We alſo remark with much ſatisfaction that the Britiſh government has of late years thought fit to rendder the improvement of agriculture an object of public attention and encouragement, by the inſtitution of a *board of agriculture*.—About the year 1790, Sir John Sinclair, Bart. invited the clergy of the church of Scotland to tranſmit to him deſcriptions of the ſtate of their different pariſhes, with a view to the publication of what is called a *Statiſtical Account of Scotland*. The whole members of this body having readily complied with his requeſt, a work in 20 volumes octavo was compiled from the materials afforded by them, containing an account of the agriculture, manufactures, and population of the country. The ſame gentleman, about that period, was alſo active in obtaining the inſtitution of a private ſociety, called *The Britiſh Wool Society*, which was very ſucceſsful in calling the attention of the public to the improvement of that important article of national growth and manufacture. By theſe patriotic exertions, having acquired a conſiderable ſhare of popularity, he was encouraged on 15th May 1793, to make a motion in the houſe of commons, of which he

he was a member, for an addreſs to the crown, recommending the inſtitution of a board of agriculture. The chancellor of the exchequer, Mr Pitt, on perceiving that the propoſal was acceptable to the majority of the houſe, gave it a decided ſupport, and on the 17th May, to which the debate had been adjourned, the motion, was carried for an addreſs to his majeſty to inſtitute ſuch a board, at an expence not exceeding 3000l.—In conſequence of this application, a charter paſſed the great ſeal, incorporating the members of adminiſtration for the time, with the archbiſhops of Canterbury and York, and all their ſucceſſors in office, together with certain other noblemen and gentlemen, into a board or ſociety, by the name of the *Board* or *Society for the encouragement of Agriculture and internal improvement*, under the patronage of the crown; with power to the members to elect office-bearers and ſucceſſors to themſelves: and in the mean time Sir John Sinclair was appointed to be the firſt preſident, to continue in office till 25th March following; Sir John Caul, Bart. was appointed to be the firſt treaſurer, and Arthur Young, Eſq. ſo well known for his agricultural publications, was appointed ſecretary.

9 Commencement of its ſittings.

The regular ſittings of the board did not commence till 23d January 1794, ſince which time it has continued to exert a very conſiderable degree of activity in eſtabliſhing an extenſive foreign correſpondence, and in procuring and publiſhing every kind of uſeful domeſtic agricultural intelligence, ſome ſpecimens of which we ſhall afterwards have occaſion to notice. This board, ſoon after its inſtitution, alſo employed perſons of known reputation to prepare agricultural ſurveys of every county in the iſland of Great Britain.—Many of theſe ſurveys have been publiſhed, and form treatiſes upon this important art, which, for extent of intelligence and ability of execution, have not been exceeded in any age or country. The board has alſo obtained parliamentary rewards to ſome individuals for important diſcoveries, and has offered premiums for eſſays or treatiſes upon ſubjects connected with the purpoſe of its inſtitution, which have produced a great variety of valuable and ingenious diſquiſitions.

THEORY OF AGRICULTURE.

IN an art that is ſo neceſſary to mankind, and that has been ſo univerſally practiſed, it might perhaps be expected, that the principles upon which its operations depend, would have been by this time completely and accurately inveſtigated, and conſequently that a correct theory of agriculture could eaſily be exhibited. This, however, is by no means the caſe; and it is not a little ſingular, that, in this moſt uſeful of all arts, the theory ſhould ſtill be more defective than in almoſt any ſcience with which we are acquainted. It is fortunate, however, for the human race, that in moſt caſes, or at leaſt in all important arts, they ſucceed better in practice than in ſpeculation. During many ages, various artiſts were accuſtomed to extract the moſt ordinary, but moſt uſeful metals, from the ſtate of ore or earth in which nature produces them, and to reduce them back from their metallic form and luſtre, to a ſtate of ore or earth again. Theſe artiſts were unacquainted with the principles upon which the ſucceſs of their operations depended; and it is only within theſe few years that ſome ingenious chemiſts have ſucceſsfully inveſtigated the nature of theſe proceſſes, and have explained what they have called the oxygenation and diſoxygenation of metals. The ſame thing has happened in agriculture. Men have often cultivated the ground well, while they have ſpeculated ill concerning the mode of doing ſo.

10 The theory of agriculture is defective.

11 Difficulty of forming

Various reaſons render it ſtill more difficult to form a complete theory of agriculture, than of chemiſtry, mechanics, or other arts. In agriculture, an experiment cannot be made in an inſtant, or even in an hour, or in a day or two. A whole ſeaſon muſt paſs away before a ſingle experiment can be performed, and after all, as in other arts, the inquirer after truth may be miſled by ſome unobſerved circumſtances. Some fact, quite foreign to the experiment itſelf, ariſing out of the peculiar ſtate of the ſoil, or of the train of ſeaſons, may produce plentiful crops for a year or two, though, in ordinary circumſtances, no ſuch effect would follow; and the ingenious contriver of the experiment, who thought he had made an important diſcovery, may afterwards derive from it only diſappointment and mortification. But human life is too ſhort to admit of a very great variety of agricultural experiments to be performed by the ſame individual. After a few ſeaſons, he muſt leave his place to be occupied by a new inquirer, poſſeſſed of a different character and of different views. Unfortunately, till of late years, it was not uſual for huſbandmen to publiſh, and thus to immortalize and diffuſe over whole nations, the reſult of their private experience and reflections. Scattered over the face of great countries, and having little intercourſe with foreigners, or even with each other, they knew little of what was done by men engaged in the ſame profeſſion, though at no great diſtance.—In this way, the benefit of local diſcoveries was not communicated to the world at large, nor was an opportunity afforded of eradicating local prejudices and erroneous practices. As the ſtate of this valuable profeſſion is now rapidly altering in theſe reſpects, there is little doubt that we are faſt approaching towards a period at which it will be poſſible to exhibit a clear and correct theory of agriculture, or to arrange under a few ſimple heads the rules or principles upon which the practice of the art depends.—What we are now to offer, is not to be conſidered as perfect, nor even as poſſeſſing any near approximation towards a perfect theory of the huſbandman's art; but merely, ſuch a general ſtatement of its principles as reſults from the degree of information hitherto collected upon the ſubject.

12 What it ought to contain.

A theory, or general view of the principles of agriculture ſeems neceſſarily to reſolve itſelf into the two following inveſtigations: 1ſt, To inquire, among the great variety of vegetables that exiſt in nature, what particular plants ought to be regarded as moſt worthy of cultivation: and 2dly, To conſider the beſt mode of cultivating with ſucceſs the plants thus ſelected.

13 The value of vegetables is abſolute and relative.

With regard to the firſt of theſe diviſions of the ſubject, or the vegetables that ought to be choſen as moſt valuable and worthy of cultivation, it may be obſerved, that the value of a plant is of two kinds, *abſolute*, or *relative*;

Vegetables Food for Man.

relative: The *abſolute* value of a plant depends upon its fitneſs to afford ſubſiſtence to the human ſpecies, whereas its *relative* value conſiſts of the tendency which the cultivation of it will have to enrich a particular huſbandman, or claſs of huſbandmen, either becauſe their lands are well adapted for its growth, or becauſe there is a ready market for it in the vicinity, where it bears a high price.

14 They are uſeful directly and indirectly.

Concerning the abſolute value of plants, or their tendency to afford ſubſiſtence to mankind, it is to be obſerved, that ſome plants are *directly* uſeful or valuable, becauſe they are immediately conſumed as food by man, ſuch as wheat, oats, or potatoes; whereas mankind derive ſubſiſtence from another claſs of plants, only in an *indirect* manner, by giving them to cattle, and afterwards eating the fleſh of theſe cattle, as happens with regard to graſs and ſtraw of all kinds.

SECT. I. *Of Vegetables to be cultivated as Food for Man.*

15 Men feed on fruits and roots.

SOME vegetables afford ſubſiſtence to the human ſpecies by means of the fruit that grows upon them, which hangs, and is brought to maturity in the air, at the ſummit of their ſtems. Other vegetables derive their value from producing roots which come to maturity in the boſom of the ſoil, and are dug from thence to be conſumed by mankind.

16 Fruit trees not truſted to for food,

Of fruit-bearing vegetables, thoſe called trees, which riſe aloft with a ſtrong trunk, are the moſt permanent and remarkable. It is ſaid that a ſpot of ground, occupied by ſome kinds of trees, ſuch as cheſnuts or dates, is capable of producing a very great portion of food, uſeful for the ſupport of the human ſpecies. One advantage attending the cultivation of ſuch vegetables, would be that, after the trees are planted, and ſecured by fences for a few years againſt animals, they would for ever after, or at leaſt for many years, continue to grow and flouriſh without care or labour. It does not appear, however, that in any nation of ancient or modern times, foreſts of fruit-bearing trees have been reared with a view to afford ſubſiſtence to the community. For this two reaſons may be aſſigned. In the firſt place, a conſiderable number of years muſt elapſe, before ſuch plants could arrive at maturity, and fulfil the purpoſe of their deſtination. Of whatever uſe therefore they might be to future ages, it is evident that they could afford little benefit to the generation which planted them. But in a queſtion about ſubſiſtence, mankind are uſually under the neceſſity of conſidering their own immediate wants, and hence they have been led to the cultivation of ſuch plants, as afford the moſt ſpeedy reward for the efforts of their induſtry. Another reaſon for preferring the culture of ſmall annual plants, to the greater and more permanent productions of nature, would ariſe, in the early ages of the world, from the turbulent ſtate of ſociety and the frequency of wars. A community that ſhould depend for its ſubſiſtence upon the fruit of foreſt trees, might be ruined for half a century by the inroad of an enemy. An example of this was exhibited in the war between Great Britain and her North American colonies. When the parent ſtate hired the ſavages on the weſtern frontier, to join her party, and to make inroads upon the coloniſts, the latter retaliated upon the ſavages in the following manner. Several of the colonies united

17 becauſe they ripen ſlowly, and are deſtroyed in war.

in ſending an expedition againſt the Indians. The bodies of militia employed upon this expedition, were ſurpriſed to find ſmall corn fields around a conſiderable number of the Indian hamlets. They were not ſatisfied however with deſtroying the huts of the natives, and theſe incipient efforts of ſavage induſtry; but they anxiouſly ſought out and deſtroyed every fruit-bearing tree that they found in their progreſs of almoſt a thouſand miles, thereby rendering the wilderneſs utterly uninhabitable to a people deſtitute of agriculture, and who could not always depend for ſubſiſtence upon their ſucceſs in hunting. From this example we ſee that the frequent wars ariſing from the barbarous character of ancient nations, would compel them to ſeek ſubſiſtence, not from the fruit of foreſt trees, but from grain, which ſpeedily arrives at maturity, and which when deſtroyed can ſoon be renewed. Thus war becomes a leſs waſteful ſcourge to the human race, and communities are enabled ſpeedily to recover from the devaſtation which it produces. Had the nations of Europe depended for ſubſiſtence, upon any fruits which could not be ſpeedily reſtored when deſtroyed, it is evident, that, in the late ſanguinary conflict, the greater number of them muſt have been irretrievably ruined.

Vegetable Food for Man

18 Men rather truſt to grain.

Hence it appears that the cultivation of plants of annual growth, as a ſource of ſubſiſtence, is favourable to the permanence of civilization in the world; and that before nations can venture to rely for their ſubſiſtence upon the fruit of plants of ſlower growth, their character muſt have arrived at a degree of moral amelioration far ſuperior to what it has ever been known to poſſeſs.

Of annual plants cultivated for fruit, wheat has always been accounted the moſt valuable. This has probably ariſen from the extreme facility with which the flour of it undergoes a proceſs of fermentation, which renders it capable of becoming a more light and agreeable kind of bread than the flour of any other grain. This quality is believed to ariſe from a quantity of a ſubſtance contained in wheat that is of the ſame nature with the gluten, or glue, that is prepared from animal bodies. In other reſpects, however, is does not appear that wheat is more valuable than ſome other kinds of grain; by means of long boiling, a given weight of barley, or even of oats, will render a quantity of water as thick or full of mulcilage as can be done by the ſame weight of wheat.

