to dysentery. I claim (and shall give positive proof) where the atmosphere is congenial to the cluster, and they have access to and full control of the entrance of the hive, that under no circumstances whatever, will they discharge their excrement in a liquid state.

Well may you ask whose apiary is free from this most dreaded disease, which is brought about only by over-consumption of honey and pollen, chiefly the former. Let us reason together, therefore, and see if the position I have taken is correct.

The standard amount of honey for a colony on which to winter, if I mistake not, is about 25 lbs., and in poor seasons, when the extractor is used exclusively, a large amount of our bees are allowed to go into winter quarters with not to exceed 15 lbs., and in nearly every instance, when such is consumed before the first of April, it has been supposed by many they died of dysentery, caused by starvation, which I consider perfectly absurd, for did they not consume their allotted amount. Was it not then their time to die? Still we find bees dying with dysentery, leaving from 1 to 15 lbs., yes, apparently nearly all of their honey, how is it, with such, is it not true, with you men of experience, when hives are filled solid with sealed combs, that the space between them, is greatly contracted, often caused by the superseding of queens, late in the season, thus diminishing the quantity of bees in each space, though it may

have the appearance of a good colony, while the fact is the reverse. Why then should they consume much honey, for they seldom survive the first half of the winter, but we often see when they are wintered on their summer stands, and are privileged with frequent flights, they come out in the spring with plenty of bees, and apparently in a good condition, with nearly all their honey consumed, and while they have a large amount of brood, a portion of which is hatching daily, it is after the expiration of several weeks before there seems to be an increase to the size of the colony, and in many instances, the colony, though strong in numbers when they take their first flight in March or April, they become, before the first of May, entirely depopulated, (commonly called spring dwindling), and often leaving quite a large quantity of brood. This excessive loss heretofore from supposition, has been said to be old bees, which I shall positively contradict; for how can bees be old, who have not seen but a few days, and many, on which the light of the sun has never shone; is it not a fact that these bees from the excessive amount of labor devolved upon them in nursing the brood, shortened their lives by an over-consumption of food. Although it was accomplished in a few days, for I affirm, that each bee had consumed the portion of honey allotted to her, and a bee is not old until it has seen at least seven months, and while in a semi-dormant state, where the atmosphere is congenial to them, not being obliged to take food to produce animal heat, they have often been known to survive much longer, and that too, without a cleansing flight. Again might we ask, how is it with the queen, does she fly for this purpose? No, no, would be the general response. But how oft do we hear the complaint after a long and severe winter, and the first few sunny days in spring, my bees are swarming out, and what is the trouble. Has not their numbers, during such a winter, been so greatly reduced that the queen, like all true hearted mothers, willing to share the same fate with her own; have also taken an over-supply of food, to assist in maintaining the necessary heat, improves the first opportunity to exude her distended body, and in order that we may save them, two or more such small swarms are united in one hive, and the surplus queens introduced to queenless colonies, or fill some early order for dollar queens, most of which you all well know will not survive but a few weeks at the longest; and what is true with the queen, is equally so with the whole colony, which is positive proof bees do die from an over-consumption of food in a less given time than is due them, compelling them to discharge their excrements in a liquid state: thus the cause of dysentery. And the true and only prevention of this most dreaded disease is: First, a good cellar or house of some kind, so that the air can, if necessary, be changed every two hours, in order that the interior may be free from the smell of bees.

Second, perfect quietness.

Third, the atmosphere outside the cluster, should not fall much below 60° F., and with these conditions the excrements will be discharged in dry state, and a colony of six spaces will not consume more than 1½ lbs. per month. They may also be confined to the repository at least six months, with a loss less than one percent. As I purpose to show to you a few samples of excrements which I have with me, not only for the benefit of those who already believe, but that I may convince the most skeptical, the position I have taken. I must close by these remarks.

Our elder brother, M. Quinby, the father of this new doctrine, has finished his work, and has gone to his long rest, though his body now sleeps in our mother earth, he is not dead, he still lives. The seed he has sown has germinated, and is taking root, out of which I am able to say Eureka. Although your humble servant, who is now addressing you, was one of the first to ridicule this doctrine, not from prejudice, however, but for the reason of the dense cloud, that this light once shone through so dimly. However, it is human to err, and to repent is wisdom, and who is it that desireth not knowledge, for God said, "to him that asketh it shall be given; so be of good cheer my brother, and be not sad over the late mortality among your bees, for out of it has grown a great light, such as has never appeared unto us until this day.

Marcellus, N. Y.

☞ A meeting of the bee-keepers of Franklin county, Ind., will be held at the court house in Brookville, on Saturday, March 25, 1882, at 10 a. m., to organize a County Association. All interested in apiculture are cordially invited to attend. J. W. Sturwold, S. S. Herrel, and Henry Kimble, committee on call.

CORRESPONDENCE

For the American Bee Journal.

"To the Law and to the Testimony."

G. W. DEMAREE.

When I was penning those remarks concerning Mr. Heddon's private letter to Mr. Dadant, which the latter gentleman published as a part of his reply to my article, I did not have the remotest idea that I was getting into a controversy with Mr. Heddon, the old war horse with his "dread bolted thunder." By taking a glance at page 105 of the present volume of the BEE JOURNAL the reader will not fail to see the whole thing in a nut shell. Mr. Dadant, after crediting me with language that I never used, viz: That "the Cyprian race is gentle and peaceable," politely and gracefully retires. Mr. Heddon then rushes into the field of battle, brandishing his "little pen," which is doubtless "more powerful than the sword."

Really, I thought that I spoke very mildly and gently concerning Mr. H.'s opinion, but it would seem that he is unwilling to reason. I only intended to say that he did not help Mr. Dadant so far as the main issue between us was concerned, i. e., the question of purity of blood of the Italian race. I have as much respect for Mr. Dadant as Mr. Heddon has. That he has been before the public as an importer and dealer in bees, etc., for nearly a score of years without any complaints concerning his manner of treating his customers is a better endorsement than any amount of "word praise" that Mr. H. or myself could give. The only wonder is that a man of his experience should be slow to learn that the imported Italian is a hybrid. It is not so surprising, however, that a person holding such views as those propagated of late by Mr. Heddon, should be found in darkness.

It is well to warn Mr. Heddon that hundreds of intelligent bee-keepers all over this great country will move forward in their careful experimenting with, and breeding up the races of bees to the highest point of excellence, regardless of his opposition. It will be concluded, I think, that bee-keepers, by their careful experimenting with, and breeding the Italian from selected specimens, have removed the scales from the eyes of the "bee as is a bee" sort of bee-keepers, of whom Mr. H. is chief, and caused them to see that the imported bees are hybrid in character, and therefore capable of being bred up to most any type to suit the fancy of the apiarist. These "pure blood" scientists, however, are not the men to jog along behind, the light having once flashed upon their pathway, they will soon be in the lead, shouting "I told you so." Mr. Heddon has already paved the way by intimating that he was aware long ago that his long dark Italians were

spiced with a "dash of black blood." Mr. H. should not talk so, having undertaken to help Mr. Dadant, who was grieved because I said that his dark imported bees were hybrids, (and he really thought that I had added that they were "ferocious," but I did not use that terrible expression, except in a playful way) and he obtained those "dark" bees from a certain dealer who obtained them from Mr. Dadant. Now for him to say that those "long, leather colored bees" have a "dash of black blood," is hard on his client.

Mr. Heddon brings forward two witnesses to prove that the "golden Italians of the period" have no working qualities. These witnesses are unknown to the bee-keeping fraternity, who must be the jury in this case. Such testimony as he offers in proof of his proposition would be rejected in any cross road police court. That somebody told him that somebody told him that "Aunt Hanna had said," why, the lawyers would stop you before you could say all of that, no matter how lively you might speak.

Of course it would be asking considerable of me to say just why the golden Italians of the two unknown witnesses failed to gather surplus stores right where hybrids were storing a "perfectly enormous" yield of surplus. I was not there to examine for the causes which may have been present. Having no diagnosis from which to reason, I can only surmise, in view of the fact that the yellow bees, belonging to other people can work, and do work efficiently, that there was something wrong with those bees; perhaps the bungling bee-keepers may have "tinkered" with them just at the right time to destroy their usefulness for the season. It does not take much of a blunder to do this sometimes, as most of us have learned by experience.

Mr. Heddon has failed to make a *prima facie* case, upon the evidence of those two unknown witnesses, even though we should admit the validity of the testimony endorsed by so good a bee-keeper as Mr. Heddon. But as he demands it I will introduce a few "live" witnesses for his special benefit and edification.

All admit that Mr. G. M. Doolittle makes large reports from year to year. He gets his large yields of honey by breeding from queens whose progeny show the 3 bands while standing on the combs. Mr. O. O. Poppleton, of Iowa, reported at the National Convention, at Lexington, Ky., that he had obtained 14,725 lbs of surplus from 108 colonies during the past season. This being a good yield, I asked him publicly what strain of bees he worked to get it, his answer was "Light Italians." It will be admitted that Mr. D. A. Jones handles some honey every season. He keeps none but yellow bees. Mr. Heddon called out Mr. W. J. Davis as a witness in favor of dark bees, and that gentleman testified in favor of the yellow bees. These witnesses need no vouching for, and they could be multiplied to any reasonable extent if necessary. I am now willing to submit the case

upon the evidence without further delay.

Until Mr. Heddon brings forward some proof that bees can gather a large yield of honey in a location where nature has provided but little nectar, or to show that bees can gather honey where there is none to be gathered, I can rest easy by repeating the self evident fact that a good location is essential to a large yield of surplus.

Christiansburg, Ky.

The Cows and Bees.

J. H. MARTIN.

For the benefit of Mr. Reynolds and any others interested, I will give my experience in conducting a dairy in connection with an apiary.

I find that the cows and the bees are the best of friends, and I fail to observe that nutriment is taken from our clovers; on the contrary, the bees perpetuate the clover for the cows. I have heretofore heard farmers complain that bees must take much nutriment from pasture lands. Now let us see if the charge is well founded.

Our pasture lands are first seeded to red clover, and other grasses, and, after a year or more, white clover and various wild grasses come in spontaneously.

The first season, red clover completely covers the ground, and the field is red with bloom. If we now turn our cows into this splendid feed, we find that the blossoms, although abundant and rich with honey, are discarded for the luxuriant and rich foliage, and the blossoms are trampled ruthlessly under foot. The superior richness of clover, then, comes from its foliage. This is still more evident from the fact that in all dairy regions, white clover comes in very abundantly, while with the pasturage of sheep, the white clover is nearly all killed out, from the fact that sheep feed upon the blossoms and prevent the maturing of seed, while the cow feeds only upon the foliage, allowing our dairy lands to become white with the tiny blossoms and consequent production of seed. The honey being in the blossom I fail to see how it will affect the nourishment of cattle when they do not eat it.

The effect of the blossom upon mutton, I think would be very slight, if at all appreciable, for our best mutton is raised upon pastures with a variety of grasses and a rich soil.

I would further state a well known fact, that our richest milk is obtained in the fall months. At this time the dairyman turns his cows upon his meadows covered with a thick growth of aftermath. In this there is seldom found white clover. It is constituted of various grasses of a tame and wild nature, having no blossoms and no honey. Still it has a superior richness.

The foregoing is the result of my observations in this locality. I find here a beautiful law of nature, a natural aid of two greatly different

ances of God's beings. The cows spare the blossoms for the bees, and the bees fertilize them that they may bring forth seeds and perpetuate the foliage of the plant for the nourishment of the cows.

Even our ancient progenitors, in Bible times, understood this law much better than do many at the present day, for the promised land "flowed with milk and honey," as one of its chief characteristics. The cow and the bee were not antagonistic in the Holy Land, why should they be here now in our land.

If I were to locate an apiary for white clover I would put my bees in a rich dairy region. Our most successful eastern apiaries are thus located. L. C. Root & Bro.'s, and G. M. Doolittle's great yields of honey are obtained in one of the richest dairy regions in the country; still the butter and cheese from that region command the highest market price.

I would also prefer locating a dairy in a region where many bees are kept for the many advantages that would accrue to the benefit of the dairy. For the highest success of either of these industries, I am positive they should be conducted in the same locality.

Hartford, N. Y.

For the American Bee Journal.

Bacterium the Cause of Dysentery.

CHAS. F. MUTH.

I just noticed "bacterium" in No. 8, page 122, of the BEE JOURNAL, which, perhaps, allows of a few suggestions. Doctor Southwick says, very properly, as follows: "Bacteria do not work much below temperate, and not at all below freezing. They work better the hotter it is, until it gets hot enough to destroy vegetable life. Let us compare this with bee dysentery. Bees are most apt to have the dysentery in long spells of severe, cold weather, when the bees are quiet and the hive at its lowest temperature, at a time when bacteria work but little if any," etc.

Let me suggest, right here, that this is the very point where bees try their utmost to create all the heat they are able to. All that is needed yet is insufficient ventilation, and you have the very hot-bed of bacteria. Water stands and hangs in big drops on the combs, walls and under the covering; this, aided by the great heat created by the bees, turns the honey about their cluster sour, and as the bees gradually die off by dysentery, and the heat diminishes, mold commences to cover the combs and keeps growing thicker as long as there are bees enough left to keep up the necessary temperature.

Mr. Heddon wrote one of the best articles on wintering (in *Gleanings*, I believe) I have seen for some time at the conclusion of which he states that bees are safest when the inside of their hive is kept dry. This can only be done by a proper upward ventilation. My covering of the brood chamber is a straw mat. Last fall I bored

a 1½ inch hole through each side of the upper story, near the top, and my bees never looked drier and healthier than they do now, and I have never found less dead bees in the bottom of the hives. I had, accidentally, skipped two hives and forgot to bore those ventilating holes through the upper stories on which the covers were resting tight. These two are the only hives with moldy combs. The bees are in good condition, because our winter was a mild one, and they were not obliged to create a heat as they would have done if the winter had been as severe as last winter. Otherwise, heat and dampness would have brought bacteria, and those two colonies would very likely have died of dysentery.

For the American Bee Journal.

Another Call from "Strange Visitor."

L. W. VAN KIRK.

I am still living, Mr. Doolittle, having passed through the "ordeal," but not without incurring some of the ulterior penalties which are so common when one tramples on the corns of a "specialist." I have followed your writings for years, and somewhere in the "lumber room" of my memory I have stored a few thoughts that I cannot pass without an explanation. You say "if we wish a good yield of box honey, use so few frames in the hive that the queen keeps them literally full of brood," and in your report for 1880 you say: "June 18th found us feeding to keep from starving, and on July 13th basswood closed, after which our bees hardly obtained a living." Here is what I don't understand: If your queens keep the brood chamber literally full of brood during the honey season, where does their winter stores come from? If June 18th found you feeding bees to keep them from starving, and the season closed July 13th, your bees must have been short of stores in the brood chamber, if you kept the queens laying right along. Again, if your queens kept the brood chamber literally full of brood, from whence cometh those frames of sealed honey that you speak of converting into brood in the spring? Have you another apiary to work for the one from which you report?

As you were free to give the readers of the JOURNAL what you learned from the "chat," perhaps I may have the same privilege. "Mine host," in his report for 1881, says: "One thing we noticed with pleasure, our colonies gave nearly an equal yield per colony," and adds, "this is what I have been breeding for during the past few years. Reader, if you wish to obtain nearly an equal yield per hive, unite till you get all strong, take frames of brood from the strong and give to the weak, mix them up thoroughly, give them an even start and keep them that way, as nearly as possible, and you will get nearly an equal yield per hive. Then attribute the result to your skill in breeding and not manip-

ulations. Again, bee-keeping to be most profitable should become a speciality, and the culture of small fruits, etc., a side issue. You must arise and proclaim to the bee-keeping fraternity that you have bred a superior strain of bees, and that you don't raise cheap queens, etc., and when you find that "this stand don't sell all the cakes," come down to dollar queens and grades.

In a word, get all you can out of your bees, then let them nearly all die in the winter, and say they just died and you can't tell why. Your loss will help to balance your big report and show that none but a "specialist" need try to make bee-keeping pay.

Various Colors in Bees.

S. A. SHUCK.

Of all that has been written in favor of fine color in bees, I have not seen any reason, save for the sake of beauty (if that is a reason), given in favor of the golden stripes.

It seems to me that some in their eagerness, have forgotten that it is facts and argument, that is required to settle this controversy. If we have no reasons to give, let us give up the battle.

Bees, like all nature, animate or inanimate, must have color, and if the beautiful can be as useful as that not so beautiful, I beg the privilege of taking my choice; if not, give me that which is most useful. Color belongs to everything, and many things are known by their color. How could we tell whether our bees were Italian, German, or Hybrid, if it were not for color?

The various races of people are as peculiar in color, as in language or form. Certain colors belong to certain classes of animals, fowls, and insects. Who ever saw a red horse? And of all animals, who ever saw a golden colored one?

Among the feathery tribes we find all colors, but this yellow color is not as common as many others. But of insects, who has not seen yellow in all its various shades. If we find that this golden color is common in insects, or anything, is there any quality, trait of character, or disposition attributable to this color, that should make us fear or condemn its possessor?

Of the different races of bees in all parts of the world, those possessing yellow bands are the most common. (Judging from what I can gather from books and journals). If this be true, and if the Italian bees have proven their superiority (who will deny it), as a race, over any black bees known, will some of the friends, who are insisting so strongly for dark or leather-colored bees, please show us wherein, or how, these golden bands interfere with the various traits of character of these industrious little creatures?

I am willing to admit that I believe that many apiarists have made serious mistakes while breeding for color. But I do not believe the mis-

take to be in the color, but the oversight or neglect of other qualities. The testimony of thousands of bee-keepers from all parts of the country, concerning the better qualities of the two races, stands more than ten to one in favor of that possessing the yellow bands.

Judging from this and the experience of those engaged in the production of fine stock, horses, cattle, hogs, sheep, and poultry of all descriptions, it is reasonable to expect a greater improvement by breeding the best of the superior race, rather than that of the inferior. Nor does it look reasonable that the superior can be improved by the inferior.

Bryant, Ill.

For the American Bee Journal.

Bee-Pasturage in Louisiana.

EDWARD NOTLEE.

Wintering bees, and the almost endless variety of life-saving apparatus, is of no interest or value whatever down South, as there is nothing of the sort required here. As to your vast array of honey-producing plants, trees and flowers, we have almost nothing of the same kind here, we have plenty of clover, but it is worth nothing for honey, the hot weather is said to make it too dry. Strange to say, we have no honey-producing material to any great extent for white marketable honey near New Orleans; only from the maple, in February, and the abundant willow, which continue to bloom for 6 weeks from the first of March to the middle of April. All honey made after that is too dark for the market. But this grand blooming willow we have in splendid abundance. And the bushes, which are not very high generally, and the luxuriant feathery bloom in its drooping beauty, with the busy bees on them, are seen to great advantage. Mr. Grabbe says the Louisiana willow is far superior to any willow in your Northern or Western States. There are a variety of species here which continue to bloom in fine rotation in the most splendid order for bee accommodation, although this willow honey comes early, and is white and beautiful to look at, but I regret to say it is not in taste and quality equal to very much which your bees produce in the Western States. It has a very perceptible willow bitter, and consequently will never be a choice article of much demand here. But Louisiana can well boast of her sugar-growing capacity. Those who do not know enough of bee management to have their bees strong and rushing by the first of March, in Louisiana, will never make a fortune in this line, or enough to pay off the national debt. If we could produce anything equal to your Spanish needle honey it would be in great demand, and very generally used. Mr. Perrine's bees supplied us some fine specimens of this rare quality when they returned from their celebrated trip of "floating apiary" renown.

In the long ago when I first changed my bees from the old box to frames,

and could examine their condition, generally in October there would not be more than 3 or 4 lbs. of honey to the colony and sometimes less; for one or two years I was greatly afraid they would starve, but by the middle of December they had always gathered plenty for winter. I suppose they get this late supply from the large amount of sugar everywhere coming in by rail and boat. I found Mr. Perrine's bees in the same condition in October, two years ago, and wrote to him about it; he sent a large quantity of honey from Chicago to feed them.

With the lights of the past and after twenty years experience here, I find that Louisiana, as a rule, produces an almost illimitable amount of willow honey during March and April; from June the yield is much less in quantity and quality up to August, and then almost nothing on to November. But in the next six weeks, to the middle of December, they never fail in gathering a full supply for winter. I have found a large quantity of honey even in October, but this is a rare exception, and does not happen oftener than one year in five.

For the American Bee Journal.

Bee-Keeping in Australia.

S. MACDONNELL.

Since the advent of the Italian bees imported by me last July from Mr. A. H. Newman, of Chicago, I have been devoting my attention to queen rearing, expecting that this season, owing to the prevalence of black drones, I should get my queens cross-fertilized and that next year I should have none but Italian drones about my hives, which condition, combined with the absence of other bees in the vicinity, would give me a fair chance of having a second batch of queens from my imported stock purely fertilized, or rather, a certainty of having them purely fertilized if they met the drone offspring of their elder sisters. The interesting Dzierzon theory, which most bee-keepers have accepted as infallible, was, of course, the standard to which I attached my programme, on the good faith of the wide reception of the theory and the recommendation by the American bee papers of the course planned for my operations. In the AMERICAN BEE JOURNAL, 1881, page 299, I find that Dr. Tinker has the temerity to attempt to undermine one of my household gods, the Dzierzon theory, as he holds that an Italian queen impregnated by a black drone does produce other than pure Italian drones. Dr. Tinker handles the matter in hand so well, and shows such clear insight and observation, that I fear a very troublesome antagonist has entered the arena, and if he substantiates his case, many who have depended on the drone progeny of an Italian queen, fertilized by a black drone, for rearing pure Italians, will have necessity for a great deal of faith to eliminate the black blood from their stock. Although I might have sufficient faith

to counteract the black blood in one or two colonies, it certainly would fall short for twenty colonies, and when the time comes on for rearing a second batch of queens, I shall take pains to have them fertilized by drones from my imported stock, and shall risk the evils attending in-and-in breeding. I may here mention that the one experiment of pure impregnation which I tried resulted successfully. The process was a modification given in the *British Bee Journal*, of the Kohler process. It consists virtually in securing the entire population in the hives containing the virgin queens and the selected drones and in letting the inmates have a fly as soon as the drones in other hives have gone to roost. For this experiment the Langstroth hive, with portico is useful, as a frame covered with wire netting can easily be attached to the portico, providing adequate ventilation and yet confining the bees.

In my last report I noted that a German bee-farmer had arrived here to establish the industry of bee-farming. At that time I saw but little chance of his obtaining an opening, on account of the serious total of the expenditure necessary. I was, however, very loth to lose the services of a bee-keeper who had matriculated under the late Dathe, and on representing the matter to a few friends, I found no difficulty in forming a company of six, each subscribing £75, to give bee culture on a commercial scale a trial in this winterless land. Our capital £450 (\$2,250), under the management of Mr. Abram, the German referred to, and who is one of the capitalists, will enable us to operate on a sufficiently large scale to give the venture a fair test. Our company is styled "The Italian Bee Company." I shall report our doings from time to time. This company, for the present will supersede the Langstroth farm mentioned in my last.

While Italianizing, two of my young impregnated queens flew from the frames, on examination of hives. At the time that one flew a small swarm of bees was in the air, and in due course they settled on a vine close to the hives. Mr. Abram, who was assisting me at the time, or rather, who was doing all the work while I looked on, pointed to a small ball of bees at the foot of the vine, and in the midst of the ball we found our truant queen uninjured. The other queen did not return and had to be replaced.

A gentleman in Sydney received from California a colony of Italian bees. As soon as I heard thereof I placed myself in communication with the owner and inspected his bees. I found them in an American hive (square frames) literally crammed full of comb and bees, an immense swarm with a splendid queen. The frames had been misplaced and the comb generally was in very bad order. The hive was so full of bees that there was no alternative but to swarm. I transferred them, comb included, to a double story Langstroth hive, and ultimately divided them, setting my friend, who has now a strong attack

of the bee-fever, on the road to rear a queen, in which he has succeeded, and he is consequently well pleased.

Sydney, Australia, Jan. 19, 1882.

For the American Bee Journal.

How to Deal With Ants.

DR. G. L. TINKER.

The small reddish ants that may be found almost anywhere burrowing in the ground, are a very troublesome pest to the bees. Although they do little real mischief in warm weather they are great depredators of the hives in cool weather when the bees cannot fly, forming long lines from their nests to the hives with every returning ant filled with honey.

Two years since I noticed on a warm April day a great ado among the ants. In fact the ant queens were all coming out of their holes for a wedding flight. They were about $\frac{3}{8}$ inch long, some with, and some without wings. They were reddish like the worker ants and flew about rather clumsily. The ant drones which had preceded the queens in coming out were small blackish winged ants and inclined to gather over little grassy plats about 3 feet from the ground where the air would be swarming with them.

Finding the queens mating with the drones after the usual fashion of insects, it occurred to me if I would kill them the annihilation would be about as effectual as to destroy the queens of the hive bees. I got a hoe and began to dig into a nest and found that but few had yet come out and the greater number were being nursed and made ready by the workers within two or three inches of the surface. As the nests were easy to find I had in the course of two hours killed a great many hundred of them. Some nests had only a few and some over 50 queens.

The ant nuisance was immediately abated and there were few to be seen about the hives the following summer. Last spring I found only a few nests and treated them with like results. Two or three boys might easily clear out the ants from an acre of ground in one afternoon, as the ant queens only come out from 12 m. to 4 p. m.

Two years ago the queens came out about the 1st of April, but last spring not until the middle of April. They may be looked for after the first two or three days of hot sunshine to warm up the soil in the early part of April. The first indication of the queens coming out will be the little clouds of swarming drones.

New Philadelphia, O.

For the American Bee Journal.

High Fence Around the Apiary.

WM. C. CASSON.

I have been very much interested in Mr. Heddon's articles on extracted honey until he came to that high board fence, to surround the apiary, and if Mr. Heddon will bear criticism

ing I shall object to that, and will give my reasons why. It is a hindrance to the loaded bee on returning home.

When the bees emerge from the hive and go in search of honey, they will find no trouble in scaling that high fence. But in the middle of a warm day, in cloudy, cool, windy days, and just at the close of the day, when they fly so slow and low, being loaded down, often tacking to the right and left, against a strong wind—then to raise over the high fence, just as they reach home, is a little too much.

In the month of April when our little busy workers go forth and find the first pollen, they are very eager and will stay out until quite cool, toward the close of the day. Any obstruction just as they begin to hover, for a place to alight, may cause them to drop, which ends their day, for before morning they are gone.

I have one hive which is shaded by my house after 4 o'clock, and I have often picked up 40 bees from the ground within 1 foot of the hive with their legs loaded down with pollen, warmed them up, and had the pleasure of seeing them go home rejoicing.

In the month of April bees are of more importance than at any other time in the year. A few bees in early spring bear about the same ratio to success as seed potatoes do to the whole crop. Our hives should be all provided with slanting boards from the front to the ground, so that all that fail to alight can crawl up.

Suppose that some authorities should surround our homes with a high fence and provide steps up one side and down the other and oblige us to carry everything, even our wood and water, over it, how would we like it? Mr. H. may say we cannot fly; this is true, but we can walk and carry a burden up hill just as well as they.

Another objection is appearance. The apiary should be a thing of beauty—an ornament to the neighborhood, in which it is located.

If Mr. H. should surround his apiary with that high fence, people as they pass by may say Mr. H. has become a bull tamer, or keeps the town pound. Addison, N. Y.

SELECTIONS FROM OUR LETTER BOX

New Foundation.—Seeing an article by J. W. Porter, in the BEE JOURNAL on "Fresh Made Comb Foundation," let me say that my experience, and that of a large number of other beekeepers, is decidedly in accordance with Mr. Porter's views of the matter. So thoroughly convinced am I of this, that I use no surplus foundation over 2 weeks, and no brood foundation over 3 weeks old. This I know entails considerable extra expense, because it brings all the work, when my apiary needs me, yet I know that the quality of the foundation more

than pays for the extra cost. There is also a proper time to roll the sheets into foundation, and the fact is, that the making of good foundation is not child's play.

T. L. VON DORN.
Omaha, Neb.

Gathering Pollen.—Bees in this section of Ohio are in prime condition; I have lost none. I put all but two in my winter bee house on Dec. 31, 1881, and put them out Feb. 14. My bees gathered their first pollen on Feb. 27. I find plenty of brood in all stages. I have 67 colonies all in good condition.

LEONIDAS CARSON.
Frederick, O., March 10, 1882.

Forty-six Days Earlier.—There has not been more than 6 inches of snow here this winter, if it had all been added together. The coldest day through the winter was January 17th, the mercury went down to 8° below zero. It did not remain so long, for the bees had frequent flights through each month of the winter. I packed 26 colonies in straw and chaff, and 8 in a bank cave last November. All wintered well. They carried in the first pollen that I took notice of March 2d. That was 46 days earlier than they did last spring. There are no Cyprian or Palestine bees in this part of the country.

Palmyra, Pa. HIBERT CLARK.

Prospect Never Better.—Bees are Wintering well, both in doors and out; and if those out do not come through safely it will not be from a lack of "purifying flights." The weather has been so mild that there was scarcely a week in which they could not fly. Of course, March and April must tell the story of our wintering, but our bees are all well now, and we think they will come through "booming" from present appearances. Certainly the prospect was never better at this season.

C. S. BURR.
Brecksville, O., March 9, 1882.

Returning Combs with Pollen.—I have a number of combs, extracted last fall, which contain a great deal of pollen. Will this pollen be cleaned out by the bees, when I give the combs back to them as soon as they can fly freely, or is it not advisable to give such combs to the bees? Will such old pollen probably injure the bees and brood? Please answer in BEE JOURNAL.

Grand Island, Neb. W. S.

[Unless moldy, soured, or very hard, give them to the bees. They will be a valuable assistance in building up.—ED.]

Wants a Queen Early.—I have a colony of bees the queen in which is unfertilized. Where can I get one about the 1st of April? I have black bees, and wish to Italianize them.

Holland, Mich. M. PELON.

[By referring to our advertising columns you will get the desired information.—ED.]

Ice Attracting Moisture.—On page 412, vol. 15, of the BEE JOURNAL, I find a statement by Chas. Dadant, that ice, placed in a bee-cellar to keep down the temperature in spring, will draw moisture to itself, instead of giving it off; and if I remember correctly, I think it was Professor Cook who said that water in the cellar would accomplish the same purpose. In view of a discussion in another paper just now this matter is of special interest. I have great confidence in Mr. Dadant as one of our most scientific bee-keepers. If he would explain through the JOURNAL how it is that ice will take moisture from the air, making it drier, and how such is known to be the fact, perhaps he would oblige others besides.

Lindsay, Ont. A BEE-KEEPER.

Bees in Maine.—I am much pleased with the BEE JOURNAL, and am especially interested in the correspondents' columns, when the writers give their own methods in the management of bees, together with the result obtained, so that by studying the experiences of many, all may learn wisdom in the management of the apiary. As I take it for granted that in this business, as in everything else, all is not yet known that may be. Much is said in the JOURNAL about Mrs. Lizzie E. Cotton, and in nearly every instance it is to her discredit. Mrs. C. may have treated some others in a manner to convince them that she is a fraud, and if what some of the correspondents say in the BEE JOURNAL is true, she certainly deserves censure. I believe in speaking well for a bridge that carries one safely over, and must, in justice to Mrs. Cotton, say that in my dealings with her she has been perfectly "square." I judge this has been a good winter for bees in this section of the country. Mine have had a flight nearly every week, although some days the mercury went 28° below zero. The cold would last but a day or two, then we would have several days of warm, sunny weather, and the "yellow jackets" would come out for a sport in the open air. As I write, the mercury in my yard near the hives stands at 60° above. How is that for southern Vermont in mid-winter.

SEYMOUR H. WOOD.

St. Albans, Vt., Feb. 15, 1882.

Does Cold Weather Kill the Bees.—I think my bees will come out all right this spring. I am wintering out of doors, as I did last year. They have not been a month without having a flight all the winter. What a contrast to last year, when from Oct. 18, 1880, till the middle of March, 1881, not a bee was out of the hive. Mine were out yesterday and flying all over the village, and appear very strong and healthy, with no sign of dysentery. The cold wave struck here in January; 33° below zero; only a 1 inch board (the hive) between that cold and my bees, and yet they are alive, strong, and healthy—is it the cold that kills bees? I think not, or mine would have been dead now.

Geo. GARLICK.

Warsaw, Ont., March 3, 1882.

How My Bees Wintered.—I have about 65 colonies of bees of my own and 10 others under my care. Of these 75 colonies I has died from starvation and 2 from queenlessness. I have 20 colonies that I am working on the shares, which I have not seen yet. I have no doubt but they are doing well, as they were in a good cave. I left 9 colonies on the summer stand. Those that were in the cellar did the best. Some think that bees winter best on the summer stands, but I beg to differ. There is nothing better for bees than a good dry cellar, and that can be obtained by walling with brick, flooring with brick and cementing the whole with a coat of plastering; ventilate the cellar with a pipe from the center above, to allow the foul air to escape, to give health to the bees.

THOMAS PRALL.

Carlisle, Iowa, March 3, 1882.

Humbug.—I enclose you a circular which I received from Mrs. L. E. Cotton. I sent her six dollars for one of her controllable hives, expecting to receive a full size hive, but in return got a little model worth about 10c. I consider that I did not receive any value for my money, as the whole thing cost me \$6.75, and was of no value whatever except fire wood. I think she should be published as a first-class humbug. C. H. PARKER.

Coldbrook Springs, Mass.

[In the circular of Mrs. Cotton, she proposes to furnish "one sample hive complete," and she should do so, or be content to be classed as a fraud.—ED.]

A Correction.—The BEE JOURNAL for Feb. 22 is at hand. In my article on page 120, 2d line from the bottom of the 1st column, the types make me say, "capable of sexual semen and fecundation," etc., instead of "capable of sexual union," etc. Please make correction.

WM. R. HOWARD.

Kingston, Tex.

Bee Bacterium.—I must inform Dr. Southwick that I, too, have an encyclopedia, and that I was aware of the technical definition of the words bacteria and bacterium; but that I used it with the meaning usually applied by chemists and physicians. As the Doctor says they are the beginning of fermentation, and I guess the middle and end of it, too, those conditions which favor fermentation, favor bacteria. More honey ferments in the hives about the time that dysentery is present (in spring and winter) than at any other time. All of the "considerate," please consider this fact, viz: That bacteria thrives best in a damp, medium temperature when in bee hives, as is proven by all our experiences. I am getting out a patent on bacteria, and I wish the Doctor would desist from meddling with it. I have just spent a pleasant 24 hours with George Grimm, here at my home, and I was surprised to find a man of only 22 years. But then, he cannot blame me for this mistake, for he was surprised

at not finding me "much older;" probably he expected to find me in my dotage. We had a hard-fisted practical visit, talking over marketing honey, overstocking the field, etc., not saying a word about bees by the lb., or Cyprians in any quantity whatever. We had the pleasure of seeing the bees flying strong and lively, and carrying in large loads of pollen from the pussy willows and soft maples on that day, March 2. Bees all through this vicinity are in fine order; that is, all there are left from 1880-81 winter's fury.

JAMES HEDDON.

Dowagiac, Mich., March 4, 1882.

Albino Bee.—I would like a description of the Albino bee.

Canton, O. CHAS. A. PONTIUS.

[See BEE JOURNAL for Oct. 19, 1881, page 331. The article is too lengthy for reproduction, with justice to our readers.—ED.]

Remarkably Strong.—I examined my bees March 2, and was surprised to find some light colonies, that I put on to four or five frames last November, to be strong in bees now, and hundreds of young bees hatching. I had to give them more room, and the full colonies then have brood in 6 frames now. Only 1 colony in the yard that had no brood, and that was a black queen that I obtained late last fall, to put in a queenless colony—the only black queen I have, and I have sold her, with 10 others, if I can get ready early in the season. If the weather holds favorable, I can divide by May 1, if I can get the queens.

JAS. S. LORD.

Linden, N. Y., March 6, 1882.

From Oregon.—I found a man on the other side of the Santiam river that had 5 colonies of bees, and I prevailed on him to sell me 1 colony, as he said he only aimed to keep about 4 colonies as there was danger of overstocking. I think it is a good place for bees, for the settlers say there is a good number of wild bees in the woods, and it has been less than 30 years since the first were brought here and sold for \$140 per colony. They have increased very fast to be many in the woods. There is very little interest taken in keeping bees here. We do not have winter here like in Illinois; it rains almost any day, and snows some, and the sun shines some. I sowed some wheat here the 23d day of December. It is up and looks very nice.

DAVID RICE.

Lebanon, Ore., Feb. 15, 1882.

Rye Meal for Bees.—The best way to feed bees with rye flour, is to fill a bag made of mosquito netting and hang it up in a box with the open part exposed to the sun. In this way the bees are not smothered. They cluster around the outside of the bag and gather the flour through the meshes. My bees are working at it now very busily. D. C. MILLET.

Holmesburg, Pa., March 3, 1882.

Sweet Clover for Texas.—I see you recommend sweet clover (*Melilotus Alba*) as a honey producer. 1. Do you think it would succeed in Northern Texas? 2. What time should it be sown in this latitude? I embarked in the bee business last spring with 14 colonies, and increased to 34. All are in fine condition this spring. Beekeepers will meet in McKinney the 10th inst., for the purpose of organizing a County Association. I am well pleased with the BEE JOURNAL.

T. C. BOONE.

McKinney, Tex., March 3, 1882.

[1. We think sweet clover will prove better than anything you can plant, as it stands heat, drouth, rain, and cold admirably.

2. Plant in fall, winter, spring or summer; in fact, any time when the ground is damp; but do not expect to see it in bloom till the second season.

—ED.

The Season in California.—We have just had a glorious rain; to-day is fine. About all the old honey is out of first hands and scarce. I sold 1,000 lbs. of surplus, at good prices, at home; could have sold several thousand pounds more, if pushed, if I had it on hand. Hard to tell what the prospect is for a good honey season, but hope. Almonds are in bloom, also crocus; wild buckwheat just coming, willows, wild gooseberries, wild currants, and a few acacias are giving abundance of bloom for pollen, and the bees do not lose a minute. We have had enough rain in this section; at present the ground is too wet to plow. Bees commenced to breed in January. No brood from Oct. 15 to Jan. 1. Bees are in good condition, with plenty of natural stores. The season has been very cold and is backward. Manzanita was a total failure here—cause, frost more than usual. The BEE JOURNAL will be wanted as long as I am in the business, "and don't you forget it." J. D. ENAS.

Napa, Cal., March 2, 1882.

An Open Winter in Kentucky.—My bees are of my own rearing, as I go with Doolittle and Heddon, and think I was ahead of them before I ever heard the leather-colored bees discussed. Bees this winter, contrary to my expectation, have wintered splendidly. I have not lost a colony, and only such as had but about 3 lbs. of honey, last fall, have starved. I could have bought bees last fall for almost a song, but could not tell what sort of a winter we would have. Now I cannot buy them at any price. I had hoped that, as my neighbors would persist in keeping common bees and would neither sell nor Italianize them, that they would all die this winter, but the winter was warm with nothing but rain and mud all through; no ice, except Nov. 28th.

My advertisement in the BEE JOURNAL of last year brought so many orders that I could have sold twice as many bees as I could spare.

Paint Lick, Ky.

R. M. ARGO.

Cleaning Barrels.—I have a cask which has contained whisky and grape vinegar, but I wish to use it to put my dissolved sugar in for bee feed. Please state how to treat it to make it suitable for that purpose.

Canton, O.

E. H. MORRIS.

[If for spring feeding, when bees are flying quite frequently, scald it out with a strong solution of soda. If for winter feeding, do not use it. You cannot be too careful of the character of feed for winter, and should risk nothing to chance.—ED.]

A Difference in Races.—I find a great difference in the races of bees in regard to breeding early. The Cyprians with me the last four seasons have outstripped the Italians amazingly. I now have the Syrians, but as yet they are behind the Cyprians. I have 30 colonies of the latter in booming condition, with brood in from 2 to 4 frames. The Italians are also breeding nicely, but as yet the Syrians have very little brood. Yesterday they brought in new pollen, and to-day they just rolled it in. What is the difference between Bokhara and sweet clover?

G. J. YODER.

Middlebury, Ind., March 2, 1882.

[There is no difference that we can distinguish.—ED.]

Bees in Cellar.—My 90 colonies of bees are all in the cellar, and are, so far, in splendid condition. I had two or three out yesterday to examine. These are very dry and healthy. The queens have been laying for about two weeks and have brood in all stages. While in winter quarters, I give thorough ventilation and kept the temperature from 42° to 45°. Some claim that bees cannot be wintered well in a cellar during a warm winter like this, but my experience is against it. We have had no zero weather yet; 15° above is the coldest we have had.

L. W. VAN KIRK.

Washington, Pa.

Very Mild Winter.—My bees have all come through except 1 colony. They were busy carrying in pollen the 2nd inst., and yesterday they seemed to be getting honey from some source, but I cannot think where they would get honey this time of the year. March is here, and at this place we had no zero weather the past winter. The coldest it has been was 4° above zero, which was on the 24th of January, while the average temperature for the month of December was 34° above zero. The average for January, 24°, and the average for February, 32° above zero. So, you see, we have not had much cold here, but we have plenty of rain. I went into winter quarters with 11 colonies, packed in chaff on their summer stands; have lost but one so far—cause, sudden cold overtaking them before they could regain the cluster. The other colonies are all in good shape except 2, which are weak.

J. H. EBY.

North Robinson, O.

Preparing for Spring Work.—I am a disciple of Langstroth, and, on account of his poor health, am without a leader. My bees are all pure Italians, and are in Langstroth hives. The queens are from 4 to 5 years old; each colony is in fair condition, but yet not as strong as I should like. All have full sets of combs for upper and lower stories, but drone and worker comb is in the same frame. I am not so desirous for increase as I am for honey, and have never thought that I got as much as I should. Please instruct me as to the best mode of procedure the coming season? I want, as soon as possible, to have my bees in the best condition, for honey gathering. What should be the difference in price, between extracted honey in bulk, and the same put up in one pound square glass jars, neatly labeled and capped.

Oxford, O.

LYNN BONHAM.

[On page 133 of the BEE JOURNAL for March 1, you will find an article from the pen of G. M. Doolittle, treating upon the subject of spring preparation. We can heartily commend its careful perusal to any bee-keeper who prefers to run for honey, supplementing it, however, with the advice to carefully trim out all patches of drone comb with a narrow-bladed, sharp knife. This, of course, can be done without injuring worker brood, and if done early will be rebuilt with worker comb, if given to the colony only as fast as required.

The difference in price of extracted honey in bulk, and the same in attractive small packages of any kind, neatly labeled, should more than balance the difference in cost of packages, the time and expense of preparation, and a remunerative profit as recompense for superior taste and care. Where honey is sold in bulk the producer has only to convince the first purchaser as to purity and desirableness of the article, after which he becomes unknown in connection with future transactions; but with the small packages, when neatly labeled, and with producer's name printed or written on each label (as it should be) as a guarantee or voucher for the article, he becomes morally accountable to each individual consumer, and the profits should be proportionate to the responsibility or accountability.—ED.]

Bees Doing Well.—Bees are carrying pollen and some honey from early fruit bloom and breeding up rapidly. We have had no winter here; not 4 days together that bees could not fly. My early garden plants, etc., are all up and growing fine.

E. P. MASSEY.

Waco, Texas, March 4, 1882.

Old Fogy Bee-Keepers.—I am somewhat bothered with foggy bee-keepers in our neighborhood, who keep black bees which mate with our Italian queens, and we cannot prevent it. They are also in our way in the honey market. We go to a good deal of expense and trouble to get our honey in nice shape for market, and ask a reasonable price for it, and along comes one of the fogies with a coffee box or a cigar box may-be half full, and offers it for 10 or 12 cents a pound, thus putting our price down, or tries to, at least. One neighbor whom I call fogy (I do not know what others may call him), has his bees all in box hives, sitting on crooked, warped boards. The ants, roaches, cold, rain and snow, can get in and through the hives, and yet he has earlier swarms than I have; his bees always come out pretty well in the spring, and he always sells so much honey. Last season he sold two cigar boxes full of honey. Another, who has all black bees in box hives, when a swarm issues, runs and gets an old board and saws it up, and nails it together for his bees, if he has no empty nail-keg handy. An enterprising bee-keeper, a friend of mine, asked him if he would sell some of his bees. In reply he said he did not know how many he had—his old woman did not like to sell any, as she would sell her luck. So it is with them; they know more than anybody else, and they have and will learn no way but their own. One neighbor has one colony, and the hens have taken it for a roosting-place; it will come out all right next spring. My bees are doing well on the summer stands. 1. What must I do to prevent robbing? I lost 6 colonies one season by robbers. 2. Are hybrid bees as good honey-gatherers as pure Italians. 3. I am feeding some weak colonies—can I feed too much? 4. What is the best feed for bees? S. J. SMITH.

Myersville, Md.

(1. Close the entrances to the colonies being robbed so as to let in but one bee at a time; if this does not stop it, exchange places with the hives.

2. Yes; if the honey-field be near at hand.

3. No; but more than is necessary is a waste of feed. However, do not feed to the extent of embarrassing the queen.

4. Good honey in spring, with a little warm water to thin it, is the best you can use.—ED.]

Prospect Cheerful.—Bees are in good condition here. I had 4 colonies last fall; 1 become queenless and died; the rest are strong in numbers. They are bringing in pollen to-day. I lost 9 last winter—all I had. I obtained 1 in the spring, and they gave me 3 increase. I think this will be a good honey season. I am always glad to get the BEE JOURNAL.

E. P. HADLEY.

Sheridan, Ind., March 1, 1882.

Location Selected.—I have heard old bee-hunters—not bee-keepers—say that when a swarm left the hive and flew away, that they always had their tree selected and cleaned out. I did not dispute them, but had my own opinion about it. Is it so?

H. L. EASTMAN.

Findley's Lake, N. Y.

* [No, it is not always the case, but we think it may be true sometimes. It is true, however, that scouts generally move in advance of the swarm.—ED.]

Bees and Bloom.—I think, Mr. Editor, you are mistaken in your inference drawn from Mr. Mehan's statement (see page 130). As I understand it, his idea was that when grapes were ripe and ready to pick, if there were no flowers to draw the attention of the bees, they were very destructive to the grape crop, but not to blossoms. The bloom spoken of in the latter part of the quotation has reference to bloom on the ripe grape, and not flowers. E. B. SOUTHWICK.

Mendon, Mich.

[Perhaps so, yet the general argument is unchanged.—ED.]

Delirious With Joy.—I am in a delirium ov joy, and mi ski iz a meller golden sunset. Mi bees hev kommensed 2 swarm nearly 3 months earlier than iz kustomary for the latitooode ov Detroit. i haint took eny sirpluss yit, butt am preparin furt he "sweet" okasion with vigger. Thee fremont ov mi enthoosyasm iz bilen at 65 F. in the sun. 3 swarms kum owt 2-da and awl went into won hive. This iz a bigg thing, & speeks volumes for mi managemnt, & strain ov prolific queens. I am goin 2 drive under thee wire next fall, with the biggest hunney report on reckerd. You may kommense sellin pools now. Mi feelings indikate a pressure ov 200 lbs. 2 the squar inch ov surfase. B. HIX.

Not One Queenless.—About Feb. 20, I took a part of my bees out of the cellar, and found them in fine condition. I opened 2 hives and found brood in 2 combs; it came on cold and I put them back. March 2, I carried them all out, opened them, and every one had a queen and brood in 2 and some 3 combs. I had 2 Cyprians and 3 blacks that I bought this winter, and I could not see that any Cyprians or blacks had any more brood or were in any better shape. I have 21 colonies and 3 nuclei. I would mark 16 out of the 17 I put in last fall "extra," and 1 small; it was made up from a nucleus late in the fall, queen had just begun to lay. This reminds me of the condition of my bees last spring when I took them out, this was on April 9. The most of them had brood in two combs. One I noticed had not begun to lay; I thought it very strange; it was a very fine, large colony of Italians, but soon she began, and I watched it with no little interest. When honey time

came the hive was full of bees, and I sold it for \$12.00. It gathered about 300 lbs. of honey. One other had just laid eggs, and another did not lay for a few days, and from these facts I think early breeding to much extent of no use; still, when we open our hives and find about the expected amount of brood, we say they are doing well. I will sometime give my little experience with 3 banded bees.

Rockton, Ill.

R. GAMMON.

Drone Excluders.—Did you not make a mistake in the size of holes for drone excluders in last week's BEE JOURNAL. L. DENSMORE, Livonia, N. Y., Feb. 27, 1882.

[It is possible; we have never used them, but took the dimensions from 3 samples in the BEE JOURNAL museum—two were of English and the other American manufacture.—ED.]

Hive Improvement.—1. Will you give a description of "an improvement on the Langstroth style of frame and a model for illustrating a new style of hive for wintering out-of-doors," referred to on page 411 of the JOURNAL, with size and opinion of same. 2. Would it be any disadvantage to run the brood frames across the Langstroth hive? The frames would then be 13½ long, and nice to operate. It would also be a convenient length for nucleus hives, and consequently interchangeable. We have a cold snap just now. Weather so far has been very fine, and bees are looking just splendid. N. EMMERSON.

Exeter, Kans.

[1. If you will address D. A. Jones, Beeton, Ont., he will probably give you the desired information; we cannot.

2. You would then have to put the entrance in the side; which would make practically a "long-idea" hive. There are several in use approximating nearly the same thing.—ED.]

Good Instruction.—The article by Mr. G. M. Doolittle in the BEE JOURNAL for Feb. 8, is worth to me more than a year's subscription. My bees are in the best condition, at this season of the year, that I have ever known them to be. We usually have an abundant poplar bloom about the middle of May, but heretofore the bees would not be strong enough to gather it; but Mr. Doolittle has told us how to secure it.

W. C. R. KEMP.

Orleans, Ind., March 3, 1882.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., March 22, 1882.

No. 12.

THE AMERICAN BEE JOURNAL

Published every Wednesday, by

THOMAS G. NEWMAN,
EDITOR AND PROPRIETOR,

974 WEST MADISON ST., CHICAGO, ILL.

TERMS OF SUBSCRIPTION:

WEEKLY—(52 numbers) \$2 a year, in advance.
Three or Six Months at the same rate.

Entered at Chicago post office as second class matter.

The Cheap Queen Traffic Again.

The communication from Mr. W. Z. Hutchinson, on page 183, on this subject, calls for a few remarks.

Our correspondent certainly misunderstood our expression, which he attempts to reproduce in his first paragraph. Had he copied the sentence entire, it would give the impression that where one might economize more, scores of prudent breeders would far exceed Mr. Salisbury's expenses. Not only have we cited several cases where experienced and extensive breeders have found the cheap queen traffic undesirable, but in this issue we publish a letter (on page 187) from another.

We have carefully read our article through to find the word "stripes" which our correspondent quotes upon us—it is not there, but, instead, in our closing paragraph we said the "bee-keepers want better stock, more honey, longer-lived bees, and certain profits." The matter of stripes was certainly and purposely omitted, for the "best bees" will have just the requisite number, whether it be one or a dozen. As we have understood the matter, queens are not tested for stripes alone, but for the best business qualities, and if this object is not kept in view in testing, why, untested queens might fill the bill for all but stripes.

Nor did we say anything about "hybrid queens," as charged in the third paragraph given, but "worthless trash" is what we spoke of, and many queens sent out, which throw three-banded workers may be quite as worthless as many which show not one band plainly. But when a

"tested" queen is bought or sold, it is supposed her progeny will prove among the best for all desirable qualities, as well as possess the "three bands," which are only a "test of purity," or pure mating.

The correspondent's citation of the case of Dr. J. P. H. Brown establishes no point, except that the Doctor, as we all know, is an honest, conscientious gentleman, who would not send out any inferior stock, if he knew or suspected it to be such, for any price; and further, he states in his circular that all his queens are reared from imported stock. They are not reared from "dollar" queens.

We do not wish to controvert anything in the sixth paragraph, nor in either of the succeeding ones, except where "stripes" are unfortunately and persistently attributed to us.

Again we repeat, the bee-keepers of America want the "best bee," and to this end all bees should be tested before leaving the hands of the breeder.

"The Oriental Casket," published at 912 Arch St., Philadelphia, Pa., is a literary gem. The March number is full of things both interesting and useful. In appearance it is elegant; in price moderate; in all things it is a credit to art, and a pleasure to the reader.

Flower Shows in England.—"Flower Shows," says the *Gardeners' Chronicle*, "have become everywhere local institutions; they teach and they expand ideas; they promote that contact amongst horticulturists of all sections that was previously wanting, and have and are doing a power of good." The love for flowers is now universal. So says *Vick's Monthly*. Bee shows will soon become as popular as flower shows in Great Britain.

Conflicting Theories of Bee-Keepers.

Mr. Jacob Spence, of Toronto, Canada, wishes a formulation of the various theories, now so conflicting, into creeds, so that the less advanced bee-keeper may have certain landmarks which he can keep in view while acquiring a knowledge of the more intricate details of the business. Below will be found his views upon the subject, and a call for our committal, which we cheerfully respond to:

To some of us it is distressingly bewildering to find so many directly conflicting theories held by those who ought to be entitled to be looked up to as safe instructors. I think, too, that one very good way of bringing out truth is by clear statement of consistent theory—fairly founded on well ascertained facts and experiences. There are many interesting minor methods of detail, on which no doubt many various ways of working may be almost equally successful in bee increase and honey production—but, then, to keep the bees alive must be taken as the vital one thing needful.

Safe wintering and spring dwindling seem closely connected (or disconnected), and now to find out certain how to secure the one and prevent the other beyond ordinary per-adventure, is where the real difficulty comes in. To know the cause (beyond doubt, of course), would be the proper key to the "how to prevent the dreadful spring dwindling;" and to really know the needful conditions of safe wintering, would go far toward this fulfillment. Here, then, would it not be especially important to make out very distinctly, particularly on these two points, how far all reputed orthodox authorities agree, and set down what can so be taken as fully settled creed, requiring little if any further discussion, but decidedly correct, and as such to be propounded to disciples as being thus far no longer doubtful? My idea is in this way to transfer as much as possible (especially in essentials) from the domain of the dubious into that of knowledge, and then proceed on this line.

I can only claim to class as a "novice" engaged in making experiments, results of which I may sometime deem worthy to communicate, but would much prefer to have less experimenting needful. This, it seems to me, should be accomplished less problematically, as well as less expensively, by utilizing confirmed conclusions and experiences, such as might be looked for from the fathers in the fascinating art.

I do earnestly wish, Mr. Editor, that yourself, and more of your very able correspondents, would turn more to these two vital parts of the programme. Do let us have fixed (not conflicting) creed on the ways and means of preserving the precious life of the "coming bee."

Bee-keeping, as an art or profession, is yet in its infancy, and the creeds to

be determined are proportioned to the magnitude of the business. Were wintering the *only* problem to be solved, it would have been satisfactorily settled long ago; but scores of questions have been constantly arising, some of greater and others of lesser importance, and each claiming more or less the attention of all. Again, these experiments and results are all conducted from different standpoints, and reached through various channels, and hence diverse convictions are reached, and each as logical as the others.

Could nature and the variations of winter be controlled by artificial means as easily as can be the certainty of honey flow in summer, then the success of one winter's experiments can be duplicated the next; but until then, for any man to formulate his theories into a creed, or the majority of his successes into an invariable doctrine, would be to stamp him as an egotist, and bring disaster on his followers.

We are reaching results quite rapidly, and many important questions are settling in convictions; but to arrive at harmonious conclusions, on all the main topics, will be impossible, owing to the vast extent of country and difference of climate involved, as well as different phases of human nature to be drifted into one channel. More unanimity of thought on very many questions is desirable, but time will be required, and a convincing need of such unanimity, before it will be reached.

We are glad Mr. Spence is moved by the spirit of experiment, and is himself assisting to overcome some of the obstacles to uniform success, but in many things he will find that a creed which may be life-saving in his extreme latitude, would be as certain to work destruction further south or west. Still, it is none the less his imperative duty to investigate, as his own success depends in a great measure upon the modification he may make in the creeds of others.

Mr. W. C. Barry, of Mount Hope nurseries, Rochester, N. Y., has our thanks for a neatly printed pamphlet containing his two essays on "Ornamental Planting" and "Native Fruits," both of which we have read with much pleasure and profit.

No. 2 of the *California Apiculturist* has come to hand with an additional 4 pages, making 12 in all.

"Miner" Points.—In the *Home and Science Gossip*, of Rockford, Ills., Mr. F. M. Miner writes as follows:

In the BEE JOURNAL, July 6, there is an ebullition of spleen, ignorance and self-conceit from one Robinson. Among other silly things he says he knows how to winter bees—snow excludes air; and Mr. Newman has sent his trash over the wide world to the disgrace of American prestige, and excluded any reply. Some of us ought to be in the insane asylum, claiming to be authorities while we differ radically on essentials.

We are astonished at the language used by Mr. Miner. The facts are that he sent us a communication last fall, and we put it into our "correspondence drawer," without reading, awaiting its selection to go into the BEE JOURNAL. Some time after he wrote us that the editor of the *Guide* wanted him to write for it, and unless we could print it soon, he would be glad to have it to send to the *Guide*. As we were crowded with matter, and our compositors could not "set up" Mr. M.'s articles until they were copied, and as we were to busy to do so, at the "rush" at the end of the year, we at once sent the article to the *Guide*, as requested, without ever having read it. Mr. M.'s strong language is, therefore, wholly uncalled for.

During all the winter months we have a large drawer full of "communications," and another full of "letters" in waiting, all the time, and from this "store," we select such as we deem best to give our readers a savory meal each week. We are sorry if any should feel aggrieved, but cannot expect to please all. We shall, however, continue to do our best to serve up a good meal to those who sit at our table—the BEE JOURNAL.

The editor of the *Terrell, Texas, Knight*, after mentioning the BEE JOURNAL's recent change to 16 pages, adds: "The change has added to its prosperity and popularity. Its field of influence has been extended, and the industry it ably represents has been greatly advanced by the weekly publication." The *Knight* has our thanks for its very kind notice. To advance the industry of bee-keeping is our aim, on every occasion, and by every means at our command.

The *New England Bee-Journal* has again made its appearance, having been suspended from November to March. It is now expected to appear monthly, if sufficient support shall warrant it.

Bee-Keeping in Florida.

Mr. W. S. Hart, Vice President of the National Society for Florida, has sent us a copy of the *Florida Agriculturist*, which contains his "address to the Bee-Keepers' and Fair Directors of the State of Florida," advocating more and larger premiums for bees and honey at the next State Fair. Mr. Hart says that since its publication \$27.50 has been added to the prizes for honey.

Having lately received the premium list for the State Fair, I have gone carefully over it, and can say that I not only have no fault to find with the awards there offered, but on the contrary consider every one well and wisely placed. Yet it seems to me that one of our rural industries that, with a little encouragement may greatly surpass in importance to the State, some for which liberal premiums are offered in the list, is sadly neglected. I refer to the bee-keeping interest, which includes the production of honey and wax, the raising of early queens for the northern bee-keepers, and the supplying of bees by the pound to replace those lost during the cold winters of the North. To be sure, there is a "Department O, for Poultry, Bees and Rabbits," but with seventy dollars offered for poultry, I do not see the first cent offered for bees. In "Department E, Table Luxuries," we find No. 12,—best specimen Florida honey \$3.00. Also, No. 42,—best home made vinegar of any kind \$1.00." Those two items afford the only chances for the bee-keeper to win a prize, and they together amount to \$4.00. As the reason for this lack of encouragement probably rests more with the bee-keepers themselves, in not making known the importance of their industry, than with the Directors of the Exposition, I now take the liberty of presenting a few facts and figures to show that bees and their productions are, to say the least, worthy of as much consideration as poultry.

Mr. Thomas G. Newman, editor of the AMERICAN BEE JOURNAL, a large and handsome weekly, published at Chicago, Ill., in a late issue called for reports from the bee-keepers of the country, stating their success during the present year. In No. 41, issued Oct. 12th, is given a tabulated statement of the returns as far as received. The footings are as follows: colonies in the spring 137,636; fall 235,510; average increase 71 per cent. Extracted honey 5,477,176 pounds; comb honey 3,990,446 pounds, giving a total of 9,467,622 pounds, or an average of 69 pounds to the colony. Florida's share in this list so far as reported is, colonies in the spring, 2,354, in the fall 4,712; per cent. of increase 100. Extracted honey produced, 167,918 pounds; comb honey, 19,734 pounds; average per colony, 84 pounds. In commenting on these results, Mr. Newman remarks:—"There are in America about 3,000,000 colonies of

bees, but our reports are from less than a quarter of a million, or one-twelfth of the whole. If the one-twelfth that are reported are a fair average of the whole, then the crop of American honey for 1881 amounts to 120,000,000 pounds. If we call it only a hundred millions, it is worth \$15,000,000. Surely the industry is of sufficient magnitude to satisfy the most enthusiastic of its devotees." In Southern California, there are six hundred men who are engaged exclusively in bee-keeping, and yet they get a full crop on an average but once in three years, and some years thousands of colonies starve to death. While here in Florida I can not find any one that has ever known the crop to fail. This has been called a poor year for bees, yet my colonies have increased over 100 per cent. and produced 200 pounds of honey to the colony. The bees of several of my neighbors have done nearly as well. All are not fitted for bee-keepers, neither will all parts of this State produce honey in paying quantities, yet there is room for hundreds of industrious bee-keepers to come and locate where they can do annually as well and better than I have this year. For several reasons I think it probable that a larger per cent. of the apiarists of Florida reported to Mr. Newman than from most of the other States, so we will call the number one-sixth, which is certainly within bounds. Now multiply the 187,652 pounds of honey reported, by six, to get the approximate production of the State, and we have 1,125,912 pounds, worth \$168,866.80. Perhaps a better idea of this amount may be had by stating that the editor of the *Florida Dispatch* (who ought to be a good judge) estimates the orange crop of the State for 1881 at 300,000 boxes of 140 oranges to the box, worth at \$15.00 per thousand (about the usual average price obtained) \$675,544, or not four times the value of the unnoticed honey crop. Hundreds of young orange groves are just coming into bearing, so that a few years will show several times our present production of the golden fruit. In the same ratio may our honey and beeswax crop be made to foot up among the millions of dollars' worth annually, if those who are fitted for the business will only take hold and make a *study* of the business, instead of trusting to the old "happy go lucky" way. The climate of Florida is not only peculiarly fitted for successful bee-keeping, as our harvest time is long, and we have no wintering troubles, but it also attracts many people from the North who come here seeking health without the strength to do heavy work, or the capital to hire it done for them. To such bee-keeping offers many inducements.

As Vice President for the State of Florida of the North American Bee-keepers' Society, I would respectfully call the attention of the Directors of our various State and County Fairs, and also that of the apiarists of the State to the above remarks, and ask them one and all to "put a shoulder to the wheel," and help to make bee-keeping one of the great money re-

sources of this "land of flowers," in every legitimate way possible. Let us have liberal prizes offered at our fairs for bees and their products, and let the bee-keepers strive with each other to make the best display of their stock. Much may also be learned by forming bee-keepers' societies and holding conventions one or more times each year, where all can meet together and exchange ideas, and display their hives, extractors, extracted and comb honey, etc.

New Smyrna, Fla., Oct. 31, 1881.

P. S. I see no better way of settling up the coast and river country of all South Florida than by encouraging bee-keepers to come and locate where they find every requisite of success. As we depend almost entirely on wild pasturage for our bees, a wild, unsettled country is as good or better for an apiarist than any other, provided it be on the coast or some water course that will give him transportation in his own boat to some point of public transportation. In all South Florida there can scarcely be found a spot near the coast or some river, but what would be a profitable one for the bee-keeper. There also is found the land best suited to the orange, and as apiculture and orange culture are peculiarly fitted to go together, the apiarist can, during his leisure hours, clear a piece of land and plant it to trees, thereby forming a permanent nucleus for a future settlement.

MISCELLANEOUS.

A Standard Frame.—The annual meeting of the British Bee-keepers' Association, was held last month, and the following is a digest of the proceedings on this subject:

The most important motion affecting bee-keepers and bee-keeping generally was brought forward by the Rev. George Raynor as follows: "That it is desirable that the British Bee-keepers' Association do set forth a standard frame, stamped by its sanction and authority, with the view to bringing such frame into general use, its size and form to be determined by a committee appointed for that purpose."

The question of a standard frame for general use has been discussed by all leading apiarists for a considerable length of time, the general opinion being that the matter should be taken up by the British Bee-keepers' Association.

Mr. Raynor in introducing the motion spoke as follows: The resolution is one of no small importance to the bee-keepers of this country, and indeed I may say to all who are technically or otherwise interested in the

art of bee-keeping. I will endeavor to state a few of the more prominent advantages such a frame should possess. First would be the interchangeability of all frames. How great a boon this would be I must chiefly leave to the makers of hives and the vendors of bees to tell you. This point cannot well be over-estimated, especially now that bee-culture is being taken up so extensively by some of our leading farmers.

A few days ago I received a letter from a cultivator of many acres in Lincolnshire to the effect that he was investing largely in bee-culture, and upon modern and approved principles. And what a field is opened to the bee-keeper by the thousands of acres of mustard with its fragrant golden bloom which this plant affords, the fields of white clover, and other mellifluous plants?

We must all rejoice that the farming interest at last is showing signs of a growing appreciation of this long-neglected industry; and in this view how highly necessary is it that, far more so than at any other period, that we should have a standard frame, as affording the greatest facility for the transfer and sale of bees, hives, and appliances. Honey extractors would come into more general use, since one size alone would be required, and their use would be greatly extended.

Now a "standard frame" does not imply a "standard hive." The hive may be of any size—i. e., may contain any number you please of standard frames, hence the desirability of making the frame, and not the hive, the standard. Hence also it would appear best to state inside dimensions of frame, since some may prefer to use stouter material for frames than others, and it is important that the comb-surface should not vary.

"As regards our shows, I would say, do not make your 'standard frame' a *sine qua non* for hive competitions, but give it the preference *cæteris paribus*. It may be expected that I should state my own views of the size and form of frame most desirable, but this, I think, is a matter that may be well left to a committee to deal with. I may, however, say that the general view appears to be that a shallow rather than a deep frame should be adopted, providing the depth be not less than 8½ inches, nor the length than 12¾, in order that the frame may receive six 1 lb. sections.

The shape I think of less importance, although as giving a decided preference to a tapered frame I should advocate a 'double standard,' in other words a reetangular and a tapered frame of the same superficial contents, and from what I have stated above, the size would most nearly approach the Woodbury frame. Shallow frames are most easy of manipulation, better for extracting, are more easily suspended in a vertical position in the hive, and there is no necessity for those abominations or queen-destroyers, called racks, to keep them in their places. It is said that bees winter better in deep frames, but with our modern appliances for winter and the contraction of the hive this

objection has no force. Heat ascends, therefore with a deep frame, when the bees cluster at the top of the frames, the space below will be filled with cold air."

The motion was seconded by Mr. T. W. Cowan, and after some discussion was adopted unanimously. The following gentlemen were nominated as the Committee to carry out the resolution: Mr. C. N. Abbott, Mr. T. W. Cowan, Mr. F. Cheshire, Mr. J. G. Desborough, Mr. J. M. Hooker, Mr. A. Neighbour, Rev. G. Raynor, Rev. F. T. Scott.

Bee Pasturage.—The *Semi-Tropic California* has the following on this subject:

Very soon the warm, dry weather will come and the planting of trees for permanent bee pasturage should be attended to without a day's delay. Some experiments point to the Loynot or Japanese plum as a very valuable honey producer, blooming in the fall or winter and producing a fruit that is unequaled for jelly making. It withstands the frosts and is an evergreen, that is ornamental as well as useful. It would not perhaps be out of place to again call attention to the value of the acacia; besides the bloom it yields, which furnishes both pollen and honey, the timber is valuable as fuel, being equal if not superior to willow, and the wood being very light and white is just the kind of timber to convert into sections for comb honey; it can be prepared for that purpose on a good foot power buzz saw by any handy bee-keeper at home at spare times, thus saving a money outlay that has been a considerable item in the bee-keeper's expense account heretofore. It will, on ordinary good soil, grow to the size suitable to such purposes in two years from the planting of the seed, which should be put in the ground in the month of March. Blue gum is another tree of equal if not greater value, both on account of its honey producing qualities and its timber. The handling of the plants must necessarily require more attention than the acacia, but it will well repay the attention and expense bestowed upon it, as when once well rooted it will grow even in poor, sandy soil, and in a few years afford timber and fire-wood; and the time usually spent by the bee-keeper in clambering over crags and cliffs, and up almost impassable canons to secure his supply of fuel, if judiciously used in tree planting would afford a better result for his work, besides furnishing his bees with honey close at hand year after year, and but little if any danger of failure on account of dry weather. When the blue gum is cut down for any purpose, it will immediately sprout from the root and make a vigorous growth. This is not so with the acacia; but as it is no more trouble to grow it from the seed than to grow corn, the bee-keeper should not complain. As soon as the danger of spring frosts are over, plant. The delicate and agreeable fragrance of mignonette, which is imparted to the

honey produced from it ranks it as of first importance among the flowers to be cultivated by the bee-keeper. During the month of March, or as soon as danger from frost is gone, sow the seed and spare not; be assured that nothing is better for bees, and very few if any blooming plants are better suited to our climate than mignonette.

Reversible Frame.—Mr. F. W. Burgess, Huntingdon, L. I., writes to *Gleanings* as follows on this subject.

At the convention recently held in Battle Creek, Mich., L. C. Whiting read a paper about the coming hive with reversible frames, etc., originated by Van Deusen, of Sprout Brook, N. Y. It may interest some to know that, a year ago, I made frames reversible, and have experienced the benefits enumerated in this paper. It can be applied to any frame with comb in, if desired. I have my material cut for frames for next year, and all are to use the metal arm. I use the L. frame with wires; for the support in the center, I use a strip ⅜ wide, of picture-back stuff—and by its use secure openings by its side through the cards for winter passages. I have always pressed the wires into

the wax by the use of an "excavator" (everybody will know what that is, if they have ever been to a dentist), bending the point to an angle of 45 degrees, and on that foot cutting a slot to ride on the wire. Your button-hook arrangement is the same.

One great advantage of the reversible frame is to secure the comb well drawn out, and attached to both top and bottom bar.

I will suggest, that with my frame there is but little chance for the bees to stick them down—a metal arm resting on a metal rabbet. Again, it will always hang perpendicularly, there being but one place of contact; and if desirable to raise the frames from the bottom-board for winter, it is easily done by placing blocks under the lower arm.

By turning one arm under the bottom-bar, the other is secured fixed for hanging on the rabbet, and *vice versa*.

Spring Dwindling.—The *London Journal of Horticulture* remarks as follows:

Some bee-keepers are taking alarm at the large numbers of dead bees found in front of certain hives. These are generally cases where a large proportion of the stores had either been of unwholesome quality, as honey dew, or had not been properly sealed in autumn from too late feeding. An examination will generally reveal an abnormal quantity of food. How significant the fact that bees, as well as plants, hasten to propagate their

species on the approach of danger to their own existence! There is a danger of such colonies working themselves to death. This is the American trouble known as "spring dwindling." The only cure for it is to remove all combs with unsealed or unwholesome stores, and supply others if they can be had of better quality, or give dry combs and sugar cake. At the same time contract the brood nest till the bees are crowded, and give any comb containing brood beyond what the bees can be crowded on, to any other healthy colony.

Bee-Stings.—Respecting the effect of bee-stings in rheumatism, a correspondent of *Gleanings* says:

About a month since, a neighbor, living about six miles in the country, called on me to go out and examine a colony of blacks that he thought the moth were troubling. While there the lady told me that bee-stings had cured her of rheumatism. She said that she had for a long time been so troubled with it in her thigh and hip that it was difficult for her to walk across the house. Last summer she and her sister undertook to transfer a swarm of bees from an old gum, and not being acquainted with that kind of business, never having seen the operation performed, they got terribly stung before they got through. She was so badly stung that it made her quite sick; but since that time she has not been bothered with rheumatism.

How to Start in Keeping Bees in Texas.—Dr. Wm. R. Howard, in the *Kansas Bee-Keeper*, says:

An apiary should be located within easy range of both prairie and timber, near some small stream, in order to have the advantage of the thicket and bottom, as well as prairie range. In the thickets and bottoms we have elms, wild plums, red-bud, raton vines, honey locust, and many other honey plants of minor importance. On the prairie we have the horsemints, milkweeds, etc. Horsemint is one of our very best honey plants.

The best way to get a start of bees here is to buy the blacks in box hives and transfer and Italianize them. Another way is to furnish hives and transfer on the halves. We have tried both plans and there is but little difference, where you don't go too far for the bees. We always bring our bees home in the boxes and transfer, either immediately before allowing to fly, or four or five days afterward, when they have become acquainted with their new location.

To Beginners.—The *American Agriculturist*, gives this good advice to the beginner:

Those who contemplate starting in bee-keeping the coming season should procure at once, and thoroughly master some one of the several excellent manuals that treat of bees. This

done, the prospective apiarist should subscribe for one of the apicultural papers, several of which are published in this country. The text book study will prepare one to read understandingly the paper, and by such reading a person will keep abreast of the improvements, and so will be in the way to take advantage of all that may help him. Apiculture is advancing rapidly, and he who does not keep informed will soon be left in the wake of his more enterprising brother. After a thorough study of the subject, it will pay well to visit some wide-awake bee-keeper, and spend a day or two with him. We are happy to state that one does not need to go far now in any part of the country to find such an one. Such a visit will do much to remove the timidity that one is apt to feel in approaching these insects. The book-knowledge will become practical, as the various truths and descriptions are illustrated.

For the American Bee Journal.

Some Slovenly Bee-Keeping.

REV. L. JOHNSON.

"How many colonies of bees have you?"

"Ten or twelve."

"How have they wintered?"

"I don't know."

"How have you prepared them for wintering?"

"I have paid no attention to them. I have been too busy."

Such was the substance of a conversation I had with an old bee-keeper, as I arrived at his house late one evening not long since. Frequently had he requested me to come to see him and talk about bee-keeping. Until a late hour at night we remained up and almost every subject connected with the interest was discussed in his way. But as he took no bee paper, and never attended our Conventions, I found him far behind.

Next morning early we were in his bee-yard following him around to receive "instructions." His hives were of all shapes and patterns; some in boxes, some in movable combs, yet the frames of no two exactly of the same size. The tops of most of the hives were leaky or warped so that dampness and snow was penetrating the inside every storm. Many of them were tilted back so that rain falling on the alighting board would run into the hive. Some pigs had been running in the yard all winter, and these had rooked up the ground around the hives until the entrance of some of them was nearly blocked.

Three or four of the best were sitting under a cherry tree, in which the fowls had roosted all winter, and the tops were covered two or three inches deep with their droppings, which was

being soaked into the hives and combs. When the hives were opened I found a little bunch of bees, perhaps a quart, old, black and sickly looking. When I told him I had hives with 10 or 11 combs covered, and young bees flying, he wondered why his did not do better, as he thought he had a good location.

This may be an extreme case, yet all over our land we find hundreds keeping bees who do but little better, yet these men say "bee-keeping does not pay." Suppose their sheep, hogs, or even larger stock were kept after the same fashion, who would expect anything but failure? These men are generally the most self-conceited men on bee matters of any we meet. They "have long ago learned everything about bees." "You can't tell me anything," etc. Some years ago, I sold one of these men 2 good colonies, and delivered them in good order; that winter he let them die for want of attention; next spring he reported around that I had not sold him good colonies, etc. I have no doubt many of our queen breeders and bee dealers have suffered in the same way. If anything is worth doing at all, it is worth doing well, and the proper care of bees will pay a larger return than almost anything else. If we possibly can, brother bee-keepers, let us try to convert our slovenly brethren from the error of their ways, and if we cannot, it will be an act of mercy toward our little pets, as well as beneficial to the craft, to induce them to quit the business entirely.

Walton, Ky., March 13, 1882.

For the American Bee Journal.

A Few Practical Hints.

C. A. HATCH.

To keep one-piece sections from breaking in bending, hold as many as you can conveniently grasp, edge up, over a pail, and pour boiling water from a tea-kettle on the places which are to be bent, and be careful and not wet the rest of the piece. The strips should all be laid so the grooved sides are one way; this gives a chance for the hot water to wet both sides nicely, and only just where it is needed. The advantage over steaming or wetting the whole piece is, the dovetailed ends are not wet at all, and therefore will not loosen after being driven together, by shrinking.

Have always run my bees for extracting, and never used many sections; but prefer the one-piece to any other tried. I think they are nicer, stronger, and quicker put together; do not remember ever breaking one treated as above. A light mallet is the best tool to drive them together with.

Can fully indorse all J. W. Porter says in the *BEE JOURNAL* as to the age of foundation. Rather melt up after it is one year old and make over, than to use. Think the best plan to keep it would be to pack close in a covered box. Anyway, do not fasten into frames until most ready to put in the hive, and do not put in the hive

until the bees are ready to go to work at it, as the heat of the hive will harden it more in one day than one month in a close pile, not exposed to the air. Too damp a place will not do; have had it mold and spoil even in a dry cellar.

To make a fair test of different kinds of foundation, it should not only be of the same age, but made of the same kind of wax. We had some nearly spoiled last year with rosin: not over $\frac{1}{4}$ ounce to the lb. of wax. The bees were sharp enough to detect even that small amount, and why not the same with other foreign substance?

I prefer moulded foundation to rolled; have never used any made on a press.

Ithaca, Wis.

For the American Bee Journal.

Bee-Keeping in Nebraska.

J. B. SKINNER.

Being a merchant and publisher my time is pretty well occupied, but with the peculiar inspiration of scientific apiculture, I am constrained to keep a few bees for pastime and experiment, as the sequel has proven a time or two, perhaps "experience" would be the better word.

This section of country (Southern Central Nebraska) is reasonably well adapted to bees, though the past season was here, as elsewhere, too dry for more than a moderate yield of honey. My bees came through last winter very much like those of many other bee-keepers, losing 100 per cent. of the total (24 colonies) attributable, of course, to the terribly severe winter—how convenient to have somewhere to place the responsibility!

In the spring another colony was procured and divided into 6 during the season, which were put into winter quarters in good order, and are yet doing well, as the unusually mild weather has given them opportunity to fly every few days, showing a strong and healthy condition.

As the country here is new, bees are scarce (I have knowledge of but 6 or 8 colonies and none nearer than ten miles of my location) hence we have discussions, and other convention proceedings, and interchange opinions, and observations, through the bee papers only, so the BEE JOURNAL, the single bee paper I am taking at present, has a pretty thorough reading here.

Reading Mr. T. C. Mace's experience with stings in the JOURNAL for Feb. 1, I was reminded of a similar experience myself during the past summer; stings usually hurt me but little, but on this occasion I had been standing in a stooping posture for some moments, causing a flow of blood to the head; the day was intensely hot, and perspiration flowed freely, when a little "pet," with "malice aforethought," injected her "beautiful, polished shaft" into the side of my nose, it was brushed away without hesitation, with no thought of more than momentary pain. Within five minutes, however, my face and

mouth were so swollen that I could scarcely see or speak, a few moments later my hands and feet were swelling, and my heart palpitating so severely that much effort was required to breathe. My "better half" becoming alarmed began a liberal application of Centaur liniment, the first remedy she happened to find, and within 20 minutes after the first application, the pain and palpitation were entirely relieved, and the swelling rapidly reducing. Next day the sting was repeated on the same unfortunate organ, but without other than the usual result—momentary pain.

Inoculation proved of no avail in this first instance, but as to what spirits might have done I could not say; their value, however, is recognized in some instances, as witness the following:

A neighbor, while hauling rock some years ago, narrowly escaped being bitten by a rattle snake that lay coiled under a stone; he was very much unnerved, and after returning home, concluded to take an antidote—having purchased some spirits a few days before for making vinegar—like Mr. Mace, he imagined that it was beneficial, and deeming prevention better than cure, next morning, as he was starting to work, took another portion, and so on each day, and at the close of the season triumphantly declared that he had not been bitten once during the year; adding, half apologetically, that no vinegar was made though.

Mr. Mace might succeed equally well with it as a preventive, and thus save, not only the pain of the stings to himself, but the possible risk of death to Mr. Clarke to whom he refers, should the latter gentleman attempt to prove the question of inoculation.

Honey from Corn.

M. MAHIN.

The correspondent of *Gleanings*, quoted in the BEE JOURNAL of March 8th is mistaken when he says that bees gather honey from corn. If he will watch the bees at work on corn tassels, as I have done perhaps hundreds of times, he will observe that they never pause on the flowers and apply their tongues to them as they do to flowers that yield honey. That the said correspondent is not a close observer is evident from the fact that he says the bees gather honey from corn at the time that they gather the dark green pollen. It is certainly not true that bees gather dark green pollen from corn. The pollen from that source is not dark green but light yellow, as anyone may observe when the corn is in bloom. Bees work on many flowers from which they never get a particle of honey, and among them are corn tassels.

Corn affords an abundance of pollen, and at a time when there are few other pollen bearing plants in bloom it is of considerable value, no doubt,

as the bees work freely on it. A careful observer can always tell whether bees are gathering honey or pollen only. If they keep in constant motion, as they do on the corn flowers, they are getting no honey. I have never been able to detect bees gathering honey from soft maples, and I doubt whether they ever get any from it. If they get any it is very little.

For the American Bee Journal.

Practical Use of Comb Foundation.