19 The uſe of grain has been objected to.

It may not be improper here to remark, that, in modern times, an author of no mean reputation, has ariſen, who endeavours to prove that wheat ought not to be cultivated, nor bread to be eaten. This is M. Linguet, who has written a treatiſe expreſsly upon the ſubject, and, ridiculous as the aſſertion may ſeem, it has been thought worthy of a formal refutation by Dr Tiſſot.—One of M. Linguet's arguments it, that wheat impoveriſhes the ground on which it grows: but in oppoſition to this, Dr Tiſſot argues, that corn is more eaſily cultivated than graſs; and that conſequently in the country he ſpeaks of, Switzerland, the beſt fields are appropriated to hay, and the worſt to corn. "If there are ſome diſtricts of very poor land (ſays he) almoſt entirely ſown with corn, they are not poor becauſe they produce only corn, but becauſe they are not fit to produce any thing elſe. Their ſoil is ſo bad, that they can grow but very little fodder: conſequently they maintain only ſuch cattle as are abſolutely neceſſary for

labour,

Vegetables Food for Man.

labour; and thoſe are ill fed, and frequently periſh, They have but little manure, and their crops are ſmall; for large crops of all ſorts can only be expected from lands naturally rich or ſtrongly manured. Thus the poverty of the inhabitants is only owing to their poſſeſſing an ungrateful ſoil. What proves evidently that it is the natural ſoil which is in the fault, and not the corn which impoveriſhes it, is, that where there is meadow and arable land, the price of the meadow land is much more conſiderable than that of the arable. In moſt parts of this country the proportion is nearly ten to one; and there are even ſome meadows, for one part of which they would give 30 of field lands; and ſome of vines, for which 100 of arable would be given. Thoſe diſtricts where the ſoil will produce nothing but corn, are poor; but in thoſe which furniſh fodder, and alſo fine crops of grain, the inhabitants are wealthy and happy, unleſs they are oppreſſed by taxes."

M. Linguet draws another objection from the length of time required to cultivate wheat: but Tiſſot, by another calculation, ſhows, that 48 days work throughout the year would cultivate more wheat than is ſufficient for a family of ſix perſons. The time neceſſary for cultivation of arable land alſo does not increaſe in proportion to its extent; but in caſe more is cultivated than is requiſite for the ſubſiſtence of the family, a trade is formed, which might be increaſed to an unlimited extent. He then compares the time requiſite for the cultivation of vines, which are recommended by M. Linguet, and finds it to be much longer than that required for wheat. "I know very well (ſays he) that the one requires cattle, and the other does not: but theſe cattle, far from being expenſive, will, if properly managed, increaſe the gain of the farmer: therefore they muſt not be looked upon as any expence. Corn is ſubject to many accidents, but vines are ſubject to many more; thoſe which the vines ſuffer, ſometimes ſpoil the vintage for ſeveral years; whereas thoſe which happen to arable land, only ſpoil the crop for the ſeaſon; and as the expence of cultivating vines, for which only manual labour can be employed, is much more conſiderable, therefore the *vigneron* (or perſon who cultivates vines), who engages more largely than the farmer, will conſequently be a much greater loſer if unſucceſsful.—Hay is alſo ſubject to frequent and very diſagreeable accidents; the ſecuring it is ſometimes very difficult; and, when it is badly made, it is very hurtful to cattle.—A ſingle fact will be ſufficient to prove the caſualties to which hay is ſubject; viz. that it varies in price as much as grain. Accidents of hay mows taking fire are but too frequent: and this is not to be feared in corn mows."

The other objections of M. Linguet to wheat appear to be quite frivolous; ſo that concerning the cultivation of this grain, Dr Tiſſot draws the following concluſions: "It appears then, from what has been ſaid, that wheat is not a commodity that is impoveriſhing in itſelf; and that this grain will grow indifferently at leaſt in lands and ſituations which are unfavourable to other plants. This grain is likewiſe adapted to moſt climates; and if there are diſtricts almoſt entirely ſown with wheat, and yet poor, it is the fault of the ſoil, and not of this uſeful grain."

But the moſt extraordinary argument perhaps ever thought of on this ſubject is M. Linguet's aſſertion, that the uſe of wheat, or bread made from it, is detrimental to population; and that the countries where this grain is cultivated are poor and thinly inhabited, whereas thoſe which abound with vineyards and paſture lands are rich and populous. But this, in Dr Tiſſot's opinion, ſhows only that one ſoil is more rich than another, and that a fertile ſoil will maintain moſt inhabitants. "No perſon (ſays he) is more capable of aſſigning the cauſe of the ſubjection of the Roman empire to the northern powers, than M. Linguet; but he cannot ſurely be ſerious when he ſays, that they were enabled to conquer it becauſe thoſe northern countries produced no corn, and that population decreaſed ſince the introduction of grain. I ſhall make three obſervations on this paſſage: Firſt, The armies of Guſtavus Adolphus, Charles XII. and the king of Pruſſia, whoſe food was bread, would be as formidable againſt the Italians of thoſe times, who eat leſs than was eaten in the days of Scipio, as their anceſtors were 1400 years ago againſt the Romans: and M. Linguet muſt certainly know, that thoſe Greeks who ſubſiſted on bread, thoſe Romans who ate nothing but bread and vegetables in pottage, ſubdued all the known world, among whom were many nations who ate leſs bread than themſelves. A Roman ſoldier's allowance of bread was much greater than what ſoldiers have at preſent; and by the uſe of this food they had much more ſtrength than our modern ſoldiers can boaſt of. The allowance to a Roman ſoldier was 64 pounds of wheat *per* month; and this he was ſtrictly forbidden either to ſell or exchange. Their ſoldiers had very ſeldom any cheeſe, bacon, or pulſe; ſo that wheat was almoſt their only food, and the proportion was double what is allowed ſoldiers in our days. They ate it in bread, in flour-milk, and in thin cakes; and they were not ſubject to epidemic or putrid diſorders, which is too much the caſe with our modern armies. We may eaſily judge, from the weight of their accoutrements, that the Roman ſoldiers were not poſſeſſed of leſs perſonal ſtrength than thoſe who compoſe the armies at this day: they were not leſs brave, nor did their food render them in any way unhealthy: on the contrary, where there is ſuch difficulty in procuring a ſupply of good animal food to an army, as is often the caſe in modern times, it is probable that reducing them to the ſimple diet of a Roman ſoldier would be the moſt proper method of preventing epidemic diſeaſes among them. Secondly, It is very doubtful whether thoſe countries were more populous formerly than they are at this time; it is even probable that they were leſs ſo. Laſtly, The people of theſe northern countries were not without wheat; is was the baſis of their food and drink: without quoting other authors who atteſt it, ſuffice it to ſay, that Tacitus affirms it," &c.

In this laſt particular, however, our author appears to be miſtaken; but whatever may be in this, we apprehend that few of our readers will entertain any doubt concerning the wholeſomeneſs of wheat, or the propriety of making it into bread after once it is cultivated.

Vegetables Food for Man.

20

Oats a valuable grain.

After wheat, oats have in our country been conſidered as of very great importance. It is a hardy and beautiful plant; grows with little cultivation, and is particularly well ſuited for lands newly brought in from a ſtate of nature, upon which it was always uſed at the firſt crop, till the introduction of the turnip huſbandry.

Vegetables Food for Man.

bandry. The meal of it is usually very coarsely ground, and mixed with a considerable quantity of the inner covering of the grain. Hence it has always a considerable degree of roughness, and is harsh, and unsuited to very delicate constitutions; but this very harshness, from its stimulant effect, producing a feeling of warmth in the stomach, renders it more grateful to persons much exposed to the open air, and accustomed to hard labour, who account it a hearty kind of food. Essentially, and in its intrinsic qualities, this grain differs little from some others.

21 Barley valuable from its convertible to a saccharine substance.

Barley is chiefly valued in consequence of the facility with which it produces a great quantity of saccharine matter by the process of vegetation or malting, which fits it for the preparation of vinous or spirituous liquors. Pease are also sometimes used when grinded into meal as an article of human food; but on account of their viscid and indigestible quality, they can never become valuable in that point of view, unless to persons engaged in the open air, in the most active and severe kinds of labour.

22 Different kinds of grain are not essentially different.

In other respects, however, it does not appear that there is much difference in point of quality or wholesomeness between the various kinds of grain cultivated in different countries. They are all capable of affording nourishment to the human constitution, and of preserving it in health and vigour: When grinded into meal, they require little farther preparation, and are easily made into bread, or otherwise prepared for immediate consumption, by being mixed according to the fancy or taste of different nations, with a small quantity of water, or any other liquid.

23 Roots used as human food.

Of the roots which are used to afford subsistence to man, the potato has hitherto been the principal. The rest, consisting chiefly of carrots, turnips, and parsnips, are never used as a sole nutriment, being rather adopted for the purpose of giving variety and relish to other food, and chiefly to butchers meat. The potato, however, is in some measure an exception to this general rule. It contains a large quantity of starch, which does not seem inferior to the starch prepared from wheat, so far at least as that ingredient is to be regarded as contributing to the nourishing qualities of the grain. Its taste resembles, more nearly than any other root, the taste of bread; and accordingly it is daily beginning to be more extensively used, and to form a larger portion of the food of the poor. The celebrated Dr Adam Smith long since remarked its tendency to produce a strong and handsome race of people, as demonstrated by its effect upon the common people of Ireland, who have for a considerable length of time in a great measure subsisted upon it.

24 They produce more food on the same extent of soil than grain.

It is to be observed concerning all the roots now mentioned, that a crop of them always contains a much larger quantity of human food than a crop of any kind of grain upon the same extent of ground. A Scots acre of good land, which will not produce more than 1280 pounds weight of oatmeal, will easily produce 20,000 pounds weight of potatoes, and will sometimes in favourable seasons produce 30,000 or 35,000 pounds weight of that valuable root. Supposing one pound of oatmeal to contain as much nourishment as four pounds of potatoes, still it is evident, that, where an extent of territory employed in the production of oats can only support one million of people, the same territory employed in the cultivation of potatoes will support fifteen millions of persons.

Vegetable Food for Man.

Potatoes, however, and all the other roots, have hitherto possessed these radical defects: The carriage of them is extremely expensive, in consequence of their weight, arising from the vast quantity of moisture they contain. Hence they can only be cultivated in abundance in the vicinity of great towns, or where they are meant to be consumed upon the farm as the food of cattle.

25 Their defect as food.

26 The transportation of them expensive.

Roots are also incapable of long preservation. In the winter they are destroyed by frost, and in summer by heat, which causes them to vegetate or to corrupt; both of which changes render them unfit to be used as food.

27 Are unfit for long preservation.

These roots are also much more bulky than grain in proportion to the quantity of nourishment contained in them. Hence they are rendered less fit to be consumed by persons engaged in sedentary professions. Such persons accordingly seldom fail to find them injurious to the stomach, by their bulkiness, and their tendency to injure the powers of digestion, by producing flatulencies and other unpleasant consequences.

28 Too bulky for the stomach.

On the whole, the difference between these succulent roots and the grain of corn plants seems to amount to this, that, although they are both formed of similar substances, the potato being analogous to wheat, and the carrot and parsnip to rye, or rather to barley after it has been converted into malt, yet, as the roots are formed in the bosom of the soil, and are of a loose and watery texture, their formation requires from nature a slighter effort than the bringing to perfection the small grains which are produced in the air at the top of corn plants. She therefore compensates by an abundant crop the diminished quality of her work.

29 Wherein they differ from grain.

Hence it has appeared an important problem in economics, to devise a plan by which the succulent roots of vegetables may be deprived of their superfluous moisture, that thus human art may perform for them what nature has not accomplished; and that they may be rendered completely equal in value to grain in point of quality, while in quantity they are so superior. With this view different processes have been adopted. Potatoes have been grated down in their raw state, and repeatedly washed with water: the result of which operation is, that the starch contained in them is obtained with great labour; but the rest of the root is lost; and this operation cannot be applied to other kinds of roots with success. Another mode of accomplishing the object was devised a few years ago by M. Grenet, and published in the Journal of the Lyceum of Arts of Paris. It is performed in this manner: The potatoes must first be boiled by the heat of the steam of boiling water, without touching the water itself. They are then stript of their skin, and allowed to cool, and made use of in the following way:—A white iron tube of two inches diameter, and eight inches in length, open at the one end and close at the other, is everywhere perforated with small holes, and a round piece of wood is prepared, which easily goes into the tube, but which at the same time fills it. Things being thus in readiness, a quantity of the potatoes, boiled as already mentioned, is put into the tube till it is full. They are then forcibly rammed down with the round piece of wood or piston; the consequence of which operation

30 How the may be rendered equal in value to grain.

31 Potato-starch.

32 Grenet's mode of granulating potatoes.

Vegetables Food for Man.

operation is, that they are forced through the little holes in the ſides of the tube, and come out in the ſhape of worms. They are received upon linen cloths, covered with unſized paper, and dried in the heat of the ſun, or in a warm room. The ſmall pieces muſt be ſtirred from time to time; and it is ſaid, that in leſs than 12 hours, the preparation dries ſo as to be capable of being preſerved.

The defect of this proceſs evidently is, that it is a petty operation, which can only proceed ſlowly, and upon a diminutive ſcale. It is therefore unlikely to be adopted in the great operations of an extenſive agriculture, as a mode of preparing or preſerving human food.

33 Mr Forſyth's proceſs for converting roots into flour.

At the beginning of the preſent year 1802, another proceſs for accompliſhing this important object was contrived by Robert Forſyth, Eſq. advocate. Of this proceſs, which has been communicated to the Board of Agriculture, we are authorized to give the following account:

The whole difficulty of diſcovering a proceſs, with the view to render ſucculent roots as eaſily preſerved and tranſported, and therefore in every reſpect as valuable as grain, ſeems to ariſe from our not having the command of ſuch a degree of ſteady and vigorous, but moderate heat, as will deprive them of their moiſture, while at the ſame time they are prevented from being burnt or ſcorched in the way that coffee-beans are treated before being grinded. This requiſite degree of heat may be obtained in a very cheap and eaſy manner, by making uſe of the ſteam of boiling water, which never can burn any vegetable ſubſtance. Upon this principle, Mr Forſyth's proceſs is founded, and is conducted in the following manner:

1ſt, Let a quantity of potatoes, or carrots, or parſnips, &c. be waſhed, and then cut or chopped into very ſmall pieces,

2dly, Lay them upon a metallic plate, and dry them with the heat of ſteam tranſmitted through the metal. They are then in a ſtate analogous to grain, and ſeem capable of being preſerved for any length of time.

3dly. Reduce them into flour or meal, by grinding in any mill, or with any inſtrument capable of grinding grain.

The meal or flour thus prepared has no tendency to attract moiſture from the atmoſphere, and may be preſerved during any length of time, if cloſely preſſed or packed. Without this precaution, Mr Forſyth has preſerved it for ſix months, when it had been coarſely grinded in a coffee mill.

The drying proceſs is not tedious. As potatoes contain a great quantity of ſtarch or gummy matter, the pieces of them, while drying, are apt to adhere to each other; they muſt therefore be frequently turned or ſtirred during that part of the operation. When dry, they are almoſt as hard as barley, and taſte ſomewhat like the ſkin of a roaſted potato.

Carrots and parſnips contain leſs gummy matter. They require leſs attention while drying, and do not become ſo hard. They may be grinded with eaſe. Their flour is very ſweet to the taſte. Its ſmell is fragrant, and though the taſte of the roots cannot be ſaid to be altered, it is rendered rich and agreeable by the concentration produced by the proceſs. This is more particularly the caſe with regard to the parſnips. Their meal, when coarſely grinded, and expoſed to the air for a month or two, loſes its grateful ſmell, but the taſte continues unchanged. The taſte is communicated very rapidly to lukewarm water, by pouring it upon the meal, ſo that it may probably prove of ſome value when ſubjected to the vinous fermentation; and it ſeems not improbable, that if ſugar is ever to be produced in abundance from plants of European growth, it muſt be by preparing them according to this proceſs.

Vegetables Food for Man.

Mr Forſyth performed his experiments with a ſteam apparatus, which, with ſome alterations, may prove not unſuitable, when erected upon a great ſcale.

34 Mr Forſyth's ſteam apparatus.

A, Plate XII, A ſhallow veſſel of white iron, one foot ſquare, and two inches in depth, for containing ſubſtances to be dried.

B, a ſmall round veſſel, in which water is kept boiling by a lamp, C, with three wicks.

D, a tube, by which the ſteam paſſes into E, which contains the drying veſſel A, and is cloſely ſoldered all round to the bottom of it.

F, a tube, by which the water formed by the condenſed ſteam flows from the ſteam veſſel, E, back into the boiler B, entering at the bottom of the boiler.

G, a crooked tube, by which the ſuperfluous ſteam eſcapes into the open air. It is crooked, that it may retard the paſſage of the ſteam when the veſſel is at work, which forces it to depoſite more of its heat on the bottom of the drying veſſel A.

H, a tube by which the boiler B is filled with hot water.

I, a tube paſſing up through the centre of the boiler, and ſerving as a chimney to the lamp C. It does not communicate with the water in the boiler.

K ſhows the figure of the cover of the drying veſſel A. The cover has a groove or gutter LL, paſſing round its lower edge. The vapour which riſes from the roots when drying, condenſes on touching the cover, and flows down to the gutter, from which it eſcapes in the ſtate of water, by a hole left for that purpoſe at each corner. The cover is only uſed for the neatneſs requiſite in making experiments.

The whole is ſupported by four moveable feet, attached to the corners of the drying veſſel A, but not appearing in the figure. Every part of it is made of white iron or tinned plate.

Inſtead of the lamp C, a ſmall iron pan filled with pieces of burning charcoal, was ſometimes uſed to keep the water boiling, and a ſtill more convenient plan was at times adopted during the winter ſeaſon. It conſiſted of reſting the bottom of the boiler B, upon the front of the grate of the chamber, while a fire was burning, the reſt of the inſtrument being at the ſame time ſupported by a rope attached to the back of a chair, to a nail or peg in the wall for hanging a picture, or to any other convenient ſupport. When uſed in this laſt manner, however, the inſtrument has this defect, that the water in the tube H boils over at times into the fire, which might be avoided, by placing the tube on the oppoſite ſide of the boiler.

Upon the above contrivance, it may be remarked, that a kiln formed of a large metallic plate, heated by the ſteam of boiling water, may prove valuable in many proceſſes. In particular, it will probably be found

Food for Cattle.

found useful for drying malt, with a view to prevent the ale formed of it from having a brown colour. It may also, perhaps, be used with success for drying wheat that is intended to be sown, to prevent the future crop from suffering by mildew, as will be afterwards mentioned; and it affords a ready and cheap mode of drying not only roots, but all vegetable productions, without burning them, or altering their taste or other essential properties.

Sect. II. *Of the most proper kinds of Vegetables to be raised for the purposes of feeding Cattle.*

Though this must be an article of the utmost consequence to every farmer, we do not find that it has been much considered. Mr Anderson seems to have been the first writer on agriculture who hath properly attended to this subject; and what he hath wrote upon it, is rather a catalogue of desiderata than any thing else: and indeed the desiderata on this subject are so many and so great, that we must acknowledge ourselves very unable to fill them up.——To attain to a competent knowledge in this respect, the following things must be taken into consideration. (1.) The

35 Qualities of the food requisite for cattle.

wholesomeness of the food for cattle, with regard to health and strength, or fatness. (2.) The quantity that any extent of ground is capable of yielding. (3.) The quantity necessary to feed the different kinds of cattle. (4.) The labour of cultivation; and, (5.) The soil they require to bring them to perfection, and the effect they have upon it.

With regard to the wholesomeness, it is plain, that as the natural food of wild cattle is the green succulent plants they meet with all the year round, food of this kind, could it be had, must be preferable to hay; and accordingly we find that cattle will always prefer succulent vegetables where they can get them. To find plants of this kind, and having proper qualities in other respects, we must search among those which continue green all the year round, or come to their greatest perfection in the winter time.—Of these, cabbages

36 Cabbages, their properties.

bid fair for holding the first place; both as being very succulent, and a very large quantity of them growing upon a small space of ground. In Mr Young's Six Months Tour, we have an account of the produce of cabbages in many different places, and on a variety of soils. The produce by Mr Crow at Keplin, on a clay soil, was, on an average of six years, 35 tons per acre; by Mr Smelt at the Leases, on a sandy gravel, 18 tons per acre; by Mr Scroop at Danby, on an average of six years, 37 tons per acre: and the general average of all the accounts given by Mr Young, is 36 tons per acre.

Cabbages, however, have the great inconveniency of sometimes imparting a disagreeable flavour to the milk of cows fed with them, and even to the flesh of other cattle. This, it is said, may be prevented by carefully picking off the decayed and withered leaves: and very probably this is the case; for no vegetable inclines more to putrefaction than this; and therefore particular care ought to be taken to pull off all the leaves that have any symptoms of decay. Dr Priestley

37 Air rendered noxious by them.

found that air was rendered noxious by a cabbage leaf remaining in it for one night, though the leaf did not show any symptom of putrefaction.—For milk cows, probably, the cabbages might be rendered more proper food by boiling them.

Food for Cattle.

The culture of the turnip-rooted cabbage has lately been much practised, and greatly recommended, particularly for the purpose of a late spring feed; and seems indeed to be a most important article in the farming economy, as will be shown in its proper place.

38 Turnip-rooted cabbage.

Turnips likewise produce very bulky crops, though far inferior to those of cabbages. According to Mr Young's calculations, the finest soil does not produce about five tons of turnips per acre; which is indeed a very great disproportion: but possibly such a quantity of turnips may not be consumed by cattle as of cabbages; an ox, of 80 stone weight, ate 210lb. of cabbages in 24 hours, besides seven pounds of hay.

39 Turnips.

Carrots are found to be an excellent food for cattle of all kinds, and are greatly relished by them. In a rich sand, according to Mr Young's account, the produce of this root was 200 bushels per acre. In a finer soil, it was 640 bushels per acre. A lean hog was fatted by carrots in ten days time: he ate 196 lb; and his fat was very fine, white, firm, and did not boil away in the dressing. They were preferred to turnips by the cattle; which having tasted the carrots, soon became so fond of them, as difficultly to be made to eat the turnips at all. It is probable, indeed, that carrots will make a more wholesome food for cattle than either cabbages or turnips, as they are strongly antiseptic; insomuch as to be used in poultices for correcting the sanies of cancers. It is probably owing to this, that the milk of cows fed on carrots is never found to have any bad taste. Six horses kept on them through the winter without oats, performed their work as usual, and looked equally well. This may be looked upon as a proof of their salubrity as a food; and it certainly can be no detriment to a farmer to be so much versant in medical matters, as to know the impropriety of giving putrescent food to his cattle. It is well known what a prodigious difference there is in the health of the human species when fed on putrid meats, in comparison of what they enjoy when supplied with food of a contrary nature; and why may there not be a difference in the health of beasts, as well as of men, when in similar circumstances?—It is also very probable, that as carrots are more solid than cabbages or turnips, they will go much farther in feeding cattle than either of them. The above-mentioned example of the hog seems some kind of confirmation of this: he being fed, for ten days together, with 21lb. less weight of carrots, than what an ox devoured of cabbages and hay in one day. There is a great disproportion, it must be owned, between the bulk of an ox and that of a hog; but we can scarce think that an ox will eat as much at a time as ten hogs. At Parlington in Yorkshire, 20 work horses, four bullocks, and six milk cows, were fed on the carrots that grew on three acres; from the end of September till the beginning of May; and the animals never tasted any other food but a little hay. The milk was excellent, and 30 hogs were fattened upon what was left by the cattle.

40 Carrots.

Potatoes likewise appear to be a very palatable food for all kinds of cattle; and not only oxen, hogs, &c. are easily fed by them, but even poultry. The cheapness of potatoes compared with other kinds of food for cattle, cannot well be known, as, besides the advantage

41 Potatoes.

of

Food for Cattle.

of the crop, they improve the ground more than any other known vegetable. According to a correſpondent of the Bath Society *, "roaſting pork is never ſo moiſt and delicate as when fed with potatoes, and killed from the barn doors without any confinement. For bacon and hams, two buſhels of pea-meal ſhould be well incorporated with four buſhels of boiled potatoes, which quantity will fat a hog of twelve ſtone, (fourteen pounds to the ſtone). Cows are particularly fond of them: half a buſhel at night, and the ſame proportion in the morning, with a ſmall quantity of hay, is ſufficient to keep three cows in full milk; they will yield as much and as ſweet butter as the beſt graſs. In fattening cattle, I allow them all they will eat: a beaſt of about 35 ſtone will require a buſhel per day, but will fatten one-third ſooner than on turnips. The potatoes ſhould be clean waſhed, and not given until they are dry. They do not require boiling for any purpoſe but fattening hogs for bacon, or poultry; the latter eat them greedily. I prefer the champion potato to any ſort I ever cultivated. They do not anſwer ſo well for horſes and colts as I expected (at leaſt they have not with me), though ſome other gentlemen have approved of them as ſubſtitutes for oats."

* *Letters and Papers on Agriculture, &c.* vol. iii. art. 16.