G. W. STANLEY.

Much has been said and written on the subject of comb foundation, and yet there is room for more remarks. When Mr. C. R. Isham, of Peoria, N. Y., took that decided stand in favor of comb foundation at the North-eastern Convention some years ago, I was using foundation made on the first mill that A. I. Root ever sold. From that time to this I have produced about 20,000 lbs. of comb honey, and my bees have never been left to fill a box without a full-sized starter of comb foundation. The foundation made on the above mill was very imperfect, in comparison with work done on machines now in use, as there was but very little wall, and the foundation then used for sections did not run more than 7 square feet to the pound, and, of course, there was some "fish-bone" in the honey; but I can say that my honey has always brought high prices, which statement will be indorsed by any of the leading bee-keepers through this section, and I have never had a crate of honey come back on account of "fish-bone" or any other cause. When J. Van Deusen advertised the flat-bottomed foundation for sale, I stopped using the Root foundation in sections on account of not enough surface, and for the season of 1880 I used the Van Deusen flat-bottom, running from $8\frac{1}{2}$ to 10 feet per lb. This kind worked fairly while new and fresh, if the bees were getting just enough honey for comb building, as they would then have time to change the base of the cell, and as the wall was light the wax was all used up; but when honey came with a rush, as it does in our basswood flow, the bees would add wax to the base to make it the natural shape, and thus make the base much thicker than it was when it came from the mill. Now, on the other hand, when honey was coming in very slowly, or perhaps not at all, as is the case here when no basswood, if the foundation was a little dry and old, the bees would take it out at the entrance to the hive, while a piece of natural comb in the next box would be left untouched until full honey commenced to come in, and the natural shaped foundation would be drawn out and filled with honey. When these truths had made themselves manifest, I began to look around for a mill that would make foundation 10 square feet per lb., with natural shaped base, and found what I wanted in the Vandervort mill for making

light foundation. If the work is properly and carefully done on this mill, the foundation will run 10 square feet per lb., and the base will be very thin and even, not leaving one part of the septum thicker than the other two parts, as you will observe in most other foundation, and at the same time the wall will be very thin and sharp, so that if honey came with a rush you will not get a chunk of wax in the center of each comb, as the base is as thin as the bees would have made it.

In speaking of brood-comb foundation I will be very brief, as nearly all bee-keepers are convinced of the necessity of it in order to get straight combs and to exclude drone comb, to say nothing of the great saving of time and honey that the bees would use in making their own comb. If foundation has a high wall, of the proper shape and weight, so that with a rather light base the foundation will run about 5 feet per lb., there will be no trouble from sagging. In my opinion, if this fact had been known 3 years ago, wired foundation would not have been used to any extent, as the wires made it much more expensive, besides being constantly in the way of taking out queen cells, etc. What first raised the complaint of foundation sagging in the brood chamber was the fact that it was made about 6 or 6½ feet per lb., and the wax was about all in the base, but the high-walled mill now obviates that difficulty, if proper care is taken in fastening the foundation in the frames.

For the American Bee Journal

The Temperature of Cellars.

JACOB SPENCE.

I have been watching the BEE JOURNAL to see more particularly brought up the question (and answer to the question) whether indoor even temperature is really desirable or not. It seems to me more reasonable to believe, as the normal condition of bees wintering in hollow trees would be alternating sunshine and frost, that in bee-house or cellar they should, too, have such variations of temperature as would give them a chance to move and again compel them to cluster?

I value much to have a competent bee-keeper's opinion or judgment—at same time greatly prefer good reason given or well conducted experiment in support of consistent theory. I would vastly like also that we could have a well sifted and selected list of just how many things are undisputed in regard to wintering, if any? Or if not undisputed, at least generally accepted as essentials, toward bringing the creatures through with life. This looks to me where the dead-lock yet comes in. But surely the combined wisdom and experience now available, ought to be competent to clear away the mist yet around the dominion of wintering.

Toronto, Canada.

For the American Bee Journal.

Untested or "Dollar" Queens.

W. Z. HUTCHINSON.

MR. EDITOR: You say that scores of prudent breeders would, in some particulars, exceed the expenses as given in Rev. A. Salisbury's balance-sheet; if not too much trouble, give the details, showing in what particulars a prudent breeder could be more extravagant?

You speak of breeders making a specialty of tested queens, and availing themselves of the "untested" feature to work off worthless trash in filling orders for tested queens, provided, that the "worthless trash" produced bees with the requisite number of "stripes." I believe that some of our apiarists are waking up to the fact that the worst fault of a queen is not always that she produces hybrids.

You say: "We have long been convinced that 'waranted' or 'untested' queens were not only worthless, but an actual damage to the bee-keeping interest. In reply to this let me ask a question: Suppose that, about July 1st, any of our most reliable breeders had 100 queens that had just commenced to lay. (I know of only one breeder who rears his "dollar" queens differently from his tested queens, and that is Mr. Doolittle. He very explicitly states the fact in his circular, and I honor him for it.) If from such reliable breeder I should order 30 "dollar" or untested queens, and 30 of these young queens should be sent me; in ten days more I should order 30 "tested" queens, and, of the 40 remaining queens, 30 had been found to be purely mated, and they should be sent to me; now, Mr. Editor, which lot of queens do you think would be the best. I could destroy the mated queens, or, if I chose to keep them, would they not produce as good honey gatherers as the purely mated queen? But, you say the breeder can send out, as dollar queens, the ten hybrid queens that he has left. Granted; but the breeder who would do this would also send out superannuated and worthless queens, when filling orders for tested queens, if he had any such queens that produced three banded bees.

You say: "That it (the cheap queen traffic) does open a wide door for fraud no one can deny." A queen whose progeny shows the three yellow bands is sold as a tested queen, does not this also open a wide door for fraud? Suppose that the Ohio dealer had ordered 100 tested queens, and suppose further, that he had stipulated that they should be young queens and bred from an imported mother, if that western apiarist and queen breeder had seen fit to do so, could he not have filled the order with old or "cull'd" queens? In regard to these "sharp" breeders, who never miss an opportunity to send out old and worthless queens, isn't it a trifle strange that their names are never given to the public along with their boasts and "chuckles" over their dishonorable practices? In my opinion an honest

man is honest at all times, and under all circumstances, while a breeder that would cheat the purchaser of a "dollar" queen, would not hesitate to defraud a customer that ordered a tested queen.

Again you say: "But we do not believe, among them all, there is one who is reckless enough to expect to buy a single queen for \$1 or 100 queens for \$65 which would be fit to rear even untested queens from." Please turn to page 169 of the *Bee-Keeper's Exchange* for 1881, and you will find that H. P. Sayles writes as follows: "As an illustration of American untested queens, I will say I received 5 strong nuclei from Dr. Brown, of Georgia, price \$3 each. All the queens were superior in appearance. Of the untested queens above mentioned, one proved to be impurely mated. From two I reared a few queens which proved beauties in all respects, and but for the fact that their mothers cost but \$1 each, they would delight the eyes and fill the hives of our customers next season. As it is, they must remain and do service at home. Such experiences as the above, produce the call for the American bee. From my experiments, I should certainly prefer the dollar American from one of our reliable breeders, for breeding or any other purpose, to the untested imported queen."

I have purchased quite a number of both tested and untested queens, and I have found fully as large a proportion of good queens among the untested as among the tested, and I presume that other purchasers have had the same experience. Untested queens are shipped as soon as they commence laying, before the breeder knows anything in regard to their qualities, while tested queens are kept at least three weeks, and, if the breeder chooses to do so, he can keep, for his own use, the very best among them, leaving the second class queens to be shipped as "tested" queens.

I cordially agree with you, Mr. Newman, when you say: "What bee-keepers want is better stock, more honey, longer lived bees, and certain profits;" but I firmly believe that these results will never be obtained by testing queens in regard to "stripes;" and I am glad to see such men as Heddon, Alley, and Doolittle take the position that they have. If ever I felt like saying "amen," it was when I read the following, in Mr. Alley's article: "Queens should be reared and tested for business, and not for purity. In ordering queens the purchaser should say: 'Please send me a queen that you know to be very prolific, active, and vigorous; let her be pure Italian if possible, but send me a good one or none, as I want to obtain honey.'"

Mr. Alley says that he has more orders for queens than he can possibly fill, and yet he finds the rearing of dollar queens unprofitable. It would hardly seem proper for a young bee-keeper, like myself, to give advice to an old hand like Mr. Alley, but I presume that I may be allowed to suggest that he follow the course adopted a year or two ago, by Mr.

Oatman, of Ill., i. e., drop the dollar queen business altogether, and sell nothing but tested queens. He could thus continue in the business that has become "second nature to him," and could also make money.

Rogersville, Mich.

CORRECTION: About the middle of the second column, page 149, is a sentence that commences as follows: "I, at one time, had nuclei." It should read: "I, at one time, had eighty nuclei." W. Z. II.

[A reply to the above may be found on the first page.—Ed.]

For the American Bee Journal.

Does it Pay to Rear Cheap Queens?

REV. A. SALISBURY.

It does seem to me almost any one can observe, that the advocates of untested queens rely but little upon their own arguments, as proof that the business is remunerative. Mr. Hutchinson asks the question, on page 149 of the BEE JOURNAL: "Mr. S., I ask if you have not indulged in too many spread eagle advertisements?" He also informs us when the flow of honey is scarce, he feeds cheap food—"It was grape sugar that I used for feeding." Of course, Mr. H. is not a sloven or stingy, that he does not like to see a neat advertisement, but economy says, "can't afford it on dollar queens." The same is also true of grape sugar (glucose). He knows, as well as any of us (from reports made on glucose), it is inferior and unhealthy food, compared with good granulated or coffee A sugar, or honey; but economy says take the dose—economy with Mr. H., and likely money in his pocket, but hard on the constitutions of embryo queens. If the reader will take the trouble to turn to Mr. H.'s article he will see, to make a good showing on untested queens, that Mr. H. puts all his increase of colonies at \$7 each, and all his surplus honey at 15 cents per pound. To me that is a new leaf just turned. He also acknowledges in that report that he allowed his expert nothing for time spent in rearing the queens; and it is altogether probable he boarded himself. A weak showing for an honorable, remunerative business.

Mr. A. G. Hill, editor of the *Bee-Keepers' Guide*, (once if not now an advocate of dollar queens), in the sequel of his review of the article referred to in the BEE JOURNAL, says: "And even with our economy and improvements, we can hardly make the price of a suit of clothes more than Mr. Salisbury." My balance sheet fell short \$12. This looks to me like a very small business—half a suit of clothes for a season's labor (don't forget the \$12 discrepancy in my balance sheet comes out of Mr. Hill's suit, which leaves him with half a suit, if he intended a \$24 suit). He evidently felt it was a poor showing for a remunerative business. It may do for a man of leisure, or boys that

have nothing else to do, but preposterous for a man of experience, with a family to maintain and children to educate.

It is true that the cheap queen traffic opens a wide door for fraud upon the purchaser. The presumable harm it has already done, yet doubtless largely lies cloaked behind the curtain. Like the glucose trade, it was a fraud in the beginning, which drove honest houses out of the sugar trade, and supplied the public with an inferior, unhealthy article as a substitute. Notwithstanding this may be the case in our business, it does not necessarily follow that all queens sold for untested are a fraud upon the purchaser. All tested queens come from those once untested. The truth in a nutshell is, first, it presents a strong temptation to the queen-breeder; second, he cannot make an honorable living dependent upon selling "dollar queens," and last, the purchaser runs a risk in getting a good queen.

While it is a fact, that all honest dealers discard and destroy all queens that present any external appearance of imperfection, yet imperfections are sometimes concealed from the eye, and after a queen has been tested, however valuable the mother and fine the stock, she is found not to be worth hive room, and no one to blame—it is the sporting of nature.

Is Our Chemist Abroad?

J. H. MARTIN.

While reading your editorial, page 66, upon granulating glucose, I became disagreeably conscious that our chemist is not abroad with eyes and ears open, to learn the wondrous progress of the present age, and to keep the bee-keeping industry upon an even race with other and recently discovered industries. Here we have an industry and a product, the history of which we can trace back through the ages, that has not in its chemical features progressed one step. The honey that is put upon our tables, in the comb or liquid, is just the same as when Samson ate the comb honey from the lion's carcass, and lapped the extracted honey from his fingers.

But I hear some one say: My dear sir, what do you propose to do with our beautiful honey, are you not satisfied with the pure, wholesome, clean article, as now put upon the market? In answer, I may say: I am not; for I know there is a wide field here for improvement.

The first improvement I would suggest, is to bleach or extract the coloring matter from our dark grades of honey. Buckwheat honey seems to be the best subject to commence upon and I would inform our chemist, that a fortune awaits him, as soon as he will present to us the magic filter that will remove the disagreeable color, and give us a nearly uniform grade of honey. I think the proper time to attack the color is when the honey is first gathered and before it is sealed.

My next suggestion is to dry granulate our honey. That it can be done is hinted to us very strongly by dame nature herself, for every bee-keeper who has handled extracted honey, knows that small patches of honey upon the staves of the barrel will often be found in an apparently granulated condition so that it can be handled like dry sugar. Will our chemist tell us why these particular parts dry, and also tell us how to serve the whole barrel in like manner? The only experiment I can recall, that has been tried upon this problem, was by Mr. A. I. Root, several years ago. This peculiarity of certain grades of honey came to his notice and several parcels of candied honey were hung up in wire baskets, to dry, but I think the experiment was a total failure.

I could give other suggestions for improvements, as to the use of honey, but will leave the subject for our chemist to give us much needed information upon the chemical constituents of honey, the coloring matter, and the flavor.

The glucose industry, not a score of years old, has passed from one stage of improvement to another until a substance hard and bitter, and loaded with acids, is now to be put upon the market, with the bitterness eliminated and in granulated form; and although used as an adulterant in all other sweets, the spirit of improvement, which possesses the manufacturer is worthy of imitation by the bee-keeping fraternity.

Unless our chemist gets around lively, he will be left so far behind he will never win his share of the laurels of renown.

Hartford, N. Y.

Manufacture of Comb Honey.

H. S. HACKMAN.

MR. EDITOR:—I thank you for the kind notice given to my last communication on Honey in Sections. Hoping it will not be intruding on your good nature, by my again calling the attention of the first question, "Do people in large cities buy and use our beautiful section honey, and at the same time think they are using or eating artificial comb honey?" I think they do.

It was not my aim to prove or disprove the possibility or impossibility of making artificial comb honey, for that is a settled fact with me—it has not yet been done. But to prove to my honey producing friends that pure matured honey is bought and used largely by consumers, under the impression that it is manufactured honey. This false impression is partly brought about by unprincipled, over-anxious men in producing something new and novel.

I had the following conversation with one of our grain merchants some 2 years ago, which will partly explain my assertions. He said: "I saw a nice lot of comb honey at the Exposition building in Chicago, and so much

of it, you would be surprised; and it is made in Chicago."

"That is not so; for no one can make comb honey."

"They do make it, comb and all, for the man that had it on exhibition told me so, and I afterwards saw the place where they make it. I saw an immense pile in their show window."

But he had forgotten the street and number, so I could not trace the matter up.

Another reason why I am convinced of the above fact, is that while I have sold my honey from house to house, many people would look at the sections, turn them over and over, again and again, in the most surprising manner, and then ask: "Is this the way you put up comb honey?" I told them no; that the bees made it that way; that the bees gathered the honey always. Some seemed doubtful.

One more strong evidence: My friend who ate the artificial comb honey at his sister's table in Chicago, promised to send me a sample of it when he got back to the city, but the sample has not come to hand, and I have no doubt but that he found the honey he had eaten for artificial honey was the pure article, for it is two months since he was here.

Honey taken from bee-trees, log gums, box hives, and promiscuously thrown into tubs and carried to market, is so different from our nice clean sections of to-day, people can hardly realize the fact that our nice honey in sections is pure.

Section honey in country places is something new. Many people have never seen any. Producers always ship their best honey to the city markets, and the above statement explains the mistaken idea among city consumers. This false idea is detrimental to honey producing, but how can we remedy it?

Peru, Ill.

For the American Bee Journal.

"Do Bees Puncture Grapes?"

A. F. MOON.

The members of the Northeastern Convention, which recently held its annual session, very wisely discussed this question; much credit is due them, for a just and "wise decision."

For thousands of years the honey bee has been a companion of man, in the way of supplying him with the grandest luxury ever placed before an epicure. Bees have greatly aided in the fructifying of fruit in carrying pollen from "flower to flower;" it is needless to give the manner in which they were cultivated, and managed in olden times, but we will say that within the last thirty years, "came the promise of deliverance—the foreshadowing of the beginning of great things"—and that foreshadowing was the introduction of movable frame hives. Up to that period but little interest, comparatively, had been manifested, "except by a few, knowing the worth of this noble insect." Latterly came more important inventions, such as the honey and wax ex-

tractors, comb foundation machines and other valuable inventions, which gave this rural branch an impetus never before excelled in any country. All this has had the effect to place this commodity in proper shape to meet the approval of other nations who are striving to compete with America. While this great revolution has been going on, the little busy bees has, like the gigantic railroad system, spread far and wide, notwithstanding their great enemy, which is the worst of all, "the ignorance of man;" they have contrived to increase and emigrate to the far west. They have crossed the Mississippi, making their way westward until the Rocky Mountains are no longer their boundaries. Yes, this wonderful insect has pushed its way onward over the mountains and the plains, passing Dakota, Nebraska, Colorado, Wyoming, Montana, Utah, Nevada, Idaho, Oregon, and the far Washington Territory; their march has been westward, and mostly in advance of the human family.

The wonderful growth in apiculture during the last 30 years has far excelled any thing in the world's history. The revenue derived from the bee excels any other branch of industry for the capital invested, and their nature and habits have become familiar to almost every school boy. Notwithstanding their long existence upon the earth, we have a class of men who are trying to banish them from the land by accusing them of "puncturing grapes, peaches and other fruit." How strange it is that the honey bee has been cultivated for so long a period and never learned until a few years how to open and suck the juice of fruit!

When this complaint was first made we had the curiosity to test it, although we had kept a large lot of both bees and grapes, yet never knew of any injury done to grapes, peaches or any fruit by them.

We selected from the Delaware, which, by the way, is one of the most tender of all varieties, placing them in an empty hive, and putting a colony of bees in the hive, but not a grape was punctured, but the bees died. I have frequently placed a bunch of grapes in front of a hive of bees when but little or no honey could be gathered, and have covered them with syrup; they would lick up the syrup but did not destroy the grapes, neither do we believe they can. If they possessed the power they would undoubtedly use it long ago, for they have been raised together, and we do not think the bees possess any more knowledge to-day than they did when first known to man. They have not changed—they work by the same rule, and are governed by the same law now, that they were 2,000 years ago.

It is somewhat astonishing to look upon the most refined and intelligent communities of modern times and behold the ignorance that still exists, and where knowledge should prevail, the ignorance of merely fashionable training are twins—Gog and Ma-gog.

If the question is to be settled whether bees puncture grapes, we

hope that practical disinterested men will be chosen; some great blunders have been made by those who claim to be practical scientists, which has caused the little bee to lose much of its character. A few years ago a man in New York tried to expel bees from the place because the bees sucked honey from his buckwheat.

Rome, Ga.

SELECTIONS FROM OUR LETTER BOX

Honey from Cotton.—My bees are doing well, gathering some honey, and are breeding up very fast. Maple, peach and plum trees are in full bloom; the weather is warm, and the little fellows are busy all day. I have 32 colonies, all in good condition. I have them all in movable frame hives; I would have no other. I use full sheets of Dunham foundation, and find the bees work on it readily. There is no other person in this locality using the frame hive, nor is there any Italian bees except my own. It is thought bees will not pay in this country, but I am going to give them a fair trial this year. I saw drones flying on March 12. I shall begin queen-rearing soon, and expect to breed some fine queens for my own use. I took last season as high as 80 lbs. of honey from one hive, made from cotton bloom. I send you a sample. I want to know how it will compare with white clover honey. The sample is not a fair one, as it was not extracted. It was strained from the comb. H. M. WILLIAMS, M. D.

Bowden, Ga., March 13, 1882.

[The sample came duly; but it is not as light, nor as pleasant to the taste as white clover.—Ed.]

Foundation Fastener.—Is Goodrich's machine, intended to fasten foundation in frames not wired? If so, will the sheets of foundation have to be but the whole size of frame? I should like to buy a machine that would fasten whole sheets of foundation in frames, that will not warp or stretch, when the bees commence to work on it.

HENRY FILLEY.

Castle Hill, Me.

[The foundation should be full size of frame—and may be wired or not.—Ed.]

Coral Berry Bush.—The coral berry bush grows wild here on hundreds of acres. It commences to bloom in August, and blossoms till late frost. Drouth does not effect it, and it is better than white clover. I have been observing it for 4 years, and find it grows anywhere, either on high or low land. It can be easily plowed out with a good team. J. E. SAMPLE.

Beman, Kan.

[We have several specimens, which have been sent from others.—Ed.]

The Uses of Glucose.—Mr. Editor: I think you are mistaken in your opinion about the uses of glucose—that its only use is to adulterate. The grocers of the country sell large quantities of a fine looking syrup in 5 and 10 gallon kegs, which is, I think, the genuine glucose. They call it down here “corn syrup,” and do not pretend it is anything else. It retails at 65 cents per gallon. It is very clear, light color, transparent, with, to me, a sickish sweet taste. Most people are fond of it, many preferring it to the best sorghum syrups, and paying for it a higher price. It is utterly worthless for cooking purposes, and known to be so by the consumers. It is used only as a table syrup, and will be found in almost every house. Of course, the great mass of the people are ignorant of its true character, and believe it harmless and wholesome. There is only now and then a person who knows it to be worthless and unhealthy and who will not have it in their house. D. P. NORTON.

Council Grove, Kan.

[Being ignorant of its real character the people use it, but if they knew what they were eating, they would never think of using it. Is it not, therefore, a fraud and a snare, detrimental alike to health and life? And should its real character not be exposed in the interest of common humanity?—Ed.]

Drouth in Kansas.—Bees did well in this locality until the commencement of the basswood flow, after which they barely gathered sufficient for brood rearing, the drouth being continuous the entire season. As a consequence many colonies died of starvation, and are generally in a weak condition. JOHN Y. DETWILER.

Doniphan, Kan.

Syrian Bees.—I will give my experience with the Syrian bees, as I see that Messrs. Pike and Valentine have each given theirs. I do not rear nuclei for sale, therefore have no axe to grind. When Mr. Jones first imported the Syrians, in 1850, I purchased 8 queens, having but 9 colonies at the time, which made 8 colonies of Syrians and 1 of Italians, that fall. The winter of 1850-51 killed nearly all the bees in this part of the country, but 6 of my Syrians came out in good condition, having lost the Italians and the 2 weakest of the Syrians. The season of 1851 was a very poor season for honey, so all the bee-keepers say here, but my 6 colonies increased by natural swarming to 24, which are all in good condition at the present time, besides getting more surplus honey than Italians ever did for me. I find the Syrians splendid honey gatherers, working early and late; mine carry heavy loads of honey, and lots of them. Last fall, when I prepared my bees for winter, I found nearly every colony had twice as much honey as they needed to winter on, having the brood chamber full, with the exception of about 2 combs, which were

about half full of brood. I can handle my bees without gloves or veil, and not get stung any more than with the Italians. Give me the Syrian bee every time, even if the Marylanders have better ones. LIZZY HARTMAN.

South West, Ind.

Sweet Clover with Wheat.—Can I seed a piece of winter wheat this spring with sweet clover, without injury to the wheat, and the clover do as well as other clovers sown on winter wheat in the spring? We seed winter wheat in this country generally in the spring with clovers and timothy, and they do well. Bees are doing well in this locality. March 2d my bees brought in pollen. I have 75 colonies packed in chaff on their summer stands. We have had a very mild winter so far. ELI BROOKS, JR.

Center Road Station, Pa.

[Certainly; the growth of the sweet clover will be so slow the first season that the wheat will get out of its way, and the clover will take no harm from the wheat.—Ed.]

Red Clover Queens and Bees.—Much is said about red clover queens, or queens that will produce worker bees that will gather honey from red clover, but I don't see anything strange about having such queens. My bees gather honey from the first and second bloom every season. Some seasons they gather half of my crop of honey from red clover. Every queen in my two apiaries will produce worker bees that will gather honey from the first bloom of red clover in Western Maryland. D. A. PIKE.

Smithsburg, Md.

Kentucky Bees All Right.—I send the glorious news of a safe passage, without the loss of 1 colony out of 28. Last winter I lost 21 out of 33. Bees have been bringing in pollen for 2 weeks. On the 9th of March I noticed a number of peach trees in bloom nearly opened to full size. I opened some colonies on the 5th of March, and found young bees capped, brood and eggs, all in abundance. One had some drone brood capped. At this rate, I expect swarming to commence early in April. The BEE JOURNAL improves all the time.

G. W. ASHEY.

Valley Station, Ky.

Bees in Better Condition than for Many Years.—One year ago I lost all my bees except 3 colonies. I had nearly 50 colonies. I have just bought 7 more good strong colonies. Bees are in better condition this spring than they have been for many years.

W. G. PORTER.

Weston, Mich., Feb. 9, 1882.

The Outlook the Best for Years.—Our bees have wintered well, and are now gathering honey fast. The outlook is the best for years.

W. K. MARSHALL.

Marshall, Texas, March 16, 1882.

A Veteran Bee-Keeper.—I commenced bee-keeping when 18 years old; and have kept bees since. I am now 74 years old; was born in North Wales in 1807, and came to America in 1832. I have taken much pleasure in working in the apiary, and have made it pay very well some years. Please tell me what are Albino bees?

WM. ROBERTS,

Vaughansville, O.

[We believe they are the result of carefully breeding the lighter strains of Italians, until their peculiarities have become a fixity.—Ed.]

Feeding Syrups.—I wish to inquire if the syrup which has a soda or potash taste is fit to be used to feed my 10 colonies to induce early swarming? Our grocers call it clover honey syrup. It has an abominable taste when eaten on warm cakes. C. M. CLARK.

Lincolnsville, Pa.

[Clover honey syrup is probably only another name for glucose or grape sugar. Do not feed your bees on anything you would be unwilling to eat yourself, unless it be something you know to be a natural production. Better mix honey with warm water, or make a syrup of pure cane sugar.—Ed.]

Experimental Wintering.—I am trying to winter my bees by three different methods in order that I may solve the winter problem; 33 are packed in chaff, which are wintering finely, and they have had several good flights; two I placed in the cellar on Nov. 22, and are doing well; 58 are buried in the ground. I shall be unable to ascertain their condition until I take them out. Should you want to know the result of the three different methods, I will inform you by the 1st of May. Many are anxious about the burying process, and are coming several miles when I take them out. I think of sowing an acre of mammoth mignonette, together with sweet clover. I like the present form of the BEE JOURNAL much better than last year. I value it more and more every day. G. H. ADAMS.

North Nassau, N. Y.

[By all means, give the public the result or your experiments, and the conclusions you arrive at.—Ed.]

Bees in Kansas.—Bees have wintered finely in this region. I know only of three colonies having perished during the past winter, and they were weak and died from starvation. A little care would have saved them.

J. W. MARGRAVE.

Hiawatha, Kan., March 14, 1882.

Lost One out of Fifty-three.—Bees have come through the winter well, so far. I have lost 1 out of 53, but the bees went up into the upper story and starved on empty combs during the first cold spell. JOHN F. FRY.

Ronceverte, W. Va., March 16, 1882.

Clipping Queen's Wing.—Is it a good plan to clip the queen's wing to prevent the bees going off; and if clipped, how far from the hive will they go generally, when the hive is close to the ground, and where would the bees cluster? Would they find her on the ground or return to the hive? I put my bees in the cellar on Nov. 11, the temperature of which has been very regular at 42° since, with one thickness of cotton over the frames and no cover on, and they have had no flight except 1 colony that became uneasy. I gave those a flight in the shop, as I could not do so out-of-doors. I found them very strong with plenty of honey, and brood, in all stages on 4 combs, and about 2 quarts of bees behind the division board. I gave them more room, and returned them to the cellar. I intend letting the balance alone, unless they get uneasy. Is that a good or bad record?

WM. A. PEARSON.

Lacolle, Queb., March 6, 1882.

[If you cannot give your bees constant attention, it is a good plan to clip the queen's wing, then when the bees swarm out she will get but a few feet from the hive when the bees, discovering her helplessness will some of them cluster on her on the ground, while the others will mostly return to the hive from whence they emerged; some may go into other hives. Should you find her on the ground, destroy the queen cells in the hive and return her. Your record is good, but with so much breeding going on they will soon get uneasy, and be better out-of-doors.—ED.]

A Reversible Frame.—I am using a simple invention by which any square frame can be reversed, or either side turned up or down in an instant, also any other frame having square corners, such as the Langstroth, can be reversed immediately. This is of great advantage where bees are inclined to store honey along the top bar. I would like to hear from you and others on this point. My bees are in excellent condition. One colony has about 8 or 10 square inches of drone brood capped over, and five frames of brood mostly capped. I fear the present "cold snap" may destroy some of the brood. I, like Mr. Alley, am glad to see the "dollar" queen question brought up. From my experience I am satisfied that it will not pay to rear queens for \$1, nor to "warrant" a queen for \$1.50. Although I think your classing warranted queens with untested as equally worthless, is hardly fair; at least the warrant I give them, for they should be not only warranted to be pure, but prolific and good queens in every respect, but they cannot be reared for less than \$2. I hope this question will be agitated until buyers will see that it is to their interest to pay a reasonable price for a good queen, tested not only for purity but business.

L. C. McFATRIDGE.

Carroll, Ind., March 13, 1882.

Foundation Holder.—I send you a frame ready to put the foundation in, with a frame to hold it. A piece is sawed out of the top-bar, beveled a little; turn that piece the other side up and that brings the two sharp edges together, by looking at the end of the top bar you can see; I have left one end piece off so that you can see how it will take hold of the foundation. I have tacked the frame to the board so that it will not rattle around in shipping, loosen the frame from the board by drawing the tacks, then take off the bevel piece; lay on the foundation, put the bevel piece on the top of the foundation; crowd the piece down sufficiently to hold the foundation; put in two or three tacks and then you have it fast, and if you ever want to cut the old comb out and put in new, take off this piece, put in your foundation and tack it back, and it is all right. It is but little work to make the top bars of the frame like this, for every one keeping bees has, or ought to have, one of Barnes' foot power saws.

H. W. CONKLIN.

Rockton, Ill.

[The implement is an ingenious contrivance for holding the frame firmly, and the foundation straight, while tacking the strip to the top-bar to hold the foundation.—ED.]

How I Bind the Bee Journal.—Having adopted a cheap plan of binding the BEE JOURNAL, I will give its readers the benefit of it. I take it for granted that every subscriber is keeping all the numbers on file. I use two strips of leather 6 inches long by ½ inch wide, and cut 2 holes in each near the fold at the edge of the paper. I cut holes in the paper and insert in each a shoe lacer; as soon as a number is received it is filed, and at the end of the year they are all bound at a cost of 1 cent. Bee-keepers of Connecticut, let us organize a State Society. I will put my name on the roll.

FRED. OFFINGER.

Stamford, Conn.

What a Contrast.—Last spring we were all lamenting for the dead bees, ready to exclaim, put me in the list of "blasted hoppers." This spring we are all rejoicing, thinking, when we send in our report next fall, it will be a "whopper." Judging from the present condition of my bees, they will swarm early in April. What a contrast from last spring! When I put my bees into winter quarters on Nov. 10, I weighed each of the 50 hives, the total weight being 3,100 lbs., making an average of 62 lbs. each. On March 1st I weighed them again, the figures being 2,750 lbs., making an average of 55 lbs. each, the average consumption being but 7 lbs. per colony. Who would have thought a hive of bees could have lived 110 days on 7 lbs. of honey? Hardly an ounce per day; and all are on summer stands at that. Who wouldn't be a bee-man? I wouldn't give my bees and fancy poultry for a little gold mine.

J. F. KIGHT.

Poseyville, Ind., March 13, 1882.

Profits for One Year.—For several years I have run a farm and apiary together. Last year I had my farm worked on shares, and gave my time and attention to the bees with the following result: Commenced the season of 1881 with 72 colonies; increased by natural swarming to 120; have sold 7,422 lbs. of comb and 749 lbs. of extracted honey, for which I received \$995.06; my expenses were \$118.70, which leaves \$876.36 for my work. I had empty hives and honey racks left from 1880. I would advise those who think of sowing sweet clover for hay to try a little at first, as it makes pretty coarse hay; but is one of the best of honey plants. There are two kinds—white and yellow blossom; the white yields very white honey.

W. S. WARD.

Fuller's Station, N. Y.

[The white sweet clover (*Melilotus alba*) is what is wanted by bee-keepers. The yellow blooms 2 to 3 weeks earlier than the white, but we have never seen a bee working on it, either for honey or pollen. However, we had but a few stalks of it on trial, and, of course, this was not a satisfactory proof, as bees will frequently neglect a few stalks of even the best honey plant, to work on more profuse bloom of some other and not so good a kind. We destroyed the yellow-flowered sweet clover before it went to seed.—ED.]

The Winter in Nebraska.—After celebrating Christmas, while "on the wing," my bees were confined by colder weather till Feb. 2, when the thermometer went up to 54° Fahr. in the shade, and my bees had a good flight again. Since then they were out on the following days: Feb. 3, thermometer 60° F. in the shade; Feb. 5, 64°; Feb. 6, 74°; Feb. 9, 57°; Feb. 10, 62°; Feb. 11, 60°; Feb. 15, 70°; Feb. 25, 60°; Feb. 26, 60°. The lowest dip we had Feb. 18 and 19, when the thermometer stood at sunrise at 2° below zero, and on the 20th and 21st we had a snowfall of about 12 inches on the level, with thermometer 2° F. below zero. So far my bees are in a good condition, and fly but little even on very nice days, although they are strong and healthy.

WM. STOLLEY.

Grand Island, Neb. 28, 1882.

Doing Well.—Our bees are doing well; they gathered pollen on March 3d from soft maple. I will try and give you my report next fall. I have 7 colonies, increased from 2 last year, and intend to work one for honey to see what they can do with my help, and the rest I shall run for increase.

MORRIS ROSSITER.

Sunbury, Pa.

Bees Feeding on Pudding and Molasses.—I wish to say to Mr. Heddon that I think his experiment proves that bees will not winter well on

RATES FOR ADVERTISING.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space.

Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements for the Weekly as follows, if paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 ".....	20 " " " " " "
" 13 " (3 months).....	30 " " " " " "
" 26 " (6 months).....	40 " " " " " "
" 39 " (9 months).....	50 " " " " " "
" 52 " (1 year).....	60 " " " " " "

Discount, for 1 year, in the Monthly alone, 25 per cent., 6 months, 10 per cent.

Discount, for 1 year, in the Semi-Monthly alone, 40 per cent., 6 months, 20 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

Transient Advertisements payable in advance. —Yearly Contracts payable quarterly, in advance.

THOMAS G. NEWMAN,

974 West Madison Street., Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the *best* advertising medium, but the lowest rates on yearly contracts.

The **Apiary Register** devotes 2 pages to each colony, ruled and printed, and is so arranged that a single glance will give a complete history of the colony.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

To Promote a Vigorous Growth of the hair, use Parker's Hair Balsam. It restores the youthful color to gray hair, removes dandruff, and cures itching of the scalp. 11w5t

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

Honey as Food and Medicine.

We have just issued a new edition of our pamphlet bearing the above title. It has been revised and enlarged from 24 pages to 32, the new pages being devoted to *new* Recipes for Honey Medicines, as well as all kinds of cooking in which honey is used.

It is undeniable that *pure honey* is the simplest, the healthiest, the most natural, and the most strengthening article of food for healthy persons, as well as the best remedy for the sick; and for the convalescent it is the true balsam of life, to restore them to their wonted strength and health.

What is needed is to educate the community up to this idea, and in no way can that be done so well as by directing their attention to the merits of honey.

This little pamphlet should be scattered by thousands all over the country, by honey producers. In this way it will create a home market in almost any locality.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

When 100 or more copies are wanted, they will be sent by express, at the expense of the purchaser.

When changing a postoffice address, mention the *old* as well as the new address.

A Sample Copy of the Weekly BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

It is a fact that horse dealers are buying horses with ringbones and spavins, because they can make money by using Kendall's Spavin Cure. 9w5t

"How do You Manage," said a lady to her friend, "to appear so happy all the time?" "I always have Parker's Ginger Tonic handy," was the reply, "and thus keep myself and family in good health. When I am well I always feel good natured." See other column. 11w5t

New Price Lists.—We have received new Apian Catalogues and Price Lists from the following:

- J. W. Calder, Williamstown, Ont.
- O. Foster, Mt. Vernon, Iowa.
- E. L. Briggs, Wilton, Iowa.

Also the Gardener's Guide by Parker & Gannett, 49 North Market street, Boston, Mass.—an excellent seed catalogue.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

Sweet Clover Seed Wanted.

I wish to purchase several bushels of Sweet Clover (*Melilotus alba*) Seed. Address, stating quantity and price, **A. H. NEWMAN,** 12wtf 972 W. Madison Street, Chicago, Ill.

FOR SALE—Any number of colonies of choice Italian and Cyprian Bees, in 10 frame standard Langstroth hives. Also, Hives, Sections, and choice bred Queens in their season, at popular prices. Will sell the entire Apiary of 200 colonies, and everything to run them the coming season, at a bargain. Also, wanted, an active man to work at the bee business 7 or 12 months. Correspondence solicited. Address, **T. S. ROYS,** Columbus, Wis. 12wtf

Basswood, or Linden, Trees.

One foot and under \$2 per 100, by mail \$3; 2, 4, 6, 8 and 10 feet high for 4, 6, 8, 10 and 12 cents apiece respectively. Special rates by the hundred or thousand. **GEO. E. HILTON,** 12wtf Fremont Center, Newaygo Co., Mich.

WANTED—A man to work on farm, in apiary and supply shop, with chance to learn the business. Must be industrious, temperate, and well recommended. Address, stating wages, 12wtf **C. A. GRAVES,** Birmingham, O.

BEE SWAX.

I wish to buy a quantity of good yellow Beeswax. I am paying 22c. per pound, delivered here, Cash on arrival. Shipments solicited.

ALFRED H. NEWMAN, 972 West Madison Street, CHICAGO, ILL

OLDEST BEE PAPER

ESTABLISHED
IN 1861

BEE JOURNAL

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., March 29, 1882.

No. 13.

Published every Wednesday by

THOMAS C. NEWMAN,
EDITOR AND PROPRIETOR.

974 WEST MADISON ST., CHICAGO, ILL.
At \$2.00 a Year, in Advance.

Remit by money-order, registered letter, express or bank draft on Chicago or New York, payable to our order. Such only are at our risk. Checks on local banks cost us 25 cents for collecting.

Free of postage in the United States or Canada.
Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

Glucose as a Patent Monopoly.

In the *Farmer's Review*, for last Saturday, we find the following item:

"Another monopoly has arisen under the fostering care of our patent laws. This time a monopoly is an adulterant. The "National Confectionery Company" claims patents on the use of glucose in candies, and demand payment of royalties on all the glucose used by the confectioners in the past, amounting to \$10,000,000 or more, and a royalty of 1/4 cent a pound for the future. This will be rough on the candy men and dishonest sugar "refiners," but the public will perhaps be benefited, as the confectioners say they will not use the glucose under such conditions."

We sincerely hope that the result may be as stated by the *Review*—the abandonment of the use of that abominable trash in candies. It is indeed painful to see millions of children eating that death-dealing humbug—glucose—under the guise of candy.

It is steadily being driven out of use, and we are glad to see that one by one, the manufacturers, who use it as an adulterant, are dropping it. No matter what may be the cause, so long as it is done.

It has been used by the makers of printers' rollers, but as its use destroys the elasticity of the rollers so soon—they are dropping it!

It has been used extensively in feeding bees; but the death of large numbers during the winter of 1880-1, and the physical degeneration of bees and consequent losses in spring, are too much for the "bee-keepers" to endure, and they are dropping it!

The candy manufacturers have used it so extensively as to cause a

protest to come from physicians against its use—but as the children are tempted to obtain the vile trash, and have not sufficient judgment or knowledge to control their appetites, let us hope that the "Company" above alluded to, may, in their avariciousness, remedy this evil.

Thousands of thousands are rapidly going down to the grave, who might have been spared many years to their friends and their country but for the use of this monster adulterant.

It is a great moloch, but it must fall—let us "work and pray" for its complete destruction.

Wired Foundation.—We have received from Mr. J. H. Martin, Hartford, N. Y., samples of his foundation. One is showing his method of shipping wired foundation in little rims weighing about half an ounce. These are to be fastened into the regular frames, and will save the trouble of wiring the frames for those who desire to use the wired foundation. The other is a sample of thin foundation for surplus honey, the bases of the cells being lozenge-shaped, and all equally thin. The samples are very nice.

New Price Lists.—We have received new Aparian Catalogues and Price Lists from the following:

H. H. Brown, Light Street, Pa.
J. M. C. Taylor, Lewistown, Md.
J. B. Bray, Lynnville, Tenn.
J. H. Martin, Hartford, N. Y.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

Articles for publication must be written on a separate piece of paper from items of business.

Mr. G. M. Doolittle is recovering from his sickness, but Mrs. D. is now prostrated by the same disease. We hope both may soon recover.

Increase by Division.

Mr. D. D. Marsh, of Massachusetts, in January last propounded some inquiries, which we give below, regarding feeding and division, the answer to which we have withheld till the present time, in order to give them seasonable insertion and save repetition, as they will possess more or less interest for all who have had but little experience in this line.

1. Will it do to feed during April and May, for stimulative breeding, brown sugar, such as is found in the bottom of molasses barrels? I can buy this of grocers for 3 and 4 cents per lb.

2. Will you give in detail the best method of artificial swarming, on the nucleus plan, for one who has 10 colonies in Langstroth hives, and wishes to make about 8 new ones with the least interference with the crop of section and extracted honey?

3. How to get queen cells?

4. When to make up the nuclei—before or after the sections are put on?

5. Whether section racks are to be lifted from time to time to get frames of bees and brood?

1. Yes, if it be pure molasses. For stimulative and breeding purposes it should be dissolved and thinned with warm water, and fed only as fast as consumed.

2. This is perhaps one of the most interesting features in the management of an apiary. All operations will be governed somewhat by the number of colonies to be manipulated, and the amount of increase desired; it should also be borne in mind that, although the amount of increase possible is almost unlimited, all excessive increase will be at the expense of the surplus honey yield. In order to be better understood, we will suppose the apiarist has 4 good colonies which he wishes to increase to 9. As a progressive bee-keeper, he will be actuated by a desire to possess the best; therefore, the colony which has heretofore proven the most satisfactory in all things, will be selected as the one from which to rear queens for new colonies. This colony, for convenience in summarizing, we will designate No. 1. As soon as spring opens, feed No. 1 about half a pint of thin cane-sugar syrup or honey diluted with warm water. This had better be fed at the entrance in the evening, to avoid robbing, and be given slightly warmed. Keep this up till there is capped drone brood in some of the combs, or better still, till you have drones emerging from the cells. Now

move one of the other colonies from its stand (which we will designate No. 2); place No. 2 on a new stand, put a new or empty hive on the stand vacated; lift the frame from No. 1 on which you find the queen and place in the empty hive (No. 3); place a frame of foundation in No. 1 and close the hive. From No. 2, and each of the two hives not numbered lift 2 frames of brood well advanced, shake off the old bees, and place in No. 3, with the queen lately placed there. These last frames put in should be alternated as much as possible, so as to confuse the working bees from No. 2, which will naturally return to the old stand and enter No. 3. Fill up the latter hive with frames of foundation, alternated with the brood combs, to its full complement. If a 10-frame hive, this will give it 7 frames of brood, 3 frames of foundation, and your best queen. If you have bright, clean, empty combs, they will answer about as well as foundation, though we prefer the best foundation. Put in foundation or combs to supply the places of those taken from the other hives, close them, and your first division is completed, making 6 colonies.

In ten to twelve days, examine carefully the combs in No. 1, to see how many good queen cells you have capped over. Close the hive carefully, and let it remain 24 to 36 hours. As soon as you have determined the number of cells, remove each of the 4 colonies which have queens to new stands, and place empty hives where they stood. Take the brood frame from each on which you will find the queen, and place in the empty hive where they were moved from. Add three more brood frames to each, place two frames of foundation or empty combs in the center of these, put a division-board on the outside of the combs, and close the hives. The hives from which these were taken will each be left with six brood frames; to these add two empty combs or sheets of foundation, put in division-boards at the outsides, and close for 24 or 36 hours. You now have 4 new colonies with queens, 4 without queens, and 1 with queen cells.

At the end of 24 hours you will find queen cells started, or preparations to start them, in the 4 queenless colonies. With a sharp, narrow-bladed knife circle out 4 of the best queen cells from No. 1, leaving a good one; cut a

round hole, about $1\frac{1}{2}$ inches in diameter, from the center of a brood frame in each of the queenless colonies, and slip in a queen cell. These should fit pretty tightly, so they will not drop out. Great care must be observed not to bruise any of them, and they must not be cut so close to the cell as to run a chance of injuring the young queen yet in the cell. In a few days these young queens will be hatched, mated and laying, and you now have 9 colonies. As fast as the foundation in these colonies is drawn out, the combs can be spread and new foundation or combs added, until the full complement are in the hive.

You will now have 9 colonies from the four in early spring, and by close attention in supplying good foundation as fast as they are prepared to receive it, with a good white clover and basswood yield, or a few acres of sweet clover pasture, you may expect a fine surplus yield of extracted honey.

With 10 strong colonies to start in with, the strongest and best should be removed from its stand, and an empty hive be put in its place; now select a comb from the colony with only fresh eggs and place in the empty hive on the old stand; put in two combs of honey from some other colony, and an empty comb or sheet of foundation on each side, now confine all to the center with division boards, and shake the bees from the combs in front of the new hive. Twenty-four hours before the queen cells are ripe enough to cut out, form a three-frame nucleus from each full colony, and after they have started queen cells, destroy them, and graft in your ripe cells. In all cases, supply foundation or empty combs in place of those taken from the colonies, and add others to the nuclei as fast as needed.

3. This is answered in the last paragraph.

4. Make your division during fruit bloom, or as soon thereafter as weather is favorable.

5. No need to lift section racks, as division and increase will be completed before white clover or basswood come into bloom.

☞ We have received several more complaints and samples of the sections sent out by that Doon, Canada, supply dealer. Mr. Mason reports, however, that he has made satisfactory amends to him. Let us hope that he may do so with all, and thus save further complaints and annoyance.

Cheap Queens Again.

Since our editorial comments regarding cheap queens, in the BEE JOURNAL for March 5th, we have received the following letters relating thereto, which we publish entire, omitting the names of the writers, to prevent any personal controversy, only desiring the arguments:

DEAR SIR.—The BEE JOURNAL for March 8 contains an editorial on "The Cheap Queen Traffic," in which you make some astonishing assertions for an editor who has no axe to grind. So far, I have passed all the articles and comments on this "dollar queen" question, unnoticed; but when I see that the editor of the AMERICAN BEE JOURNAL is inclined to denounce us (untested queen breeders) as frauds, and selling worthless trash at the expense of those purchasing, and at an actual damage to the bee-keeping interest, I cannot help but defend myself at least. Taking your editorial in the whole, the above is what you seem to impress upon your readers.

Now, sir, will you please give us the name of the "breeder, who has had more experience with cheap priced queens than any other in America, or the world, and has probably reared and sold nearly as many as all the others combined, etc.," and why, if his opinion is, that not one queen out of ten sent out, is worth a cent, did he rear and sell as many of them as all of the queen breeders combined? I think you should also give the name of that honest Michigan breeder (in justice to him) who quit after he found out that he was defrauding his innocent purchasers.

I do not think it is necessary for me to argue this point, for I know I could not convince you and those whose motives are prompted by self interest or prejudice; the only point I wish to arrive at, is to try to prevent your readers to labor under the impression that I, as a breeder of untested queens, sell worthless trash and that I am defrauding those who deal with me, and the only way is to ask every one who has purchased queens from me in 1881, to drop you a postal card and state what kind of a queen they received from me, and if 10 per cent. report worthless trash, I will pay you \$100 for the benefit of any institution—or, if you prefer, I will send you a list of all and you can drop each a postal card and I will pay you the cost and trouble. I have reared nearly 1,200 queens in 1881.

I claim to sell no queen that I would not have for myself and this has been my invariable rule. It is no more trouble to rear good queens than it is to rear poor ones, when you understand or know how to do it, etc.

I know it is more expensive to rear queens in the North, as you cannot winter nuclei, but here, mine (which are all 4 or 5 frames) remain on their summer stands all the winter, and come out in the spring ready for business.

If queens cannot be reared at \$1, from a selected mother, at a profit, can the advocates of tested queens tell us how they can rear queens fully tested at \$2, and make it pay?

I will conclude in saying that you may fight this "dollar queen" business with legal arms, but don't make your readers believe that all such breeders are selling worthless trash, etc., by citing two or three breeders' experience, though one of them has reared and sold as many queens as all the breeders of America combined!

MR. EDITOR:—Concerning your editorial on "The Cheap Queen Traffic," I would like to inquire if the quotations which you make from experienced breeders that "not one queen out of ten sent out is worth one cent," and "such were not usually worth 25 cents a dozen," refer to queens sent out by queen breeders in general, or to what is usually understood by dollar queens, viz: Queens which are the daughters of imported, or very choice mothers, and which have just begun to lay.

If they refer to the former, I cannot see how the buyer will be helped by being compelled to pay a greater price for his queens, for the breeder who will send out superannuated and worthless queens for a dollar, will certainly not scruple to send out the same for a higher price. If, on the other hand, they refer to the dollar queen as usually understood, and they are founded in fact, we are confronted by a very serious hindrance to progress in bee culture. For, if not one in ten is worth a cent, the question occurs: How many would have to be raised, tested, and destroyed, before one could be found which was really valuable, and if the rearing of such queens at a dollar each is found by experienced breeders to be unremunerative, the price of a really good queen would leave the majority of bee-keepers no choice but to do without them altogether?

I have no personal acquaintance with any queen breeder, but I believe there are many who are too conscientious to continue in a business which is such a fraud on innocent customers as the above quotations would seem to indicate.

We certainly do not want to buy queens at a dollar each, with the prospect of finding only one in fifteen or twenty that is worth her price, but if we pay three or four dollars for a queen, we want some assurance that the queen which we buy will be worth the money.

In reply to Mr. Alley's article on page 151 of the BEE JOURNAL, permit me to say that while I am willing to admit most, if not all he says about "dollar" queens; it seems to me he has made a most ludicrous blunder in winding up his article. He says: "Let all the leading queen breeders combine, and resolve not to sell queens less than \$2 each, and not sell any that are not thoroughly tested; then, if bee-keepers want a cheap article, let them purchase of those who have

not had much experience at the business."

It appears to me, from the above sentence, that Mr. Alley is endeavoring to establish a monopoly in the queen rearing business, rather than to make it more profitable to both breeder and purchaser.

It is evident that any apiarist of ordinary skill can produce untested queens, at the rate of one every 15 days, for each nucleus or colony, and many claim to do better than this. Every apiarist knows that it takes from 22 to 25 days to test a queen for prolificness and the color of her progeny; and to test the qualities of her bees will take at least 25 days more, and then, it must be at a time when honey is coming in freely. Now, it looks strange to me that there can be more profit from selling queens at \$2 each, when it takes from 65 to 70 days to rear and test them, than to sell at \$1 each, and produce them in 15 or 20 days. It surely does not require 20 years, nor 10 years, and I hardly see the necessity of its taking 5 years, to learn to breed bees; and I cannot see the consistency in Mr. Alley's making such a thrust at beginners, as appears in the above sentence.

I will offer a suggestion: Let every breeder (whether he be a leading one or not) who wishes to do an honorable business, test thoroughly, the qualities of the worker progeny of every queen he may wish to breed from, then breed from such only as are valuable. Then test the young queens for size, activity and prolificness, and their progeny for activity and uniformity of size and color, whether they are black, brown, or yellow, and then sell at a living price to the breeder, and I feel confident that the purchaser will not be defrauded.

We have long held to the opinion that "the best is the cheapest" with queens, as with everything that is worth a price, and have always been outspoken in our condemnation of the cheap queen traffic. We have not felt the necessity for condemning the breeders of such "as frauds," and we have not insinuated anything of the kind, because we know there are honorable men engaged in breeding and selling them, as also honorable men who have dropped the business from honest convictions, having been convinced that the whole thing was wrong. Nor do we feel called upon to give their names, and subject them to criticism for having obeyed the dictates of an honest conscience, preferring rather to let time prove them and ourselves correct. There may be, and probably are, unscrupulous men engaged in breeding and selling worthless queens for tested, but this establishes no point except as to their unfair dealing. When convinced that no better queens can be purchased for

a remunerative and fair price than can be bought for one dollar, we shall cease advising our readers to buy only the best, and only from the most discriminating and careful breeders. If the majority of the "dollar" queens are not as good as the majority of the high-priced tested ones, then they are not so cheap.

We think we were not extravagant in our estimate of the number of cheap queens bred and sold by Mr. Henry Alley, during the 20 years of his experience, as compared with others engaged, and certainly if, in that length of time, he could not determine the value of such queens, and the profit derived from the breeding of them, no one is competent to do so.

Our honest convictions remain, that the cheap queen traffic has been a detriment to the development and permanence of the better strain of bees, and will yet prove a curse to apiculture in America. To the future we leave the question for settlement, with every confidence that time will sustain us in our position, and the bee-keepers of the future will repair the errors of the past and present, and recover the vantage loss by a mistaken economy. Meantime, we drop the question for the present, with the injunction to *buy and breed only the best.*

Bees will be in lively demand this spring. We have hundreds of calls for copies of the BEE JOURNAL every week from beginners and those who intend to enter the ranks of bee-keepers. They want to read the advertisements and ascertain where to buy bees. Those who have any thing for sale should now be on the alert, and get their advertisements before the public. Not a week should be lost now, for the time is at hand to do business. "A word to the wise is sufficient."

By all means, bee-keepers should provide for the future by planting honey producing trees. One of the best is the basswood. Do not let a spring pass without doing something in the line of providing for the future in this way.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

New Jersey and Eastern Convention.

The bee-keepers of New Jersey and vicinity met at New Brunswick, N. J., on Wednesday, March 15, to organize a society.

The meeting was called to order at 10:15 a. m. by Mr. G. W. Thompson, of Stelton, who was subsequently elected temporary chairman. He stated the object of the gathering, and enumerated the interests involved which had brought forth such a step.

Mr. King, of New York, thought that a name for the new association should be adopted first.

H. M. Cook, with this end in view, moved that a committee of five be appointed to draw up articles embodying a constitution and suggest a name for the association.

The motion was adopted unanimously, and the following were appointed such committee: Messrs. Hasbrouck, Rue, King, Harmeling and Read.

While the committee were at work Mr. Thompson spoke at length on the subject of bee-keeping. There was an unlimited demand for pure products of the farm, especially honey, and those who were engaged in farming should organize and thus protect themselves against adulterations and spurious farm food.

Prof. Kroeh, of Hoboken, said that it had been a disadvantage to the majority of bee-keepers that they had not been in harmony and consultation with each other in regard to their products, thus losing in the money value of marketable food. Such an organization was eminently proper in his mind, and each bee-keeper should

exert himself in keeping alive the interest thus far manifested in the premises.

Prof. Hasbrouck was elected as temporary Secretary, who read the constitution and by-laws suggested by the committee appointed for that purpose, which were adopted. Adjourned.

In the afternoon, the New Jersey and Eastern Bee-keepers' Association met and unanimously elected the following as its first officers:

President, G. W. Thompson; Vice President, Ira Yeager; Secretary, Prof. J. Hasbrouck; Treasurer, Prof. C. F. Kroeh.

The following gentlemen were elected as the executive committee: T. F. Reed, Brooklyn, N. Y., three years; J. H. M. Cook, Caldwell, N. J., two years; C. H. Rue, Manalapan, N. J., one year.

Mr. Cook stated that each member should bring in a report at the next meeting, showing the condition of his bees and the net value of the honey harvested.

Prof. Kroeh moved a vote of thanks be extended to Mr. King, of New York, for the liberal donation which he had made to the Association of the proceeds of the sale of his Magazine to the members, turning the money into the treasury of the Association.

Mr. King acknowledged the action and stated that he would in addition give each lady who should join the Association a receipt for one year's subscription to his bee Magazine. This brought forth a round of applause from the members.

The gentleman referred to last, suggested that Secretary Hasbrouck keep up a correspondence with the various bee-keepers' associations throughout the country for the benefit of this organization. This suggestion met with approval, but the Secretary was not instructed to do so.

Mr. Tompkins, of Newark, stated that although a honey consumer he was not a bee-keeper, but he could not do without the pure article in his home.

Mr. King said that it would be eminently proper for this Association to offer premiums to its members for the best honey during the coming season, said honey to be put up in good and substantial manner and form. This gentleman also said that the ordinary syrups were manufactured with sulphuric acid and more than one-half glucose, which were injurious to children. Extracted honey ought to take the place of these poisons.

Mr. Cook suggested that the Association take some decided step in regard to the protection of the members from adulterations of syrups.

Mr. G. W. Thompson favored such a step but cautioned moderation in the premises.

A number of the members spoke on the subject of adulterations. One said that recently a man was found by him peddling adulterated honey from door to door. He was told to get out of the place at once or he would be prosecuted. The member submitted that adulterations were practiced to an alarming extent in this State.

Prof. Hasbrouck said that most of the adulterations in honey were put up in small bottles and tumblers, but that no successful adulteration had been found in comb honey.

The next meeting of the Association will be held in New Brunswick, at the same place, in November next.

Prof. Kroeh thought that all the members should co-operate in furthering the objects of the association, by communicating with each other and preparing notes as to bee-culture, etc. Association adjourned.

Marshall County, Iowa, Convention.

The Marshall County Bee-Keepers' Association met at the court house in Marshalltown, March 4, at 1 p. m. G. W. Keeler acted as president.

The Secretary read a short minute, stating the cause of the failure of the previous meetings. The society had an interesting talk on the subject of bee culture, which all felt beneficial. Mr. Samuel Richey joined the society.

The subject of meeting quarterly, instead of monthly, was deferred until the next meeting; also the election of officers.

The subject for discussion at the next meeting, is "care of bees in the spring, and how to manage them to secure the most honey."

Adjourned to meet on Saturday, April 1st, at 1 p. m., at the same place.

All interested in the "busy bee" in Marshall and adjoining counties, are respectively invited to attend.

G. W. KEELER, *Pres., pro tem.*
J. W. SANDERS, *Sec.*

A special meeting of the Western Michigan Bee-Keepers' Association, will be held in Supervisors' Hall, Grand Rapids, Mich., Wednesday and Thursday, April 26 and 27, 1882.

WM. M. S. DODGE, *Sec.*

The spring meeting of the Northern Ohio Bee-Keepers' Association will be held at Norwalk, O., on Saturday, April 15, 1882.

S. F. NEWMAN, *Sec.*

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.

G. W. DEMAREE, *Sec.*

Christiansburg, Ky.

The Central Michigan Bee-Keepers' Association will meet April 20, at Lansing, in the Capitol building. Programme.—President's annual address, Rev. J. Ashworth; bee hives and fixtures, E. W. Wood; Cyprian bees, J. Harper; the coming bee, Prof. A. J. Cook; care of old combs, Stephen C. Perry.

REV. J. ASHWORTH, *Pres.*

The Barren County Bee-Keepers' Association meets at Sinking Spring school house, three miles west in Glasgow, Ky., on the first Saturday of April, 1882. All bee-keepers of the county are invited.

I. N. GREER, *President.*

The semi-annual meeting of the Tuscarawas and Muskingum Valley Bee-Keepers' Convention, will be held in the Town Hall at Coshocton, O., on April 19 and 20, commencing at 10 a. m. A cordial invitation is extended to bee-keepers everywhere.

J. A. BUCKLEW, *Sec.*, Clarks, O.

The spring meeting of the Mahoning Valley Bee-Keepers' Association, will be held at Berlin Center, Mahoning Co., Ohio, in the Town Hall, on Saturday, March 25, at 1 p. m., sharp. All interested in the science of apiculture are invited to be present and participate in the discussions of the day. The following questions will be discussed: "The merits of the different races of bees." "The best method of securing surplus honey." "Which is most profitable to the bee-keeper, comb or extracted honey?" "An essay on pasturage or forage for bees will be given.

LEONIDAS CARSON, *Pres.*

The Champlain Valley Bee-Keepers' Association will hold their semi-annual meeting at Middlebury, Vt., May 11, 1882.

T. BROOKINS, *Sec.*

The Texas State Bee-Keepers' Convention will hold its meeting at Judge W. H. Andrews' Apiary, at McKinney, Texas, April 25, 1882.

WM. R. HOWARD, *Sec.*

MISCELLANEOUS.

Glucose Adulteration and Congress.

—The *Western Rural* remarks as follows on this subject:

Food adulterations have attracted the attention of Congress this winter to a commendable degree, and there are good grounds for hope that the honest producer will yet find protection from a ruinous competition, and that the consumer will have some guaranty that what he eats is pure.

The business of adulterating food-products is without a single exception the most villainous that men have ever engaged in. It not only robs the producer, but as a general thing, it destroys health and life, and does it under such false pretenses that the victim is unaware of his danger. Yet such enterprises have gained such headway during the last few years that millions of money are invested in them, and every attempt to remedy the evil is met by that peculiar sort of influence which is common with men who are engaged in disreputable practices.

The efforts in Congress this winter have been opposed by large, wealthy and influential delegations, who have probably left nothing undone to defeat the enactment of laws which shall at least compel the manufacturers of

adulterations to inform the purchaser of their character before he purchases them.

The Western delegation of glucose manufacturers represented to the ways and means committee last week that the principal opposition to glucose manufacture, comes from the sugar refiners, that it was a growing Western industry, which furnished a market for the products of the country, and that consequently it ought to be encouraged.

The first statement is absolutely false. Glucose finds an opponent in every cane grower in the country, and cane growing in a country that is compelled to import its sweets, is a vastly more important industry than glucose ever was or ever will be.

It also finds an opponent in every consumer who knows that he cannot purchase one gallon of pure syrup, either cane or maple, and that it is with the utmost difficulty that he can obtain a pound of pure maple sugar.

It also finds an opponent in every farmer who knows that he is compelled to purchase adulterated sweets and who realizes that by filling the markets with adulterations, he encourages dishonesty in all departments of production, and thus endangers his profits upon nearly everything he grows.

If glucose has friends, they are only among those who are interested in the profits of its manufacture, or who do not know what it is or what the tendencies of the business are.

Passing over the fact that in the manufacture of the stuff sulphuric acid is used, and that the product contains this poison in large quantities, it is a fraud because it does not contain near the amount of saccharine matter that cane sugar or syrup does. Even if the purchaser gets it for a few cents less than he would have to pay for sugar—which is not often the case—he is cheated because what he buys is largely destitute of sweetness.

The Prospect, in California, for Honey.—The *Prairie Farmer* of last week contains the following:

California bee-keepers are jubilant over the prospects for a profitable honey season. Colonies have wintered well and are strong and healthy. One thing there the bee-keepers begin to dread, and that is the "Heathen Chinese." Says a correspondent of the *California Agriculturist*: "When I find them taking notes, I generally try to be careless, and give them no chance to get any practical information. I understand that some bee men have Chinamen to assist them at their work. This I think a very bad arrangement. Chinamen are quite fond of sweets. Honey is too high-priced to meet their idea of prices. If they should acquire the system of bee culture, our occupation would be at once gone. That they could learn to do as they see others do is an established fact, and the honey business is no more difficult for them to master than any other, with their dogged perseverance and cheap industry. My hope is that they may never get the entering wedge."

Producing Comb Honey—No. 3.

G. M. DOOLITTLE.

In my last I stated how I built up weak colonies, and left off where all colonies were ready to receive the boxes, so the next thing is getting the boxes ready and putting them on. The getting ready part I generally work at by odd spells, during the winter and early spring, so as to have all in readiness when they are wanted; but as this is the time they are wanted, I will give the way I prefer them, and advise that none wait about this getting ready part till just as the boxes are wanted, because I gave my mode of doing so at the time the bees were ready to receive them. During the leisure hours of winter and early spring is the time to have all in readiness, and they who are not thus ready are often the losers of a good portion of the honey which might be secured.

But about boxes; what size shall we use? As my mind goes back over the past, I remember the boxes my father used, made of rough $\frac{3}{8}$ -inch lumber, of a capacity to hold 15 lbs., and large enough to cover the whole top of the hive, being perhaps 6 or 7 inches deep. This honey was generally taken to our village in the box, and there turned bottom side up to expose the tempting sweet, encased in the nice, white combs, and I well recollect with what pride father would cut out the nice cards of well filled combs, as it was exchanged for the necessities of the family. Later he used two boxes covering the top of the hive, all planed smooth and a glass in one end, which at that time was considered to be all that was required. Then came the Langstroth 6 pound box; then the Alley 3 pound box; next the prize box, holding 2 pounds, and finally, the $4\frac{1}{4} \times 4\frac{1}{4}$, with its 1 pound of honey. I often wonder what father's customers would have thought had he suddenly changed from the large 15 pound box and presented them with honey put up in nice glassed crates, filled with 1 pound sections.

To return, as I have wandered a little in tracing the steps of progress that have been made in boxes and sections, we have to-day two sizes that are generally adopted—the prize box, which is $6\frac{1}{4} \times 5\frac{1}{4} \times 2$ inches outside measure, and the $4\frac{1}{4} \times 4\frac{1}{4} \times 2$, known as the $4\frac{1}{4} \times 4\frac{1}{4}$ section, the one holding about 2 lbs., and the other about 1 lb. The market seems to favor the 1 lb. section, not only as to price, but it sells much more readily, and while the prize section goes begging a market, the $4\frac{1}{4}$ style is all sold and more is called for; therefore it is easy to see which way the future points, as to style of section, but it is not so easy to see how to change all

our equipage, adapted to the prize section, and start with the $4\frac{1}{4}$ style without a loss greater than the compensation gained for the first few years at least.

One of our largest comb honey producers writes me, "it is evident that the 1 lb. section finds a much more ready sale at better prices than larger boxes, still a change of style as regards sections would involve a loss to me of several hundred dollars, therefore I cannot entertain the idea at present." Well, this being the case, shall we stick to these prize boxes or try and see if we cannot find a way out of it, and not cause us any loss whatever. As I prefer the latter plan, I will tell you how I arrange the matter. At the N. E. Bee-Keepers' Convention, in 1880, Mr. Thurber was reported as saying that the box which sold the most readily with them was a box $3\frac{1}{4} \times 5\frac{1}{2}$, holding about $1\frac{1}{2}$ lbs., and that he thought the 1 lb. section was as much too small as the prize section was too large, or words of like import. I have not his exact words before me, but quote from memory. This set me to thinking, and I soon lit upon a box, three of which would fill a case in place of where I used two before, thus giving me a section $6\frac{1}{4} \times 3\frac{1}{2} \times 2$ outside measure. To test them, this last fall I placed them in market by the side of the 1 lb. sections, in Boston, New York, Philadelphia, and other places, where I found they sold quite as readily as did that section, and for full as satisfactory prices. Thus I had gained the desired point without the waste of any of my fixtures. All the sections I make in the near future will be of this size, and as I can soon work out all my prize boxes on hand, I shall have no loss whatever. Those using a three box case can use 1 prize box and 3 of the above style, or make their sections still narrower, so 5 will fill the case, however, I hardly think as much honey can be obtained by the use of these small sections as with larger ones, still the price and readiness of sale will overbalance this part of it.

After deciding on the style of section we will use, they are to be filled with comb foundation, if such is thought to be profitable, and if not, put a starter of nice white comb in the top of each box. I prefer to cut these starters in a triangular shape, about $1\frac{1}{2}$ inches long on each side. Now turn your sections top side down, hold a hot iron close to the box, and after holding the starter immediately above and touching the iron, draw the iron out quickly and press the starter gently on to the wood, when it is a fixture. I then fill the cases with sections, putting sections filled with comb left over from the previous season in the center case, if I have them. If I have enough such to fill two cases, I place the two apart so as to set a case having boxes with only starters in them between. When I have enough to do this, I think I am sure of a good crop of honey if such is attainable from the fields, for these combs are more profitable to an apiarist than cash in the bank. With the brood chamber filled with brood, as I

have shown you it should be, and honey coming in from the fields, these combs are at once occupied, and those sections between and immediately surrounding them, that have starters in, are soon filled with beautiful white comb, and a good yield of comb honey is a certain thing, if the flowers continue to secrete nectar.

Having all prepared and bees all in readiness, the next thing is to put on the boxes. I put on generally but 5 cases at first, and if prepared as above it will be seen that 2 of these contain sections full of comb, which are ready for the bees to commence work in at once. In about a week all are gone over with again, and if those first put on are being worked in, more are added by spreading those apart and 2 more cases are inserted near the center and by placing a tier at one side. The next time I go over them probably some will be ready to come off, and in any event as many sections are now given as can be worked in to advantage by the colony, which generally takes the full capacity of the hive.

My next will be swarming, and how I manage when working for comb honey.

Pollen and Wintering Bees.

E. L. BRIGGS.

We have heard much of late, from certain quarters, concerning "pollen and bacteria," being the causes of dysentery among bees, that if the disease were contagious, I fear we should all have contracted the malady from over doses of pollen, pollen! noon, night, and morning, and by the week, until we are more than willing to dismiss Mr. Heddon, and to put ourselves, and our bees, too, on a low diet of pure honey, and see if we cannot get over the nausea we have so long felt, under the doctor's doctoring. I suggest that he feeds all the rest of his pollen doses to his small, dark, hybrid crosses, of black and Italian "coming bees;" and if it does not kill them in the next six months, then put them upon the market as the toughest bees out; on the principle of the "survival of the fittest."

Somehow our bees, out here, will persist in living through this winter, though their combs are full of pollen, and though they have been breeding quite plentifully ever since the 1st of January. Something else besides pollen and breeding, then, causes dysentery. That something else might be found in Heddon's "brick," made of flour and sugar; fed to the bees dry. This might be impure, or adulterated honey and pollen both. Flour is not genuine pollen.

Late last fall, two or three of my colonies worked freely upon the skins and juice of grapes which were being manipulated for wine by a neighbor. The result was, in the early part of winter, while the bees were consuming this grape juice, they suffered considerable from diarrhea, spotting

the snow in their flights, and many of their bodies were so distended with the foul stuff from issuing from their hives that they were unable to take wing, and consequently perished at the mouth of their hive.

Neither can bees live upon pollen alone; for this is not their natural food. But bees can and do subsist on honey and pollen together. This is their natural and healthful diet, when they can mix it to suit their own taste. If the pollen or honey is fermented or turned sour, then it becomes unnatural, and consequently unhealthy.

Long continued and intensely cold weather, may shut them in to the limits of their brood nest, and after consuming all the honey therein, as a last resort, they try to appease their hunger on pollen, and, of course, being unnatural food, diarrhea results, and the colony perishes. One man says: "Diarrhea resulted from starvation." So it did! Another says: "It resulted from the consumption of pollen." So it did! Another says: "It resulted from long continued cold and dampness." This is true, too! But the "cold and dampness" kept them away from a supply of pure honey; hunger and starvation drove them to pollen as the only resort; this insufficient and unnatural food, produced enormous distension of the abdomen, and diarrhea; and all these causes resulted in death.

The truth in a nutshell is this: Bees in order to winter well, must have access at all times to pure honey, or some substance equally healthy to the bee, as food.

They may have access to impure honey, glucose, grape juice, cider, sorghum juice, West India molasses, or even pollen, or to Heddon's brick, in a good warm cellar, and unless they can fly out often to void their feces they will perish.

Colonies in the same yard will gather some such impure substance in the fall, perhaps many pounds of it, while others will gather none. The former may all die, while the others all do well.

Four frames, three-fourths filled with honey gathered from white clover, linden, or buckwheat, early in the season, put one inch apart into the middle of the hive, with a division board each side, and the vacant space filled with chaff, shavings, or old rags, with holes through the middle of each comb, for the free passage of the bees, will winter any colony safely. Set a box, with a cloth bottom, three inches deep, filled with chaff, on top of the frames, if wintered in the cellar; or, if wintered on their summer stands, surround the whole hive, sides, bottom, top, back, and front, with chaff 4 inches thick; with a fly-hole $\frac{1}{2}$ by 1 inch through the chaff and front part of box, to give them air, and egress, as they may choose, every fair day. If any one wishes to try the experiment, one of these middle frames may be packed full of good fresh pollen, cells covered with honey and sealed over as they usually are; and if the bees do not winter well I will pay all damages. Wintering bees is as simple as wintering stock of any other kind.

1. Keep them comfortably warm and dry.

2. Give them plenty of pure sealed honey, or pure sugar syrup, with plenty of pollen, where they can have access to it at all times. They will mix to suit themselves.

3. Let them remain in entire quietness until warm weather; and they are no more subject to disease than cattle, horses, sheep, or men.

Albino Bees—Why So Called.

S. VALENTINE.

MR. EDITOR: Frequent reference has been made by different parties to the word albino, as an improper name for the bee which is so called. In the *American Bee-Keeper*, for November, 1881, Mr. Taylor says: "If they have no black blood in them, the name albino does not sound well, as I understand it to mean white coming from black." Mr. Harrison, editor of the *American Bee-Keeper*, and others, have advanced such an idea.

What does the word albino mean? Webster says that the term is of Latin origin; that it comes from *albus*, which means white. If you will follow the term, from its origin through all its combinations, you will find that the word *albus* gives its signification to all of its forms. Sometimes, owing to a freak of nature, black parents have had offspring which possessed an unnatural whiteness, such as white negroes; but this peculiarity is not confined to any color or nationality.

White parents are known to have children of this peculiar whiteness, with white skin, hair, and pink eyes. I could give the names of 3 or 4 persons, some male, others female, possessing this peculiar whiteness, commonly called albino. Now why they are so called is evidently because of the whiteness. Refer to the "Encyclopedia Americana," and you will learn that white rabbits and white mice are known to have a similar origin.

I need not dwell longer upon this subject, for any physiologist or scholar knows that while white offspring, coming from black parents, are called albinos, it is not because the term signifies coming from black, but because the word albino signifies a peculiar whiteness. The bees which we call albino are the whitest bees that are known; therefore while they are not perfectly white, albinos is a proper name for them, until one can be found that is yet whiter.

The albino bee is of American origin. Mr. Pike, I believe, was the first to bring them to the public notice. In the spring of 1874, he noticed one of his Italian queens breeding about one-half of her progeny with albino markings. He at once bred them in, and claims that he succeeded.

In July, 1876, I bought an imported queen from Mr. Willman, of Pennsylvania, from which I produced albino bees, as may be seen in an article,

"Origin of the Albino Bees," in the *BEE JOURNAL* for December, 1880, page 557. In June, 1879, I succeeded in breeding them to a high standard of purity, breeding albino markings to every bee, which to-day stands forth as the standard for the albino bee.

Before Mr. Pike called attention to the albino bee, we occasionally heard some one here and there speaking of albino as a term. They applied to some few bees developed in their apiaries, but no especial attention, as far as we can learn, was given to this variety or name, until Mr. Pike brought them more prominently before the public.

Mr. Pike is evidently entitled to the credit of first producing and calling public attention to the albino bee, but I claim that of giving the albino bee first to the public in its purity; i. e., with albino markings. Having accomplished this, Mr. Pike or myself, or both of us, surely have the right to name the bee, as much so as the inventor has to name his invention, or the parent to name his child. *Apis Americana* would be a very good name, but it would only signify its American origin, while albino signifies its shade of color by which the eye may readily recognize it; hence, we have named our bee—the result of our experiments or discovery—albino, and we feel no little pride in the appropriateness of the name. We call our bee albino, not because it comes from green, red, blue or black blood, but because it is a whitish bee—the whitest known.

For the American Bee Journal.

About Rearing Queens.

HENRY ALLEY.

After reading Mr. Butler's article in the *BEE JOURNAL*, I am prompted to write on the above subject again. How to rear strong, healthy, hardy, and prolific queens, has been my study for the past 20 years. My experience teaches me that the more queens a colony of bees rear, the shorter-lived and poorer in every way will the young queens be.

Now, if one will examine the interior of a hive after a swarm has issued they will find from 6 to 12 queen cells. Seldom less than 6 or over 12. Now, these cells are generally all sealed before the new swarm "comes off." Why is this? It is merely to have a large number of bees to feed, keep warm, and nurse the coming queen while in the larval state. It will also be found that a larva 3 or more days old will not be selected by the bees from which to rear a queen during the preparation for natural swarming. If the queen is removed from a full colony, the bees will select eggs and larvae quite old to rear queens from. They seem to understand the need of a queen as soon as possible; but in natural swarming, the egg is selected for the young queens, and the bees seem to know that they have plenty of time in which to build the

cells. I do not think that a queen reared from a larva 3 days old will be very prolific for any great length of time. Such queens may do well for a few months, and then will disappear. I am aware that all queens reared under the swarming impulse do not prove prolific and long-lived, neither do all the artificially-reared queens. As there are a much larger number of artificial queens reared than natural ones, of course there will be a larger number of inferior queens sent out.

Now, as we must have artificial queens, the question is, how can we best rear them, and keep up the standard of prolificness, hardiness, and purity? It certainly cannot be done if queens are reared as some queen dealers say they are rearing them. I know, from several years' experience, that good hardy queens cannot be reared by inserting a frame of eggs and larvæ in all stages, in the middle of a full colony of bees. I find in such cases that the bees will select an old larva, say 1, 2, or 3 days old for a queen. I have had some colonies make as many as 60 queen cells at one batch. The colony was an extra large and powerful one, and the queens were pretty good.

I do not think very valuable queens can be reared in a hive that has just reared one lot; such queens will be very poor. But a colony of bees will continue to rear queens good or bad, if eggs are given them, so long as there is any hatching brood in the hive. Perhaps Mr. Butler will remember what I said in the JOURNAL some time ago, that I allow about 25 queens to be reared at one time, by 1 colony of bees. I think I said at that time that the bees had no other brood to care for except the 25 eggs given them to rear queens from. I find that a strong colony of bees put in a hive without any brood, except enough to rear a few queens from, will make double the number of strong and hardy queens that they will in a hive full of brood. A strong colony with not over 25 eggs, will concentrate all their forces on the small amount of brood given them, and as queen-rearing is their only object, one can expect nothing but good queens as a result. With my method for rearing queens, my full colonies are never queenless, and I use no brood in my queen-rearing hives, and still use all the bees in a strong colony for queen-rearing. To rear good, hardy, and strong queens, rear only a few to a hive. Remember that good queens cannot be reared in a strong colony by merely removing the old queen. They must start from the eggs or from larvæ only a few hours old. I well remember a remark a bee-keeping friend made to me some 20 years ago: "I will tell you how to rear nice, large queens; let the bees start them from the eggs." Twenty years experience has verified that assertion.

That artificial queens can be reared that are better in all respects than natural ones is a fact well known to me for many years. I have in my mind now a case that will prove the fact as far as it goes. I sold a good,

strong colony of bees to a neighbor; well, they swarmed twice, and the young swarms died the following winter. The parent colony did not seem to build up strong again that year. The next year they did not do any better, and the parent colony never appeared to be full of bees. I judged that the bees had reared a poor queen, and during the month of August gave them a young Italian (artificial) queen. The following year the parent colony swarmed twice, and gave 40 lbs. of honey; the first swarm filled their hive and gave 20 lbs., and the second swarm filled their hive and stored 10 lbs. in a box. I make this statement merely to prove to some people that artificial queens are as good, if not better, than natural ones. I can give many more cases of the same kind.

Wenham, Mass.

For the American Bee Journal.

My Experience with Syrian Bees.

I. R. GOOD.

I have been requested by Mr. J. E. Lay, of Texas, and others, to give my experience with Syrian bees, in the columns of the BEE JOURNAL, which I will do without prejudice, and to the best of my ability. They are crosser than Italians if not very carefully handled. If a colony is made queenless and kept so any length of time, there will laying workers appear and fill the combs with eggs. They will not stick to the combs in handling as well as the Italians, but while they have those bad qualities, they also have very good ones. The queens are very prolific, consequently, the brood department will be filled with brood by the time the honey harvest begins, and the bees will take to the surplus boxes much earlier than the Italians, and work with a will.

Last season my Syrian bees were the first in the boxes by nearly two weeks, and some of my best colonies had 25 and 30 lbs. of honey ready to come off before the Italians could be induced to commence in the surplus boxes. They have proven themselves, with me, to be a much hardier race of bees, standing the winter much better and are not as apt to spring dwindle as the Italians. They are not hard to introduce a queen to, if they have been queenless a day or two. They will accept a queen even where the hive is full of fertile workers. They are proof against moths and robbers. For fear there may be some that will say I am interested in the sale of Syrian queens, and consequently have an axe to grind, let me quote from others who are not interested in their sale. In the BEE JOURNAL, Vol. 17, page 316, Mr. Whitfield says: "We were fortunate in having 2 of the Palestine queens come through the past winter in good condition to start with in the spring; but as I had Italians that seemed to be in quite as good condition, I thought very little of them at first. About June 1, I noticed they had more than double the

bees on the wing than any other colony, and I took a glance at the inside, which showed 12 frames of brood in one and 9 in the other—frames 1 foot square. I now began to watch them with interest; they gave just double the increase, and each colony gave one-half more honey than the best Italians."

In the BEE JOURNAL for 1881, page 323, Prof. A. J. Cook says: "The tongue of the Syrian worker I find, after examining a large number of each kind, to be the same length as that of the Cyprian, and to average 006. of an inch longer than that of the Italians. The Syrians are excellent honey gatherers, certainly equal, if not superior, to the Italians. They are even more sure to repel robbers than are the Italians."

In *Gleanings* for 1882, page 132, A. I. Root says: "The strongest colony in our apiary is the Syrian one we have mentioned; they are almost the only ones that are wintering on natural stores, just because they had abundance of stores without any sugar feeding."

Now tell us your experience in the BEE JOURNAL apiary with the Syrians, as I know you have them. It is the truth in the matter we want. If the Syrian bees are no better, or not as good, as the Italians, we want to know it; and, on the other hand, if we can improve our bees by breeding Syrians or Cyprians, and crossing with our Italians, we also want to know it. The best bees are what we want.

Nappanee, Ind.

[We have, in the BEE JOURNAL apiary, two Syrian queens, supposed to have been properly mated, and several which have mated with Italian drones. Of the former, we have had but little knowledge of one, as it was quite late last season when we received her, but the other was obtained early in the spring. She proved very prolific, and we found her very useful in assisting to build up colonies. They were not fairly tested for working qualities, as the drain upon them for bees and brood was unremitting. Were it not for their irascible disposition, we would think much more favorably of them; but they certainly are much more vicious than any Italians we have had any experience with, and we have been unable to subdue them with smoke. The progeny of the younger queens, mated with Italian drones, appear larger than the full-blood Syrians, and are very docile, while the queens appear to have retained their proclivities for prolificness. We shall further test them this season for their honey-gathering qualities, in comparison with Italians, Cyprians, Southern brown bees, and hybrids of the different races.—ED.]