The above-mentioned vegetables have all of them the property of meliorating, rather than exhauſting the ſoil; and this is certainly a very valuable qualification: but carrots and cabbages will not thrive except in ſoils that are already well cultivated; while potatoes and turnips may be uſed as the firſt crops of a ſoil with great advantage. In this reſpect, they are greatly ſuperior to the others; as it may be diſagreeable to take up the beſt grounds of a farm with plants deſigned only for food to cattle.

42 Buck-wheat.

Buck-wheat (*Polygonum fagopyrum*) has been lately recommended as an uſeful article in the preſent as well as other reſpects. It has been chiefly applied to the feeding of hogs, and eſteemed equal in value to barley; it is much more eaſily ground than barley, as a malt-mill will grind it completely. Horſes are very fond of the grain; poultry of all ſorts are ſpeedily fattened by it; and the bloſſom of the plant affords food for bees at a very opportune ſeaſon of the year, when the meadows and trees are moſtly ſtripped of their flowers. Probably the grain may hereafter be even found a material article in diſtillation, ſhould a ſufficient quantity be raiſed with that view. From the ſucceſs of ſome experiments detailed in the Bath Society Papers, and for which a premium was beſtowed, it has been inferred, that this article ought in numerous caſes to ſuperſede the practice of ſummer-fallowing.

43 Whins an excellent food for horſes.

Whins have lately been recommended as a very proper food for cattle, eſpecially horſes; and are recommended by Mr Anderſon in a particular manner. They have this advantage that they require no culture, and grow on the very worſt ſoil; but they are troubleſome to cut, and require to be bruiſed in a mill conſtructed for the purpoſe; neither is the ground at all meliorated by letting whins grow upon it for any length of time. Notwithſtanding theſe diſadvantages, however, as whins continue green all the year round, and when bruiſed will afford an excellent ſucculent food, which ſeems poſſeſſed of ſtrongly invigorating qualities, they may be looked upon as the cheapeſt winter food that can poſſibly be given to cattle.—According to the calculations of Mr Eddiſon of Gateford, a ſingle acre, well cropped with whins, will winter ſix horſes: at three or four years growth, the whole crop ſhould be taken cut cloſe to the ground, and carried to the mill; in which the whins are to be bruiſed, and then given to the horſes. Four acres ought to be planted, that one may be uſed each year, at the proper age to be cut; and he reckons the labour of one man ſufficient for providing food to this number of horſes. He ſays, they all prefer the whins to hay, or even to corn.

Food for Cattle.

44 Burnet.

The herb called *burnet* hath likewiſe been recommended as proper food for cattle, on account of its being an evergreen; and further recommended, by growing almoſt as faſt in winter as in ſummer. Of this herb, however, we have very various acounts. In a letter addreſſed by Sir James Caldwell, F. R. S. to the Dublin Society, the culture of this plant is ſtrongly recommended on the authority of one Bartholomew Rocque, farmer at Walham Green, a village about three miles ſouth-weſt of London.

45 Recommended by Sir James Caldwell.

What gave occaſion to the recommendation of this plant, was, that about the year 1760, Mr Wych, chairman of the committee of Agriculture of the London Society for the encouragement of arts, manufactures, and commerce, came to Rocque (who was become very eminent by the premiums he had received from the Society), and told him, he had been thinking, that as there are many animals which ſubſiſt wholly upon the fruits of the earth, there muſt certainly be ſome plant or herb fit for them that naturally vegetates in winter; otherwiſe we muſt believe the Creator, infinitely wiſe and good, to have made creatures without providing for their ſubſiſtence; and that if there had been no ſuch plants or herbs, many ſpecies of animals would have periſhed before we took them out of the hands of nature, and provided for them dry meat at a ſeaſon, when, indigenous plants having been indiſcriminately excluded, under the name of weeds, from cultivated fields and places ſet apart for natural graſs, green or freſh meat was no longer to be found.

Rocque allowed the force of this reaſoning; but ſaid, the knowledge of a graſs, or artificial paſture, that would vegetate in winter, and produce green fodder for cattle, was loſt; at leaſt, that he knew of no ſuch plant.—Mr Wych, however, knowing how very great that advantage would be of diſcovering a green fodder for winter and early in the ſpring, wrote to Bern, and alſo to ſome conſiderable places in Sweden, ſtating the ſame argument, and aſking the ſame queſtion. His anſwers to theſe letters were the ſame that had been given by Rocque. They owned there muſt be ſuch plant, but declared they did not know it.

Mr Wych then applied again to Rocque; and deſired him to ſearch for the plant ſo much deſired, and ſo certainly exiſting. Rocque ſet about this ſearch with great aſſiduity; and finding that a pimpernel, called *burnet*, was of very ſpeedy growth, and grew nearly as faſt in winter as in ſummer, he took a handful of it and carried it into his ſtable, where there were five horſes; every one of which ate of it with the greateſt eagerneſs, ſnatching it even without firſt ſmelling it. Upon the ſucceſs of this experiment he went to London, and bought all the burnet ſeed he could get, amounting to no more than eight pounds, it having been only uſed in ſalads; and he paid for it at the rate of

Food of Cattle.

of 4s. a pound. Six of the eight pounds of feed he fowed upon half an acre of ground, in March, in the year 1761, with a quarter of a peck of ſpring wheat, both by hand. The ſeed being very bad, it came up but thin. However, he ſowed the other two pounds in the beginning of June, upon about ſix rood of ground: this he mowed in the beginning of August; and at Michaelmas he planted off the plants on about 20 rood of ground, giving each plant a foot every way, and taking care not to bury the heart. Theſe plants bore two crops of ſeed the year following; the firſt about the middle of June, the ſecond about the middle of September; but the June crop was the beſt. The year after, it grew very rank and produced two crops of ſeed, both very good. As it ought not to be cut after September, he let it ſtand till the next year; when it ſheltered itſelf, and grew very well during all the winter, except when there was a hard froſt; and even during the froſt it continued green, though it was not perceived to grow. In the March following it covered the ground very well, and was fit to receive cattle.

If the winter is not remarkably ſevere, the burnet, though cut in September, will be 18 inches long in March; and it may be fed from the beginning or February till May: if the cattle are taken off in May, there will be a good crop of ſeed in the beginning of July. Five weeks after the cattle are taken off, it may be removed, if that is preferred to its ſtanding for ſeed. It grows at the rate of an inch a-day, and is made into hay like other graſs. It may be mown three times in one ſummer, and ſhould be cut juſt before it begins to flower. Six rood of ground has produced 1150 pounds at the firſt cutting of the third year after it was ſowed; and, in autumn 1763, Rocque ſold no leſs than 300 buſhels of the ſeed.

According to Rocque, the ſoil in which burnet flouriſhes beſt, is a dry gravel; the longeſt drought never hurts it: and Sir James Caldwell aſſerts, that he ſaw a very vigorous and exuberant plant of this kind, growing from between two bricks in a wall in Rocque's ground, without any communication with the ſoil; for he had cut away all the fibres of the root that had ſtretched downward, and penetrated the earth, long before.

Burnet was found equally fit for feeding cows, ſheep, and horſes; but the ſheep muſt not be ſuffered to crop it too cloſe. Though no ſeed was left among the hay, yet it proved nouriſhing food; and Rocque kept a horſe upon nothing elſe, who, at the time of writing the account, was in good heart, and looked well. He affirmed alſo, that it cured horſes of the diſtemper called the *greaſe*, and that by its means he cured one which was thought incurable; but ſays, it is only the firſt crop which has this effect.

46 Burnet reckoned an improper food by Miller and Mr Anderſon.

This is the ſubſtance of Sir James Caldwell's letter to the Dublin Society, at leaſt as to what regards the culture of burnet; and it might reaſonably be expected, that a plant, whoſe uſe was recommended to the public with ſo much parade, would ſoon have come into univerſal eſteem. We were ſurpriſed, therefore, on looking into Mr Miller's Dictionary, to find the following words, under the article *Poterium*:—"This plant has of late been recommended by *perſons of little ſkill*, to be ſown as a winter pabulum for cattle: but we never will give themſelves the trouble to examine the grounds where it naturally grows, will find the plants left uneaten by the cattle, when the graſs about them has been cropped to the roots; beſides, in wet winters, and in ſtrong land, the plants are of ſhort duration, and therefore very unfit for that purpoſe; nor is the produce ſufficient to tempt any perſon of ſkill to engage in its culture; therefore I wiſh thoſe perſons to make trial of it in ſmall quantities, before they embark largely in theſe new ſchemes."—Mr Anderſon, too, in his Eſſays on Agriculture, mentions the produce of burnet being ſo ſmall, as not to be worth cultivating.

Food for Cattle.

47 White beet recommended.

Upon the authority of Mr Rocque, likewiſe, the white beet is recommended as a moſt excellent food for cows; that it vegetates during the whole winter, conſequently is very forward in the ſpring: and that the moſt profitable way of feeding cows is to mow this herb, and give it to them green all the ſummer. It grew in Rocque's garden, during a very great drought, no leſs than four feet high, from the 30th of May to the 3d of July; which is no more than one month and four days. In ſummer it grows more than an inch a-day; and is beſt ſown in March: a buſhel is enough for an acre, and will not coſt more than ten ſhillings. It thrives beſt in a rich, deep, light ſoil: the ſtalks are very thick and ſucculent; the cows ſhould therefore eat them green.

48 Root of Scarcity.

Another ſpecies of beet (*Beta cicla*), the Mangel Wurzel, or *Root of Scarcity*, as it has been called, has been lately extolled as food both for man and cattle; but, after all, ſeems only to deſerve attention in the latter view. It is a biennial plant; the root is large and fleſhy, ſometimes a foot in diameter. It riſes above the ground ſeveral inches, is thickeſt at the top, tapering gradually downward. The roots are of various colours, white, yellow, and red; but theſe laſt are always of a much paler colour than beetrave. It is good fodder for cows, and does not communicate any taſte to the milk. It produces great abundance of leaves in ſummer, which may be cut three or four times without injuring the plant. The leaves are more palatable to cattle than moſt other garden plants, and are found to be very wholeſome. The farmers in thoſe parts of Germany where it is chiefly cultivated, we are told, prefer this ſpecies of beet, for feeding cattle, to cabbages, principally becauſe they are not ſo liable to be hurt by worms or inſects; but they think they are not ſo nouriſhing as turnips, potatoes, or carrots, and that cattle are not nearly ſo ſoon fattened by this root as by carrots, parſnips, or cabbages. It has even been aſſerted that this root affords leſs nouriſhment than any of thoſe that have been commonly employed for feeding cattle. This does not correſpond with the pompous accounts with which the public has been entertained. Upon the whole, however, it is a plant which ſeems to deſerve the attention of our farmers; as on ſome ſoils, and in particular circumſtances, it may prove a very uſeful article for the about purpoſes.

49 Sheep's fescue graſs

In Mr Anderſon's Eſſays, we find it recommended to make trial of ſome kinds of graſſes, which probably would not only anſwer for freſh fodder during the winter, but might alſo be cut for hay in ſummer. This is particularly the caſe with that ſpecies called *ſheep's feſcue graſs*. "I had, ſays he, a ſmall patch of this graſs in winter 1773; which, having been cut in the

month

Food for Cattle.

month of Auguſt or September preceding, was ſaved from that period, and had advanced before winter to the length of five or ſix inches; forming the cloſeſt pile that could be imagined. And although we had about ſix weeks of very intenſe froſt, with ſnow; and about other ſix weeks, immediately ſucceeding that, of exceeding keen froſt every night, with frequent thaws in the day time, without any ſnow, during which time almoſt every green thing was deſtroyed; yet this little patch continued all along to retain as fine a verdure as any meadow in the month of May; hardly a point of a leaf having been withered by the uncommon ſeverity of the weather. And as this graſs begins to vegetate very early in the ſpring, I leave the reader to judge what might be the value of a field of graſs of this kind in theſe circumſtances."

50 Purple feſcue.

Of another kind of graſs, called *purple feſcue*. Mr Anderſon gives the following character: "It retained its verdure much better than rye-graſs during the winter ſeaſon; but it had more of its points killed by the weather than the former. It likewiſe riſes in the ſpring, at leaſt as early as rye-graſs."

This ingenious farmer has alſo made experiments on the culture of theſe and ſeveral other kinds of graſſes; which being very well worthy of attention, we ſhall here inſert.

1. *Purple feſcue graſs*. "Although this graſs is very often found in old paſtures, yet, as it has but few flower-ſtalks, and as it is greedily eaten by all domeſtic animals, theſe are ſeldom ſuffer to appear; ſo that it uſually remains there unperceived. But it ſeems to be better able to endure the peculiar acrimony of the dung of dogs than almoſt any other plant; and is therefore often to be met with in *dog hills*, as I call the little hills by road ſides where dogs uſually piſs and dung: and as it is allowed to grow there undiſturbed, the farmer may have an opportunity of examining the plant, and becoming acquainted with its appearance.

"The leaves are long and ſmall, and appear to be roundiſh, ſomething like a wire; but, upon examination, they are found not to be tubulated like a reed or ruſh; the ſides of the leaf being only folded together from the middle rib, exactly like the ſtrong bent graſs on the ſea ſhore. The flower-ſtalk is ſmall, and branches out in the head, a little reſembling the wild oat; only the grains are much ſmaller, and the ear does not ſpread full open, but lies bending a little to one ſide. The ſtalks are often ſpotted with reddiſh freckles, and the tops of the roots are uſually tinged with the ſame colour; from whence it has probably obtained its diſtinctive name of *feſtuca rubra*, or *red (purple) feſcue*.

"It is often to be met with in old garden walks; and, as its leaves advance very quickly after cutting, it may uſually be diſcovered above the other graſſes, about a week or fortnight after the walks are cut. Nor do they ſeem to advance only at one ſeaſon, and then ſtop and decay, like the rye-graſs; but continue to advance during the whole of the ſummer, even where they are not cut; ſo that they ſometimes attain a very great length. Laſt ſeaſon (1774), I meaſured a leaf of this graſs, that ſprung up in a neglected corner, which was four feet and four inches in length, although not thicker than a ſmall wire. It is unneceſſary to add, that theſe leaves naturally trail upon the ground, unleſs where they meet with ſome accidental ſupport; and, that if any quantity of it is ſuffered to grow for a whole ſeaſon, without being eaten down or cut, the roots of the leaves are almoſt rotted, by the overſhadowing of the tops of the other leaves, before the end of the ſeaſon.

Food for Cattle.

51 Appearance in its cultivated ſtate.

"This is the appearance and condition of the plant in its native ſituation: as it is ſeldom that it is diſcovered but in pretty old paſtures, and as in that ſtate it carries only a very few ſeed-ſtalks, it was with ſome difficulty that I could collect a ſmall handful of the ſeed, which I carefully ſowed in a ſmall patch of garden mould, to try if it could be eaſily cultivated. It came up as quickly as any other kind of graſs, but was at firſt as ſmall as hairs: the leaves, however, advanced apace; and were, before autumn, when the grain with which they had been ſowed was cut down, about 16 or 18 inches in length; but having been ſown very thin, it was neceſſary to pick out ſome other kinds of graſs that came up amongſt it, leſt it might have been choked by them. Early next ſpring it advanced with prodigious vigour, and the tufts that were formed from every ſeed became exceeding large; ſo that it quickly filled the whole ground. But now the leaves were almoſt as broad as thoſe of common rye-graſs, and the two ſides only inclined a little towards one another from the mid-rib, without any appearance of roundneſs. In due time a great many ſeed-ſtalks ſprung out, which attained very nearly to the height of four feet, and produced ſeeds in abundance; which may be as eaſily ſaved as thoſe of common rye graſs.

"The prodigious difference between this plant in its native and cultivated ſtate amazed me; but it was with a good deal of ſatisfaction that I found there would be no difficulty in procuring ſeeds from it, which I had much doubted of at firſt. It would ſeem, that nature hath endowed this plant with a ſtrong generative power during its youth, which it gradually loſes as it advances in age (for the difference perceived in this caſe could not be attributed to the richneſs of the ſoil); and that, on the contrary, when it was old, the leaves advanced with an additional vigour, in proportion to the declining ſtrength of the flower-ſtalks: for the leaves of the young plants ſeldom exceed two feet, whereas numbers of the old leaves were near four feet in length.

"From theſe peculiarities in the growth of this plant, it would ſeem to promiſe to be of great uſe to the farmer; as he could reap from a field of it, for the firſt two or three years, as great a weight of hay as he could obtain from any of the culmiferous graſſes (thoſe bearing a long jointed ſtalk); and, if he meant afterwards to paſture it, he would ſuffer no inconveniences from the flower ſtalks; and the ſucculent leaves that continue to vegetate during the whole ſummer, would at all times furniſh his cattle with abundance of wholeſome food. It has alſo been remarked, that this graſs riſes as early in the ſpring as rye-graſs; and continues green for the greateſt part of winter, which the other does not. It is moreover an abiding plant, as it ſeems never to wear out of the ground where it has once been eſtabliſhed. On all which accounts, it appears to me highly to merit the attention of the farmer; and

wel

Food for Cattle.

well deſerves to have its ſeveral qualities, and the culture that beſt agrees with it, aſcertained by accurate experiments.

52 Sheep's feſcue deſcribed.

2. "*Sheep's feſcue graſs*, or *feſtuca ovina*, is much praiſed by the Swediſh naturaliſts for its ſingular value as a paſture-graſs for ſheep; this animal being repreſented as fonder of it than of any other graſs, and fattening upon it more quickly than on any other kind of food whatever. And indeed, the general appearance of the plant, and its peculiar manner of growth, ſeems very much to favour the accounts that have been given us of it.

"This plant is of the ſame family with the former, and agrees with it in ſeveral reſpects; although they may be eaſily diſtinguiſhed from one another. Its leaves, like the former, in its natural ſtate, are always rounded, but much ſmaller; being little bigger than large horſe hairs, or ſwine-briſtles, and ſeldom exceed ſix or ſeven inches in length. But theſe ſpring out of the root in tufts, ſo cloſe upon one another, that they reſemble, in this reſpect, a cloſe hair bruſh more than any thing elſe I know: ſo that it would ſeem naturally adapted to form that thick ſhort pile of graſs in which ſheep are known chiefly to delight. Its flower-ſtalks are numerous, and ſometimes attain the height of two feet; but are more uſually about 12 or 15 inches high.

53 Its appearance when cultivated.

"Upon gathering the ſeeds of this plant, and ſowing them as the former, it was found that they ſprung up as quickly as any other kind of graſs; but the leaves are at firſt no bigger than a human hair. From each ſide ſprings up one or two of theſe hair-like filaments, that in a ſhort time ſend out new offsets, ſo as quickly to form a ſort of tuft, which grows larger and larger, till it at length attains a very large ſize, or till all the intervals are cloſed up, and then it forms the cloſeſt pile of graſs that it is poſſible to imagine. In April and May it puſhed forth an innumerable quantity of flower-ſtalks, that afforded an immenſe quantity of hay; it being ſo cloſe throughout, that the ſcythe could ſcarcely penetrate it. This was allowed to ſtand till the ſeeds ripened; but the bottoms of the ſtalks were quite blanched, and almoſt rotted for want of air before that time.

"This was the appearance that it made the firſt year after it was ſowed: but I have reaſon to think, that, after a few years, it likewiſe produces fewer ſeed-ſtalks, and a greater quantity of leaves, than at firſt. But however that may be, it is certain, that if theſe are eaten down in the ſpring, it does not, like rye graſs, perſiſt in a continued tendency to run to ſeed; but is at once determined to puſh forth a quantity of leaves without almoſt any ſtalks at all: and as all domeſtic animals, but more eſpecially ſheep, are extremely fond of this graſs, if they have liberty to paſture where it grows, they bite it ſo cloſe as never to ſuffer almoſt a ſingle ſeed-ſtalk to eſcape them; ſo that the botaniſt will often ſearch in vain for it, when he is treading upon it with his feet. The beſt way to diſcover it in any paſture, is to ſearch for it in winter, when the tufts of it may be eaſily diſtinguiſhed from every other kind of graſs, by their extraordinary cloſeneſs, and the deep green colour of the leaves.

54 What ſoil moſt proper.

"It ſeems to grow in almoſt any ſoil; although it is imagined that it would flouriſh beſt in a light ſandy ſoil, as it can evidently live with leſs moiſture than almoſt any other kind of graſs; being often ſeen to remain in the ſods that have been employed in coping for ſtone dykes, after all the other graſſes that grew in them have diſappeared. It is likewiſe found in poor barren ſoils, where hardly any other plant can be made to grow at all: and on the ſurface of dry worn-out peat moſs, where no moiſture remains ſufficient to ſupport any other plant whatever: but in neither of theſe ſituations does it thrive; as it is there only a weak and unſightly plant, very unlike what it is when it has the good fortune to be eſtabliſhed upon a good ſoil; although it is ſeldomer met with in this laſt ſtate than in the former.

Food for Cattle.

"I will not here repeat what has been already ſaid about the particular property that this plant poſſeſſes of continuing all winter; nor point out the benefits that the farmer may reap from this valuable quality.—He need not, however, expect to find any verdure in winter on ſuch plants as grow upon the looſe moſſy ſoil above mentioned; for, as the froſt in winter always hoves up the ſurface of this ſoil the roots of the plants are ſo lacerated thereby, as to make it, for ſome time in the ſpring, to all appearance dead. Nor will he often perceive much verdure in winter upon thoſe plants that grow upon poor hungry ſoils, which cannot afford abundant nouriſhment to keep them in a proper ſtate of vegetation at all times: but ſuch plants as grow on earthen dykes, which uſually begin to vegetate with vigour when the autumnal rains come on, for the moſt part retain their verdure at that ſeaſon almoſt as well as if they were in good garden-mould.

"I have been very particular in regard to this plant; becauſe, in as far as my obſervations have yet gone, it promiſes on many accounts to make a moſt valuable acquiſition to the farmer, and therefore juſtly demands a very particular ſhare of his attention."

55 Holcus lanatus.

3. The *holcus lanatus*, or creeping ſoft-graſs of Hudſon.—This is conſidered by our author as one of the moſt valuable kinds of meadow-graſſes; its pile being exceedingly cloſe, ſoft, and ſucculent. It delights much in moiſture, and is ſeldom found on dry ground, unleſs the ſoil is exceeding rich. It is often found on thoſe patches near ſprings, over which the water frequently flows; and may be known by the uncommon ſoftneſs and ſucculence of the blade, the lively light green colour of the leaves, and the matted intertexture of its roots. But, notwithſtanding the ſoftneſs of its firſt leaves, when the ſeed-ſtalks advance, they are rough to the touch, ſo that the plant then aſſumes a very different appearance from what we would have expected. The ear is branched out into a great number of fine ramifications ſomewhat like the oat, but much ſmaller.—This kind of graſs, however, would not be eaſily cultivated, on account of a kind of ſoft membrane that makes the ſeeds adhere to the ſtalk, and to one another after they are ſeparated from it, as if they were intermixed with cobweb, ſo that it is difficult to get them ſeparated from the ſtalk, or to ſpread readily in ſowing. It ſpreads, however, ſo faſt by its running roots, that a ſmall quantity ſowed very thin, would be ſufficient to ſtock a large field in a ſhort time.

Theſe are the kinds of *graſſes*, properly ſo called, which have not as yet been cultivated, that Mr Anderſon thinks the moſt likely to be of value; but, beſides theſe, he recommends the following of the pea tribe.

1. *Milk-vetch*,

Food for Cattle

56 Milk-vetch.

1. *Milk-vetch, liquorice-vetch*, or *milkwort*. This plant, in some respects, very much resembles the common white clover: from the top of the root a great number of shoots come out in the spring, spreading along the surface of the ground every way around it; from which arise a great many clusters of bright yellow flowers, exactly resembling those of the common broom. These are succeeded by hard round pods, filled with small kidney-shaped seeds. From a supposed resemblance of a cluster of these pods to the fingers of an open hand, the plant has been sometimes called *ladies fingers*. By others it is called *crow-toes*, from a fancied resemblance of the pods to the toes of a bird. Others, from the appearance of the blossom, and the part where the plant is found, have called it *feal*, improperly *fell-broom*. It is found plentifully almost everywhere in old grass fields; but as every species of domestic animals eat it, almost in preference to any other plant, it is seldom allowed to come to the flower in pasture grounds, unless where they have been accidentally saved from the cattle for some time; so that it is only about the borders of corn fields, or the sides of inclosures to which cattle have not access, that we have an opportunity of observing it. As it has been imagined that the cows which feed on the pastures, where this plant abounds, yield a quantity of rich milk, the plant has, from that circumstance, obtained its most proper English name of *milk-vetch*.