For the American Bee Journal.

Heddon's Honey Board.

JAMES HEDDON.

On page 156 of the BEE JOURNAL for March 8, Mr. Funk asks for a description of my honey board. Not quite liking your description of it, Mr. Editor, please allow me to do so.

"When I was a boy," away back in the "dim vistas" of the past, discussions about honey boards were in order and operation through the columns of the monthly BEE JOURNAL. Some stoutly averred, and all agreed, that honey boards between boxes or upper sets of frames, and the brood frames, were a great convenience, because they prevented the bees from sticking the frames together.

But some there were, who said that the honey board isolated the surplus department from the brood chamber to so great an extent that the bees would not obtain as much surplus as when these boards were not used. But Mr. Langstroth, in his book and specifications of his patent-claims pretty plainly told us that bees would put their surplus honey readily into any department where the "heat and odor" of the hive readily permeated. Inspired with this welcome and reasonable announcement, I set about constructing a honey board that I thought best adapted to the principles laid down. There is, sometimes, great convenience in placing hives on top of each other, with no board between. A super constructed properly for so doing must come down no lower than the bottom of its frames; then, when set upon the lower story the bee space above the lower frames, is the only and perfect bee space between the 2 sets of frames. Now, a flat honey board would touch the upper set of frames, whose bottom bars would be glued fast to it. This fact caused me to devise what I named my "sink honey board." I will describe it as nearly as I can:

Suppose your hive and super is made of $\frac{3}{8}$ thick lumber. Make a frame the size of the top of your hive, let the material of this frame be, end pieces, $\frac{3}{4} \times \frac{3}{8}$; side pieces, $\frac{3}{4} \times \frac{1}{2}$; rabbet these end pieces $\frac{3}{8} \times \frac{3}{8}$ on one corner; nail the side pieces to the end pieces, keeping the $\frac{3}{4}$ way of all pieces up and down. Now, I will suppose you have an 8 frame hive, (you ought to have, and a Langstroth frame at that), lay this frame on your bench rabbeted side up, have prepared 9 pieces that will reach lengthwise of the inside of your frame, and rest into the rabbets beside. They should be $\frac{3}{8}$ thick, and wide enough so that when laid in and nailed as follows the 8 spaces between them will be just $\frac{3}{8}$, nail the first one snug up to one of the side pieces, and the last one snug up to the other side piece; nail the side piece to this slat with one nail in the middle, on both sides. Now, when all are laid in and placed so that you have a board with 8 $\frac{3}{8}$ spaces running lengthwise of it, when you place it on your hive you will see that each space comes exactly over the middle of the top bar

below. When you placed this honey board upon your hive you turned it over, and found that your slats were $\frac{3}{8}$ lower than the sides of the board, so, now, if you place your super upon it, though the frames of this super come down flush with its bottom, there will be a $\frac{3}{8}$ space between them and this "sink honey board." As the slats of this board break the direct opening between the lower and upper stories, no bits of comb are built up through, and the upper frames (which should rest on a metal rabbet, but have no metal corners) move up by simply picking them up. No bees can be crushed when replacing them, as the lower space is always clear of all pieces of comb. You see that with this arrangement the heat and odor of the brood chamber is in no way retarded.

I use the same board for sections, only I add to it $\frac{3}{4} \times \frac{1}{2}$ inch cross pieces (as needed, according to the length of sections) so that the sections rest on them just at their ends, and leave bee space under all the rest of their entire length. These sections pick up clean of all dropping bits of combs, and hence remove readily, and come off clean and nice. I have used this board for comb and extracted honey for more than ten years, and when I say that they are in no way any detriment to the amount of surplus honey received, and are highly in favor of its neatness and appearance (if comb), and the convenience of the apiarist, I have no fears but what the future will verify the statement.

Dowagiac, Mich.

For the American Bee Journal.

Over-Stocking and Marketing Honey.

O. M. BLANTON.

After the sale of 25 colonies, I commenced last spring with 315. Our income up to October 15, was as follows: Extracted honey, 10,359 lbs., \$744.46; comb honey, 2,295 lbs., \$331.97; beeswax, 64 lbs., \$12.80. Total, \$1,214.23. Add 25 colonies at five dollars, \$125. Total, \$1,214.23.

From the above you will perceive that my comb honey sold for about $14\frac{1}{2}$ cts., and my extracted for about $7\frac{1}{2}$ c. My average yield per colony was about 40 lbs., and average profits about \$3.45. I lost only 1 colony from absconding, and increased to 326 colonies. A considerable amount of wax was used for the barrels, and all irregular section combs, after being extracted, and pieces of drone comb cut from the brood chamber, were tied in Langstroth frames and placed in the upper story.

I will now add in this report that of my friend, G. C. Vaught. Mr. Vaught's report is taken from the account of sales by his merchant, and the entire yield is from 32 colonies: Comb honey, 2,877 lbs., \$513.03; extracted honey, 200 lbs., \$20.00. Total, \$533.03. His extracted honey yielding 10 cts. per lb., and comb honey 17 4-5 cts., average yield per colony, 96 lbs. Profit, \$16.65.

Mr. Vaught shipped all of his comb honey to St. Louis, but sold his extracted at home. He lost 6 swarms from absconding and increased to 40 colonies. After the 15th of August he did not extract honey from the lower story. He uses the same pattern of hive that I do, and has only 2 colonies of Italians. All of my apiary is located within 2 acres in the town of Greenville, 600 yards from the Mississippi river. Mr. Vaught's is located 4 miles from the river in the country, and therefore can forage at all points of the compass.

The above reports do not show the net earnings as the cost of labor and packages must be deducted. Mr. V. was fortunate in his merchant, as his and my comb honey was of the same quality and packed in similar cases to mine, and sold at same time—his for 18c., mine for 14c., by a merchant near by. He sold some for as much as 23 and 25c.

From the above it is seen that an locality can be over-stocked; although 300 colonies can be made profitable in this county, especially in a good season. In the past season we suffered from late frosts in the spring, and severe drouth in June, July, and part of August.

Greenville, Miss.

For the American Bee Journal.

The "Call" of a "Strange Visitor."

DR. G. L. TINKER.

As Mr. G. M. Doolittle is reported to be very ill, and, moreover, since he would doubtless treat the impertinent, slurring, and disrespectful article of Mr. Van Kirk, on page 167 of the BEE JOURNAL, with contempt, it may be well for another to notice it. For myself, I must deprecate such an attack, and confess that I felt pained upon reading it. It will not do, in this manner especially, to call in question the honest statements of our foremost apiarists who have so generously, freely, and without reserve, given to bee-keepers everywhere the benefit of their various modes of management, which has contributed so much to make modern bee-keeping what it is to-day. They are not only entitled to great credit and respect, but we owe to them a debt of gratitude. Mr. Van Kirk can ill afford to attack men who have done so much in his behalf.

Mr. Doolittle is not the only one who has made "big reports," nor the only one among skilled and experienced apiarists to suffer serious losses. As to reports, other bee-keepers have made more astounding ones, and yet others have suffered far greater losses in wintering.

Doubtless, if Mr. Van Kirk were to go over the writings of other frequent contributors to the BEE JOURNAL, he might find apparently conflicting statements, which, however, in the presence of all the facts, could be reconciled. But it would profit no one.

I do not care to go over Mr. Van Kirk's article in detail. It is sufficient

to note that he is inconsistent; that he has not carefully read Mr. Doolittle's writings, and, above all, that he is not honestly nor respectfully seeking information.

New Philadelphia, O.

[We are quite confident Dr. Tinker gives utterance to the sentiments of many of our readers regarding this class of commentators. Not only is it calculated to wound the feelings of the person criticised, but will have a tendency to deter many eminent contributors from communicating their improvements, or ideas, through the press columns, for fear of malevolent or sarcastic criticism. So long as discussion is confined to courteous and generous debate, much good may be derived from it; but when innuendoes and sarcasm supplant argument and reason, the article inspires disgust rather than admiration. We have exercised our prerogative to withhold several such articles from publication, and are satisfied the writers themselves will ultimately feel grateful to us for so doing.—ED.]

SELECTIONS FROM OUR LETTER BOX

Long Idea Hives.—On page 139, Mr. Fayette Lee, of Minnesota, asks you which hive will give the best returns—a long one, or a two-story hive? and you answer: "A two-story hive." I have 50 "long idea" chaff hives in my yard to-day, and no two-story hives. I have repeatedly tested them by the side of the long hives for extracted honey with results in favor of the long ones every time. I will give my mode of management. The hives are 36 and 40 inches long—mostly the latter length—made double, with slanting roof. I use a frame 13 inches long by 11 deep, inside measure. When the colony gets large enough to occupy one-half the hive, if the forage is good, I give them the whole length, spreading the brood and putting an empty comb between the whole length of the hive, and when ripe enough to extract, I empty every comb that contains enough to pay for handling, leaving one comb usually to keep the bees quiet. My 50 hives will hold 3,000 lbs., which is quite an item when a person is hurried with other business, as it can remain quite a length of time frequently. My bees last spring were reduced to mere nuclei, and I did not extract at all till they had finished their summer's labor, and then the honey was nicely ripened and mostly capped. Such hives should remain on the summer stands, as they would be quite heavy to move. I would advise Mr. Lee to try both sorts of hives until he is satisfied which is best. But when you say to

him that the two-story hive will give the best returns you are much mistaken, in your humble servant's opinion, as far as extracted honey is concerned. I do not see how the BEE JOURNAL can be improved from its present shape—it is intensely interesting now. No dwindling amongst bees this winter. They have had several flights since February 1. Brood-rearing started some in February and no loss to speak of. W. H. S. GROUT.
Kennedy, N. Y., March 13, 1882.

[Our answer to Mr. Lee's interrogatory was intended for a hive for all purposes—not comb honey alone, nor for extracting exclusively. It was a general question, and answered as such.—ED.]

Buying and Smoking Bees.—Please answer the following in the next issue of the BEE JOURNAL:

1. In buying bees, how early in the spring should the purchaser get possession of them?

2. Do those handling bees usually smoke them for all their manipulations?
J. R. CRAIG.

Beatrice, Neb.

[1. The delivery of bees depends much upon locality and season. In contracting, mention is usually made of time for giving possession, as purchasers frequently prefer taking the risk of spring dwindling, in order to have the bees sooner to assist in divisions and strengthening. Then, again, if in cellar, the vender will not give possession till all are on the summer stand, in order to give opportunity for selecting average colonies. Some dealers make a special point of not shipping or delivering till June, unless the contrary be specified, which gives them the advantage of a first swarm, or brood sufficient to nearly make one, which they consider a compensation for risk in wintering and spring dwindling.

2. No; unless quite vicious.—ED.]

Gathering Honey.—Bees are doing finely, gathering honey from willow, tame China, and locust. I notice in the JOURNAL of the 8th inst., that Mr. J. S. Tadlock, of Luling, Texas, dated Feb. 25, says he will extract new honey the first warm days. Now, will Mr. T. please inform me what it is that his bees gather so much honey from, that he can extract so early? My bees are in exactly the same latitude as his, about 156 miles due east. I have extracted about 1,000 lbs., but it is honey gathered last fall. I leave frames in the upper stories all winter, and do not believe in taking all the honey out to make a big report, and then feed back sugar or glucose, and lose half of my bees from starvation. We all know that the old bees die off very fast in spring, and it takes all they can gather for brood-rearing until the flow from linden, wild China

and horsemint. I have no swarms yet; am looking out for them now. Weather is fine; peach trees are nearly out of bloom; corn is up ready to plow. Have new potatoes and English peas. Prospects are good for honey.
J. W. ECKMAN.

Richmond, Tex., March 18, 1882.

Early Drones.—MR. EDITOR: I send you a few Italian drones; the progeny of a daughter of my imported queen, and the best marked drones I ever saw. Are they as light colored as the lightest?
J. S. TADLOCK.

Luling, Texas, March 14, 1882.

[We have the drones in a bottle of alcohol, to compare with other specimens we have in the museum. They are very fine, but not as purely yellow as several specimens, some of which have been here for 3 years. They are not as fine as those we exhibited in Italy in 1849.—ED.]

Clipping Queen's Wing.—Please inform me how and the proper time to clip queens' wings; also, how to proceed to Italianize an apiary? I have 1 colony of Italians and 14 of blacks, and wish them all Italians.

Earlville, Iowa. A. L. CONGER.

[During fruit bloom, or early white clover, we have found the most convenient time for clipping a queen's wing. By lifting a frame gently from the hive, so as not to frighten the queen or anger the bees, with a small pair of scissors and a steady nerve, the wing can be clipped off without the queen scarcely knowing it. If, however, you are nervous in movement, better lift the queen by grasping her gently at the fore part where the wings join the body, and deliberately cut off about one-third of one wing. Care must be observed not to grasp her by the abdomen.

The great majority of your bees being blacks, you will have to cut out the drone comb very closely from the blacks, then stimulate your Italian colony rapidly, both by stimulative feeding and giving sheets of worker brood from your black colonies; then insert drone combs to get drone eggs and brood as soon as possible. When you have Italian drone brood capped, remove the queen into a black colony, and let the Italian colony build queen cells. When these are ripe, remove your black queens, or form queen-testing nuclei from your black colonies, and thirty-six or forty-eight hours after graft in the queen cells. If you have been successful in forwarding Italian drones, and suppressing those from the blacks, your work will be easily accomplished; otherwise, it will be quite difficult.—ED.]

Wintering Well.—The winter has been very favorable for our bees so far, whether on summer stands or in cellar. Last winter my bees were left on the summer stands in very open hives; in fact, they were so open at the sides and top that I expected to lose all of them before spring, but out of 18 I only lost 2 colonies; they were in box and log hives. When the season opened last spring I transferred them to frame hives, and increased to 25 by using foundation comb (Dunham), putting it in with Goodrich's fastener. This machine works nicely and places the foundation solid in the center of the frame. I was very successful with the foundation; not one sheet dropped, and I put in large swarms. What were once log and box hives, now have frames, so that I can handle them with some pleasure. I have them in the cellar, with the tops raised and bottoms open; they seem to be very quiet. Should they be put out for a fly, or leave them until spring opens up, so that they will not have to be put back in the cellar? W. H. BECKWITH.

Saybrook, Ill.

[If the bees show signs of uneasiness, put them out for a fly; otherwise, let them remain in the cellar while all is going well—"let well enough alone," is an old maxim as applicable to bee-keeping as anything else.—ED.]

Ninety Colonies in the Cellar.—Have had 90 colonies in the cellar since Nov. 24; a few show signs of dysentery; 2 in the open air are quite strong. Bees in this section have wintered well. J. C. THORN, M. D.

Streetsville, Canada.

Good Bee Pasturage.—I have 57 colonies and cannot get along without the BEE JOURNAL. The last was a poor season for honey in this locality. My bees are in good condition. We have one of the finest localities in the State for bee pasturage.

HEZEKIAH SMITH.

Fredericksville, Ill.

The Season, Smokers, etc.—The opinion of many writers for the JOURNAL is that we shall get a large crop of honey the coming season. I suppose they base their opinion on the condition of bees at the present, but we should not shout too loud until we get nearer the clearing; we have a spring to contend with, just ahead of us; then comes the harvest. Farmers in this vicinity are all expecting a very light crop of grass; they say that the winter has been very unfavorable for the meadows; that timothy and clover have "winter-killed." The roots are on the top of the ground, thrown out by the frost. Bees are in splendid condition; that is good so far, but if white clover is killed out, we cannot expect a very large surplus. In No. 9, page 137, Mr. T. F. Bingham has an article entitled, "A Partial Review." I think the action of the Northeastern Bee-Keepers' Associa-

tion must have touched him in a sore spot. Be that as it may, I do not desire to keep rasping on a sore spot, when one is found, so I will try to heal it up. Mr. Bingham in his remarks, brings me in, and all I want to say is that if I understand the ease, I do not wish to take back what I said, but to reiterate it in fully as strong language. I understand that Mr. Quinby was the first to get up a practicable bellows smoker, and I believe he is accorded that by all. I am informed that Mr. Bingham got out a patent on bellows smokers; I do not know what the patent covers, but I am told that he came down and forbade L. C. Root and others from manufacturing the bellows smokers. My point is this, if Mr. Bingham patented what others had invented, and tried to stop others from making, I condemn such in the strongest terms; but if Mr. Bingham's fertile brain has originated anything that is worthy of a patent, he is entitled to all its benefits, and I will hold up both hands to sustain him or any other man in his or their rights. W. E. CLARK.

Oriskany, N. Y., March 17, 1882.

Beginning.—I am commencing with bees here, and have 8 colonies, and will report progress hereafter. There are quite a number of amateurs here and all need such instructions and help as the BEE JOURNAL gives. Boulder, Col. C. P. WALDRON.

Answered to Roll Call.—On the 18th inst. my 21 colonies answered to roll call. My apiary is in my yard, which contains about one acre, and is well set in blue grass and beautifully arranged shade trees and shrubs. In the southeast corner of my apiary, where there are no hives yet, I put some boards and set some troughs on them in which I put syrup made of pure A sugar, and then placed a layer of dry corn stalks on the syrup. At 10 a. m. I procured a few coals on a shovel, and put a little piece of old comb on the fire, and in less than 3 hours the syrup was all gone clean and dry, and only 3 dead bees left at the troughs. They put in the rest of the day bringing pollen from the maples and elms, which are plentiful here, and in the evening I found that colony No. 8, was robbing colony No. 4. They would not let any others rob them but No. 8. They would fight all others, and all winter this colony No. 4 was uneasy, and at times acted like they would swarm, so I examined them and found that No. 8 had all the honey, and both are strong colonies of bees. I then took the brood chamber of No. 4, and set it on top of the brood chamber of No. 8; they remained there about 20 minutes; I then took it off; the bees had gone down into No. 8, and left their queen alone above. I then examined her and found her to be a deformed, unmated young queen with 1 leg off. I killed her and the bees united and went to work without any trouble. My 20 colonies are now hatching young brood. The prospects are good, although too much rain. R. M. OSBORN.

Kane, Ill., March 20, 1882.

A High Fence.—I think Mr. Casson is right regarding the high fence around the apiary. I had a colony that got to robbing last season. There was an orchard in their line, and some of the bees in coming back would go around the orchard instead of going over it. I wish to make some foundation for section boxes. I have a set of dies, but do not know how to prepare the sheets to be pressed. Will you give me light on the subject?

H. W. CLEVELAND.

North Sheffield, O.

[Nearly every manufacturer has, from experience, acquired methods peculiarly his own in some of the details of preparing sheets for the rolls or press. Until quite recently, the method was generally to dip a sheet of galvanized iron or thin wood into a boiler of melted wax. Care must be taken that the wax is about the right heat, and the dipping plate or board is kept cool by immersing in cold water before putting it in the hot wax. A solution of soap bark, as it is called, and which may be procured from nearly all druggists, is used in washing the plate or board, and especially the edges to prevent the wax from sticking, after they have been unused for some time. Some little practice will be required to make everything work smoothly and satisfactorily.—ED.]

Improvements in Bee Hives.—I hope the bee hive question is not too hackneyed to merit special and general discussion at present. I have given the subject much consideration, and would like to have the question fully discussed, for it seems to me that important changes are imminent.

Montpelier, Vt. A. WEBSTER.

Good Increase.—In the spring of 1880 I commenced with 4 colonies of black bees. I transferred them to frames 8½x15 inches, with success for a new hand. Increased to 10 in fair condition, but lost all but 2 weak colonies in the spring of 1881. In May I bought a colony in a box hive, and on transferring them found the combs full of brood. This colony started me up afresh, and I increased to 12 good-sized colonies, and obtained 50 lbs. of honey in 1 lb. sections. Of these, 5 strong colonies were left on their summer stands, in double boxes filled with sawdust all around, and lime cushions over them, which were covered with cut straw, and corn-stalks set all around. The 7 lighter colonies were put in an 8x16 cellar under the house, partitioned off from the other cellar, with a 4 inch pipe under ground. I bored 3 holes in the floor under a partition, which takes the dampness up to the rafters of the house, and by which it escapes. The bee cellar is always fresh. I put the bees in the 18th of November. They seem to like it, and are very quiet.

RATES FOR ADVERTISING.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space.

Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements for the **Weekly** as follows, if paid in advance :

For 4 weeks.....	10 per cent. discount.
" 8 " (3 months).....	20 " "
" 13 " (6 months).....	30 " "
" 26 " (9 months).....	40 " "
" 39 " (1 year).....	50 " "

Discount, for 1 year, in the Monthly alone, **25 per cent.**, 6 months, **10 per cent.**

Discount, for 1 year, in the Semi-Monthly alone, **40 per cent.**, 6 months, **20 per cent.**

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

Transient Advertisements payable in advance. —Yearly Contracts payable quarterly, in advance.

THOMAS G. NEWMAN,

974 West Madison Street., Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the *best* advertising medium, but the lowest rates on yearly contracts.

A Sample Copy of the Weekly **BEE JOURNAL** will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly **BEE JOURNAL** for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the **BEE JOURNAL**.

To Promote a Vigorous Growth of the hair, use Parker's Hair Balsam. It restores the youthful color to gray hair, removes dandruff, and cures itching of the scalp. 11w5t

The Apiary Register.

As the time is now at hand to commence the use of this valuable book, all who intend to be systematic in their work during the coming season, should obtain a copy and commence to use it. We give the following notices by the bee papers of America, which most thoroughly endorse its use :

"Every bee-keeper should have a good understanding of the condition of every colony of bees in his apiary; he should also become aware of the superior and inferior qualities of his bees, and know the colonies to which these traits belong. He should record the amount of honey, in pounds, which is taken from each colony and thereby learn which colonies are the greatest honey gatherers, and therefore the most profitable. He will thus be enabled to learn and decide for himself which queens will pay him the best to breed from, and how such queens look—whether the color or size decides in any way the superiority, and more than one question which is harrowing our minds to-day, each may settle for himself by the following bee-keeping in a systematic and orderly way. When such a day comes we predict a more harmonious and satisfactory time for bee-keepers. We have long urged the need of systematic bee-keeping, and one of its necessities has been brought forth by T. G. Newman, of Chicago, from whom we have received a copy of the *Apiary Register*, which was devised to contain a complete record of each colony in the apiary. The book is leather bound and well gotten up."—*Bee-Keepers' Guide*.

"The latest thing out in the way of convenience for systematizing work in the apiary, is an *Apiary Register* book, gotten up by Mr. T. G. Newman, to whom we are indebted for a sample copy of the work. Two pages of the book are devoted to each colony, with rulings and proper headings, so that a glance will give a complete history of the colony. On the front pages are plain directions for using the Register, with two sample pages, showing how to fill up the blanks."—*Kansas Bee-Keeper*.

"**APIARY REGISTER.**—We have just received one of friend Newman's *Apiary Registers*, and we must say we are delighted with it and wonder how our bee folks got along without it. The one we have is for 100 colonies of bees, with something like 220 pages; there is one page devoted exclusively to the colony on general principles, bees, honey, etc. Then the opposite page is devoted exclusively to the queen, and in the back there is sufficient number of pages devoted to the cash account, so the whole business of your apiary can be kept together. It also has a page and a half devoted to things worth knowing. A complete glossary, and a nice little table of abbreviations. It is neatly bound in full sheep, and one book will do a single apiary for 2 or 3 years."—*American Beekeeper*.

"The *Apiary Register*, published by T. G. Newman, is a book that fills a long-felt want, and one that every apiarist should have. Two pages, ruled and printed, are devoted to each colony, it being so arranged that a single glance will give its complete history. It is strongly bound in leather, and of very convenient size, being small enough to carry handily in the pocket."—*Bee-Keepers' Instructor*.

"We are indebted to Mr. Newman for a sample copy of his *Apiary Register*. This is something new and fills a needed want in the bee yard. The one we have is calculated for 100 colonies and is so complete in its systematic and condensed arrangement that the whole story of each is told on one leaf about 4x6 inches—which makes a book for 100 colonies 3/4 of an inch thick. Can be carried in the beekeepers' pocket without any inconvenience. Thus he can know the exact condition of any colony in a moment. It has only to be seen to be appreciated."—*Beekeepers' Exchange*.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

"We are sometimes asked who our authorized agents are? Every subscriber is such an agent; we have no others, and greatly desire that each one would at least send in one new subscriber with his own renewal.

"Those who may wish to change from other editions to the *Weekly*, can do so by paying the difference.

"Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

"It is a fact that horse dealers are buying horses with ringbones and spavins, because they can make money by using Kendall's Spavin Cure. 9w5t

"How do You Manage," said a lady to her friend, "to appear so happy all the time?" "I always have Parker's Ginger Tonic handy," was the reply, "and thus keep myself and family in good health. When I am well I always feel good natured." See other column. 11w5t

ITALIAN BEES AND QUEENS.

Full Colonies, Nuclei, Tested and Untested Italian Queens, bees by the pound. I guarantee safe arrival. Address, **OTTO KLEINOW,** 13wtf Opposite Fort Wayne, Detroit, Mich.

BEE JOURNAL

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., April 5, 1882.

No. 14.

ESTABLISHED IN 1861
THE AMERICAN
BEE JOURNAL

Published every Wednesday by

THOMAS C. NEWMAN,
EDITOR AND PROPRIETOR.

374 WEST MADISON ST., CHICAGO, ILL.
At \$2.00 a Year, in Advance.

Remit by money-order, registered letter, express or bank draft on Chicago or New York, payable to our order. Such only are at our risk. Checks from local banks cost us 25 cents for collecting.

Free of postage in the United States or Canada.
Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. This is a new pamphlet of 32 pages which we have just published. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

The "Conqueror."—We have received from Messrs. Bingham & Hetherington a sample of their large smoker, which they call the "Conqueror." It certainly possesses capacity sufficient to conquer the worst colony of hybrids that can be found. The stove or fire-pot is 3x7 inches, with a chimney 7 inches high, and bellows in proportion. Almost any body would be justified in making a *great blow* with this smoker.

Articles for publication must be written on a separate piece of paper from items of business.

On Friday, March 24th, America lost her most distinguished poet by the death of Henry W. Longfellow, at the ripe age of 75 years. For fifty years his sweet and tender poems and charming stories have been read and re-read by the people, and they were enjoyed by rich and poor, learned and unlearned alike.—*Ex.*

A Reversible Frame.—J. S. Duncan, of Browning, Mo., has sent us a sample of his reversible frame for bee hives. Accompanying it is the following description, which will give as good an idea of it as we could do:

By the loose link at each corner and the movable arm the frame is reversible, and with the square frame, sides or bottom may become top, for the frame the pieces are all cut one length, and the one nailed on the other; this is for hives with rabbets. The triangle link is hung on the accompanying hooks, properly spaced and driven into the side of the hive, making the hive simpler and easier of construction. To keep the frames from swinging against each other, I use a thin strip of wood with wire drawn through the proper distance, and fastened to the bottom of the hive. The links are made by having a piece of wood or iron the shape you want the link, roll the wire around and cut.

A correspondent in North Carolina wishes to know how to prepare bees in the Simplicity hive for transportation by rail, to hold frames steady, etc., which we briefly answer: Prepare a bottom gauge, by using a strip $\frac{3}{4}$ of an inch thick by 1 inch wide; let this be as long as the hive is wide; saw notches to the number of the frames, in which to fit the bottom bars to hold them steady; now set the frames in firmly, spread them properly, and drive a $1\frac{1}{2}$ inch wire nail in the lug at each end of the top-bar. Cover the whole hive (if the weather be hot) with 16-mesh wire cloth; put 3 strips (1 at each end and middle) of inch lumber by 2 inches wide, crosswise; fold a cotton cloth 8 thicknesses, dampen it and tuck under one strip, then at night close the entrance tight. Properly mark it, on top, "Live Bees—this side up; keep out of sun and rain." If weather be cool, use much wider cross-blocks on top.

Artificial Comb Honey, Beeswax, etc.

Mr. H. S. Hackman, of Peru, Ill., propounds below a few questions relating to the beeswax production of the United States. Short and pointed as are the questions, but slight reflection will be required to convince the reader of their importance:

I have received a letter from Mr. R. A. Barnett, commission merchant in Chicago, in which he says: "Happening to pick up the BEE JOURNAL of this city, I noticed your communication on comb honey. It is true that many people think all the nice comb honey that they see in my store is manufactured and tell me so daily; I am often so weary of the effort to convince them of the impossibility of its being manufactured, that many are allowed to deceive themselves. Perhaps that is better than that they should think I lied about it." This corroborates my last article on artificial comb honey. Will you or some of your contributors please write an article on beeswax, and answer the following questions: 1. What is the wax product of the United States annually? 2. What is the principal use wax is employed in or for? 3. Can any other product or substance be substituted for beeswax? 4. What will be the commercial value of wax, as scientific bee-keeping advances? 5. Can a progressive bee-keeper afford to sell wax at 20 cents a pound?

1. There are no data for arriving at the wax product of the United States with anything like precision. Several years ago, with the information then at hand, we estimated the beeswax product of the country to be about 3,000,000 pounds, which, at 20c. per pound, would amount to \$600,000.

2. For wax candles, artificial flowers, medicinal uses, varnishes, and many other purposes. The most of it, till quite recently, has found a foreign market, since which there has been a ready market at home for nearly all the beeswax produced.

3. Yes, in many ways: it is largely mixed with ceresine, paraffine, and perhaps other substances, for various purposes. Much of the bleached beeswax of commerce, and white wax, is composed principally of ceresine or paraffine, and in many cases they have entirely supplanted beeswax. We do not believe, however, any substitute for it can be used in the apiary, or any adulteration practiced with economy, for purposes in which it is to be brought into contact with the bees. Several attempts of this kind have been made, but they always resulted in failure so far as we have been informed.

4. It is impossible to foretell. Per-

haps its value will not advance proportionately with the decrease in production, owing to the employment of cheap substitutes for it.

5. No, as compared with the price of honey, and the ready market being established for the latter. Probably, in the near future, the majority of the wax production of America will be consumed in the manufacture of comb foundation, and many progressive apiarists will themselves become buyers in the market instead of sellers, as the tendency of progress appears to be to prevent production rather than to encourage it. If twenty pounds of honey, or the time of the bees equivalent to that amount, be required in the making of one pound of comb, certainly no thoughtful bee-keeper will encourage or allow its production if he can profitably prevent it.

Artificial Swarming.

The season is rapidly approaching when the bee-keeper will wish to take every advantage to secure the early flow of honey. Many may have bees in box hives which they do not wish to transfer, either from want of time or timidity, or, perhaps, they may prefer to keep them in the boxes, and to run the swarms into frame hives. For this purpose we suggest the following methods of artificial swarming, which will be found preferable, we think, to natural swarming, as they are attended with no risk, but little loss of time to the bee-keeper, and scarcely no interruption of work with the bees, as is always the case with natural swarming, occurring as it does just at the time when time is most valuable with them: Select some bright, clear day, when the workers are busily engaged in the fields, remove the hive 10 to 20 feet from the stand, and put in its stead a frame hive, with half or two-thirds its complement of frames filled with bright, clean combs, or good foundation and division boards at the sides; turn the old hive bottom up, and invert an empty box over the open end; now blow in a little smoke from the lower end of the hive, and commence a series of sharp drumming or rapping on the sides of the hive with a small hammer or stick; do not drum hard enough to loosen the combs or start them to dripping; after rapping 4 or 5 minutes, cease for a minute, then resume again, and keep it up for five minutes longer, or until the bees have deserted the hive and clustered

in the box, which is a pretty sure indication the queen is with them. Now cover a sheet over the old hive, and empty the bees from the box on a sheet in front of the new hive on a old stand; watch them as they crawl up to discover the queen; if she goes in, place the old box on a new stand, and your work is accomplished.

If the bees to be operated with are in frame hives, remove the old hive to a distance, and place a new or empty one on the old stand, when the bees are working busiest; lift the comb on which you find the queen from the old hive, destroy queen cells on it, if any, and place in the center of the new one, with the queen; fill in frames each side filled with clean combs or foundation, proportionate to the strength of the colony, and confine to the center of the hive with division boards; put on the blanket and hive cover; now take the frames one at a time from the old hive, and shake most of the bees off in front of the new hive, destroy all the queen cells in the old hive but the two best, or give them a laying queen after destroying or removing all the cells; put in an empty comb or frame of foundation in place of the one removed to the new hive, spread the blanket over, or put on second story with sections or extracting combs, and place the hive on a new stand well removed from the old one. The above methods are usually an effectual cure for "swarming fever," and interferes but a few hours with work.

Another method which can be practiced with good results, is to examine the colony threatening to swarm, remove all queen cells started, then remove the hive to the stand occupied by a very weak colony, and remove the weak colony to the stand formerly occupied by the strong colony. In strengthening and depleting in this manner, however, it is much safer to confine each queen on the surface of a comb in her respective hive for twenty-four hours, to protect her from the returning bees, which sometimes regard her as an intruder. For this purpose a cap from a Harris introducing cage will be found best.

In all cases where foundation or empty combs and division boards are used in dividing or artificial swarming, care must be used to spread the brood chamber and give additional combs or foundation as fast as the bees are ready for it. Use good foundation in preference to doubtful combs.

A House Apiary in Italy.

The Italian monthly periodical, *L'Apicoltore*, published at Milano, Italy, furnishes a long descriptive and historic sketch of the very substantial building to accommodate about 150 colonies of bees with a permanent home, provided by that eminent bee master, Signor F. Bianchi. By the engraving on this page it will be seen that there is an observatory tower and *horloge* (clock) at one end, and a two-story tower and flag staff at the other, with an elevation for a "study" over the passage-way in the center.

MISCELLANEOUS.

Queer Industries in New York City.

—The following item, clipped from the Lewis Co., N. Y., *Democrat* of Feb. 23, 1881, was sent to us by Mr. N. F. Case, of Glensdale, N. Y., who wants us to "notice" it:

The investigation of the census men have led to some queer developments in the manufactories of New

are filled with glucose, which is the sweet syrup of common corn, and looks and tastes like honey. The cells, once filled, are closed by smearing a hot iron plate over the wax tops, and the product is sold as the "best clover honey." It is in great demand, and outsells the regular honey. Gallons and gallons of the best tomato catsup are made from the tomato skins which are purchased from the great tomato canning establishment.

There are frauds enough to enumerate the real ones, without adding the fanciful stories about fraudulent comb honey, which are but the vague imaginations of some "crank." There is no truth in that part of the item.

Apiary of Signor F. Bianchi, in Italy.

The hives in Italy have doors at the back, for examination and manipulation—the interior of the long building is, therefore, used for that purpose.

The whole building has a substantial appearance and is very attractive not only to the bee-keepers of the surrounding country, but to Italians in general. There the care of bees is a pastime and study for the wealthy and learned, and such a building is a *pride* to its owner; but here, where bees are kept more for the money that can be made out of their labors rather than for a patient study of their habits and peculiarities, such a building is not desirable; and on many accounts would be decidedly objectionable.

York and adjoining cities. The largest single industry in New York is that of custom made clothes. The making of paper patterns employs hundreds of hands, and, ten large houses being engaged in it, use tons of paper. There are factories for making dried blood, the dummies that milliners use to show dresses on, theatrical armor and jewsharps. The use of adulterating substances is getting to be general. Castile soap is made of grease and terra alba, or white earth, and which earth is used largely in candy making. Glucose, which is corn starch, is used heavily by the sugar refiners. There is a firm engaged in making honey and honey comb. The honey comb is made by machinery of paraffine wax, and is an exact imitation of the regular thing, except that the bees fashion their cells of walls only 1-125th of an inch wide, while human artificers have not yet become that deft. The cells

Too Much Honey.—The Los Angeles (Cal.) *Times* tells this story:

Eastern people do not always appreciate the scale upon which Californians lay out their work. A case in point, is that of an eastern merchant who wrote to a Los Angeles County bee man for a sample of his extracted honey. His request was complied with, and the merchant was so well pleased with the appearance and good quality of the honey that he sent an order for all the man had like that. The gentleman, thinking the merchant might not be reckoning on the amount he had in stock, wrote him that he had 16 tons on hand, but that he might as well make it 20 tons, which would be just 2 car loads, and that he would ship it immediately. He received a telegram a few days after, saying: "Keep your honey! I only want a case or two."

For the American Bee Journal.

Bacterium—Its Relation to Dysentery.

GEO. THOMPSON.

Ever since the BEE JOURNAL was started, dysentery and its cause or causes have been more or less discussed; but of late there seems to be a growing desire to thoroughly investigate this so-called bee disease. Beekeepers are becoming conscious of the fact that a knowledge of the causes and prevention is as necessary to successful, and therefore profitable bee-keeping, as bee pasturage. I have watched and read with much interest the divers opinions upon the subject, and I think from present indications the time is not far distant when all the facts will be generally understood and settled. I have never taken much stock in the pollen or bacteria theory, because I think the reasons given are not tenable. What is bacteria? According to the well-versed in science in this country, and in Europe as well, bacteria is found everywhere in decay and fermentation, and in looking over the "Library of Universal Knowledge," I find the following description: "*Bacterium*—a minute and low form of vegetable organism, refractive, spherical and mobile. It occurs as a fossil; is found in the sap of plants, in the fluids of men, animals, insects, larva and eggs; is abundant in incipient stages of fermentation and decay of animal and vegetable tissues and substances. Bacteria act as a ferment, changing cane sugar and starch to glucose. They are communicated as germs floating in the air; they assist in the ripening of fruit, and in the regeneration of organic matter during the formation of cell structure. They thrive equally well in acid, alkaline or neutral fluids. Many phenomena, otherwise attributed to spontaneous generation, are caused by these minute and omnipresent organisms."

The above, in a very clear and succinct manner, informs us what it is, where it is to be found, and what it accomplishes. It is no reason, to me at least, because bacteria are found in fermented pollen or honey, that they are the cause of dysentery. As well might we say if a man has the same malady, that bacteria was the cause of it because they are found in his food, and in the very air he breathes. As well might we argue that an animal is brought into the same condition by eating decayed vegetables, because they are found there. I consider that this state or condition is brought about, not by bacteria, but by a changed condition of food.

Geo. Grimm, in February *Gleanings*, has an excellent article upon the subject, one well worth reading three times over. And on page 104 of the BEE JOURNAL is an article by Chas. Dadant, one of the best I have ever

seen. I believe with him, that diarrhea is a more appropriate term. I have often questioned the propriety of calling it a disease, for in the most of cases a good cleansing flight is all the remedy the bees require. Geneva, Ill.

For the American Bee Journal.

The Coming Bee—Its Production.

THOMAS BALCOMB.

Not seeing much of late in regard to the "coming bee," I hope the suggestion or two I make will not be out of place. I have taken considerable interest in the articles that appeared from time to time in the BEE JOURNAL upon the coming bee, and I think it hardly advisable to let so important a subject cool down, considering its great importance, and the vast field that is open for study and practical experiments.

I have no doubt that there are many apiarists whose greatest wish is to produce that coming bee, and are working their apiaries with that object in view. But, on the other hand, there are those who ridicule the subject, and think the coming bee will never come. Be that as it may, it is evident that there is a great variety of opinions upon the subject, also upon the qualities of the various races of bees, for there are very many that consider the Italians good enough, and others that can see a superiority in other races over the Italians, and even a few that prefer the black or German bee to the Italian.

As this coming bee must have the desirable good qualities that are now disseminated throughout the various races of bees, and as opinions differ so much in regard to these various good qualities, it may seem difficult to many where to make the starting point to produce this coming bee. I have no doubt that if the matter was left to itself, that in the distant future there would be *Apis Americana* from natural causes, inasmuch as the Asiatic and other races of bees are getting introduced and disseminated throughout the land, they must in the course of time get so hybridized that a distinct variety of bees would be the result, best suited to the climate and surroundings. For any one man to undertake to produce the coming bee, I think would only result in a partial failure. True, the apiarist that can control a considerable area of country can, by a careful selection and crossing, produce a superior strain of bees; but with such a variety of climates and opinions, it is doubtful in my mind, whether the experiments of a few would benefit the apiarists of the country generally.

Still, notwithstanding the many difficulties that stand in the way, I think much good would result by co-operation in which many might participate to help to bring to light *Apis Americana*. I think that if a society was formed of the advanced apiarists of the country for the purpose of accurately testing the good qualities of the various races of bees, then, by a

careful system of crossing, I think something definite might be arrived at, but even with the formation of such a society, it will take many generations of bees, and many failures, before anything satisfactory is accomplished; therefore, at present, I see nothing to indicate a near future for the coming bee. That should not deter those that love our interesting occupation from experimenting and improving their bees.

The coming bee must arrive sooner or later. The possibilities of fertilization in confinement are so few, that we can hardly expect any assistance from that source, unless experiments are conducted more extensively, which could be done by the same society. I think success will seldom be reached by those who conduct their experiments on a small scale, such as boxes, barrels or the like, for I think the queen, like the higher order of animals, has her period of heat, therefore to be successful, I think some kind of a structure will have to be erected in which heat and light can both be regulated and so arranged as to accommodate several hives containing the queen and drones to be mated; but each hive to have two entrances, one opening on the inside of the structures, and the other covered with perforated tin, opening on the outside. Even then many failures will result from the queen being able to pass through the entrances that were only intended for the workers.

Luling, Tex.

For the American Bee Journal.

A Standard Frame.

W. J. DAVIS.

The action of the British Bee-Keepers' Association, as reported on pages 179-180 of the BEE JOURNAL for March 22, comes so near my own views of the right size of frames for the brood chamber, that I will take the liberty of reporting my experience with frames.

I have used the standard Langstroth frame for 21 years. I think the depth of frame right (viz: $8\frac{1}{2}$ inches, inside measure). But I am convinced that for this latitude it is too long. It is a point that all skillful apiarists of the colder parts of our country agree upon, that the size of the brood chamber should be contracted, during winter and spring, for the better husbanding of the heat generated by the bees. It is also a fact that when the bees of a colony cluster for mutual protection against the cold, they form as near a sphere, or ball, as their home and combs will admit of, and no one will question but what that shape will expose the least number of bees on the outside of cluster. Now it follows that if the compact cluster of bees be 6 inches in diameter (and such a colony would be considered a good one in the month of March), and the combs be 18 inches in length, from front to rear, they occupy in the greatest diameter but $\frac{1}{2}$ the length of the hive when reduced to its smallest size by the use of division boards. The unoccupied part

of the combs would remain cold, or warmed at the expense of large consumption of stores, if not in comfortable winter quarters. With this view of the matter I made a frame with 14 inch top bar, making a frame $8\frac{1}{2} \times 11\frac{1}{2}$, inside measure. For top bar and ends I use $\frac{3}{8}$ stuff, $1\frac{1}{8}$ inch wide. I have used them 2 years, and can say that for both winter and summer I am highly pleased with them. I have at present 35 of my colonies in short frames. They are simply the Langstroth frame shortened.

I do not write with the view of having any one adopt the size I have mentioned; neither do I claim that it is the size, but I will venture to predict that for all localities where it is necessary to economize the heat of the hive for 7 months of the year (as is certainly the case in this locality), shorter frames than the original Langstroth will grow more and more in favor with bee-keepers. There are economic reasons for the use of short frames even in warmer latitudes, which I may mention in the future. The Rev. George Raynor rightly says: "The size of the frame does not necessarily fix the size of the hive."

Youngsville, Pa.

For the American Bee Journal.

Reply to Messrs. Demaree and Casson.

JAMES HEDDON.

Probably the discussion of the bee question, and best way of getting better ones, has gone as far as the readers care to go with us. We have had a good time, and I, as one of the disputants, have enjoyed the discussion, if no one else has. I like to read all of Mr. Demaree's articles, because they possess that vigor of expression that the lover of literature relishes. I cannot, however, refrain from making a statement, the truth of which is only equaled by its plainness, which is, that it seems to me Mr. D. is lacking in clearly understanding my premises and drawing logical deductions from them. Perhaps I do not make myself clear enough:

1st. I believe the best bees that have ever been imported to this country are Italians, and that they are the longer-bodied, darker-colored variety.

2d. I believe that while these bees are the best, all things considered together, the brown German bees are in several leading and important peculiarities, superior to them and all others.

3d. I believe that traits in bees are hereditary, and that the better way to get the best bees quickest, is to cross these two races, and in so doing breed in the desirable, and out the undesirable qualities of each, to the best of our ability.

4th. If I can understand the sentences penned by Messrs. Doolittle, Root, Langstroth, Newman, and last, but not least, Chas. Dadant, these gentlemen think about the same. Trusting to the memory of the reader, I do not think it necessary to quote from these writers. True, Mr. Davis, a gentleman of integrity and experi-

ence, has returned to the goldens, but yet, if he has not some goldens of far more illustrious habits than the ones I purchased from him some ten years ago, he has yet something of great value to learn.

This country is full of experienced men, such as E. J. Oatman, and the Dadants, who would be very hard to convince that Mr. Davis, or any other man, had any bright Italians equal to the leather-colored variety. He undoubtedly thinks so, but I do not, and cannot, though it is ever so true. I have not had the evidence, and owing to the fact that I have had such a good chance to have it, I doubt its existence. Back numbers of the BEE JOURNAL show that Mr. Dadant understands the argument of Mr. Demaree to be against the virtues of the leather-colored or dark Italians; so do I. Whether these dark bees are pure or hybrids, that they are the best, is the claim that Mr. Dadant and others of us urge. In speaking of Mr. Dadant and myself, Mr. Demaree says: "The only wonder is that a man of his (Dadant's) experience, should be slow to learn that the imported Italian is a hybrid. It is not so surprising, however, that a person holding such views as those propagated by Mr. Heddon should be found in darkness." I shall have to say to this, as the Chicago Times did of J. Cook's lecture: "One hundred dollars reward is offered for any man that can tell what Mr. (Demaree) is talking about."

Then he warns me that hundreds of bee-keepers are going right on breeding up to the highest point of excellence, regardless of my opposition. To this I reply: You who have read my views on this subject, tell me, is this lawyer insane?

I can hardly suppose it would become one who believes the golden Italians to be "hybrids in character," to make such a dreadful fuss about a little more hybridizing with so valuable a bee as the brown German, especially when governed by the wisdom of American bee-keepers of the nineteenth century. I did not say that I was "aware" that leather-colored bees were hybrid; I said I suspected it, and wrote so among the first, or was the first. I thought best to leave it to such explorers and experimenters as Mr. Dadant, to become "aware."

Mr. Demaree objects to my witnesses, ostensibly because their names were not given, but perhaps because they do not testify to suit him. I have known lawyers to do just such things. I may have failed, but I have sought to gain a reputation for common honesty where there was nothing at stake at least, and I was led to think that if I said that these men were of experience and well known to be such, and wished their names kept private to save postage stamps and time, that my word would suffice. I think so still. In this respect I am willing to grant to others all I ask for myself. I see no proper comparison between the precision of witnesses in this discussion and a case tried in a Justice court. Does Mr. Demaree

not hold some stories as divinely true, whose witnesses lost the cheerful habit of living in this world, some hundreds of years ago? I see no proof sustaining Mr. D.'s premises, from his "live witnesses." I have met and talked with Messrs. Jones and Poppleton, and I have corresponded and heard something semi-occasionally from Messrs. Davis and Doolittle, and truly, I should be surprised if I found on inspection, their bees more yellow than my own. Messrs. Poppleton and Jones run for extracted honey, and they do not miss the lack of comb building qualities in their brightest yellow bees, which they may possess to some extent. None of these men had any special strain of crossed bees to compare side by side in the same field and season.

In what I quoted verbatim from a man of close observation and study, and one who makes honey production his entire business and support, and not a side issue, I showed to all who are willing to credit me with that common honesty which would not fabricate something from nothing, that well bred crosses can "gather a large yield," where there is "but little nectar," or "none to be gathered" by the golden Italians of the amateur.

I wish to thank Mr. Casson for his kind words and manner of giving timely caution, in regard to high board fences, and no one can doubt that his experience in regard to the house proves that house shade on certain days is dangerous to some loaded bees; but it also proves that there is a difference between houses and fences, because, though I have kept my bees for more than one-half of my time in yards surrounded with high board fences, I have never seen the loss of a single bee result from it. We are told that bees make from 4 to 10 trips daily, each; that they can fly from 1 to 4 miles per minute, and that the time is mostly used up in loading and unloading, etc. Now, if you have a yard of $\frac{1}{4}$ acre in size, and a bee starts from one fence and flies over the opposite one, the elevation is so slight that I think it hardly worth our mention, and those near the fence that is between them and their direction, pass out and into the yard by a circular motion that loses not more than one-thousandth part of the time occupied in that trip. So far as I have ever been able to determine the losses by rise and fall of lines, and shade in cool weather, has been tenfold offset by the gain of shade in hot weather, and more especially by time saved from idle gossippers and thieves, children and stock getting stung, and nervous people fearing the same. When I start another apiary out in the country, perhaps I will omit the fence and use barbed wire, and then if I get twice as much honey, I will let you all know it, by the "brandishing of my little pen."

I am just making into kindling-wood 100 bottom-stands that had slanting alighting-boards. I used them till they were too old to be of service. I used them because I had them. I have made none but square ones for the past 7 years. My bees

prefer crawling up, to crawling down hill, loaded or unloaded. (No bred-in trait, they had it when I first obtained them). When one of them would alight just enough below the top of the slant of the alighting board so he could not see over, he would puff a few times and rise on the wing to see if he was surely all right about location. I shall waste no more time beveling boards.

One of my witnesses (the fellow who obtained no surplus from the "goldens of the period,") still enjoys the cheerful habit of living in this world, and writes that he is ready to be cross-questioned upon Mr. Demaree's witness stand. His name is J. Vanderwort, Laceyville, Pa.

Dowagiac, Mich.

For the American Bee Journal.

Yellow, or Leather-Colored Bees.

J. A. BUCHANAN.

Quite an animated controversy concerning the color of the Italian bee has been vigorously conducted in the BEE JOURNAL of late, and I am pleased to see it, since, by the discussion much valuable information, and no little fun, has grown out of it. Practical bee-keepers, of unlimited experience, have long since become aware of the fact that the dark leather-colored Italians are superior in nearly all respects to the light-colored bees. It is true that in selecting and breeding to obtain a light color, an occasional colony will prove to be very good honey gatherers and comb builders, but this is an exception, and not the rule.

Since the summer of 1865, I have been experimenting with the Italian bee. Prior to that time, I felt a great anxiety to test that race of bees, but serving in the army and bee-keeping would not go well together. Since that my specialty has been the cultivation of the Italian bee. For the first ten years I spared neither time nor expense in my efforts to produce a strain of bees that would have no superior as to lightness of color, and at one time it was gratifying to me to have my visitors acknowledge I had the finest colored Italians they had yet seen; but they were a miserable failure in almost all other respects. They were poor comb-builders outside the brood department, were generally light in stores, weak in the spring, and by no means equal to the old black bees. I had my satisfaction in color, but it became necessary in my case to get some profit, and I was about to give up the business, when I was advised by a friend to send for leather-colored stock. This was done, and I soon became satisfied that they were greatly superior to any bee I had yet seen. Here my views of the Italian bee changed again. The first impression I had was that there must be some blood of the German bee introduced into their make-up, and am still of opinion that this strain was procured from districts in Italy where still exists blood of the black race. Although this dark strain of Italians

has the appearance of a hybrid whose blood of the yellow race predominates, there is in its nature nothing that would lead one to believe it a cross-bred bee. There is no disposition to become alarmed and rush down off the combs, and quarrel with the operator, as do the hybrids of this country.

For some years I have been experimenting in crossing the blood of the German and Italian bees, and am convinced that by a judicious system of cross-mating the two races with a view of correcting the defects found in both, we can produce a strain of bees having the good qualities of both united in one, and but few, if any, of the objectionable points retained. The German bee possesses some valuable traits not found in the Italian bee, and of course some very undesirable traits, prominent among which is the disposition to allow the moth worm to overcome them at times when weak in numbers, and their annoying habit of dropping from the combs while being handled. Both these, as well as other faults, may be corrected by the introduction of some blood of a strain of Italians possessing great perseverance and gentleness of disposition.

It is my firm belief that the "coming bee" will not be of any pure bred race. To those who are selecting and breeding their very choicest yellow Italians, expecting to produce a strain that will outstrip all others, I want to say, you may spend your whole lifetime at this and then you will have no better bee for profit than you can produce by crossing the German and Italian races.

To advocate the breeding of anything other than the golden-colored Italian, is to bring down upon our heads anathemas, thick and heavy; but as I am an old and confirmed sinner on this subject, and have plenty of good company traveling in the same boat, I have no need to feel alarmed about my wayward condition. Holliday's Cove, W. Va.

Do Bees Excrete a Dry Powder?

WM. J. WHITEFIELD.

In the BEE JOURNAL of Jan. 11, 1882, page 26, Prof. A. J. Cook says: "I have never found any support of the theory of the late Mr. Quinby, that bees excrete a dry powder in winter." What I wish to know is this, if bees young or old, when in a perfectly healthy condition, let it be summer or winter, do not void their feces in a dry powder, how then? I have thought they did so for years. I have had bees confined to the hive for over 5 months, so they could not get out of the hive, and when liberated in the spring parted with nothing that I could see, but would leave a large quantity of dry powder on the bottom board. This I always took for their excrement. In my opinion, any plan for wintering that does not look to this end is at fault. I have gone to quite a heavy expense with this end

in view with my bee-house, and if it should fail to bring about this result, I shall consider it a failure, for I know I can accomplish it out-of-doors; but with a number of hives it is a great deal more trouble and expense. Now, if Prof. Cook will agree to fix one or more hives this fall as I shall direct, I will give a plan, and he to report the result through the BEE JOURNAL, that will keep bees confined to the hive for 6 months, and at the end of that time, when liberated, will void nothing but a dry powder, and if he wishes to see what they void through the winter he can put a dish under the hive and collect it. I shall put him to some trouble, but not much expense.

The plan is this: Take a bottom board 3 feet square, nail it down on a 3x4 scantling just at the two ends, put this on 2 more pieces; fix it to face the south, the scantling to run east and west in the center of the bottom board; cut out a piece 8 inches square, cover this with wire-cloth as coarse as you can get and not let the bees through; now, from the end of the wire-cloth to the end of the bottom cut out $\frac{3}{8}$ inch deep by 8 inches wide, for an entrance. If you have not a close-end frame hive, you had better use a box hive, for you must not let the bees get off the combs, as they will surely do if you use any of the hanging frames that I have seen; the hive must be not less than 1,800 square inches; 2,000 would be better; must be filled with combs and bees, and have not less than 35 lbs. of good honey. On the first of September set the hive on the bottom board just over the wire cloth; have it fit tight down on it all around, put a piece of board on over the entrance where the $\frac{3}{8}$ was taken out, to come from the hive to within 1 inch of the front, put a 3 foot square box on the bottom board. This must be 3 feet high, well made, so that it is tight; fill this in with dry sawdust. It must be dry, well packed down, and well covered. The finer it is, the better. Put a piece of board on under the wire-cloth; have it fit tight. It will be well to rub a piece of tallow on the wire-cloth, or the bees might wax it over; now leave it entirely alone. Let the bees wax it up tight all around the bottom, top and sides; let them carry in all the pollen they wish to. About the middle of October close up the entrance tight, and take away the board under the wire cloth, to give the bees air. Have another box ready to put over the first, just 1 inch larger, made tight and well covered; let it come down just 3 inches lower than the bottom board and rest on the same pieces that the 3x4 scantling does; keep it up 2 or 3 inches from the ground, to let the air pass freely under all. Do not touch it again till the yellow willow is in bloom, then just at dark take away the outside box, open the entrance and let the bees out, clean all dead bees or dirt there may be in the way, so you are sure they are free to get out, put on the board under the wire-cloth and get up the next morning to see them fly out. I think you have got the powder all right, and that the bees will void nothing on flying out first.

The idea is to prove or disprove the theory of Mr. Quinby, and as we let the bees wax all tight but the wire-cloth, we must keep them warm and dry outside of the hive. Have it so they do not know when the weather changes, let it be hot or cold. The bees will send all the moisture out below, if they do not feel the cold above or on the sides.

For the American Bee Journal.

How the Grapes are Destroyed.

M. RICHARDSON.

There appears to be a mistaken idea with a good many about bees biting grapes. It seems to me that among men as sharp as the bee men are about most things, there need not be such a diversity of opinion. In the first place, I will say that I know as well as I know anything that they do not do it. Let us take a little close observation and see if we cannot prove how they are opened. All that I have seen were as follows: The skin is picked up near the top of the grape and torn down the grape, usually the hole growing wider as it descends, and the skin left hanging in a sort of tag about half an inch long. The skin is not bitten on the sides of the wound, but torn from the top where it was first taken hold of. Now what kind of a bee could take hold of a grape skin and tear it like that? If it had hold of the end with its teeth, it would have to stand on its two hind feet, and be able to tear both sides at once, which no honey bee living is half strong enough to do; and more than that, if a bee will not bite through a red clover blossom where there is plenty of nice honey to be obtained, she never would bite through a grape skin, which is three times as thick, to get at a thin, watery juice, that she will hardly suck at all until the sun and air have dried and sweetened it. Then she will work on it some and buzz around it a great deal, and a careless observer is ready to lay it to them, simply because they are there and he does not see anything else to lay it to.

My son lived near me and raised a good many grapes, and I kept bees. He kept complaining to me that my bees were destroying his grapes, it was too bad, etc. I had some grapes between my house and barn, which were torn in the same way, that I passed often, and I did not have to watch long to find out where the trouble was. I pointed it out to him, since which I do not hear any more about my bees destroying his grapes. The marauder was the oriole, fire hang-bird, red bird, or English robin, for it is known by all these names in different places, although the red bird is a darker red, and lives in the woods. I suppose grape growers will expect to see the bright peach-blow colored bird that is seen and heard in apple blossom time, tuning up his song of gladness as he hops among the flowers. The oriole, like the turkey and some other of the male birds, is nearly

twice as large as the female. The female is a small, brown bird, with a tinge of yellow and some light spots on close examination, but at a little distance looks brown, and the young ones are all of the same color until they shed their down, which they do at the south in the winter. But when you see a small, brown bird, that might be easily mistaken for a sparrow, that seems to come from the top of a tree or the clouds, and flies right into the leaves of a vine—for they seldom light where they can be seen, but go very quietly, and when you drive it out, lies right into the leaves again to alight, and as he flies says, quink, quink, quink—that's it every time. They make another loud chattering noise when disturbed, but not as often. Look where it started from and you will find fresh work. What satisfaction it is for it to pick open so many grapes (it will do a hundred in a few minutes) when it does not eat three, I do not know; but I suppose it tastes the juice and looks for a sweeter one, and when it gets enough they don't taste so good, and it keeps looking for one that tastes better, as children do when they go into an orchard. It is just as bad on sweet corn, only that the husk makes so much hard work that it is glad to stop when it gets enough. I have had them tear open bushels of wild-goose plums when ripe, red and soft, and followed them around the orchard to get a shot at them; but they would always fly out from the opposite side of the tree and keep behind it till they reached another, so I could not shoot without putting the whole charge into the tree top. They seldom alight where they can be seen, and seldom remain still long. Adam laid the taking the forbidden fruit to Eve, so here it is the female and young ones who generally do the harm. The males seem to leave very early and go by themselves. Wild turkeys do the same, the old gobblers go in a flock by themselves, and the females and young ones in another, as soon as the mating season is over.

For the American Bee Journal.

Lower versus Upper Ventilation.

R. CORBETT.

"How shall I winter my bees to insure success?" is a question which no doubt occupies the minds of many apiarists at the present day, and even at this season of the year. I have read the many plans set forth in the BEE JOURNAL, and, from my observations, I do not wonder that many fail.

I have been handling bees for over 50 years, in the old box hive, until 1865, and I think I have gained much knowledge from my experience. My memory carries me back to the winter of 1831-32, when there was a snowfall early in January to the depth of nearly 3 feet. The wind changed to the northwest, and blew for over 6 weeks, never changing its course, the mercury ranging from 10° to 20° below zero, and one or two days at 28° below. That winter my bees stood on a bench

two feet from the ground. The hives were raised from $\frac{1}{2}$ to 1 inch, on blocks, open all around the bottom, and out of 17 colonies 16 came through strong and good, while the other starved for want of honey. The bees had not the least bit of ventilation at the top, not so much as to exude their own moisture, which proves that upward ventilation is not necessary. However, I think that bees do need something to absorb their own moisture, but no direct draft.

There are some points in the shape and size of the hives essential. In the case alluded to, I think the hives were 17 or 18 inches deep by 10 inches in the clear. In those primitive days we had no holes cut through the comb for bees to pass through for their food. The honey being above them, it was kept from freezing by their own heat, therefore it was always soft and moist, and ready for them to partake of when they were hungry.

I will refer you to a couple of instances I have read of. Dr. McClain, of Oskaloosa, Iowa, I think, concluded to test the problem of wintering, by putting some in a cellar, burying some, leaving some on the summer stands, and for one he drove 4 stakes in the ground, nailed cleats on the sides of the hive, and hung it by the cleats on top of the stakes, with the mouth 10 or 15 inches from the ground. This hung there for 5 successive winters, good and strong, and how much longer I have no information.

Another gentleman, a Mr. Jackson, for an experiment took one of his colonies and hung it 4 or 5 feet from the ground, against the side of his house, and there it remained 3 successive years. In both instances the month of the hive was open full size of the hive. As we do not have 3 or 5 winters in succession without a severe one, I think this goes far to prove that downward is what is needed, and not upward—all other conditions being right. Neither method will save them without provisions of the proper kind. I hardly ever lost any bees that had enough to live on. Once I lost all I had (9 colonies) well filled with bees and honey. I thought I would do things up in a nice manner, and closed the hives all up around the bottom with the exception of a small entrance. I then covered them around the outside to shelter them from the winds and storms, and just smothered them. (This was before I read the BEE JOURNAL.)

Now when I fix my bees for winter, I take the oil-cloth from the top of the frames and lay on my quilts, pressing them down tight at the sides, and using some weight to hold it well in place, then fill with some absorbent and put on a good cap or roof to keep all dry. This is sufficient for the top without any other ventilation. For the bottom I have a manipulating block 2x10 inches with $\frac{3}{8}$ or $\frac{1}{2}$ inch taken out of the bottom of the block for a passage-way. This can be removed when they get a little uneasy, as they sometimes will in the cellar.

From what experience I have had in wintering bees, and from observations for a long time, open bottom

hives are the surest and safest for wintering our pets, whether in or out of cellar, and the plan I have thought of is to take 2-inch planks, 8 or 10 inches wide, set on edge by nailing cleats across the top to hold them firm the width of the hive, or we can take 3 and make a kind of trough, to secure them from the mice. This plan keeps the bees and combs free from all filth that accumulates on the bottom of tight hives, also from stench, which is very offensive, and, I believe, injurious to the bees. Let it be understood, if out-of-doors, they will need the same protection as any other plan. I do hope some of our progressive bee-keepers will try this plan the coming winter, and report conclusions the following spring.

Read before the Marion Co., Ind., Convention.

Spring Management of Bees.

MRS. C. ROBBINS.

The first thing to be done in the spring with bees, is to open the hive and examine each colony, ascertaining whether there are sufficient stores and a queen with which to begin spring work. I have come to the conclusion that we open our colonies too early. We know that every time we disturb them we excite them more or less, and, therefore, they consume more stores. We also know that the bees that have lived over the winter have only vitality enough to rear the bees that collect our stores in summer; therefore we should spare them their forces until the proper time, and not excite them to premature vitality. We know also that eggs laid very early in the season, if there should come a cold snap, are chilled and have to be carried out.

Every apiarist should know whether his bees have enough stores or not to last until natural pollen can be collected, also whether his hives and bees are dry or not. If enough food, then do not open the hive until the bees collect natural pollen. Then we know that the spring is open and that breeding begins in earnest, and that the labors of the bees and apiarist have begun for the season. Even yet, I would not advise removing any of the packing that may be around them. I doubt much the policy of contracting the brood chamber in the spring. Here is one hive, we leave the frames all in that have been in all winter; when the weather is too cold to fly, the bees will clean up the combs and carry the honey from the outside combs to the brood combs in the center, thus giving them employment and not exposing them to bad weather (when the bees are busy we are not troubled with robbers), and, above all, saving the apiarist so much work feeding and putting in extra combs every few days.

Beside this hive stands another. Very early in the spring, or, rather, in the latter part of winter, we open the hive, take out the outside combs that have quantities of stores in them, stir up the bees, looking for a queen that we should be pretty certain was there from thorough examination and ample preparation in the fall, put in feeders and warm syrup. By that day's work we have taken the initiatory step to spring dwindling and robbing. As we know that it only takes 6 weeks to build up a weak colony into a very strong one, if we begin the first of March, we will have our colonies ready by the middle of April, and our honey crop in this locality is not collected until the last of May and in June.

☞ The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.

Christiansburg, Ky.

Bee-Keeping in Maine.

The following are extracts from the opening address of Mr. F. O. Addition, President of the Maine Bee-Keepers' Association, at Dexter, Me., on Feb. 9, 1882:

The year of 1881 has passed away with its failures and its successes, leaving us wiser by our experience, and better fitted for our several duties in the future. Those engaged in apiculture came through the demoralizing winter of 1880-81 in many cases with but poor courage to begin another season; and the present winter may be even more disastrous. But be not discouraged; try again, and if "luck" is what makes success in bee-keeping, it may be a good turn next.

We can hardly realize the progress of apiculture in this State for the last half century. Although we are as a State still far behind some of our sister states in the quantity of honey produced, we rank among the first as to its quality; and when we become more thoroughly awake to this branch of business, with the territory we have, capable of supporting large apiaries, where from year to year the flowers blossom and die without the hum of the busy bee (except now and then one from its leafy home), when we get this vast territory to yield to us its golden nectar, then we will have for our motto, as bee-keepers, the motto of our state: *Dirigo*: "I lead."

Now, a word about this Association: It is important that we sustain it, as it is what we have long needed in Maine. Other states have their bee associations, and among their numbers we find some of the most successful bee-keepers; and this one, if properly managed, will do us a great amount of good. Although our numbers are now small, yet we must persevere in extending bee-culture more and more, until the dream of the poet shall be realized:—

"Each household of an aptary possessed,
Bee-keeping followed with unflagging zest;
Honey and milk shall flow all countries through
And home, sweet home obtains a meaning new."

There is a certain amount of pleasure which one derives from the care of bees that is both healthful and enjoyable, and if we can only get a fair interest on our money invested, and a reasonable compensation for our time, we should be satisfied; and this any wide-awake apiarist, with the improvements which have been made in bee-culture, can do.

☞ The semi-annual meeting of the Tuscarawas and Muskingum Valley Bee-Keepers' Convention, will be held in the Town Hall at Coshocton, O., on April 19 and 20, commencing at 10 a. m. A cordial invitation is extended to bee-keepers everywhere.

J. A. BUCKLEW, *Sec.*, Clarks, O.

☞ The Champlain Valley Bee-Keepers' Association will hold their semi-annual meeting at Middlebury, Vt., May 11, 1882.
T. BROOKINS, *Sec.*

SELECTIONS FROM OUR LETTER BOX

Artificial Comb Honey.—Yesterday one of our grocers, with whom I had frequently disputed in regard to the possibility of making artificial comb honey, triumphantly shoved the inclosed paragraph in my face, with the usual "I told you so" clearly marked on every feature. The article was in the *Grocers' Criterion*, published in Chicago. I should like to have the reply come out in the Monthly BEE JOURNAL, so I will get to see it.

J. H. HASSLER.

De Pue, Ill., March 16, 1882.

[The article referred to was that published in the BEE JOURNAL of Jan. 25, page 51, and accredited to Prof. Newton. We have so often denied the probability and possibility of the imposition being practiced, that to do so again at length would be a waste of time and space.—Ed.]

Prospects Cheering.—What bee men are in this part of Michigan all have the cheerful words to say, "My bees are coming through all right." I have heard of but 7 colonies being lost. We have had no zero weather this winter, with warm days every few weeks. Last spring I had 30 very light colonies left out of 101; now I expect to go through with my 70. I see the matter of bee feed is being talked up by many; well, I feel like falling in that line myself, as I intend putting in 10 acres this spring. Having sold our place here and bought again at Glendale, Mich. (my correspondents will please notice the change), a very good bee location. I intend making bee-keeping a specialty. Your *Apiary Register* I think is just the thing, but the large size which I have is rather bulky to carry in the pocket. By having a small memorandum, and then copying at your leisure, I cannot see but what it will be a great help in improving the quality of our bees. I wish every bee-keeper had one.

G. W. NAFTZGER.

South Haven, Mich., March 25, 1882.

The Secret of Success.—We see many ideas as regards bee-keeping. We find the great secret of success is in well wintering and the care exercised that they do not get too warm, or in too cold a place, so they cannot move. I find that the best temperature for wintering is at freezing, and good ventilation to take off the foul gas. The past winter bees did well in most any place. There are more bees lost from starvation than most any other way. They may starve with 30 or 40 lbs. of honey in the hive, *i. e.*, the thermometer may stand from 20° to 30° below zero for 30 to 50 days. The bees are clustered all that time without any food to keep up heat, and thus perish. I am satisfied that I

have lost bees in this way. When bees are smothered you will find them all through the hive; when they freeze they are in a compact body; when they starve, the cluster is loose, with now and then one getting to the cells for supplies. Bees should have as careful attention as stock on the farm. Bee-culture is like any other business—more lose money at it than make money. Bees are in a booming condition here. THOMAS PRALL.
Carlisle, Iowa.

A Voice from Egypt.—I see in the BEE JOURNAL a good many communications from Illinois, but none from this part. I wish people would give the county, then when I look on the map I could locate them; they seem so like neighbors. There is not much interest taken in bee-keeping here. They claim they have no "luck" any more—"the moth eats them up." "The gude mon" saw a neighbor this morning we had heard was a great bee man; found his bees in all sorts of boxes, but he was quite elated at the prospect before him. He had just heard of some kind of hive that had frames a person could lift out and look at, also just heard of extractors—was bound to have both, for he had been informed he could take 8 lbs. a day from each colony. This man is a preacher, and if preachers wake up who knows what will be the result? Well we cannot brag much. I like James Heddon, he says *we*, and believes in women's rights. I think all the James do. When we came on our farm, two years ago, we did not know a drone from a worker, and never saw a queen, and the first two colonies we bought, one was dead with about a teacup full of dead bees. Instead of 8 lbs. a day, we had 15 colonies to feed last summer from the 20th of July to the last of August, when, thanks to a kind Providence, the rain came, and and bees filled their hives and gave us about 100 lbs. of surplus. But I thought we had an elephant on our hands, and did not know but we would have to feed all winter. After tinkering one year, we concluded we must have a bee paper. We supposed there must be one somewhere. Accidentally we saw a list of bee literature in some paper, and found the country was flooded. We decided on the *Bee-Keepers' Magazine*, but found a once-a-month bee paper too much like the "once a month" preaching down here in some places—a slow starvation. The BEE JOURNAL fills the bill. To make any business a success, we must understand the whys and wherefores. It seems bee-keeping has more whys and wherefores than any other business. Now I want to ask two or three simple questions—very simple to those who know. 1. Why should frames be hung from front to rear? We have them both ways; they were hung that way when we bought the hives, and we want the best way. 2. When is the best time to divide bees—before the white clover or after, to get the most honey? 3. We found a plant on our farm that I have been unable to find a name for. Our attention was

attracted to it the 1st of September, by the great number of bees on it. We found only five plants, although we looked far and near; about 5 feet high, branching like mustard, a small pink and white blossom similar to radish bloom; applying the tongue, found the blossom very sweet. I do not know how long it had been in bloom. I found bloom in November, and marked the stalks, but they are all dead, root and branch. I sent seed to Mr. Stewart, Eminence, Ky., who said it was a stranger to him; also to call it Allison's honey plant. I do not like to blow a horn, so I will call it the silver nectarine plant. I inclose a few seeds, as you may be able to throw some light on the plant.

Noble, Ill. MRS. C. J. ALLISON.

[1. The frames are run from front to rear because the bees build straighter combs in that manner; also, because the natural instinct of the bees prompts them to run their combs from the entrance.

2. After white clover, unless fruit bloom is very abundant and the weather pleasant.

3. The seeds are too few and dried to determine the name. Be kind enough to send a twig in bloom this fall, when we will name it, if possible.—Ed.]

Honey from Maple Blossoms.—On Feb. 18th my wife was looking at the bees working, when she came in and said, "How the bees fall at the mouth of the hive; they seem to be loaded with honey and pollen." She seemed somewhat excited about the bees working so lively. I went out and saw that they were heavily loaded both with honey and pollen. The maple trees were plenty, standing all around the hives, and a good many of them were in bloom. I saw the bees take the honey from the blossoms, or, at least, go through the motions. There was nothing in bloom at that time but the maples. I have watched the bees work on corn, but never thought they gathered honey from the tassels; I know they gather pollen from them.

ED. DELAIR.

Oketo, Kan., March 26, 1882.

Brood-Rearing in Wired Cells.—I was told yesterday that there would be no brood reared in cells over the wires in foundation, after it has been used 2 years, except in an occasional cell. Is such the case? I used wired foundation (wire No. 36, tinned) last season, and saw no difference in cells with or without wire. I believe if brood is not reared over the wires after two seasons, I will still use the wired foundation; it is so much stronger and less liable to sag.

A. B. MASON.

Wagon Works, O., March 24, 1882.

[Can some of our correspondents, who have been using wired foundation, give the information desired?—Ed.]

More About Mrs. Cotton's Transactions.—I have been waiting patiently since the publication of my letter of Dec. 9, in the BEE JOURNAL, page 40, of this year, in which I offered \$5 for proof that any person had ever sent Mrs. Cotton money for goods and had neither received the goods nor the return of the money—for some person to step forward and claim the money. As yet not a person has intimated to me directly or indirectly that they have any claim on my money, nor did I suppose there would, for I have made a very careful investigation of Mrs. Cotton's affairs and way of doing business, and had become thoroughly satisfied that she was trying to do an honest and legitimate business. The only "peep" I have heard from any one is the query on page 91 of the BEE JOURNAL, by J. W. Merrifield, if I regard a certain transaction described by Mr. Fletcher "as straight." The transaction with Mr. Fletcher is not published, but one with his mother (apparently the same) is published. Mrs. Cotton advertised a "sample" hive for \$4, and, through ignorance, sent a "model" hive instead of a "sample" one. In my investigations, I came across transactions of this kind, but also ascertained that as soon as the difference between "sample" and "model" was pointed out to Mrs. Cotton, she furnished a full-sized hive, and has sent no more "models," nor advertised any more "samples" since. If one will examine the dictionaries for the difference of meaning between the words "sample" and "model," they will find that it is more in the common use of the words than in the actual meaning. Now as to her "model" I make this statement: If a box-hive man should pay for a model, and by it be led to use any movable frame hive, he would be amply repaid, even if he had to pay 95 cents express charges. The transaction was not intended as a swindle, and I think was not.

R. E. HOLMES.

West Winsted, Conn., March 27.

[We have not the slightest desire to hinder any one from doing an honest business, but until Mrs. Cotton adjusts the many complaints against her method of doing business, she certainly has no claim to be reckoned among honorable dealers. She has recently published a vindication in the *Farm and Workshop*, in which she says:

"I have learned that many of the bee journals and bee-keepers' associations are conducted wholly in the interests of some individual or company of men for the sole purpose of making money for the sale of some particular, and often worthless, bee hive or fixture, without regard to its real merit or value to the practical bee-keeper. The country is full of this class, and they always combine to crush out real merit in anything pertaining to bee-culture brought before the public by individual bee-keepers. The greater the merit of

the invention, the greater the effort to crush it."

This is a bare-faced falsehood; she has been doing business in such a manner that her customers complain, and the bee papers, much against their inclination, have given place to the facts as stated by their correspondents, simply in the interests of honest dealing, and to protect the innocent from being imposed upon. When she has satisfied her complainants will be quite time enough to attack the bee periodicals, until then, she must expect adverse criticisms.—Ed.]

Queens Behind Division Boards.—By answering the following questions you will very greatly oblige: 1. Are queens often found to lay behind the division board? While preparing 7 colonies in American frames last fall, I placed a comb behind the division board in each hive, with the hope that the bees would carry the honey forward. They were not crowded for room in front. On examination, two days later, I found all the vacant cells had been used in these combs by the queens—an egg in each. This happened in 5 out of the 7 colonies. It was the end of November. The queens are hybrids. All the combs in the body of the hives contained brood. I put this forward also. Examined the bees early this month and found many very young ones among them. They were all packed in a straw clamp in a sheltered position. 2. Are the queens likely prolific? 3. What amount of honey can be put into 1 lb. of comb? 4. How do the Arkansas brown bees compare with the blacks in essential qualities; and the albinos with the Italians? 5. I find there are 2 sizes of Langstroth frames used—the one about $\frac{1}{2}$ inch shorter than the other. The former will just contain 8 $4\frac{1}{4} \times 4\frac{1}{4}$ section boxes. Can you tell me which size is the more used? Spring seems rather behind this year, nothing budded yet and the weather cold; but to-day we are having warm showers. Bees have wintered well so far.

G. B. JONES.

Berlin, Ont., March 27, 1882.

[1. Very seldom, and then only when the passage-ways are large and the brood chamber crowded.

2. Yes; they had been packed away quite warmly, and the winter being unusually open toward the latter part, young bees had an opportunity to arrive at maturity.

3. We do not know.

4. They are said to be larger, are straighter and more rapid comb-builders, remarkably docile in disposition, and of strong flight. They do not run down and drop from the combs as do the blacks, unless persistently smoked. We cannot answer your interrogatory regarding albinos, as our knowledge

regarding them has been derived from our columns. We suppose, however, inasmuch as they are Italians, their habits in many respects are similar. Probably their points of superiority, if any, have been developed by a careful and judicious breeding.

5. The standard Langstroth frame is $9\frac{1}{8} \times 17\frac{3}{8}$ inches, outside measure; the top-bar being $19\frac{1}{8}$ from end to end. This holds 8 $4\frac{1}{4} \times 4\frac{1}{4}$ sections. This size is mostly used.—Ed.]

How I Use the Bee Journal.—The binder for the BEE JOURNAL is just the right thing. I have all the numbers, so far, for 1882, put in tight and nice. It is so handy, when one writer refers to another, to turn back and see what he has said. In this way we get the ideas of different ones on the same subjects. Bees have wintered well and are strong; drones were flying from my large palace hive on March 20. I predict a large flow of honey this season.

AARON BENEDICT.

Bennington, O., March 23, 1882.

My Misfortunes.—Two years ago I bought 5 untested or dollar queens from a noted queen breeder, whose name I will withhold at present; 4 out of the 5 produced hybrid workers. Last spring I purchased a \$3 tested queen from another big bee man in good standing. She laid eggs 4 weeks and died of old age. For fear some one will ask how you know she died of old age, I will state, first, I claim a judge of bees can tell an old bee or queen at a glimpse; second, an old queen does not keep her hive well stocked with bees. This is the best proof of an old queen I can give. In July I purchased another tested queen of the same man; she kept her hive fairly stocked until October, when she failed. On examining this spring, I find she is worthless. The worker larvae is very scarce, and there is about half a frame of drone larvae in the hive, while all my other colonies have from 4 to 6 frames of brood. Now, I would like for some one to tell us what we are to do to avoid being swindled. When one wishes to Italianize his apiary it will not do to buy untested or dollar queens. My experience in the five above mentioned, 4 were worthless, making the good one cost me \$5, and the majority of the tested ones are so old they are ready to die when we get them. Fortunately, I have a good strain, and can rear my own queens hereafter.

Poseyville, Ind. J. F. KIGHT.

[It is easy to understand how your first tested queen might have been old, as, having been purchased quite early in the season, the party from whom she was purchased had wintered her over and forgotten her age, and, not having time or neglecting to test her anew, took it for granted she was all right. With an "Apiary Reg-

ister" properly kept, it would be impossible for these mistakes to occur. We can hardly imagine how to account for the failure of the queen sent you in July, if she had been bred and tested by the person from whom you obtained her.—ED.]

Combs Destroyed by Moths.—Bees are bringing in pollen and some honey, although they are sitting on fences, fustles and anything convenient, on account of the floods which have swept through here. My bees brought in pollen in December, and they have not quit brood-rearing during the winter. I have failed to keep my extra combs over winter on account of moths. Will some one give me their plan of preserving them? I hung mine in a tight room, and burnt sulphur at the rate of one pound in two weeks, and yet they ruined them.

W. G. MCLINDON.

Lake Village, Ark., March 28, 1882.

[You did not use sulphur enough. They should be fumigated with it several times, at intervals of about 16 days, and using at least a pound of the sulphur at each operation. If you have interchangeable second stories, a good plan would be to fill a hive with combs, then set on a second story with no bottom, fill that with combs, then put on a third, and so on till all the combs are hung in bottomless hives over each other; now put on an empty second story, place in this an iron pot with some live coals in it, then plenty of sulphur, and cover the hive; open the entrance of the lower hive to afford a draft. Sulphur fumes being heavier than air, they will slowly descend, and destroy all insect life. The operation will need to be repeated about three times, to kill the larvae which may hatch after the first and second operations. The trouble with fumigating with sulphur ordinarily is that, unless the room is very close, the combs get very little smoke, as they are usually hung up, and the fumes do not ascend, but escape from the lower sides of the building.—ED.]

Honey from Corn.—I can tell Mr. Mahin that bees do gather honey from corn tassels, and if he will call at my house he can have some very nice corn honey to eat, which my bees gathered late last fall from a patch of fodder-corn that I sowed just before harvest. The weather set in dry, and it made very little growth till in September, when the rain came and the corn started growing. It soon tasseled out and blossomed profusely, and as there was no frost till late in the fall, my bees had a rich harvest. The way they filled up their section boxes was a joy to behold; they worked on that corn as long as there was a green tassel left. Probably that corre-

spondent in *Gleanings*, referred to by Mr. Mahin, is a closer observer than he (Mr. Mahin) is aware of; but that bees gather honey from corn tassels is no new feature to me. What say other bee-keepers? Now, I want to ask a question—do bees ever refuse to work on melilot clover? I had a patch last summer, the seed of which I obtained from Chicago, but the bees paid no attention to it. I inclose a sample of the seed, is it genuine.

West Liberty, O. L. Z. LANTZ.