57 Its good qualities.

One of the greatest recommendations of this plant is, that it grows in poor barren ground, where almost no other plant can live. It has been observed in ground so poor, that even heath, or ling (*erica communis*), would scarcely grow; and upon bare obdurate clays, where no other plant could be made to vegetate; insomuch that the surface remained entirely uncovered, unless where a plant of this kind chanced to be established: yet, even in these unfavourable circumstances, it flourished with an uncommon degree of luxuriance, and yielded as tender and succulent, though not such abundant shoots, as if reared in the richest manured fields. In dry barren sands, also, where almost no other plant could be made to live, it has been found to send out such a number of healthy shoots all round, as to cover the earth with the closest and most beautiful carpet that can be desired.

The stalks of the milk-vetch are weak and slender, so that they spread upon the surface of the ground, unless they are supported by some other vegetable. In ordinary soils they do not grow to a great length, nor produce many flowers; but in richer fields the stalks grow to a much greater length, branch out a good deal, but carry few or no flowers or seeds. From these qualities our author did not attempt at first to cultivate it with any other view than that of pasture; and, with this intention, sowed it with his ordinary hay seeds, expecting no material benefit from it till he desisted from cutting his field. In this, however, he was agreeably disappointed; the milk-vetch growing the first season as tall as his great clover, and forming exceeding fine hay; being scarce distinguishable from lucerne, but by the slenderness of the stalk, and proportional smallness of the leaf.

Another recommendation to this plant is, that it is perennial. It is several years after it is sowed before it attains to its full perfection; but, when once established, it probably remains for a great number of years in full vigour, and produces annually a great quantity of fodder. In autumn 1773, Mr Anderson cut the stalk from an old plant that grew on a very indifferent soil; and, after having thoroughly dried it, he found that it weighed 14 ounces and a half. Food for Cattle.

The stalks of this plant die down entirely in winter, and do not come up in the spring till the same time that clover begins to advance; nor does it advance very fast, even in summer, when once cut down or eaten over: so that it seems much inferior to the above-mentioned grasses; but it might be of use to cover the worst parts of a farm, on which no other vegetable could thrive.

58 Yellow vetchling.

2. The *common yellow vetchling* (*Lathyrus pratensis*), or *everlasting tare*, grows with great luxuriance in stiff clay soils, and continues to yield annually a great weight of fodder, of the very best quality, for any length of time. This is equally fit for pasture or hay; and grows with equal vigour in the end of summer as in the beginning of it; so would admit being pastured upon in the spring, till the middle, or even the end of May, without endangering the loss of the crop of hay. This is an advantage which no other plant except clover possesses; but clover is equally unfit for early pasture or for hay. Sainfoin is the only plant whose qualities approach to it in this respect, and the yellow vetchling will grow in such soils as are utterly unfit for producing sainfoin.—It is also a perennial plant, and increases so fast by its running roots, that a small quantity of the seed would produce a sufficient number of plants to fill a whole field in a very short time. If a small patch of good ground is sowed with the seeds of this plant in rows, about a foot distance from one another, and the intervals kept clear of weeds for that season, the roots will spread so much as to fill up the whole patch next year; when the stalks may be cut for green fodder or hay. And if that patch were dug over in the spring following, and the roots taken out, it would furnish a great quantity of plants, which might be planted at two or three feet distance from one another, where they would probably overspread the whole field in a short time.

59 Blue tare.

3. The *common blue tare* seems more likely than the former to produce a more flourishing kind of hay, as it abounds much more in seeds; but as the stalks come up more thinly from the root, and branch more above, it does not appear to be so well adapted for a pasture grass as the other. The leaves of this plant are much smaller, and more divided, than those of the other; the stalks are likewise smaller, and grow to a much greater length. Though it produces a great quantity of seeds, yet the small birds are so fond of them, that, unless the field were carefully guarded, few of them would be allowed to ripen.

60 Bush-vetch.

4. The *vicia sepium, purple everlasting*, or *bush-vetch*. Our author gives the preference to this plant beyond all others of the same tribe for pasture. The roots of it spread on every side a little below the surface of the ground, from which, in the spring, many stems arise quite close by one another; and as these have a broad tufted top covered with many leaves, it forms as close a pile as could be desired. It grows very quickly after being cut or cropt, but does not arrive at any great height; so that it seems more proper for pasturage than

Food for Cattle.

making hay; although, upon a good ſoil, it will grow ſufficiently high for that purpoſe; but the ſtalks grow ſo cloſe upon one another, that there is great danger of having it rotted at the root, if the ſeaſon ſhould prove damp. It ſeems to thrive beſt in a clayey ſoil.

61 Everlaſting pea.

Beſides theſe, there are a variety of others of the ſame claſs, which he thinks might be uſeful to the farmer. The common garden everlaſting pea, cultivated as a flowering plant, he conjectures, would yield a prodigious weight of hay upon an acre; as it grows to the height of ten or twelve feet, having very ſtrong ſtalks, that could ſupport themſelves without rotting till they attained a great height.

62 Achillea millefolium.

One other plant, hitherto unnoticed, is recommended by our author to the attention of the farmer; it is the *common yarrow* (*Achillea millefolium*), or *hundred-leaved graſs*. Concerning this plant, he remarks, that in almoſt every fine old paſture, a great proportion of the growing vegetables with which the field is covered conſiſts of it; but the animals which feed there are ſo fond of the yarrow, as never to allow one ſeed-ſtalk of it to come to perfection. Hence theſe ſeed-ſtalks are never found but in neglected corners, or by the ſides of roads; and are ſo diſagreeable to cattle, that they are never taſted; and thus it has been erroneouſly thought that the whole plant was refuſed by them.—The leaves of this plant have a great tendency to grow very thick upon one another, and are therefore peculiarly adapted for paſturage. It arrives at its greateſt perfection in rich fields that are naturally fit for producing a large and ſucculent crop of graſs. It grows alſo upon clays; and is among the firſt plants that ſtrike root in any barren clay that has been lately dug from any conſiderable depth; ſo that this plant, and thiſtles, are uſually the firſt that appear on the banks of deep ditches formed in a clayey ſoil. All animals delight to eat it; but, from the dry aromatic taſte it poſſeſſes, it would ſeem peculiarly favourable to the conſtitution of ſheep. It ſeems altogether unfit for hay.

63 Lucerne.

Beſides theſe plants, which are natives of our own country, there are others which, though natives of a foreign climate, are found to thrive very well in Britain; and have been raiſed with ſuch ſucceſs by individuals, as highly to merit the attention of every farmer. Among theſe the firſt place is claimed by lucerne.

This is the plant called *medica* by the ancients, becauſe it came originally from Media, and on the culture of which they beſtowed ſuch great care and pains. It hath a perennial root, and annual ſtalks, which, in a good ſoil, riſe to three feet, or ſometimes more, in height; its leaves grow at a joint like thoſe of clover; the flowers, which appear in June, are purple; and its pods are of a ſcrew-like ſhape, containing ſeeds which ripen in September. All ſorts of domeſtic cattle are fond of this plant, eſpecially when allowed to eat it green, and black cattle may be fed very well with the hay made from it; but an exceſs of this food is ſaid to be very dangerous.

Lucerne has the property of growing very quickly after it is cut down, inſomuch that Mr Roeque has mowed it five times in a ſeaſon, and Mr Anderſon affirms he has cut it no leſs than ſix times. It is, however, not very eaſily cultivated; in conſequence of which it ſometimes does not ſucceed.

64 Timothy graſs.

Another graſs was brought from Virginia, where it is a native, and ſown by Rocque in 1763. This graſs is called *timothy*, from its being brought from New-York to Carolina by one Timothy Hanſon. It grows beſt in a wet ſoil; but will thrive in almoſt any. If it is ſown in Auguſt, it will be fit for cutting in the latter end of May or beginning of June. Horſes are very fond of it, and will leave lucerne to eat it. It is alſo preferred by black cattle and ſheep; for a ſquare piece of land having been divided into four equal parts, and one part ſowed with lucerne, another with ſainfoin, a third with clover, and the fourth with timothy, ſome horſes, black cattle, and ſheep, were turned into it, when the plants were all in a condition for paſturage; and the timothy was eaten quite bare, before the clover, lucerne, or ſainfoin, was touched.

Food for Cattle.

One valuable property of this graſs is, that its roots are ſo ſtrong and interwoven with one another, that they render the wetteſt and ſofteſt land, on which a horſe could not find footing, firm enough to bear the heavieſt cart. With the view of improving boggy lands, therefore, ſo as to prevent their being poached with the feet of cattle, Mr Anderſon recommends the cultivation of this kind of graſs, from which he has little expectation in other reſpects.

65 Grazing compared with the plough.

On this ſubject, of the kind of plants moſt proper to be raiſed for feeding cattle, one general queſtion ought not to paſs unnoticed concerning the propriety of feeding them upon roots and plants cultivated by the aid of the plough, or upon leaving them to derive their ſubſiſtence from lands allowed to remain continually in paſturage. The advantages of the latter practice are ſet forth by Thomas Davis, Eſq. of Longleet, in the following words. "Experience ſufficiently evinces the extreme difficulty of perſuading tenants that they get more (generally ſpeaking) by feeding their lands, than by ploughing them; yet it requires very few arguments to convince a landlord, that, in cold wet land eſpecially, the leſs ploughed land you have, the leſs you put it in the tenant's power to ruin your eſtate. That a tenant of 60l. *per annum* on a dairy farm will get money, while a corn farm of the ſame ſize will ſtarve its occupier (though perhaps the former gives 15s. per acre for his land, and the latter only 10s.), is ſelf-evident. The plough is a friend of every body's, though its advantages are very far from being particularly and locally felt; corn being an article that will bear keeping till the whim or caprice, or ſuppoſed advantage of its poſſeſſor, call it forth. But the produce of the cow is far otherwiſe. Cheeſe muſt neceſſarily be ſold at a certain period: it is a ponderous article; and one-twelfth, or at leaſt one-fifteenth of its value, is often paid for carrying it to a fair 50 miles off; and the butter and ſkimmed milk find their way no great diſtance from home, as is evident by the price of butter varying frequently one third in 20 or 30 miles. Every inhabitant of Bath muſt be ſenſible, that butter and cheeſe have riſen one-third or more in price within 20 years. Is not this owing to the great encouragement given to the plough and to grazing, at a time when, on account of the increaſed demand for milk, cream, butter, and cheeſe, every exertion on behalf of the dairy ſhould have been encouraged?" &c.

Bath Papers, vol.

In ſome remarks on this letter by Mr Billingſley, the ſame ſuperiority of dairy farms to the arable kind is aſſerted in the moſt poſitive terms. "Perhaps (ſays he)

Food for Cattle.

he) there cannot be a ſtronger proof of the inferiority of the plough with reſpect to profit, than the ſuperior punctuality of the dairy farmer in the payment of his rent. This obſervation, I believe, moſt ſtewards who ſuperintend manors devoted partly to corn and partly to dairy farms, will verify; at leaſt I have never met with one who controverts it. But perhaps the advocate for the plough will deſire me not to confound the abuſe of a thing with its intrinſic excellence; and ſay, that the generality of corn farmers are moſt egregious ſlovens; that lands devoted to the plough are not confined to ſuch a mediocrity of profit as 20s. per acre; that the produce of artificial graſſes (without which a well managed arable farm cannot exiſt), far exceeds that of natural graſs both in reſpect of quantity and nutrition: that the ſtraw yard is a moſt convenient receptacle for the cow when freed from the pail. Theſe, and many other reaſons, may be adduced to ſhow the propriety of walking in the middle path, and of judiciouſly blending *arable* with *paſture*, in the proportion perhaps of *three* of the latter to *one* of the former."