[The seed you send is genuine. We never but once before heard of bees refusing to work on sweet clover, and in that instance there were but few stalks of it within reach. There is, however, a variety of sweet clover which produces yellow blossoms, on which we do not believe the bees will work to any extent; but the white blossomed (*melilotus alba*) will, if growing to any extent, always be covered with bees.—ED.]

Feeding Maple Sugar.—I am wintering my bees in a cellar, and am feeding some of them with maple sugar, by laying it on the frames. Is it good feed for them? C. M. SLACK.

Eldred, Pa.

[A mild winter, such as this has been, it may do; but we would be fearful of the consequences, unless they were out-of-doors and could fly frequently.—ED.]

Color, Pleasure and Profit.—I apprehend the color most eagerly sought after, by the majority of apiarists, is the color of the pocket, and those which give the most universal satisfaction are the greenback color or gold metal hue. It matters not to the great mass of bee-keepers whether the contents of the hive are gathered by brown, black, yellow, or leather-colored bees, provided these products swell the aggregate amount of profits each year, and return to their owner satisfactory remuneration for the labor bestowed upon them. The profits are what 99 out of 100 keep bees for. Talk of keeping bees for pleasure, without profit, if you can show me such an apiarist, I must candidly confess that I have seen a curiosity of the genus *homo*. If bending over hives, examining nuclei, extracting honey, cutting out and inserting queen cells, rendering beeswax, caging and shipping queens, and writing a score of letters daily is a pleasure to while away the leisure moments from other pursuits, I must cheerfully confess that I will be somewhat careful about calling for pleasure too often when traveling. What the mass of bee-keepers want is plain, practical knowledge in the mode of keeping bees. What cares the average bee-keeper for the fine hair-splitting points regarding the color of the bee; they would rather have one inch of Mr. Doolittle's plain, practical experience conveyed to paper in his instructive

manner, than reams of fine points and theoretical reasonings. I think all of even a limited experience, are ready to admit that, by judicious selection from colonies possessing the most desirable qualities, we can breed our bees up to a high standard of profit.

Fredonia, N. Y. U. E. DODGE.

Bokhara or Sweet Clover.—I would like to know if Bokhara clover and sweet clover are one and the same thing? 2. How much is sown to the acre. 3. What is the cost per lb.? My bees are in the cellar and doing well. Have not lost any yet, nor do I expect to. I am beginning; but will report my progress next fall, all being well.

A. SUBSCRIBER.

Columbus, Ont.

[I. We believe Bokhara or sweet clover (*melilotus alba*) to be the same; at least we fail to observe any difference, and we have frequently seen them growing together. The bloom, too, is apparently the same.

2. Five or six pounds. If in drills, a little less.

3. The retail price in Chicago has been 30 and 50 cents per lb. The former for domestic, and the latter for imported seed.—ED.]

Grease in Foundation.—In manufacturing foundation comb, is grease of any kind extensively used? and if so, is it sometimes, or very frequently, of a filthy nature, or that taken from diseased animals? Quite recently I saw it asserted in a very influential paper, that such is the case. If it savors of the oleomargarine fraud, I want to know it, for above everything else, let my "sweetness" be pure. As your valuable JOURNAL occupies the front rank in publications of the kind, will you kindly give your views, and the facts as far as you are able, to the public, through its columns, as there are doubtless a great many others, like myself, who would be glad to hear from you on the matter. Bees are doing well, and, as a general thing, no thanks to their keepers, for there is very little intelligent care given them in this country.

Salado, Tex. W. P. HANCOCK.

[It is not true that grease is used in the manufacture of foundation. It is possible that some inexperienced persons may have tried greasing the rolls, to release the sheets from them, but even such would soon be obliged to abandon the practice, as their bees would utterly refuse to work it out, and customers would be apt to return it to the manufacturer because of its worthlessness. The freshest, purest and brightest wax in the foundation, makes it most acceptable to the bees, and, consequently, most profitable to the bee-keeper. Even soap-suds, with which to wash the rolls, is very objectionable.—ED.]

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 ".....	20 " "
" 13 " (3 months).....	30 " "
" 24 " (6 months).....	40 " "
" 30 " (9 months).....	50 " "
" 52 " (1 year).....	60 " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

974 West Madison Street., Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the *best* advertising medium, but the lowest rates on yearly contracts.

A Sample Copy of the Weekly BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

"How do You Manage," said a lady to her friend, "to appear so happy all the time?" "I always have Parker's Ginger Tonic handy," was the reply, "and thus keep myself and family in good health. When I am well I always feel good natured." See other column. 11w5t

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—a copy of "Bees and Honey."	
" " 3,—an Emerson Binder for 1882.	
" " 4,—Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.	
" " 5,—" " " cloth.	
" " 6,—Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.	

Or they may deduct 10 per cent in cash for their labor in getting up the club.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

To any one sending two *new* Weekly subscribers for a year, we will present a volume of the BEE JOURNAL for 1880, bound in paper covers. It contains much valuable information, and it will pay any one who does not already possess it, to obtain a copy. Many of our *new* subscribers will be pleased to learn that they can get it for \$1.00, by sending for it *at once*, before they are all gone.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

The Texas State Bee-Keepers' Convention will hold its meeting at Judge W. H. Andrews' Apiary, at McKinney, Texas, April 25, 1882.

WM. R. HOWARD, Sec.

For man it has no equal; for beasts it is not excelled. What? Kendall's Spavin Cure. 14w4t

To Promote a Vigorous Growth of the hair, use Parker's Hair Balsam. It restores the youthful color to gray hair, removes dandruff, and cures itching of the scalp. 11w5t

CLUBBING LIST FOR 1882.

We supply the Weekly *American Bee Journal* and any of the following periodicals, for 1882 at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., April 3, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—As the season is well advanced, sales of extracted honey are slow and prices remain unchanged. 1 am paying 8c. for dark and 10c. for light, cash on arrival. Good comb honey is scarce and rules high.
BEESWAX—1 am paying 22c. for good yellow wax, on arrival; 18@20c. for medium grade, and 15@17c. for dark.
AL. H. NEWMAN, 972 W. Madison St.

CINCINNATI.

HONEY—The demand for comb honey is slow, and prices nominal at 16@20c. on arrival. Extracted honey is in fair demand. Our jobbing prices for 1 lb. jars of clover honey are, per gross, \$25; for 2 lb. do., per gross, \$42. The demand for manufacturing purposes is very good. We pay 8@10c. on arrival.
BEESWAX—Brings 18@22c. The demand exceeds the offerings.
C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—Choice white comb honey is very scarce and commands 25@30c. per pound. Other grades, partly dark and dark are very slow sale. Extracted firm at 9@12c., according to quality and style of package.
R. A. BURNETT, 165 South Water St.

NEW YORK.

HONEY—There is a liberal supply of honey here for which trade is very little demand, and prices rule weak and irregular.
We quote as follows: White comb, in small boxes, 18@19c.; dark, in small boxes, 12@14c. Extracted, white, 10@11c.; dark, 7@9c.
BEESWAX—Prime quality, 21@23c.
THORN & CO., 11 and 13 Devoe avenue.

SAN FRANCISCO.

HONEY—The bright prospects for a large yield this season is causing spot lots to be offered at reductions on late asking rates. White comb and white extracted are virtually out of market, and prices for them nominal.
We quote white comb, 16@20c.; dark to good, 10@14c. Extracted, choice to extra white, 8@10c.; dark and candied, 7c. **BEESWAX**—23@25c.
STEARN & SMITH, 423 Front Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.
BEESWAX—Prime quality, 25c.
CROCKER & BLAKE, 57 Chatham Street.

ST. LOUIS.

HONEY—Strained dull, at 8@9c.; no comb here to speak of—worth 18@22c.
BEESWAX—Stiff at 20@21c. for prime.
R. C. GREER & CO., 117 N. Main Street.

CLEVELAND.

HONEY—The market remains unchanged: 1 and 2 lb. sections of No. 1 white are in regular and quick demand at 21@22c. No. 2 white has dragged a little of late, but took a lively start to-day at 20c. cleaning out all stock on hand. Buckwheat no sales. Extracted is quite active at 12c. for small and 11c. for large packages.
BEESWAX—25@30c.
A. C. KENDEL, 115 Ontario Street.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

BINGHAM'S CORNER.

Columbus, Ind., March 23, 1882.

GENTS: Your smoker circular came to hand this morning. I notice the price for your largest (2 1/2 inch) is \$1.75 by mail; but in your advertisement in the Bee Journal you mention the prices from 65 cents to \$2.00 each. Now, as I want one of your largest and latest Improved Smokers, I send you the \$2.00. Please send by mail, and oblige

Yours, respectfully, JON. M. BROOKS.

P. S.—I have been using one of your first make for five years I think, and although it has received constant rough treatment it is yet good for duty, and as my brother will use it this season, I now order another for my own use.

J. M. B.

Sweet Clover Seed Wanted.

I wish to purchase several bushels of Sweet Clover (*Melilotus alba*) Seed. Address, stating quantity and price, A. H. NEWMAN, 12wtf 972 W. Madison Street, Chicago, Ill.

FOR SALE—150 Colonies of Italian Bees in improved Quinby hives, in prime condition. 39wt1y L. C. AXTELL, Roseville, Warren Co., Ill.

HONEY PLANTS AND TREES BY MAIL, POSTPAID.

Ten Basswood Seedlings, 25c.; 10 Catalpa species, good as basswood for honey, wood never decays, 25c.; 12 Turner Raspberry, stand Dakota winters, splendid for fruit and honey, 25c. Special rates by the 100 or 1,000. H. M. MORRIS, Nurseryman, Rantoul, Ill. 10wt5f

1882-J. S. TADLOCK.—1882 LULING, CALDWELL CO., TEXAS.

Breeder of Pure Italian Queens. I use one of J. H. Nelis' best imported queens. Tested Queen, \$2.50; per half-dozen, \$13.50. Select Tested, \$3; per half-dozen, \$16. No "Dollar" or nuclei-queens handled. Safe arrival and satisfaction guaranteed, if possible. 14w39t

BEES and HONEY FOR SALE.

JNO. P. HOLLOWAY, Monclova, Ohio. 14wt1p

WANTED—A good, temperate, industrious man that has had some experience in the business, to work in an apiary. Give age, experience, and wages wanted. Address, W. D. WRIGHT, Knowersville, Albany Co., N. Y. 14w14wt1p

BINGHAM SMOKERS.

I can sell the above Smokers at MANUFACTURER'S PRICES, by mail or express, at wholesale or retail. All the latest improvements, including the CONQUEROR.

Send for my 32-page Illustrated Catalogue of Bee-Keepers' Supplies of every description.

ALFRED H. NEWMAN, 972 W. Madison, CHICAGO, ILL.

EGG-KEEPING COMPOSITION.—Used by some of the largest egg dealers in Western N. Y., for keeping spring and summer eggs for fall and winter market. A good business, when suitably located, to follow with bee-keeping. Write for terms and particulars. C. R. ISHAM, Peoria, Wyo. Co., N. Y. 14wt1p

ITALIAN BEES AND QUEENS.

Full Colonies, Nuclei, Tested and Untested Italian Queens, bees by the pound. I guarantee safe arrival. Address, OTTO KLEINOW, 13wtf Opposite Fort Wayne, Detroit, Mich.

THE RURAL CANADIAN,

A Fortnightly Journal of

Agriculture, Horticulture and Rural Affairs.

Edited by W. F. CLARKE, and

Published at 5 Jordan street, Toronto, Ontario, Canada, at \$1.00 a year, by C. Blackett Robinson, Liberal inducements to local agents. 4wt1f

FREE! FREE!

Send for our 28-page Illustrated Catalogue of Bees, Queens and Bee-Keepers' Supplies before purchasing elsewhere. Choice bees, good goods, and satisfaction guaranteed. 11wt1f E. A. THOMAS & Co., Coleraine, Mass.

Bees and Queens a Specialty.

I have a choice lot of Tested Italian Queens, also Full Colonies of Bees. I offer for sale cheap. I shall breed and have for sale after June 1st, young Queens from the best of imported stock. Satisfaction guaranteed. Price list free. 11w5wt I. S. CROWFOOT, Hartford, Wis.

THE LATEST and THE BEST.

The Excelsior Cold-Blast Smoker sent to any address, postpaid, on receipt of \$1.00. 14w21tp W. C. R. KEMP, Orleans, Orange Co., Ind.*

65 ENGRAVINGS.

The Horse

BY B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with rules for telling the age of the horse; a valuable collection of recipes, and much valuable information. Price 25 cents.—Sent on receipt of price, by

THOMAS G. NEWMAN, 974 West Madison Street, CHICAGO, ILL.

CHEAP.—CHEAP.

We offer for sale 180 good Colonies of pure Italian and Cyprian Bees, mostly in Langstroth and American Hives, at \$4 each; 300 new, painted, Langstroth and American Hives at \$1.50 each; 3,500 Boss Sections, \$2 per 500; about 30 Queens, tested, \$1 each; 300 lbs. Comb Foundation, 30c. per lb; two new Extractors, Muth's and Everett's, \$4 each; one 12-inch roll Foundation Machine, \$15. We will pay shipping charges on orders of \$5 and upwards. Satisfaction given or money refunded. 11wt6t A. T. SEDGEWICK, Corning, Ohio.

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, Township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles east of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber. It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 6 sections, including the above, to J. M. Murphy, for \$3,000, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession. I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN, 974 West Madison Street, CHICAGO, ILL.

Thirty-six Varieties of Cabbage; 26 of Corn, 28 of Cucumber, 41 of Melon, 33 of Peas, 28 of Beans, 17 of Squash, 23 of Beet and 40 of Tomato, with other varieties in proportion; a large portion of which were grown on my five seed farms, will be found in my Vegetable and Flower Seed Catalogue for 1882, sent FREE to all who apply. Customers of last season need not write for it. All seed sold from my establishment warranted to be both fresh and true to name, so far, that should it prove otherwise, I will refill the order gratis. The original introducer of Early Ohio and Burbank Potatoes, Marblehead Early Corn, the Hubbard Squash, Marblehead Cabbage, Phinney's Melon, and a score of other new Vegetables. I invite the patronage of the public. New Vegetables a specialty.

James J. H. Gregory, Marblehead, Mass. 49wt5f

NARMORE & WOOD, NORTH LANSING, MICH.

Manufacturers of Bee Hives, All-in-one-piece Section Boxes, FANNING MILLS, SASH, DOORS & BLINDS. 13w13t Italian Bees for sale.

THE CONQUEROR.

Large Smokers need wide shields, Bingham's have them, and springs that do not rust or break, and bellows that sparks and smoke do not enter. The Conqueror has all improvements made to date, and a 3x7 inch stove, and 5x7 inch bellows. Sent postpaid for \$2. Address,

BINGHAM & HETHERINGTON, 13wtf Abromia, Mich.

FLAT-BOTTOM COMB FOUNDATION,

high side-walls, 4 to 16 square feet to the pound. Circular and samples free. J. VAN DEUSEN & SONS, Sole Manufacturers, Sprout Brook, Mont. Co., N. Y.

974 West Madison Street, Chicago, Ill.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

- Excepting with the \$8.00 Extractors, all the different styles have extractors over the canal leading to the honey gate, and moving sides in the Comb Baskets.
- | | |
|--|---------|
| For 2 American frames, 13x13 inches..... | \$ 8 00 |
| For 2 Langstroth " 10x18 " | 8 00 |
| For 3 " " 10x18 " | 10 00 |
| For 4 " " 10x18 " | 14 00 |
| For 2 frames of any size, 13x20 | 12 00 |
| For 3 " " 12 1/2 x 20 " | 12 00 |
| For 4 " " 13x20 " | 16 00 |

ALFRED H. NEWMAN, 972 West Madison Street, CHICAGO, ILL.

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY, By A. J. COOK,

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

320 Pages; 133 Fine Illustrations.

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculteur*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY**.

It appears to have out the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. P. WEST**.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**E. H. WYNKOOP**.

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Fur.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL**.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—**WM. VAN ANTWERP, M. D.**

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—**L'ABBE DU BOIS**, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *vade mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular the most interesting of all occupations.—*American Inventor*.

PRICE—Bound in cloth, \$1.25; in paper cover, \$1.00, by mail prepaid. Published by

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by

THOMAS G. NEWMAN,

974 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully up with the times, on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping, by L. C. Root.— The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.— This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25; paper, \$1.

King's Bee-Keepers' Text-Book, by A. J. King.— This edition is revised and brought down to the present time. Cloth, \$1.00; paper, 75c.

Langstroth on the Hive and Honey Bee.— This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.— A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, \$1.00.

Bees and Honey; or, successful management of the Apiary, by Thomas G. Newman.— This embraces the following subjects: Location of the Apiary— Honey Plants— Queen Rearing— Feeding— Swarming— Dividing— Transferring— Italianizing— Introducing Queens— Extracting— Queening and Handling Bees— Marketing Honey, etc. It is published in English and German.— Price for either edition, 40 cents, postpaid.

Dzierzon Theory;— presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Honey, as Food and Medicine, by Thomas G. Newman.— This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 8c.; per dozen, 50c.

Wintering Bees.— This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof. Cook's Essay, which is here given in full. Price, 10c.

The Hive I Use— Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.— A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages. 50c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc. of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

Kendall's Horse Book.— No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Ropp's Easy Calculator.— These are handy tables for all kinds of merchandise and interest. It is really a lightning calculator, well bound, with slate and pocket. Cloth, \$1.; Morocco, \$1.50.

Chicken Cholera, by A. J. Hill.— A treatise on its cause, symptoms and cure. Price, 25c.

974 WEST MADISON ST., CHICAGO, ILL.
At \$2.00 a Year, in Advance.

Remit by money-order, registered letter, express or bank draft on Chicago or New York, payable to our order. Such only are at our risk. Checks on local banks cost us 25 cents for collecting.

Free of postage in the United States or Canada.
Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

EDITORIAL

Malicious.—The two bee papers for April, published in the state of New York, each contain malicious attacks on us by Mr. C. J. Robinson. Last year we published several articles written by him, some of which called forth criticisms from the Rev. L. L. Langstroth, T. B. Miner, Dr. Howard, Prof. Cook, A. R. Kohnke, and others. To these Mr. Robinson sent us replies full of abusive epithets instead of argument. On Jan. 2, 1882, we wrote him thus concerning a communication then sent us :

CHICAGO, Ill., Jan. 2, 1882.

DEAR SIR—Your letter and article are received, and I am sorry you are so "bitter" and unnecessarily sarcastic in your remarks. For that reason I have already delayed some of your articles, for it is better for you, as well as for others, that such a "spirit" as is therein manifested, should not be exhibited publicly. I have no objection to your having opposite views of parthenogenesis, or the "hive" of our much respected friend, Mr. Langstroth—but when you stigmatize such men as Dr. W. R. Howard, Prof. A. J. Cook, and others as "cranks," you offer an "insult" to all honest men, and degrade what should be a fair criticism, to the level of its now frequent use by a cowardly assassin (Guiteau). Yours, etc. T. G. NEWMAN.

To this he has made no reply except the abusive articles in the N. Y. bee papers, whose editors will hardly be able to find any justification, for permitting him to use their columns for such malevolence. Should they refuse him, however, they will soon learn how small a matter will cause him to single them out for ridicule and abuse.

This explanation is due to our readers, but we shall take no further notice of Mr. Robinson—for one who has no more manhood than to malign Mr. Langstroth when mentally unable to defend himself, by reason of wasting disease—is unworthy of notice, say what he may. His abuse cannot injure us in the least, nor hurt our feelings.

Honey Prospects for 1882.

From nearly every quarter come cheering reports of the prospect for a plenteous yield of honey the coming season. The clover sward is generally reported as uninjured by the winter; fruit bloom promises to be unusually abundant; elms and maples are already blossoming, and very industriously worked upon by the bees everywhere, and are reported to be rich in nectar; basswood or linden will undoubtedly be much above an average, and we can see no good reason why summer and fall flowers should be below an average. Unless unpropitious weather should prevail for a lengthened period, the season of 1882 will be a glad one for bee-keepers who may find themselves in condition to take advantage of it.

We have yet to hear of a locality where bees wintered poorly; in fact, where the success of wintering was not far above the average, and they are all in condition to breed up rapidly, if properly manipulated. Messrs. W. Thomas & Sons, write us from Somerset, Ky., April 3d :

Our bees are doing finely. Some of our colonies had hatching brood the first of last month, and are now breeding up strong. Peach bloom is about gone, and cherry and apple are just coming in. We look forward hoping for a plentiful honey season.

Our bees brought in their first pollen and honey simultaneously last Sunday (2d inst.), and breeding started up vigorously. Since then the weather has been variable, high winds prevailing most of the time with considerable rain, but we hope for a change for the better soon, and have every confidence in the succeeding weather. Bee-keepers have but little time to lose, if they have not already put themselves in condition to make the most of every opportunity which may be offered.

Rearing Queens.

A correspondent in Earlville, Iowa, asks for information bearing upon the above subject, and as there may be others desirous of more light, we will give a somewhat elaborate reply: He writes:

I do not understand, in Italianizing my apiary (BEE JOURNAL, page 202), when the queen has been removed from my Italian colony for the purpose of obtaining queen cells, how eggs are deposited in these cells, the queen not being replaced in the Italian colony; and how am I to know when queen cells are ripe? Please answer in the BEE JOURNAL.

The bees will build the queen cells around eggs or larvæ, or remove the egg or larva and place it in the cell. Scientists and apiarists are divided in opinion as to whether the cell is constructed around the egg, or the egg placed in the cell by the bees. It is possible, nay probable, that both are right. We have seen several cases, in the course of our observations, which led us to believe that bees frequently remove eggs from one comb to another; if they may do so, for convenience or other cause, for the purpose of rearing worker brood, why may they not do so in the case of rearing queens? It would be improbable that a queen could be removed from a prosperous colony without leaving an ample number of fresh eggs or young larvæ from which to rear all the queens which may be desired. If, however, there is a doubt about the matter, an outside frame of honey may be removed from the brood chamber, and the remaining frames be then spread so as to admit of placing a nice, clean comb in the center, or a sheet of fresh foundation, and in three or four days the new comb will be found filled with eggs, when the queen can be removed.

If many cells are wanted, the following will be found an excellent plan: Remove from its stand the hive containing your most populous black colony of bees, and put in its place an empty hive; in this put four nice, clean, empty combs, leaving room in the middle for a fifth, and placing a division board at each outer side. The hive removed put on a stand three or four rods distant, and cage the queen securely; now take from the hive you wish to rear queens from a comb containing only eggs (leaving the queen in her own hive), cut off, say, one-third of the lower part of the comb, lengthwise from front to rear, put the frame with the

remaining two-thirds of comb containing eggs in the center of the new hive; throw a blanket over the frames, put on the cover of the hive, and lay a board slanting from the ground to the entrance; now take out the frames one at a time from the hive removed, and shake and brush all the bees from the combs in front of the new hive, then replace the combs in the black colony and release the queen. The object in cutting the comb is to give a full, unfinished surface to facilitate and encourage the building of numerous queen cells, as bees seem to prefer mutilated spots for starting them, and they are easier removed from an extended surface, or edge, than if grouped, so that one cannot be cut out without injuring others. By adopting this plan, you not only secure a greater number of cells, but you know, also, that the queens are reared from very young larvæ, and, consequently, are fed on royal jelly from the time they are hatched from the eggs.

After about the seventh day from the time the larvæ are hatched, you will find the queen cells capped over. This capping will be quite rough and irregular, and have the appearance of being rudely daubed or plastered on the end with coarse wax. In ten days the worker bees will be working on the point; on the twelfth day the point will be trimmed down, and on the fourteenth will have lost its waxy appearance, and be dressed down quite smooth, when the cell is what is termed "ripe." These dates of time are based upon cells built with only eggs in the hive. We have known queens to emerge in about twelve days after the colony was made queenless, but these were undoubtedly reared from much further advanced larvæ, and such queens are generally supposed to be not as good.

Several objects are gained by artificially swarming a colony to rear queens as above, chief among which are: 1st. Greater number of queen cells; 2d. No drones are reared in the hive, as they have no male eggs from which to rear them; 3d. The parent Italian queen is still left in her own stimulated colony to rear Italian drones; 4th. A good cell can be left in the hive, to Italianize the black colony; 5th. There will be no hatching black bees to add confusion in testing the young queen. 6th. There is but one fractional frame of brood to divert the cares of the bees from their queen-rearing.

Forty-eight hours before cutting out the queen cells, form nuclei for as many queens as you wish to rear, or as you may have good cells, by taking a frame of sealed and hatching brood, and placing, with an empty comb, in a hive with division boards each side, then close the entrance and fasten the bees in for 24 hours, and on the following day, cut out and graft a queen cell in each nucleus. Combs or foundation can be added to the nuclei from time to time as they may be needed. In twenty-one days after the young queens are mated and begin laying, their progeny should be emerging from the cells. Many other plans are practiced besides those described above, but none, we believe, more simple in detail and as satisfactory in results.

Mr. H. Jones, Chesaning, Mich., kindly sends us an item entitled "Glucose," credited to the N. Y. City, Item. We have already published the substance matter of the article—in fact, it is partly made up from editorial matter in the BEE JOURNAL, and for which, by some oversight, we failed to receive proper credit. We are always pleased to receive these items, as it is not only an indication that our patrons are *in accord* with us in our efforts to effect needed reforms, but they frequently bring to our notice transactions which we might otherwise overlook, or have no opportunity of observing. It also affords us pleasure to be able to assure our readers that the public are rapidly becoming aware of the baneful influence of food adulterations, and that even Congress seems inspired to attempt a reform in the matter. *Nous verrons.*

Deluged With Letters.—One of our advertisers writes thus: "Stop my advertisement in the BEE JOURNAL. I am deluged with letters. I cannot answer half of them." This shows the good results of advertising in the BEE JOURNAL, when anything of value is offered for sale.

Mr. J. W. Margrave, of Hiawatha, Kas., reports that J. V. Cornell, a young bee-keeper of that place has "left for parts unknown," leaving a young wife and babe to the tender mercies of a cold world. Mr. M. adds: "He ought to be published in all the bee periodicals as a base villain." Pass him around.

MISCELLANEOUS.

The Standard Size of Frame.—The *London Journal of Horticulture*, says:

A meeting of the special committee appointed by the members of the Association at the recent general meeting, held on Feb. 15, for the purpose of determining the form and size of a standard frame for general use throughout the United Kingdom, was held at the Langham Hotel, on Thursday, March 16. Present: Messrs. T. W. Cowan (in the chair), C. N. Abbott, F. Cheshire, J. M. Hooker, A. Neighbour, Rev. G. Raynor, and the Rev. F. T. Scott. Mr. J. G. Desborough was unavoidably prevented from being present. After the consideration of a large amount of correspondence, and the question having been fully discussed, it was unanimously resolved that the outside dimensions of the standard frame should be 14 inches long, 8½ inches deep; the top bar to be ⅜ of an inch thick; bottom bar ⅛ of an inch thick; side bars ¼ of an inch thick. These dimensions do not refer to anything outside of the rectangle. It was also resolved that standard frames duly stamped should be provided at one shilling each.

Fastening Starters.—Dr. C. C. Miller, Marengo, Ill., gives the following suggestions in *Gleanings* for April:

I have had some trouble with foundation dropping out of sections just at the most annoying time when honey is coming in with a rush, and every minute counts; and I suppose others who use full-size starters are not entirely free from this trouble. Where they have been fastened with Parker's foundation fastener, I have found it to occur either where the starter was put in too cold or where too big a "bite" was taken by the fastener. I have been putting in several thousand starters in sections with my own hands, and apprehend less difficulty the coming season. I formerly supposed that I could not well put in starters in cold weather; but I now prefer winter. Perhaps I had better tell you just how I do it. I do the work in the kitchen. The fastener is screwed tight to a board which is clamped tight to a table, the fastener being close to the edge of the board nearest me, the length of the fastener running parallel with the board, and the handle at the right side. The table without the board would be as well, or better, only I do not want to drive screws in the table. Just beyond the fastener I put a pile of, say, 50 starters, and at the left of the pile stands a hot flat-iron, such as the women-folks use for ironing, while another iron stands on the stove ready to replace this one when it gets cold.

Seated on a seat 6 inches higher than an ordinary chair (I put a chair on a hive cover), I am ready for work. The edge of the starter next the flat-iron is heated so that it is quite soft; I care little how soft, so that none of the starters are actually melted. This soft edge is the one, of course, to be mashed down by the fastener, and the object is to get as small a "bite" as possible, only so that a little of the wax is actually mashed the whole width of the starter. The ordinary direction is to put the foundation under ⅛ inch, which I think quite too much. Instead of "turning the piece of foundation up against the end of the lever," as usually directed, I leave it lying flat till I pick up the section; and on turning the section right side up, the foundation will, by its own weight, be found hanging right every time without any attention.

Frauds.—The punishment of frauds and adulterations is now commanding much attention. The *New York Tribune* of March 21st, gives the following item:

Some of those oily reformers who cry so loudly now for anti-monopoly may soon have an opportunity to reform that will be in their own immediate grocery line. Considerable progress is reported toward making laws of the bills at present under consideration in the State Legislature to prevent the sale of imitation butter, and to do away with the fraudulent use of glucose and the like. The Anti-Oleomargarine bill passed the Senate yesterday.

Out Door Feeding.—From the *Bee-keepers' Magazine* we copy I. L. Scofield's (Chenango Bridge, N. Y.) method of feeding bees in the open air:

He makes a box 3x3 feet square, 2½ feet deep, and hangs two pans, 2½ inches deep, 30 inches long, and 10 inches wide, down in the top of the box. Cut a door-hole in one side, to put the lamps in under the pans; these are common kerosene oil lamps. Put the feed in the pan, and a float on it, so the bees will not sink it, and get daubed; regulate the lamps so that they will keep the food about 85° to 90° F. Put the box in some sheltered place in the yard; put some boards up to keep the cold winds from it. Every day the bees can fly with safety, have this feeder ready for their use, the feed quite thin. Sap from the maple tree, with a little extra "C" sugar added, makes a good feed; there is no danger in using "C" sugar when the bees are flying every day or two. The bees fly from the hive, and get the feed in the natural way, and when they fill their sacs with feed at a temperature of 85° to 90° F., they are in as good condition to get home to the hive as they were to get out of it and fly to the feeder, and you lose no bees as you do by their filling their sacs with cold water at the creek, or

some other place, then tremble and shake for some time, and if the sun clouds over they never return to the hive, but if it shines out brightly they will come back with a load of water, to thin their honey so they can raise brood. The bees all stay at home until there is pollen on the trees and they can fly with safety. The two pans will feed a yard of from 60 to 80 colonies. The pans and float must be kept clean, and the feed not let get sour. This management makes a little summer for the bees just when it is most wanted.

"The King Bee."—Mr. J. M. Hicks, in the *Grange Bulletin*, relates a little of his experience as follows:

Bees throughout the country have wintered well. Now and then we visit farmers who keep and have kept bees for many years, and find that they think the "king bee" is monarch of the hive and boss of all the other bees. Sometimes they still have it that the old king lays all the eggs and produces all the bees. We quite often get a rebuff from such ignorance. We cannot help but feel sorry for them and in several instances have changed Italian queens with such in order to prove our assertion—first capturing the native queen and then introducing the Italian queen at once before the eyes of my Old Father Luck, and as per agreement, if the bees were not of a different color from the occupants of the hive in 65 days, I should lose the Italian queen and pay Old Father Luck ten dollars for the native queen destroyed, but if otherwise, then they were my bees, free of charge. You may guess I carried the bees home, and the old gent is wiser than he was before.

CLUBBING LIST FOR 1882.

We supply the *Weekly American Bee Journal* and any of the following periodicals, for 1882 at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

	Publishers' Price.	Club.
The <i>Weekly Bee Journal</i> ,	\$2 00.	
and <i>Gleanings in Bee-Culture</i> (A. L. Root) 3 00.	2 75	
<i>Bee-Keepers' Magazine</i> (A. J. King), 3 00.	2 60	
<i>Bee-Keepers' Instructor</i> (W. Thomas) 2 50.	2 35	
The 4 above-named papers,	4 50.	4 00
<i>Bee-Keepers' Exchange</i> (Houk & Peet) 3 00.	2 80	
<i>Bee-Keepers' Guide</i> (A. G. Hill)	2 50.	2 35
<i>Kansas Bee-Keeper</i> ,	2 60.	2 40
The 7 above-named papers,	6 30.	5 50
The <i>Weekly Bee Journal</i> one year and Prof. Cook's <i>Mammal</i> (bound in cloth) 3 25.	3 00	
<i>Bees and Honey</i> , (T. G. Newman) ..	2 40.	2 25
<i>Binder for Weekly Bee Journal</i> ,	2 85.	2 75
<i>Binder for Weekly Bee Journal</i> ,	2 75.	2 50

Premiums.—Those who get up clubs for the *Weekly Bee Journal* for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

- For a Club of 2,—a copy of "Bees and Honey."
- " " 3,—an Emerson Binder for 1882.
- " " 4,—Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
- " " 5,—" " cloth.
- " " 6,—*Weekly Bee Journal* for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

CORRESPONDENCE

For the American Bee Journal.

Criticisms from Bruce, Ontario.

J. ANDERSON.

The articles written by some of the BEE JOURNAL correspondents show that the writers have much yet to learn connected with bee-keeping; while others clearly demonstrate that their authors are no mere novices.

There can be no good reason why bees should die, as last season, where the winter is only of eight or ten weeks' duration. Nothing but injudicious and improper treatment could cause their destruction in such localities. If men, for the sake of adding a little more to the gains of the season, rob their bees of the good and wholesome food which nature teaches them to store up for the stormy day, and then scantily supply them with that which is unwholesome, or if they deprive them of the full amount of heat so essential for the cold nights of winter, by an undue number of swarms and divisions the previous season, or by boring holes in their boxes, or scraping away the plaster by which the little things so industriously exclude the cold air from their combs, without supplying them with substitutes, then it is but just that such persons should find out that nature is wiser than men, and that their imaginary gains are but real losses.

I seldom lose a colony during the first three months of winter's confinement. Of course, I winter within doors. I have found out by hard experience, that outside wintering will never do where the winter is severe and long, and the elements changeable, as in Bruce. Any losses worth noticing, which I sustain, occur about the end of confinement; after the bees are shut up without light or liberty for about five months, as they were last winter; nor do such losses occur through any disease among the bees, but simply for want of food. Some bees consume far more food than others; and it is difficult, indeed impossible to test, on this point, before winter, the progeny of young queens, so as to know the gluttons from those more sparing of their winter supplies. I have had some colonies which consumed between 60 and 70 pounds of food during winter, and died of want; while others, about the same strength, wintered well aside them without consuming a quarter of that amount. Not a single tear was shed over the grave of those gluttons.

I highly value and largely indorse the able and interesting articles which recently appeared in the JOURNAL from the ready pens of Messrs. Dadant and Heddon; but would not, on any account, adopt all their views. To exclude pollen from the bees during a long winter would, in my humble

judgment, cause their ruin. It is true I may be mistaken, as I never tested it, but the opposite I have tested to my entire satisfaction. I have been the keeper of bees for 30 years, and for half that period it has been my uniform practice to follow the bees' own habits, and place frames with bee-bread within reach of the bees during their winter imprisonment. Now, I flatter myself with the idea that my bees always winter well; so well, that I find but few dead bees in many of my hives when taken out; not a cupful in some of them; so I have no more fears that my bees will die in winter, than that my horse or cow will die. These will certainly die, if not properly attended to, and so will my bees. They must be attended to at the right time. This success in wintering is reached by little and little. Experience will teach the intelligent bee-keeper that the same identical practice will not secure perfect success in all kinds of winter receptacles, and that, while general principles are never to be violated, yet in numerous details, the apiarist must largely draw upon his judgment and experience, according to circumstances and the state of his bees. One essential principle in wintering is, to keep the bees still. Excitement or restlessness is sure to cause diarrhea, and, finally, death. This restlessness may be caused by the want or loss of a queen, by too much heat or cold, by unhealthy food or scarcity of food, or by dampness, or any external disturbance. A flight in winter is unnecessary; for it does more harm than good, when the bees are wintering well. Some seem to have an impression that healthy bees retain in their intestines all the food they consume during their confinement. But this is not the case; when bees winter well, they discharge their feces very freely, but what they pass is as hard as wax.

In the numerous reports of winter losses, given last season in the JOURNAL, spring losses, or spring dwindling, was not given. This oversight is a misfortune, for spring dwindling is as great an evil as winter losses, and the one as difficult to overcome as the other. If our colonies are not strong, in the beginning of summer, when the blossoms appear, then our honey harvest will be a failure that season, especially in localities where fall blossoms are scarce. How is this common evil then to be met, is a question of vast importance to many? Numerous remedies are, of course, proposed; but many of them are worthless. Late fall breeding is good as far as it goes, but early spring breeding, in my experience, is far better. If young bees are hatching in large numbers, just when the hives are put on their summer stands; then there will be no fear of spring dwindling. But how is this early breeding to be produced without an undue excitement of the bees? Can any one tell? Sometimes I have had the pleasure of witnessing it without any effort on my part to produce it. Where bees have plenty of good honey and pollen during their confinement, and are wintering well, breeding will

be commenced before the bees can with safety be put on their summer stands. Deprive the bees of their pollen, and this would be impossible. When I took out my bees last spring (April 10th) I found, to my pleasure, that about as many young bees were hatched as there were dead in the hives, and as large numbers were hatching every day, dwindling was not perceptible. I am not prepared to say that there is more dwindling in spring than in summer or fall. I know, we readily speak of the age of bees, and fix the number of their busy days; but are we certain that we are correct? Does not excessive labor make a bee old? Old age is not the only thing that destroys bees. The bees that I winter do but little work, as our fall blossoms are but scant, and the bees having plenty of food in their hives, do not expose themselves very much in search of those flowers; they can, therefore, do a large amount of work in spring, after their 5 months rest. Of this I am satisfied, that a large number of the same identical bees that occupy my hives in September may exist and actively labor in June the following year, perhaps longer. This I have frequently proven by colonies that lost their queens early in spring, when I had none to give them. Let a strong colony be left without brood or queen when honey is abundant in the fields, and then we shall witness a greater dwindling than anything we ever experienced in spring. The grand remedy then for spring dwindling, or rather its preventive, is early breeding, together with prolific queens. To have early breeding we must have plenty of pollen in our hives, and to have prolific queens we must learn to distinguish such queens from those that are worthless, and should never be wintered.

In drawing my remarks to a close—which I fear are already too lengthy—let us have a word or two connected with the stings of bees. How different the effects produced by the small drop of poison attached to these fine weapons! Some men care nothing for it, and I have the fortune to be of that favored class. Bee stings never trouble me, though scores of them get to my blood at once, consequently I use smoke but very seldom. If my bees make an attack upon me—well, let them do so; for I have been in the fault. Something occurred that might have been prevented; and by their sharp weapons they teach me to be more careful in my next visit to their home. But all are not of this class; some have a fearful dread of bees, and can only approach a hive with trembling, as they know the sting pains and disfigures them. But there is still a third class of persons who have a greater reason to be afraid than those last alluded to, for the effects produced on them by a single bee sting are most serious and alarming. The eyes become bloody, suffocation is experienced, coughing is produced, vomiting sets in, the whole body becomes covered with large blisters, and the whole circulation of the blood is interrupted. All

this occurs in less than five minutes, and the result, I believe, may be fatal, if no aid is given. Can any of your numerous correspondents tell us how such cases are to be treated? If there be an unfailing remedy, all beekeepers should know it. The only remedy familiar to me, consists in the use of good brandy for inward stimulation, together with a cold sponging of the body. But a better remedy may be in use; if so, let us know it.
Bruce County, Ont.

For the American Bee Journal.

Producing Comb Honey—No. 4.

G. M. DOOLITTLE.

After getting our bees all in proper condition, and the boxes put on as I have before described, the next thing which will be liable to occur will be swarming. After trying all the plans of non-swarming hives given, with no success, I settled down to the conclusion that such a thing did not exist when working for comb honey, and even if it did, I doubt if as large a yield of honey could be obtained, as by the use of swarming hives. Then if we are to use swarming hives the question coming next, is, shall we make our swarms by dividing or by letting them swarm naturally. Lately I have used both ways with what seemed to me the best results. It will be seen that our bees are all in readiness 15 days before the height of the white clover harvest, and where this is the main dependence for honey, all swarming should be done within the next 5 days. In this case swarming would have to be done largely by division, but as basswood is my main honey crop, coming about July 5, I do not practice artificial swarming, only so far as is necessary to have all swarming done ten days before basswood opens. All swarms issuing previous to 15 days before basswood, are hived singly in hives containing frames of empty comb, and in a week from time of hiving the boxes are put on, in the same manner described before. Those issuing the next 5 days are hived two swarms in a hive, when convenient to do so, and the full complement of boxes put on at once. If not convenient, the new swarm after being hived is set on the stand of another hive which has not swarmed, and such colony changed to a new location, thus securing to the new swarm all the field bees from the colony moved. Each swarm thus made has given them a hive full of empty combs and the boxes are put on at once. Thus it will be seen all the new swarms are in splendid condition to take advantage of the basswood harvest as soon as it commences.

Where I have two swarms together, the queen belonging to one of the old colonies is let to go back, when such hive is moved to a new location and the double swarms set in its place. The old colony losing their queens by their going with the new swarms, are allowed to rear their own queens, as (after thoroughly trying the plan of) giving each colony a laying queen im-

mediately after swarming, has not proven a success with me. Eight days after a swarm has issued from a hive I open it, and, having ascertained that a queen has emerged from the cell, by finding one open at the end, I cut off all the rest and thus stop all second swarming. These cells thus cut off are placed in nucleus hives, if I wish more queens. By waiting till the first queen has hatched, I have a certain thing when the cells are all off, which is not the case where all but one cell is taken away 4 or 5 days after swarming, for the bees will often rear queens from the larvæ there is still in the hive at that time, and also the cell thus left will often fail to hatch.

When I think basswood will open in about 10 days, I proceed to make swarms from all the rest which have not swarmed as follows: A hive is filled with frames of empty combs and placed upon the stand of one of these colonies which have not swarmed, and all the boxes are taken off and placed thereon, then all the bees are shaken and brushed off their combs of brood and honey, in front of this prepared hive into which they will run as fast as shaken off. Thus I have a colony that is ready for "biz" as soon as the honey harvest comes, as they have the queen, bees and part-filled boxes all in readiness for work. Previous to this, nuclei have been started, so that I have plenty of laying queens to use as I need them.

I next take all the combs of brood from which the bees were brushed, except one, arranging them in the hive the bees were shaken out of, and carry them to the stand of another colony which has not swarmed. Next I take the comb of brood which was left out and go to one of the nuclei, taking out the frame having the laying queen on it, and place the comb of brood in its place. Take the frame, bees, queen and all, and set it in the place left vacant for it when arranging the combs of brood. Now put on the boxes, and, having all complete, I move the colony to a new stand, and set the prepared hive in its place. Thus I have a laying queen and enough of her own bees to protect her, together with a hive filled with combs of brood and all the field bees from the removed colony. In a very few days these colonies are ready for the boxes, and generally make the best colonies I have for storing honey. The loss of bees to the removed colony stops the swarming impulse, and in about a week they have so regained their loss, that they are ready for the boxes again.

It will be seen my aim has been, in using these several plans, to get all my bees strong enough to work in the boxes (during the best harvest) to advantage, and still have none of them desire to swarm right in the height of the best flow of honey. By adopting a plan called "nucleus swarming," I once had my bees (after an early division) nearly all swarming right in the height of the honey harvest, by which I lost at least \$500, for swarm they would in spite of all I could do, and while the swarming fever is on but

little work will be done in the sections, as all apiarists know. This taught me a lesson; I hope to profit by all such lessons, else why the use of learning them. My next will be working these boxes so as to get the largest yield possible, and taking off boxes.

Farmers' Home Journal.

Introducing Queens.

G. W. DEMAREE.

Who was the first to discover that queen bees could be removed from strong colonies, and others introduced in their places, I am not able to say; nor do I suppose that it is important to know. But that it can be done with as general success as any other important operation that requires skill and patience, I have fully demonstrated to my own satisfaction. I have paid particular attention to the many slightly differing methods resorted to, to induce bees to accept of a strange queen, and it would really appear that every apiarist claims that there is something original about his plan of proceeding.

It is worthy of note, however, that no matter how you may proceed there are certain features about the business that is essentially common to all methods and must be present to insure general success, viz: 1. The colony to which a queen is to be introduced must be queenless, and free from the influence of those pests called "fertile workers." 2. There should be no sealed queen cells. 3. The queen must be "introduced" to the bees, *i. e.*, placed in such a position that the bees can make her acquaintance without the danger of her being attacked by them if they are hostile to her at first, as they generally are disposed to be.

There are exceptions, however, to all rules. Some colonies will accept a strange queen without any trouble, while others will resist in the most stubborn and determined manner. A prominent writer thinks that there is, perhaps, one colony out of a hundred that cannot be induced to accept of a strange queen, but I have never met with one that I could not subdue, though I have on a few occasions had to resort to severe measures to accomplish it.

The first important thing to learn is how to find and remove the queen to be superseded. This operation is always a puzzle to the novice. In fact, I know of no operation, the success of which depends so much on practical knowledge and an actual practice. I doubt very much if it is possible for an inexperienced person to hunt up and remove a queen from a strong colony. But if he will commence to practice on small colonies where the bees are few in number, and learn to look up the queen, observe her habits, etc., he will soon be able to find her in any colony.

In looking up the queen in a strong colony, I put an empty hive near at hand and commence to remove the

frames, one at a time, looking carefully for the queen, setting the frames in the empty hive till all have been removed; then look carefully for the queen among the bees left in the hive. If the queen is not yet discovered I return the frames, one at a time, looking them over again till I find her. I rarely ever fail to find her in fifteen minutes of time.

Parthenogenesis in Bees.

PROF. C. F. KROEH.

Recent experiments of the Abbe Giotto Ulivi call in question the theory of parthenogenesis, which is at present almost universally received by bee-keepers and other entomologists. Briefly stated, this theory is that queens, while yet in the virgin state, may lay eggs capable of hatching, and that such eggs always produce drones. After the queen has mated with a drone and stored up the spermatheca so received in a little vesicle, she may lay at will either drone or worker eggs, according as she does or does not compress this little vesicle at the moment the eggs pass it. Some of the evidence on which this theory rests may be found in an article entitled "Modern Bee-Keeping, No. IV." in the *Scientific News*, November, 1881, page 345. The received theory also requires that queens and drones can mate only when flying, and that the drones perish in disengaging themselves because they cannot withdraw their organ.

All this is denied by Ulivi. He constructed flat observation hives, in which 3 combs were placed, one above the other. The two sides were of glass and could be darkened with shutters. Each hive was furnished with a closed tin portico having glass slides and a trap which could be so adjusted as to allow or prevent the passage of queens and drones. By the aid of these hives he performed three series of experiments. In the first series they were filled with bees, stores of honey and pollen, worker and drone brood, and queen cells sealed and unsealed; in the second series the queen cells were left out; and in the third there were no queen cells, drones, or drone brood. In none of the experiments was a queen put into the hive. He then made the following observations:

In five hives the queens, without leaving the hive, were fertilized and laid eggs that hatched into workers and drones.

In four hives he saw the queen mount a drone and curve down the extremity of her abdomen so as to bring it in contact with his virile member. This organ was at least 3 times too thick to be inserted into the vulva. Fertilization must, therefore, take place by mere touch. Indeed the fertilization of small Egyptian queens by large Italian drones could take place in no other way.

In two hives newly hatched queens were allowed to fly and were captured

on their return. They brought with them the ordinary whitish appendage to their abdomen, which has hitherto been regarded as the wrenched-off organ of the drone and the evidence of impregnation. On examination under the microscope this appendage was found to consist of excreta entirely soluble in water and containing no fleshy filaments. The drones of these hives were then imprisoned, and the queens returned to their hives. They laid eggs regularly, but these eggs never hatched. Then the drones were liberated in the hives, the queens mounted them, and the eggs they laid after that, hatched into workers and drones.

In three hives the newly-born queens were allowed to fly several times until they returned with the usual appendage to their abdomen. Then they were confined in hives containing no drones or drone brood. One of them did not lay at all. The other two laid eggs regularly, but these eggs never hatched. The two laying queens were then killed and examined, and the three nuclei united and put away for winter. The surviving queen never laid an egg. The following January she was also found dead and examined. In March the colony had neither an egg nor a drone, although there had been plenty of time for a fertile worker to develop if there were such a thing.

It is generally believed that one fertilization lasts a queen for life; but Ulivi saw three queens that had laid fertile eggs refertilize themselves by mounting drones.

He dissected five fertile queens and removed mature eggs ready to be laid from their oviducts just before they passed the spermatheca. These he substituted for others that had been freshly laid, removing the latter to other cells, and isolating both from the other eggs in the hives in which the experiments were tried. The removed eggs hatched, but those taken from the oviducts did not. Under the microscope, 6 days later, they showed no embryos nor any indication of vitality.

He isolated queens from drones for 20 days and dissected them. Their spermathecas were empty.

He caused queens to hatch in cages, so as effectually to exclude drones, and kept them caged for a long time. On dissection their spermathecas were found empty. The eggs they had laid never hatched.

He caught queens on their return from their so-called wedding flight. Although they brought with them the whitish appendage supposed to be the male organ of the drone, the microscope showed their spermathecas to be entirely empty.

He dissected 30 queens just hatched, and found their spermathecas empty.

He captured a young queen immediately after she had mounted a drone, and found her spermatheca distended and filled with liquid.

He concludes that Leuckardt, who dissected a drone-laying queen, and found no spermatozoa in vesicle, but only a clear liquid, erred in pronouncing her unimpregnated. The clear

liquid in the spermatheca was nothing but drone semen.

Having had occasion to transfer a large number of colonies from old-fashioned into movable frame hives, he observed that, contrary to the established belief, old queens do not lay a disproportionate number of drone eggs. They laid fewer eggs than young queens, but the number of worker eggs greatly exceeded that of drone eggs.

Signor Ulivi, therefore, maintains:

1. Queens are usually fertilized inside the hives.

2. They are fertilized several times.

3. Drones are not mutilated in the act of copulation. It should have been mentioned above that he several times examined all the drones in a hive in which impregnation had taken place, and found none of the drones lacerated.

4. Every egg that hatches into a male or a female has been previously fecundated with drone semen; hence there is no such thing as parthenogenesis in bees.

5. Every queen whose spermatheca is distended and filled with any liquid whatever has been fertilized.

6. The eggs of a queen that has never met a drone will not hatch.

7. There is no such thing as a fertile worker.

To explain the last conclusion it is necessary to add that Ulivi found by experiment that fertile eggs will keep through the winter and will hatch in the spring. Hence some who have put away colonies queenless in the winter and found brood in them in the spring have been deceived into believing that a worker had assumed maternal duties.

These experiments and conclusions are of the greatest scientific interest as well as of practical utility. If confirmed they will entirely revolutionize an important branch of the bee-keeper's industry. The author hopes to have an opportunity of testing the matter by experiment. Comments not supported by experiment would be of little value.

Hoboken, N. J.

[We are under obligations to several correspondents for sending us copies of the foregoing startling article, but had anticipated them by clipping it from the *Scientific American*. The deductions arrived at by the Abbe Giotto Ulivi are certainly astonishing in their boldness, and, if even partly correct in his conclusions, will not only revolutionize long-accepted theories, but will open an interesting field for experimentation to scientists and breeders; if true, fertilization in confinement can be easily and certainly accomplished, and the "coming bee" will only await the exercise of a little persevering patience, and a discriminating judgment to determine its most desirable features. We advise, however—be not too credulous.—ED.]

For the American Bee Journal.

"Dollar" Queens Again.

W. Z. HUTCHINSON.

MR. EDITOR: You say, had I copied the sentence entire, it would have given the impression that where one might economize more, scores of prudent breeders would far exceed Mr. Salisbury's expenses; which is exactly as I understood the matter; and I then asked you to go into details, and show in what particulars a prudent breeder could be more extravagant. In reply, you say that you have cited several cases where experienced and extensive breeders have found the cheap-queen traffic undesirable, which may be true; but it does not answer my question; or, rather, my simple request has not been complied with.

No, Mr. Editor, you did not use the word "stripes," and I fail to see where I quoted you as using it. It is true that I enclosed the word in quotation marks, but it was done merely to show that I used it in a peculiar sense, as is often done when a word is used in a new or uncommon manner. My reason for employing the word is, that I understood that queens were usually tested in regard to the "stripes" of their progeny. But let us suppose, for the sake of argument, that tested queens are tested in regard to business qualities, what is there to prevent a dishonest breeder from sending out a non-prolific queen as a tested queen, provided that she produces bees with the requisite number of "stripes?" If the purchaser grumbles, he can be told that perhaps she was injured in shipping, or in introducing, or that his method of management may be defective, or that the yield of honey may not be large enough, etc. The prolificness of a queen is such an indefinite quality. To get right down to the bottom of this matter, it all depends upon the breeder (this you substantially admit, in your remarks about Dr. Brown); if the breeder is honest and conscientious, he will rear queens in a proper manner, and will send out only good queens; while a dishonest breeder will cheat his customers, if he can; and it makes little difference whether said customers buy "dollar" or "tested" queens. I have recently written to several of the leading queen-breeders, asking them if their "dollar" or untested queens were reared in a different manner from their tested queens, and if they considered their tested queens superior to their untested queens, except that they knew how the tested queens were mated. They all agreed in saying that their queens were all reared in exactly the same manner, and that they did not consider their tested queens superior, except that they were known to be purely mated; or, in other words, they tested their queens in regard to "stripes," and nothing more. If necessary, I can give the names of these breeders.

In using the words "hybrid queens," in the third paragraph, I did not intend to convey the idea that you had

used the words. I was merely anticipating what you might say in reply. I will admit, however, that it would have been better had I so worded the sentence that there could have been no mistaking its meaning, but I supposed that the context would make it all clear.

You say: "But when a 'tested' queen is bought or sold, it is supposed her progeny will prove among the best for all desirable qualities, as well as possess the 'three bands,' which are only a 'test of purity,' or pure mating." Quite often, when reading your editorials, I have found myself almost envying you your command of language, but if ever you put the right word in the right place, it was when you used the word "supposed" in the above quotation.

You say that my citation of the case of Dr. J. P. H. Brown establishes no point, except that the Doctor is an honest, conscientious gentleman, etc. When H. P. Sayles obtains "dollar" queens from Dr. Brown, and these queens prove so excellent that Mr. Sayles is willing to rear queens from them, does not this establish a point, fully as much as your mere assertion that, "we do not believe, among them all, there is one who is reckless enough to expect to buy a single queen for \$1, or 100 queens for \$65, which would be fit to rear even untested queens from?" You say that "Dr. B. states in his circular that all his queens are reared from imported stock. They are not reared from 'dollar' queens." Where is the breeder of any pretensions or reliability, that does not rear his queens from imported mothers, or from well-tested home-bred mothers? Where is the breeder that rears his queens from "dollar" queens, without first thoroughly testing them? After a "dollar" queen has been tested, and found to be an excellent queen, is she not fit to breed from? In other words, does it make any difference who tests a queen, *i. e.*, the breeder, or the purchaser?

Again I agree with you, Mr. Editor, when you say: "The bee-keepers of America want the 'best bee,' and to this end all bees should be tested before leaving the hands of the breeder;" but I do not agree with you in thinking that all, or even a majority, of the so-called "tested" queens are tested for their "best business qualities."

REPLY TO MR. SALISBURY.

Mr. Salisbury, you say that "the advocates of untested queens rely but little upon their own arguments." Did I not give my own experience as an argument?

No, Mr. S., I am not a sloven, and neither am I stingy, and I do like to see a neat advertisement, just the same as I like to see a neatly dressed individual; but I do not like to see a person showily dressed, neither do I see any great beauty in a spread eagle advertisement. In my opinion, a plain, neat, straightforward advertisement is fully as artistic as one of the spread eagle style. If you prefer displayed advertisements to having the balance upon the right side of the ledger, and you can afford such indulgen-

cies, I do not know that it is anybody's business but your own. You say that I know, as well as any of us (from reports made on glucose), that it is inferior and unhealthy food, compared with good granulated or coffee A sugar, or honey. Mr. S., you know, as well as any of us, "from reports made," that there are different grades of grape sugar, that some grades are impure, while others are practically pure. It was the best quality that I used. I used it only one season, and probably shall never use it again; simply because I have doubts as to whether it is any cheaper, in the end, than the best granulated cane sugar. You say that it (grape sugar) was hard on the constitutions of the embryo queens. How do you know that it was? Did you ever rear queens by feeding grape sugar, or do you merely "guess" how it would operate? The queens reared when I was feeding grape sugar were as fine looking, as prolific, and as long-lived as any that I have ever owned. But, for argument's sake, let us suppose that I had fed coffee A sugar, and, still further, let us suppose that I had found it necessary to feed the same number of pounds as I did of grape sugar, this would have increased my expenses only \$24, and there would yet have remained a large profit.

You seem to intimate that, in order to make a good showing, I purposely estimated my surplus honey and increase of colonies at a high figure. Did I not explicitly state that the figures given were a *bona fide* account? By the way, you have not yet told us whether the balance sheet that you gave is real or imaginary. My honey was sold at home for 15 cents per lb., and my bees were also sold at home, at \$7 per colony; but, as all queen-breeders might not be so fortunate, let us again suppose, for the sake of argument, that the honey was sold for 10 cents a pound, and the bees at \$5 a colony; this would reduce the profits \$38. To this add the \$24 that we supposed my expenses would have been increased had I fed coffee A sugar, and we have a total of \$62, and yet the profits are \$140.80. Surely, Mr. S., you do not suppose that I would resort to deception in order to sustain an argument? I care not one iota which one of us "gets the best end of the argument" if we only arrive at the truth. When I mentioned that I used grape sugar, I felt quite certain that, if you did reply, the burden of your reply would be "grape sugar," "glucose," "cheap food," etc. How easily I could have avoided mentioning what it was that I used for feed, but these arguments do the most good when they bring out facts.

You say that I acknowledge that I allowed nothing for time spent in rearing queens. Did I not say: "But if I should deduct \$160 for my labor, do you not see that there would yet be a good profit?" Farther on I said: "If I deduct \$160 for my labor, my profits would average about \$10 per colony, each year." That there yet remained a good profit, after deducting a proper amount for labor, you simply ignore. You also "slip" over that part of my

article where I show the extravagance of some of the items in your balance sheet., "500 cages, \$50;" "lamp nursery and oil, \$7." If the figures in these two items were reduced to a reasonable amount, the laugh would be upon the other side of your face.

Again you say: "It may do for a man of leisure, or boys that have nothing else to do, but preposterous for a man of experience, with a family to maintain and children to educate." Under which of these heads, Mr. S., do you class yourself? I have a wife and three children to maintain; this I do, principally, by rearing "dollar" queens; is not one such fact as this worth more than a column after column of theory and argument?

CORRECTIONS: Words left out, and improper punctuation, make nonsense of the fore part of the second paragraph, in my article on page 183; it should read as follows: "You speak of breeders making a specialty of tested queens, and availing themselves of the untested feature to work off worthless trash. What is there to hinder a breeder from working off worthless trash in filling orders for tested queens, provided, that the 'worthless trash' produces bees with the requisite number of 'stripes'?"

In my illustrations of buying "dollar," "warranted," and "tested" queens, (see third paragraph, same article and page) the "warranted" queens were not mentioned; I presume that it was a compositor's mistake. By the way, Mr. Editor, you did not say which lot of queens you thought would be the best.

Rogersville, Mich.

[Our correspondent very concisely and fairly sums up the whole gist of this controversy with us in his seventh paragraph above, as follows:

Again I agree with you, Mr. Editor, when you say: "The bee-keepers of America want the 'best bee,' and to this end all bees should be tested before leaving the hands of the breeder;" but I do not agree with you in thinking that all, or even a majority, of the so-called "tested" queens are tested for their "best business qualities."

The third paragraph frankly admits his quotation was only in anticipation of what we might say, and, of course, the argument, we suppose is lost until we are prepared to make the assertions which they may cover.

He admires our ingenuous manner of using the "right word in the right place," and again agrees with us, as is evident upon reading his fourth paragraph.

The interrogatory in the first paragraph was not answered, simply because a difference in opinion or judgment of different breeders, would induce one to be more lavish where another would be more economical, and *vice versa*; as, one might pay high prices for good stock to rear from,

while another might suppose cheap queens good enough to rear cheap queens from. We have had no experience in rearing cheap queens for the market, but the evidence of experienced breeders is cumulative that they could not make it remunerative.

The second paragraph scarcely requires notice, notwithstanding its length. He admits that we did not stick for stripes; we in turn admit it is possible for queen-breeders to be deceptive, and all must admit it savors much of free advertising for cheap queen dealers.

His fifth paragraph is summed up in the last three lines, and we answer, "no."

And while there is no difference of opinion between us on the general issue, as quoted, we can scarcely appreciate the necessity for continuing these lengthy discussions, where the last word will be gained only by an ingenious "play upon words."

With the future we leave the determination of the verdict as to "dollar" queens, as we have no wish to prolong these wordy discussions. In general they become mere individual contests, productive of no good, and detracting from the general interest of the BEE JOURNAL. While we gladly welcome all correspondence which has a tendency to develop scientific bee-keeping or inculcate progressive ideas, we cannot but deplore the tendency to weary the reader with personal explanations or illogical arguments.—ED.]

For the American Bee Journal.

Holy Land or Syrian Bees.

E. A. THOMAS.

As there are many bee-keepers who are anxious to hear how the work of testing the Holy Land or Syrian bees progresses, I will give the result of my experience with them. I have given these bees a pretty careful study during the past season, and I find them possessed of so many remarkable qualities that I shall continue the work of testing them, believing that they will one day be proved a valuable race.

I will speak first of the disposition of these bees. Some attribute them with having a very ferocious disposition, while others speak of them as being equally as mild as the Italians. I wish to add my testimony on the side of the latter, having always found them easy to handle; indeed, with proper care, I can manipulate my Syrian bees at pleasure. I do not doubt but that many have been troubled with what they call pure Syrian bees, but I am inclined to believe that they have a little Cyprian blood in them. I think I have as pure

Syrian bees as can be found in the country, and after giving them a long and thorough trial, I find that the two races, although resembling each other in many points, are entirely different as regards their disposition. Although I am not discussing the merits of the Cyprians, I will say here that I have not found them as desirable a race as I expected, chiefly on account of the difficulty in handling them; but I wish to experiment further before I come to any definite decision in regard to them.

My Syrian bees, although not near as docile as my Italians, may be handled with impunity, and I never take any unusual pains in manipulating them; and I do not believe that pure Syrian bees will give any one any trouble in this respect. I am aware that this testimony conflicts with that of many who have tried them, but it is my honest, unprejudiced opinion, formed after a long and thorough test of the bees in question.

The Syrian bees are inclined to build but little drone comb. This will not enhance their value in the eyes of the most of us, but to those who do not use comb foundation it might prove a valuable quality; and foundation has not come into universal use yet, by any means, and many only use it for starters.

Another remarkable point about these bees is, that they seem to be impervious to the attacks of robbers, defending their home with a vigor and energy that is truly surprising. Last season after the honey flow had ceased, and the robbers were on the alert for mischief, I opened a Syrian colony and kept it open until the robbers swarmed around so thick that they almost hid the hive from view, and then closed it and left them to fight the invaders alone, determined to see if it was possible for them to get robbed. Great was my surprise—for I certainly expected to be obliged to interfere in order to save the colony—to see the bees clearing out the hive of robbers, nothing daunted at the invading host; such fighting I never saw on an alighting board of a hive, and it was not long before they had driven the last robber away and were basking in the sun as quietly as before they were disturbed. I opened Syrian colonies after that at all times of day without fear of the robbers, and I have never yet had a colony robbed out, although working on them sometimes until I was driven away. It is handy to have such bees when one is in a hurry and cannot wait for robbers to cool down.

Another remarkable quality about these bees is, that they are very judicious about going out in unsuitable weather. This must recommend them to those who are troubled with spring dwindling, and who have not the time or patience to prevent it. (See BEE JOURNAL for March 9, 1881, page 75). We might infer from this characteristic that the Syrian bees were lacking in ambition, in which case this point would be against them rather than in their favor. I gave some attention to this point last sea-

son, and found no reason to form such an opinion, but as I wish to test the matter further, I will leave the question open, as far as I am concerned.

Nearly all who have tested these bees agree that the queens are very prolific, and I can say that such has been my own experience with them; and not only have I found them wonderfully prolific, but very late breeders, a quality which all will appreciate, as furnishing the colony with young, vigorous bees to withstand the long, cold winter.

While, at the present writing, I have every reason to regard the Syrians as a valuable race, I may, after further experimenting with, and studying their habits, discover traits of character which will lead me to change my mind; but of this thing I am certain, that if they prove equal to the Italians in other respects, they will certainly excel as breeders.

Coleraine, Mass.

For the American Bee Journal.

Florida as a Location for Bees.

T. S. ROYS.

Florida, the land of flowers—the land of white sand, swamps, and alligators, would, I think, be equally appropriate. I write these lines sitting in my room with three large windows open and the mercury at 89° in the shade. The busy bees have been at work upon the fragrant orange blossoms beneath my windows for the past three weeks. We have experienced a very warm season in Florida. I landed in the State on Dec. 26 last, and there have been but very few days up to the present when the mercury has ranged lower than 70° F. I noticed an enquiry in the JOURNAL a short time ago from parties who were contemplating coming to this State to reside, relative to its honey resources, etc. My observations have only extended to the peninsular portion of the state, and from what I know of that, would say don't come here to go into the bee business. I am something of a beausticus myself, and know whereof I speak, and my advice to any and everyone coming to this State with a view to settle, would be to look thoroughly before you leap. Too much cannot be said in its favor as a winter resort or climate, but in almost every other particular it has been terribly exaggerated. Orange culture is the chief pursuit, and I do not know but I might say the only one of any importance, and always will be. Fertilizers are in good demand.

The JOURNAL has been received regularly, notwithstanding my migratory habits. I observe that the great guns are playing away at one another and also at the cause of bee dysentery, diarrhea, etc. These friendly discussions are all very good and are often the vehicles of much valuable information, progress and improvement. But it seems to me that the theories advocated from time to time as to the cause of bee dysentery in winter, or at least the most of them, are so far

from being the true cause that I cannot refrain from making a few remarks upon the subject.

In order to bring the said theories before the mind's eye I shall have to enumerate some of them. The first that came under my observation was bacteria as being the cause. This seems to me to be purely imaginary, and entirely without foundation; and I think we had better discard it entirely.

The second cause is pollen. From my observations in wintering bees, pollen is no more the cause of dysentery than propolis. They are both very essential requisites to successful wintering.

The third theory is "breeding in winter." This is a greater mistake than either of the others. The colonies that breed the most, will invariably be the best and strongest on the first day of May; and those that are the strongest at that date, will be the most profitable.

For several winters I conducted a regular system of experiments to discover some means of getting my bees to breed more while in winter quarters. I found they would commence breeding regularly about Jan. 1 to 10, and that they would as regularly stop about Feb. 20 to March 1, and would not recommence until put out of the winter quarters. This abnormal condition is usually the cause of spring dwindling, desertion, etc.

The fourth and last theory that I will enumerate is "starvation." This is about as serious a state of affairs as could possibly exist without coupling any other fatality with it. Bees in a starving condition will sometimes soil the combs with excrement, particularly if in a cold, damp atmosphere, but is never the cause of dysentery in the general meaning of the term. Bees kept in special depositories are apt to be kept too quiet or dormant. This I attribute to a lack of vital air or oxygen, and if the temperature is raised and fresh air admitted they will quickly revive, and resume the low, cheerful hum of happy industry, etc.

Cold is the primary cause of bee dysentery in winter. All of the other causes or conditions as set forth in your valuable paper during the last few months, and not herein enumerated, are secondary in their nature and tend to aggravate the disease, but never produce it. It is always traceable to too low a degree of temperature in some way or form. I have verified the truth of this fact to my entire satisfaction.

I am well aware that since the introduction of the broad, shallow hive, that there has been much serious trouble experienced in wintering bees. In fact it is almost impossible to winter out-of-doors successfully in this form of hive; and those wintered in special depositories, as a general thing, have fared but little better. The former usually perish in the middle of the winter, while the latter are apt to dwindle away and come to naught, soon after being set out.

T. Brookins, Sec., East Shoreham, Vt.
- 16—N. W. Ill. and S. W. Wis., at Rock City, Ill.
Jonathan Stewart, Sec., Rock City, Ill.
- 25—Iowa Central, at Winterset, Iowa.
Henry Wallace, Sec.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

The Central Michigan Bee-Keepers' Association will meet April 20, at Lansing, in the Capitol building. Programme.—President's annual address, Rev. J. Ashworth; bee hives and fixtures, E. W. Wood; Cyprian bees, J. Harper; the coming bee, Prof. A. J. Cook; care of old combs, Stephen C. Perry.

REV. J. ASHWORTH, *Pres.*

A special meeting of the Western Michigan Bee-Keepers' Association, will be held in Supervisors' Hall, Grand Rapids, Mich., Wednesday and Thursday, April 26 and 27, 1882.
Wm. M. S. Dodge, *Sec.*

The spring meeting of the Northern Ohio Bee-Keepers' Association will be held at Norwalk, O., on Saturday, April 15, 1882.
S. F. Newman, *Sec.*

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.
G. W. DEMAREE, *Sec.*
Christiansburg, Ky.

The semi-annual meeting of the Tuscarawas and Muskingum Valley Bee-Keepers' Convention, will be held in the Town Hall at Coshocton, O., on April 19 and 20, commencing at 10 a. m. A cordial invitation is extended to bee-keepers everywhere.
J. A. BUCKLEW, *Sec.*, Clarks, O.

The Texas State Bee-Keepers' Convention will hold its meeting at Judge W. H. Andrews' Apiary, at McKinney, Texas, April 25, 1882.
Wm. R. HOWARD, *Sec.*

Colorado Farmer.

Bee-Culture in Colorado.

The following is an address read before Loveland Farmer's Institute, Feb. 17, 1882, by Mr. J. McMillan: The subject assigned me on the present occasion is one of importance; second to none investigated at this Institute except water. It is one on which much might be said with profit. For several reasons I shall be brief and will only speak of that part of bee-culture that I think is adapted to the wants of this country. I will examine the subject under three heads: 1st. Will it pay? 2d. Can I succeed in the business? 3d. The management of bees.

As a prelude, we take it for granted that nearly everybody is fond of honey, and would like to have it if they could without too much trouble. Ah, there it is—trouble! Now, I want to tell you at the start, you cannot have as good a thing as honey is without some trouble.

"Will it pay?" is, I presume, an inquiry in the minds of almost every person here to-day. Whether it will pay or not depends entirely upon circumstances. If you get some bees and put them in a hollow log or a square box, leaving them to take care of themselves, being exposed to the ravages of insects and all kinds of weather, it won't pay. You might just as well expect to succeed in farming with the old wooden plow, drag your seed in with a brush, reap your harvest with a hook, thresh your grain out with a flail, clean out the chaff with a sheet, go to mill on a horse, with grain in one end of the sack and a rock in the other, as to expect to make it pay by keeping bees in a hollow log or square box. One of the most essential things in order to make it pay is good stock—strong colonies of pure Italians or hybrids. There is but little difference in their working qualities. I prefer the pure Italians; they are easier managed, and can work on some flowers that the others cannot. When any branch of business pays its way and a net profit equal to the usual rates of interest, it is considered a paying business. I submit a statement which makes a better showing for the little busy bee than common interest.

The first of last May I bought 2 colonies of Italian bees. When on their stands ready for work, they cost me about as follows:

Two hives (each, \$12.00).....	\$24 00	
Five new hives.....	12 50	
Total cost.....	\$36 50	
By honey, 250 pounds, @ 25 cents.....	\$ 64.75	
By five swarms (\$12.00 each).....	60.00	
Total.....	\$124.75	
Deduct cost.....	36.50	
		\$ 88.25

The above shows a net profit of about 240 per cent.

The second inquiry by several is, "Can I succeed?"

I take it for granted that what one person has done others may, all things being equal. If you will study the nature of bees, and become acquainted with their habits, and attend to

them as you would your horses, cattle or sheep, I can see no reason why you should not succeed.

If our cattle or sheep men would treat their stock like many persons do their bees, they would soon quit the business.

The first and one of the most important things in the management of bees is a good hive. What I mean by a good hive is one that has movable comb frames, convenient in its construction and durable in its make-up. They may differ in form, but those three points every hive should have. It is better for all the hives in the apiary to be alike, so you can divide and change frames from one hive to another. I would recommend dividing for increase, instead of swarming; not so apt to lose bees. But don't go too fast. From three to six times is enough, if you want to keep your bees healthy and strong.

You need a one-and-a-half or two story hive for taking honey, either in boxes or with an extractor. I have not found it profitable to take much honey from the brood chamber. Be sure and leave plenty of honey in the brood chamber, or near it, for winter supply.

Bees should have shade in summer, and comfortable quarters in winter. I do not think anything more is needed here in winter than a tight board house, with an opening for bees to pass out when they want to. But be sure and keep the snow and ice out of the lower part of the hives, so the bees will not smother.

Last, but not least, in the management of bees, is bee pasture. Nature has furnished this country with some of the finest honey plants I have ever got acquainted with. The two most prominent I have noticed in the past season, was the cleoma and the coreopsis. There is quite a variety of honey plants that may be grown here successfully, if farmers and gardeners would scatter the seed where there is moisture. White clover and mignonne would grow here in many places if the seed were sown, but the natural resources for honey will not be exhausted for some time to come. A majority of the native flowers furnish honey or pollen, besides many trees. Every acre of land brought under cultivation adds resources to bee range. There is no necessity for California or Utah honey being brought here to supply our markets when we have plenty right at our doors, if we will only gather it in. Within a radius of five miles from the center of Loveland, during the past season, there was ten thousand dollars' worth of honey lost for want of bees to gather it, and of a quality that will compare favorably with the honey of any country.

Mr. Washburn: How do you divide a colony?

Mr. McMillan: I would make a new colony about the 1st of May, though much depends on circumstances and season. Some years I can divide more than others, as, for instance, last year, I commenced earlier and divided oftener. Whenever drones begin to make their appearance I di-

vide. Some say to wait until queen cells are formed, but you can divide sooner. I have two ways of dividing. 1st. Take half the frames from a well filled hive and place in an empty one. Might take more than half. 2d. Take one frame each from eight hives and place in new hive. Let them alone and they will rear a queen. Both plans are successful. Don't divide your bees too much. I did mine the first year and by fall had a big showing, but in the spring I could not braga bit.

Mr. Washburn: In the second method, does it make any difference what frames you take?

Mr. McMillan: Yes; do not take outside frames, for they are not as sure to contain enough young bees, larvæ and eggs as those nearer the center.

Mr. Sprague: Can bees be reared with success 8,000 feet above sea level?

Mr. McMillan: As a rule, wherever flowers bloom and seeds mature, bees can exist. The only difficulty would be in winter. I think bees could exist in the mountains.

Mr. Hollowell: Will bees remain in the new hive? Won't they go back?

Mr. McMillan: They will stay. In moving frames from one hive to another a number of old bees will be moved to new hives. These bees will, for the most part, stay with the hive and care for the younger ones.

Mr. Cole: Price of your hive?

Mr. McMillan: About \$3.50, painted and in good shape. Some say that bees are neat and prefer nicely painted hives to any other—will do much better there. But paint your hives, at any rate; they will last longer.

Mr. Himman: What is the length of life of a worker bee?

Mr. McMillan: Cannot give this from my own observation. But they live 25 to 30 days. After a bee leaves the hive and goes to work it soon works itself out.

Mr. Himman: Must not bees kept over winter have a place to breed? Would not the swarm otherwise cease to exist?

Mr. McMillan: There is such a thing as their raising young bees during the winter; but bees go into a certain state and live longer in that state than under ordinary circumstances. It is best not to meddle with them in the fall. Let them fill their hives with honey in the fall, and they will come out all right in the spring. I tried taking part of the honey away from some of my bees one fall and left the rest as they had provided for winter. Those I made room for came out in bad shape in the spring. You can be too anxious with your bees. Give your bees a chance and they will succeed.

☞ The Champlain Valley Bee-Keepers' Association will hold their semi-annual meeting at Middlebury, Vt., May 11, 1882. T. BROOKINS, Sec.

☞ Those who may wish to change from other editions to the Weekly can do so by paying the difference.

SELECTIONS FROM OUR LETTER BOX

Wistaria Blossoms.—Herewith you will find some blossoms of the wistaria, which has been in bloom for some time. It is a rapid climber, and looks so beautiful, and seems to give my bees so much pleasure, I cannot resist the temptation to send you a couple of elusters. We have the finest prospect for a good honey yield that we have ever had, I think.

JAMES A. AUSTIN.
Huntsville, Ala., March 31, 1882.

[The flowers are very pretty, and nothing is more attractive than a wistaria vine in full bloom.—ED.]

The Hive I Use.—I have had considerable experience in bee-keeping, and have tried quite a number of different hives, but was not suited with them. I have gotten up a hive of my own—a double-wall, sawdust hive. My smallest hive measures inside 20x14 inches, by 14 deep. The frames are 13½ inches outside, both ways, and 12½ inside, making it a square frame, and will hold 9 of the small section boxes. These hives are nailed on strips of scantling 22 or 24 inches long, 2x2½, forming the hollow wall for sawdust, and extending down for legs to stand on, allowing the air to pass underneath the hive to prevent all dampness. I have some of those hives 40 inches long, with two entrances, intended for two colonies, with partition between. In some of these I have single colonies filling up the whole space. I find I receive the most profit from these strong colonies. I have frequently wintered these on 18 combs. I use a honey-board over my frames, leaving ¾ of an inch between the board and frames. My hives all have doors at each end, so by using a glass instead of a partition board, I can at any time see how they are coming on. The honey-board has a square piece to lift out of the center, 5x8 inches. Over this I put a piece of canvas, and then cover over all with sawdust. The bottom of the hive is hollow and filled the same as the sides. The ends between the doors and bees I have not filled in the summer time, on account of the observing glass.

Benmiller, Ont. P. FISHER.

Notes from Nebraska.—For some time past we have had a succession of small hurricanes of about the second magnitude, in this locality. On last Saturday the wind blew a furious gale from the southwest, and to-day (Monday) it has been repeated again with redoubled violence, filling the air with a cloud of dust and dirt, and doing considerable damage to fall breaking, drifting it in places like snow. It is very dry here now, and a good rain would be welcomed by all. The peach trees are in bloom nicely, and the cherries and plums will soon be out with their robes of white; but the in-

dustrious little bee has to keep close at home these windy days. I am just beginning with bees—have three colonies which I bought this spring at \$6 per colony. They are in the improved champion hive, and are in good condition at present. I am a subscriber for the BEE JOURNAL, hence I come to its columns for information. The bees glue some of the frames to the lid of the hive, and in removing it they sometimes fall an inch or more, causing quite a commotion among them, now how can this trouble be righted? W. H. MARTIN.

Falls City, Neb., April 3, 1882.

[Use a cotton or woolen blanket on top the frames, and clean the lid of the hive free from wax, so there will be none to stick it fast to the blanket. There should be just ¾ of an inch space between the top bars of the frames and the lid, if you use no blanket, and the bees will not be so apt to bridge between.—ED.]

Dollar Queens Again.—In discussing a subject of such vital importance to the bee-keepers of our country, I was in hopes that the truth would shine brighter than the almighty dollar. In natural swarming I never saw more than 5 queen cells designed by the worker bees to become perfect mothers; 3 is the rule. All the rest are inferior, and the queen-breeder that does not know this, does not know how to do it. How often do we hear the queen-breeder boast that he can get 20 to 30 fine queen cells built in one nucleus? I suppose such breeders must know how to do it, for they often remove the cells from the nucleus, and graft in more larvae for another batch, in which case rarely more than one cell receives attention enough to become more than half queen and half worker.

A MICHIGAN BREEDER.

What Shall I do with Them.—I have two colonies in movable frame hives, started without foundation. The bees have built the combs every way except straight with the frames. What shall I do with them? My bees brought in pollen yesterday, for the first time this season.

H. J. NORTHROP.

Lausburgh, N. Y., April 4, 1882.

[Artificially swarm them on good foundation, as described on page 210, of last week's BEE JOURNAL, 3d paragraph, 3d column, as soon as fruit is in bloom. Then trim out and save what brood you can.—ED.]

First Swarm Reported.—Had the first swarm for the season to-day—full Italians, and the largest I think I ever saw. Bees are beginning well. The hives are full of honey from fruit bloom, and I am extracting to make room for the queens. My 30 colonies are just as strong as they well can be. The prospect now is certainly encouraging.

F. N. WILDER.

Forsyth, Ga., March 25, 1882.

Net Weight.—Is it customary to include the weight of the can with the honey—that is, 10 lbs. or less, as the case may be, to weigh 10 lbs. honey and all, at so much per lb.; or is the tin deducted as tare? Please answer in the BEE JOURNAL.

Tiverton, Ont. A SUBSCRIBER

[We do not know what practice prevails, where tin cans are not labeled, but would imagine, if we bought from a reliable dealer, he would give us 10 lbs. net weight, if we inquired for 10 lbs. of honey. When labeled, the label generally states the net weight of contents, and the can or pail is charged for extra, or an addition made to price of money to cover the cost of the tin. In selling comb honey, the section box is charged in the weight of honey, because it saves to the purchaser its cost in dripping and waste honey, which would otherwise occur if the comb was cut to accommodate with a small amount.—ED.]

At Last We Agree.—I must thank Mr. Briggs for his manly and public confession of the soundness of my bacteria-pollen theories, as given in the BEE JOURNAL of March 29, page 198, wherein he says, "if pollen or honey is fermented or turned sour (bacterial), then it becomes unnatural, and, consequently unhealthy;" and also, for stating in regard to excessive pollen-eating when confined, "this insufficient and unnatural food produces enormous distension of the abdomen, and diarrhea; and all these causes resulted in death." That is just what I said. We are now pretty well agreed, only I must say that the experience of the most skillful hardly warrants me, the champion of Mr. Briggs' opinions, in believing that already the problem of "wintering bees is as simple as wintering stock of any other kind." I have enjoyed Mr. Briggs' attempts at some of the smart hits that Mr. Clarke speaks of. JAMES HEDDON.
Dowagiac, Mich.