On theſe letters we ſhall only remark, that for the good of mankind we hope the opinions they contain will never come into general practice: as thus the price of bread muſt be raiſed ſo high, that the lower claſſes of people would be entirely deprived of it. In the Bath Papers, vol. v. p. 43. we have a method propoſed by Mr Wimpey of improving ſmall arable farms in ſuch a manner as to make them yield as much milk, butter, and cheeſe, as thoſe which are kept continually in paſture. He agrees with the maxim already mentioned, that ſmall arable farms do not afford the occupier ſo good a maintenance as dairy farms of the ſame value; and that the poſſeſſor of a dairy farm will do well and ſave money, while the former, with much toil and trouble, is ſtarving himſelf and family. Notwithſtanding this, he maintains, that there is an eſſential difference between ground that is naturally arable, and ſuch as is by nature adapted for paſture. Land which is naturally arable, according to him, can by no means be converted into paſture of any duration. "Such as, from a wild ſtate of nature, overrun with furze, fern, buſhes and brambles, has been rendered fertile by means of the plough, muſt be kept in that improved ſtate by its frequent uſe; otherwiſe it would ſoon revert to that wild barren ſtate which was its original condition. A farm, therefore, which conſiſts wholly, or almoſt ſo, of land that is properly arable, muſt ever continue arable; for it is not practicable to render it in any degree fertile but by means of the plough, or to keep it long in that ſtate even when it is made ſo." He is of opinion, however, that by raiſing crops proper for feeding cattle, the poſſeſſor of an arable farm may raiſe as great a number of horned cattle as one who has a paſture farm; the only queſtion is, Whether he can be reimburſed of his expences by the produce? "To aſcertain this fact (ſays he), we muſt inquire what may be the average expences of keeping a milch cow on a dairy farm for any given time. It is ſaid, upon very good authority, that the expence is generally from 3l. to 3l. 10s. per annum. Two acres and a half of paſture fit for this uſe is ſufficient to keep a cow the whole year through, and ſuch land is valued at from 25s. to 30s. per acre. At 25s. the keeping of each cow would amount to 3l. 2s. 6d. per annum. A dairy farm, therefore, conſiſting of 48 acres, at 25s. per annum, would amount to 60l. rent; and the number of cows that might be kept on ſuch a farm would be about 20. In the next place, with regard to the expence of keeping a cow upon food raiſed in arable land as a ſuccedaneum for graſs, we are aſſured by unqueſtionable authority, that a buſhel of potatoes, given half at night and half in the morning, with a ſmall allowance of hay, is ſufficient to keep three cows a day; by which allowance their milk will be as rich and as good as in the ſummer months when the cows are in paſture. An acre of land, properly cultivated with potatoes, will yield 337 buſhels; and the total expence of cultivation, rent and tithe included, will not exceed 6l. 13s. If three cows eat ſeven buſhels per week, then they would eat 364 buſhels in a year; and 20 cows would conſume 2433 buſhels:" So that, according to this calculation, ſeven acres and a quarter would nearly maintain as many cows as on the paſture farm could be maintained by 48 acres. If then the cultivation of one acre of ground coſts 6l. 13s. the cultivation of ſeven acres and a quarter will coſt about 48l. We have ſeen, however, that the rent of a dairy farm capable of maintaining 20 milch cows, is not leſs than 60l. ſo that the calculation is thus entirely in favour of the arable farm; ſeven or eight acres of the arable farm being ſuperior by 12l. in value, when cultivated with potatoes, to 48 acres of meadow or paſture ground." "It muſt indeed be obſerved (adds our author), that in this ſtatement no allowance is made for the ſmall quantity of hay given to the cows with the potatoes. It muſt be noted alſo, that the account of cultivation is charged with 40s. an acre for manure, and ſome expence for ploughing, which of right is chargeable to the crop of wheat that is to follow. Now, if we deduct 40s. an acre from the expence of cultivating the potatoes, it reduces the ſum to 4l. 13s. and the whole expence upon ſeven acres and a quarter is thus leſs than 34l. and conſequently the keeping of 20 cows is little more than half to the occupier of the arable farm what it is to the occupier of the grazing farm. If this concluſion be fairly drawn, and the calculation free from errors, it is matter of the greateſt importance, eſpecially to the little arable farmer. It plainly raiſes him from a ſtate of acknowledged inferiority to one greatly ſuperior."

Food for Cattle.

66 Objection anſwered from an experiment of Mr Vagg.

Our author next proceeds to obviate an objection, "that the whole of his reaſoning muſt be indeciſive, as relating only to potatoes." In oppoſition to this, he adduces an experiment made on a pretty large ſcale by Mr Vagg; from which it appears, that cabbages, when raiſed upon arable ground, are nearly as much ſuperior to a natural crop as potatoes are. Twelve acres were employed in this experiment, and thoſe of an indifferent quality. The rent was 30s. per acre, and the whole expence of culture and carting off the crop amounted only to 11. 14s. ſo that all the coſt of the twelve acres was 38l. 9s. From the produce were fed 45 oxen and upwards of 60 ſheep; and he was aſſured that they improved as faſt upon it as they do in the beſt paſture months, May, June, and July. "Now (ſays Mr Wimpey), if inſtead of 60 ſheep we reckon 15 oxen, or that four ſheep are equal to about

67 Number of cattle fed from 12 acres of cabbages.

Profit from different Vegetables.

one ox, in which we cannot err much; then 60 oxen were kept well for three months, or, which is the ſame thing, 15 for a whole year, for 38l. 9s.; and conſequently 20 oxen would coſt 51l. 5s. 4d. which is not quite 3l. more than the keeping of 20 cows would coſt in potatoes. Turnips, turnip-rooted cabbage, carrots, parſnips, and ſome other articles, by many experiments often repeated, have been found quite adequate to the ſame valuable purpoſes; at leaſt ſo far as to be more lucrative than meadow or paſture. Clover and rye graſs are omitted, as having been long in general practice; but are in common very ſhort of the advantages which may be derived from the cultivation of the other articles recommended." Sainfoin is greatly recommended; but our author acknowledges that it makes but a miſerable appearance the firſt year, though afterwards he is of opinion that one acre of ſainfoin is equal to two of middling paſture ground; for which reaſon he accuſes the farmer of intolerable indolence who does not cultivate ſo uſeful a plant. On this ſubject, however, we muſt remember, that the culture of ſainfoin is clogged with the loſs of one if not two crops; which may ſometimes be inconvenient, though afterwards it remains in perfection for no leſs than 20 years. The moſt advantageous method of raiſing it he ſuppoſes to be after potatoes. Thus it will thrive even upon very poor ground; as the culture and manure neceſſary for the potatoes both pulverize the ſoil and enrich it to a ſufficient degree.

68 Feeding of cattle not brought to perfection.

We ſhall afterwards have an opportunity of attending to this ſubject when we come to conſider the ſubject of feeding cattle. In the mean time, it may be remarked, that this branch of the art of the huſbandman, has by no means hitherto been carried to its higheſt perfection in this country; and that in proportion as it is improved, and cattle are more carefully fed, the value of the plough will appear more conſpicuous.

Sect. III. *Of the comparative Profit to be derived from the Cultivation of different Vegetables.*

69 Circumſtances that render vegetables profitable or not.

Like every other artiſt or tradeſman, a huſbandman will always be under the neceſſity of regarding himſelf as the ſervant of the community, and muſt endeavour to rear the vegetables that are in greateſt demand, and that will enable him to derive the greateſt profit from the portion of territory which he occupies. The product of ſome ſoils and ſituations is ſo fixed by nature, that it is in vain for human art or induſtry to alter her deſtination. In our own and in many other countries, there are extenſive tracts of lofty and rugged mountains, from which the art of agriculture ſeems to be for ever baniſhed. Such ſituations belong excluſively to the ſhepherd and his flock, to the utter excluſion of the plough. Even on ſome arable lands it may be found fruitleſs to attempt to rear many of the more valuable vegetable productions. In many bleak and unſheltered fields of the higher country of Scotland, in which turnips and oats are cultivated with tolerable ſucceſs, it would be in vain to expect regular crops of wheat; and though potatoes are found to proſper in a ſandy, or even a moſſy ſoil, it would be in vain to expect them to produce an equally valuable crop upon a ſtiff clay, in which the roots cannot ſwell or expand to a proper ſize. In forming a plan of agriculture, therefore, the huſbandman muſt not overlook the peculiar nature of the ſoil that has fallen to his lot, or its phyſical relation to the nature of certain vegetables, as he can only hope for ſucceſs by adapting the one of theſe to the other.

Profit from different Vegetables

The huſbandman muſt alſo have a ſpecial regard to the ſtate of the market to which his commodities are to be brought. It is in vain for him to cultivate large quantities of roots, ſuch as potatoes or carrots, at a diſtance from great towns, which alone can afford a market for them, unleſs he intend to conſume them upon his own farm by feeding cattle. In a part of the country, however, in which great breweries are eſtabliſhed, if his ſoil is fit for the purpoſe, he may ſafely venture to rear large quantities of barley; as he cannot in ſuch a ſituation be at any time deſtitute of a market. Hence we can perceive, that it is the ſtate of the market which muſt at all times regulate the enterpriſes of the agriculturiſt, and the kind of crops which he is to bring forward. Thus alſo we ſee the mode in which agriculture may be moſt ſucceſsfully encouraged by a nation. Let an abundant market be provided for the produce of the ſoil, and that produce will infallibly be augmented. In this way, it is evident that the conſumption of grain, by means of diſtilleries or breweries, is highly favourable to the production of it in great quantities. They are even favourable to the exiſtence of plenty, or of abundance of bread for the uſe of the people. In good ſeaſons, by affording a ready market, they give activity to the huſbandman, and in bad ſeaſons their operations can be arreſted by law, and the ſuperfluous quantity of grain which was meant to be conſumed by them, can be converted into human food. Thus they operate in ſome meaſure like a great public granary, in which proviſions ſhould be kept againſt an accidental ſcarcity.

It may ſometimes happen, that by the character of the age in which he lives, and the ſtate of the market which it produces, a huſbandman may find himſelf moſt profitably employed, when rearing a kind of food which is by no means the moſt advantageous to the population of his country. This takes place, when he is employed in preparing butchers meat inſtead of bread; that is, when he finds it more profitable to rear upon his lands vegetables which can only be conſumed by cattle, and thus contribute only in an indirect manner to the ſuſtenance of the human ſpecies, than to cultivate thoſe vegetable productions which are ſuited to the human ſtomach, and which therefore directly and immediately afford ſubſiſtence to man. According to Archdeacon Hiſlop's comparative ſtatement, lately publiſhed, the weight of food from an acre of arable land, on the average of three years, a fallow year being included, is nine and a half times greater than from an acre of feeding ſtock; and, according to the calculations of the Rev. Dr Walker, at Collington, profeſſor of natural hiſtory at Edinburgh, a Scots acre of land in paſture, fed with ſheep, produces only 120 pounds weight of meat, whereas the ſame land will yield 1280 pounds of oatmeal, or above ten times as much. Let it even be ſuppoſed, then, that one pound of mutton contains in itſelf as much ſubſtantial nouriſhment for the human conſtitution, as

70 Paſturage and agriculture compared.

two

Profit from different vegetables.

two pounds weight of oat meal; ſtill it will follow, that lands cultivated for the production of oats, will ſupport a population five times greater in number, than can be ſupported by the ſame land when uſed for the paſture of ſheep; and, where one million of people are found to exiſt upon a territory occupied in the one way, between five and ſix millions of people might exiſt upon the ſame land if it were cultivated for raiſing grain, and if the inhabitants would conſent to uſe it as their food. Were any contrivance adopted, of the nature of thoſe already mentioned, for converting the ſucculent roots of potatoes, carrots, &c. into dry meal or flour; the ſame proportional difference of population would continue to exiſt, between nations in which that kind of flour ſhould be conſumed as human food, and in which it ſhould be uſed for feeding cattle: For a man always commits an enormous waſte of food, who, inſtead of eating grain himſelf, gives it to an inferior animal, in the expectation of afterwards receiving an equivalent, by devouring the fleſh of that animal.

71 Population greateſt where men live on vegetable food.

Accordingly, it ſeems impoſſible for any nation to reach a very extenſive degree of population, unleſs the people at large conſent to ſubſiſt chiefly, or altogether, upon vegetable food. In China, where the practice of polygamy renders the families of rich men very numerous, and where the equal diſtribution of the property among the children of the ſame family prevents the accumulation of great wealth by individuals, almoſt all perſons have found it convenient or neceſſary to relinquiſh the ordinary uſe of butchers meat, and to have recourſe to vegetable food. It is only in conſequence of this circumſtance, that the enormous population of that empire is ſupported. The quantity of butchers meat conſumed in a country will, therefore, always in ſpite of every agricultural improvement, ſet bounds to its population. A nation of hunters and ſhepherds, who live upon wild animals, or upon flocks and herds, muſt always be few in number. By agriculture, the numbers of theſe animals may indeed be increaſed; but the men who can find ſubſiſtence by conſuming them, will always be five or ſix times fewer in number, than might live upon the ſame territory, were the cattle expelled, and the lands occupied in rearing food to be immediately uſed by man.