Bees in Massachusetts.—March 28th being a nice day, with mercury at 55° in the shade, I thought I would look at my bees—25 colonies. They are all in nice shape, with plenty of bees and stores; were bringing in natural pollen at that date for the first time. That is just 3 days earlier than last year. I have been watching them close every warm day to see which colony brought in pollen first, but, to my surprise, I found every colony commenced the same day. I send you a blossom of spider plant, to show we can have them quite early here. But we have had it growing in the house all winter. D. S. BASSETT.
Farnumsville, Mass.

Bringing in Pollen.—My bees are bringing in natural pollen to-day—15 days earlier than they did last year.

W. C. GILLETTE.

Le Roy, N. Y., April 3, 1882.

Paint for Hives.—I prepared for winter 82 colonies; all of them are now living and very populous. I have drones flying, and some colonies seem to work almost as busy as though it were June, and right in the honey season. They are working on willows and maples. I have about 100 hives that ought to be painted; can you give me a formula of cheap paint that would answer the purpose, and still be durable. J. RUDY ROEBUCK.
Burton City, O.

[If you wish to paint them white, nothing is better than white lead and boiled linseed oil. If you mix it yourself, the cost will be about 8 cents per pound. For a yellow, beryl yellow and boiled linseed oil, will be durable; cost 7 to 7½ cents per pound. Dark brown, use what painters call Ohio mineral and boiled linseed oil; cost 7½ cents per pound. Reddish brown, Wisconsin mineral and boiled linseed oil; cost 7¼ to 7½ cents per pound. Exercise your own judgment in mixing to have it spread to advantage. These will all make durable paints, and one coat, well put on, will be sufficient. Of course the quantity used per hive will depend upon their age, smoothness, and kind of material.—Ed.]

Bees in Minnesota.—Bees in this part of Minnesota have wintered finely. I have 98 colonies out of 103 last fall, not one moldy comb to be found. My bees are breeding very fast and appear to be in the best condition that I ever had bees at this time of the year. There are 2 colonies of Cyprians here in this village, which I have been watching with interest, to see if they were in any way superior to the Italians, which I have failed to see, only in disposition. They are not as light in color as the Italians or as large, but can put in more sharp points to the square inch in a minute than any hybrid that I ever saw. I think disposition might be improved by crossing with good Italians. Taking them all around, they have a better disposition for sting than either blacks or Italians. The prospects are good for a good honey season, plenty of clover making its appearance. WM. LOSSING.
Hokah, Minn., April 6, 1882.

A Floral City.—My bees have done well. I wintered them in the cellar and lost none. They are now busily at work on the flowers. Mr. Editor, it would do you good to go upon the tower of our court house and look over the city. It is a perfect flower garden. JONATHAN GEORGE.
Independence, Mo., April 3, 1882.

Bees Healthy.—My bees are in good condition; they have wintered nicely and appear to be healthy. JOEL BREWER.
Lincolnton, Ind., April 1, 1882.

Last Year's Record.—Last spring I started with 5 colonies in fair condition. On the second day of February I took them from the cellar, putting them on the summer stand. The day was very warm, and they took a good airing. That night became cold, the next day colder, until 16° below zero was reached. Meantime I covered them with hay, and kept them there till the last week in March, when I uncovered them, and they came out as bright and merry as May birds. They increased in strength faster than I ever had bees increase before. By the first of May the hives were full and running over with bees. I increased to 23; sold 1; in the fall united 2, and 1 left for distant parts. I put 20 into winter quarters—13 in fair condition, and 7 rather light. The spring season was good for honey till the middle of May or 1st of June, when the drouth commenced. This made things dark and discouraging. During July and August they ate more than they gathered. September and October they obtained enough to stimulate to breeding. My surplus was light. I took 50 lbs., worth 25c. I estimate my profits for the season at \$128.80, on honey, increase and sales. ROBERT CORBETT.
Manhattan, Kan.

Early Drones.—I find that the drones are flying to-day from three colonies of bees. These are the first I have heard of in this section. Is it not early for this latitude? JAMES S. LORD.
Linden, N. Y., March 27, 1882.

[Yes; but everything is earlier this spring, than common.—Ed.]

Roaches in Hives.—I have bought 4 colonies of bees this spring, one in an old-fashioned gum hive. I can hear the bees, but very few come out, not even in warm days. I find a number of roaches in all the hives. Would like to know if they are injurious in any way whatever to the bees? I have not seen an article on this subject in the BEE JOURNAL. O. PARKER BAKER.
Woodberry, Md.

[We recently saw a car-load of bees which had been just brought from the South. There were hundreds of roaches about some of the hives, but as the bees were very numerous, we can hardly believe the roaches could have been injurious, unless, indeed, they had eaten some of the honey, of which there was a great abundance left.—Ed.]

Gathering Pollen March 1st.—My bees brought in pollen March 1st. I tried two ways of wintering on the summer stand—one-half packed, and the remainder without packing, and the latter came through much better for two winters in succession. Some years ago I buried my bees, on the Langstroth plan, and they came out all right. WM. ROBERTS.
Vaughansville, O.

Extracting Before Swarming.—My pets are doing well, and are very busy carrying in honey and pollen. Is it advisable to extract the honey before swarming, as they have between 40 and 50 lbs. to the colony? RACINE, WIS. F. A. GIBSON.

[Yes; if you want to run for honey, as that quantity now in the hives will greatly deter brood-rearing, and will force swarming or idleness.—Ed.]

Honey from Asters.—Our bees are doing finely—yes, boomingly. Saw drones, plenty of them, on the 15th inst.—more than 6 weeks ahead of last year. I have not lost a colony this winter, all 23 are in fine condition. If the weather continues propitious, will have early swarms and a sweet time this season. The aster saved our bees last fall; if it had not been for this little giant all of our pets would have starved. It was the only thing that withstood the fearful drouth of last summer. J. A. BURROW, M. D.
Santa Fe, Tenn., March 28, 1882.

Doing Finely.—Bees seem to be doing very finely; indeed, they were never in better condition at this time of year, that is, judging from those out-of-doors; those in the cellar are very quiet. We keep the door and 3 windows open both night and day, shaded so as to break off the rays of light, most of the time, except bright days, when we close them 5 or 6 hours in the middle of the day. The chaff packing keeps them warm and dry, so the cellar can be thoroughly ventilated. L. C. AXTELL.
Rosedale, Ill.

Editorial Items.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. This is a new pamphlet of 32 pages which we have just published. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

Cold Weather and Frosts.

Since the last issue of the BEE JOURNAL, the weather has been quite cold and unpropitious for bee-keeping, and the encouraging outlook has in some localities been somewhat checked. Through the Central States frosts have prevailed to a considerable extent, to the great detriment of the fruit crop, and in some localities early fruits and vegetables have suffered to a considerable extent. Hon. G. W. Demaree writes us from Kentucky, under date of April 13, as follows:

The cold wave struck us on last Monday; temperature went down to 30°; thin ice formed Monday and Tuesday nights; fruit all killed, and much other damage done—it is like "death in the midst of life." The orchards and trees look like they had been scorched with fire. It is feared that the growing wheat crop will be shortened by reason of the freeze. Some fields were nearly ready to head out. We can only hope for the best. Our bees are flying to-day, but they evidently realize the loss of the most profuse bloom ever seen about here.

In the vicinity of Chicago, several days of cold, wet weather were followed with heavy white frosts on last Saturday, Sunday, and Monday mornings, with cold west winds and clearing weather. The few sources of honey flow have been temporarily checked, pollen gathering ceased, and in colonies where brood-rearing had commenced, the consumption of honey and dwindling has been almost unprecedented. Every bee-keeper should see to it that the bees have feed in abundance, and provide it where wanted. We do not think the gen-

eral prospect for a honey crop is diminished, except, perhaps, where hopes were entertained regarding the fruit bloom giving a surplus.

Advices from Continental Europe, as late as April 10 report cold weather and hard frosts in the valley of the Danube. Fruit trees, vines, and young wheat in Roumania are almost entirely destroyed.

Small Money Orders.—The post-office committee of Congress has agreed upon a bill providing for sending small sums of money by mail. The charge is 4 cents for any sum under \$5, and will be very convenient to those sending small sums to newspapers or for supplies. The order is made payable to bearer at some particular office, which avoids the necessity for the duplication and identification necessary for the larger orders. The card is to be punched on the margin, which has figures showing the various amounts in dollars, dimes, and cents which can be transmitted. It will, no doubt, be very similar to the new orders of the Express Co's.

Catalogues.—We acknowledge the receipt of apianian catalogues from S. Valentine, Double Pipe Creek, Md.; George W. Baker, Lewisville, Ind.; Rev. J. S. Woodburn, Livermore, Pa., and S. D. McLean, Columbia, Tenn.

Selling Bees.—The demand for bees this spring is very large. Mr. Richardson, of Canada, remarks as follows: "I successfully wintered 25 colonies and have since sold all of them but 5 colonies, and could sell 100 more had I them for sale." Those having bees to dispose of should advertise them at once, so that those wanting them will know where to apply for them.

Pure Races of Bees.

Mr. Frank Benton, wrote the following letter, from the Mount Lebanon Apiary, Beyrout, Syria, dated March 6, 1882, to the editor of the *British Bee Journal*, to correct an editorial statement in the February number of that paper:

In the *British Bee Journal*, for February, page 214, I find in the "Reply to Query No. 443," signed "Ed.," the following statements, which are such as to demand a word of correction from me:

"It was claimed by Messrs. Jones and Benton that the Cyprian and Syrian bees were distinct in character, and they immediately set to work to breed both races in the Cyprians' apiary; and the Italian breeders have been doing worse by breeding Cyprians and Syrians in their Ligurian apiaries, so that eventually it will be difficult to find or keep a pure race at all."

True, Mr. Jones as well as myself, think the Cyprian and Syrian bee sufficiently "distinct in character" to merit different names. But the next statement can best be answered by a brief account of the work undertaken by Mr. Jones and myself. We came to Cyprus together in March, 1880, and immediately established an apiary in Larnaca. While purchasing colonies in Cyprus and rearing queens in the apiary at Larnaca, Mr. Jones went to Syria and obtained a number of colonies of Syrian bees, also from Palestine a number of colonies were obtained. These were brought to Cyprus and transferred at once from the clay cylinders into frame hives. The drones were destroyed in order to prevent the mis-mating of young Cyprian queens; and, in order to ascertain what effect crossing Syrian queens with Cyprian drones (the handsomest of all drones) would have, a few Syrian and a few Palestine queens were hatched in the apiary at Larnaca. Then Mr. Jones started on his homeward journey, taking with him every Syrian queen and every Palestine queen which he had brought to Cyprus, and also all queens reared from those mothers.

After that a few daughters of the original imported Syrian queens were permitted to hatch, and were sent out by me as Syrian queens fertilized by Cyprian drones, but none of these were sent to England or to Italy, except a single one sent to the editor of the *British Bee Journal*, and mentioned on page 45, of July number, 1880. All colonies having been supplied with queen cells from Cyprian mothers, and the hatching of Syrian and Palestine drones having been prevented, it will readily be seen that there was not after that time a drop of Syrian or Palestine blood in the apiary, except, of course, the few worker bees, the progeny of the queens sent away.

The past season also I obtained a few colonies from the mainland, and, after sending the queens away, hatched a few daughters from their

brood, so as to produce a cross between Syrian queens and Cyprian drones, and all the latter were sent to Mr. Jones, in Canada, for purposes of experiment. Thus, at the present time there are no bees in Cyprus that contain the least taint of any foreign blood, nor has there in fact any admixture of races taken place. Furthermore, as the statement above quoted brings in question the quality of queens sent out by me, I have only to say that every queen sent out as a Cyprian queen is bred in Cyprus; every one sent out as a Syrian is bred in Syria; and every Palestine queen comes from Palestine, and at least in this part of the world, if not in other parts, there exists not the least chance of an intermixture of the races.

It is true that the Italian queen breeders have been getting Cyprian bees. This they have done in the belief that the latter would improve their own bees, and if they continue in this direction they are not likely to be disappointed, for the bees of Cyprus, as well as those of Syria, possess an animal vigor and power of transmitting their qualities to their offspring with other bees, not found among Italian bees.

Speaking of crossing Cyprian and Italian bees, Count Gaetano Barbo, President of the National Society for the Encouragement of Bee-Culture in Italy, and one of the highest authorities in that country on bee matters, recently wrote: "I am convinced that the crossing of Cyprian drones with Italian queens will give good results."

Professor Sartori, of Milan, another of Italy's first authorities in bee-culture, it was who imported the first Cyprian bees into Italy, and since then other prominent queen breeders there have obtained them. I have sent a number of consignments direct from Cyprus there, but have sent no Syrian as yet, nor do I think any of this last race have gone there alive.

I have good reason to believe that all the Syrian and Palestine bees thus far landed in Italy were collected in alcohol by an Italian queen breeder, who then wrote some columns for publication, in order to tell of his wonderful exploit in capturing them!

In closing I would like to mention still another point which may not be generally known in England, as I am sure it is not in America, namely, the fact that black bees exist in Italy. Of this I can adduce many authorities, and from the Italian bee journals themselves, as witnesses. Thus I do not believe the introduction of Cyprian bees there will make things any worse, but it is quite possible an improvement may be effected in the bees of Italy.

We had supposed it to be pretty generally known in America that there are, or have been, black bees in Italy. The testimony on this point is not only direct, but many of the bees brought from there are more or less corroborative on this point, unless it be admitted that the Italian bees

themselves are a mixed or non-distinctive race; and perhaps both views of the case are correct, as Count Barbo has asserted that Italian bees have been bred there with the peculiar markings of the Cyprians. Queens have been imported from there which produced hybrid bees, and it is notorious that neither the queens nor the bees there are uniform in themselves, or among their progeny. Yet we do know that superior bees have been bred in America from the imported Italians, either direct or through discriminating selection.

The proof is positive, however, that black bees do exist in Italy. Mr. D. A. Jones asserted publicly and positively he had seen black bees in the vicinity of Rome itself; Mr. Frank Benton says they exist in Italy, and we stated in the National Convention, at its session in Chicago, that we had seen hybrids there. Other evidence can also be adduced to the same effect.

Mr. W. D. Wright, Knowersville, N. Y., writes us as follows, on April 13, 1882: "The Rev. Jasper Hazen died at his home in Woodstock, Vt., on the 30th ult., aged 92 years. The older readers of the *BEE JOURNAL* will remember him as a frequent correspondent in the earlier volumes. The deceased formerly lived in Albany, N. Y., where he was much respected and esteemed."

Premiums.—Those who get up clubs for the *Weekly BEE JOURNAL* for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—a copy of "Bees and Honey."
 " " 3,—an Emerson Binder for 1882.
 " " 4,—Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
 " " 5,—" " cloth.
 " " 6,—Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

CLUBBING LIST.

We supply the *Weekly American Bee Journal* and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

	Publishers' Price.	Club.
The <i>Weekly Bee Journal</i>	\$2 00.

Blunderers in High Places.

The *Indiana Farmer*, of recent date, has the following article, which will be read with interest not unmingled with contempt, by all honey producers in this country:

Gov. Porter, in his address at Columbus, before the Farmers' Institute, said in reference to glucose, that it is converted into a choice syrup that is extensively used as a table syrup, and exceedingly attractive in appearance. In its taste it resembles more than any other sweet, the maple syrup. A honey is manufactured from it that is not distinguishable in taste from the honey of the bee, and, both in a liquid form and in a comb manufactured by some artificial process and undistinguishable from bees' comb, is sold most extensively as bees' honey. Prof. Riley, before the Institute at Crawfordsville, repeated in sum and substance about the same thing, adding that really better honey could be made from glucose, than the genuine article itself. It is undoubtedly a good thing for corn growers, so far as the sale of corn goes, that so much of it is consumed in the manufacture of glucose, so also that so much corn is used in the manufacture of whisky.

That a politician who delivers addresses before farmers' institutes should make such gross blunders as are attributed to Gov. Porter, is not to be wondered at, especially when we take into consideration that the very swindlers who are imposing upon the public with their glucose imitations have perhaps made it convenient for him to see things in that light; but it is a serious reflection either upon his judgment or his candor, to suppose he knows anything of what he is talking about. We do wonder, however, at the recklessness of Prof. Riley in some of his reputed assertions, especially the addendum above, and hope that his address has been incorrectly reported. If his conclusions regarding entomology are as conveniently arrived at as are those relating to food economy, we fear his posthumous reputation as a scientist will scarcely survive the obituary. There is no justification for such blunders. That it is impossible to make a superior honey from glucose any reflecting individual may convince himself, if the trouble be taken to sample the genuine honey and counterfeit article together. Even the counterfeiters find it necessary to use a portion of genuine honey, either extracted or comb, to give flavor to their stuff. It is about time, however, that we should hear no more regarding the artificial comb honey. It is no credit to any person's

intelligence to believe the story; and the scientist impeaches his own reliability when he asserts that artificial comb is manufactured by machinery, filled with glucose, and capped over independent of the labor of the bees.

MISCELLANEOUS.

Paying Your Money but not Having Your Choice.—Mr. Zopha Mills, Jr., of New York, sends us the following excellent article from the *New York Journal of Commerce*, published under the above caption:

"If people do not like glucose they need not buy it." This is the *Herald's* comment on what it calls "unnecessary legislation." Unfortunately the dictum does not square with the facts. The sale of glucose does not depend on the like or dislike of the people. They never see and know glucose sold by that name. "O! no, we never mention it; its name is never heard," the grocers would say if asked if they kept glucose for sale. It masquerades under a hundred fancy titles of syrups, or gives a deceitful whiteness to coarse brown sugar; but in all its protean changes it never once reappears as glucose. If one of the *Herald's* readers should start out with the determination to buy glucose, and see whether he liked it or not, he could not find any—sold as such. It is not advertised in any newspaper. It is not quoted in any market report. It is not placarded in any corner grocery. It has no recognized existence among the "people," but is only known to those who are in the secret of its uses for purposes of adulteration or substitution. Until it is sold openly for what it really is, and not for something else, the people's preferences cannot be said to be consulted. The average citizen is not a chemist. He has no sure and ready means of telling whether his milk is watered or chalked, his beer and whisky doctored, his butter larded and his syrup or sugar robbed of half its sweetening power by the admixture of glucose. If he is defrauded by adulterations, he has a right to complain. It is not a sufficient answer to say that he is not obliged to buy such impositions unless he wants them. As we have shown, he cannot buy glucose wet or dry (under its real name) of his grocer, however much he wants to try it. He might as well ask a milkman for watered milk, or a liquor-seller for turpentine gin, or a confectioner for candy with 50 per cent. of *terra alba*. Such articles are never to be had by retail consumers on inquiry. We therefore cannot accept the dogma of our contemporary as entirely fair to the people, since it is not possible to con-

sult their tastes, while glucose, like oleomargarine, is never sold to them on its own merits. No reasonable man asks that the manufacture and sale of these substances shall be stopped. It is not alleged against them that they are poisonous or deleterious so far as known. They may have their proper places among the foods of the people. But oleomargarine is not butter, either "gilt-edged," "creamery" or "prime dairy." Glucose is not "maple syrup" any more than it is "bees' honey." Even if its healthfulness were admitted—of which we are by no means assured—it suffices to object that the pockets of the people as well as their stomachs need to be guarded against frauds in food. Will some manufacturer of oleomargarine or glucose be candid enough to give a single good reason why his product should not be always sold under its own name?

A Standard Frame.—Mr. Wm. Riatt, in the *London Journal of Horticulture*, remarks as follows on the subject of deciding upon a standard frame for Great Britain:

I am pleased to observe that the British Bee-Keepers' Association has resolved on the discussion of the question of a standard frame to be "stamped with its sanction and authority." This Association now happily occupies such a paternal relation to bee-keepers generally as, I think, justifies it in at least attempting to grapple with this question. The pity is that it could not have been done years ago.

Then, even though a bee-keeper adopts and determinedly adheres to a size of his own, he often finds himself in a difficulty when, through purchase or present, he may become the owner of a colony in another hive. Neither can he exchange or borrow a frame or two of brood, honey, or empty comb without in many cases having to make a transfer to his own frames, or tolerate an odd-sized frame for a time. And, after all, it can scarcely be said that any of the leading frames in use are other than arbitrary in dimensions. The discussion of the question, though opportune, is thus beset with great difficulties, and its settlement can scarcely fail to create unpleasant feelings somewhere. We may foresee, however, that if a decision is arrived at at all, it must be in the adoption of some style of frame at present extensively used.

As a small contribution to the discussion from the Scottish point of view, and from one who does not make hives for sale, I may safely affirm that we in Scotland are all but unanimous in using what I may call the Scottish Woodbury frame. Mr. Woodbury probably adopted the internal dimensions of his hive, 14½ inches square, from the calculation that ten combs would occupy about the space of 14½ inches. We may, however, dismiss the idea of length—that is, measuring across the combs—as it is evident that hives may profitably contain more than ten frames.

The other dimension, which we shall call the width, is that which regulates the size of the frame. The internal dimensions of a Woodbury frame, whose end bars are $\frac{3}{8}$ inch wood, and bottom rail $\frac{1}{2}$ inch, will be $13\frac{1}{4}$ inches by $8\frac{1}{2}$ inches. I am in a position to say that this size of frame is pretty general in England and Ireland as well as in Scotland.

I have been thus particular in regard to dimensions, not that I may ride a hobby, but because this particular frame contains within its measurements a unit I think ought to be in any frame claiming to be a standard. That unit is $4\frac{1}{2}$ inches, the dimensions either way of the American 1 lb. section. The Langstroth frame, most generally used in America, holds eight of these sections; the frame I have described holds six exactly as to depth, but with about three-eighths of an inch of room to spare in the length. All bee-keepers who work sections in frames, either in the body of the hive or in a top story similar to that below, will at once see the force of my proposal that the dimensions of this section should be taken as the unit of measure in the British standard frame.

It seems to me, therefore, that there is ground for claiming that the standard that is to be should either be the improved Woodbury or the Langstroth. The latter hive is scarcely used in this country, and we believe its frames are too long for our short seasons and moist winters. Certainly it is more difficult to handle.

Bees as Weather Prophets.—The California *Apiculturist* remarks as follows on this subject:

Nature in her generous gift and liberal economy is not endowed man alone with premonitions of changes of the weather, but to all living creatures, more or less. It is said that the swine herald the coming storm, by running to and fro carrying straw, weeds or other material for the formation of a bed. Likewise geese, by running, flying, and by a continuous quacking and chatter. But from the close experience of a learned German apiarist, it would seem that nature has endowed the "blessed bee" with more instinct in this respect than she has most of the animal kingdom. As we have never given the subject much attention ourselves, we give the following from a bee-keeper who has done so:

"When on Wednesday your colony leaves the hives, coming out of the holes in a mass, and hover about, you may be certain that on Sunday the weather will be nice, or at least, will bring a good swarming day. Should this happen on Thursday, the good weather will set in on Monday, etc. At least, here in Germany this is the case; but whether in America it is likewise, must be ascertained from observation. When bad weather is about to set in, or a scarce time for the bees, the signs are as follows: Should the bees fly later than usual in the evening, it will generally rain the

next day. Should they sit thick around the entrance-holes, lift the abdomen up, flapping with their wings, or move backward or forward with the head, as if they wished to chink up the place (we call this movement Hobeln), from 8 to 14 days of scarcity for the bees will follow, which days are noticeable for continued rain, wind and cold."

Adulteration Frauds.—Mr. G. W. Stanley in the *Empire State Agriculturist*, Rochester, N. Y., remarks as follows on this subject:

Since the oleomargarine frauds have come to the public notice, and since the facts have become known that some extensive dealers have seen fit to manufacture syrups and extracted honey of glucose or corn sugar, some persons, from what cause I know not, have seen fit to advance the idea that comb honey is also being manufactured and sold for the genuine article. Now, if there is one article that we eat, aside from our meat and potatoes, that comes to our hands in just the shape that it should, that article is comb honey. If those who are inclined to think that this is made in the way spoken of, which is to make the comb of paraffine complete, and then run in the melted corn sugar and seal over with a hot iron, will stop to think, they will at once see the mechanical impossibility of the thing. I know from long experience that it takes a vast amount of patience and some skill to make comb foundation as thin as the bees make it, without even attempting to make the side walls to the cells; and when we come to realize that these side walls are so thin that it takes 192 of them to make an inch in thickness, and at the same time those walls are made $\frac{1}{4}$ of an inch high in ordinary comb honey, it will be very easily seen that the thing is impossible. There is no Yankee yet so smart that he has invented a machine that will make comb foundation with base as thin as natural comb, and at the same time with walls 1-16 of an inch high.

This adulteration of food is bad enough, but let us enjoy, while we can, the blessing of knowing that some articles of food are still handed to us in their purity. If the adulteration of sweets could be stopped, the honey producers could then sell an article of extracted honey for 15 cts. per lb. that would be equally as good an article as the comb honey, for which he pays 20 cts. per lb., and still his profits would be as large and the consumer would get more for his money; but if we wish to find what can be done with a nice lot of extracted honey in tumblers, we rush to some of the large dealers in our cities and we get the answer: "We cannot sell your goods in that shape, as our customers want the goods put up fresh." Now, what does this word "fresh" mean? It means, you send us your honey in barrels, and we will take out 5 per cent. commission and pay you 9 or 10 cts. per lb. for it, delivered, and mix it with glucose that costs us 3 cts. per lb.

and sell it for 20 cts. per lb. in tumblers. Thus the producers and consumers are alike swindled, and our honey loses its reputation, and the dealer makes 200 per cent.; the consumer eats glucose, and the man who produces the honey realizes about 8 cts. for his extracted honey. If those buying honey, either extracted or comb, would buy from the producer and not from the dealer, they would get a better article of extracted honey for 15 cts. than they now get for 20 cts., and the same comb honey that now costs 25 to 28 cts. at retail, could be had for 20 cts. in 25-lb. crates.

You need have no fear of getting impure comb honey, but when you buy extracted honey at the grocery, see that it has the name and address of the producer on the label, with guarantee of purity, and the nearer that producer is located the better.

Be Kind to the Bees.—The *Rural Canadian* says:

Considering that during the honey season, when we have most occasion to handle bees, their average life is not over three months, there is but little chance to cultivate friendship with them. Besides, the first smell of you they decide whether to treat you as a friend or a foe. No kind treatment that you can give them will ever change their dislike of you into love. Be gentle with them always, but gentleness will not conquer their aversion if they have taken a "scunner" at you. It is people who are bee-loved who should make a life-work of apiculture. The most that others can do is to let the little insects know from the start that they have their master.

Buying Bees and Transferring.—The *Indiana Farmer* remarks as follows:

To those who contemplate buying bees, we would say do so at once, so as to take advantage of all the season's work. A good colony now may well be expected to pay in honey its first cost or more. If you cannot afford to buy full colonies, get good strong nuclei, and they will soon grow into quite large colonies, especially if you help them with comb or foundation. The very best time for transferring bees is during fruit bloom. If you contemplate doing any of this kind of work, you should get your hives and fixtures all ready at once, so as to be in complete readiness when the time comes.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. This is a new pamphlet of 32 pages which we have just published. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

CORRESPONDENCE

For the American Bee Journal.

Storing Honey in Sections.

C. H. DEANE.

Some of my correspondents are complaining, that if I have a good thing, I ought not to be afraid to show it up, and as I certainly want all the bee-keepers in the land to give it a trial I will make the effort.

My system for top and side storing is composed of eleven cases, 2 hoop iron frames, 2 wooden clamps and 2 wire loops; these make one set for a 1½ story hive, by adding 7 more

Deane's Section Case.

cases and 2 clamps, it can be made 2 stories, and increase the capacity from 44 to 72 lbs., and so on up as high as it is desirable to tier. To handle these cases you are to place 7 cases side by side and a clamp on each side; these clamps have 2 screws in each end; you now take the wire loop mentioned above, and put it over these screws, and this gives you 2 parallel wires running from one clamp to the other and about 2½ inches apart; place 2 small wire loops around these wires drawing them nearly together in the center. Now truss the cases up by shoving the small loops toward the screws in clamps; and if properly done the wires will ring like fiddle strings.

The iron frames are to suspend 2 of these cases on each side of the brood nest in the lower story, and are made

Section, showing Joints.

to fit the cases. Any practical bee-keeper ought to be able to make this system, if he has a saw for dovetailing; but let him bear in mind, that it is absolutely necessary that the bottom bar come directly in the center of the end pieces, otherwise, in tiering up, the slots will not come directly over one another, as they should, in order that the bees may pass from one to the other. The system can be applied to any hive with movable combs.

The advantages of this system are: 1. The cases have no top bar, and the sections can be manipulated with perfect ease by the operator.

2. You can loosen the whole 7 cases in an instant, simply by shoving the small loops of wire to the center and lifting off the clamps. You can then pick out any case or section without disturbing any other.

3. You can use them with or without separators. When used without separators, use perforated division board in lower story.

4. The cases can be alternated from top to side.

5. They can be sent to market just as they come from the hive, simply by placing heavy brown paper on top and bottom and tacking strips across bottom and top and into clamps.

6. When trussed up you can handle the 7 cases like a solid box.

Iron Broad-Frame for Sections.

7. By arranging ¼ inch strips all around on top of brood frames and resting the cases on these, you can throw all the heat into the sections.

8. The sections fit the cases so snugly that there is neither end nor side shake when trussed up, and in consequence the bees will not stick the sections with propolis.

9. Any Langstroth or simplicity hive, 14¼ inches wide, inside measure, will take 7 of these cases and leave ¼ inch to spare.

It seems to me, Mr. Editor, that the advantages enumerated above are unnecessary; for after the testimony of the North American Bee-Keepers' Society that "it combines all the necessary arrangements simple and complete," (See BEE JOURNAL, vol. xvii, No. 42, page 333), that every bee-keeper in America ought to give this system a trial and test its merits. Mortonsville, Ky., Feb. 2, 1882.

For the American Bee Journal.

Some more Slovenly Bee-Keeping.

J. H. MARTIN.

On page 181 of the BEE JOURNAL, the Rev. L. Johnson, gives us an extreme case of slovenly bee-keeping. And I venture to say, that nearly every bee-keeper in the country can point to just about such bee-keeping in his own vicinity.

Their object in keeping bees is to get just a little honey for their own use, and thereby save buying it, and it is a precious little they use, for the very first full box of white honey they take off is trotted off to the store and traded off for cheap molasses, at whatever price the merchant may put upon it. The "honey for home consumption" comes from those late swarms that are brimstoned in the fall. Such a class of bee-keepers ruin the country markets, and bring discredit upon the whole fraternity by their slovenly management, and finally their cruel taking off of the

bees with brimstone. It is a great mistake for bee-keepers to give encouragement or aid to any person who has no taste for the business. If such a one is started in the business and subscribes for a bee paper, the reading is all Dutch to him, unless he posts himself from some standard work, and this but very few of this class will take the time or trouble to do, and the bee paper is soon thrown aside. Furthermore, a farmer that has all he can attend to, has no business to engage in bee-keeping, for where there are many irons in the fire some will burn, and it is sure to be the bee-keeping that will burn. There are many farmers' wives that would make capital managers of the neglected apiary, but household cares, numerous children, no taste for study, are barriers but few seldom surmount.

We have a plan that works very well with this class of beemen. If they are within six or eight miles of us, we first talk purchase to them. If they sell at a reasonable price we buy their entire apiary. If we cannot buy, we then make them an offer to take them on shares, and usually we can make a bargain with them to our mutual benefit. The farmer gets the benefit of expert handling, and gets more honey than he ever dreamed his bees could gather, while the expert bee-keeper will also reap a fair return for his labor.

Let us, therefore, encourage the person who is really in earnest and proposes to make it his business, and discourage the man who wants to keep bees just to get a little for his own use, by brimstoning his bees.

Hartford, N. Y.

For the American Bee Journal.

About Bee-Keeping in Colorado.

WOMAN'S INDUSTRIAL ASS'N.

There are at least 2,000 colonies of bees, mainly Italians, in the State. Colorado is as well adapted to profitable bee-keeping as California, and the honey we can produce is sweeter and whiter than any other introduced in the market. There is hardly a farm or garden in the west where bees will not prosper, and the mountain foothills are peculiarly adapted to them.

In the spring of 1870, Dr. King, of Boulder, Col., sent to Indiana for one colony of bees. They arrived in good order. Being a novice in the art of handling the little creatures, and having the fear of their sting in his mind, he had a hired man attend to them and get them comfortably fixed in their new quarters before he visited them. But, as all bee-keepers do, he soon learned that the fear was an idle one, and in a short time he could handle them as if they were house flies.

Allowing his bees to cast only one swarm from each hive, he doubled his number, and had a fine crop of honey. One colony filled 5 stories of the American hive full of honey.

Obtaining some imported Italian queens, he has since bred from them

until now he has Italians in all their beauty and purity. Careless owners have allowed colonies to escape at swarming time and are now to be found wild in the mountains. Many trees have been found and cut down during the past 2 years for the sake of the honey stored in them. It even seems certain that they have gone "over the range," as they have been found by prospectors on the west side of Gray's peak within the last year, and, being Italians, must have crossed from this side. Locations at the foot of the mountains are in many places first-class. Such points as Golden, Boulder, Collins and Morrison in the north, and Manitou, Canon City and La Veta on the south, as well as many others probably equally as good, might be named. Indeed, any point that is in close proximity to low foothills and gulches that will give bees an opportunity to reach the higher altitudes without having to fly over high and steep mountains, can be set down as being a good location for bees; and these points string all along the range of hills from Wyoming to the borders of New Mexico.

But, in addition to this, bees do well also on all streams that are settled up and where the land is under fence and in cultivation; for the face of nature is covered from early spring time to late fall with flowers that afford honey in great abundance. Trees, wild flowers, vegetables, wild grasses, all offer their stores of sweet treasure to the ever busy bees.

The National Mining and Industrial Exposition, which is to be held in Denver, will open Aug. 1, this coming summer. The managers are now pushing the scheme through, and intend to have the main building ready for the reception of exhibits by the 15th of July.

Denver, Col., March 29th, 1882.

For the American Bee Journal.

The Bee Controversy.

G. W. DEMAREE.

Like Mr. Heddon, I have enjoyed the cross-fire controversy hugely. And I am willing that he shall have the closing argument—as between myself and him, though, "lawyer like," he has brought in a regular broadsider. Friend H. reminds me of a sermon preached by an old colored preacher about here some years ago. He was discussing the "st' a' fas'ness" of his faith; and as he waxed warm he went on to illustrate—"My brithering, my faith is liken unto the shakin' a possum outen de top ob a tall 'simmon tree—ah! you may shake, and shake, and shake, and he lets one foot holt go—ah! And you may shake, and shake, and shake, and he let anudder foot holt go—ah! And you may shake, and shake, and shake, and he let anudder foot holt go—ah! And you may shake, and shake, and shake, and he let de last foot holt go—ah! But you may shake, and shake, and shake, and shake, but all h—l will nebber make him break him tail holt—ah, ah!"

I have shaken Mr. Heddon loose all over, and yet he hangs in the tail "simmon tree" without so much as the tail holt left. The discussion of the subject of "bands" and "pure" bees has become quite extended. Mr. G. M. Doolittle has favored me with a copy of the March No. of *Gleanings*. The author of A B C is evidently undergoing considerable tribulation. Mr. Doolittle has enlightened him on the subject of "bands," and there is to be an "amended clause" added to the A B C "window test," and falls back on to "alcohol" and the microscope, and finally begs for quarter. Medina has been "headquarters" for daughters of the imported "herd" for years past, and they must have "bands."

There is evidently a shaking going on among the "dry bones." A few years ago a man dared not hint that the famous Italian was a "thoroughbred" bee, and must be bred by selection to insure improvement. We are all "learners;" let the light shine, though all our cherished notions fall like autumn leaves.

N. W. Iowa and S. E. Dakota.

W. PAXTON.

My report for 1881 is too insignificant to note, except to cover a locality unrepresented—Northwestern Iowa and Southeastern Dakota. In March I closed out the last of my Delaware Co. apiary, in the keeping of Mr. Meader, at \$4 each, and in May purchased 3 colonies for \$18, in bad condition, transferring them the last of May. One contained scarcely $\frac{1}{2}$ lb. of bees, two were in better condition, but had not yet cleaned out the dead bees. I took about 130 lbs. of extracted honey, and increased to 7 by division—not quite so strong as I could desire, yet I hope to bring them through. Increase was my main object. From scarcity of drones, I lost 5 queens in mating, which put me back somewhat.

Our honey plants differ from those I have seen East, but my limited botany will not permit me to name them. The river banks are skirted with brushwood, called timber here, cottonwood, soft maple, box elder, elm, 4 varieties of willow, ash, and, at a distance of one mile, considerable basswood, walnut, and oak. Milkweed, of which we have several varieties, is abundant, taking possession of all vacant ground. My bees visited it for a long season, but I think the honey rather rank-flavored. Snow-drop grows wild in profusion, and its delicate pink blossom seems a favorite. Heartsease and a few prairie flowers give some honey, but the most persistent bloomer, is a plant growing 2 feet high, quite branching, long spikes of purple bloom, grows on roadsides and plentiful in hog pastures, visited all day, and every sunny day from early summer till frost. With this plant and the variety of willow blooming in July I wish further ac-

quaintance. Of wild fruit we have currants, gooseberries, and abundance of plums, choke cherries, and grapes; but the honey plant which of all others I most esteem is rape, grown at first for seed, and since giving a volunteer crop. From this I think my bees got the first start, and from this I think they took pollen on the 5th of November.

The coming bee is a subject in which I feel a deep interest, being from boyhood an admirer of the little pets. Mr. Heddon and other renowned apiarists will pardon me if I lean to the side of beauty, and if I conclude to wait a further trial before stocking with Syrians from D. A. Jones. I shall take the bright and gentle Italians.

The coming bee hive is of equal interest with the coming bee. I have given the subject some thought, and although a bee-keeper for near half a century, I am free to confess I have never seen or used a hive that quite suited me, and while I have generally given a wide berth to patents, moth-proof and clap-trap generally, yet if all I have used were piled up to appear in judgment, it would not all be on the side of simplicity and utility. After wandering for things new, experience generally brings us back to the Langstroth; yet I am not quite reconciled to be shut out from the brood chamber while using a second story for surplus, and like Stewart and Whiting, see, or fancy I see, an advantage in reversing combs, and especially in transferring. I wish these men had given us a description of their frame and hive, and this reminds me that others may get an idea from a description of and help perfect the hive I use.

My frame is square to render it reversible, and give a compact form for brood. I have adopted $11\frac{1}{4} \times 11\frac{1}{4}$ to give a double-wal for brood, with space for Langstroth frames above, the frames running parallel, so that by removing a frame above I can reach one below. This I design for out-door wintering and protection against spring and fall chilling. Two cushion division boards $\frac{3}{8}$ in thickness, contracts the hive at will, giving space for chaff when needed. A summer entrance at each end, with one in the middle through the bottom-board, admits of cutting up into three nuclei, for which the size and shape of frames are suitable.

My object in explaining is the hope that some one may give a more simple, cheap and convenient hive, and at same time possibly return in part the many useful crumbs gleaned from correspondents of the BEE JOURNAL.

Notwithstanding the expensive experiments and partial failure of Messrs. Perrine and others, I am disposed to think favorably of cheap bees, safe wintering, and the advanced seasons of the sunny South. With an abundant flow of the sweetest nectar in the North, and direct communication by water and rail, is whereon I base my conclusions that a practical man at each end should make it win.

But what I intended as a brief report has grown too long, and I will

close with the suggestion that in looking for the coming bee, breeders should direct attention to this isolated region where mating in the open air can be controlled as thoroughly as on D. A. Jones' isolated island, and with less risk of drowning.

Improvement in Bees, Etc.

WM. H. BALCH.

Twenty years ago, after I had kept bees for 5 years, I thought I was the smartest bee-keeper in all this region. I had read Quinby and some other bee literature, visited all the apiaries for miles around, asked all the questions and got all the knowledge I could, and I have been doing the same ever since. But about that time I began to find that there was more to learn, and, as I learned and experimented, the more ignorant I saw I was, and I have come to the conclusion that I do not know but little in comparison to what there is to be learned in the great field of bee-culture.

I am glad the BEE JOURNAL has taken so decided a stand on the grape sugar and adulteration question. Let us one and all take an active part and urge all to take hold with an earnest zeal to put down this adulteration business.

My bees last spring were, with a few exceptions, weak. I sold quite a number, some weak and some strong, just as customers wanted. I put 70 colonies into winter quarters, and right here (as I have been breeding for certain points), I want to speak about one colony in particular, as it contained one of the queens I had placed at the head. After the long winter there came a thaw, bees commenced to fly, and I began to shovel away snow and examine; now and then I came to one dead, and when I came to this one there was no stir. I gave it a bump with the shovel, but no response. Supposing the bees dead, I passed on. Not very long after it thawed again. As I had to go away, I gave particular orders to my boy to mark all hives where bees did not stir, so that we could take care of the combs and not disturb hives with bees in. In a few days after we commenced to pull out the hives of dead bees, when we came to this we pulled it out, took off the cover, and, to our surprise, there were 5 spaces filled with live bees, plenty of honey, and not one gill of dead bees. The next thaw was warmer than the previous spells, and these bees had a fine fly. They had as much pollen as any in the fall, and plenty then. This colony kept quiet all through bad weather, and did not dwindle nor increase very fast, but when it became warm enough for bees to get out and back alive, they made it count. I used it extensively for queen-raising, and increased it to 7 colonies, which filled their hives with honey.

Do not think I am enthusiastic over this colony. I merely speak of this colony to illustrate that bees are ca-

pable of being improved in the right direction, by close application and judgment. The best that I ever realized was 4 years ago. I had 45 colonies in my home apiary from which I sold \$900 worth of comb honey and \$600 worth of bees and had 60 good colonies to go into winter quarters with. They were not fed anything but about 100 lbs. buckwheat meal in the spring. Fifteen of the above did not swarm; these gave me a little over 300 lbs. of comb honey each.

In vol. 18, page 52, BEE JOURNAL, I cannot agree with Dr. Brown in regard to feeding all at once; they are more apt to crowd the brood nest, and when the feed stops are prowling about to rob; but the rest the Doctor says I can most heartily agree with.

I have often said that nearly all the honey gathered in the United States might be consumed at home in the country and small cities at a good price, without sending it to commission houses. I have experimented on this point for more than 20 years, and home trade will net on an average over 10 per cent. more than to sell it on commission. My trade far exceeds my production, and I cannot fill orders for want of honey. Some of the very men that 20 years ago I had to urge to buy one box, have within the last few years bought from 8, 10 and one as high as \$13 worth each year.

Oran, N. Y.

For the American Bee Journal.

Notes from Washington Territory.

C. THEILMANN.

There are no bees in this part of the country, but I have seen some at Walla Walla, on Puget Sound, and at Portland. They were all neglected, however, and those who have bees know but little about them, not even about using smoke. One man was very much astonished when I puffed a little smoke on the bees that were clustered outside a gum, to see them all quietly moving into the hive.

After leaving Puget Sound and Portland, I have seen but two little patches of white clover, near a house-yard, at Walla Walla. Bees would probably do well in that vicinity, on account of the abundance of all kinds of fruits, flowers, berries, and shrubbery. There are also many kinds of wild flowers, willows and honey producing trees, and one kind of sage brush. All the bees that I have examined were strong, with plenty of honey. The winters in this locality are generally very mild, and bees would usually have an opportunity to fly every three to five weeks.

The climate here (Medical Lake, Spokane County) is somewhat like northern Illinois and Iowa. Eighteen degrees below zero was the lowest here this last winter, with about 2 feet of snow on the level, which is now rapidly disappearing, and some spots of ground are visible.

The country on this coast, so far as I have traveled, is not so compactly there as Iowa, Minnesota, or Dakota. There are many rocky places between

the good lands, and only here and there have I found valleys and prairies, of from 15 to 50 miles long by 10 to 30 miles wide, all good land, where they raise from 30 to 60 bushels of wheat per acre: most of the wheat is soft, but plump. Roots and vegetables grow to enormous size. The climate east of the Cascade Mountains seems to be very healthy.

Spokane County, Wash. Ter.

[Mr. Theilmann, formerly of Theilmanton, Minn., has sent us a box of the Medical Lake powders, which he writes us are prepared by boiling the water from the lake till it resolves itself into a whitish or cream-colored powder, and has something of an alkaline taste. Mr. Theilmann speaks very highly of the curative powers of the water in the lake. This lake he describes as being formed in the shape of a kidney, $1\frac{1}{4}$ miles long by 100 rods wide, with a belt of pine timber surrounding it, and is about 50 feet below the surface of the land around it, with sloping banks to the water. It has some insects in the water, but no fish. There is no inlet nor outlet to the lake.—ED.]

For the American Bee Journal.

Anomalous Cases of Success.

G. W. ASHBY.

I see and read so much about upward ventilation, and again about putting cushions on top of the hives, etc., I do not know which to follow. I put woolen carpets over mine—some I put close on top, and others I left one corner open. I could see no difference in condition.

I went to see one of my neighbors; I did not know he had a bee on his farm till I walked around in the yard behind his house and saw two old box hives in a low damp corner of the yard, surrounded by plum trees, so thick when in leaf no ray of sunlight could ever penetrate them. I said to the gentleman: Are there bees in those old hives? He answered, I believe so. I went to them, turned one up, and out hopped two mice. It had stood there till the top had rotted off, with a crack in the side from bottom to top. I could put my finger in one corner, and it had sagged so it would hardly stand up. The man was going to move away, and wished to sell his bees. I told him they were worth nothing in that shape. He said the old box stood there in the winter of 1880-81, and cast off a swarm in 1881. Finally he said I might take them home and nurse them up, and if I could save them I might pay him what I thought they were worth. This was about March 14, 1882. I tied a rope around it to hold it together, put the two in my spring wagon, took them home, fed them till the 4th of April, then transferred them into Langstroth hives. The rotten one was the strongest, had

more young bees and even drones out, and had more honey than the sound one. The honey was so old it was almost red.

Here was a case without any protection on top save rotten plank, glued together, and the side and corner open, which wintered safely through 1880-81, and after the dry year to winter again and have more honey than my Langstroths blanketed up and closed all but a very small entrance. It must have been the good old honey stored away that saved them, and it must be the bad honey that gives the bees dysentery and probably produces bacterium, and all the diseases known to the bee race. Here were mice, moths, and plum seeds carried in by the mice and glued up by the bees, with ants in abundance, all housed together. The bees look large and stout. Really, they are lively pets.

This case shows plainly, I think, that bees ought not to have the warm rays of the sun to cause them to fly out when the air is so cold as to cause them to fall and never rise again, thereby depleting the colony in the spring. This I count a rare case indeed. I have been keeping bees for upward of 25 years; in fact, worked with them when a boy, but I never saw such carelessness on the part of any man before.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—Ed.

The semi-annual meeting of the Tuscarawas and Muskingum Valley Bee-Keepers' Convention, will be held in the Town Hall at Coshocton, O., on April 19 and 20, commencing at 10 a. m. A cordial invitation is extended to bee-keepers everywhere.

J. A. BUCKLEW, Sec., Clarks, O.

Barren County, Ky.

The bee-keepers of Barren Co., Ky., met in Convention at the Sinking Spring School House, near Glasgow, on the first Saturday in April. The house was called to order by the Hon. President, I. N. Greer. The roll-call being dispensed with, the President called for new members, and several came forward and gave their names.

The minutes of the previous meeting were called for, read by the Secretary, and approved.

The Convention then proceeded to elect their officers for the next year, which resulted as follows: I. N. Greer, President; Mike Wynager, Vice President, and H. C. Davis, Secretary.

The following subjects were then discussed: What is the best plan to prepare bees for winter to prevent dysentery in the spring?

N. H. Holman said he wintered on summer stands, by placing a box over the hive with about 6 inches space between the box and hive, with the entrance open; he confines his bees in the lower story with the honey-board; has holes in the honey-board covered with perforated tin, to let the moisture escape.

Mr. Wynager said he removes the combs from the walls of the hives, and inserts an inch plank with quilt on top, with leaves or chaff for absorbents.

Dr. Allen said dysentery was caused by impure honey and too long confinement; give your bees plenty of good sealed honey, and keep them dry; winter on honey gathered early, and not on fall honey.

The President appointed the following committees to report after dinner: 1st. To arrange for honey show, R. J. Parker, W. J. Bradford, Wm. Arnot, Mike Wynager.

On questions for discussion: N. H. Holman, M. S. Reynolds.

Dr. Allen being called for, gave a very interesting lecture on the production of bees and honey. Among the many things he said, honey was a god-given sweet, and good enough for the gods to eat, and that all farmers could have honey, and many others, if they would give a little time and attention to bees.

The committee on time and place of meeting report Browder's Chapel as the place, and the second Saturday in August as the time. The report was received and the committee discharged.

The Convention discussed the subject which is better, natural or artificial swarming?

Mr. Wynager said, let your bees swarm if you are not an expert.

N. H. Holman said he prefers artificial swarming.

A. C. Davis said he thought artificial swarming the most desirable.

Wm. Arnot prefers natural swarms.

Question—Will it be profitable for every farmer to keep 10 or 12 colonies of bees, or is there any danger of being over-stocked?

N. H. Holman said we may over-stock by all keeping bees.

M. S. Reynolds said we might over-stock if we do not provide bee pasture.

Mr. Wynager thinks there is no danger of over-stocking, if they are looked after as you do other stock.

Question—Which is the most profitable, extracted or comb honey?

N. H. Holman said if you wish to increase, extracted is the most profitable; if you want no increase, comb honey is the most profitable.

Mr. Wynager said extracted was the most profitable, unless you use comb foundation.

J. T. Gray said he sells his extracted honey for 15 cents per lb.; thinks you may get double the amount in extracted. The discussion then closed.

On motion, J. H. Adams, of Glasgow Junction, Barren Co., Ky., was appointed purchasing agent for apiarian supplies.

On motion, the Secretary was ordered to furnish the AMERICAN BEE JOURNAL, Farmers' Home Journal, Bee-Keepers' Instructor, and the Glasgow Times, with a copy for publication.

The thanks of the Convention were tendered to the above papers, also to the neighborhood of Sinking Spring School House for their good attendance, and especially the ladies for their presence and their good dinner.

Adjourned to meet at Browder's Chapel the second Saturday in August.

I. N. GREER, *Pres.*

H. C. DAVIS, *Sec.*

The Mahoning Valley Bee-Keepers' Association will meet at Town Hall in Berlin Center, Mahoning Co., Ohio, on Saturday, April 29th, 1882, at 1 p. m., sharp. All interested in the busy bee are invited.

LEONIDAS CARSON, *Sec.*

The Central Michigan Bee-Keepers' Association will meet April 20, at Lansing, in the Capitol building. Programme.—President's annual address, Rev. J. Ashworth; bee hives and fixtures, E. W. Wood; Cyprian bees, J. Harper; the coming bee, Prof. A. J. Cook; care of old combs, Stephen C. Perry.

REV. J. ASHWORTH, *Pres.*

A special meeting of the Western Michigan Bee-Keepers' Association, will be held in Supervisors' Hall, Grand Rapids, Mich., Wednesday and Thursday, April 26 and 27, 1882.

WM. M. S. DODGE, *Sec.*

The Union Bee-Keepers' Association will meet at Eminence, Ky., on the 27th day of April, 1882. A full attendance is very much desired, as important business will be transacted.

G. W. DEMAREE, *Sec.*

The Texas State Bee-Keepers' Convention will hold its meeting at Judge W. H. Andrews' Apiary, at McKinney, Texas, April 25, 1882.

WM. R. HOWARD, *Sec.*

The Champlain Valley Bee-Keepers' Association will hold their semi-annual meeting at Middlebury, Vt., May 11, 1882.

T. BROOKINS, *Sec.*

SELECTIONS FROM OUR LETTER BOX

Narrow-Top Sections.—My bees came through the winter all right. They have been quite busy gathering pollen and honey for two weeks. Bees are in a better condition now than they were the first of May last year. The prospect for a good honey crop is encouraging and white clover is coming in abundance. I see in A. H. Newman's price list two kinds of sections or honey boxes—one with open top, like the bottom, are they better, and why are they so? Would you recommend tin corners for frames? Please answer in the next BEE JOURNAL.

D. S. KALLEY.
Mansfield, Ind.

[In tiering up sections on the hives, as many prefer to do, it is necessary to have insets in the tops of the boxes, as well as at the bottoms, to allow the bees to pass up. When placed on the hive, the upper tier or set should be covered with a blanket or cloth of some kind, to prevent the bees escaping from the tops of the boxes. We do not admire metal corners for frames, and more especially where metal rabbets are used.—ED.]

Laurel Honey Poisonous.—Bees appear to have wintered well this year, if protected on the summer stands. Last season was a very poor one in this locality for any kind of honey. Little or no honey in clover and basswood, and but a short supply of surplus from buckwheat and fall flowers. The failure was caused mostly by the drouth. There is a large tract of uncultivated land on this island, called the Plains, on which grows extensively the broad-leaved laurel, known here by kill-calf, the same as kill-lamb, or stagger-bush of other places, which blooms about the same time as white clover. In dry seasons the honey gathered in the vicinity of this tract is very apt to be poisonous. Some bee-keepers take no surplus till buckwheat is in bloom, as the early-gathered is the only kind affected. In 1880, white clover yielded abundantly for a time, and then a severe drouth commenced, and honey from clover stopped. There were published in the county newspapers so many accounts of poisoning from eating honey, that people in this county feared to eat it, and the sale was hurt thereby. I believe the plan I adopted that year, of using and selling only white clover honey, that which was capped before the clover supply was cut short, prevented any poisoning from mine. The uncapped was left for the bees. If any one knows of another plan I would like to hear from them through the JOURNAL. As the white clover appears to have been killed by last year's drouth, our prospect this year is unfavorable, unless we sow buck-

wheat early as possible to clear the frost in spring, and continue at intervals through the season. The medium and late was good for the bees last year, but of little use some other years.

SAMUEL HICKS.
Old Westbury, Long Island, N. Y.

But One Nucleus Colony Dead.—I have not had time and enough good weather since my return home to look over my bees and clean out all the hives. But there is only one colony dead out of 136 (a 5-frame nucleus), and not more than half a dozen, at the extreme, showing any signs of disease. I found them remarkably free from having commenced to rear brood, considering the warm winter.

O. O. POPPLETON.
Williamstown, Iowa, April 10, 1882.

For Honey as well as Ornament.—We have here a plant, called *Bacconia Japonica*, which is a hardy perennial, and if once established in a garden or lawn it will sprout very rapidly. I have had it in my garden for many

years, and my bees work on it all the time it is in bloom. I consider it good for honey and pollen. It would suit your inquirer, Mr. A. Montreville, exactly, as he wants something ornamental as well as for the bees to feed on; he would have to get the roots, if he wants it to bloom the first year. From seed it blooms the second year. *Phacelia* is also a honey plant; it is an annual and blooms all the summer and fall until frost. There are two kinds, white and blue.

High Hill, Mo. JOHN NEBEL.

Introducing Queens.—I have seen a good deal in the bee papers about introducing queens, but I think I have a method that beats them all for convenience at least, and for safety. I would use it in all cases where the queen has not been long confined (as an imported queen just arrived, when I would put her in a closed hive with frames of hatching brood and no bees but her own, as has been often recommended). I use an introducing liquid with which I wet the queen thoroughly, and immediately drop her into the hive among the bees, which I have had queenless at least

12 hours. In warm weather I often let her run in at the entrance, but must watch for a few minutes, for she sometimes runs out again and might get lost. There are doubtless many things that will do for an introducing liquid, but from my experience I would say that the liquid must contain, 1st, enough, and no more acid, to make it about half as strong as good vinegar; 2d, some substance that will adhere for a short time to the body of the queen after the volatile portion has evaporated, and not be injurious to her; 3d, some strong scent not offensive to bees. The first requisite is the most important, the second next, and the third least. I have been very successful with a weak solution of citric acid sweetened a little with sugar or honey, and scented with essence of peppermint. I have also succeeded under most adverse circumstances with the fresh juice of ripe Siberian crab apples. This season I have used weak vinegar (that has not "worked" enough) in a few cases, and succeeded perfectly. The advantages of this method will be recognized by all when once convinced of its safety. If those who wish to be convinced will try it on some cheap queens first, using either of the above preparations (warm of course), and letting the queens go, as soon as thoroughly wet, into the colony that has been 12 hours queenless, and have no queen cells or fertile workers, I think they will succeed every time. I would advise all trying this method not to open the hive until the subsequent day, when the queen will nearly always be found laying; but if not, it is not conclusive evidence that she is lost, for I had one queen wait a week or so before she began to lay. I have never known a queen to be injured by the bees when introduced in this way, unless they already had a queen or fertile worker, and sometimes not then.

T. W. LIVINGSTON.
Ainsworth, Iowa.

High Water's Ravages.—Most all of the bees in our section are drowned out. Mr. M. A. Garrett has 70 colonies which are almost destroyed by the overflow, and Henry Stecla's are in the same fix. The water is still rising, with five feet where the bees stood. Bees can gather no honey. In some places the water is 3 feet above high-water mark.

CH. SONNEMANN.
New Iberia, La., April 7, 1882.

Better Prospects.—The spring never was more promising for bee-culture. The overflow is rapidly receding, and good crops of cotton will be made. Greenville, and a large district below the town, was not inundated—the only portion of the great Yazoo Delta.

O. M. BLANTON.
Greenville, Miss.

Gathered Some Honey.—I put 28 colonies of bees in the cellar last fall, and they all wintered very nicely. They have gathered a little honey to this date.

HENRY SCHIMADAKA.
Germanville, Iowa, April 9, 1882.

Wintered Well.—Last fall I put my 19 colonies of bees in my cellar, all in good condition, though one or two colonies were rather light, but were strong enough to winter. On taking them out this spring they were all alive, and in good condition. The light colonies I had to feed, but they are all doing well now. They are gathering pollen. I began keeping bees 3 years ago, and have never lost but one colony in wintering.

STEPHEN WALSWORTH.

Onslow, Iowa.

Several Points.—If ordinary honey comb is 1 inch thick, cells $\frac{1}{2}$ inch deep, and the bee's honey sac 6 times full will fill each cell, and in time of plenty of honey within $\frac{1}{2}$ mile of the apiary, with pleasant days for bees to gather said honey, how many trips will an industrious bee make, say, in 10 hours, and how far will a bee travel in 1 minute on a bee-line to the honey field; and if it makes only 12 trips it will fill 2 cells; and if the hive furnishes only 6,000 honey-gatherers per day, they may fill 12,000 cells, and each frame contains 4,000 cells, the bees then will fill 3 frames per day, or 9 frames in 3 days; the 4,000 cells when full of honey and capped weigh 6 lbs., and the 9 frames would weigh 54 lbs.—why not the bees fill the honey boxes at the same rate, in time of good harvest, provided the colony contains 6,000 comb-builders and cappers, and 6,000 to gather pollen and water, and 6,000 to wax and clean and guard the hive, and 6,000 to care for the eggs, larvæ and young bees, and 6,000 young bees not able to work, but are on hand taking lessons to fill the places of those that perish every day by old age and labor? Thirty thousand is a very good colony of honest laborers. The honey-sac, when well filled, holds about the amount of one drop of water as dripped from the tip-end of the fore finger. If I am not correct, please give me the benefit of a full correction. R. M. OSBORN.

Kane, Ill.

[We cannot attempt to critically answer your query; but there is evidently something wrong in your figures. First, we might suggest your relay of 6,000 young bees constantly on hand is too large, as to keep it up to that standard would require a queen with a capacity to lay that number of eggs daily; second, no account is taken of the honey to be consumed by those comb-builders and cappers to accomplish their work; third, perhaps you have estimated too largely for the holding capacity of the honey-sac; fourth, as much time is probably lost in finding a suitable place to deposit the load when the bee returns from the field as it has taken to gather it; and fifth, we think you are a "little off" when you average 3 frames filled in one day, or 9 frames in three days, giving a yield of 18 pounds during each good working day. Let us con-

tinue your figures a little further: Suppose the white clover yield continues 21 days, and the 6,000 laborers work 18 days; then the basswood yield continues 18 days, and the bees work 15 on it, and after a while golden rod, buckwheat and asters furnish 23 days' work (with willow, fruit, box-elder and other bloom thrown in to make liberal weight), it would average 1,008 lbs. per colony—where in the wide world would we get spruce kegs enough to hold the honey crop of the United States?—ED.]

Honey Resources of Texas.—I arrived in this State in November last, and have visited a small portion of the country. I am much pleased with the climate and country for stock-raising, and especially for honey-producing. There are many who keep bees, but only few who are up with the improved methods of the North. J. G. Taylor, of Austin, says he took about 290 lbs. of honey from one colony. Others here report about the same. Mr. Fernoy, of San Antonio, has about 50 colonies, and is quite an enthusiast on bee-keeping. These, with one or two others, are all I have come across who make any pretensions to scientific bee-keeping. Texas is a brushy, grazing country, and nearly all the shrubs are bloomers. The whole face of the country is one vast flower-bed, so to speak, and I am told the honey-dews are abundant, which is a great assistance. Practical beekeepers command good wages here; I have been offered \$2.50 per day. There are many who keep bees in old boxes and logs; but few who keep them in "patent gums," as the Texans designate frame hives. When I came here it was for my health, which is much improved, and I think some of remaining if it continues as the season advances. Winter before last closed out my bee-keeping in Michigan. Out of 60 colonies I had but 5 left, and was sorry they did not die.

ERASTUS WEEKS.

Austin, Tex., April 9, 1882.

"Out of the Woods."—I guess I can say, "out of the woods." Weather is mild as June since the first of the month; every colony (23) in fine condition; a perfect world of bloom; apples not fairly open, and bees bringing in honey at a tremendous rate. Had to extract from one colony today to give the queen room; honey dark and very fragrant. With the above conditions for 2 weeks, I expect to take hundreds of pounds of honey from the apple bloom. White clover prospects very flattering. Three cheers and a tiger for the Weekly BEE JOURNAL.

C. H. DEANE.

Mortonsville, Ky., April 8, 1882.

An Early Swarm.—April 8th I had a rousing swarm of Italians. Who can beat it in the West, North, or East?

J. F. KIGHT.

Poseyville, Ind.

Bee Moths.—I inclose herewith, for examination, something taken from a hybrid colony of bees. The hive referred to is a Langstroth frame, in my own style of hive. I wintered in what is called a "cold frame," formerly used for flowers. My covering for the brood chamber was of dried blue grass, packed 5 or 6 inches deep around the hive, the bottom board elevated 4 or 5 inches from the ground. I first noticed the space before the hive covered with, as I at first supposed, the refuse of old comb, but discovered on examining it through a microscope, to consist of wax and pollen filled with minute insects. The inside of the hive was dry; the bees, queen, and 8 frames of comb, in good condition, well filled with brood, honey and pollen, while two of the outside frames were entirely deserted, and all but a few cells destroyed. I collected a pint of—what is it? I treated the hive to a bath of boiling water, returned the eight frames, and 2 of foundation, and now await developments. I have consulted several of my amateur bee friends, and, as it was something new, we have concluded to refer the subject to you, and trust you will give us the benefit of your knowledge. I am located within one mile of the city limits, have only 10 colonies of bees, and it is with me a labor of love rather than of profit.

JAS. B. SIMMONS.

Louisville, Ky.

[The sample sent is refuse or cleanings from the hive. It has the appearance of having been infested with moths, and the bees allowed them undisputed possession of the combs till such time as they wanted to prepare them for use, when they have cleared away damaged comb, moths, and dirt. There were several well developed moths in the rubbish when it reached the BEE JOURNAL, and several bits of moth-web.—ED.]

More About Albinos.—It was with much pleasure that I read the article of Mr. Valentine, in the BEE JOURNAL of March 29, 1882. I think the gentleman has very plainly shown the appropriateness of the name "albino," and hereafter I mean to call them as before, the "albino" bee. I thank him for the courtesy he has shown me in the article, and for the explicit manner of saying that I was not only the first to produce the bees, but also the first to call public attention to them. But I must differ with him when he says he was the first to give the albino bee to the public in its purity. He says that in 1879 he succeeded in breeding them "to a high standard of purity." If the gentleman will take the trouble to look up his BEE JOURNALS for 1876, he will see that I had them advertised "pure albino queens," and this was 3 years before he professes to have had them in their purity. He will also remember getting a queen from me in 1877, from which, by crossing, he procured his bees advertised in 1879.

I have a letter in my possession from Mr. J. L. Davis, of Michigan, dated Dec. 19, 1881, in which he speaks of an albino queen which he obtained from me in 1876, and also says he has 30 colonies of pure albino bees now in his apiary from her. I deem this, of itself, sufficient proof that I had the bee in its purity 3 years before Mr. V. Smithsburg, Md. D. A. PRIKE.

Standard Langstroth Frame.—Allow me respectfully to ask the BEE JOURNAL'S authority for asserting that the "standard" Langstroth frame is 17 $\frac{3}{8}$ outside measure. Surely, if there is a standard it is that put forth by Mr. Langstroth himself, which, at page 372, 3d edition, "Hive and Honey Bee," he gives: Bottom 17 $\frac{3}{8}$ outside, and inside triangular piece of top-bar, 16 $\frac{3}{8}$, his sides being $\frac{1}{2}$ inch thick. This would not take eight 4 $\frac{1}{4}$ sections. I believe this difference in the size of frames and hives has caused much inconvenience. W. P. T.

Fitzroy Harbor, Ont., Canada.

The Langstroth Hive.—Please give the size of the standard Langstroth hive and frame in the BEE JOURNAL. Van Wert, O. R. H. BLACK.

[This matter has heretofore been called in question, and a reference to it was made on page 163 of the BEE JOURNAL for 1879. Mr. Langstroth's book was written more than 20 years ago, and it is not to be wondered at that a slight modification should be made in the frames, and the hives, also, for that matter, and gain his preference as this has done. The standard Langstroth hive, therefore, as recognized at the present day, is 18 $\frac{3}{8}$ x14 $\frac{1}{8}$ inches inside measure, with a capacity for ten frames 17 $\frac{3}{8}$ x9 $\frac{1}{8}$ inches outside measure.—ED.]

Doing Splendidly in Florida.—Our bees are doing splendidly. To give an idea, we will state what we did with 2 frames of brood in making an artificial swarm: Formed the swarm by taking 2 frames of brood from an Italian colony on the 16th of March; on the 26th of the same month it sent out a line swarm; again, in 3 days after, it sent forth another swarm, besides furnishing us with 9 queens in the meantime.

ALDERMAN & ROBERTS.

Iola, Fla., April 7, 1882.

When and How to Clip Queen's Wing.—I believe the majority of apiarists of to-day prefer natural swarming to artificial. I have found it to be most successful in several respects. 1. Bees will swarm just as well with honey boxes on as they will with them off, and nearly as early. 2. You will get from 10 to 25 lbs. of honey before they swarm. 3. There is no danger of robbing; where, on the other hand, it takes very close watching to prevent it in divided colonies. Therefore, it is necessary to devise some plan to prevent bees from absconding

and clipping the queen's wing is just what will do it, for bees to abscond without a mother means death. The best, easiest and quickest way to clip a queen's wing, is to lift the frame she is on gently, place it on your easel, and with a pair of small pocket shears gently lift her off the frame by putting the shears under her, let her crawl on your left forefinger, and now just place your thumb on one of her feet, and you have her at your command, raise one wing with your little shears, clip about $\frac{1}{2}$ of it, and let her crawl back. It is quicker done than told. I clipped 36 in 2 hours, March 27th. They should be clipped before fruit trees bloom, as they are easier to find before the hive gets very populous. J. F. KENT.

Poseyville, Ind.

Preparing to Swarm.—Bees are getting ready to swarm, with sealed queen cells and plenty of drones flying. It is no trouble to winter bees here in Brazoria County, Texas. Keep plenty of bees in your hives, and you will have no moths. There was not a week this past winter that bees did not gather pollen—about December and January from mustard, and in February from an evergreen tree called the wild peach. It is the first tree in bloom here, and the prairie and fields are full of blossoms now. By-the-way, is 2 $\frac{1}{2}$ miles too far off from the timber or woods for bees to work profitably. Planted $\frac{1}{2}$ acre of silver hull buckwheat, which came up in four days. I do not know whether it will do in this climate on the Gulf coast; will report in the BEE JOURNAL if allowed to. Bee-keepers that would like to correspond and find out about bee-keeping in this part of the world can address JOHN W. ROSS.

Velasco, Tex., March 26, 1882.

[Two and a half miles is too far to work with profit, unless there are forest trees like linden, or tulip, or sourwood, where the bees can load quickly and easily, without much trouble.—ED.]

Safely Through The Winter.—In looking over my bees, I find that they are all in fine condition—not one lost out of 135 colonies in the fall. I wintered them on the summer stand. They are very strong indeed, and have been working on soft maple bloom for the last week; in fact, the hives are well filled with bees, and have large sheets of brood in all stages. I find in several colonies capped drone brood. I would not be surprised if they would cast swarms this month if left alone. But this I will not do, as I intend to run them for honey and queen-rearing. I will just here state that I must convert my bees into ready cash; just as fast as I can, for on last Thursday night burglars entered my store, and with drill, sledge and punch, broke open both of my safes and carried off all of my watches, jewelry and money, to the sum of \$2,600, besides all of my customers' watches, and now for the second time the bees came to the res-

cue. Four years ago my store was broken open and robbed, but while there is life there is hope. I do think that my little pets will help me up the hill again. I am forced to sell them off closer than I otherwise would have done; but hoping that some of the many readers of the BEE JOURNAL may wish some of my golden Italians, and in that way help "a friend in need." L. J. DIEHL.

Batler, Ind.

[Mr. Diehl certainly will receive the sympathy of all bee-keepers throughout the country. His loss must be somewhat discouraging to him, but we can assure him it is not as bad as it might have been, were it not for his well known reputation for integrity, and his unblemished business character.—ED.]

Honey Prospects in California.—At this date I have to report everything in a prosperous condition. We have had plenty of late rains to insure a good honey crop (or at least such is the opinion of the old bee men). We think the outlook for a good yield has not been as promising since the spring of 1878 as it is now. The bees are making every preparation for the harvest that is now so very close at hand. Between Christmas and New Year we moved our apiary from the mountains to the low lands, or willow country, where they have had the time and opportunity to breed up strong, and you can set it down for a fact that they are strong. The black willow is just coming into bloom, the filliree is at its best, with the mustard fast maturing, and then will come the valley harvest. We hope to harvest the valley crop, and still have time to move back to the mountains in time for the sages, thus securing 2 crops, one of dark and one of light honey—the valley being dark. One word for the Syrians: Last year being a poor honey year in California, and the first season we had handled the Syrians, we were not prepared to say much about them, and even now, only of their breeding qualities, which is A 1. Ours, this spring have bred faster and earlier than the Italians, and at this date (March 31) there are some of the Syrian colonies in the apiary that are as strong as Italians usually are the 15th of May, when sage harvest commences; but for all they are such extraordinary breeders, I do not expect any better results from them when the summer harvest comes than from the Italians. We aim to give each an equal chance when the sage harvest comes, and see which will carry off the laurels. Will report results next fall through the BEE JOURNAL. A. W. OSBURN.

El Monte, Cal., March 31, 1882.

Gathering Pollen.—From 57 colonies of bees last fall, I now have 50. One starved and 6 smothered by the entrance becoming choked. Bees gathered pollen here from the tag elder on April 1st. J. CHAPMAN.

Home, Mich.

Fruit in Bloom in Kansas.—My bees are doing well. I have Italians and "they are daisies." All the fruit trees are in full bloom.

S. C. FREDERICK.
Coal Vale, Kans., April 8, 1882.

As Strong as Last Fall.—My bees are in good condition. They are as strong as they were in the fall. I wintered my 12 colonies in a cellar, which was not dry by any means, but I had plenty of ventilation. I have made double-wall chaff hives for next winter, which will hold the regular Langstroth frame, $17\frac{1}{2} \times 9\frac{1}{2}$. My bees gathered honey last week, but to-day is cold, and down to freezing.

FRED VARNAUF.
Cambridge City, Ind., April 12, 1882.

In and Out-Door Wintering.—The winter is past and appears to have been very favorable for our bees. Mine have come through nicely—about one-half I wintered out-of-doors, the others in a cellar. I cannot see much difference. Those that were out are in fine condition. Those that were in cellar are in good condition, the hives were left open at the top and bottom; were put in the day before Thanksgiving, and taken out April 1st. Bees have generally wintered well in this vicinity, very little loss.

S. GOODRICH.
Urbana, Ill., April 5, 1882.

Mrs. Mayburn's Twins, by John Habberton, author of "Helen's Babies," is a book that will go straight to the heart of every mother in the land, and that mamma does not exist who will not vote it delightful? Natural as life, it sparkles on every page with delicious humor, and its occasional pathos is touching in the extreme, while the style of composition betrays a master hand. No one who likes to read about children, their mothers and the home circle, should miss this truly absorbing and fascinating story. It is a gem of the first water in a setting that adds vastly to its attractiveness. Mothers and fathers especially will find it a treat of the rarest kind. It is published in a large square duodecimo volume, paper cover, uniform with "Helen's Babies," price 50 cents, and will be found for sale by all Booksellers, at all News Stands, and on all Railroad Trains, or copies of it will be sent post-paid, on remitting the price in a letter to the Publishers, T. B. Peterson & Brothers, Philadelphia, Pa.

☞ The Southeastern Michigan Beekeepers' Association will meet at Jackson, Mich., in the City Council Hall, April 20, 1882, by order of the President. All bee-keepers are invited to attend; let there be a good turn-out.
J. H. MURDOCK, Sec., Dexter, Mich.

To Promote a Vigorous Growth of the hair, use Parker's Hair Balsam. It restores the youthful color to gray hair, removes dandruff, and cures itching of the scalp. 11w5t

THE AMERICAN BEE JOURNAL

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 " (3 months)....	20 " "
" 13 " (6 months)....	30 " "
" 26 " (9 months)....	50 " "
" 52 " (1 year).....	60 " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

974 West Madison Street, Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the best advertising medium, but the lowest rates on yearly contracts.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

☞ The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

"How do You Manage," said a lady to her friend. "to appear so happy all the time?" "I always have Parker's Ginger Tonic handy," was the reply, "and thus keep myself and family in good health. When I am well I always feel good natured." See other column. 11w5t

The Apiary Register.

As the time is now at hand to commence the use of this valuable book, all who intend to be systematic in their work during the coming season, should obtain a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

☞ To any one sending two new Weekly subscribers for a year, we will present a volume of the BEE JOURNAL for 1880, bound in paper covers. It contains much valuable information, and it will pay any one who does not already possess it, to obtain a copy. Many of our new subscribers will be pleased to learn that they can get it for \$1.00, by sending for it at once, before they are all gone.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

☞ We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75.

OLDEST BEE PAPER
IN AMERICA

Removal of Our Office.

It will be observed that our number is now changed to 925 West Madison street, Chicago, Ill., just one block east of our former location. As our mail is so very large, the change will make no confusion, for the postal carriers are quite familiar with it, that whether addressed to one number or the other, letters will reach us just as promptly.

In 1873, nine years ago, when we purchased the BEE JOURNAL, a small room on the third floor was all that was required. In our new location, all on the first floor, the BEE JOURNAL and our Son's supply establishment (which is also moved to obtain increased facilities) occupies 23 times as many square feet of floor surface as in 1873.

The Postoffice Department has created a new branch postoffice within a few doors of our new location which will also be very convenient both for our patrons and ourselves.

We have a telephone connecting us with every part of the city, and should any of our subscribers be in the city, they can step into almost any store and talk with us, even if they cannot come and see us.

Foreign Buyers in Our Markets.

It will be seen, by reference to the letter, from Mr. J. E. Pleasants, Anaheim, Cal., on page 267 of this issue, that foreign buyers are already in our markets, gathering up the prospective honey crop. He says: "There are parties here now making very

liberal offers for the coming crop." This we foresaw months ago, and predicted it in the BEE JOURNAL as an inevitable event: and perhaps in this connection we may congratulate the bee-keepers of California on their meager honey crop last season, which has had a tendency to advance prices higher than could have been done with a plethoric market. It will be a matter for self-reproach, if the apiarists of California do not hereafter find a remunerative market at their very doors for every pound of honey they have to dispose of, instead of being obliged to pay excessive transportation rates to bring their honey into competition with the product of a vast country as generous as their own in production, and quite its equal in quality, on this side of the mountains. The question is no longer—Where will we find a market? but, How best can we secure the production? Again do we suggest the careful and unprejudiced consideration of the bee pasturage problem. Every bee-keeper in America should settle the question for himself, from actual investigation, whether he can prolong the yield, or secure a continuous honey flow. He should know from actual, personal knowledge, what is best for his climate, soil, and convenience. For many honey-producing plants now is the time to procure the seeds and deposit them in the ground. Three or four liberal patches, planted this spring, may insure success in the future.

The Bees' Tongue Register which we noticed in a late number of the BEE JOURNAL as being received from Mr. J. H. Martin, may be seen illustrated on page 273 of this Journal, to which we would call attention. It looks pretty but as we have had no chance to test it, we cannot speak of it practically.

Priority in Use of Sections.

Mr. Friedemann Greiner, Naples, N. Y., writes us as follows:

In one of the last numbers of the *Bienen Zeitung*, Herr Griflay claims to have invented the section box before it was used in America. Now, if the invention was made by an American before the year 1875, and this is stated in the *AMERICAN BEE JOURNAL* of 1874 or 1875, please inform me, as I was not a reader of the *JOURNAL* then.

There were several patents taken out for sections prior to the date mentioned above, many of which were described and some illustrated in the *AMERICAN BEE JOURNAL*, from which we select the following:

April 6th, 1852, Mr. E. W. Phelps received a patent for section boxes in frames, which was twelve years prior to the date given by our German contemporary.

Dr. A. V. Conklin, of Bennington, O., patented his summer and winter bee hive Oct. 20, 1868, which contained

Conklin Hive and Sections.

sections for surplus comb honey, and which was described and illustrated in the *AMERICAN BEE JOURNAL* for April, 1869, page 187.

In our paper for June, 1870, Dr. J. M. Price, of Buffalo Grove, Iowa, illustrated and published, on page 257,

Price Hive and Sections.

his patent bee hive, the surplus arrangement of which he describes as follows:

The surplus honey can be had in boxes or sections, and can be taken from the top or side of the hive.... The surplus honey sections are in close connection with the brood chamber and with one another.... The sections can be used to the full capacity of the

hive or of the bees to fill them, and the bees can be forced to work on any number at once, thereby greatly increasing the yield.

He claimed that this invention was destined to mark a new era in profitable bee-keeping.

On Nov. 22, 1870, Mr. Geo. T. Wheeler, of Mexico, N. Y., received a patent on tin separators, to be used in connection with one-comb honey sections. Mr. Wheeler remarked at that time, that he did not claim to be the

Farmers' Friend and Sections.

inventor of section boxes, but had commenced his experiments with separators as early as 1867, which is corroborative proof that sections were in use before that time—probably many years before.

Messrs. Reynolds & Brooks, of Lexington, Ill., patented the "farmers' bee hive." March 28, 1871. This was largely advertised and illustrated in

Reynolds & Brooks Hive and Sections.

the *AMERICAN BEE JOURNAL* of May, 1873, and the cut used of the hive at that time shows the sections in place on top.

On January 7, 1873, Messrs Barker & Dicer, of Marshall, Mich., patented a "dovetailed sectional honey box, made with two wide and two narrow pieces so arranged that they form openings between each section." The narrow pieces are to allow a free entrance for the bees, and also to facili-

tate their use in tiering up. This is the dovetailed section in use at the present day.

The "Climax bee hive," patented in 1873, was advertised in this paper in

Climax Hive and Sections.

the April number, 1875, and illustrated with a rack of sections sitting on top.

Thus we have shown that sections for surplus comb honey were in use in America for fully thirty years, as can be substantiated by the official records in the Patent Office at Washington, D. C. How long a time prior to that date they may have been in use, we

Nailed and Glassed Section.

have no means at hand of determining—but probably long previously. It is notable that among the first devices for the purpose of securing small packages of comb honey, was substantially the prize section of the present day, and which has quite recently become so popular in Germany, England and elsewhere. The case or broad frame, to hold the sections in the brood chamber or super, was also

Case of to-day, with 4x4 Sections.

used in connection with some of the hives, and will be seen illustrated in some of the cuts.

The illustrations given in this article (except two last) are printed on the identical cuts used in the *BEE JOURNAL* at the dates mentioned above. The broad frame or case of to-day we illustrate to show, by comparison, that it is only a modification of those long preceding it, and it is almost a counterpart of that used by Dr. Price.

MISCELLANEOUS.

Apiculturist.

The Ariel of the Spring.

ALBERT F. KERCHEVAL.

Tireless toiler, with thy wing,
Winnowing soft the breath of spring,
Darkling doubt is over, sing!—

Sing of bright and summer hours,
Sing of dreamy summer bowers,
Sing of fragrance-haunting flowers,

Laden with their nectar sweet,
Glad that wait the lips to greet,
As when trembling lovers meet;

Sighing, beck'ning everywhere—
On the mountain slope afar
Lifting high its mighty bar,

In the valley, on the plain,
Nestling 'mid the cereal grain,
Kiss'd by sun and dew and rain,

Wreathing Nature's smiling face,
Bending with their tender grace
Over each lone vacant space.

O, thou arial spirit fleet,
Flitting swift from sweet to sweet,
Every flowery queen to greet,

Sipping nature's fairy wine;
O, that thy sweet life were mine;
Even brief and bright as thine!

One sweet revel all the hours
'Mid the dreamy, tender bowers,
Then to die 'mid dying flowers!

Los Angeles, Cal., March 20, 1882.

Artificial Swarming in 1762.—Mr. J. M. Hicks, in the *Grange Bulletin*, gives the following historical item:

Swammerdam, who wrote in the latter part of the seventeenth century, mentions a bee-keeper, who knew the art of producing queen bees at pleasure, and of securing thereby four times as many swarms annually as were usually obtained by the old plan of natural swarming. In 1762, Grae-well, in his "Approved Bee Culture," gave directions for making artificial swarms and dividing colonies, and Schirach published a special treatise on the subject in 1770, in which he first announced the fact, previously known to but few, that bees are able to raise a queen from worker brood. The practice seems to have been of but little success, as many facts having an important influence were then unknown, and the hives then in use were ill-adapted to the business. The elder Huber and others of his time, made a success of artificial swarming, when they developed the movable-frame system and made their important discoveries in the physiology of the bee. Their practice, though, was necessarily imperfect, and was seldom

practiced successfully, except by the most expert and well-informed apiarists. Since that time rapid advances have been made in this branch of bee-culture. It would require a volume to describe all of the different modifications of artificial swarming, with the advantages and disadvantages of each. The reader can consult the works already published, in most of which this subject has been extensively discussed.

Watching the Bees.—Mrs. L. Harrison, in the *Prairie Farmer*, gives the following account of an interview between herself and a neighbor.

"I couldn't find you in the house, and I suppose if I want to see you I shall have to come to the bee-yard until October."

"Isn't it a nice place, this delightful weather?—take this rustic seat and watch the bees, sailing in loaded."

"My grandmother used to keep bees in the old country, and in the fall she would dig a hole in the ground, make a little fire of sticks dipped in brimstone, and set her hive over it, and in a few moments all the bees would be dead. Her hives were not like yours, they were straw skips, just like you see in pictures. Oh! look at the bees with their legs covered with wax. How I would like to see one load his feet."

"That isn't wax, Peggie, but pollen, what we call bee-bread—the bees feed their young with it. Those that drop down so heavily, are either gathering honey or carrying water."

"Indade, sometimes I'm afraid of me life, when I go to the well after water, there are bees in the pump spout and in the gravel around it—they are not always particular about what they drink, for sure haven't I seen them sucking the manure piles after a rain, and when Tim Shay plastered his house, they were in the mortar bed ating it, and the boys killed a dale of 'em, pelting 'em and spatting 'em into the mortar with shingle paddles. I told the wicked craythurs to stop it, but not a bit would they bide my bidding."

"People think they must have some badly tasting stuff called medicine, or bitters like tansy and whisky in the spring, to regulate their digestion, and the bees are only following their example. I've known doctors to prescribe lime water for a little baby, and bees love salt and ammonia, and who knows but that they may need lime, if they haven't any bones."

"What have you that sack tied to the limb of that tree for, with a stick in its mouth to keep it open?"

"Sugar was brought home in it, and as it was pretty damp; it stuck to it so much that it could not be used for anything else, and I hung it there for the bees to clean it up. It is as clean and free from stickiness now as a new one. I put out some closet shelves, that had honey on them, that had oozed out of some broken boxes during the winter, for the bees to clean up, and had a lively time in consequence of it. Honey excites

them more than sugar, and when it was gone they hunted for more. I had left a window open upstairs, and there were boxes of honey in the room. Hearing a buzz and a roar, we found that apparently a million bees were flying in and out of that window. I drove out what I could with a smoker, but had to put the window down, as so many came back, and it was two days before I got them all out. All this trouble on account of carelessness."

"Is that barrel of sugar, that the groceryman is rolling in, for the bees?"

"Yes, I'm feeding every colony I have. As I've not enough feeders to go around, I'm using all sorts of things—here is an old sugar bowl with one ear broken off, peach cans, Mason's jars, etc. I make little sacks of thin muslin, and tie them over the can, so that as fast as the syrup is eaten, the sack sinks with it, and not a bee will get drowned. I fill this large pitcher with sugar, pour in boiling water, and stir it well, and feed it warm; of course, not hot enough to burn them."

"Indade, ma'am, you've a dale of trouble with your bees."

"Yes, we can't have anything without work. I suppose St. Patrick had hard work to rid Ireland of frogs and snakes, but he succeeded."

"Won't you please give me a little honey for Paddy, he has a bad cough. God bless you ma'am."

Grafting Wax.—The *American Agriculturist* for May, gives the following recipe:

Rosin, beeswax, and tallow, are the essentials. Some use equal parts by weight of these; others prefer, as warm weather approaches, more rosin and less tallow. A good recipe is rosin 2 lbs., beeswax 1½ lbs., tallow 12 ounces. These should be melted well together over a gentle fire, and stirred as the mixture cools. It is most conveniently used upon strips of cloth. Any old calico or muslin that will tear readily, may be torn into strips 2 inches wide, made into balls and soaked in the melted wax, until thoroughly saturated. We prefer to roll the cloth upon a short stick, to afford a handle. If paper is to be used, the warm wax is spread with a brush upon one side of this Manila paper. Some grafters prefer a wax made with raw linseed oil, using a pint of oil instead of a pound of tallow.

The Eastern New York Bee-Keepers' Union will hold their 10th Semi-Annual Convention on Tuesday and Wednesday, May 2d and 3d, 1882, at the parlors of the Hotel Augustan, Cobleskill, Schoharie County, N. Y., at 10 o'clock a. m. All interested in the bee business are invited to attend.

W. L. TENNANT, *Pres't.*C. QUACKENBUSH, *Sec.*

The Champlain Valley Bee-Keepers' Association will hold their semi-annual meeting at Middlebury, Vt., May 11 1882. T. BROOKINS, *Sec.*

Producing Comb Honey—No. 5.

G. M. DOOLITTLE.

Having the bees all in, and swarming all done up, the next work is to manipulate the bees and boxes so as to get the largest possible yield from them. Now do not understand that I never have a swarm issue after I have all swarming done (as it should be when the honey harvest is at its best), for such is not the case. Some of the first swarms will frequently swarm again, or some of those which were moved so as to draw off the old bees, getting populous again, may swarm; but in such instances they are put back where they came from, after extracting every particle of honey from the brood nest, and cutting out all the queen cells. Still, as a rule, not many swarms issue after all are prepared as I have described. If a colony is determined to swarm after this treatment, I generally take off the boxes and put on a second story, filled with empty combs, in which case they will generally go to work with a will. If I cannot make one plan work, I try another; until I strike one that will, and if a colony is bent on swarming and will not work in a hive where the lower combs are filled with brood, I take all the brood away. Colonies having the swarming fever, will not do much of anything but swarm, unless some material change is made with the interior of the hive more than the cutting out of queen cells, and the sooner this fever is broken up (when it comes during a yield of honey) the better the results. However, but few bother in this way, as most of them settle down to business and stick to it after the swarming proper is over.

After the colonies are all made up, I see that all nuclei have the means of getting a laying queen as speedily as possible; then I am ready to go over the yard for box honey. In doing this, I remove the cap and unkey the cases, when they are pried apart a little in the center, blowing in a little smoke to make the bees run out of the way. As the bees clear aside I can see down the flat side of the sections and, if any are capped down to the bottom, they are ready to come off. If ready I pry the opposite side of the case lose, when the cases are spread apart a little and the one having the finished sections in it, is lifted out. I now smoke the bees off, in the manner I described on page 257 of the BEE JOURNAL for 1881, to get the bees off the brood combs. They can be nearly all shaken off, except a few behind the tin separator.

I then take the sections out of the case and place them in boxes which will hold 18 prize sections or 24 of the 1½ lb. sections. These boxes have

nails driven in the bottom so as to project ¼ inch above the bottom of the box, and are so arranged, that, by beginning at either side, the nails strike close to one edge of the bottom of the sections, so their weight will keep them pressed close to that side, and then they will not be liable to tip over. The object of these boxes, are first, to prevent killing bees should there be a few not shaken off; secondly, to prevent the sections getting daubed, should any of the combs get bruised, so as to leak honey; and, thirdly, they can be packed nicely on a wheel-barrow so as to be wheeled to and from the honey house, as well as being handy to carry from the wheel-barrow into the honey room. Before going to the bee yard these boxes are filled with empty sections, having starters all ready for use.

When the full sections are all out of the case it is filled with empty ones, and put down at the side of the hive when more are taken in the same way, if any more are ready to come off. After taking all those finished, the rest are placed close together, and enough partly-filled sections from the sides are raised to the top (by lifting cases, sections and all) till the number wanted is reached, when the cases filled with empty sections are placed at the sides, in place of those raised to the top, when the hive is closed. I now place a small flat stone on top of this hive, that can be seen from any part of the yard, which indicates that I have taken the honey from it. Thus I keep on till the whole yard is gone over.

If the yield of honey is still good I work in the same way, going over them again a week later, except that this time the little stone is taken off and placed beneath the bottom board of the hive. By using this stone I can see, by glancing over the yard, just how far I have been each time, and the hives which have not been looked at.

As a rule, when I am ready to go over the yard again, the basswood yield is drawing to a close, so I work accordingly, by narrowing up the surplus room. As the cases are raised from the sides at this time, the follower is moved up, so as to shut the bees out of ½ the side cases, unless in case of some extremely populous colony, which is treated the same as before. By this means the working force is thrown into a more compact space, the result of which is, a tendency toward completing the sections they have commenced work in, rather than building comb in more. After another week I go over the whole yard again, this time shutting the bees out of the side boxes entirely, which throws the full force of bees into the top boxes, and, although the honey season may now be over, by getting this force of bees all together they will cap the partly-filled boxes, where they otherwise would not. This gives sections lighter in weight, but makes much more of our crop in a salable form.

At the end of another week, all the white honey is ready to come off the hives, and as a rule, my honey harvest

is over. In seasons when buckwheat does yield a surplus, I seldom let the bees into the side boxes again, but keep them shut in the top cases.

Thus I have given you the way I proceed to get comb honey. By going over the yard once a week, the honey comes off with a whiteness of comb not attainable when left on the hives till the end of the season, as some do; and also the bees are kept working to their utmost capacity. Those who think they have a better way of procedure, will doubtless think Doolittle does not adopt the best plan to get comb honey. I will simply say that an average of 92 lbs. each year, for each colony, for the past 9 years, is all I have to recommend this plan. This ends the production part of this series of articles.

Borodino, N. Y.

For the American Bee Journal.

Odds and Ends.

O. CLUTE.

Last fall I promised to report this spring my method of wintering, and its success. The winter has been so favorable that it required no skill to bring the blessed bees through all right. He who could not winter with success the past winter must be a poor bee-keeper indeed. A few of my bees were in chaff hives on the summer stands. All these have come through in good condition. The larger part of my bees were in simplicity hives in the cellar. All these are in good condition. Not a colony has been lost either out-door or in the cellar.

The first pollen was gathered Feb. 16. After several days of warm, beautiful weather the maples opened on that day, and the bees had a happy time; but the next day brought a frost that nipped the maples, and kept the bees in. Some of the coldest weather of the season followed. Since the middle of March the bees have been flying more or less every week. Maples, elms, cotton-woods, and box-elders have given pollen and some honey. To-day is clear and beautiful, with a still air, and warm sunshine. Willows are open, and I think some of the cotton-woods. The bees are very active, carrying pollen of a brilliant yellow, which I think they get from willows, and some of a darker color which I suppose comes from cotton-woods.

Although the winter has been very open, the clover seems not to have suffered. Already the white clover is pushing up its green leaves everywhere, and promises to be very abundant. The fruit trees are well laden with fruit buds, and if no frosts prevent, will give an abundant bloom. On the nights of the 10th and 11th inst. we had freezing weather, which is thought to have been a serious injury to the early cherries, but it is hoped that other fruits were not far enough advanced to be injured.

I hope other bee-keepers are more fortunate than I am in finding workmen who will make hives exactly right. The average workman seems

to have no ability to conceive that $\frac{1}{8}$ or $\frac{1}{4}$ of an inch is of any account in making a bee hive. They say that you are only "fussing" when you insist that every measurement shall be exact. I have been having a large number of new hives made, and have had my patience severely tried. I gave the workman at the factory a pattern hive which was just right. He rather elevated his nose when I urgently directed him to be sure to follow the pattern in cutting out stuff. But he made an exasperating blunder. I paid the wages of an expert carpenter to a man to nail hives, because I wanted the job done well and quickly. I showed him how, and then left him to do the work, and he did much of it badly. These workmen, and many days of cold or stormy weather, prevented me from sending bees promptly to some customers; but all will now go, and I hope will be all right.

California Apiculturist.

The Hive I Use and Prefer.

WM. MUTH-RASMUSSEN.

After leaving Los Angeles, Cal., I commenced bee-keeping anew, and bought bees in frame hives, which, however, had not been made by a practical bee-keeper, and were therefore wanting in uniformity and relative proportions between the frames and their respective hives. The surplus frames were also of a different size from that of the brood frames. Having to make new hives, I considered that I might sometime want to produce comb honey for sale, and the 1 lb. section would be the most preferable package in which to place this article in the market. At the same time I knew, that on account of insufficient shipping facilities, general difficulty of shipping comb honey and probable future preference for extracted honey, my product for the present would be principally the latter article. Not liking the regular Langstroth frame, on account of its shape and size, and inconvenience in hanging it right side up in the extractor, I decided on a frame which would hold 6 1 lb. sections, instead of 8, and which therefore would be alike adapted to comb and extracted honey. I mean, of course, that the frame for comb honey should be 2 inches wide, and used only to hold the sections, while the frame for extracting and brood combs would be $\frac{3}{8}$ of an inch wide, but the size in length and depth would be the same for both. The 1 lb. section is $4\frac{1}{4}$ inches square, outside measure. My frame made of $\frac{3}{8}$ inch stuff is $8\frac{1}{2} \times 12\frac{3}{4}$ inside, and $9\frac{1}{4} \times 13\frac{1}{2}$ inches, outside measure. The top bar is $15\frac{1}{4}$ inches long, and the side pieces ($8\frac{1}{2}$ inches), are nailed between the top and bottom bars. I do not use the triangular comb guide, which adds only more work and expense to the frame, with comparatively little additional strength, but make instead (unless I use comb foundation), a thin comb guide of wax, painted into the frame with a small

brush of feathers. This comb guide takes nothing away from the interior space of the frame, and I have never had the bees fail to follow it. I use $1\frac{1}{4}$ inch finishing nails for the frames; and have yet to see a frame come apart by ordinary careful handling.

My hive takes 10 of these frames, and is therefore 15 inches long from front to rear, $14\frac{1}{4}$ inches wide, and $10\frac{3}{8}$ inches deep, inside. It will be observed, that there is an extra $\frac{1}{8}$ of an inch in the depth, which I allow for shrinkage, after the hive is nailed together, and therefore make the space under the frames $\frac{1}{2}$ inch. The entrance is in one of the ends of the hive, parallel to the frames, and is $\frac{3}{8}$ of an inch high by 6 inches long. By arranging the entrance thus, I need only one division board to diminish the size of the hive for nuclei. Six-inch pieces of ordinary frame stuff are used to contract the entrances in winter, or for entirely closing them, when necessary. For convenience in moving, the bottoms are nailed on. A small board, 2 inches wide, six inches long in front and 11 inches behind, is nailed in front of the entrance, the nails going through the bevelled ends of the doorstep and driven only partly in, so that the doorstep can be easily taken off, when the hives are to be moved in a wagon. This hive has a capacity of 2,084 inches. It is otherwise made exactly like the style of Langstroth hive, introduced into Los Angeles county by Mr. John Beckley, and extensively used by bee-keepers there. The upper story corresponds to the lower, and takes the same frame, but for extracting I use only 9 frames above. My hives rest upon four small blocks, cut from waste pieces of scantling, and placed directly upon the ground.

It will be seen, that this makes a very compact, nearly square hive, easily made, convenient to handle, and with a shape and size of frame, which suits all requirements. If a honey rack is used, the hive will hold 21 1 lb. sections in one tier, and another tier may be placed on top by clamping them together. If wide frames are preferred, the upper story will hold 7 of these, containing 42 sections, and a brood frame or division board, inserted to fill the 1 inch space, left in one end.

Now I would not advise anybody already having an established apiary of uniform and well made hives, or of any certain style, used to some extent in his neighborhood, to change from what he already has, unless the demand and price for comb honey in 1 lb. sections should become such as to justify him in going to the trouble and expense of such a change; or unless he sees some particular merit in my hive over the one he is at present using; but to anyone making a start in bee-keeping, and having no particular favorite among the hives already in use, I would recommend my hive for consideration, and I seriously think that it fills the bill for a hive, suited to this climate and to the various purposes for which it may be used, better than any other hive with which I have become ac-

quainted during my twelve years' experience in bee-keeping. I call it the "Three-Quarter Langstroth Hive," because the frames are three-fourths the size of the regular Langstroth, and it has already become the standard hive in this locality. No patent, gentlemen. Use it if you like, and criticize it, if you think it has any defects. Perhaps you can thereby help me to improve it in some particular, which I may have overlooked.

Light or Dark Colored Italians.

O. O. POPPLETON.

I see that the old question of the relative value of light and dark colored Italian bees is again occupying the attention of the BEE JOURNAL. I think this is an important question to practical bee-keepers, and worthy of full and free discussion.

I think it is now conceded by the most of bee-keepers that the Italians are not a strictly pure race, but have a slight admixture of the German bee. This is not admitted by all, but from what I can learn I judge that a large majority of our best bee-keepers believe such to be the fact. The admixture, if any there is, seems to have been so far back, that the traits of the mixed race have become quite firmly fixed, yet not so firmly but what there is some variation in both markings and traits of character between different strains of Italians that are all as undoubtedly pure as any we have. My experience is that those bees that most resemble in appearance and color the yellow race, also possess in a greater degree the traits of character that are peculiar to the Italians, and in this particular I agree with Mr. Heddon's latest writings, in which he says: "The dark Italians and hybrids possess some traits of the German bees, that the lighter Italians do not.

There are at least three traits that all writers on bee-culture agree the Italians possess in a greater degree than do our common bees. These are, 1st. Being lighter in color, the queen is more conspicuous on the combs, and therefore easier to be found, saving both time and labor in certain manipulations of the hive. This is of more practical importance than some think, especially in large apiaries where the bee-keeper has all the work he can do, and time is valuable. 2d. More inclined to defend their stores when attacked by robbers, or infested with moth worms. This trait needs no argument to prove its value, but I cannot say the difference in this is very marked between light and dark Italians. 3d. More inclined to cease other operations in the hive, and fill their brood combs with honey whenever the flowers are yielding largely. This is the most important trait of all.

I have of late years raised such a small amount of box or section honey, that I cannot say from experience whether they are less inclined to store honey outside of brood chamber

than are the black bees, but a large number of our best comb honey raisers say such is the fact.

As some are aware, I run my entire apiary for the production of extracted honey, and the kind of bees I want are those that will give me the largest amount of that kind of honey, and yet not be deficient in vigor, hardiness, or ease of handling. In this section flowers usually yield very copiously for a short time, then partially cease for a time, then give another large flow, and so on. During the season of 1879, white clover yielded good for about two weeks, then ceased almost altogether, and about the 20th of August buckwheat gave a large yield for a week or ten days only. During all the rest of the season, just enough honey was gathered to keep brood rearing going on nicely. Now, I think all can readily see that those colonies of bees stored by far the most honey that partially ceased brood rearing during these flows, and bent their whole energies to the storing of honey, and this rule of course works to a greater or less degree every season. Nearly all bee-keepers desire to have their queens raise as largely as possible of brood during all times in the season, but I want queens that will be very prolific at all times during the season except during heavy flows of honey, and then have their progeny fill their combs with honey as quick as they can. It is my business to see that the combs are emptied often enough to allow her majesty a fair chance to perform her special duties. I have carefully observed this matter for years, and have no hesitation in saying that the colonies containing my extra prolific queens have not averaged so large a yield of honey as have those not raising so much brood.

As I have already said, the more my bees have shown by their color and markings their affinity to their yellow progenitors, the more thoroughly do they seem to possess those traits I have mentioned, especially the first and third ones.

Some make the claim that the yellow bees are not so hardy as are the dark or leather colored ones. Now, really, I don't like to be disrespectful toward anyone's opinion, but I really do think all such talk is simple bosh and hardly worth arguing.

I cannot say from experience how much truth there is in the claim of Messrs. Heddon and others that the German bees store more readily in sections than do Italians, but certainly do not doubt but such may be the fact, and can very readily see that for their purposes the dark Italians or hybrids might be much preferable. If their claims are correct, then it seems that the different management adopted by different bee-keepers is the real cause of so much difference of opinion among the most practical men we have in our ranks, as to the relative values of light and dark Italians.

I do not wonder at all that Mr. Buchanan, as well as others who have bred entirely for color and nothing else, made miserable failures. I only

wonder that they attribute their failure to their bees, instead of to themselves, where the blame really belongs. I think if a judicious breeder will select the best of his light colored colonies to breed from, he will not have to report a failure.

I see several lay a great deal of stress in having or going to build up a special strain of hybrids. Now, gentlemen, have you looked this matter over carefully in the light of experience gained by men in the breeding of other kinds of stock?

Their experience proves that it takes a great many generations, dozens at least, and very great care and judgment in selections, before a strain can be built up from two different breeds containing the best qualities of both, without the poorest of either, and those desirable qualities permanently fixed. In my humble opinion it would take at least half of an ordinary life time, and the use of a sure method of controlling fertilization, before a valuable fixed strain of hybrids can be obtained.

I make a special business of bee-keeping; everything else, even my farm, being side issues, and I several years ago decided that I could succeed better by confining myself to one branch of bee-keeping, letting all others alone. I have therefore devoted my entire attention to the production of extracted honey, and have steadily refused to be drawn into the queen rearing, bee-selling, or supply-dealing branches of the business. The opinions I have expressed are therefore those formed while engaged in the one branch of bee-keeping named.

Williamstown, Iowa, April 10, 1882.

For the American Bee Journal.

Chemical Properties Required in Soil.

A. R. KOHNKE.

On page 389, vol. 17, of the BEE JOURNAL, a German bee-keeper in the *Bienenvater* is giving his experience as to certain elements necessary in the soil, to cause plants to yield honey. Special mention is made of nitrogenous compounds and lime, but that buckwheat would yield an abundance of honey on rocky soil. But other agents may be present in such a soil, which are the main cause of a profuse honey flow, to discover which the bee-keeper who intends to plant for honey would have to experiment, to find out whether it does or does not pay. By the word "experiment," I mean for the bee-keeper to find out what fertilizer is wanted to give his own soil the quality of causing plants growing thereon to yield honey. M. G. Ville, a French experimenter, makes this statement in his fifth lecture: "If the agriculturist desires to restore sugar to his beet root, he must supply the soil with potassa." Potassa or potash in the most available form is found in wood ashes. If this plant food is absent, all the other agents present will not be of much avail. Experiments which I am about to make next summer will hold good only to soil at my disposal, which is a

rich, sandy loam, hence not conclusive for any other part of the country or even this county.

Now as to the question whether or not it will pay to raise plants especially for honey, depends altogether upon circumstances. In one of my late articles referring to a German writer, who thinks that it pays to raise them, instead of potatoes, I expressed my doubt as to its being a good investment, though a correspondent of the BEE JOURNAL makes me say the very opposite. Where land is worth from \$500 to \$1,000 per acre, as it is here, and the profits of market gardening are from \$300 to \$500 per acre, it would not pay. But lands worth from \$10 to \$30 per acre, which do not rent for more than \$1.00, or at most \$2.00, per acre, would pay better in honey plants. Some years ago I saw in the State of New York a field of potatoes, where two men had worked digging them a half a day; the proceeds were not quite a bushel; the owner abandoned the task of harvesting them. On the other hand, I have seen fields yielding 300 bushels per acre, selling at a dollar per bushel. Where it will pay under all circumstances, is in waste places, such as are not or cannot be cultivated; but, do not plant a little of everything and not much of anything; that is poor policy.

In gathering honey bees do not visit different kinds of flowers in one trip, but gather honey from one kind of flower only; if they are obliged to fly long distances to find them, they lose much valuable time in getting a load; if a bee-keeper wishes to try different kinds of honey plants, the seed of each kind should be scattered as near in one spot as possible; this will not only be an advantage to the bees, but to the bee-keeper to facilitate the observations he should make, to discover their value in his locality.

Youngstown, O.

For the American Bee Journal.

Bee-Keeping in Sweden.

T. G. STALHAMMAR.

In Sweden, last year was a very bad and trying one so far as concerned apiculture. No honey, but few swarms, and no possibility for them to build up or store honey for winter, except by giving foundation and using feeders. This I have been doing, and must feed every colony eight pounds of loaf sugar, at the entrance. Last winter (1880-81) was a very trying one for the bees as well as for mankind in this country, the thermometer sometimes showing 30° C. I saw a colony which took up its abode in a pillar or column, the cavity being one foot square, made of four boards 1½ inches thick, nailed together, airy and windy all along for 9 feet. It was covered up and downward, but insufficiently, the bees having easy access upward, as well as wind and rain. The bees had built their combs nice and straight 2½ feet long, which were well stored. Our examination was made in April, when the winter had passed, and they

were found in very good condition. After a month had passed they were destroyed by mice.

During the autumn of 1880 I purchased some late swarms in skeps, and had no opportunity to transfer them into hives. I gave them sufficient food, and as an experiment, cut off a corda (one twist) of the round bottom-board $1\frac{1}{2}$ inches high. My bees are wintered on the summer stand, but in some way or other protected. These colonies lived through. In hives with contracted entrances, but otherwise in fair condition, the bees were wet and died.

As an anomaly, I will mention that *Tilia Americana*, in the horticultural garden of this place, was in bloom as late as Sept. 14, last. Does it ever bloom so late in your country?

I am much pleased with the Weekly BEE JOURNAL. I expect and long for each number in advance. The contents are such that nobody can justly ask for better and more honest information, and for the future I will never be without it.

Gothenbourg, Sweden, Feb. 1, 1882.

[Mr. Stalhammar is editor of the *Swedish Bee Journal*, and his letter will be read with interest. We have never known *Tilia Americana* (linden or basswood) to bloom so late as Sept. 14.—ED.]

For the American Bee Journal.

Bees' Tongue Register.

J. H. MARTIN.

In the spring of 1881 I obtained a few colonies of black bees from a neighbor, and when red clover came into bloom I observed black bees at work upon it, and but few Italians. I wanted some instrument to test accurately and quickly the tongues of those twenty colonies of black bees, and find if possible where those long-tongued fellows lived. I made a self-registering instrument with a float to operate the pointer upon a dial, but I could not depend upon it for accurate measurement, for every time I filled the reservoir I would get honey or syrup, the specific gravity of which would be different from that previously used, and my float would not give accurate readings on the dial. I did not make much use of my instrument upon which I had spent much time in experimenting, but still kept thinking I would like an accurate instrument for the purpose.

When our National Convention came off, I was interested in finding that Prof. Cook and Dr. Brown had been experimenting in the same line, and Dr. Brown seems to have made his float and dial work to his satisfaction, but he recorded only 32ds of an inch.

I then concluded to let Dr. Brown or Prof. Cook do the measuring of tongues and give us an instrument; but soon after the idea came to me with this question, why not let the bees take the honey from a tube, and afterward measure? I soon answered

the question with a practical instrument with which I could measure to a hair's breadth. I knew that bee-keepers would not be satisfied with 32ds, so I made my instrument to record by 100ths and one 400ths or even higher, can be registered by reading between the inches. It will measure the tongue of any insect that will empty the tube to the depth of 1 inch. Here now is a chance for *Apis dorsata*.

To operate the instrument, turn back the corner upon which the wire-cloth is attached, fill the glass feeding tube there found with any sweet liquid the bees will take, give the bees access to it whose tongues you wish to test, until they remove all they can reach. Remove then, and sit upon a level place and uncover the tube, turn the thumb-screw upon the back of the instrument until the ring that encircles the tube is on a line with the extreme upper surface of the honey. The pointer will now register the length of tongue upon the dial in 100th parts of an inch.

Although it is early in the season in this locality to measure tongues (our bees being in the cellar yet), I have

tested a few, and find that they do not empty the tube so far by several 100ths as they do in the height of the honey season. I also find that the mesh of the wire-cloth makes some difference. It should be so as to let the mandibles through. I find 3-32 of an inch mesh gives the best results, and use that size.

Hartford, N. Y.

For the American Bee Journal.

Improvement in Italian Bees.

O. H. TOWNSEND.

Can they be improved? I answer, yes! Now the question, how? I will try to answer the question, endeavoring at the same time to give proofs which have been brought out by long experience, I having made bee-keeping a specialty for 17 years, and having had the Italians 14 years.

First, we must have a queen whose progeny is of good disposition, whose markings indicate absolute purity, which winter well, and last, but of the greatest importance, they must, as honey gatherers, have no rivals, not only in filling combs which are given them, but they must go into the

honey boxes with a "rush" as soon as there is honey in the flowers. If all queens are reared from such a queen, and reared with the proper care, no one can fail to see good results. There may be some queens which will be an improvement over their mother; when this is the case, then such should be used from which to rear our queens. If the foregoing directions are followed up for a few years, there will be a very marked improvement. Instead of having some colonies which will store in a season 200 lbs. surplus, some 100, and others little or none, they will show that there has been some care used on the part of the apiarist in his choice of queens from which to rear the young queens.

Until within the last few years any one might have come into my apiary and found, at the end of a good honey harvest, some hives with a good yield of box honey, others medium, and some with none, or perhaps with a very little; but since I have followed the above rules to the letter for the last 4 years, it is different, for now my bees will go into the boxes to work at about the same time. There is no more necessity for keeping poor bees than for the dairyman to keep poor cows. By the way, poor cows can be sold for beef, but it would not pay to sell poor queens, but kill them and supply good ones in their stead.

I bought my first Italian queen 14 years ago. Her bees were gentle, and good to store honey in finished combs, but very loth to work in boxes. I reared my queens from this queen and her progeny for 8 or 9 years, during which time I never succeeded in getting them (the bees) to work in boxes to my satisfaction. Four years ago I received my first imported queen. Her progeny were well marked Italians, rather dark in color, No. 1 bees to handle, more hardy than my first Italians, and good workers for both comb and extracted honey. After using over 100 of her queens, I found a few of her daughters were more profitable than their mother. In 1880 I bought two imported queens. The first one produced hybrids (I do not know whether she ever crossed the ocean or not). I only reared one queen from this one. Her progeny were noted for long stings, and a good knowledge of their use. The other was a young queen. It came direct to me from Italy. This queen, which I now have, is the best imported queen I have tried. Her bees are well marked (not light Italians), and good-natured. I never knew them to sting any one, and I never saw their equal to work in boxes. They stored and sealed 90 lbs. of honey last season, all from the first crop of red clover, and cast a very large swarm. I also took several full combs of hatching brood during May and the forepart of June. They are sure to have a large supply for winter in the body of the hive. Wintered out-of-doors last winter in a box with 3 inches of chaff, and did not fly for over 5 months, and came out in the best possible shape. As yet I have failed to get a queen to beat her except for size.

I am thoroughly satisfied that if all

the poor queens are weeded out, and good ones introduced from such stock as described above, thereby insuring good drones, then the reports from all our different colonies will be uniformly good.

I see that Mr. Henry Alley advocates the yellow drone theory; but I must say, since following the principles given above, my drones have lost their bands of yellow. When I had the most hybrids I had the most yellow drones. I do not wish to convey the idea that yellow drones are an indication of impurity, for I am well aware that we may breed for such drones with success, and yet keep our stock pure.

In regard to the new races of bees, I think that if we have our Italians bred up to a high standard of excellence, we had better be slow to introduce new blood into our apiaries. From past experience I say, good-bye hybrids.

Kalamazoo, Mich.

Local Convention Directory.

1882.	<i>Time and Place of Meeting.</i>
April 29—	Muskingum Valley, at Berlin Center, O. Leonidas Carson, Sec., Frederick, O.
May 2, 3—	Eastern N. Y. Union, at Cobleskill, N. Y. C. Quackenbush, Sec., Barnesville, N. Y.
11—	Champlain Valley, at Middlebury, Vt. T. Brookins, Sec., East Shoreham, Vt.
16—	N. W. Ill. and S. W. Wis., at Rock City, Ill. Jonathan Stewart, Sec., Rock City, Ill.
25—	Iowa Central, at Winterset, Iowa. Henry Wallace, Sec.

 In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Saunders County, Neb., Convention.

The Saunders County Bee-Keepers' Association held their semi-annual meeting at Wahoo, Neb., April 1, 1882.

After the usual business had been transacted, the following subjects were discussed:

What is comb foundation, and how made? Can bees be fed too much early in the spring?

Spring dwindling, and how prevented.

Extracting honey and extractors.

What plants to raise for bees to work on.

The Association decided to hold a special meeting about the middle of June, at some one of the apiaries near by. Considered a better place to discuss the subject of bees than in town.

The report given showed that of 82 colonies put in winter quarters, only 8 were lost, and only 5 by wintering.

The meeting then adjourned.

Mrs. C. L. STOCKING, Sec.

Michigan Farmer.

Eastern Michigan Convention.

The Eastern Michigan Bee-Keepers' Association held its second annual meeting in Detroit, April 11, President Pierce in the chair.

He delivered a brief congratulatory address, in which he commented upon the growth of the Society. One year ago it had been formed under discouraging circumstances; an unusually hard winter had just been passed through, and a majority of the bees in the country had been killed. This spring our bees are all in good condition, and the prospect good. The Society has increased in membership, having drawn to itself apiarists from distant parts of the State, and from Canada.

The subject of raising queens occupied a good deal of attention.

Messrs. W. Z. Hutchinson and J. H. Robertson, both extensive breeders, detailed their experience, and gave many valuable hints. The fact was brought out that as good queens can be produced by artificial stimulation, as those reared during a honey yield; also that the color of queens is in a measure decided by that of the honey upon which they are fed. The definition of a tested queen is one that produces three-banded workers. Mr. Robertson said that he is using some combs which are 25 years old, and finds them good still. For pasturage he prefers alsike clover and figwort. He purifies wax with salt or vinegar. Both these gentlemen use queen nurseries.

There was much interest taken in the honey market. Mr. Robertson sells his own honey, and last year he disposed of 20,000 pounds. He strongly advocated that honey producers deal as directly as possible with consumers. None of those present had ever known of honey being adulterated, and it was agreed that bee-keepers have no use for glucose. Mr. Hutchinson had tried feeding it to weak nuclei in summer, and he now believed that pure cane sugar is cheaper even at three times the price. Several members stored extracted honey in stone crocks and large tin cans, and kept them in a warm, dry place.

The following is from the question box: Which is the best sized frame for wintering?

Mr. Robertson believed that more depended on the bee-keeper than the frame; he commenced to prepare his bees for winter in the preceding June, and had them prepared for winter before it came. This season he had wintered 509 colonies out of 511, and had noticed that bees cannot go from one comb to another as easily as along the length of a comb.

What kind of bees are the best?

Most of those present believed that we would obtain the best results by careful breeding.

One member had tried the Syrians; he found them very good workers, also very cross.

It was agreed that Italians would protect themselves much better against moths than the blacks.

For winter packing, inside of the hive, the following substances were recommended in the order mentioned, fine, dry sawdust, planer shavings and oat chaff.

The meeting adjourned, to meet at the call of the Secretary, some time next October. A. B. WEED, Sec.

 The Mahoning Valley Bee-Keepers' Association will meet at Town Hall in Berlin Center, Mahoning Co., Ohio, on Saturday, April 29th, 1882, at 1 p. m., sharp. All interested in the busy bee are invited.

LEONIDAS CARSON, Sec.

 The Bee-Keepers of Virginia and Maryland are invited to meet at the Court House in Hagerstown, Md., on April 20, at 11 a. m., to organize an association.

D. A. PIKE.

SELECTIONS FROM OUR LETTER BOX

Cool Yet.—The weather is cool here yet: I took my bees out of the cellar two weeks ago to-day; put in 45 last November, and took out 42 colonies alive, with about one-half in very fine condition, the balance thinly settled. 1. The three lost had no bees either dead or alive, can you assign a cause? They also had consumed more honey than those coming through all right. Nearly every colony has three to four frames of sealed and candied honey to spare. 2. How can I get it out.

D. H. HOPKINS.

Bear Lake, Mich., April 15, 1882.

[1. The three colonies mentioned were probably queenless, and the bees deserted and doubled in with other colonies. Sometimes when stronger colonies rob weaker ones, the bees being robbed go out with the robbers, or force an entrance to other colonies.

2. We would recommend to shave off the cappings and put the combs one at a time in the center of the brood nest. The bees will take out the honey, and liquefy and replace it in other combs. The following method is that adopted by Mrs. Harrison:

The honey was washed up in a pan, and set over a kettle of boiling water, and stirred frequently. Before the honey was very hot, the wax had risen to the surface, and being set out in the cold, quickly congealed, so that the warm honey could be poured from under it, through a coffee strainer into another vessel, leaving the wax in the pan. After the honey was melted, the wax was all melted up together, and considerable honey of inferior quality was under it, which can be kept separate and be used for cooking, making gingerbread, etc. The rinsings of vessels used in ma-

nipulating the honey, will make excellent vinegar. The wax can be melted in a pan over boiling water, and should be poured, when melted, through a hot coffee strainer, and when cool, will be of a light straw color.

Frost and Swarms.—This morning when I arose I thought of the frosty mornings of November. The ground was white with frost. About 10 o'clock I was in the apiary listening to the merry hum of the beautiful Italian bees, when, to my surprise, a swarm came rushing out of the hive as if some one had cried fire. As I clip all my queens' wings, of course I had no trouble in living them. I had the job about completed when the second came. I began to think I was employed for the day, if it was Sunday. The first swarm weighed 9 lbs., and the second 8 lbs. This sounds a great deal like a whopper, but it is true, nevertheless. I have a hive of Italian bees that are in good condition, plenty of brood, and the queen was hatched the 15th of June, 1881. They are not populous enough to swarm. They built a queen cell, and she hatched the 4th of April. They killed her immediately. To-day they have two more queen cells about ready to hatch. What is the matter? They are not ready to swarm; they have plenty of room yet. The queen is young and prolific. J. F. KIGHT.
Poseyville, Ind., April 16, 1882.

[The bees are determined to supersede the queen—why, you will have to ascertain from future observations.—Ed.]

Queen Feeding a Drone.—I have never seen a queen bee embrace a drone, but I have seen a queen feed a drone. I once was exhibiting bees at a fair, and for the purpose of giving more interest to my enterprise, I took the queen out of the hive and placed her with a drone in a small paper box covered with glass, so that they could be seen. I put a small bit of candy in the box, thinking they might want to eat. I was much surprised to see the queen suck the candy, and then go to the drone and go through all the motions that bees do in feeding one another. This she repeated several times. The drone soon died. They had not been in the box but a short time. We are having quite a cold spell here. Fruit must be greatly damaged. I never had bees winter better, and do better, than they are doing now. No sick bees this spring.
Waveland, Ind. ISAAC SHARP.

Loss About Ten per cent.—My bees have come through the winter very strong, with only the loss of one queen, and one drone-laying queen. I started in the winter with 15 colonies packed in chaff. I have to-day 13 in good condition, and two queenless. The loss in this neighborhood is about 10 per cent. We have had a favorable spring but to-day (April 10) is a cold, blustery day.
P. A. RIEGLE.
Arlington, O.

Prepared for Dividing.—Thinking you would perhaps like to hear from this region in regard to bees, I am at liberty to say my bees wintered unusually well. 5 colonies of Italians, and are now very strong. On last Saturday and Sunday (Easter) one colony in particular showed its strength in laying out, and I think it would have swarmed on Monday last, only that the weather on that day turned suddenly cold, and has remained so until now, which had the effect of keeping them very quiet. I had all my preparations made for dividing them, but the weather interfered. 1. Do you think this cold snap will injure the brood? 2. What is the significance of finding, in the morning, say from 20 to 50 little round caps of wax at or near the entrance, which look like cell cappings? 3. Do you think it would pay for me, only having a few colonies of bees, to invest in a honey extractor, when prices remain so high?

HERMAN KNIRIEM.
New Albany, Ind., April 15, 1882.

[1. Where colonies are somewhat weak, the late cold snap will be found to have done considerable damage.

2. The finding of the little wax caps signifies, generally, that bees are uncapping honey preparatory to carrying it to the center of the brood-nest. In other words, that they have been obliged to resort to their reserved stores.

3. If you purpose remaining in the business, you may find it economy to obtain an extractor, because an exigency might arise for its use.—Ed.]

Water! Water!—We in the Tiche country—east side—are under water, 3 to 20 arpents (arpent 192 feet) from the bayou. My father's place is 25 arpents, and the water from the bayou is under the house, and 20 feet above low water. Our bees are still 2 feet above water, $2\frac{1}{2}$ to reach hives. April 1st we extracted 12 lbs. from 1 hive; April 8th 15 lbs. from another, to give room. We have 20 with second stories all nearly full. We could extract 500 lbs. to-day from all. We have 5 that are about ready for second stories. Ten days ago a swarm of black bees came to us. We gave them a home and put them to work. An actual inspection of all colonies shows no queen cells started. We have a sad record for others of your subscribers. Mr. Garrett has lost by water 50 colonies—has 36 left. Mr. Henry Stecker is in water, 3 miles to land, and his 140 colonies are *queen safe*, in the garret of his house. We think he is equal to the emergency. We cannot get any news of him. There is not enough cane left from the lands not overflowed to plant $\frac{1}{4}$ of the land (now planted and under water) next season. Forty arpents of corn and cotton planted and up, do not remain, and the water is rising in the bayou 2 inches in 24 hours. Back the water is at a stand to-day. Since 6 p. m., April 2d, the water has

risen 28 inches; April 1st, 11 inches; March 30 and 31, 11 and 13 inches respectively. You will know the extent of the disaster when I state the crop of cotton at 1,500 bales, sugar 1,700 hhds., molasses 2,000 bbls., on last Saturday and Sunday (Easter) one down corn, worms eat the cotton, cane is killed. We are simply done for. Well, we are in a bad fix—sickness will play havoc, and run riot here this fall. My father's large practice here will be charity for a year to come, and losses—many due for four years—will be \$20,000. Well, we will bear it, and make our bees educate us; you will see if they do not do it!

J. W. K. SHAW.
Loreauville, La., April 9, 1882.

Not Very Plain.—In the BEE JOURNAL of April 12, page 226, you give directions for rearing queens, and say, when all is finished to shake the bees in front of the new hive, and place the frames in the hive removed (the black colony), then release the queen. Do you mean to release the queen in the new hive, or return her to the hive removed 4 or 5 rods distant? Please make this plain through the JOURNAL. I think I understand the rest. I have never tried to rear queens yet.
J. HAMBLY.

Stirton, Ont.

[Return her to the hive removed (the black colony). The object in caging the queen is to have an absolute certainty that she does not get into the new hive on the old stand, and that is quickest guarded against by caging her.—Ed.]

Fruit Blossoms All Killed.—We had splendid weather from the first of April until the 10th inst. Peach, apple, cherry and pear trees were in bloom, and the bees had a good time and gathered pollen and honey in abundance; but on the night of the 11th the wind changed to the north, and was accompanied by a heavy snow storm. From that time up to date we had heavy frosts, killing all the bloom, and bees have had no fly up to date. The indications are that we will have a change by to-morrow. Bees are in good condition, however, full of brood and honey. We hope that we will have a good honey harvest this season, although the fruit bloom was killed. Our Association in Franklin County, Ind., will meet on the last Saturday in April, to adopt a constitution and by-laws, and I think we will make a grand success of it.

J. W. STURWOLD.
Haymond, Ind., April 17, 1882.

Jubilant.—To-day bees fly nicely, after some cold weather. I finished taking out my bees April 4, the last having been confined 5 months lacking a day. Out of 177 I have lost only 1, and that was put in weak and queenless. Throwing up hats is in order. Cherry blossoms killed, but we can feed at that time and apples will soon bloom.
C. C. MILLER.
Marengo, Ill., April 15, 1882.

The Golden Bee-Hive.—Bees in this neighborhood appear to be doing very well at this time. I examined one on the 22d of March, which had plenty of old sealed honey, with fresh honey and brood in all stages. 1. Can I feed extracted honey at any time to the bees, and have them store it without waste? 2. Will they take up extracted honey and store it in the boxes, when they are at work in the boxes above. I am afflicted with cataract on both eyes, so it is with difficulty I can see to read or write, hence I can be but a very poor bee-keeper. I think I will take my 15-year old boy with me, and try to use his eyes with my brains, so that between us both my pets may be taken care of the best I can. I keep but few, but I am loth to give them up, and will not as long as it can be helped. Just at this time this part of Alabama is blessed (or cursed) with a patent right bee-hive vender, selling rights to the people to make what he terms the "golden bee-hive." I have seen the hive and think it to be a sorry affair. Do you or any of your readers know anything about it? James B. Pickerell is the name of the vender. 4. Who is he?

W. E. FREEMAN.

Olustee Creek, Ala., April 13, 1882.

[1. Bees will not take up extracted honey and store it without considerable diminution.

2. In time of scarce honey flow, the bees will store extracted honey in the sections, where already at work in them; but in time of an abundant honey flow, they will look upon extracted honey with indifference.

3. The "golden bee-hive" was patented by David Thompson. We obtained from the Patent Office in Washington, in 1880, an official copy, from which we extract:

What I claim as new, and desire to secure by letters patent is: The combination, with the hive proper of the supplemental hive or box B, feed-board A, feed-cup C, and key and lever E, all arranged substantially as described and shown.

The patent does not cover the hive proper (brood chamber), nor the frames or division board. Mr. Thompson only claims the "combination" of his surplus arrangement with the hive proper. This arrangement consists of small frames of the same length of the brood frames, but about $\frac{1}{2}$ their depth; these hang by the top-bar, over the brood frames, and both the frames and their manner of hanging, together with their position on the hive, are all old, and have long been common property. The "combination" which Mr. Thompson claims is simply the attaching of his "supplemental hive, or surplus box, to "the hive proper," and he has no claim upon any movable frames, or any of

the desirable features of the ordinary hives, or upon division boards. His "feeder," "key" and "lever," are the main points in his patent, and these are, perhaps, of the least importance to bee-keepers.

4. We do not know Mr. James B. Pickerell.—ED.]

Planting for Honey.—You have raised such a tempest in my brain about planting for honey, that I resolved at once to set apart 20 acres adjoining my apiary for that purpose, and wrote to the editors of the *Kansas Bee-Keeper*, asking them to open the question, "Is planting for honey needed in Kansas; if so, what, how, and when shall we plant?" I expect a notice in the next issue. I shall not be able to plant the whole patch this year, but I would like to ask for the proportion of seeding for such a farm, on the supposition that my bees had no other resource—perhaps your pamphlet on planting answers my question. My land is a very fine, deep, rich, black loam, rectangular in form in the proportion of 4 to 9. Many thanks for the weekly visits of the *BEE JOURNAL*. I once heard an elderly gentleman advise a young man in the following words: "Go, and make yourself indispensable," were you there at the time?

Exeter, Kans. N. EMMERSON.

[We think you will find your question answered more satisfactorily in the pamphlet, "Bee Pasturage a Necessity," than we could do in a newspaper article.—ED.]

Grateful.—I am a bee-keeper in a small way, compared with some of our American apiarists, and depend a great deal on the *BEE JOURNAL* and its correspondents. I desire to return my thanks to Rev. A. Salisbury and Mr. G. M. Doolittle for many valuable suggestions. The latter just strikes me exactly. I like to read articles that come right out and tell me what to do—that is business. The Syrian bees are beauties, what I have seen of them, and I think ought not to be classed as ferocious. There are about five apiaries in our vicinity or the north half of our county (Douglas), all run for comb honey, except Mr. Salisbury's, which is partly run for honey and partly for queens. The five apiaries contain about 440 colonies, 70 of which are my own. These were wintered in a cave without loss. My yield in 1881 was about 50 lbs. of comb honey per colony, in prize sections, and thirty per cent. increase. They filled the brood chambers in the fall to the extent of crowding out the queens, and consequently they are weak this spring. I am going to adopt Mr. Doolittle's plan with them, and think I will have about 55 colonies when united for clover honey gathering. Next fall they will have better attention, as I have resolved to devote my whole time to the production of honey.

BARTLETT Z. SMITH.

Tuscola, Ill.

Honey Store-Room.—I have a two-story building 18x24 feet, and desire to use the upper story for a store-room, and the ground floor for workshop and room to keep comb honey in. The honey room is at the west end and is ceiled up on the inside, and has racks to place the honey on. The room has but one window, and blinds will be placed on the outside with wire screen and curtain on the inside. Which would be the best for the good keeping of the honey, a dry ground floor or a plank floor? There will be a board chimney 10x12 inches from the honey room, with a slide to open or close the same, so that when the sulphur fumes have been on the honey long enough they may be carried off as soon as possible, so as not to settle down on the honey and color the comb. The chimney may also be used as a ventilator. Please state in the *BEE JOURNAL* what you think of the above arrangement for keeping comb honey.

D. M. KETCHAM.

Arcadia, N. Y.

[If perfectly dry, we think we would prefer the ground floor, then with the chimney near the bottom for the escape of the sulphur fumes, your room will probably give satisfaction.—ED.]

Universally Cold.—I see by the *BEE JOURNAL* that most of our fraternity are having an early spring, and that bees are gathering pollen finely. Not so with me, however, for the spring has been universally cold. Vegetation has not started in the least as yet, and the past week has been one of cold and snow, the mercury going as low as 14°. It has been so cold I have been unable to dig plants except for about a week, making me late in filling orders, at which some of my Southern patrons feel disposed to growl a little. No pollen yet, and but very little brood in the hives. However, my colonies were never stronger in bees at this time of the year than now.

G. M. DOOLITTLE.

Borodino, N. Y., April 17, 1882.

Pollen.—It is supposed that bees feed their young ones on neither pollen or honey in the raw state, nor soften it, like pigeons do, for instance in the crop, and then feed; but that both pollen and honey are converted by them in chyle or milk, so to say, and then fed. Anyone who has tasted the stuff left in the queen cells will come to this conclusion. If, therefore, bees raise young ones in the spring without pollen, they do so at the cost of their own vitality, the same as animals live, which hibernate, but could never do it very long.

Terre Haute, Ind. T. HULMAN.

Bees Swarming.—Bees are in fine condition, and are swarming occasionally notwithstanding the cold wave which passed over our latitude during the past few days. The poplar, one of our chief honey-producing trees, is just coming into bloom.

S. D. McLEAN.

Columbia, Tenn., April 17, 1882.

Removing Queen Cells.—In your recent directions on queen rearing, dividing, etc., you say, "in 10 or 12 days from the removal of the queen, the queen cells may be cut out and used." In "Quinby's New Bee-Keeping" directions are given to remove the cells in the latter part of the ninth day, or the early part of the tenth day, from the removal of the queen—that if put off later a queen will likely emerge and destroy the other cells. Now if such a thing should occur, of course our object would be defeated. On the other hand, I understand we run some risk of injuring the queen if cut out too soon, besides, when we divide, as you recommend, by supplying a colony with a queen cell, or cause the colony to wait unnecessarily long for a laying queen. Please answer: 1. Where no special combs are furnished beforehand, what is the longest time we can safely wait after the removal of the queen, before cutting out the queen cells? 2. What age larvae (dated from the laying of the eggs) do the bees prefer to use to rear queens? G. M. ALVES.

Henderson, Ky.

[1. Twelve days; and this will be governed by the progress made by the bees in ripening the cell. To determine this, an examination should be made previously.

2. From three to five or six days. Usually about four. We prefer, always, to watch the development of the cells closely, so as to let the young queens be as thoroughly developed and vigorous as possible before removing or handling the cells. The best queens we have had were those from cells removed but a few minutes before hatching.—Ed.]

Plenty of Bloom.—We have plenty of bloom here, and bees are doing well. I want to know how to get the most honey, and hence I take the JOURNAL. JOHN ERWIN.
Louisville, Ill., April 19, 1882.

Clover Uninjured.—Bees are well—only one colony has perished; but, best of all, the clover is uninjured by the open winter. The honey prospect is fine for 1882, in Michigan.

T. F. BINGHAM.

Abronia, Mich., April 17, 1882.

Bees at the College.—The College bees are in splendid condition. I never knew bees to have so much brood at this time of the year, yet when I removed the bees from the cellar on the 1st of April, they had no brood, as there was no pollen in the hives. Bees here commenced to bring in pollen on April 1. This is five days earlier than any previous year. Possibly they would have brought it in earlier had they been able to fly. Our meeting last Thursday was very largely attended and was a great success. A. J. COOK.

Lansing, Mich., April 24, 1882.

Harmless.—I inclose an insect, and often see such around the hives. Do they do any harm to the bees?

A SUBSCRIBER.

Navarino, N. Y.

[We have often seen them around the hives, as well as on flowers, attracted no doubt by the smell of honey. After much observation, we cannot accuse them of any harm, intentional or otherwise.—Ed.]

Cheerfulness Prevails.—The outlook for the California bee-keeper, up to Feb. 1, was indeed very gloomy, owing to the scarcity of rain. Since that date it has rained copiously, and the prospect for a good crop of honey, perhaps, was never better at this season of the year. Consequently, the faces of the bee-keepers have been transformed from a woe-begone expression to that of smiles and cheerfulness. You may prepare yourself for a good report from California this year, though let her crop of honey be what it may, we shall depend almost exclusively upon Europe for our market. There are parties here now making very liberal offers for the coming crop. J. E. PLEASANTS.

Anaheim, Cal., April 13, 1882.

Flowers on Every Side.—Bees are doing well here now, with some swarming going on. Poplar (tulip) is beginning to bloom, and raspberries will be due in a few days. I wish you could see our country now. All nature is green and fresh, with flowers on every side. W. J. WILLARD.
Jonesboro, Ill., April 17, 1882.

Cyprian Bees.—Having heard so much about Cyprian bees and their good qualities, I purchased a queen last season. I found them more gentle than the blacks, and better workers, but, when once disturbed, they are very hard to quiet down. All my black bees cannot rob them. On the 1st of April I made an artificial swarm by placing in an empty hive three frames of brood from the old one, then moving the old hive a good distance off and setting the new one in its place. By the 16th I took from it 15 queens and it swarmed once. I have left them 15 capped queen cells, hoping that they will swarm again. I think that they keep out moths better than the blacks. I expect to try the Italians next. D. R. KEYES.
Wewahitchka, Fla.

Bee-Pasturage.—Your pamphlet on this subject, Mr. Editor, is something which every bee-keeper needs. I have long been looking for such a work. I have planted different kinds of honey plants this season, and shall plant more in due time. We are having an early spring in Kansas. The fruit trees are in bloom, but the weather has been windy and cool, and we have had but few days when the bees could fly. The past winter was mild.

E. ZABEL.

Williamsburg, Kas., April 12, 1882.

Gnawing Off Combs.—I want to ask a question, and, of course, want an answer: I have one colony of bees, and know nothing of their habits. 1. I find that they are carrying out the comb; some frames are being nearly eaten off at the top. What makes them do so; and, 2. Is pure maple sugar good food for bees in spring? Bees have been gathering pollen for about ten days. SUBSCRIBER.

Fairchild, Wis., April 20, 1882.

[1. The combs are objectionable; we have known the bees frequently to gnaw off the cells of the combs when honey was candied very solid in them.

2. Yes, almost anything will do to feed in spring, when constantly flying, but, of course, good honey and sugar syrup are best.—Ed.

Prospect of Honey Harvest.—My bees are stronger than I have ever had them at this season, before. I have had but one swarm yet and that was yesterday. I have been holding back my swarming for the ratan honey harvest. Several of my neighbors' bees have swarmed, which has proved very disastrous, as a genuine "Norther" blew up on the 11th inst., and the weather continued wet and cold four or five days, chilling the brood in the parent hive, and severely damaging recent swarms. It is warmer now and the prospect is for a heavy honey yield the coming season.

WM. R. HOWARD.

Kingston, Texas, April 17, 1882.

Bee Stings.—The remedy for the third class of bee-keepers, mentioned by J. Anderson, whom the stings affect so seriously, is bromide of potassium. With me, the pain is cured instantly by rubbing honey over a large surface about the sting, but all the symptoms that he mentions follow, unless I have this remedy at hand; then I am ready for work again in 10 minutes. M. SIMONS.

Brockton, N. Y.

Wintered in Cellar.—I wintered my bees in a well ventilated cellar and lost 11 out of 58 colonies. Ten of them starved. J. F. POWELL.

Tracy, Minn., April 13, 1882.

Building Up.—My bees wintered without loss and are building up rapidly. W. H. MILLER.

Berrien Springs, Mich., April 14.

☞ We are sometimes asked who our authorized agents are? Every subscriber is such an agent; we have no others, and greatly desire that each one would at least send in one new subscriber with his own renewal.

☞ When changing a postoffice address, mention the *old* as well as the new address.

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 "	20 " "
" 13 " (3 months)...	30 " "
" 26 " (6 months)....	40 " "
" 39 " (9 months)....	50 " "
" 52 " (1 year).....	60 " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the best advertising medium, but the lowest rates on yearly contracts.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

Articles for publication must be written on a separate piece of paper from items of business.

For man it has no equal; for beasts it is not excelled. What? Kendall's Spavin Cure. 14w4t

The Apiary Register.

As the time is now at hand to commence the use of this valuable book, all who intend to be systematic in their work during the coming season, should obtain a copy and commence to use it.

For 50 colonies (120 pages).....	\$1 00
" 100 colonies (220 pages).....	1 50
" 200 colonies (420 pages).....	2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

To any one sending two new Weekly subscribers for a year, we will present a volume of the BEE JOURNAL for 1880, bound in paper covers. It contains much valuable information, and it will pay any one who does not already possess it, to obtain a copy. Many of our new subscribers will be pleased to learn that they can get it for \$1.00, by sending for it at once, before they are all gone.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, } Monday, 19 a. m., April 17, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—As the season is well advanced, sales of extracted honey are slow and prices remain unchanged. I am paying 5c. for dark and 10c. for light, cash on arrival. Good comb honey is scarce and rates high.

BEESSWAX—I am paying 24c. for good yellow wax, on arrival; 18@22c. for medium grade, and 15@17c. for dark.

A. L. H. NEWMAN, 972 W. Madison St.

CINCINNATI.

HONEY—The demand for comb honey is slow, and prices nominal at 16@20c. on arrival. Extracted honey is in fair demand. Our jobbing prices for 1 lb. jars of clover honey are, per gross, \$25; for 2 lb. do., per gross, \$42. The demand for manufacturing purposes is very good. We pay 8@10c. on arrival.

BEESSWAX—Brings 18@22c. The demand exceeds the offerings. C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—Our honey market would be good, as there is considerable inquiry for white honey in sections, with none to satisfy the demand. It would bring 22c. readily for choice. Buckwheat honey, no sale. Extracted, 11@12c. per lb.

BEESSWAX—25@30c.

R. A. BURNETT, 165 South Water St.

SAN FRANCISCO.

HONEY—All reports from the honey-producing districts in the southern part of the State are of the same tenor, viz.: that there will be a heavy yield this season. Bees are having an abundance of flowers, full of sweet nectar, and are gathering large quantities of honey and making brood comb. Our quotations are mainly nominal, as there is little doing at present.

We quote white comb, 16@18c.; dark to good, 10@14c. Extracted, choice to extra white, 8@9c.; dark and candied, 7c. BEESSWAX—23@25c.

STEARNS & SMITH, 423 Front Street.

CLEVELAND.

HONEY—The demand for honey is light, most of the trade finding fault with the best offered, as it is more or less candied. Values are not steady, prices being made to meet the views of the purchasers.

BEESSWAX—Scarce, and in demand at 23@25c. A. C. KENZEL, 115 Ontario Street.

NEW YORK.

HONEY—Scarcely any demand reported for honey; prices weak and little more than nominal.

We quote as follows: White comb, in small boxes, 15@17c.; dark, in small boxes, 11@12c. Extracted, white, 9@10c.; dark, 7@8c.

BEESSWAX.—Western pure, 24@25c.; Southern, pure, 23@24c.

THORN & Co., 11 and 13 Devoe avenue.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.

BEESSWAX—Prime quality, 25c. CROCKER & BLAKE, 37 Chatham Street.

ST. LOUIS.

HONEY—In fair demand. Strained selling at 8@10c.; comb scarce—nominal at 18@22c.

BEESSWAX—Slut at 20@21c. for prime. R. C. GREER & Co., 117 N. Main Street.

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

- For a Club of 2,—a copy of "Bees and Honey."
- " " 3,—an Emerson Binder for 1882.
- " " 4,—Apiary Register for 50 Colonies, or Cook's (Bee) Manual, paper.
- " " 5,— " " " cloth.
- " " 6,—Weekly Bee Journal for 1 year, or Apiary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

Advertisements.

THE AMERICAN BEE JOURNAL is the oldest Bee Paper in America, and has a large circulation in every State, Territory and Province, among farmers, mechanics, professional and business men, and is, therefore, the best advertising medium.

Florida Land--640 Acres

CHEAP FOR CASH.

DESCRIPTION.—Sec. 4, township 7, south range 7 west, Franklin county, Florida, situated about 50 miles south of the Georgia line, 25 miles west of the city of Tallahassee, the capital of the State, and about 25 miles northeast of the city of Apalachicola, a seaport on the Gulf of Mexico, and within 2 sections (5 and 6) of the Apalachicola river; the soil is a rich, sandy loam, covered with timber.

It was conveyed on Dec. 31st, 1875, by Col. Alexander McDonald, who owned 5 sections, including the above, to J. M. Murphy, for \$3,200, and on Sept. 5th, 1877, by him conveyed to the undersigned for \$3,000. The title is perfect, and it is unincumbered, as shown by an abstract from the Records of the county, duly attested by the County Clerk; the taxes are all paid and the receipts are in my possession.

I will sell the above at a bargain for cash, or trade for a small farm, or other desirable property. An offer for it is respectfully solicited. Address,

THOMAS G. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

Honey as Food and Medicine.

We have just issued a new edition of our pamphlet bearing the above title. It has been revised and enlarged from 24 pages to 32, the new pages being devoted to new Recipes for Honey Medicines, and all kinds of cooking in which honey is used.

It is undeniable that pure honey is the simplest, the healthiest, the most natural, and the most strengthening article of food for healthy persons, as well as for the convalescent it is the true balsam of life, to restore them to their wonted strength and health.

What is needed is to educate the community up to this idea, and in no way can that be done so well as by directing their attention to the merits of honey.

This little pamphlet should be scattered by thousands all over the country, by honey producers. In this way it will create a home market in almost any locality.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

When 100 or more copies are wanted, they will be sent by express, at the expense of the purchaser.

Bees and Honey, or Management of an Apiary for Pleasure and Profit. This is the title of our new book. The first and second editions having been exhausted, and being desirous of having it "fully up with the times," including all the various improvements and inventions in this rapidly increasing pursuit, we have thoroughly revised it, re-writing some chapters and adding several new ones, in order to present the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth 75 cents; in paper covers 50 cents, post paid. The following is its Table of Contents:

NATURAL HISTORY OF BEES..... PAGE..... 11 Introduction..... 11 The Races of Bees..... 13 The Queen Bee..... 13 The Drone Bee..... 16 The Worker Bee..... 17 Brood..... 19 Production of Wax and Comb..... 24 Pollen, or Bee-Bread..... 24 Propolis, or Bee Glue..... 24 ESTABLISHMENT OF AN APIARY..... 25 Situation and Arrangement..... 25 Bee-Keeping a Science..... 25 Who Should Keep Bees..... 26 Suitable Location..... 26 Which Way Should Hives Face..... 28 When to Commence..... 28 How Many Colonies to begin With..... 28 Removing Bees..... 28 What Kind of Bees to Get..... 29 Buying Swarms..... 30 How to Care for a First Colony..... 30 Bees Kept on Shares..... 30 Bees Marking their Location..... 31 Clearing the Location..... 31 Will Bees Injure Fruit?..... 32 Cleansing Combs of Dead Brood..... 33 Ants in the Apiary..... 34 Removing Propolis from Hands..... 34 HIVES AND SURPLUS RECEPTACLES..... 35 What Hive to Use..... 35 The Langstroth Hive..... 36 Production of Choice Honey..... 38 Single Comb Honey Sections..... 39 One-Piece Honey Sections..... 40 Cases for Holding Sections..... 40 Making Hives and Surplus Boxes..... 43 PRODUCTION AND CARE OF HONEY..... 45 Preparation for the Market..... 45 How Should Honey be Marketed..... 45 Assort and Grade the Honey..... 47 How to Get Bees out of Boxes..... 47 Management of Comb Honey..... 47 Honey in Unclassed Sections..... 49 Handling and Shipping..... 50 Canded Comb Honey..... 51 Management of Extracted Honey..... 51 Honey Must be Ripened..... 56 Metal Corners for Frames..... 57 Putting the Honey in the Sections..... 57 Honey as a Commercial Product..... 58 MANAGEMENT OF AN APIARY..... 59 Link or Scientific Management..... 59 The Italian Bees..... 59 Italianizing the Apiary..... 60 Introducing a Queen..... 60 Inserting a Queen-Cell..... 62 Nucleus Colonies..... 64 Dividing the Colonies..... 65 Swarming; how to Control it..... 67 How to Have a Swarm..... 69 The Loss of the Queen..... 69 What are Fertile Workers..... 71 Transferring from Box Hives..... 72 Transferring from Frame Hives..... 74 United Weak Colonies..... 74 Clipping the Queen's Wing..... 75 Washing Out Drone Brood..... 75 Removing Bees from the Combs..... 75 Preparing Bees for Shipment..... 76 Uniting Colonies in the Spring..... 78 How to Separate Swarms..... 80 Feeding Bees..... 80 Quietling and Handling Bees..... 82

Complete Apiary for Sale.

An Apiary of **90 COLONIES OF ITALIAN BEES**, with buildings and all modern appliances for running the same; are within 23 miles of Chicago, in a splendid location for wild pasturage. These bees show a good record for last season—**2,064 lbs. comb honey from 13 colonies**, and increased to **100 colonies**. They are in prime condition now, with

PROSPECTS OF A GOOD SEASON.

I want to go into other business this fall, and would sell now, giving the purchaser the benefit of this season's work (and my services if wanted), as an inducement to buy. Terms will be reasonable, and partly on time if necessary. Correspondence solicited.

Two Apiaries for Sale.

Having purchased the Apiaries of A. T. Williams, in which I was a partner, I now offer them for sale. These apiaries are now divided, one portion of 150 colonies, are in Illinois, about 50 miles from St. Louis, Mo., and the remaining 250 colonies about 6 miles from New Orleans, La. Both Apiaries are in good honey locations, and the bees are in fine order. The Apiaries are well stocked with supplies of all kinds, with 100 new hives made of cypress lumber, and ready for bees when they swarm. The bees are all

CYPRIAN AND ITALIANS.

All the hives are the Improved Quinby, and thoroughly painted. The bees here were brought last fall. My reason for selling: Engaged in other business and cannot attend to them. I will take for them \$3.00 per colony net for all of them, or will sell in lots to suit purchasers for \$8 net. I have on hand two honey houses, one foot-power saw, two honey extractors, all kinds of tools for apianary work, 16,000 sections (one-piece), 125 lbs. foundation, and all the hives supplied with section cases all tinned.

This is an **EXTRA BARGAIN** for a party or parties to invest in an enterprise of this kind.

JOHN ENOCH,

15w4t **Gretna P. O., La.**

PRIZE QUEENS FOR 1882, From the Evergreen Apiary.

REV. E. L. BRIGGS, of Wilton Junction, Iowa, will furnish Italian Queens from either of his Prize Mothers as early in the coming season as they can be bred, at the following rates: Tested Queens, \$3; Warranted Queens, \$2; Queens without guarantee, \$1; Two comb Nucleus, with Tested Queen, \$4. Orders filled in rotation, as received, if accompanied with the cash. 3w26t

Italian Bees for Sale.

I have for sale about 40 Colonies in 10 frame Langstroth hives. All are in prime condition, and have young queens. Will be delivered after April 20th. Price, for Italians, \$9; a few good Hybrids, \$1 less. Satisfaction guaranteed.
15w4t **JOHN F. DIFMAN,** Fremont, Ohio.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langleys frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for an 8 size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the canal leading to the honey gate, and movable sides in the Comb Baskets.
For 2 American frames, 13x13 inches.....\$8 00
For 2 Langstroth " 10x18 " 8 00

BEES ON SHARES.

I desire to take about 10 strong colonies of Italian Bees to run on shares in the customary way, and invite correspondence to this end. I can care for them both in winter and summer, having a good place and pasturage. 16w2t **H. L. PENFIELD,** Hunnewell, Mo.

THE KANSAS BEE-KEEPER,

Devoted entirely to the best interests of those who keep bees. The question department, conducted by Dr. Wm. K. Howard, is of especial interest to beginners in bee-culture. Jas. Heddon will write a practical article for every number for 1882; 20 pages handsomely gotten up in book form. Every number worth the price of a year's subscription. Sample copies and premium list free to any address. Agents wanted. Address, **SCOVELL & ANDERSON,** 28wtf Columbus, Kansas.

SIXTH SEASON DETROIT EVENING NEWS' EXCURSIONS

From Detroit to the Sea,
Via Grand Trunk R. R. and St. Lawrence River Steamers, through the THOUSAND ISLANDS and FAMOUS RAPIDS, to MONTREAL, WHITE MOUNTAINS, and SEA SHORE at PORTLAND, ME., near Boston; thence back to Detroit, via Quebec, Niagara Falls and Buffalo, will leave Detroit July 5, 20 & 27.
\$20.00 for the round trip of over 2,000 miles.
Special trains on the G. T. R. R., and special steamer on the St. Lawrence River.
Each tour personally conducted by W. H. BREAIRLEY, of the DETROIT EVENING NEWS.
All tickets good to September 3d.
Send 3-cent stamp for circular.
A superb new Illustrated Guide Book, with descriptions and information, over 40 maps engraved especially for this edition, and a perfect copy of an oil painting, in its colors, of Glen Ellis Falls (near Glen House) for the first page of cover, will be sent to any address for 30 cents. Address—**W. H. BREAIRLEY,** Office Detroit Evening News.

The Bee-keeper's Guide;

OR,
MANUAL OF THE APIARY,
By **A. J. COOK,**

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.
—:0:—
320 Pages; 133 Fine Illustrations.
—:0:—

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

Read the following opinions of the Book;
All agree that it is the work of a master and of real value.—*L. Apiculture, Paris.*

I think Cook's Manual is the best of our American works.—*LEWIS T. COLBY.*

It appears to have cut the ground from under future book-makers.—*British Bee Journal.*

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—*J. P. WEST.*

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—*E. H. WYNKOOP.*

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald, Monticello, Ill.*

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—*A. E. WENZEL.*

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—*W. VAN ANSWER, M. D.*

It is the latest book on the bee, and treats of both the bee and hives, with their appliances. It is of value to all bee-raisers.—*Ky. Live Stock Record.*

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—*L'ABBE DU BOIS,* editor of the *Bulletin D'Apiculture, France.*

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat, Pulaski, N. Y.*

We have perused with great pleasure this *vide mecum* of the bee-keeper. It is replete with the best information on everything pertaining to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist, Quebec.*

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture to Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every beginner in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist.*

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor.*

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by
THOMAS C. NEWMAN,
925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide, or, Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a mastery production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quincy's New Bee-Keeping, by L. C. Root.— The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root.— This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.— This edition is revised and brought down to the present time. Cloth, \$1.00

Langstroth on the Hive and Honey Bee— This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.— A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.— Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Dzierzon Theory— presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.— This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as Food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.— This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof. Cook's Essay, which is here given in full. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use— Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.— A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman.— Giving advanced views on this important subject, with suggestions what to plant, and when and how. Illustrated with 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. "This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c."

Kendall's Horse Book.— No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.— A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 Items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and will weigh in gold to any Business Man, or Farmer. Price, postage paid, \$2.50.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Entered at Chicago post office as second class matter.

Fraud in Food.

The Chicago Tribune, of April 23d, remarks under the above caption :

There is scarcely an article of food in the market sold for man's consumption that is not adulterated in some manner. From flour to candy, and from brandy to mixed pickles, the work of the adulterator is seen. Nothing is too large or too small for him to tamper with, and the only guard against this growing evil is the possession of a thorough scientific knowledge and a microscope. Scientists say that food adulteration is the worst evil with which sanitary science has to battle. Many of the states have tried to suppress it, and much has been written against it, but to no avail. Sloe leaves and sand still continue to reduce the purity of tea and sugar, and the boarder still revels in chicory, plumbago, Prussian blue, oleomargarine, starch, alum, burnt sugar, glucose, rye, beans, ground almond shells, salts of tin, gypsum, and enough of the insoluble to make a Pennsylvania goat die of indigestion in a week. Scientists divide adulterations into three kinds, fraudulent, deleterious and accidental. The latter, of course, scarcely enters into the question. It is said by the virtuous grocers that adulterated articles never reach even the medium class of customers, but are confined to the trade which demands, through necessity, the cheapest grade of goods. They say that a sufficient number of articles have been so reduced in price as to make adulteration unnecessary and impossible. This is denied, however, by a great portion of the people and by chemists, who say they are constantly analyzing specimens of adulterated goods bought from reputable stores. Each grocer has his own excuse, and they all generally lay the blame upon the wholesaler or producer. The farmers and millers are "out" a convenient distance, and, therefore, come in for their share of the responsibility. These parties in

turn claim that their produce is adulterated by the middlemen, which class disclaim the accusation and give it to the dealers themselves.

Thus it is impossible to fix the responsibility upon any one class, and the people have their choice, if they wish to do anything in the way of anathema, when the almond-shell in the coffee swells the swarful yearn in the human breast. Legislation in this matter is next to impossible, because it is seldom that the complaining parties can trace their injury, if any, to the suspected article, and the case, therefore, goes by default.

Among the adulterations which are most common and most injurious is the practice of putting copper in pickles, lead in pepper, and poisonous colors in candy, the weakening of drugs, and, last but not least, the dilution of milk with water, thus weakening the food of children. The fraudulent adulterations are the most common, because legislation is powerless in their case. This last includes the mixing of low grades with the high grades of an article, such as flour, sugar, tea, coffee, oils and liquors, putting flour in mustard (after coloring it with tumeric), corn syrup and glucose into cane syrup, oleomargarine into butter, etc.

The accidental adulterations might possibly include sand in sugar and milk, dust in tea, and lead from mill stones in flour. Through ignorance, a "green" miller can spoil the best flour by running his millstones too far apart or too close, or by the selection of damp grain. Tea brought by railroad from San Francisco, accumulates more or less dust on the journey, so the grocers say, but the railway men deny the fact.

The following list of articles is given, with the deleterious substances used to adulterate them :

Bread, alum, sulphate of copper; butter, copper; canned vegetables and meats, salts of copper, lead; cheese, salts of mercury in the rind; candy, poisonous colors, grape sugar; flour, alum; fruit jellies, poisonous colors; lard, lime; milk, water; pickles, salts of copper, alum; sugar, salts of tin and lead, gypsum; spices, flour, starch; cloves, arrow root; tea, foreign leaves, plumbago, gum, indigo, Prussian blue, soapstone, gypsum;

vinegar, sulphuric and hydro-chloric acids; wine, poisonous colors, brandy.

The adulteration of butter has become so flagrant that special legislation has been obtained in this State, and manufacturers of the spurious article are obliged to label each package with the proper name, together with the proportion of the ingredients. In this way the public has been warned and educated to something like discrimination, but there are other articles, the adulteration of which is just as flagrant to decency and as injurious to health.

Of late, cheese has been put upon the market and sold in large quantities which consisted mainly of lard and potatoes, artificially colored with annato. Canned meats and vegetables are sold every day which are tainted with lead, copper, or tin from the cans. The articles themselves are almost invariably sweetened with syrup... Sugar, too, suffers greatly at the hands of the adulterator. Not content with mixing the brands, he uses glucose in every grade, even in the pulverized and granulated brands. Rice flour and molasses are also used with an unsparing hand, and importers have been known to have the color changed to that of a lower grade, to escape the high tariff, and then to bleach it to its original shade after it had arrived at its destination. This is but a very imperfect list, but it will serve to keep the public informed as to the terrible extent to which these frauds are carried on, and to prepare it for future articles on the same subject.

The Chicago *Herald*, of April 29th, propounds the significant query, "Are Sweets Poisoned?" and follows it with the following letter from J. M. Chapman, Chicago:

A farmer bought one barrel of prime open kettle New Orleans molasses, but after a short use returned it, with word that while it might perhaps do at the South and in such a wicked city as Chicago, yet for a regular diet sweetened physic was a total failure among farmers. A letter was sent to the New Orleans shipper, asking him to look up the planter who made it and discover the cause of the trouble, suggesting that while the business of poisoning molasses for 5 cents a gallon might not be stopped, it could at least be located, and now rested upon him and the planters. To this he replied it was "straight plantation molasses," and certainly was not tampered with there.

In another case, a barrel of table syrup shipped to Iowa from Chicago produced burning sensations in the stomach after eating, and caused the death of one man who used it freely. Nothing was done about it.

One more consumer asks the question: Are not syrups poisoned?

As the *Tribune* frankly admits above, State legislation has proven incompetent to suppress the traffic in adulterated foods, but it has in some instances succeeded in embarrassing

it. With the above showing of adulterants, it is certainly within the province of Congress to stop the greater portion of the traffic, as a needed sanitary reform, and with our faith in the final triumph of right, we firmly believe the day is not far distant when all articles will be sold for what they are, and the component adulterants be specified.

The British Bee-Keepers' Association will hold their eighth great exhibition of bees and their produce, hives, and bee furniture, and fair for the sale of English honey, at the Royal Horticultural Society's Gardens, South Kensington, in connection with the Society's flower show, on Thursday, Friday, Saturday, Monday, and Tuesday, August 3, 4, 5, 7, and 8, 1882. Entrance Fees: Members of the Association, 2s. each entry; non-members, 4s. each entry. The prizes consist of silver and bronze medals, certificates, and over \$200 in money. Any one wishing to obtain an "entry form" and schedule of prizes can obtain it at this office.

By a notice in our advertising columns it will be seen that a German bee paper is to be published in Louisville, Ky., at 75 cents a year. Those who desire to have an American bee paper in German will no doubt be pleased at the prospect. We hope it may be a success.

The first quarterly report of the Kansas State Board of Agriculture for 1882 is received, and is a report of the condition of agriculture in the State up to March 31. In addition to the regular crop and stock reports, the book contains special reports upon the subjects of forest-tree growing in Kansas, the raising and management of sheep in different portions of the State, a paper on the cultivation of tame grasses, and the usual meteorological summary for the quarter. Any one desiring a copy can obtain it by enclosing a 3c stamp for postage to William Sims, Topeka, Kan.

Of catalogues we are in receipt of one each from G. J. Pammel, La Crosse, Wis., and L. E. Douglass, Whitmore Lake, Mich.

Binders cannot be sent to Canada by mail—the International law will not permit anything but samples of merchandise weighing less than 8oz.

Removal of Our Office.

It will be observed that our number is now changed to 925 West Madison street, Chicago, Ill., just one block east of our former location. As our mail is so very large, the change will make no confusion, for the postal carriers are quite familiar with it, that whether addressed to one number or the other, letters will reach us just as promptly.

In 1873, nine years ago, when we purchased the BEE JOURNAL, a small room on the third floor was all that was required. In our new location, all on the first floor, the BEE JOURNAL and our Son's supply establishment (which is also moved to obtain increased facilities) occupies 23 times as many square feet of floor surface as in 1873.

The Postoffice Department has created a new branch postoffice within a few doors of our new location which will also be very convenient both for our patrons and ourselves.

We have a telephone connecting us with every part of the city, and should any of our subscribers be in the city, they can step into almost any store and talk with us, even if they cannot come and see us.

Novice has issued what he calls the "Boys' and Girls' Bee Journal," which he expects to issue occasionally free. It is not the most friendly thing to do, to copy our name, BEE JOURNAL, without so much as saying "by your leave."

Mr. J. S. Tadlock has located in Luling, Texas, and we notice that he is writing short articles on bee-keeping for the local papers there.

We have received a copy of the "Verdict March," composed by Eugene L. Blake. It is written in an easy style, so that it can be played on either piano or organ. The title page is very handsome, containing portraits of Hon. Geo. B. Corkhill, Hon. J. K. Porter, and Judge W. S. Cox; also a picture of the twelve jurymen who convicted the assassin of our late President. Published at 40 cents, by F. W. Helmick, Cincinnati, O.

Always forward us money either by postal order, registered letter, or by draft on Chicago or New York. Drafts on other cities, or local checks, are not taken by the banks in this city except at a discount of 25 cents, to pay expense of collecting them.

MISCELLANEOUS.

See that the Bees have Honey.—The *Prairie Farmer* advises all to now look well to the bees, and adds :

The first week in April was delightful—we ate it, drank it, and rolled in it. How the bees improved it—the young sporting in the glad sunshine, and the workers with heavily laden paniers, sailing into port. On Sunday the 9th inst., we divided our time between the peach bloom and the bees. The bloom was almost continuous on the branches of the peach trees, and the humming of the bees, as they passed from flower to flower, reminding us of the time when basswood is rich in nectar. We sat on a rustic seat, and watched the bees rushing in and out of the hives, intent on making the most of the bloom and fine weather. It is well they improved it, for how soon the petals of the peach bloom were limp and wilted, from freezing.

The mild winter and spring has been very favorable for brood rearing, and naturalists tell us, that an insect during its larvæ state consumes more food than during the rest of its life, consequently large quantities of honey have been consumed. No honey has been gathered since the freeze, and if this cool weather lasts much longer, it will result in the destruction of many fine colonies, unless they are fed. We have known colonies to starve in May, during a dearth of honey. Every colony should be carefully watched and fed, and none left to perish, as there are not enough bees in the country now to gather the nectar and fertilize the bloom.

Rules for Economic Apiaries Competition.—The London (Eng.) *Journal of Horticulture* gives the following as the rules adopted by the British Bee-Keepers' Association, for the government of competitors at the bee and honey shows. It will interest some of our readers in this country as well as Europe :

1. The object of this competition is to show the relative merits of different systems of bee-keeping, and to prove that bee-keeping if conducted on economical principles is highly remunerative to the bee-keeper.

2. Competitors shall be members of county associations affiliated with the British Bee-Keepers' Association residing within the recognized boundaries of their respective counties, or members of the British Bee-Keepers' Association residing in the county of Middlesex. Each competitor shall be limited to one entry, and shall pay an entry fee of 5s.

3. Prizes of £6, £5, £4, £3, £2, and £1 shall be awarded in the order of merit to the competitors who shall derive the greatest profit from an experimental apiary on not more than 2 hives at the outset, which may be increased to any extent by natural or artificial swarming. The total capital to be employed in commencing and maintaining the apiary must not exceed £2, and the competition to extend from May 20th, 1882, to August 30th, 1883.

4. The apiary shall be established in the garden of some cottager to be selected by the competitor and approved by the Secretary of the County Association, or in the case of the county of Middlesex by the Secretary of the British Bee-Keepers' Association.

5. The competitor shall keep a diary (a duplicate of which shall be kept at the cottage), in which all transactions connected with the apiary shall be recorded, and each item of expenditure and receipt entered; such diary to become the property of the British Bee-Keepers' Association at the close of the competition.

6. Each hive shall be weighed, and the weight minus the roof and covering shall be recorded in the diary. The hives shall be stocked with bees without combs; the bees to be valued at 4s. per lb. Comb foundation may be used at any period of the competition at 2s. 6d. per lb. for thick, and 3s. per lb. for thin. No bees, brood, or natural comb to be imported into the apiary after commencing. Queens may be introduced into the hives at any period of the competition, and shall be valued as follows: In the month of May, 8s. each; in June, 6s. each; in July, 4s. each; and any other month, 3s. each. All expenses incurred after the commencement of the competition must be defrayed from the original capital of £2. Vouchers must be produced for all purchases made throughout the competition, including hives, bees, and any appliances used at the commencement.

7. Each competitor may make his own hives and supers, but vouchers for the cost of the materials must be produced, and the workmanship valued by the Secretary of the County Association or an expert appointed by him.

8. Every amount expended in the apiary for food or any other incidental matter of whatever nature shall be charged against the apiary, and everything legitimately sold shall be set down in its favor. Vouchers must be produced for all bees and honey sold during the competition, according to the printed forms supplied to each competitor for this purpose.

9. The Secretary of the County Association may visit the competing apiary at any reasonable time, or may appoint an expert to do so. The record of such visits, together with any remarks which it may be advisable to make, to be entered in the diary, which shall always be accessible for the purpose.

10. The competitor shall certify that during its continuance he has fulfilled all the conditions imposed by these rules, and that all his entries in the diary are true. The Secretary, or his expert, shall certify as to the quantity and value of the honey produced by each competitor.

11. Any attempt at fraud will be punished by disqualification.

12. All entries must be made on the proper printed forms and accompanied with the entry fees on or before May 1st, 1882. Application for entry forms to be made to the Assistant Secretary, Mr. J. Huckle, King's Langiey, Watford, Herts.

Successful.—The *Union*, of Oneida, N. Y., gives the following :

About the most successful apiarist we know of, in this section, is Ed. B. Beebee, who has been experimenting with the "little busy bodies" for several years. Out of the 94 colonies which he had last fall, he has succeeded in wintering 90, all of which seem to be in a thrifty condition. His bees consist of the Italian, Syrian and Cyprian varieties, which are conceded to be superior to our native breed. In addition to producing honey, Mr. Beebee turns his attention to the breeding of queen bees and manufacturing honey comb foundation, for which there is a wide-spread demand among apiarists. Mr. B. expects with proper management this season to reap a harvest of 10,000 lbs. of honey, and have at least 200 thrifty colonies on hand to winter.

A Bee Lawsuit in Germany.—Mr. Alfred Neighbour, of London, England, translates the following from the *Bienen-Zeitung* of Jan., 1882, on the above subject. The translator says that the damages awarded shows that there must have been 900 colonies on one farm :

The Royal High Court of Justice here has recorded a judgment which is of great importance to bee-keepers. For more than 15 years many bee-keepers of Rhineland and Westphalia had been in the habit of removing their bees to the fields of a farmer whose estate was adjoining a moor belonging to the brothers Von Raesfeld, which was visited by the bees in their search for honey. The brothers Von Raesfeld objected to this, and summoned the bee-keepers for trespass, but the case was dismissed. Thereupon they ordered some boxes to be exposed on the heath. The inside of these was covered with honey, and when a considerable number of bees had collected there the lids of the boxes were closed and the bees killed with brimstone by men specially engaged for the work. This conduct was the cause of an action by the bee-keepers against the Raesfelds, who were condemned by the Court to pay damages at the rate of 5.80 per hive, amounting to 5,000 m.

CORRESPONDENCE

For the American Bee Journal.

My Reply to Mr. Heddon.

WM. F. CLARKE.

Absence and a consequent accumulation of work when at home, have rendered it impossible for me to do more than bestow a hasty glance on the BEE JOURNAL for more than a month past. Only to-day, while engaged in the pleasant task of "reading up" the back numbers, I have become aware that Mr. Heddon had been after me with "a sharp stick" in the issue of March 8th. Now I have a sincere respect for Mr. H., and, though I do not rate him quite so high as Prof. Cook in scientific attainments, I have no doubt he knows more about bees and bee-keeping than I do. Still, I do not accept him or anybody else, as infallible. Hence I should be sorry to have Mr. H. imagine that I am either offended or convinced, when I am not, and as he might deduce one or other of these incorrect conclusions from my silence, I will say something by way of reply to him.

First of all, I must flatly contradict his initial statement, "I have just read Mr. Clarke's attack on Prof. Cook." Mr. H. never read anything of the kind, because I never wrote anything of the kind. What he calls my "attack on Prof. Cook," the Prof. himself correctly designates "honest and kind criticism," in the BEE JOURNAL of Feb. 8, page 84. That was what was intended, at any rate. "Attack" implies hostility in feeling and intention. Men do sometimes make their theories so vital a part of themselves, that they regard criticism as personal attack. This is the very essence of bigotry.

As I cherish only the most kindly and respectful regard for both Prof. Cook and Mr. H., I must request and insist that "honest and kind criticism" shall not be labelled "attack." If I ever so far forget myself as to write anything for the BEE JOURNAL that deserves to be so called, I hope the editor will consign it to the oblivion of the waste-paper basket,—its proper place. What ails Mr. H. that he should resent so warmly and characterize so unjustly, what Prof. Cook, the party intimately concerned, had already accepted in the spirit in which it was penned? I have said thus much on this matter because it is vital to the BEE JOURNAL which will be deprived of one of its most valuable and useful features, if we cannot have free discussion in its columns within the bounds of courtesy. If when these bounds are sacredly respected, we are liable to be accused of making "attacks," we shall soon be afraid to differ from anybody, and then the BEE JOURNAL will be so tame and dull, that it will not be half so interesting as it is now.

Mr. H. says he has read my article on Prof. C. "with much interest and instruction." He adds, "I have re-read it, and re-re-read it, and to save my life, I can't see any argument in it." I suppose that is intended to be sharp and witty, but I am just as unable to see where the sharpness and wit come in, as Mr. H. is unable to see my argument. They may all be "thar" however, though neither he nor I can see them. Mr. H. says he read my lucubration with "much instruction," but it seems to me he got precious little, not near so much as he might have done, if he had been a more attentive reader. "First, he 'trembles' a little more before Cook than Heddon," not a very important item of information certainly, seeing that the trembling was only a harmless "goak," any how. "Second, that as long as he cries out 'more proofs' he doesn't know he is beaten." For "beaten" read "convinced," and there will be a small modicum of information, if not instruction, given. "Third, he recognizes no answer to his wordy sarcasms, in what I have said in my reply to his attack on the 'pollen theory.'" Here again for "attack" read "criticism." I assure Mr. H. that I do recognize his article as an "answer," but then it is not satisfactory and convincing. Some people can see in objects what others cannot see. It is said that "love is blind," but some humorist has remarked, that sweethearts see in one another what nobody else can.

Mr. H. says he "saw evidence," when examining "several hundred dysentery-killed colonies," that "pollen-eating caused the disease." I have no doubt he thought he saw it. I respect the sincerity of his conviction, but yet do not share it. I may be too exacting in the matter of evidence. It takes less to convince some than it does others. I am a natural-born doubter. It takes very clear evidence to convince me on any subject. This may be more than infirmity in me,—possibly a fault, but strong-minded believers like Mr. H. should be patient with those who are "weak in the faith" like me. Mr. H. details his experiment with "flour-brick," and asks, "I wonder if the above experiment will convince Mr. Clarke any?" To which I reply, not much, for the simple reason, that "flour-brick" is not pollen, exactly.

After all, I am only in the same unbelieving box with Mr. H. He says in his reply to Messrs. Demaree and Casson, April 5, BEE JOURNAL, page 213: "I see no proof sustaining Mr. D.'s premises." Mr. D. sees the proof plain as daylight, Mr. H. does not. In this connection, Mr. H. asks, "Does Mr. Demaree not hold some stories as divinely true, whose witnesses lost the cheerful habit of living in this world some hundreds of years ago?" The only "stories" that anybody holds to be "divinely true" are those of the Bible, and while I question the wisdom or propriety of such an allusion in the columns of the BEE JOURNAL, yet taking my cue from Mr. H., I will borrow an illustration from one of them. There was a disci-

ple who has been nicknamed all through the ages of the Christian era, "Unbelieving Thomas." He saw no proof of the resurrection, but stated what evidence would convince him. Possibly he asked too much. But the very evidence he demanded was given, and then he owned himself, not "beaten," but convinced. Pile on the evidence, Mr. H. As Daniel Webster said, "it is the facts we want." When they are furnished, I shall bow to them. I think I have understood that Mr. H. does not accept the stories he refers to as "divinely true." If so, I am sorry, but not vexed at him, nor angry with him. They command my faith, and I wish they did his. But I feel none the less kindly towards him, because he considers the evidence insufficient.

Now about that "excreta" business. If I am not mistaken, for I write from memory, it was not that "Prof. Cook has never seen the dry pellets," but that he has never seen proof that they are the feces of the bee. I cited L. C. Root in addition to Quinby and others as holding the opinion that the "dry pellets" were the excreta of bees. Is it fair to call the evidence of such witnesses "undefined observations," less worthy of credence than his own "careful examinations?"

I am astonished at Mr. H.'s bold assertion that Dr. Donhoff's "subject for analysis was dysentery excreta." It was nothing of the sort, but natural, healthy, normal, ordinary excreta, taken from the rectum of the bee. If therefore it proves anything, it proves just what I stated, that pollen forms part of the food of adult as well as young bees.

Mr. H. tells us that when he uses the plural of majesty, he speaks not only for himself, but for Mrs. H. "and the children." He says, "our opinion is the opinion of all of us." Happy family! If the Heddon family is thus "like kindred drops, that mingle into one"—if he never speaks for himself alone, but always for "we, us & Co.," he has my full permission to use the plural of majesty every time! But I am reminded of a little incident. In a social gathering not 100 miles from where I write, a fond husband remarked that he and his wife had been married, I forget how many years, without ever having a difference. A married lady present exclaimed: "What a dull time they must have had!" But if the entire family is always behind Mr. H.'s pen, he is a more formidable man than the Professor, unless all the Cooks uniformly back up "the head of the house!" Plainly I have not "trembled" enough, and must try to feel more awed in future.

"What ails Mr. Heddon?" I wish I knew. It seems to me that pollen or something has turned sour on his stomach toward me. I would like to sweeten him up if I knew how. But I can't say I believe what I don't, even to make him good-natured and pleasant. If I have ever said an unkind, harsh, or disrespectful word of

him or to him, I take it all back, apologize for it, and metaphorically "smoke the pipe of peace" with him. Listowel, April 15, 1882.

For the American Bee Journal.

Review of the Dzierzon Theory.

DR. WM. R. HOWARD.

Judge W. H. Andrews wishes me to tell the readers of the AMERICAN BEE JOURNAL, whether I think that the "Dzierzon Theory" necessarily follows from the establishment of the much cherished idea of parthenogenesis.

The Dzierzon theory is a series of propositions, 13 in number, being a full elucidation of scientific bee-culture, and is ably defended by the Baron of Berlepsch, who adduces many unquestionable facts in their support. Propositions Nos. 8, 9, and 10 having direct reference to the production of drones, are the principal ones relating to parthenogenesis, the subject now under consideration. Proposition 9 is as follows:

"All eggs germinated in the ovary of the queen develop as males, unless impregnated by the male sperm while passing the mouth of the seminal sac or spermatheca, when descending the oviduct. If they be thus impregnated in their downward passage, (which impregnation the queen can effect or omit at pleasure), they develop as females."

This proposition contains the most peculiar and characteristic feature of the Dzierzon theory. The Baron of Berlepsch, from his interesting experiments, came to the following conclusions in 1855: "Common queens fecundated by Italian drones produce mixed or hybrid workers indeed, but pure common drones, exclusively." . . . "Still," says the Baron, "the demonstrative scientific proof of its correctness was wanting." By the aid of Profs. C. T. Von Siebold and R. Leuckart, he was able to "demonstrate the presence of spermatozoa in female eggs and their absence in male eggs—thus solving the interesting problem scientifically, and settling the question."

I will now quote proposition 10:

"If a queen remain unfecundated, she ordinarily does not lay eggs. Still exceptional cases do occur; and the eggs then laid produce drones only."

That these exceptional cases are more common than was formerly supposed, is evident. This proposition has direct connection with parthenogenesis, and if we admit the following proposition we admit the parthenogenesis all the way through:

Prop. 8. "The ovaries of the queen are not impregnated in copulation; but a small vesicle or sac which is situated near the termination of the oviduct, and communicating therewith, becomes charged with the semen of the drone."

Many careful observers, sufficiently competent, have come to the same conclusions that the Baron of Berlepsch did in 1855; viz: that fecundation, pure or impure, does not affect the drone progeny, regarding its purity. L. L. Langstroth, L. C. Root, the late and lamented M. Quinby, A. I. Root, A. J. Cook, King and others teach this; and all offer the proof contained in the above propositions.

On the other hand we have many

careful and practical experimenters who, setting aside all theories, bring up evidence which in its nature is irrefutable, and cannot be explained by the Dzierzon theory. For instance it is held by them that the male and female progeny are alike influenced by fecundation; which the theory might allow, but its best and ablest advocates deny.

As Mr. Andrews wishes to put some one "on record," and claims that the writers on the subject will not do so, for his benefit, I will give him my views, not that I wish to have any controversy with him or any one else, but that he has asked it of me in a polite manner, and I have not refused.

I have read the Dzierzon theory, and have carefully examined it, with the Baron of Berlepsch's experiments, and taking it as a whole, it is the most practically scientific work for so few pages that I have ever examined. There never has been such a series of experiments given to the public, so interesting, so exhausting, or so expansive; if we will except our own L. L. Langstroth, of this country.

I may make some statements that do not seem in keeping with a believer in the Dzierzon theory, yet if I am skeptical I will give my reasons as well as possible.

That a fecundated queen is only enabled to produce worker eggs, and that this fecundation or fertilization is the only advantage gained by sexual union, over her virgin power and usefulness, I must say that I do not recognize as a fixed fact, for several reasons, some of which I will briefly state:

A drone-egg laying or unfecundated queen, like a laying worker, deposits her eggs promiscuously in both drone and worker cells, sometimes hundreds in one cell. These eggs are disposed of very irregularly from base to the extent of the side-walls, there is not that systematic arrangement, which marks the work of a fecundated queen—the brood in a compact circular cluster. She does not always examine the cell before depositing the eggs, and will often deposit a score or more in the same cell without changing her position; her position while depositing is not like that of a fertile queen, almost any position suits her, while a fertile queen invariably assumes one position every time she deposits an egg, so far as my observations have been extended, and that position, after carefully examining the cell, she turns herself obliquely across the comb the head inclined downward, to the right or left, at the same time curving her abdomen, introducing it into the cell, withdrawing it in about 5 seconds, leaving the egg firmly attached to the base of the cell. The drone-egg laying queen and laying workers are not jealous rivals, neither will these queens engage in combat with each other as readily as they once would have done. Virgin queens are rivals until they have completed their wedding tours. I have had four of these queens and I don't know how many laying workers all living peaceably in one

hive, all having free access to the same combs at the same time. The conditions of these individuals are the results of circumstances—influences of early life.

A virgin queen after having made several unsuccessful bridal trips, gradually loses her sexual propensities, and toward the last fails to attract her aerial gallants, which under ordinary circumstances are so quick to respond, and after a time she ceases to sally forth, and settles herself to become, if she ever lays at all, a drone mother, a useless incumbent in the hive, with no maternal cares, short lived, even if allowed to run her course. The ovaries are undeveloped; the spermatheca a useless appendage, without muscular power, finally becomes solid. The ovarian nervous ganglion diminished in size forms a mere apology for what it once was, or might have been. She displays neither gracefulness in motion, magnitude, instinct or regality. Her progeny are subjects of "agamie" reproduction, living individuals produced without the congress of the sexes—parthenogenesis.

A fecundated queen deposits her eggs in regular order, except, sometimes when a young queen first begins to lay, she may occasionally deposit 2 eggs in one cell,* and in rare cases drone eggs in worker cells, which is accounted for by some authors in this way: That the muscles of these delicate organs are not well practiced, or sufficiently developed by training to give the queen the proper control of them, which she afterward acquires. I have noticed that a young queen commencing to lay did not as carefully examine the cells before depositing, as older queens, and sometimes I have noticed her to examine one cell and lay in another, as if by mistake, and this I had supposed to be the cause of the frequency of 2 eggs in one cell. It has been stated that queens deposit their eggs promiscuously, and that the workers—nurse bees perhaps—remove them and systematically arrange them, and one isolated case is cited to justify the assertion; yet, as above stated, a fecundated queen deposits her eggs with precision. As the young fecundated queen increases in age, she gradually increases in size, assumes a graceful appearance, exercises a seeming maternal judgment, as her cares increase, deposits eggs more or less according to the influx of food or necessity requires, always provident of the future welfare of the colony by never leaving it hopelessly queenless when accompanying a swarm. [Who ever heard of a drone-egg laying queen exercising any of these traits?] She has respectability among her subjects, and allows no rivals.†

It will be seen that fecundation not only qualifies a queen to lay worker

* I have noticed cases wherein a good vigorous queen has deposited 2 eggs in one cell when a natural swarm had been placed in an empty hive, and only constructed a few square inches of comb, and it yet unfinished.

† I have in a few rare cases observed 2 queens, in well regulated colonies, dwelling amicably together.

eggs, but causes a complete development of the generative organs. The ovaries enlarge, the spermatheca performs its office of fecundating the passing ovum at will. The ovarian ganglion retains a healthy appearance. In fact a complete development of all the animal tissues in the anatomy of the queen bee, giving her longevity, energy, strength, prolificness, complete maternal instinct, in a word, perfection, is but the result directly or indirectly of fecundation.

I will here state that I am unable to prove from my own extended experiments with bees that the drone progeny of a fecundated queen is not influenced by impure mating; as I have on several occasions noticed hybrid drones from black queens, as well as hybrid drones whose grandmothers gave as pure well marked a progeny as any I ever had. One case in point I will relate. I bought from Judge Andrews last year in May, one Italian queen whose worker progeny were all well marked; at the same time I obtained a sealed queen cell from the same hive, and three others from as fine bees as could be found in the Judge's yard—which he could vouch for as being pure—three of these cells hatched as beautiful queens as any one would wish to see—the fourth cell never hatched. Two of these queens were mated with black drones, one of which was from the cell obtained from the queen I purchased. The third queen was purely mated, and gave a well marked progeny. The first two produced hybrid workers and occasionally a black drone, yet the most of their drone progeny were well marked Italians. This strange exception might be accounted for by the variation of individuals of the same species and as the Italian bee is not generally recognized by naturalists as a distinct species of *Apis*, but a climatic variety of *Apis mellifica*, it may yet turn out that these occasional outcroppings of impurity are the result of progenitive inheritance.

I am of the opinion that the subject is one of much importance, and needs further investigation, and that many theories, hypotheses, etc., will rise and fall, before anything like a definite conclusion will be arrived at, upon which all may agree.

For the American Bee Journal.

Italianizing Cyprian Bees.

EDWARD P. ABBE.

In 1880 I received from Mr. Jones one of his imported Cyprian queens, early enough to rear one forced queen in the fall—and a very handsome one she was—a duplicate of her mother, prolific and long-lived. She is a reigning beauty now.

During last summer I reared about a dozen other queens from the imported one, when I lost her by carelessness. All of these young queens were very nearly, if not quite, duplicates of each other and of the old one. These gave me an opportunity to test

some of the qualities of full breeds and of the half breeds—*i. e.*, half Cyprian and half Italian. There is no need of my mentioning that the pure Cyprian is a cross, active, industrious, prolific beauty; for all, or nearly all accounts agree upon these points.

For one whose only object in the apiary is the pleasure derived from it, the Cyprian is, in its purity, a calamity. But with the mixture of Italian blood to quiet down the rampant growth of Cyprian spirit, I think they are a blessing, for they infuse a new and pure blood, increase the fertility and tendency to late breeding, and fix more certainly and permanently the characteristic yellow band, adding beauty and grace to the whole apiary. This is my experience, and I for one am not sorry that I have tried them; but very glad to have got through with the trouble and stinging labor of this infusion of new blood. I had, for the past 10 years, devoted my apiary of 20 colonies to perfecting a strain of Italians, until it was as good as I think Italians could be made. The bees were large, industrious, three-banded, beautiful, gentle, and easily handled, but there was a strong tendency to lose the broad yellow stripes and run into what are called "dark Italians." If I have checked this tendency, and have fixed the characteristic bands of the Italian more permanently, I am satisfied. I shall now breed back again to gentleness.

Extracted Honey—No. 3.

JAMES HEDDON.

The upper story spoken of in our last article (No. 2), on page 55, has a capacity of 40 to 50 lbs. of honey, net, and it will probably be a week or more before it is necessary to examine the supers. Then go to your strongest colonies and remove the covers (and right here allow me to say, that the great secret of successful and speedy subjugation of bees depends upon giving them the first blast of smoke before they have had time to "think twice," after you make the first jar), and smoke down the bees, look at the tops of the combs, and the one that looks the "fattest" and brightest (usually near the center) will contain the most honey; lift this one, and look at it, then one near the outside, and you will form a close estimate of the amount of honey the super (that part of the hive which contains the surplus) contains, and the speed of development, within the super. Your register shows the date at which the bees commenced to work in the upper frames. Suppose you have found the super $\frac{1}{2}$ full, just set your "amount pin" to $\frac{1}{4}$, and the date pin to the date, and so on over the apiary.

The 10 or 20 colonies most advanced, will need looking at again in 5 to 8 days, and even less, if the rate of the flow is rapidly increasing. When the time has arrived, your registers show

you a rod or two away, which are the 10 colonies out of your 50 or 500 that need looking at. Upon examination, if none are quite ready to extract, it is a safe rule to go by, that none in the apiary are. But if, on the other hand, many of these 10 colonies need extracting, look well to the next foremost turned pins, as soon as the job is done, and follow this method of search and work through the year.

But a much disputed point arises as to what condition the super must be in, to warrant the emptying of it. Messrs. Dadants, who are good authority, believe in having all the combs sealed or capped over before extracting the honey, and more than this, they believe in letting it stand on the hive, lifting it up, and placing another set of combs under it, and so on to the end of the flow, until that flow is over, as they think that on the hive is the best place for the honey to "ripen," or take on that smooth, rich, oily condition. On the other hand, as good authority as Prof. Cook says there is no need to wait for the capping over of honey. The Professor has the facts, that the waiting process involves increased capital and labor upon this side of the argument. All the Dadants have to sustain their side of the question is, that with their process, the honey is of much better quality.

I have thoroughly tried both plans, and if the honey taken is to be consumed as sweet sauce (as most of our surplus now is, the minority being used for manufacturing purposes, as yet), I stand strongly on the Dadant side of the argument. Their words sound as if they came from experience, and from those who depended upon the favor shown their goods, for their success, viz: the specialist.

I will say that if you have the combs, use the tiering up plan of the Dadants. It is good. I have tried it more years than one. It gives you more time to do your work in; you need not rush because the season does; if you use this plan, at the end of the white honey flow remove all your supers, just as you would boxes or cases of sections, smoking down the bees, and carrying your supers into your room prepared for "getting bees out of boxes," and when the few adhering bees have gone, you can uncap and extract the combs at your leisure. But on the other hand, if your combs are scarce, or you are just making them from comb foundation, and you feel that your capital will not warrant the making so many the first season, prepare yourself with a light box, with tight bottom, and the size of the hive, with a cloth lid, and convenient handles, put 6 combs or frames of foundation in it, and approach the hive to be extracted from. The tools I carry are a heavy I X L knife, smoker and turkey quill. I open the hive, smoke down the bees all I can quickly, and then trade combs with them, taking the 6 fullest ones out of the 7, and brushing all clean of every bee. Thus I open and close the hive at one operation. The condition of the 6 combs is this: The honey is partly sealed; the sealed places are

those spots farthest from the septum, and, fortunately, the easiest to uncap.

The one comb left is hardly fit to extract, and is the odd comb that saved the bees from being crowded and idle; the 6 will make just 3 pairs, and 3 whirls, and contain a very good article of nearly ripened honey. Of the ripened condition of this "throw" much will depend upon the stage of the blossoming, and state of the atmosphere. Blossoms yield the thinnest honey at first, and richest at the close, even to the "strippings." One thing is sure, you cannot wait till the honey in the super is all sealed, without losing the filling of a second super, unless you adopt the tiering up plan, spoken of at first.

Sometimes you will find brood in all stages in your super combs. There is a slow, continuous motion of the crank that will throw out the honey, but not the brood, and this motion, which only experience can teach, must be adopted for broody combs.

I very frequently receive letters and postal cards inquiring if drone comb is not best for sections and super frames, to which I always answer, No. One of the blessings that comb foundation has brought to us, is the fact that by filling the brood frames of the hive full of it, we get rid of a class of consumers called drones, and at the same time get almost complete control over fertilization. In doing so, we are working against the instincts of the bees, and the queen, anxiously looking for drone cells, will be sure to go into your surplus department to deposit eggs if you have drone foundation above, and a proper lack of it below. Experience must drive every drone foundation mill back into type metal.

As soon as your extractor contains all it will hold below the frame, draw off at the gate, into one gallon stone crocks, which should be piled up on each other about 6 to 8 feet high. If pieces of wood $\frac{3}{4}$ x $1\frac{1}{2}$ x6 inches are laid across the tops of the crocks (2 to each crock), the spaces thus made will allow of a circulation of air that will allow of improvement of the honey as it stands. The honey house should be dry and airy, and thoroughly screened against bees and flies. Do not forget that you will have a damp air in a cool room. Cool air (as in double-wall houses), like a cool pitcher of ice-water, drains dampness. With this third article of general remarks, I will close what I have to say about extracting honey, for the present.

In regard to marketing it, I have never adopted a course that I think as good as the one laid down in Dadant's book.

The uses for extracted honey are encouragingly on the increase. It is already used as a table food, confectionery, in medicinal syrups, manufacturing tobacco, wines, liquors, mead, methelgin, soda water, printers' rollers (entirely supplanting sugar syrup), cakes, pastry, preserving fruits in natural state, jellies and jams, medicinal syrups, ointments, salves for sores, cures for asthma, indigestion, see "Honey as Medicine;" licorice, egg-foam, vinegar, rose honey,

table syrups, and many other purposes.

And now in closing let me say, while you should not build "air castles" and dream of "cisterns full of honey," you should know that just at rare intervals during good honey seasons, the gathering powers of some colonies are great; that Hosmer reports 53 lbs. of extracted honey in one day; Gallup 60 lbs., and I had 30 lbs. gathered in the same period of time, all from the basswood—the bee-keeper's friend.

Dowagiac, Mich.

Rearing the "Best," Bees.

W. Z. HUTCHINSON.

I have been much interested in the "best bees" controversy, and cannot refrain from a few remarks on the subject. In all this broad land there is probably not one bee-keeper who does not wish for the best bees, the difference of opinion being in regard to which are the best bees, and how to obtain them.

As to which are preferable, the light or the dark Italians, I will say that I have tried both, obtaining them from a dozen different sources, and I unhesitatingly pronounce in favor of the dark, leather-colored Italians. I consider the light-colored bees a trifle easier to handle, but the dark bees are so much more energetic, and store so much more honey, that I am more than willing to overlook any of their little outbursts of temper.

My experience with hybrids is as follows: I commenced bee-keeping with black bees in box hives, but the bees did not long remain in box hives. Located within a mile of my place were two Italian apiaries, and one-half of my young black queens mated with Italian drones. From what I had read I expected that there would be some "fun" in handling these hybrids, but, to my astonishment, they proved to be more amiable than the blacks. I have seen some pure Italians that were more irascible in their disposition than were the hybrids. In the fall I sold three of these hybrid colonies, and with the proceeds bought queens and Italianized my whole apiary. The next year I bought an imported queen, reared queens, and Italianized all the black bees within three miles of my apiary. Of course, some of my young Italian queens mated with black drones, and they produced hybrids that—well, I took back all that I had ever said about book-makers not knowing what they were talking about when they said that hybrids were "cross." To go back a little, the three hybrid colonies that I sold, those having the black queens mated with Italian drones, outstripped my Italians. Of course, I attributed this to the difference in location (the locality really was an excellent one), but the next year the owner of the hybrids had his whole apiary Italianized, and since then, a period of three years, he has never had the yield of honey, nor in-

crease of colonies that he had the first year with the hybrids.

Will Mr. Heddon, or any one else who knows, say whether these hybrids can be bred in-and-in, and their good qualities be preserved at the same time, or must the strains be kept up by a continual crossing of the pure races?

Mr. Editor, you may have different views from myself upon the "dollar" queen business, but when you say: "The 'best bees' will have just the requisite number of stripes, whether it be one or a dozen," we agree exactly.

Rogersville, Mich.

For the American Bee Journal.

More About Bellows Smokers.

J. H. MARTIN.

Every bee-keeper, if familiar with the history of the smoker, is ready to accord to Mr. Quinby the honor of putting upon the market the first bellows smoker. Every subsequent original inventor found the bellows, the valves, the fire-tube and the wind. It is a mystery to not a few, what subsequent inventors could claim as original. The mystery is explained by the claim that some punched a hole and let in air, where air could not get in before. Mr. Bingham has enlarged this hole to a space between the bellows and fire-tube, and there you have the original smoker. We have no doubt but that this point can be legally protected by a patent, for as trivial things have often been passed upon as improvements, and worthy of a patent as this. For instance, an inventor improved letter envelopes by inserting a thread across the end of the envelope, one end of the thread projecting so as to be taken between the thumb and finger and the envelope easily torn open.

Another inventor grasped the brilliant idea that a knot in the end of the thread to give a firm hold, was a great improvement, and applied for a patent, which was granted upon the ground that it was an improvement over the previous method. Now suppose our last inventor of the knot had proclaimed himself as the only original inventor of the envelope for letters, he would have been no more unreasonable than for the inventor who punched the hole to claim that he is alone the original inventor of the smoker. Neither can any one claim to be the inventor of the first successful smoker, for we used one of Quinby's first smokers and it was a great success for a new invention. Since then we have used various so-called improvements, some of which were no better than the first Quinby.

We wish to exercise due charity for all, and accord honor for all improvements where honor is due, but when the man who tied the knot in the end of the thread claims to be the original inventor of all envelopes, we have a right, as a letter writer, to protest against so broad a claim.

Hartford, N. Y.

Local Convention Directory.

1882. *Time and Place of Meeting.*
May 11—Champlain Valley, at Middlebury, Vt.
 T. Brookins, Sec., East Shoreham, Vt.
 16—N. W. 111. and S. W. Wis., at Rock City, Ill.
 Jonathan Stewart, Sec., Rock City, Ill.
 25—Iowa Central, at Winterset, Iowa.
 Henry Wallace, Sec.
 June 3—Hart County, Ky., at Woodsonville, Ky.

In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

For the American Bee Journal.

Central Michigan Convention.

The Central Michigan Bee-Keepers' Association met at Lansing, at 10 a. m., April 20, and was called to order by President Ashworth. E. N. Wood was appointed Secretary *pro tem.*, and 22 names were added to the Association.

In his annual address the President alluded to the mutual benefit derived by interchange of thought at the meetings, and also spoke of the importance of providing bee-pasture, especially in Lansing where there are so many bee-keepers in such close proximity. He urged bee-keepers to provide for larger exhibitions of the products of the apiary, and presented a tabulated statement of those products for 1881.

Reports and estimates show that about 120,000,000 lbs. of honey were produced in the United States last year. At 12 cts. per lb. this would amount to \$14,400,000.

An interesting discussion ensued on the topics suggested in the address.

The following officers were elected for the ensuing year:

President—Rev. J. Ashworth.
 Secretary—E. N. Wood.
 Treasurer—Mrs. T. Harris.
 Vice Presidents—Mrs. S. J. Gibson, Clinton; W. O. Wilson, Ingham; James Frye, Jackson; E. W. Lowe, Ionia; C. Clement, Livingston; E. Curtis, Shiawassee.

An opportunity having been given, a number of bee hives, section boxes and other aparian supplies were exhibited, and also an ingenious device by Prof. Cook for measuring the length of the tongues of the different races of bees.

E. N. Wood read an essay on the "Bee Hive," describing various styles, and especially the hive manufactured by Narmore & Wood, of North Lansing.

A discussion of the merits of the Cyprian bee was led by J. Harper, after which Prof. Cook was called on for an address on the "coming bee." He did not decide positively from which race the "coming bee" would spring, but earnestly assured the Convention that the dollar queen trade would not hasten its approach.

A resolution to make a large exhibit of aparian products at the Central Michigan Fair next fall was adopted unanimously; as was also the resolution offered by Prof. Cook making the President and Secretary a committee to request the agricultural society to provide a building for this object. The Society then adjourned to meet on the Tuesday preceding the autumn fair. REV. J. ASHWORTH, *Pres.*
 E. N. WOOD, *Sec.*

Hagerstown (Md.) News.

Md., Va. and W. Va. Convention.

A number of bee-keepers of these States met at Hagerstown, Md., on April 20, and organized the Union Bee-Keepers' Association of Maryland, Virginia and West Virginia. Mr. D. A. Pike, of Smithsburg, was chairman, and J. Luther Bowers, of Berryville, Va., Secretary.

Messrs. J. F. Brown, of Winchester, Va., S. Valentine, of Double Pipe Creek, Md., and Wm. Anderson, of Harper's Ferry, W. Va., were constituted a committee to select a name for the Association, who reported the name as above given.

The organization was perfected by the election of the following permanent officers: D. A. Pike, Smithsburg, Md., President; J. L. Bowers, Berryville, Va., Secretary; A. Burton, Harper's Ferry, W. Va., Treasurer.

It was resolved to hold the next meeting of the Association in this place on some day, to be named by the President, during the Washington County Agricultural Fair, the coming fall.

Messrs. A. Burton, J. F. Brown and S. Valentine were appointed a committee to draft a constitution for the Association.

It was determined that, at the next meeting, each member exhibit something to the apiary.

Various subjects connected with bee-culture were discussed, among them, "The best way to get surplus honey," "The best method of queen rearing," and "The best method of transferring bees." The discussion elicited many new ideas on the subject of bee-culture, and much important information was imparted by this interchange of views

A bee-keepers' convention will be held at Richland Center, Wis., on May 4th and 5th. All interested are cordially invited.

The Champlain Valley Bee-Keepers' Association will hold their semi-annual meeting at Middlebury, Vt., May 11, 1882. T. BROOKINS, *Sec.*

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Those who may wish to change from other editions to the Weekly, can do so by paying the difference.

SELECTIONS FROM OUR LETTER BOX

Artificial Comb Honey.—Mr. Bright, editor of the *Christian at Work*, and myself, have had some correspondence on artificial comb made of paraffine, etc., in the course of which he stated that he had seen the artificial comb. I called the attention of Mr. A. J. King to it, and also denied his statement. Mr. King offered Mr. Bright \$50 for proof that he was right, and the latter sent me a postal half way admitting that it was comb foundation that he saw. All this I believe Mr. King intends to publish in the *May Bee-Keepers' Magazine*. Mr. Stanley's article from the *Empire State Agriculturist*, printed on page 244 of the BEE JOURNAL, has a very good paragraph on the impracticability of making comb artificially, and I wish to send a marked copy of the article to Mr. Bright, as a sort of "parting shot" aimed at his erroneous statements. He probably thought artificial comb and comb foundation are one and the same thing. He is undoubtedly wiser now than when he wrote the article last February. ZOPHAR MILL, JR.
 New York, April 26, 1882.

Gleucose.—To say that the above never candies, is a mistake. Some time ago I saw 100 bbls.—2 car loads—returned to the factory because it had so thickened that it did not run out the barrel. I have also seen it thickened in glass jars put up with comb honey to be sold for pure honey. To tell, therefore, that all candied honey is pure would lead to a wrong opinion. We had hard frost here several nights after a week or more of warm weather, when the thermometer was up to 86° in the shade. Much injury, of course; but I hope the white clover was not killed here last summer, when we had no rain for about 2 months, and the heat up to 156° in the shade; it is said that clover does not give honey the first year. T. HULMAN, SR.
 Terre Haute, Ind.

Very Encouraging.—Our bees are in fine condition, and things look promising for the coming season. We have had the same weather you describe in the last BEE JOURNAL, and it still continues. The fruit is somewhat injured, but not nearly all killed. My bees are working finely to-day, and the combs are filling up nicely with capped brood, the drones are also hatching, and some of them flying.
 W. B. SPENCE.

Sidney, O., April 24, 1882.

Three Weeks Ahead of Time.—I had a fine swarm of Italian bees the 21st of April. My bees are three weeks ahead of any year I ever had them—now twenty years.

L. T. MOBBERLY.
 Long Grove, Ky., April 24, 1882.

Snakes Eating Bees.—I read with a great deal of interest that article in your last paper by Prof. C. F. Kroeh on the parthenogenesis of bees. I hope Prof. Cook, Mr. G. M. Doolittle, and some of the other big guns will favor us with their views on the subject. Bees here are doing well, in spite of the water, which has ruined most of us—that is all but those which were placed upon sheds and ratts before the water came up. The snakes, however, are devouring great numbers of them. I should like to know whether they eat them for the honey?

T. K.

Point Coupee, La., April 20, 1882.

[They probably eat them for the same reason they devour flies, snails, and other insects.—Ed.]

My Early Work.—Bees are booming, gathering honey rapidly from horsemint and various other flowers. I have one of Root's chaff hives, with 80 1-lb. sections on it, and about half a bushel of bees in it, if they were dead and measured. About half the boxes have been partly filled with new honey for nearly 2 months. A few rainy days causes the bees to draw on the sections to feed the brood and larvæ in the lower story; for there has been but very little space in all my hives; that is, the lower story, for nearly 3 months for honey, it being so completely filled with brood. I notice in the BEE JOURNAL of the 29th ult., that Mr. J. W. Eckman, of Richmond, Tex., wants to know "what it was that my bees were getting so much honey from, that I could extract so early?" Now, I did not say that I was going to extract a barrel of new honey, but I did extract some new honey, just as I said I would, and I believe it was gathered from fruit blossoms. If Mr. E. will come up and spend a day or two with me, I think I can show him how I get my bees in a condition in very early spring to take advantage of the first flow of honey from any source. I do not want over 1,000 cubic inches of comb in the brood-nest, *a la* Doolittle. I use two styles of frames, the Langstroth $9\frac{1}{8} \times 17\frac{5}{8}$, and a nucleus frame $9\frac{1}{8} \times 12\frac{3}{4}$. I use 7 of the former and 8 of the latter in the brood nest. In early spring, that is, as soon as I see a little white comb along near the top-bar, I raise the two outside frames, spread from the center of the brood nest, making room for the first two frames. This I do about every ten days or two weeks, according to the weather. Continue this way of promoting brood-rearing, and you will soon have the brood-nest so filled with brood that there will be no place for honey; then it is that the bees will put the honey they gather into any thing you may choose to give them; even a nail keg. I do not leave any frames in the upper story in winter, but take them all out, put two thicknesses of old corn sacks on top the brood frames, fill the upper story half full with good dry cotton seed, and if not disturbed during bad weather, nearly the whole force will live through our winters here, besides the

increase during winter that is being added daily. Last fall I had 50 strong colonies. About the last of January I doubled back to 27. I have had to date 26 new swarms (some I have returned), besides about 40 three-frame nuclei, keeping queens until their progeny hatches, and I have done all in my power to keep back all swarms by giving more room, shading, and some tiered up three stories high.

J. S. TADLOCK.

Luling, Tex., April 17, 1882.

Judge Andrews' Lecture.—A subscriber wishes to trouble you with a few notes. Quite an interest is being taken here on the subject of bee-culture. We have a County Bee-Keepers' Association, which meets monthly; the State Association assembles here on April 25th, and our citizens are preparing to entertain all visitors and members free of charge, and last, but not least, Judge Andrews is delivering a course of lectures to a large class, among which are some of our best bee-keepers. The lecturer advises his class to read the books and BEE JOURNAL, but to do their own thinking. He is especially severe on so-called moth-proof hives and vendors. The lecturer admits the theory of parthenogenesis, and rejects the "pure mother, pure drone theory." He says the male of the bee, as in other life, impresses his characteristics more strongly and clearly on the offspring than the female, and impressed on his class the importance of the pure blooded drone. The lecturer dwelt at length on the queen bee, illustrating his subject and exhibiting specimens from his apiary at every stage of life, and wound up his last lecture on the queen by giving his class an opportunity to witness a royal combat. During one of his lectures the Judge exhibited to his class some worked over comb. On several points the Judge differed from the books, but some of these he wished to verify before positive assertion, and lest I report him wrongly, I shall omit them for the present.

A SUBSCRIBER.

McKinney, Texas, April 22, 1882.

Almost a Blizzard.—We have a cold snap on hand now, which has lasted from the 9th to the 23d, and bids fair to reign with winter's rigor still a while longer—a gloomy prospect for my pets. We had a profuse apple and peach bloom, but it was all lost to the bees; they had to stay in to keep the young brood warm. Throughout March the prospect was very fine, but the greater part of April so far has blasted our prospects. I have been feeding my bees for two weeks. When it was warm enough for them to venture out, some would gorge themselves, become benumbed, crawl off a little distance, lay up and die, unless caught up and put in a hive, of which class I took up a great many and put in at the top of the hive without any bad results so far as I could see. The first was so severe as to wilt some of the young grape shoots and kill most of the fruit, and fears are entertained that it will fall off yet, though pro-

tected more or less by the fog from the river. We are in a beautiful vale below Louisville, drained of its many ponds, and now very fertile, producing fine hay crops, wheat and corn, and running back to the hills, with fine ridges of sand suitable for gardening purposes, grapes, melons, cantaloupes, etc. Along some of the smaller streams and wet places grow some of the asters and goldenrods. I have about one acre sowed in sweet clover and mignonette, some of which is looking very fine; I have also sowed some Alsike clover, and about one acre in white mustard. This fall I will sow 5 or 6 acres in sweet clover, and in the spring sow the same in mignonette. I wish to treat my pets well. I have now 37 colonies. No swarms yet, though in March I expected a good many ere this time. I have some now which from all appearances, will swarm as soon as the weather will admit of their doing so. We have a fair prospect for a good locust bloom, should the weather get warm enough for the bees to gather it; if not, woe to the bees. I have contracted 15 colonies to a man in Louisville when I have them, and will sell more if I find a purchaser. Success to the BEE JOURNAL. I would give up the business if it was not for it. I gain all the information I need from its pages.

G. W. ASHBY.

Valley Station, Ky., April 23, 1882.

Preparing Pasturage.—We have 77 colonies to commence spring work with. The most of them are strong for this time of the year; 50 of this number we bought this spring from neighbors that wished to dispose of their bees. The weather is very unfavorable at this time, cold and rainy. Bees cannot fly. Cherry and plum trees are in bloom. We want a little sunshine to make us and the little workers happy. We have sown two acres of alfalfa for forage, and intend next season to sow Alsike. We sell our extracted honey readily for 15 cts. per pound. Every one that comes to get honey wants to see the extractor; it is a great curiosity to them. When we extract they are coming to see the honey taken out of the combs.

Mrs. C. M. KINGSLEY.

Elvaston, Ill., April 24, 1882.

Bee Notes from Kentucky.—Bees in Kentucky are in fine condition. We have an encouraging outlook. I have lately attended a meeting of the Barren County, Kentucky, Bee-Keepers' Society; we had a good meeting, and all seemed in good spirits. I also attended a meeting of the Hart County Bee-Keepers Association, at Munfordville, Ky., and assisted in organizing a county association. We had a large attendance and organized a society that promises to do much good. The next meeting will be on the first Saturday in June, at Woodsonville, Hart County, Ky. We hope all the Vice Presidents of our State Society will call meetings in their localities and organize. We have not yet fixed the time of the State meet-

ing at Louisville, but are waiting for the time of the North American Bee-Keepers' Society to be fixed at Cincinnati, as we want to meet just before that, so that we can go right on to the National Convention.

N. P. ALLEN.
Smith's Grove, Ky., April 24, 1882.

Care of Comb Foundation.—What is the proper method of treating comb foundation which has been kept over since last year? Should it be softened by heat, and if so, to what degree of warmth should it be subjected?

E. R. BULLER.
Campbellford, Ont.

[Hang it, one sheet at a time, in a strong colony. The bees will heat it to the proper degree for working. No criterion can be given for heat, as some makes are harder than others, and age and exposure will affect it differently.—ED.]

An Error.—I was in error in giving the size of my frame in the BEE JOURNAL, of April 12, page 235. It should read 12 $\frac{3}{4}$ inches in the 10th line, instead of 12 $\frac{1}{2}$ inches, so as to take 3 one-pound sections each way.

Benmiller, Ont. PETER FISHER.

The Industrial Exposition in Denver.—Colorado is fast taking rank with the older States of the Union in the matter of bee-culture, and before another decade, no doubt, it will be an important industry in this State. There is no method at present of gaining valuable statistics in regard to the extent of the business, but if such information could be obtained, people in and out of Colorado would be astonished at its magnitude. This is especially gratifying; the more so, because it has only been a few years since there was no bee-culture of any importance in the State. To have accomplished the results as at present existing, in so short a time, is a magnificent tribute to the energy and progressive spirit of our people. Bee-culture is being recognized as an important factor in the commerce of the country, and if properly fostered and encouraged, will soon grow to large proportions. A bee-keepers' association was organized in Denver, Dec. 15, 1881, consisting of 20 members, who owned 425 colonies of bees; but this is scarcely a shadow of the number owned in the State at large. The programme of the first annual exhibition of the National Mining and Industrial Exposition, to be opened the 1st of August, 1882, has just been issued. Space for exhibits is offered free of charge. Every industry in the country will be represented. Dairying, agriculture, floriculture, horticulture, apiculture, manufacturing, household goods, ornamenting, the arts, food and medicinal preparations, will be exhibited in abundance. People from every nation will visit the Exposition this summer. Excursions are being arranged on all roads. The best place to invest a small capital is in some of these Western States and

Territories. Colorado, Wyoming, New Mexico, Utah, Idaho and Montana are the poor man's paradise.

WOMAN'S INDUSTRIAL ASS'N.
Denver, Col., April 18, 1882.

Last Year's Record.—Last spring I started with 7 colonies in old box hives. On the 16th and 17th of May I transferred them to movable frame hives, filling 6 frames for each hive with comb and brood, and some honey, leaving a surplus of about 100 lbs. of honey; fed back about 20 lbs.; increased to 31 colonies, and obtained 250 lbs. of honey. They have come through the winter splendidly; wintered in the cellar; lost 2 by spring dwindling. They have been carrying in pollen; had a swarm April 4—earliest ever heard of here. Am feeding them. As a subscriber to the BEE JOURNAL will ask, can I expect to bring them through and how, as the weather is too cold at present for them to fly, and little yet in bloom but willows. Am looking with bright hopes for the present year with my busy bees, with the aid of the welcome BEE JOURNAL. S. MCLEES.

Tuscola, Mich., April 13, 1882.

[Yes; you can easily bring the swarm through nicely. Give them a couple combs of brood from some hive which can spare them, and feed plentifully till fruit is in bloom.—ED.]

Saw Palmetto.—I send you in this mail two flower stalks and one leaf and stem of the saw palmetto; I tried to get an average size, as you will see I have cut off part of the stem of the larger flower stalk. I done it in order to pack it better. I send the small one because it is fully blown, though I fear all the blossoms will drop off before you get it, it is about the smallest stalk I ever saw. I can give you very little data now, as I have never given the matter any attention; later on I think that I will be better posted as I intend to observe closely all the honey plants that are here. I saw the first flower stalks about March 1st, and the same stalks that I saw then are only to-day partly in bloom, so they evidently require quite a while to become perfect. These stalks were evidently the "early" ones, as the great bulk are just in bud. There are from 3 to 6 stalks to one plant—it is a small and weak one that produces less than 3. On the large and thrifty plants the flower stalks are from 2 $\frac{1}{2}$ to 3 feet in length, with numerous lateral branches, making an immense mass of blossoms. As to the length of time that it remains in bloom I cannot say, nor its value as a honey plant. I will observe these points and write you later on. I examined the colonies yesterday, but found no increase of honey. Judging from the length of time that the bloom requires to open, I think there will not be much gathered before May 1st. I am a novice in the business, having never even opened a bee hive until a couple of months ago, so that I am not overflowing with bee lore, but any information that I can give you I will cheer-

fully send. Should any question occur to you that I have not answered, please write me and I will do my best; when cabbage palmetto blooms I will send you all the data that I can. If the bloom is lost or spoiled so that you cannot use it, advise me and I will send you again.

W. H. STEACY.
Tampa, Fla., April 10, 1882.

[The saw palmetto stalk and flower came to hand, and Mr. Steacy has our thanks for the same. Much interest has been felt regarding Florida for apiculture—its climate, soil and spontaneous bloom—and any information on the subject will be highly appreciated.—ED.]

California Notes.—The honey season last year came very suddenly, some 2 weeks earlier than the season before, and the bees were just booming at the time of the frost. I had a number of colonies with 2 tiers of sections, but very few perished. At the time the bees got to swarming, I had a considerable number of young queens being fertilized in nuclei, and queens and swarms got mixed (my old queens had clipped wings). I got a bunch of bees that had 6 queens; 1 got killed. They were on a low bush, and more than I could lift. The cluster was full 3 feet high, just clearing the ground by about 1 inch, about 10 inches thick, and about 16 inches wide one way. They filled 3 hives with bees, one of which filled a tier of top sections. I should judge they must have weighed over 50 lbs., possibly 75. The surplus queens I utilized. If my subscription expires before you hear from me, do not stop the BEE JOURNAL—I should feel like a lost sheep without it. I have succeeded in sending queens to Oregon the past season successfully. I find sugar better than honey in shipping queens, but they must have water. A very good bottle is made of tin, with just a little hole. Atmospheric pressure keeps it from leaking. I have sent them with only a cake of sugar and the water. They have to go by steamer. In overhauling my nuclei last winter, I united several, using the cage mentioned in a former number of the BEE JOURNAL. The next day, as the bees were quiet, I released the queen without trouble. I never cut or mutilate the combs. Sometimes the bees will release her. Ordinarily I raise the cage and let them get together, always watching to see if the queen is well received. I am so well satisfied with it, that I shall not look further. I have even introduced virgin queens successfully with it. The form I use is 2x3 inches, $\frac{1}{2}$ inch tin sides, No. 12 unpainted wire cloth. I know of a number of cases where parties had to be shown a queen for the first time, who were successful with it. In breaking up nuclei, I found it very convenient to make an upper story and place the frames with all adhering bees therein; there was no confusion nor quarrelling. Some combs that had chilled brood were entirely cleaned out, and

are as perfect to-day as ever. About half of my hives use the Langstroth frame, but I prefer a frame 15 inches long by 9 deep; the top of the hive will take the Langstroth rack, frames above, in false ends. To save my perfect surplus combs, I have a box, no top or bottom, $\frac{1}{2}$ of one side, with hinges and a bottom, a loose top, with 6 square holes to take the upper story of the hive. The frames hang on false ends $\frac{1}{2}$ inch apart; when full, lay empty burlap sacks on top, and cover on them. Burn sulphur often enough to kill the moths. I have used this method several years, and save the combs. Imperfect combs make into wax. J. D. ENAS.
Napa, Cal.

What Hive to Use.—1. What is the simplest and easiest hive to make and handle for a beginner? 2. Can you give me the dimensions of such a hive, and size of the frames? 3. What kind and size sections to use in said frames? 4. Must the inside of frames and sections be dressed? 5. What is the best prevention against bee moths? I am ranching in Western Texas, and every farmer and stockman has from two to a dozen colonies, but their ignorance of everything pertaining to the bee is truly sublime, therefore I hope you will answer the above questions in the next issue of the BEE JOURNAL. LYNN B. LADD.
Medina, Tex.

[1. Any of the standard hives are simple and easy to handle—either the Langstroth, American or Gallup.

2. Langstroth hive is $18\frac{3}{8}$ inches long, by 14 wide and $9\frac{1}{8}$ deep, inside measure. Frames are $17\frac{5}{8}$ by $9\frac{1}{8}$, outside measure. Top-bar $19\frac{1}{8}$ inches long.

3. The brood frames hold 8 sections each, $4\frac{1}{4} \times 4\frac{1}{4}$ inches, called one-pound sections. This hive is also used with a 7-inch cap or cover, and will accommodate 18 two-pound boxes, $5\frac{1}{4} \times 6\frac{1}{4}$ outside. The standard Langstroth contains 10 brood frames, or 7 section cases.

4. Sections should be, but it is not necessary for the brood frames.

5. Italian bees. If you have black bees, moths will not trouble so much if colonies are kept strong.—Ed.]

First Experience with Italian Bees.—I have kept bees for several years, and never had very good success with them till I was in Toronto, at the exhibition, and by chance came across Mr. Jones, of Beeton, Ont., and had a short conversation with him. The next spring I purchased one of him. The next spring I purchased one of his movable comb hives for a pattern, made new hives and transferred my bees into them. I purchased "Cook's Manual," and made myself acquainted with the management of bees. I then became anxious to get Italians, and bought 8 queens at \$1 each; 4 of them died,

the remaining 4 have done very well. I then purchased 2 more at \$2.50 each. One was dead when received, and the other died 2 hours after introduction. But I was not discouraged, and purchased 6 more queens which all did well, and a healthier lot of bees than they are I think would be hard to find. My bees have wintered well. I wintered in three different styles, and may give my methods in the BEE JOURNAL at some future time.

Stirton, Ont. J. HAMBLY.

Queenless Colonies.—After unpacking my bees I find two colonies are queenless, both blacks. One had drones hatched, more capped, and some not capped, but not a sign of worker brood. The drone brood was confined to the drone comb, a patch about 4 by 6 inches, being all the drone comb there is in the hive. I gave them a frame of worker and drone brood from another hive, but they are starting no queen cells. I have been in the bee business some time, but never had anything happen like it. What is the matter?

Bryan, O. II. HANCE.

[There are two solutions of the enigma: 1st. The queen may have been old or been injured in some manner, becoming a drone laying queen, and killed or died quite recently; 2nd. The queen may have been lost some time ago, and a fertile worker developed. The fact of the drone brood all being in a small piece of drone comb, would indicate that the former hypothesis is correct; while their failure to start queen cells would disprove it, as a fertile worker will deposit her eggs anywhere. However, you can easily determine the matter. Remove the frame with the drone brood, also that which you gave them; then, if you know they have no queen, and eggs continue to be deposited, it is proof positive of the presence of a fertile worker.—Ed.]

Dreary Outlook.—More snow and ground frozen quite hard here this morning, with a cold northwest wind. Bees have gathered no pollen as yet; and do not seem as strong as they did a week ago. I do not know but I shouted "bees in good condition" too soon, for if this weather holds on long it will be hard on their rapidly decreasing numbers.

Borodino, N. Y., April 22, 1882.

LATER:—Our cold weather still continues, and as I write the mercury stands at 18° , and the ground is frozen so it fairly rings as you walk over it. Bees are clustered as close as in winter, and with the exception of winter wheat, our fields look as bare as they did in February. If it does not warm up soon, some of my weaker colonies must perish.

G. M. DOOLITTLE.
Borodino, N. Y., April 25, 1882.

Stray Swarm.—I would like to know what you think of the simplicity hive used on the Langstroth for making a second story, that is, those bevel edges like A. I. Root uses? Are they better than the Langstroth, that has the top to slide over the bottom hive? Do you think they will warp much and crack, so that ants, roaches and moths will get in? Those insects are harbored around my hives too much. Do you advise metal bearings for frames? Poplar and white clover are in bloom, and bees are gathering honey. I caught a runaway swarm to-day. R. H. C. MITCHELL.

Humboldt, Tenn., April 21, 1882.

[The simplicity hive is virtually a Langstroth, and ought not warp much if properly made and painted. The bevel joint between would be a substitute for the square rabbet, and equally good for those who prefer that kind. We do not admire metal bearings for frames; but can highly recommend metal rabbets inside the hives for the frames to hang upon.—Ed.]

Cold in Massachusetts.—Weather has been very cold here for 10 days. Ice has made $\frac{1}{2}$ inch thick for several nights. Very unfavorable for bees and queen-rearing. Early queens reared in New England will be rather expensive to the one who rears them. Some bee-keepers will expect to buy them for \$1, notwithstanding the fact that they will cost \$2. H. ALLEY.

Wenham, Mass., April 25, 1882.

CLUBBING LIST.

We supply the Weekly American Bee Journal and any of the following periodicals, one year, at the prices quoted in the last column of figures. The first column gives the regular price of both. All postage is prepaid by the publishers.

	Publishers' Price.	Club.
The Weekly Bee Journal,	\$2 00.	
and Gleanings in Bee-Culture (A. I. Root) 3 00.	2 75	
Bee-Keepers' Magazine (A. J. King) 3 00.	2 60	
Bee-Keepers' Instructor (W. Thomas) 2 50.	2 35	
The 4 above-named papers,	4 50.	4 00
Bee-Keepers' Exchange (Hook & Peet) 3 00.	2 80	
Bee-Keepers' Guide (A. G. Hill) 2 50.	2 35	
Kansas Bee-keeper,	2 80.	2 40
The 7 above-named papers,	6 30.	5 50
The Weekly Bee Journal one year and Prof. Cook's Manual (bound in cloth) 3 25.	3 00	
Bees and Honey, (T. G. Newman) " 2 75.	2 50	
Binder for Weekly, 1881,	2 85.	2 75
Binder for Weekly for 1882,	2 75.	2 50

Premiums.—Those who get up clubs for the Weekly BEE JOURNAL for 1882, will be entitled to the following premiums. Their own subscription may count in the club:

For a Club of 2,—a copy of "Bees and Honey."
" " 3,—an Emerson Binder for 1882.
" " 4,—Aplary Register for 50 Colonies, or Cook's (Bee) Manual, paper, cloth.
" " 5,—" " " " " "
" " 6,—Weekly Bee Journal for 1 year, or Aplary Register for 200 Col's.

Or they may deduct 10 per cent in cash for their labor in getting up the club.

When changing a postoffice address, mention the old as well as the new address.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about **eight words**; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10	per cent. discount.
" 8 ".....	20	" "
" 13 " (3 months).....	30	" "
" 26 " (6 months).....	40	" "
" 39 " (9 months).....	50	" "
" 52 " (1 year).....	60	" "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

To Advertisers.—By reference to our schedule of rates for advertising by the year, it will be seen that considerable reduction has been made. This, in connection with our large and increasing circulation, makes it advantageous to dealers to avail themselves of its weekly visits to the bee-keepers of America to make their announcements for the coming season's trade. We not only offer the *best* advertising medium, but the lowest rates on yearly contracts.

A Sample Copy of the Weekly BEE JOURNAL will be sent *free* to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

We are sometimes asked who our authorized agents are? Every subscriber is such an agent; we have no others, and greatly desire that each one would at least send in one new subscriber with his own renewal.

The Apiary Register.

As the time is now at hand to commence the use of this valuable book, all who intend to be systematic in their work during the coming season, should obtain a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
 " 100 colonies (220 pages)..... 1 50
 " 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent post paid by mail for 75 cents.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

To any one sending two *new* Weekly subscribers for a year, we will present a volume of the BEE JOURNAL for 1880, bound in paper covers. It contains much valuable information, and it will pay any one who does not already possess it, to obtain a copy. Many of our *new* subscribers will be pleased to learn that they can get it for \$1.00, by sending for it *at once*, before they are all gone.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75.

Articles for publication must be written on a separate piece of paper from items of business.

Honey as Food and Medicine.

We have just issued a new edition of our pamphlet bearing the above title. It has been revised and enlarged from 24 pages to 32, the new pages being devoted to *new* Recipes for Honey Medicines, and all kinds of cooking in which honey is used.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit!

Bees and Honey, or Management of an Apiary for Pleasure and Profit. This is the title of our new book. The first and second editions having been exhausted, and being desirous of having it "fully up with the times," including all the various improvements and inventions in this rapidly increasing pursuit, we have thoroughly revised it, re-writing some chapters and adding several new ones, in order to present the apiarist with everything that can aid in the successful management of the Honey Bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth 75 cents; in paper covers 50 cents.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. This is a new pamphlet of 32 pages which we have just published. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

This one fact is being brought before the minds of the people of the United States: Kendall's Spavin Cure is not excelled as a liniment. 18w4t

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., May 1, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—As the season is well advanced, sales of extracted honey are slow and prices remain unchanged. I am paying 8c. for dark and 10c. for light, cash on arrival. Good comb honey is scarce and rules high.

BEEWAX—I am paying 24c. for good yellow wax, on arrival; 18@22c. for medium grade, and 15@17c. for dark.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for comb honey is slow, and prices nominal at 16@20c. on arrival. Extracted honey is in fair demand. Our jobbing prices for 1 lb. jars of clover honey are, per gross, \$25; for 2 lb. do., per gross, \$42. The demand for manufacturing purposes is very good. We pay 8@10c. on arrival.

BEEWAX—Hings 18@22c. The demand exceeds the offerings. C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for honey is light, most of the trade finding fault with the best offered, as it is more or less candied. Values are not steady, prices being made to meet the views of the purchaser.

BEEWAX—Scarce, and in demand at 23@25c. R. A. BURNETT, 165 South Water St.

CLEVELAND.

HONEY—Our honey market would be good, as there is considerable inquiry for white honey in sections, with none to satisfy the demand. It would bring 22c. readily for choice. Buckwheat honey, no sale. Extracted, 11@12c. per lb.

BEEWAX—25@30c. A. C. KENDEL, 115 Ontario Street.

NEW YORK.

HONEY—Scarcely any demand reported for honey; prices weak and little more than nominal. We quote as follows: White comb, in small boxes, 15@17c; dark, in small boxes, 11@12c. Extracted, white, 9@10c.; dark, 7@8c.

BEEWAX—Western, pure, 24@25c.; Southern, pure, 23@24c.

THORN & Co., 11 and 13 Devoe avenue.

SAN FRANCISCO.

HONEY—Sellers are more numerous than buyers. In fact, the latter are very hard to find. Comb of fair quality is seeking customers at 11@12c. Nearly 300 cases, mostly extracted, arrived this week, the bulk of which went to a packing house.

We quote white comb, 15@18c.; dark to good, 10@14c. Extracted, choice to extra white, 8@9c.; dark and candied, 6@8c. **BEEWAX**—25@25c.

STEARNS & SMITH, 423 Front Street.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.

BEEWAX—Prime material, 25c. CROCKER & BLAKE, 57 Chatham Street.

ST. LOUIS.

HONEY—In fair demand. Strained selling at 8@10c.; comb scarce—nominal at 21@22c.

BEEWAX—Stiff at 20@21c. for prime. R. C. GREER & Co., 117 N. Main Street.

BINGHAM SMOKERS.

I can sell the above Smokers at MANUFACTURERS' PRICES, by mail or express, at wholesale or retail. All the latest improvements, including the CONQUEROR.

Send for my 32-page Illustrated Catalogue of Bee-Keepers' Supplies of every description.

NOW READY, LAKES CIRCULAR
ITALIAN BEES & QUEENS
HIVES, SECTIONS, FEEDERS, ETC.
BALTIMORE **COLUMBIA STATION**

Stanley's Vandervort Foundation.

We have just purchased a large amount of bright yellow beeswax, and are now prepared to furnish comb foundation in any size, either heavy or light. Our old prices were based on the low prices of wax last year, but as wax has now advanced about 4c. per lb., and we have looked for still greater improvements in our mode of cleansing the wax, we are obliged to advance the price of our foundation 5c. per lb., making now thin foundation, 10 feet per lb., 55c., and heavy foundation, 5 ft. per lb., 43c. If 100 lbs. is wanted at one time, deduct 2c. per lb. from the above list. We would advise our friends to order soon, as we look for still greater advances in wax, and we can make much nicer thin foundation before hot weather comes. Send for samples to **G. W. STANLEY & BRO.** Wyoming, N. Y.

TO BEE-KEEPERS.

Having had so great a call for Hives and Supplies the past season, I have purchased steam power and machinery and fitted up a factory for the sole purpose of manufacturing Apian supplies. I am now ready to furnish Hives, Section Boxes, or anything in the Apian line, kept on hand or made to order. Having wintered my bees successfully the past winter, I will sell a few colonies at the following prices: Black bees, \$6.50 per colony; Italians, \$8.50; Italian Queens, untested, \$1; tested, \$2. Probably there will be no queens ready before June 1st. Bees per pound, \$1.50; to those not used to introducing queens, it will probably be better to get a pound of bees with a queen, turn them loose on empty comb, or a hive filled with comb foundation, and they will build up to a good strong colony during the season. L. E. WELCH, Linden, Mich.

PRIZE QUEENS FOR 1882, From the Evergreen Apiary.

REV. E. L. BRIGGS, of Wilton Junction, Iowa, will furnish Italian Queens from either of his Prize Mothers, as early in the coming season as they can be bred, at the following rates: Tested Queens, \$3; Warranted Queens, \$2; Queens without guarantee, \$1; Two comb Nucleus, with Tested Queen, \$4. Orders filled in rotation, as received, if accompanied with the cash. 3w26t

Italian Bees for Sale.

I have for sale about 40 Colonies in 10 frame Langstroth hives. All are in prime condition, and have young queens. Will be delivered after April 20th. Price, for Italians, \$3; a few good Hybrids, \$1 less. Satisfaction guaranteed. 15w4t **JOHN F. DIPMAN**, Fremont, Ohio.

MAPS AND CHARTS—\$1,000 can be made in six months selling Thunison's Maps and Charts—34 page Catalogue free. Address, H. C. TUNISON, Jacksonville, Ill., or Columbus, O. 18w5t

GERMAN POULTRY AND BEE GAZETTE.

Deutsche Gefuegel und Bienen-Zeitung. The only paper of its kind in America; 75 cents a year—sample copies 10 cents.

C. C. STUECKER, Publisher, 18mtf Louisville, Ky.

FOR SALE—10-inch Dunham Foundation Machine, good as new, \$35. A. B. WEED, 18w1tp 75 Baggs Street, Detroit, Mich.

Complete Apiary for Sale.

An Apiary of 90 COLONIES OF ITALIAN BEES, with buildings and all modern appliances for running the same; are within 23 miles of Chicago, in a splendid location for wild pasturing. These bees show a good record for last season—2,064 lbs. comb honey from 43 colonies, and increased to 100 colonies. They are in prime condition now, with

PROSPECTS OF A GOOD SEASON.

I want to go into other business this fall, and would sell now, giving the purchaser the benefit of this season's work (and my services if wanted), as an inducement to buy. Terms will be reasonable, and partly on time if necessary. Correspondence solicited.

H. W. ANDERSON,

17wtf Gibson's Station, Ind.

FINE ITALIANS.

75 Colonies for sale. If you wish bees for work, send for prices. **SOUTHARD & HANNEY**, Kalamazoo, Mich. 17w2tp

ONE-PIECE SECTIONS a specialty. Pound size, \$4.50 per 1,000. L. Hives 50c. Also, Italian bees for \$8 per colony. Circular free. 85m12tp **BYRON WALKER & CO.**, Capac, Mich.

1882. - ITALIAN QUEENS. - 1882.

I am now booking orders for my GOLDEN ITALIANS, reared from the best-stock in the country. Warranted Queens, \$1; Tested Queens, early in the season, \$2.50; after July, \$2; 2 frame Nucleus, with Tested Queen, \$4; Full Colony, with Tested Queen, \$10. The Best Quinby Smoker for \$1.50. Address all orders to **L. J. DIEHL**, (Money Order Office)—Batler, DeKalb Co., Ind. 10w1f

HIVES AND SECTIONS.

We are in better shape than ever to furnish Bee Hives and Sections, having remodeled our machinery, and put everything in tip-top order for the coming season. We make a specialty of our

"BOSS" ONE-PIECE SECTION.

We have not sold any rights to manufacture, therefore we are the sole manufacturers in the United States. Send for Price List.

JAS. FORNCROOK & CO.
 Watertown, Wis., Dec. 1881.

NOTICE--Some persons having infringed upon our Patent "One-Piece Section," we hereby give notice, that we shall prosecute all manufacturers. We shall not molest bee-keepers for USING those purchased before Dec. 1st, 1881, but hereby caution them against buying any except those bearing our stamp. It has been reported by some that it is our intention only to prosecute bee-keepers for using those One-Piece Sections heretofore purchased; this is wholly untrue and false. **JAS. FORNCROOK & CO.** Watertown, Wis., Dec. 15, 1881. 51mtf

CHAMPION BEE-HIVE MANUFACTORY.

One of the largest manufactories of Apiarian Supplies in the world.

BEE-KEEPERS.

I have made a reduction from 5 to 15 per cent. on all Hives, Section Boxes and Comb Foundation.

The above cut represents my all-in-one-piece section, which is made in thickness according to size. Try one box of these sections, and you will never use any other. Printed directions in every box, showing how to fold them. Last year I could not fill all of my orders for sections, but I have a large stock of them on hand at present. Give me a trial. Send for FREE price list.

TIN POINTS for GLASSING HONEY

Cut by machinery; are much cheaper and better than hand-cut, and perfectly straight; 1,000 to 5,000, 25c.; 6,000 to 10,000, 22c.; over 10,000, 20c.; 6c. per 1,000 extra by mail. Samples for 3c. stamp. **W. C. GILLETTE,** 15sm5t LeRoy, Genesee Co., N. Y.

EXCELSIOR HONEY EXTRACTORS.

In answer to frequent inquiries for Extractors carrying 3 and 4 Langstroth frames, I have concluded to adopt these two new sizes. The 3 frame basket is in a can of the same size and style as the 2 frame. The 4 frame basket is in the larger can, with the cone or metal standard for the basket to revolve upon, leaving room underneath the basket for 75 or 80 lbs. of honey. It will be complete, with covers, and in every way identical, except in size, with the \$16.00 Extractor, 13x20, which is intended for any size of frame.

Excepting with the \$8.00 Extractors, all the different styles have strainers over the usual leading to the honey gate, and move-sides in the Comb Baskets.

For 2 American frames, 13x13 inches.....	\$8 00
For 2 Langstroth " 10x18 "	8 00
For 3 " " 10x18 "	10 00
For 4 " " 10x18 "	14 00
For 2 frames of any size, 13x20 "	12 00
For 3 " " 12x20 "	12 00
For 4 " " 13x20 "	16 00

The Bee-Keeper's Guide;

OR,
MANUAL OF THE APIARY,

By **A. J. COOK,**

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

—:—:
320 Pages; 133 Fine Illustrations.
—:—:

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 3,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

—:—:
Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—*LEWIS T. COLBY*.

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—*J. F. WEST*.

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—*E. H. WYNKOOP*.

This book is just what everyone interested in bees ought to have, and which, no one who obtains it, will ever regret having purchased.—*Mich. Far.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—*A. E. WENZEL*.

My success has been so great as to almost astonish myself, and much of it is due to the clear, disinterested information contained in Cook's Manual.—*WM. VAN ANTWERP, M. D.*

It is the latest book on the bee, and treats of both the bee and hives, with their implements. It is of value to all bee-raisers.—*Ky. Live Stock Record*.

It is a credit to the author as well as the publisher. I have never met with a work, either French or foreign, which I like so much.—*L'ABBE DU BOIS*, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these loathsome insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *code mecum* of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee-man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of occupations.—*American Inventor*.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by
THOMAS C. NEWMAN,
925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterpiece of production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping, by L. C. Root— The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.— \$1.50.

NoVICE'S ABC OF Bee-Culture, by A. I. Root— This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King— This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee— This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.— A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.— Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage and Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 160 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 50c., postpaid.

Buzzer Theory;— presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15c.

Honey, as Food and Medicine, by Thomas G. Newman.— This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foam, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 6c.; per dozen, 50c.

Wintering Bees.— This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof. Cook's Essay, which is here given in full. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use— Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.— A 24-page pamphlet, by Ch. & C. P. Dadant, giving in detail the methods and management adopted in their apiary. This contains many useful hints.— Price 15c.

Bee Pasturage Necessity, by Thomas G. Newman— Giving advanced views on this important subject, with suggestions what to plant, and when and how. Illustrated with 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.— No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensible manner. It has received a table of doses, and much valuable horse information. Paper, 25c.

Cholera Cholera, by A. J. Hill.— A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Mechanists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gliders, Metal and Wood Workers of every kind. The work contains 1,016 pages, in a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Vol. XVIII.

Chicago, Ill., May 10, 1882.

No. 19.

ESTABLISHED 1861

THE AMERICAN BEE JOURNAL

Published every Wednesday by

THOMAS C. NEWMAN,
EDITOR AND PROPRIETOR,

925 WEST MADISON ST., CHICAGO, ILL.
At \$2.00 a Year, in Advance.

WEEKLY—(52 numbers) \$2 a year, in advance.
Three or Six Months at the same rate.

Any person sending a club of six is entitled to an extra copy (like the club) sent to any address desired. Sample copies furnished free.

Entered at Chicago post office as second class matter.

Only a Slight Perversion.

From the May number of *Gleanings* we clip the following paragraph :

Several of the friends have remonstrated because we have not replied to the unkind things that have been said in regard to dollar queens, and those who make a business of raising them. It is because I have a sort of feeling that the best reply we can make is to keep on raising and sending out extra nice queens, and they will do the talking, just as they have done all along.

Perhaps we should not have noticed the matter were it not for the inuendo so skillfully interwoven into it, and which cannot well be criticised without presuming it was aimed at the BEE JOURNAL. It is true we have felt impelled to warn apiarists against the apparent drift of sentiment toward cheaper stock, which we believe to be pernicious in its tendency, and a great mistake in an economic point of view ; so, too, have we warned apiarists against the use and tendency of glucose; against pretenders with worthless hives; against "cheap John" schemes—in fact, against prejudices and errors of every description. The glucose traffic we have in general terms denominated fraudulent and dishonest, because its principal consumption has been under the name and guise of reputable articles, but regarding "dollar queens," we emphatically deny having said "unkind things" about "those who make a business of raising them." Believing most of them to be honest and conscientious, we have endeavored to accord them the same consideration we desire for ourselves, and have

studiously avoided personalities, to prevent involving others in the controversy against their wish. The hardest words we have published regarding cheap queens, have come from those who have been prominent breeders of them.

Things by their Right Names.

The following paragraph we clip from a Western local paper, of recent date :

I have just witnessed a most beautiful operation—the manufacture of foundation comb for the convenience of honey bees. By the use of this prepared comb the bee is ready almost instantly to commence the honey deposit.

The whole article is evidently written with an intention of calling attention to the bee-keeping interest, and exhibits a commendable spirit; but we most earnestly protest against inculcating false impressions in the minds of those unacquainted with the details of apiculture, eight out of ten of whom will imagine, after reading the above paragraph, that "foundationcombs" and "prepared combs" are given to the bees to be filled with honey, and will foster the foolish belief which many entertain, that artificial comb honey is now on the market, and sold to a great extent to innocent consumers. Had the writer properly called it comb foundation, no false impression would be encouraged. Merely a slight transposition of words will make all the difference in the world in public opinion, and save much trouble in contradicting. Call things by their right names, and save misunderstandings.

We have received Price Lists of queens and bees from Henry Alley, Wenham, Mass., and of bees, queens and apiarian supplies from J. L. Bowers, Berryville, Va.

MISCELLANEOUS.

Michigan State Convention.—Mr. A. B. Weed gave an address before the Eastern Michigan Convention, at Detroit, on April 11, in which he criticises the State Convention in the following language, as published in the *Michigan Farmer* of last week:

The place for holding the next meeting was warmly discussed, and Kalamazoo was finally selected. Any locality where the Convention is held, can, of course, furnish a strong local representation, and unless the choosing of the next place is done in a spirit of fairness, a majority vote is apt to hold future meetings in its own neighborhood. In this case the location changed but 23 miles. The same influence is at work in the national conventions. If this thing is persisted in, it will, besides destroying the general features of the conventions, defeat in a large measure their intended object, and they will degenerate into local institutions.

Hints to Beginners.—A correspondent in the *Prairie Farmer* gives this advice to beginners:

Spring is undoubtedly the best time to start an apiary. The danger of loss in wintering is past, and bees have little brood and honey, so that they can be moved easily and safely. A person unacquainted with bees should beware of purchasing "a pig in a poke," as every hive containing comb and bees may not be a perfect colony. We may infer that a colony is all right if during the early spring months the hive is full of bees, as such a colony must contain a young, vigorous queen. It is a poor policy for a beginner to purchase black bees in boxes and gums, intending to transfer and Italianize. Such work as this barely pays in the skillful hands of veterans, and had better not be undertaken by novices. A better plan would be to select the hive of a desired pattern for the whole apiary, as the profit and pleasure derived from it consists, in a large degree, in having every part of each hive exactly alike. The life of many a colony of bees is saved by giving it a frame of brood or honey from a more prosperous one, and this could not be done if the frames and hives were not alike. If a person is not able to secure a strong colony in the hive preferred, then a new hive of the desired pattern might be taken to a bee-keeper, and a first swarm put into it.

Bee-keeping is a science, and not acquired in one day, by talking with a person "who knows all about bees." Therefore, to insure success commence slowly with not more than two colonies, and let your knowledge in-

crease in like ratio to your bees. If you can make money with these, it will be safe for you to invest in more. It is absurd to suppose that a person who knows nothing about bees, except that they sting and gather honey, could manage a large apiary successfully.

The Detroit Convention.—In the *Country Gentleman* of last week, Mr. W. Z. Hutchinson gave some "notes" of the late Convention in Detroit, a report of which we gave on page 264. We extract the following items not in that report:

At this meeting nearly 1,000 colonies were represented. No essays were read, and there was scarcely any attempt at addresses, almost the whole time being passed in a conversational and sociable manner.

Both Mr. Robertson and Mr. Hutchinson hatch their queens in a lamp nursery. Mr. Robertson found it necessary to examine the nursery several times during the night, in order to cage any queens that might hatch, otherwise they would bite into cells and destroy unhatched queens. Mr. Hutchinson examined every cell about 9 o'clock in the evening, by holding it up before a light, and each cell that appeared nearly ready to hatch was cut out and placed in a cage by itself.

When the subject of artificial pasturage was brought up, Mr. M. H. Hunt, who lives near Detroit, said that he raises alsike clover, and had induced his neighbors to raise it by furnishing them seed at wholesale rates. After a farmer had given it a trial, he always continued to raise it. Mr. Robertson had not only found alsike clover to be an excellent honey producing plant, but it makes splendid hay, and is unsurpassed as pasture for stock. Mr. Robertson's bees had access to 500 acres of alsike clover. Mr. Hunt has an interest in an apiary located near D. M. Ferry's seed farm, and he found that the bees gathered enormous quantities of honey from the onion blossoms. This honey is of a green-glass color, and is nearly as good as white clover honey. Mr. Robertson had tried sweet clover, and, not finding it valuable, had plowed it up, and summer fallowed the field, which completely eradicated the clover. But he had lately seen so many favorable reports in regard to it, that he thought he should give it another trial. He thought that the season and locality might have an influence upon the honey producing properties of this clover.

During the discussion about the different varieties of bees, Otto Kleinow, of Detroit, raised quite a laugh by saying that honey boxes given, last July, to a colony of Syrian or Holy Land bees, were yet in the hive, the bees being so ferocious that it is impossible to remove the boxes. He had found that it is impossible to subdue this variety of bees with smoke. He had found them very prolific, but not more so than some of his Italians.

American Express Company's Money Orders.—The *Chicago Herald* of last Thursday gives the following item regarding these money orders:

The new money order system recently adopted by the American Express Company is working so advantageously that the Company has felt called upon to still further enlarge its operations. Heretofore money orders have been issued from each of the 4,000 offices scattered all over the United States, but at only comparatively few of these have paying offices been established. The Company has now determined upon making all of its offices both paying and issuing offices, and yesterday orders to this effect were issued by the President of the Company, Mr. Fargo.

Bee-Keeping in Europe.—Dr. E. Parmly, of New York, has sent us an article from the *London Globe*, which though mostly of local interest only contains the following:

During the present month an international exhibition of bees, of bee products, and of the apparatus used in bee-culture, will be held in Vienna. In England such objects are frequently exhibited at our agricultural shows, but only as minor supplements to machinery and farm produce. That Austria should devote an entire exhibition to it is significant of the high esteem in which bees are held in many parts of the Continent, and of the intelligent and widely diffused interest they excite. In Germany and Switzerland particularly, the bee is an important agent in the economy of a household; for in those countries honey is in far more frequent use than with us. The Germans hold periodical conferences on bee-culture, and the small towns, and many of the villages, have their bee societies, where notes are compared as to different methods of management, and the results of experiments are communicated. In addition to this, apiculture is taught in schools and colleges, as in Bavaria, for example, where it forms part of the course through which horticultural students must pass.

Local Convention Directory.

1882. *Time and Place of Meeting.*

- May 11—Champlain Valley, at Middlebury, Vt.
T. Brookins, Sec., East Shoreham, Vt.
- 16—N. W. Ill. and S. W. Wis., at Rock City, Ill.
Jonathan Stewart, Sec., Rock City, Ill.
- 25—Iowa Central, at Winterset, Iowa.
Henry Wallace, Sec.
- June 3—Hart County, Ky., at Woodsonville, Ky.
- Oct. 5—Kentucky Union, at Shelbyville, Ky.
G. W. Demaree, Sec., Christiansburg, Ky.

☞ In order to have this table complete, Secretaries are requested to forward full particulars of time and place of future meetings.—ED.

Ribbon Badges, for bee-keepers, on which are printed a large bee in gold, we send for 10 cts. each, or \$8 per 100.

Union Bee-Keepers' Association.

The Union Bee-Keepers' Association met at the rooms of the Moody House, in Eminence, Ky., on the 27th day of April, President Dr. L. E. Brown in the chair.

After the transaction of the usual business of the Association, an invitation was given to any person present to become a member of the Association, and several names were added to the list. On motion, J. H. Reed, of Indiana, was made an honorary member of our Association. The President then delivered his annual address. He said the outlook for the future prosperity of the bee-keeper is not so bright at this time as it was before the severe frosts. Much of the early resources for honey was cut off. Nevertheless, the future is before us and an abundant white clover bloom may yet cause the bee-keeper to forget the late disaster.

Dr. E. Drane then addressed the Convention on the subject, "Are we profiting any one by our meetings?" The speaker took the grounds that no good had resulted from the foolish fashion of advising everybody to keep bees. He thought that bee-culture will pay only in the hands of those who are fitted for the occupation. None others should be advised to undertake it.

G. W. Demaree said he approved of every word of the speaker; yet, he could see much good resulting from our meetings. They are a pleasure to all of us, besides they educate the people, giving them a proper understanding of the products of the apiary. Our Association has contributed much to our good local honey market.

Mr. J. H. Reed, of New Orleans, Ind., said that the last speaker had demonstrated that it is possible to educate the consumers, as in the cases named.

Dr. Drane explained that while he thought it time lost to attempt to educate people to keep bees intelligently, he admitted that if you can induce a fellow to taste of honey, that will educate, for "honey is good."

Elder W. J. Mason being in the room, said if he was allowed to speak, he would like to say that he was quite an old man, and that he had handled bees for 40 years in the State of Missouri: he was satisfied that there was no hive as good to keep bees in as the common box hives with boxes on them. He knew that bees all died in Missouri in "patent gums."

The Secretary had a case of one-pound sections in the room, all primed ready for the bees.

President Brown arose and drew out one of the sections and held it up, with the thin foundation looking as natural as the handiwork of the bee, and explained its use; that tons of honey were being produced and sold for the cash—sent across the Ocean,

everywhere—the result of improvements over the old box hive system.

G. W. Demaree said that his old friend was 40 years behind the times; that bees are always uncertain property in any kind of hive when not in the care of an intelligent bee-keeper, but are as easily reared and as certain in their life tenure as other beings created when properly managed. An old gentleman, Mr. Woodbridge, arose to inquire of the Association, "how they keep the moths from taking their bees?"

Mr. Reed, of Indiana, said "keep them out with Italian bees. They are proof against the bee moth."

W. T. Stewart said, "keep your bees strong and in a healthy condition, and they will take care of themselves."

Elder Mason insisted that there was a wide difference between the systems (as he heard it here) of bee-keeping in this State and in the State of Missouri.

Dr. Drane said that he had no doubt but our improved system of bee-keeping is essentially different to what it was in Missouri 40 years ago, or anywhere else. But intelligent, progressive bee-keepers in Missouri keep bees now—just like intelligent, progressive bee-keepers keep them in Kentucky or elsewhere.

The question box furnished the following questions: What is the value of a colony of bees in a box hive in April?

Dr. Drane said the queen is worth, at that time of year, \$2; bees, \$2; 10 lbs. of honey in bad shape, for feeding, \$1; less \$1 for transferring, the colony is worth \$4.

Mr. Reed, of Indiana, said that he had not been in the habit of buying box hives, and believed the queen and bees to be worth nothing while in a box hive.

Mr. Demaree thought that a queen in a box hive was most likely to be a "scrub," and he would have no use for her but a short time, and would say that \$1 was enough for her.

What is the value of a good colony of bees in a movable frame hive in April?

Dr. Drane said \$10; if extra fine Italians, \$12.

Mr. Demaree thought that a skillful bee-keeper can safely pay \$10 for a good colony of bees in April, but he did not believe it will pay a novice to buy bees at that price.

President Brown said he gave \$25 for his first colony of Italian bees, and he had realized \$5.00 from the investment.

The Convention then adjourned to meet after dinner at Stewart's gallery.

AFTERNOON SESSION.

Convention called to order by the President, and the Association proceeded to elect their officers for the ensuing year.

Dr. E. Drane was elected President; Dr. Wm. M. Rogers, of Shelbyville, Vice President for Shelby County; W. T. Stewart Vice President for Henry County; G. W. Ashby Vice President for Jefferson County;

G. W. Demaree, Christiansburg, Secretary, and Dr. L. E. Brown, Treasurer.

Dr. Drane then took the chair and said he was "pumped dry;" would only thank the Association for the honors conferred on him.

The discussion of the forenoon was resumed.

At what actual cost can a pound of honey be produced, in good marketable shape?

Mr. Demaree thought it as easy to answer the question as it is for the former to answer what it costs him to produce a pound of beef or pork. Of course locality had much to do with it, but he believed that he could produce it at an actual cost of 5 cts. per pound. It would take a high order of skill to do it. Honey is, therefore, worth at least 20 cts. per pound.

President Drane thought it could not be done.

W. T. Stewart thought he could produce honey at an actual cost of 5 cents per pound.

Mr. Reed gives his attention to queen-rearing, and was not prepared to say what could be done.

Mr. Ashby was not prepared to decide.

The following resolution was then adopted:

Resolved, That this Association tenders its thanks to W. T. Stewart, Dr. E. Drane, and the ladies, for the princely manner in which they entertained members of the Convention; and to the editors of the AMERICAN BEE JOURNAL, *Bee-Keepers' Instructor* and *California Apiculturist* for sample copies of their valuable papers; and to Mr. Holland for his presence in the interest of the Louisville *Daily Commercial*, and the *Henry County Constitutionalist*, and that copies of these proceedings be forwarded for publication to the *Farmers' Home Journal*, AMERICAN BEE JOURNAL, and *Bee-Keepers' Instructor*.

The Convention then adjourned to meet at Shelbyville, Ky., on the 5th day of October, 1882.

E. DRANE, *Pres.*

G. W. DEMAREE, *Sec.*

Read at the Meeting of the Georgia State Agricultural Convention, in Augusta, Ga.

Bee-Keeping for Profit.

J. P. H. BROWN.

I shall not consume your time by dwelling upon the natural history of the honey bee, and upon the wonderful economy of the hive, but will proceed at once to consider the subject of bee-culture as a source of profit.

From the fact that the hive bee has been a subject of deep study by the learned in every age, and that apiculture has been successfully conducted by the ancients, it may sound strange to you when I tell you that it has only been within the last 40 years that bee-culture has been developed into a science by correct observations of the natural history of this insect, by increased knowledge of its proper mode of management, and by the introduction of the movable frame hive, the

honey extractor, comb foundation, and numerous other appliances to make easy and to facilitate apiarian operations.

Comparatively few persons, outside of the business, have any correct idea of the amount of the honey product of the United States. From the latest and most authentic records, we find the amount produced in 1881 to be 100,000,000 pounds, worth at the present average selling price \$15,000,000. This estimate falls a little short of the average, owing to the unprecedented drouth that prevailed that year.

Bee-farming is becoming a special business of no mean pretensions in many portions of our country, eclipsing, in the way of profits, many of your large cotton plantations. California takes the lead in the production of honey, and probably contains the largest producers in the world. J. S. Harbison, of San Diego county, has 3,000 colonies worked by 5 assistants; total product for the year 1880, 310,000 pounds; value, \$31,000. The Hetherington Bros., of Cherry Valley, N. Y., come in second to Harbison. Root Bros., of Mohawk, same State, took the past season from 160 strong colonies in the spring, 32,809 pounds; while in the same State there are dozens of apiaries that yield respectively from 6,000 to 30,000 pounds. In the Northwest, there are hundreds of apiaries that run from 3,000 to 20,000 pounds. In our Southern country, comparatively little attention has been paid to the small rural industries. The assumed prestige that has always shrouded the little "cotton planter," awed them into background. There is more attention paid to apiculture in Florida and Louisiana than in any other southern States. Many apiaries in those States produce from 6,000 to 30,000 pounds of honey per annum.

Fully four-fifths of all the honey that goes to market is slung from the combs by a machine called a honey extractor, which consists of a large tin can containing a revolving frame to hold the combs, and which removes the honey from the cells by centrifugal force the same as water is slung from a grindstone when rapidly turned. Before the comb is put into this machine the cells are all uncapped by a knife made expressly for the business. By this arrangement the honey is secured at a great saving of comb, which is put back again into the hive to be again filled by the bees. The comb or wax the bees make from honey, and it has been determined that in making one pound of comb, they consume from 10 to 15 pounds of honey in its production.

The most of American honey finds a ready market in our large cities, where there are merchants who make a specialty of handling it. Hundreds of tons go to England and to the continent, and large orders for it have recently come from China and Japan. In our Northern and Western markets, the honey is all graded as to quality. Light shades, such as white clover, command the best price, running from 15 to 25 cents per pound for comb, and from 12 to 15 cents for ex-

tracted. The dark shades bring a less price, and are mostly consumed by manufacturers. Extracted honey sold at 10 cents per pound pays you as well as comb honey sold at 15 cents, from the fact that you can get fully one-third more honey from your bees when worked for the use of the extractor than when manipulated for comb.

In marketing honey it is very necessary, if good prices are any consideration, to put it up in convenient packages, observing all the conditions to have it neat and inviting in appearance. With many persons this latter requisite has more influence than prime quality. We in the South are too far distant from the Northern and Western markets to ship comb honey successfully—breakage and leakage would consume all the profits; but we can ship extracted honey at paying prices. For this object it should be put up in tight well made wooden kegs or barrels, of about 20 gallons capacity. This size is the most convenient to handle. Some shippers, in order to guard against leaking, wax their barrels on the inside by pouring in boiling wax and then rolling them around, by which means the inside is coated. I advise this precaution; for a barrel that may hold water, will not always hold honey, as the latter article has not the property of swelling out the particles of wood like water.

It is best for small producers to find a market as near home as possible. As a general thing home markets are the best, as they save freights and often commissions. I believe there are very few places where honey cannot be sold. A friend, both a physician and planter, located in a small village in middle Georgia, had been keeping bees for several years more for pleasure than profit, but last season he concluded to run them with a view to make them pay, and he found his dozen colonies of bees brought him more money than any two acres he had in cotton. Before this, he thought he could find no one to buy his honey, but after he put it up in nice shape and offered it for sale, he had no trouble to sell all he had at a fair price. Hence it is possible, with proper exertion and management, to build up home markets for honey. Thousands of pounds could be sold where now a few pounds are considered a great luxury.

Honey, instead of being regarded as a luxury by many persons, is becoming every year more of a staple article. One reason of this is, a waking up of the people to a realization of the fearful consequences of the adulteration of our syrups and sugars, by glucose and unwholesome articles, made by the action of acids upon starch. It can also be made by chemical process of old rags and woody fibre. Chemists tell us that fully 75 per cent. of glucose syrup can be added to cane syrup and 25 per cent. of crushed or pulverized glucose can be added to cane sugar with no risk of detection, by the ordinary consumer. It is easy, then, to imagine what becomes of a large portion of the thousands of tons of glucose that are manufactured every 24 hours by the glucose factories

in the United States. Would it not be infinitely better, instead of eating commercial syrups of fancy brands that contribute to disease and death, to supply your families with pure extracted honey, the syrup that God distills in the laboratory of the flower?

Bee-keeping is like any other sort of business that is subject to failure and success. It does not follow, neither can it be supposed, that every one who takes hold of it is going to make it a success. In this business there is no such thing as that abstract something called "luck." Luck in bee-culture is always measured by "pluck," and by an observance of all those conditions upon which its successful prosecution depends.

First, it is all important for an apiarist to have a taste for the business, combined with the necessary knowledge or experience. He must possess a large share of that faculty that prompts to do things at the right time. Many persons will invest dollars in hives and fixtures, but not a cent in bee books and periodicals that impart information upon the instincts of the bee, and upon its most successful mode of management.

Secondly, the apiary should be located in a locality where there is an abundance of honey-producing plants. Honey is a natural secretion of the flower, and not a manufactured product of the bee as is usually supposed. Therefore, suitable flora is required, otherwise no yield of honey can be expected. In our Southern country, the best pasturage is usually found along our water-courses, where abound alder, maple, poplar, holly, sourwood, persimmon, black-gum, bay, etc., and many species of flowering shrubs and plants. All fruit blossoms yield more or less honey. In some seasons the cotton bloom secretes honey abundantly, which is of a light color and of good flavor. The flow of honey is always influenced by the sort of weather prevailing at the time. Too much rain will wash away the nectar, while during a protracted drouth the flow will stop. A very hot sun will evaporate the honey as fast as the nectaries secrete it. Hence, on such days, bees only go to the pasture very early in the morning and late in the evening. Bee-keepers should pay more attention to the preservation of their pastures, guard against its wanton destruction, and encourage its planting and growth. Much can be planted and sown that will have value besides the yield of honey. Prominent among this class, I may name fruit trees, cow peas, rape, mustard and the clovers. The latter can be grown on moderately rich clay soil, but will not thrive on sandy. The finest grade of honey is gathered from clover. Italian bees will work on red clover, while the common black bees will not. Buckwheat is very unreliable as a honey plant in our climate. Many extensive bee-keepers in the west find that it pays them to cultivate forage expressly for their bees.

Thirdly, the bee-keeper must avail himself of those appliances required to facilitate his business. No one can successfully manipulate his bees, and

obtain perfect control over them, unless they are in hives that have movable frames. As the combs are built in these frames, and the frame so hung in the hive that the bees cannot glue them fast with propolis, they can be easily removed and every part of the comb examined. Any frame hive that will not admit of easy removal of the frames when filled with comb and bees is of no practical use in the apiary. The neatest, most convenient, and most profitable way to secure surplus comb honey, is in small frames or section boxes that hold from 1 to 3 pounds. These sections are nested and placed either above the frames in the brood chamber, or on their side. In our climate, I prefer the former arrangement. The introduction of comb foundation into the apiary has been an event of as great importance as the invention of the honey extractor, to which I have already referred. Comb foundation consists of sheets of wax, passed through a machine that stamps upon it the lozenge-shaped bases of the cells of the comb, and defines the bases of the cell-walls by heavy lines of wax. The bees have no new wax to make, but only to draw out the wax in the foundation given them into the complete comb. This is a great saving of time and material. By the use of this foundation colonies can be increased and built up into strong colonies with astonishing rapidity, and the comb will be beautiful and straight, a great desideratum in an apiary where it is often necessary to exchange frames of comb with other hives. If the combs are crooked and irregular, this exchange can only be done with great difficulty.

A few years ago an ignited roll of old rags, or a smudge, was the favorite appliance for generating smoke to subdue or quiet bees. The breath was used to blow the smoke upon the bees, but usually more found its way into your eyes and throat than any where else. Now, we have an instrument called the "smoker," made expressly to blow and convey the smoke to any desired part of the hive. This instrument is indispensable to every one who handles bees. For the protection of the face against stings, a bee-veil is necessary. Rubber gloves can be used to protect the hands, but after one gets accustomed to handling bees, the gloves are soon laid aside as useless.

In this paper I have endeavored to make plain to you that bee-keeping, as one of the rural industries, can be made profitable, and will pay a larger dividend upon the capital invested than any other farm pursuit. There is not a locality in Georgia where bees cannot be kept with a profit to their owner, if well managed; and when we take into consideration the extent of our State, and the small number of colonies of bees kept, we can safely conclude that there are tons of honey, worth thousands of dollars, lost annually.

As an agricultural people, we are too extravagant and wasteful. When we learn to take care of and economize these small blessings that God

has showered around us, then will we be on the road to prosperity.—*Southern Cultivator.*

For the American Bee Journal.

Characteristics of the Coming Bee.

A. R. KOHNKE.

Much has been said and written about the "coming bee;" but as to what it is to be, and to what an extent desirable points may be developed there seems to be but a vague idea. Hon. W. H. Andrews, of Texas, seems to be contented with our present attainments of Italians, whilst Mr. T. G. Newman wants further improvements, judging by what is said in No. 45 of the BEE JOURNAL for 1881. Mr. Newman mentions three desirable points, viz: 1st, a long tongue; 2d, prolificness; 3d, amiability; to this I would add, 4th, industry.

It should be borne in mind, that the first and second points refer to the body, and the third and fourth to the character of the bee, and of all these points No. 2 is to be a property of the queen exclusively, whilst 1, 3 and 4 are qualities of the workers only.

It will be conceded that there is a vast difference not only between the different races of bees with reference to the above mentioned points, but also between different colonies of the same race, which may appear to such an extent that black bees may do better than Italians. This experience probably induced Von Berlepsch to hold on to the German bee against the Italians, which latter he never seemed to fancy much, and up to this very day there are bee-keepers in this country as well as in Germany, who prefer the German bee, though as a rule the Italians will do better.

Before going into a discussion as to the desirableness or possibility of a further improvement of our best Italians, I beg leave to state some general laws of nature:

1. Nature preserves a certain symmetrical proportion of all the parts of an individual of her production.

2. Whenever such parts are changed or more developed by breeding or accommodation to changed conditions, so as to be out of proportion with reference to the whole body, it takes place at the expense of another part of that body, or the deterioration of the same part in a different direction. Whenever such deterioration is desirable conjointly with the development of such parts, it may be very profitable to not only develop but deteriorate by breeding as much as we can; but when the latter is a disadvantage, I think we had better stop and count the cost first, before we proceed.

To illustrate: Here is a kangaroo, large, powerful hind legs and tail,

and insignificant fore legs and head; there is a giraffe, long fore legs and neck, and small hind quarters; here is a hare, long ears, short tail, small fore legs, long hind legs; there is a specimen of the bovine race from Texas, long horns and little milk; here the short horn and polled cattle, little or no horns, but rich milk and plenty of it. In pigs the large, heavy bones are bred out to get increase of flesh and muscle; and so on. I hope, the reader will understand and admit the validity of reasoning from these facts of nature, which go to prove that there is a certain limit of development of an animal's body, beyond which it would not be prudent to go, for it would not be practicable to decrease, for instance, the bones of a pig to such an extent that they could not support the animal.

Bees being no exception to this rule we can easily draw conclusions as to the coming bee. That they are no exception may be discovered by the following: Compare a worker and a queen. The latter has certain parts of her body more developed than the former, which development has taken place at the expense of other parts; for if we measure the length of a worker and queen, the extended tongue and sting included, we will find both of the same length; but on comparing corresponding parts of both, we find the worker has a longer tongue and sting, but smaller body than the queen, which, besides having a larger body, has the generative organs fully developed. Here is not the place to enumerate all these different developments of queen and worker to show and prove where one gained and the other suffered a corresponding loss, as enough has been said to prove the rule, that we cannot gain on one part of an animal's body without losing somewhere else.

Applying what has been said thus far, to all the races of bees, we will discuss now the desirable points.

1. Length of tongue. Can the same be increased? May be, it can; but are we willing to sacrifice the proper development of some other part of the bee's body? Will Prof. Cook, who takes a special interest in this part of the bee's body, please tell us whether or not the tongue of a bee gains, not only in length, but in diameter also, or if an increase of length is accompanied by a decrease of diameter. I am inclined to believe that the desirableness of a longer tongue is overrated. It is true, that if the bee had a tongue long enough to get the nectar of red clover it would certainly be an advantage; but red clover being the only plant for which the use of a longer tongue is claimed, furnishing nectar in abundance which at present blacks and most Italians cannot reach, is it not a mistaken notion to attempt to change our beautiful, amiable Italians for the sake of one honey plant? Besides, I think Alsike serves every purpose for which red clover is raised, if we only take the trouble to introduce its use with the farmer, leaving out of consideration that red clover may fail to yield nectar as well as other honey

plants; in some districts the main stay, white clover, quite often disappears.

2. Prolificness. This is a very desirable trait, and cannot be overlooked. But then, we have in this respect good and poor queens in all the different races, and it seems to depend more on the colony having plenty of young bees to rear a first class queen, than on the particular race; besides that, we are able to increase the prolificness of a queen artificially. But will it be desirable or advantageous to do so? It is a well known fact, that the prolificness of any organic body is in an inverse ratio to its life's duration. Any increase (natural or artificial) of prolificness in an individual or species is equivalent to a shortening of its life. This rule, if properly made use of, will hold good if inverted, that is, if by some means or natural tendency the average life of a species of animals is shortened, its prolificness will be increased. As to the prolificness of a queen there is another very important factor to be considered, which, as far as I can see, cannot so readily be governed, viz: The amount of semen entering the seminal sack of the queen, and the sooner with a fertile queen that store of life-giving cells is exhausted the sooner a queen will be worthless, though otherwise she may be in the prime of life. Hence it appears that there is a limit to prolificness.

3. Amiability. The Germans, in all their different shades, can be mastered by smoke; hybrids are rather irascible, and more so than the pure German bee; but the Italians may be handled without smoke, most of the time, with a little care; they become used to certain disturbances so that they will not take offense, when other bees do. Three years ago last summer, I saw a colony of Italians in New York, on Chatham street, near the postoffice, about $4\frac{1}{2}$ feet elevated, but close to the sidewalk, being kept by a retail dealer of candy and ice cream. Crowds of people passing to and fro, not further than two feet from the hive, but the bees have never been known to sting.

4. Industry. This is a very desirable character of our bees. For if bees had all other commendable points and lacked in this one, we would derive not much benefit from them. It is generally admitted that the Italians are superior to the Germans in this respect, though some are not yet ready to concede it.

But suppose we had a bee as industrious as we would like to have them, it will not avail anything if there is nothing to be had in garden, field and forest. This leads me to dwell with particular emphasis on the necessary industry of the bee-keeper. Let him provide pasture for his bees if nature has not, and his honey pots and sections will be filled correspondingly. Let him scatter nectar secreting honey plant seeds, blooming at different times, and an entire failure of a honey crop will be a thing of the past, at least so far as plants are concerned. And we have all reason to believe that, if plenty of forage is

supplied, the Italians will avail themselves of every opportunity to obtain the nectar. Look at the report of L. C. Root, in No. 49, vol. xvii of the BEE JOURNAL, what his best Italians did; the nectar was evidently there, and they got it, too. Do we want or can we expect anything better? Over 20 lbs. in one day; nearly a quarter of a ton up to Aug 27, from one colony.

It is claimed that the Cyprians excel the Italians, especially with reference to length of tongue, prolificness and industry; but are ferocious—much more so than the worst hybrids. Of course, the advocates of that strain concede this last character rather reluctantly, for reasons too apparent to be stated here. Personally, I have had no experience with them, nor do I wish to have any; the experience of persons not prejudiced or interested in any particular strain, is sufficient as far as I am concerned. It is not necessary for a man to go to Africa to find out that there are tigers and lions, and that they are rather dangerous animals; still, if a person takes delight in fighting tigers, lions or bees for their skins or honey, nobody can have any objection, if he goes where they are; but to breed and rear them in a civilized community where they endanger the life of people and domestic animals, is not desirable, and bee-keeping of that sort will before long be regarded a nuisance. That their temper is ungovernable when aroused, we have abundant proof from well known bee-keepers in this country as well as in Germany; in fact, in Germany their ungovernable temper is regarded as proof conclusive that the colony is a pure Cyprian. How the Michigan State Convention could, in the face of these facts, disapprove of the sentiment expressed in Mr. Marsh's paper, urging caution, I cannot understand.

This article is not intended to discourage further improvement in our bees, nor to belittle the meritorious efforts toward improvements by importation of foreign races such as Cyprians or Syrians; but I would discourage an indiscriminate cross between German, Italian, Cyprian and Syrian, and also warn against the disproportionate development of certain parts of the bee's body to the deterioration of others.

For the American Bee Journal.

Mrs. Cotton's Transactions.

A. P. FLETCHER.

In the JOURNAL of Jan. 18, I saw my account of Mrs. Lizzie Cotton's frauds, etc. I remained in the northern part of the State all winter, and did not have the reading of the JOURNAL until I returned a few days ago. In regard to Mr. R. E. Holmes' offer to pay \$5 to you or any one who will furnish proof of Mrs. Cotton's swindling, I would like to know what he means. Have not you, and has he not ample proof from many sources, that she practices swindling right along? To-day I heard Mr. Nathaniel C. Nor-

ton, of this place, a practical bee-keeper of the first class, read two quite lengthy articles from the New York *Tribune*, written by Prof. Cook, that reflected very strongly and directly upon Mrs. Cotton. Mrs. C. has advertised in that paper the same as she has in many other papers. The late Franklin Butler, editor of the *Windsor Journal*, once told me that Mrs. Cotton sent her advertisement to him for publication for three months, but sending no pay, he became suspicious, after inserting it a few weeks, that she was a fraud and took it out and sent her his bill, which she did not answer. What kind of proof does Mr. Holmes require—what more can he have than he already has? I sent to Mrs. C. for a bee hive, but before I sent the money (\$4), I wrote her, asking the shape and size of her hives, and what kind of lumber they were made of, to which she replied that her "hive was 2 feet square, 1 foot deep, with thirty glass boxes top and bottom, and made of pine lumber planed on both sides." I sent the \$4, and received what I called a model of her so-called "sample controllable bee hive." It was a very roughly made basswood thing, only 6 inches deep, and 6x10 inches inside. What is that but fraud? Mr. Holmes need not take my word for it, hundreds of others have received the same, no doubt. I can cite several. If Mr. Holmes means to do as he says, he cannot do anything less than to hand over \$5 to somebody. He says: "I will give \$5 for proof of money sent to her, and received, without returns being made." No doubt Mr. A. I. Root can furnish ample proof that he sent \$1 for her book, and received acknowledgement, but never the book nor the money back. Is such the "returns" Mr. Holmes means? I received "returns" for my \$4, in the shape of the "model" above referred to. The lady in Berkshire received "returns" for her \$20, in the shape of a hive with a small swarm of bees—only a handful—on only 5 frames, when the equivalent could have been bought of her near neighbors for $\frac{1}{4}$ the price. I think that Mr. Holmes ought not to uphold Mrs. Cotton in her fraudulent transactions in the face and eyes of so many of her defrauded customers all over the land. Mr. Holmes says he does not think you have any right to say what you do about her, unless you are ready to prove "several instances" of what you claim. For conscience sake, how many more instances does he ask you to prove, in addition to the many already proven, before he is ready to come down with his \$5? Mr. Holmes is very much like the gentleman from Connecticut, whom I met at Mr. A. I. Root's, who pretended to "know all about Mrs. Cotton," but on asking him a few questions, I found he had never seen her, or been at her place. He said she did not send me that little bee hive to swindle me, but she did it because she did not know any better: that she was as ignorant as a "horse-block," etc., and that the "old man" had been through bankruptcy and didn't amount to any-

thing. Well, the piece before me in the BEE JOURNAL reads very similar to what that Connecticut gentleman said, and if he is the same, then I have had the honor of seeing Mr. Holmes. Mr. Editor, as you say, I consider myself worse swindled by receiving what I did, than as if I had received nothing, for it only added 95 cents to the price of the thing which was of no practical use. I cannot write anything about Mrs. Cotton without feeling "kind o' nervous." for I dislike swindlers.

For the American Bee Journal.

Results of Some Experiments.

G. W. DEMAREE.

Last fall when wintering some queen-rearing colonies, I found one strong nucleus under the influence of a fertile worker—perhaps several of them, from the number of eggs that appeared in the combs. This colony, having had no young to feed and nurse for some time, and being without a queen, had filled three or four combs full of a mixture of pollen and honey. With this state of things, I conceived the idea of trying a double experiment—1. To see how long fertile workers are capable of laying eggs; and, 2. To ascertain whether or not these bees would winter safely on a mixture of pollen and honey. To this end I removed every comb that contained sealed stores, and put the bees on four frames that contained nothing but a mixture of pollen and honey. The preparation for winter was simply a division-board at the side, and two quilts spread over the tops of the frames. They reared drones in abundance at the start, but all signs of fertile workers disappeared by the middle of the winter. The experiment showed that worker bees do not have the vitality to lay eggs but a few weeks at most. These bees reared drones through the coldest part of the winter, having nothing but a mixture of honey and pollen to subsist upon, and came through the winter bright and clean.

Another experiment tried was of much interest to me, and is perhaps worthy of mention. In February last I discovered that a queen reared late in the fall had failed to "mate," and hence was a genuine drone-layer. She was quite prolific, but did not lay a single worker egg. There was a patch of drone cells near the center of the brood nest, and from these were hatched some as fine looking drones as any I ever saw. There being no drones in existence at the time except those sons of an unwedded mother, I determined to ascertain if it was possible to get a queen fertilized by them. I proceeded to destroy the unmated queen and gave the bees some larvae just hatched, and they reared a queen and she was fertilized in due time. Of course such an experiment could not be conclusive, but all the probabilities are in favor of her having mated with one of these fatherless (?) drones.

It is generally believed that queens reared by small nuclei and such as hatch out in less than thirteen days, are necessarily inferior. I have always accepted this doctrine because of the reasonableness of the conclusion. I now have two queens reared by a one frame nucleus, in a glass case for observation, that are extra good queens. I also have a queen that is laying her third, if not her fourth year, that was reared by an ordinary nucleus, and hatched on the morning of the tenth day. I have had one nine-day queen that kept her hive full of bees for more than two years. These may be exceptional cases, but they have been quite numerous with me.

I am inclined to boast of two Cyprian queens (daughters of an imported mother) mated with black drones, that produce workers that will pass anywhere as first class leather-colored Italians.

Christiansburg, Ky.

New York Tribune.

Care of Honey Locust Hedges.

JOSIAH HOOPES.

In the Northern sections of the United States, where the Osage orange is more or less injured by the winter, the honey locust is undoubtedly the

Honey Locust Tree.

most valuable plant for hedging purposes. There is no special culture necessary for it, more than is required for other species, but it needs attention for the first 2 or 3 years to form a thick base. The young hedge should be frequently cultivated and kept clear of grass and weeds all summer, otherwise mice will harbor therein and bark the young plants. In trimming, cut well back for the first 2 or 3 years, bearing in mind there is no difficulty in quickly obtaining the desired height, but it is far more troublesome to induce it to become dense and twiggy.

The best results are obtained from running one strand, or, better still,

two strands, of barbed wire along the middle of the hedge, thus preventing the inroads of unruly animals, and that bane of the honest orchardist, boys with thieving propensities. To start at the commencement, honey locust seeds should be collected in the pods as they fall from the trees in autumn, and placed in a cold exposed position until hard, freezing weather, when they can readily be threshed like beans. After cleaning the seeds from the fragments of pods, etc., place in bags and preserve dry until spring. At planting time soak the seeds in warm water until they show signs of germination, when they should be sown in drills like peas, in good, thoroughly pulverized soil. Like the larger portion of our native trees, this species forms more root than top the first year, consequently one-year seedlings are usually rather small for

Honey Locust Limb, Pod and Seed.

planting in the hedge-row, but they should not be left to remain longer than 2 years, else they will be on the other extreme. The cause of so many poor hedges, however, is neglect in cultivation, and the honey locust of all others will not thrive without care and attention.

[The honey locust makes a beautiful and hardy shade tree, and when alternated with other ornamental trees, presents a most attractive appearance. It is a good bloomer, and furnishes an abundance of light, rich honey. The instructions given above will furnish useful information for those desiring to cultivate it from the seed for a standard shade tree. We would prefer to transplant from the drills the second season. The timber is excellent.—ED.]

For the American Bee Journal.

Denver, Colorado, as a Honey Market.

C. A. CLARK.

The mildness of our climate is favorable, not only to the bee, but to the man who proposes to profit by its industry. This is my second winter in Colorado, and I have not yet seen the thermometer get down to zero as the lower extreme, nor up to 90° as

the higher. The winter just closed has been milder than usual, snow not having fallen to the depth of 5 inches at any time during the season.

Forage for the bees is plenty, and the alfalfa grass, now becoming so popular, is as helpful to bees as a field of buckwheat. All the ordinary honey producers are plentiful.

Denver is one of the best of markets for honey, which brings 26 cts. per lb. the year round. The National Mining and Industrial Exposition, to be held in Denver, in August and September, may direct attention to this promising industry, especially if bee-keepers take interest in the subject, and aid them to do so.

Denver, Col.

Rural New Yorker.

Is Bee-Keeping Profitable?

G. M. DOOLITTLE.

My crop of honey produced during the season of 1881 was, most of it, sent to commission merchants, as I was not able to find a sale for it at prices which I thought it ought to sell for, hence the present time finds me hearing from the last lot which closes out my entire crop. The most of my crop was shipped in lots of about 300 pounds each to different commission men in New York, Boston, Philadelphia, etc., and sold quickly at 20 and 22c per pound, while the lot just closed out, which was shipped to a large dealer, together with a large consignment of my neighbors' on the co-operative plan recommended by some, brought from 12 cents per pound up to 20, thus proving that the co-operative plan is not always the best.

After placing the amount of this last sale on my ledger, it was but natural that I should look over the debit and credit columns to see what my bees had paid me for my season's labor. After footing up the whole receipts, and deducting therefrom the expenses incurred by the bees, I find I have an average profit of \$29.63 for each colony I had in the spring. Thus, it will be seen, if a person can care for 100 colonies of bees (and it is done by many of our practical apiarists), it will give an income of \$2,963 a year. But to be on the safe side, suppose we call it 50 colonies, these will give a salary of \$1,481.50. I will admit that the season of 1881 was better than an average one for honey in this locality, and therefore to be sure and not get our figures too high, we will take off \$481.50 from the above, when we have left \$1,000 as an average yearly income for one person. As proof that the above is not overdrawn, I will say that I have cleared, on an average, over \$1,000 from my bees each year for the past nine years with an average of less than 50 colonies each year.

That bee-keeping will compare favorably with any other pursuit in life I firmly believe, and the cause why so many fail in it is that they do not properly attend to it. Men will give their cattle and horses the best of care, but, when it comes to the

bees, they let them take care of themselves, with the exception of hiving swarms and putting on and taking off boxes. What would they expect from their cows if treated in that way? The keeping of cows means milking twice a day for at least 210 days out of the year, and feeding them three times a day for 180 days to say nothing about cleaning stables and other work necessary to carry on a dairy. When men are willing to thus care for bees, they will find they will give a greater profit than can be obtained from cows, or any other branch of rural industry. Bee-keeping means work, energetic work, "a place for everything and everything in its place," and to know how to do things just at the right time and in the right place, if we would make it profitable. We also want the best bees, the best bee hive, and all the modern appliances, just as our enterprising dairymen would have the best breed of cows and the best utensils to care for the milk. A person will not succeed in any business unless he has enough love for his calling in life to induce him to be diligent and faithful thereto.

Borodino, N. Y.

[Mr. Doolittle's excellent article above touches upon a subject in which we have taken a deep interest—i. e., marketing honey. We have long entertained a doubt as to the feasibility of co-operation in the matter of disposing of honey, and more especially as regards pooling the whole product in the hands of a comparatively few commission merchants or "middle-men." We could see no reason why the laws of commerce would be reversed for the especial aggrandisement of honey-producers, any more than for the dairymen, the wheat or corn growers, or the hog or stock-raisers; and we thought we could see many good reasons why the whole scheme was not only impracticable, but extremely visionary. Of course we had only one opinion, based, as we thought, on reason; nor, on the other hand, was there any proof positive opposed to our opinion by those advocating the scheme. Mr. Doolittle, however, in his first paragraph above cites practical, positive experience which strengthens our views, and is worth more than all the theoretical assertions which can be adduced. Perhaps adverse circumstances combined to force the unfavorable result upon him; but could the system be so perfected as to prevent abuses, or to revolutionize the laws of trade? We think not, when we consider the many conflicting interests to be reconciled, and the many expectant producers to be satisfied as to prices and speedy returns.—ED.]

SELECTIONS FROM OUR LETTER BOX

A Month Later than Usual.—Prospects are not very flattering in regard to the bee season here. It is a month later than usual. J. P. BASSETT.
Santa Barbara, Cal., April 28, 1882.

Bees in Canada.—Bees wintered well in this neighborhood and have been working since April 3d, whenever it was warm. There has been little loss from cold winds this spring. I spent last season with D. A. Jones, of Beeton, Ont. I have 75 colonies in box hives, all black bees, and intend to transfer all to movable frame hives, and put in Italian and Syrian queens. The fruit blossom prospects are very encouraging. Should summer rape be sown before or after fruit bloom?

R. F. HOLTERMAN.

Fisherville, Ont., May 6, 1882.

[After fruit bloom; in your latitude from June 1st to 20th.—ED.]

Bees in Louisiana.—I put into winter quarters last fall 35 colonies in good condition, all in Langstroth two-story hives; used one thickness of cotton cloth, and one thickness of jute bagging as absorbents. They came through in good condition, with the exception of 3 queenless, which I doubled up March 1. I reared and had fertilized 10 fine Italian queens during April. Bees are now bringing in plenty of honey. Surplus arrangements are all on and rapidly being filled. I am working them for surplus, not wanting any increase. So far I have kept them from swarming. The flood did not reach me, as I had 4 feet more to spare. Some of my neighbors lost quite a number of colonies, but not quite all. Weather is dry and cool. The overflow is gradually falling, with no places flooded on the west bank of Bayou Teche in this parish. The cane crop is promising.

W. R. THOMSON.

New Iberia, La., May 1, 1882.

Thin vs. Thick Sections.—Why do so many bee-keepers use sections 2 inches thick or more, thereby necessitating the use of tin to get straight combs? It is no trouble for me, and some others, to get full racks of sections filled with honey, and the combs all as true as a board, in sections not more than 1½ inches thick without the use of separators; but when the sections are 2 inches thick, tin must be used or the combs will be crooked or wavy. We can also get at least ⅓ more honey without separators than with them, and as honey which is thin will evaporate and become thick much quicker in a shallow dish when exposed to heat, I hold that the bees will ripen and seal more honey in a good run in a comparatively thin comb than they will in combs with deep cells. Bees in chaff hives are doing well. O. H. TOWNSEND.

Kalamazoo, Mich.

Candied Honey.—I do not think it would dissolve to hang it in the middle of the hive, as the editor says; but lay the frame flat in some warm water, then turn over—use a shallow baking pan, for instance—the smaller the volume of water the stronger the fluid; don't take a sugar hoghead, it might make it too strong; uncap of course. We have fine weather to-day—80° in the shade. I see Mr. Doolittle reports cold weather in New York. Dr. Dzierzon, early this spring, said the last winter nearly resembled the winter of 1834, but wisely remarked, "We do not know what is in store yet for us." They had a mild winter in Germany, but lately it has turned cold there also. Dr. Dzierzon is nearly 71 years old, with a mind still clear and vigorous, and he has an article in every semi-monthly issue of the *Bienen-Zeitung* of Eichstadt.

T. HULMAN.

Terre Haute, Ind., May 4, 1882.

[We must confess we do not know what Mr. Hulman is alluding to in the first part of the above paragraph, but suppose he refers to removing candied honey from combs. We never said candied honey "would dissolve to hang it in the middle of the hive." We said, on page 264, "we would recommend to shave off the cappings and put the combs one at a time in the center of the brood nest. The bees will take out the honey, and liquefy and replace it in other combs." Mr. Hulman, however, suggests a plan for removing it from the combs, but we very much doubt whether he has tried it, or knows anything about its feasibility. Certainly its value, as honey, would be destroyed by the method he proposes, even though successful in removing it. We must question the wisdom of attempting to make corrections unless certain that error exists, and consider it almost impertinent to suggest a remedy we have not tried ourselves, or at least have good authority for presuming to be correct. Bee-keepers want truthful answers to their queries, or what has been proven satisfactory with others.—ED.]

Not Flattering.—As I have seen no reports of bees wintered in this section, in the BEE JOURNAL, I will say that, as a rule, they are in fine condition. My bees went into winter quarters about the middle of November, and the last of them came out April 27th. My loss was 6 out of 332—4 queenless and 2 deserted in the cellar, after about half were set out. The prospect for honey in this section is the poorest I ever saw on the 1st of May. Clover is nearly all killed, and that is one of the principal honey sources in St. Lawrence county. The season is about 10 days later with us than last year, as there is nothing in bloom at this date but poplars and a

few willows that stand in warm places. Cloudy weather and cold winds prevail here every day, and freezing nearly every night.

IRA BARBER.

De Kalb Junction, N. Y., May 2.

Cold in Virginia.—Bees in this locality have wintered splendidly, and from April 1st to the 8th, they toiled from early morn till late at night, gathering large quantities of pollen and considerable honey. The weather was very warm and fine, temperature 74° to 78° in the shade, consequently brood-rearing was pushed to the utmost. I believe I never saw bees so crowded with brood in so short a time. But who knows what a day will bring forth? On the 9th we had a heavy rain, on the 10th snow, and next morning 12° below freezing, and we have had cold nights and raw winds ever since. Notwithstanding all this, the most of the bees are in fine condition, and I feel hopeful of a good honey harvest, as our main reliance is on white clover, which is in fine condition.

WM. BITZER.

Wheeling, W. Va., April 25, 1882.

Honey for Bee Stings.—Just this evening I read your Navarino subscriber's question on page 267 of the BEE JOURNAL, about the harmless insect, and wonder if it be the one I have often thought of writing you about. It is the same shape and build of a bee, but smaller, has four bands, all white, as also are all its markings, while the rest is jet black. I have noticed several about my hives. 1. Is it the same? 2. Has any one tried honey as a remedy for stings? It acts with me most satisfactorily, and is always convenient. Immediately upon withdrawing the sting, I place a drop over the wound with the tip of finger. It not only draws the poison, but destroys the odor, and this prevents the bees detecting it. In about a minute, or less, the pain is gone and the honey may be washed off. I am surprised that this has not been one among the many recipes already given. The late frosts have stopped the honey flow, but the bees themselves have suffered little, yet those who have neglected to feed may have a different story to tell.

Berlin, Ont. G. B. JONES.

[1. The fly is undoubtedly the same, and their general appearance so nearly resembles the lighter Italians that an unobserving person might easily mistake them for bees. While poised on a flower or leaf, however, their wings stand further apart, and are nearly level from tip to tip, instead of lying close to and covering the body, as do the bees' wings. Catch them and examine closely, they can neither sting nor bite.

2. We have used honey for bee stings, but have not found it effective. As bee stings affect persons differently, so undoubtedly will remedies,

and where honey might relieve the pain and neutralize the poison with one, an entirely different remedy would be required for another.—ED.]

Too Cool.—My bees have been unable to gather either honey or pollen, thus far, this spring. Last year they gathered pollen on April 18. G. M. Doolittle's articles in the BEE JOURNAL contain so much practical knowledge that I find them very useful. There is more such knowledge to be found in the BEE JOURNAL than in any other bee-publication I have ever read. GILBERT W. DUNBAR.
Emden Center, Me., May 1, 1882.

Bee-Keeping in Dakota.—I had one colony of bees last fall that I packed in prairie hay, and I took them out last Saturday in splendid condition. Last summer I set a hive over the bees, full of honey, in which the bees died the winter before, and when I unpacked them they had both hives filled with bees and brood, so that I separated the hives and now have 2 strong colonies. I need your book to help me through with the care of them. My bees find plenty of pasturage, but I am going to help them to more by sowing alsike clover in my garden.

W. W. EASTMAN.

Yankton, D. T., May 3, 1882.

Unprecedented.—The state of the weather here is something unusual. We have had frosts 22 nights in succession. On the night of April 29, ice formed $\frac{1}{4}$ inch thick on tubs of water, and killed all buds on fruit trees. To-day a cold wave struck us, and at 7 this morning mercury stood 2° below freezing, and now, at 11 a. m., it stands at 4° below—something never before known here in May. Bees bred up strong in April, but have not flown for the past 8 days. What will come of it? E. A. MORGAN.

Arcadia, Wis., May 1, 1882.

Swarming Commenced.—My bees are doing finely, and the prospects for a good honey harvest were never better. Swarming has commenced, and if the weather continues favorable, we will have a busy time through the season.

W. P. WEMYSS.

Clinton, N. C., April 29, 1882.

Very Cold.—The weather is very cold here this morning. My thermometer indicated 4° below the freezing point. Queens cannot be reared while the weather is so cold. When April came in we had a few warm days, and then all supposed we would have an early spring. A colder April was never known here, and I never knew it so cold as it is this morning, so late in the month. I fed my bees all through April to induce the bees to rear drones. Have taken some of my hives into my office some cold nights so that they would not "draw in" and leave the drone brood in the cold.

HENRY ALLEY.

Wenham, Mass., May 3, 1882.

Large Hives.—With the Langstroth hive I see it recommended to use only 7 frames for brood, to induce bees to take surplus honey up into sections. Again, it is said for wintering crowd bees on 6 or 7 frames. 1. If all this be true, why not use a Langstroth hive of only seven frames, instead of 10? Some recommend stringing dead bees, a piece of black stocking, etc., suspended to a pole for bees when swarming, to cluster upon; we are also told that if a nail keg or box is put directly over a swarm of bees, when clustered, that they will go up into it. 2. Why not keep the box or keg over the decoy branch of dead bees, so that the bees, when they swarm, will get into the box themselves without any aid from the bee-keeper? If all this would work, I do not see why any swarm should be lost, for the bees, accepting the box or keg for their home, would be there when the bee-keeper came. G. M. ALVES.

Henderson, Ky.

[1. There are several successful apiarists who use 8-frame Langstroth hives, and one we know in Indiana who uses only 5 frames in the brood chamber during the honey harvest, but he uses 10 frames in building up. Last season we had a two-story Langstroth hive which contained 14 frames of eggs, larvæ and sealed brood at one time. The combs were not full, but certainly contained enough to moderately fill 10 frames. We think it better in breeding up, to employ all the frames that the queen will utilize; then, if necessary, cramp the brood chamber with division boards to force the bees to the boxes. This is perhaps more especially necessary with the Italians than with hybrids or blacks, as their attachment to the young is more marked.

2. Your scheme with swarms might work—we have never tried it. In the case of large apiaries, however, where several swarms frequently issue at once, much confusion would ensue from the doubling of several swarms in one box or keg. The keg is better than a box for running swarms into, as the roaring noise, which is so attractive, is much louder.—ED.]

Prospect Unusually Good.—The prospect for a large honey crop is unusually good with us. The cool weather has prevented the bees from gathering the usual amount of surplus honey from the fruit bloom, but it has staid in bloom double the usual length of time, and the bees have been able to gather a sufficient amount of nectar to keep brood-rearing up all the time. The result is an unusually large number of young bees in the hives for the time of year. White clover looks well, and I think will bloom 2 weeks ahead of the usual time. The demand for bees is the largest I have ever known,

and the interest in bee-keeping is good in proportion. I have always run my apiary for honey, but have had so many calls for bees this spring that I have changed my plans, and will run the entire apiary for increase this year. I have heard of but 3 colonies of bees dying during the winter. I cleared over \$300 from 16 colonies last year. I have never been able to supply the home demand for honey or bees, and I do not think I can for some time to come. I think many of our bee-keepers are too much afraid of selling bees near home, and allow others to supply their neighbors. I know of some such cases.

Rocklane, Ind. L. R. JACKSON.

When to Divide.—I have 2 colonies of bees. Took them out of the cellar about the 1st of April. They are in good condition and strong in bees—the bees covering nearly all of the frames, with brood in all stages of development. I am a beginner in the business, having obtained my first colony last July, after the swarming season was over. I wish to run my bees for comb honey rather than increase, and have determined to adopt the method of dividing suggested in your editorial, on page 210 of the BEE JOURNAL for 1882, as being the simplest and most easily understood of any I have come across; but the question with me is (and with other beginners in this vicinity), just when is the proper time to do it to subvert any future swarming? Will you please give some rule whereby a beginner can tell when to divide—a rule applicable to different latitudes and different seasons. By so doing, you will much oblige one, and probably many subscribers. J. M. B.

Morrison Ill., May 2, 1882.

[It will be a hazardous matter to fix an arbitrary time for making divisions, even in a single locality, and much will depend on the judgment of the apiarist, as it is a matter of frequent occurrence that some colonies will be very much stronger and more prosperous than others, and that, too, when the chances are apparently equal. Therefore, it does not follow that division is always practicable, unless the conditions are favorable, and no invariable rule can be established. We would, however, advise that when there are, say 7 or 8 frames of brood, larvæ and eggs in the hive, and if the weather be favorable, that when hawthorn (*Crataegus cordata*) is in bloom, the division be made. In case of plentiful fruit and spontaneous bloom, if the weather be warm and the nights not chilling, the division may safely and profitably be made when the Siberian crab is in blossom. This gives the benefit of most of the fruit for building up, and will generally give opportunity for rearing and fertilizing young queens before the

usual week of wet, chilling May weather sets in, which in this latitude most frequently occurs during the last week. Let the division be made when it will, however, it will not do to leave anything to chance. Frequent examinations should be made as to the progress being made, and with a view to supplying feed, in case it should be needed.—ED.]

Shaken Loose.—"Open confession is good for the soul." I suppose I am beaten in the "best bees" controversy. It is now decided that nature made a hybrid that man and nature combined cannot improve upon. That traits of character in bees (different from all other animals) are not hereditary. That there is no use to breed for qualities, but for marks, and these marks are three yellow bands. By their bands ye shall know them. The days of "deeds" are past. American honey producers must now realize that bright yellow bees are the open sesame to success. For all this knowledge, together with the "possum" story, are we indebted to the assiduous labors of Mr. G. W. Demaree, of Ky., my late victor. It is economical as well as comforting to discuss with a man who has not only the time and ability, but kindness to act as both chief disputant and judge.

JAMES HEDDON.

Dowagiac, Mich.

Taking Off Sections.—I see by dispatches from the Northern States, that you are still having cold weather. How strangely that sounds to us here on 29½° latitude. It is warm here and rather dry for April; our bees are storing honey now from horsemint. I took off box honey on April 12, stored from spring flowers. It is beautiful honey, and of very fine flavor. We have no wintering troubles here. A small swarm of blacks came to my apiary and settled on a limb Nov. 17; hived them on a frame of brood from Italians. They at once began to form queen cells (as they were queenless). The queen mated about Dec. 5, and began at once to rear brood, and now they are as fine a colony as any I have. Apiculture is coming to the front in this land of sunshine and flowers. Much has been said in regard to the viciousness of the Cyprians. We have them from a tested queen bought of B. F. Carroll. They are the most docile of any composing my apiary, which consists of pure Italians and hybrids. They are so much in favor with us by their good qualities in general, that we reared queens for our own use from them, rather than from the Italians. Climate, no doubt, has much to do with the different races of bees, as also with the yield of honey from various plants. Our country is healthy, and our crops are very fine. This is a fine farming country, and a splendid country for bees. Nothing troubles them here but ignorance. I suppose that is the name of it. It is indigenous with us. A good dosing with the AMERICAN

BEE JOURNAL, I trust, will cure that malady. They do not possess it on purpose. All they require is teaching. I will strive, as soon as we see the crops are safe, to get you up a class. J. E. LAY, M. D.
Hallettsville, Tex., April 28, 1882.

Floating Apiaries Unprofitable.—One of our principal honey plants is the black jack, a vine which grows in our woods here in great abundance. They have been in bloom about two weeks, and will continue three weeks longer. The flowers are small, hang in clusters, and contain large quantities of clear honey. The woods are in a perfect hum with the bees, which are busy bringing in honey and pollen. Black jack is not the only plant from which the bees gather honey. There are hundreds of other plants and trees. Mr. Henry Steckle is feeding his bees. Mr. Garrett recovered 20 out of 70 colonies. He says he does not admire a floating apiary very much. His loss on bees and honey was about \$865. C. H. SONNEMANN.

New Iberia, La., April 28, 1882.

[The vine referred to is wrongly named: black jack (*Quercus nigra*) is a species of oak, growing usually very scrubby and barren. This vine is *Solanum dulcamara*, and frequently called bitter sweet. We have it growing in the Northern States, but it is not so great a favorite with the bees as in the South. If we mistake not, it is also called "tie-vine" in Arkansas, and other States South. The reference to Mr. Garrett's floating apiary will be explained by turning to Mr. Shaw's letter on page 265 of the BEE JOURNAL.—ED.]

A Beginner.—Bees are doing splendidly, regardless of the bad weather. They have been gathering pollen ever since in March. I purchased 7 very strong colonies this spring. They are black bees, wintered well, and are working well. The drones have been flying for three weeks. I expect early swarms. I am situated in a little valley, near a small stream of water; the woodlands are decorated with wild flowers of different kinds, on which the bees are busy at work. I think the coming season is very promising to bee-keepers, as nothing but the peach bloom has been killed. This locality affords an abundance of white clover every season. I am going to try the plan of sowing buckwheat the 1st of May, and at intervals throughout the summer, which has proved a success in former years. My hives are old-fashioned box hives, in which I believe, taken one year with another, bees will do better than in any patent hive made, unless they are different from any I have seen. I have known my neighbors to buy more than 30 patent hives, and lost all the bees they put in them except one colony. The Langstroth hive may be better—I have never seen one. Why is it that bees are killing off

some of their drones this early in the season? I also want to know if basswood will grow well along creek banks, and what time to transplant?

FRANK B. RIFE.

Malaby, O., April 27, 1882.

[They are killing off drones because honey is not coming in fast enough to feed them and the working population.]

Basswood will grow well along creek banks if the ground is gravelly and filled with water near the surface, as is usually the case in the vicinity of running streams. Any time will do in the spring for transplanting basswood, if the leaves are not set. Probably for the next two or three weeks.—ED.]

Feeding.—The cold weather has taken the early swarming fever out of our bees, and they have concluded to wait till a more convenient season. We have not lost hope yet of a good honey yield from poplar and white clover. These are our main sources of supply in Southern Indiana when colonies are strong enough to secure it. Judicious feeding is what should be done now to keep colonies up to their full capacity.

W. C. R. KEMP.

Orleans, Ind., April 29, 1882.

Cold Weather.—The weather is quite cold yet. March 8th set in with northwest winds, which remained till the 17th, when the weather became warm so bees could fly again. They gathered pollen and some honey from the willows, and I had a chance to look some of them over. I found them in splendid condition, with brood in 6 frames, and capped drone brood in every colony I examined. I observed one colony where the bees flew very fast, so I opened it and was surprised to find they had started to build comb on the outside of the division boards. They had 2 pieces about 3 inches square. It has 8 frames of brood, and is as full of bees as in June. We have been feeding flour to our bees ever since—they have been flying, and I never saw them work on it as they did this spring. I think that is what makes them breed so. The outlook for a honey crop is good. White clover looks better than last spring, and bees are in better condition. I think I will get considerable honey from fruit bloom. I think I can say, with Mr. Deane, "out of the woods," as there is plenty of brood to prevent spring dwindling. I wintered 26 colonies, and one nucleus with about a pint of bees, without loss. My brother had one colony. When he first put it out they flew all right in the day time, but toward evening fighting commenced, and in the morning, when we looked, there were about a pint of dead bees in front of the hive. We supposed they were robbers. The next day was cold, so we could not watch them, and he put them in the cellar again. When it

again became warm he put them out, and we watched them, but could see no robbers around; in the evening they commenced fighting again, in the same way, and made it worse than ever—killing a terrible lot. That colony filled 8 spaces before, and afterward only 6, so it must have been their own bees. It is something new to us. If you know why it was, please let us know through the BEE JOURNAL.

H. J. SMITH.

Burlington, Wis., April 27, 1882.

[Most likely robbers were at the bottom of the trouble, but not necessarily so. We have noticed, upon several occasions, the phenomena of bees killing members of their own colony, and accounted for it upon the supposition that they were either old bees, or that the colony was more numerous than convenience or necessity required, or perhaps their safety, and not being provided with the requisites for successful swarming, they adopted this plan for depleting their population. For some one who has the time at disposal and the inclination, this would afford an interesting subject for investigation.—ED.]

Grubs.—I inclose two grubs. I found two hives that have them in. They are very active when you touch them. 1. Would like to know whether you have such travelers, and what you call them; whether they are very destructive? These I found in hives packed on summer stands, with sawdust filling. 2. Will old tin boilers, that are not rusty, do to press out for separators? 3. Are the perforated the best? A. L. ETHERINGTON.
Milton, N. S.

[The grubs sent are the larvæ of a small beetle, black in color, about $\frac{5}{8}$ of an inch long. They subsist mainly on vegetable or wood fibre, after it has been long damp, and partly decayed. They are common throughout the United States, and are frequently met with underneath the bark of partly decayed logs and stumps. We do not think they are at all injurious to either the bees or honey.]

2. So long as the tin is not rusted badly, it will not matter what it has been used for.

3. We doubt whether the perforated tin is enough better for separators to compensate for the difference in cost.—ED.]

Articles for publication must be written on a separate piece of paper from items of business.

Advertisements intended for the BEE JOURNAL must reach this office by Saturday of the previous week.

THE AMERICAN BEE JOURNAL

ADVERTISING RATES.

20c. per agate line of space, each insertion.

A line of Agate type will contain about eight words; fourteen lines will occupy 1 inch of space. Transient Advertisements payable in advance. Special Notices, 50 cents per line.

DISCOUNTS will be given on advertisements published WEEKLY as follows, if the whole is paid in advance:

For 4 weeks.....	10 per cent. discount.
" 8 ".....	20 " " "
" 13 " (3 months)....	30 " " "
" 25 " (6 months)....	40 " " "
" 39 " (9 months)....	50 " " "
" 52 " (1 year).....	60 " " "

Discount, for 1 year, in the MONTHLY alone, 25 per cent., 6 months, 10 per cent., 3 months, 5 per cent.

Discount, for 1 year, in the SEMI-MONTHLY alone, 40 per cent., 6 months, 20 per cent., 3 months, 10 per cent.

Advertisements withdrawn before the expiration of the contract, will be charged the full rate for the time the advertisement is inserted.

THOMAS G. NEWMAN,

925 West Madison Street., Chicago, Ill.

Special Notices.

A Sample Copy of the Weekly BEE JOURNAL will be sent free to any person. Any one intending to get up a club can have sample copies sent to the persons they desire to interview, by sending the names to this office.

The BEE JOURNAL is mailed at the Chicago Postoffice every Tuesday, and any irregularity in its arrival is due to the postal employes, or some cause beyond our control.

Examine the Date following your name on the wrapper label of this paper; it indicates the end of the month to which you have paid your subscription on the BEE JOURNAL.

We will send Cook's Manual in cloth, or an Apiary Register for 100 colonies, and Weekly BEE JOURNAL for one year, for \$3.00; or with King's Text-Book, in cloth, for \$2.75; or with Bees and Honey, in cloth, \$2.50.

Bee Pasturage a Necessity.—We have just issued a new pamphlet giving our views on this important subject, with suggestions what to plant, and when and how. It is illustrated with 26 engravings, and will be sent postpaid to any address for 10 cents.

The Apiary Register.

All who intend to be systematic in their work in the apiary, should get a copy and commence to use it.

For 50 colonies (120 pages).....\$1 00
" 100 colonies (220 pages)..... 1 50
" 200 colonies (420 pages)..... 2 00

The larger ones can be used for a few colonies, give room for an increase of numbers, and still keep the record all together in one book, and are therefore the most desirable ones to procure at the start.

Honey as Food and Medicine.

A new edition, revised and enlarged, the new pages being devoted to new Recipes for Honey Medicines, all kinds of cooking in which honey is used, and healthful and pleasant beverages.

We have put the price of them low to encourage bee-keepers to scatter them far and wide. Single copy 6 cents, postpaid; per dozen, 50 cents; per hundred, \$4.00. On orders of 100 or more, we print, if desired, on the cover-page, "Presented by," etc., (giving the name and address of the bee-keeper who scatters them). This alone will pay him for all his trouble and expense—enabling him to dispose of his honey at home, at a good profit.

Binders for 1882.—We have had a lot of Emerson binders made especially for the BEE JOURNAL for 1882. They are lettered in gold on the back, and make a nice and convenient way to preserve the JOURNAL as fast as received. They will be sent postpaid by mail for 75 cents.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey. A new pamphlet of 32 pages. At the last meeting of the North American Bee-Keepers' Society, we were appointed on a committee to prepare instructions on the Exhibition of Bees and Honey at Fairs; this is also added to the above. Price, 10 cents.

Constitutions and By-Laws for local Associations \$2.00 per 100. The name of the Association printed in the blanks for 50 cents extra.

This one fact is being brought before the minds of the people of the United States: Kendall's Spavin Cure is not excelled as a liniment. 18w4t

When changing a postoffice address, mention the old as well as the new address.

Honey and Beeswax Market.

OFFICE OF AMERICAN BEE JOURNAL, }
Monday, 10 a. m., May 8, 1882. }

The following are the latest quotations for honey and beeswax received up to this hour:

Quotations of Cash Buyers.

CHICAGO.

HONEY—As the season is well advanced, sales of extracted honey are slow and prices remain unchanged. I am paying 8c. for dark and 10c. for light, cash on arrival. Good comb honey is scarce and makes high.

BEESSWAX—I am paying 24c. for good yellow wax, on arrival; 18@22c. for medium grade, and 15@17c. for dark.

AL. H. NEWMAN, 923 W. Madison St.

CINCINNATI.

HONEY—The demand for comb honey is slow, and prices nominal at 16@20c. on arrival. Extracted honey is in fair demand. Our jobbing prices for 1 lb. jars of clover honey are, per gross, \$25; for 2 lb. do., per gross, \$42. The demand for manufacturing purposes is very good. We pay 8@10c. on arrival.

BEESSWAX—Brings 18@22c. The demand exceeds the offerings. C. F. MUTH.

Quotations of Commission Merchants.

CHICAGO.

HONEY—The demand for honey is light, most of the trade finding fault with the best offered, as it is more or less candied. Values are not steady, prices being made to meet the views of the purchaser.

BEESSWAX—Scarce, and in demand at 23@25c. R. A. BURNETT, 165 South Water St.

CLEVELAND.

HONEY—Our honey market would be good, as there is considerable inquiry for white honey in sections, with none to satisfy the demand. It would bring 22c. readily for choice. Buckwheat honey, no sale. Extracted, 11@12c. per lb.

BEESSWAX—25@30c. A. C. KENDEL, 115 Ontario Street.

SAN FRANCISCO.

HONEY—There is virtually no demand for comb honey from wholesale buyers. Holders are anxious to clean up, some dark and candied comb was sold this week at 6c. At any price there are a few buyers who care to handle old comb. There is a limited demand for extracted, but only at very low figures. Sales of bright amber at 6@8c.

We quote white comb, 12@14c.; dark to good, 6@10c. Extracted, choice to extra white, 7@7½c.; dark and candied, 6@6½c. BEESSWAX—25@28c. STEARNS & SMITH, 425 Front Street.

NEW YORK.

HONEY—There is no white comb honey in the market. We quote; Comb honey 11@16c.; extracted 7@11c.

BEESSWAX—Scarce; 26@27c. THURBER & Co.

BOSTON.

HONEY—Trade quiet. We quote at 20@22c., according to quality.

BEESSWAX—Prime quality, 25c. CROCKER & BLAKE, 57 Chatham Street.

ST. LOUIS.

HONEY—In fair demand. Strained selling at 8@10c.; comb scarce—nominal at 18@22c.

BEESSWAX—Stiff at 21@22c. for prime. R. C. GREER & Co., 117 N. Main Street.

Twenty-five Colonies of Italian Bees

At Nine Dollars each; Ten colonies to one address, Eight Dollars each. Twenty Colonies of hybrids at Seven Dollars each. These bees are in good, new, story-and-a-half hives, Gallop frames, 12 frames in a hive. In all respects in the best condition. O. CLUTE, Iowa City, Iowa. 19w2t

PAINE & LADD,

HALBERT E. PAINE, } WASHINGTON,
Late Comm'r Patents. }
SPRY B. LADD, } D. C.
Solicitors of Patents and Attorneys in
Patent Cases. 16w3m

HIVES FOR SALE—100 new Quinby pattern, iron standing frame, two coats of paint and sheet iron top. Been in use two seasons. Each hive contains 7 brood frames, 2 division boards, and complete side and top surplus arrangement, including tin separators. Price \$1.50 each, in lots of 10 or more. C. M. WOOLVER, Hallsville, N. Y. 19w1tp

Cyprian Bees FOR SALE.

37 COLONIES OF BEES, having queens of last year's hatch, bred from a queen of D. A. Jones' importation. They are in J. E. Moore's improved double-wall hive of seven frames, with side and top storage.

They will be securely packed and delivered on cars from the 15th to 31st of May, at the following rates: 1 to 10 colonies, \$8 each; 11 or more, \$7.50 each.

Also, **50 New Swarms**, lived on finished combs, delivered on cars from 10th of June to 5th of July for, 1 to 10 colonies, \$6.50 each; 11 or more do., \$6 each. Reason for selling: The increase of our mercantile business prevents our giving the apinary the care and attention it should have. Remit by Registered Letter to
19wt J. E. MOORE, Byron, Gen. Co., N. Y.

BEESWAX.

I wish to buy a quantity of good yellow Beeswax. I am paying 24c. per pound, delivered here, Cash on arrival. Shipments solicited.

ALFRED H. NEWMAN,
923 West Madison Street, CHICAGO, ILL.

Excelsior Dunham and Vandervort FOUNDATION.

Owing to the large advance in the price of wax, I now quote prices thus: Dunham, 10 to 50 lbs., 42c., over 50 lbs., 41c., less than 10 lbs., 44c.; Vandervort, 10 sq. feet to the lb., 1 to 10 lbs., 57c., 10 to 50 lbs., 54c. No discounts. Circular free.

J. V. CALDWELL,
3w1y Cambridge, Henry Co., Ill.

BEES FOR SALE.

60 COLONIES, in a neat two-story movable frame hive, at \$6 per colony. Nearly all Italian. For further particulars apply to
E. CARRE, Leesville P. O., Gonzales Co., Tex.

65 ENGRAVINGS

The Horse

BY B. J. KENDALL, M. D.

A TREATISE giving an index of diseases, and the symptoms; cause and treatment of each, a table giving all the principal drugs used for the horse, with the ordinary dose, effects and antidote when a poison; a table with an engraving of the horse's teeth at different ages, with a table for telling the age of the horse; a valuable collection of recipes, and much valuable information.

Price 25 cents.—Sent on receipt of price, by

THOMAS G. NEWMAN,
923 West Madison Street, CHICAGO, ILL.

Italian Bees, Queens and Sections.

Untested Queens, in May, \$1.50 each; in June, \$1.25; July and after, \$1 per dozen, after July 1, \$10. Sent by mail, with directions for introducing Italian bees by the half pound, same price as untested queens. One 2 comb nucleus, without queen (Gallup frames), in May \$3, June \$2.50, July and after \$2; 2-comb nuclei, with the standard Langstroth frames, 25 per cent. more. Sections—Placed doveetailed sections, 4 $\frac{1}{2}$ x $3\frac{1}{2}$ x $3\frac{1}{2}$, \$4.50 per 1,000; 3 $\frac{1}{2}$ x $3\frac{1}{2}$ x $3\frac{1}{2}$, \$3 per 1,000. Sections of this thickness do not need pins between them to insure straight combs, and the bees can ripen up and seal honey faster than in combs with deeper cells. See testimonials in March number of *Gleanings*. Please remit by P. O. money order, by registered letter, or by draft on New York or Chicago. Address,
O. H. TOMWINS, ENR.,
19mt Kalamazoo, Kalamazoo Co., Mich.

4—RACES OF BEES—4

Italian, Cyprian, Holy Land and Hungarian Queens.—Warranted queens, \$1.50; extra selected, \$1.75; tested, \$2. Send for my 21st Annual Circular.
19wt HENRY ALLEY, Wrentham, Mass.

A NEW BEE BOOK!

Bees & Honey

OR THE
Management of an Apiary for Pleasure and Profit; by
THOMAS G. NEWMAN,

Editor of the Weekly Bee Journal.

It contains 160 profusely illustrated pages, is "fully up" with the times in all the various improvements and inventions in this rapidly developing pursuit, and presents the apiarist with everything that can aid in the successful management of the honey bee, and at the same time produce the most honey in its best and most attractive condition. Chief among the new chapters are "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. Price, bound in cloth, **75 cents**; in paper cover, **50 cents**, postpaid.

Appreciative Notices.

Carefully prepared for beginners.—Farmers' Cabinet, Amherst, N. H.

A very valuable work to those engaged in bee-keeping.—News, Prairie City, Iowa.

We advise all who keep bees to send for this excellent work.—Journal, Louisiana, Mo.

Its chapter on marketing honey is worth many times its cost.—Citizen, Pulaski, Tenn.

Carefully prepared, and of vast importance to bee-raisers.—Indianian, Clinton, Ind.

New and valuable, and embellished with 109 beautiful engravings.—Democrat, Salem, Ind.

Much practical useful information, in a cheap form.—Daily Standard, New Bedford, Mass.

Contains all the information needed to make bee-culture successful.—Eagle, Union City, Ind.

Just such a work as should be in the hands of every beginner in bee-culture.—News, Keittsburg, Ill.

A valuable work for all who are interested in the care and management of bees.—Democrat, Allenton, Mich.

The most perfect work for the price ever yet produced on the subject of bee-culture.—Anti-Monopolist, Lebanon, Mo.

The engravings are fine. It is gotten up in the very best style, and is cheap at the price.—Farmer, Cleveland, O.

It comprises all that is necessary for successful bee-culture, save experience and good judgment.—Daily Republican, Utica, N. Y.

A manual, containing all the newest discoveries in the management of these little workers.—Plain Dealer, St. Lawrence, N. Y.

Full of practical instruction, that no one who contemplates keeping bees can do without.—Farmers' Journal, Louisville, Ky.

Gives minute details for the management and manipulations necessary to make bee-keeping a success.—Col. Valley and Farm.

Written in an interesting and attractive manner, and contains valuable information for all readers, even though they be not directly interested in the care of bees.—Sentinel, Rome, N. Y.

Describes all the newest discoveries in the art, by which the production of delicious and health-giving honey is obtained, as well as how to prepare it for the market in the most attractive shape.—Signal, Napoleon, O.

Contains a vast fund of information in regard to bee-culture. He who would keep abreast of the times must keep posted in all the improvements in his line. We advise all interested to get a copy of this book.—Daily Times, San Bernardino, Cal.

BINGHAM SMOKERS.

I can sell the above Smokers at MANUFACTURERS' PRICES, by mail or express, at wholesale or retail. All the latest improvements, including the CONQUEROR.

The Bee-Keeper's Guide; OR, MANUAL OF THE APIARY, By A. J. COOK,

Of Lansing, Professor of Entomology in the State Agricultural College of Michigan.

—:—:—
320 Pages; 133 Fine Illustrations.
—:—:—

This is a new edition of Prof. Cook's Manual of the Apiary, enlarged and elegantly illustrated. The first edition of 4,000 copies was exhausted in about 18 months—a sale unprecedented in the annals of bee-culture. This new work has been produced with great care, patient study and persistent research. It comprises a full delineation of the anatomy and physiology of the honey bee, illustrated with many costly wood engravings—the products of the Honey Bee; the races of bees; full descriptions of honey-producing plants, trees, shrubs, etc., splendidly illustrated—and last, though not least, detailed instructions for the various manipulations necessary in the apiary.

This work is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. It is fully "up with the times" on every conceivable subject that can interest the apiarist. It is not only instructive, but intensely interesting and thoroughly practical.

—:—:—
Read the following opinions of the Book:

All agree that it is the work of a master and of real value.—*L'Apiculture*, Paris.

I think Cook's Manual is the best of our American works.—**LEWIS T. COLBY.**

It appears to have cut the ground from under future book-makers.—*British Bee Journal*.

Prof. Cook's valuable Manual has been my constant guide in my operations and successful management of the apiary.—**J. P. WEST.**

I have derived more practical knowledge from Prof. Cook's New Manual of the Apiary than from any other book.—**E. H. WYNKOOP.**

This book is just what every one interested in bees ought to have, and which, no one who owns it, will ever regret having purchased.—*Mech. Fair.*

To all who wish to engage in bee-culture, a manual is a necessity. Prof. Cook's Manual is an exhaustive work.—*Herald*, Monticello, Ill.

With Cook's Manual I am more than pleased. It is fully up with the times in every particular. The richest reward awaits its author.—**A. E. WENZEL.**

My success has been so great as to almost astonish myself, and much of it is due to the clear, interesting information contained in Cook's Manual.—**W. B. VAN ANTWERP, M. D.**

It is the latest book on the bee, and treats of both the bee and hives, with their many details. It is of value to all bee-risers.—*Ky. Live Stock Record*.

It is a credit to the author as well the publisher. I have never yet met with a work, either French or foreign, which I like so much.—**L'ABBE DU BOIS**, editor of the *Bulletin D'Apiculture*, France.

It not only gives the natural history of these industrious insects, but also a thorough, practical, and clearly expressed series of directions for their management; also a botanical description of honey producing plants, and an extended account of the enemies of bees.—*Democrat*, Pulaski, N. Y.

We have perused with great pleasure this *valuable* manual of the bee-keeper. It is replete with the best information on everything belonging to apiculture. To all taking an interest in this subject, we say, obtain this valuable work, read it carefully and practice as advised.—*Agriculturist*, Quebec.

This book is pronounced by the press and leading bee-men to be the most complete and practical treatise on bee-culture in Europe or America; a scientific work on modern bee management that every experienced bee man will welcome, and it is essential to every amateur in bee-culture. It is handsomely printed, neatly bound, and is a credit to the West.—*Western Agriculturist*.

This work is undoubtedly the most complete manual for the instruction of bee-keepers which has ever been published. It gives a full explanation regarding the care and management of the apiary. There is no subject relating to the culture of bees left untouched, and in the compilation of all the work Prof. Cook has had the advantage of all the previous knowledge of apiarists, which he uses admirably to promote and make popular this most interesting of all occupations.—*American Inventor*.

Books for Bee-Keepers.

Sent by mail, postpaid, on receipt of price, by THOMAS C. NEWMAN, 925 West Madison Street, CHICAGO, ILL.

Bee-Keeper's Guide; or, Cook's Manual of the Apiary.— Entirely re-written, elegantly illustrated and fully "up with the times" on every subject of bee-culture. It is not only instructive, but intensely interesting and thoroughly practical. The book is a masterly production, and one that no bee-keeper, however limited his means, can afford to do without. Cloth, \$1.25; paper cover, \$1.

Quinby's New Bee-Keeping, by L. C. Root—The author treats the subject of bee-keeping so that it cannot fail to interest all. Its style is plain and forcible, making all its readers realize that its author is master of the subject.—\$1.50.

Novice's ABC of Bee-Culture, by A. I. Root—This embraces "everything pertaining to the care of the honey-bee," and is valuable to beginners and those more advanced. Cloth, \$1.25.

King's Bee-Keepers' Text-Book, by A. J. King.—This edition is revised and brought down to the present time. Cloth, \$1.00.

Langstroth on the Hive and Honey Bee—This is a standard scientific work. Price, \$2.

Blessed Bees, by John Allen.—A romance of bee-keeping, full of practical information and contagious enthusiasm. Cloth, 75c.

Bees and Honey, or Management of an Apiary for Pleasure and Profit, by Thomas G. Newman.—Third Edition. "Fully up with the times," including all the various improvements and inventions. Chief among the new chapters are: "Bee Pasturage a Necessity," "Management of Bees and Honey at Fairs," "Marketing Honey," etc. It contains 100 pages, and is profusely illustrated. Price, bound in cloth, 75c.; in paper covers, 60c., postpaid.

Dzierzon Theory;—presents the fundamental principles of bee-culture, and furnishes the facts and arguments to demonstrate them. 15 c.

Honey, as Food and Medicine, by Thomas G. Newman.—This pamphlet discourses upon the Ancient History of Bees and Honey, the nature, quality, sources, and preparation of Honey for the Market; Honey as food, giving recipes for making Honey Cakes, Cookies, Puddings, Foams, Wines, etc.; and Honey as Medicine, with many useful Recipes. It is intended for consumers, and should be scattered by thousands, creating a demand for honey everywhere. Published in English and German. Price for either edition, 4c.; per dozen, 50c.

Wintering Bees.—This contains the Prize Essays on this subject, read before the Centennial Bee-Keepers' Association. The Prize—\$25 in gold—was awarded to Prof. Cook's Essay, which is here given in full. Price, 10c.

Preparation of Honey for the Market, including the production and care of both comb and extracted honey, and instructions on the exhibition of bees and honey at Fairs, etc., by T. G. Newman. Price, 10c.

The Hive I Use—Being a description of the hive used by G. M. Doolittle. Price, 5c.

Extracted Honey; Harvesting, Handling and Marketing.—A 24-page pamphlet, by Ch. & C. P. Dadt, giving in detail the methods and management adopted in their apiary. This is certainly very useful hints.—Price 15c.

Bee Pasturage a Necessity, by Thomas G. Newman—Giving advanced views on this important subject, with suggestions what to plant, and when and how. Illustrated with 26 engravings. Price, 10c.

Practical Hints to Bee-Keepers, by Chas. F. Muth; 32 pages. It gives Mr. Muth's views on the management of bees. Price, 10c.

Food Adulteration; What we eat and should not eat. This book should be in every family, and ought to create a sentiment against adulteration of food products, and demand a law to protect the consumer against the numerous health-destroying adulterations offered as food. 200 pages 50c.

Kendall's Horse Book.—No book could be more useful to horse owners. It has 35 engravings illustrating positions of sick horses, and treats all diseases in a plain and comprehensive manner. It has recipes, a table of doses, and much valuable horse information. Paper, 25c.

Chicken Cholera, by A. J. Hill.—A treatise on its cause, symptoms and cure. Price, 25c.

Moore's Universal Assistant, and Complete Mechanic, contains over 1,000,000 Industrial Facts, Calculations, Processes, Trade Secrets, Legal Items, Business Forms, etc., of vast utility to every Mechanic, Farmer and Business Man. Gives 200,000 items for Gas, Steam, Civil and Mining Engineers, Machinists, Millers, Blacksmiths, Founders, Miners, Metallurgists, Assayers, Plumbers, Gas and Steam Fitters, Bronzers, Gilders, Metal and Wood Workers of every kind. The work contains 1,016 pages, is a veritable Treasury of Useful Knowledge, and worth its weight in gold to any Mechanic, Business Man, or Farmer. Price, postage paid, \$2.50.

OLDEST BEE PAPER IN AMERICA

THE AMERICAN BEE JOURNAL

ESTABLISHED IN 1861

DEVOTED EXCLUSIVELY TO PROGRESSIVE BEE CULTURE.

Free of postage in the United States or Canada.
 Postage to Europe 50 cents extra.

Entered at Chicago post office as second class matter.

The Silver Lining of the Clouds.

We have had much unfavorable weather recently—cold, chilling rains and northerly winds prevailing in the Central States, with frequent heavy frosts and snow flurries in the Northern and Eastern. During all of last week the weather was not only unfavorable for the farming interests, but bees also have suffered as well. Many colonies bred up especially early and quite strong, have consumed their stores voraciously, while those not bred up have dwindled till now very weak. One lot of a car-load located in this vicinity, shipped from Arkansas about the 20th of March, were very strong upon arrival and heavy with honey, having been wintered in two-story hives well filled with stores. In the eight weeks since shipment they have become greatly depleted in numbers, and have not only consumed all their stores, but it has been absolutely necessary to feed largely to prevent starvation. We must deeply impress upon all to look well to the condition of the bees—see that they are amply protected from cold and dampness, and are always provided with a future supply of honey, syrup or good candy, until settled weather shall have arrived; it will be found much more satisfactory to remove with the extractor a few pounds of honey that may be left over from feeding, at the beginning of white clover bloom, than to build up the starving remnants of colonies, or store away the empty hives which have been depopulated through sheer neglect to provide food when needed most.

The experience of this spring again

raises the doubt, whether it is most advisable to breed up colonies very strong till continuous mild weather has arrived—whether a prospective fruit surplus will recompense its more frequent failure?

But the provident, patient apiarist can realize no cause for despondency in our present disagreeable weather. A good surplus honey crop from the fruit trees is most frequently followed by a light yield from white clover. The prevalence of dry, hot weather during fruit bloom retards the spread and matting of the white clover rootlets and dwarfs its growth, thereby lessening the quantity of bloom and its duration. An examination this morning (May 13), revealed an unusual vigor in its growth and development in this locality; and the dandelion clumps, which usually give their blossoms only in succession, reveal scores each of flowers, which await but the sun's enlivening rays to burst forth in myriad discs of seeming gold, reflecting back its welcome from their emerald surroundings. Nor does the season forebode a repetition of last summer's drouth, to withhold the summer and fall bloom till too late to be harvested with profit; but everything is yet hopeful for the best. Get the bees in shape to take the fullest advantage of a bountiful honey bloom. It is said "every cloud has its silver lining," and we believe the despondency and gloom of the present will be transformed into mirth and gladness in the "sweet by-and-by."

Early Swarms in England.—The London *Horticultural Journal* says that Mrs. Wain at Walton-on-Thames, had a very strong swarm on April 21, and expected others the next day, had not the weather become showery and windy. The surplus sections have been on a month and are partly filled with comb.

International Exhibition in Germany.

We have received the following circular from the Executive Committee of the proposed International Congress to be held in Germany in July, 1883, which will explain itself to our readers:

In consequence of the many suggestions which have been put forward, the undersigned have combined for the holding at Hamburg, in July, 1883, of an International Exhibition of animals connected with agriculture.

Looking back to the acknowledged benefits to the farming interests which resulted from the first International Agricultural Exhibition which was held here in 1863, and which was also the first of its kind held in Germany, the undersigned are strongly of opinion that a repetition of the undertaking, after a lapse of 20 years, will be productive of similar service to the agricultural world, especially as the opportunity of international comparison, as well as competition, will be offered thereby, through the extensive progress which has been made in breeding during the last two decades.

Parties interested in this matter in all countries, are therefore cordially invited, both to take part in and to visit this Exhibition, which will be held in July, 1883, and will comprise the following departments, each of which are presided over by Special Committees:

1. Horse breeding (including mules and asses).
2. Cattle breeding.
3. Sheep breeding.
4. Pig breeding.
5. Bee-culture.
6. Pisci-culture.
7. Poultry breeding.
8. Stables, tools, etc., for the different branches of cattle breeding.
9. Scientific aids to the above.

By particular request of the Provisional Committee, the editor of the Weekly BEE JOURNAL has consented to take charge of the American bee interests at that Congress, and hopes to have the cordial co-operation of all American breeders. If we can breed up the "coming bee" and there exhibit it to the World, it will be an achievement worthy of the best endeavors of the present generation of bee masters. This is an opportunity for the sinking of all petty animosities and rivalries for the general good, and we hope that it will be accepted and improved as such.