With theſe general conſiderations, however, the practical agriculturiſt, or huſbandman, may have nothing to do. To ſucceed in his profeſſion, he muſt accommodate himſelf to the public taſte, or to the ſtate of the market around him; and muſt conſider what commodity, whether grain or butchers meat, will there bring the beſt reward for his labour. He may even find the ſtate of the market affected by other circumſtances, than the mere taſte of the public for butchers meat, in preference to vegetable food; although that muſt always be of great importance among a luxurious people. Conquering nations, who extend their political dominions over diſtant regions, never fail to draw to their native country a very great portion of the wealth of the vanquiſhed ſtates. The victorious nation never fails, in ſuch caſes, to contain a great number of wealthy individuals, whoſe revenue is not derived from the cultivation of their native ſoil, or from any branch of manufacture or of commercial induſtry carried on by them upon it; but which conſiſts of money drawn from the remote provinces of the empires, in conſequence of eſtates poſſeſſed, or fortunes acquired there, in the ſervice of government. The reſult of ſuch circumſtances naturally is, that theſe wealthy individuals not only live at home in a luxurious manner, and increaſe to an immenſe extent the conſumption of butchers meat by themſelves and their numerous retinues; but for the ſake of oſtentation, and as the only means of employing their wealth, they maintain great numbers of carriages and of riding horſes. To ſupport ſuch eſtabliſhments, they themſelves not only convert large tracts of territory from arable into paſture lands; but even the whole huſbandmen of the country are induced to do the ſame, to derive a profit from ſupplying them with butchers meat, and with food for their pleaſure horſes. In the mean time, the grain that may be wanted for the conſumption of the people, whether rich or poor, being a commodity which is eaſily preſerved and tranſported, muſt be bought from foreign nations, by a portion of the ſuperfluous wealth of the ſtate; and thus a rich and proſperous people may come to depend upon foreigners for a morſel of bread; and when theſe foreign nations happen to experience an unfortunate ſeaſon, this wealthy people may ſuffer all the horrors of famine upon a fertile ſoil, and in the midſt of overflowing treaſures.

Profit from different Vegetables.

Such was the ſtate of Italy under the ancient Romans. Every part of it was adorned with the parks and villas and gardens of the nobles, who derived their revenues from the remote parts of the empire. This ſeat of dominion exhibited a picture of boundleſs ſplendour and magnificence. But the ſoil was entirely occupied in the ſervice of oſtentation or of luxury; and Italy, one of the moſt fertile corn countries in Europe, depended for grain upon Egypt, and the weſtern provinces of Africa that border upon the Mediterranean. Such alſo, though perhaps in an inferior degree, ſeems to be the preſent ſtate of Great Britain. It has acquired vaſt and fertile and populous provinces, within the torrid zone in the eaſt, from which individuals are annually tranſporting home immenſe treaſures obtained in the public ſervice. In the weſt, alſo, within the ſame torrid zone, by a great expence of treaſure and of human lives, the cultivation of certain valuable commodities has been eſtabliſhed; and from eſtates ſituated there, individuals reſiding at home now derive great revenues. The principles which regulate human affairs are unalterable; and in every age the ſame cauſes are attended with the ſame conſequences. What occurred in ancient Italy, took place among us ſoon as the poſſeſſion of diſtant territories had leiſure to diſplay its natural effects. Britain formerly not only produced abundance of grain, for the ſupport of its own inhabitants, but it poſſeſſed a conſiderable ſurplus for exportation. After the acquiſition of foreign poſſeſſions, this ſurplus produce gradually ceaſed to exiſt; and it appears from documents, which the legiſlature has acknowledged to afford authentic and complete evidence of the truth of the fact, that, for twenty years paſt, notwithſtanding all our agricultural improvements, and the waſte lands that have been brought under the plough, the produce of grain is annually becoming more and more unequal to the conſumption; and this decreaſe appears in ſome meaſure to keep pace with the increaſing value of our diſtant poſſeſſions. In the mean time we are annually coming under

72 Circumſtances that add to the diſpoſition to prefer raiſing grain.

Principles of Cultivation.

under the neceſſity of purchaſing larger and larger ſupplies of grain, from the foreign ſtates of Europe or of North America; and thus theſe nations, without undergoing the imputation of uſurpation, and without encountering the hazard of an unfriendly climate, have been enabled, through the medium of our luxury, to obtain a ſhare of the riches of Hindoſtan, and of the profits of our Weſt India cultivation. In the mean time their agriculture is encouraged, while we are made to depend upon them for the neceſſaries of life. After all, it appears unreaſonable, and would perhaps be improper, to regret a ſtate of affairs, which is the reſult of national aggrandiſement, and of the ſuperiority and ſucceſsful enterpriſes of our countrymen. Still, however, it is obviouſly to be wiſhed, that, ſo far as agriculture is concerned, we could be reſtored to the ſtate of independence which our anceſtors enjoyed, when they were able, from their own ſoil, to ſupply themſelves with the neceſſaries of life: ſuch a ſtate is ſometimes neceſſary to the independent exiſtence of a community, and is at all times conducive to its welfare. It can only however be produced by means of agriculture. Therefore,

Ye generous Britons, venerate the *Plough*,
And o'er your hills and long withdrawing vales,
Let autumn ſpread her treaſures to the ſun;
So with ſuperior boon may your rich ſoil,
Exuberant, nature's better bleſſings pour
O'er every land, the naked nations clothe,
And be th' exhauſtleſs granary of a world!

THOMSON.

SECT. IV. *General Principles of Cultivation.*

IT is not our intention here to enter into a minute diſquiſition, concerning the nature of vegetables, or the different ſubſtances with which they may be connected, in their growth or in their decay. Such inveſtigations, in a proper arrangement of the ſciences, ought to be left to chemiſtry; but even that ſcience, ſo far as vegetable ſubſtances are concerned, is ſtill in ſuch a ſtate of imperfection, that a detail of the experiments and opinions of philoſophical chemiſts, concerning vegetables, would as yet afford but a very trifling portion of uſeful information to the huſbandman. We ſhall therefore content ourſelves with here ſtating ſuch general remarks, as appear neceſſarily connected with the important art of which we are now treating.

73 Nature of the growth of vegetables.

A vegetable is not to be regarded merely as a piece of matter, or as a mixture of certain material ſubſtances. It is an organized being, poſſeſſed of life, which it derived from another ſimilar organized being that exiſted previous to itſelf; and this former organized and living being derived its conſtitution from a parent ſtem, which grew out of a ſtill older plant, up to an antiquity of which we have no knowledge. A vegetable, in this manner, not only has a birth, but it alſo has a growth, which is ſupported by food that it takes in and conveys by peculiar organs to the particular parts for which it is deſtined. When it has arrived at maturity, or reached the perfection of its form and conſtitution, a vegetable like an animal begins to decay, and finally dies, and, by a proceſs of putrefaction, is converted into a kind of earth.

To the life of vegetables, in the ſame manner as to the life of animals, the preſence of atmoſpheric air is neceſſary. They alſo require a certain moderate degree of heat; without which their growth cannot proceed, although a great degree of it is utterly fatal even to their texture. That they require moiſture, is equally obvious; as appears from the ordinary effect of rain, or of the continued want of it, upon fields and plants. They require likewiſe to be inſerted in the earth, or in ſome way connected with a collection of its particles; for although ſome plants, particularly the bulbous-rooted kinds, vegetate in pure water and air alone, it appears that they acquire little addition of ſolid ſubſtance, and that neither they, nor any of the other larger plants, reach perfection, or produce ſeed, unleſs planted in the earth, or ſupplied with a portion of it.

Principles of Cultivation.

74 Four kind of ſoils.

As all ſoils are by no means equally adapted for ſupporting vegetables, or bringing them to maturity, it is neceſſary for the huſbandman to attend to their nature, and the modes in which they may be altered or ameliorated for his uſe. Independent of theſe hard concretions, which obtain the name of ſtones or rocks, it is to be obſerved, that the looſer and more diviſible earth which covers moſt part of the ſurface of the globe, and receives the appellation of *the ſoil*, may, upon the whole, and with ſufficient accuracy for practical purpoſes, be divided into four kinds, which are in general mixed with each other, but which receive their name, in ordinary language, from the kind that predominates or is moſt abundant. Theſe are ſand, clay, chalk, and garden mould. Of theſe, ſand and clay are in ſome meaſure the oppoſites of each other, while chalk forms a kind of medium between them. Sand allows water to filter rapidly through it, and ſpeedily becomes dry, while clay is extremely tenacious of moiſture; but a mixture of chalk renders ſand conſiderably more tenacious of water, while it renders clay more looſe, and eaſily penetrated. None of theſe ſoils are valuable for the purpoſes of agriculture.—Sand does not ſufficiently retain water for the uſe of vegetables; nor does clay ſuffer their roots to expand with freedom in queſt of nouriſhment. Chalk, or, as it is uſually called, a calcareous ſoil, is not of itſelf adapted for raiſing uſeful plants; for, although it may not have the mechanical defects of ſand and clay, yet, it is found by experience to be of little value to them, either in conſequence of its tendency to deſtroy their texture by its corroſive quality, that is, by having too much chemical affinity with the materials of which they conſiſt, or from its not containing within itſelf the proper materials neceſſary to them as food.

The fourth kind of ſoil we have denominated garden mould; becauſe it is in its higheſt perfection when it approaches neareſt to the rich black earth which receives that appellation. This is the moſt proper of all kinds of ſoil for rearing the whole of thoſe vegetables which are accounted valuable in our climate. In proper circumſtances, that is, with a moderate degree of heat and of moiſture, it never fails to ſend forth and to bring to perfection an abundant crop. In proportion to the degree in which any ſoil conſiſts of this black mould, its value increaſes. If, therefore, a huſbandman could cover the portion of territory allotted to him with a tolerable depth of this kind of ſoil, nothing more would be neceſſary to the ſucceſs of his enterpriſes, as he

Principles of Cultivation.

he could rear whatever vegetables he thought fit, in perfection, and in great profusion. It is to be observed, however, that this kind of mould or soil cannot be relied upon as permanent. If crops of grain should be taken from it year after year, it would soon lose its fertile qualities, and become unfit for the purposes of a prosperous agriculture. Here then is the remarkable difference between this kind of soil and the three others that were formerly mentioned, sand, clay, and chalk. Whatever properties these possess are unperishing, and can only be altered or modified by the operation of a fierce heat. Unfortunately, however, in their pure state, as already mentioned, they are of little value to the husbandman; and it is only in proportion to the degree in which they are mixed with the dark coloured or garden mould, that they become adapted to his purposes: but as the qualities of this mould are of a transitory nature, it is of the utmost importance, and ought indeed to form the great basis of every theory of agriculture, to explain how they may be preserved in existence, or restored when lost.

75 Nature of garden mould.

To understand this subject correctly, it is necessary to consider the nature and origin of this fertile mould. It is evidently not one of those original substances which form a part of the great mass of the solid globe of the earth, but appears to be the result of the operations and of the destruction of living and organized beings that have existed upon it. "Were a naked rock, says Mr Headrick, in an essay which we shall afterwards have occasion to mention, suddenly thrown up from the sea or from the bowels of the earth, the first plants which nature would place upon it, would be the various species of *lichens*, and such as can subsist wholly upon what they imbibe from the air, without needing a soil in which to push their roots. These plants serve the double purpose of clothing the rock, and thus preventing the fine particles that are dissolved by air and moisture from being washed away, and, from their growth and dissolution, of accumulating vegetable soil for the sustenance of more succulent plants. The rock is thus gradually made to acquire such a depth of soil, that it becomes able to sustain not only grasses and shrubs, but may become a receptacle for the oak itself." The progress here stated is correct; but some circumstances must be added to it, to render it practically useful to the husbandman. It is to be observed then, that animal substances, after they have ceased to form a part of a living body, have a tendency to proceed rapidly into a state of putrefactive fermentation, by which the greatest part of their mass is rendered volatile. When animal substances are mingled with vegetables, they speedily communicate their own fermentation or putrefaction to the vegetables, which by means of it are decomposed, fall to pieces, and are transformed into that kind of black earth, which we have called garden mould, and which forms the most fertile of all soils for the production of vegetables. It is by this process then, that is, by the fermentation of vegetable by means of animal substances, that the surface of this globe has been fertilized, or a black and rich mould produced upon it, as we daily see taking place in a variety of situations. No sooner do the small lichens or mosses cover the face of the naked rock, or gravel, or clay, than a variety of species of small animals appear, and feed upon them. As the plants and animals die in succession, their substances mingle and give rise to the putrefaction already mentioned, which is productive of a small portion of soil. A new race of plants of greater strength and bulk rises upon the ruins of the first, and supports larger animals, all destined in their turn to perish and to increase the quantity of fertile soil. More valuable grasses soon supplant the original small and coarse vegetables, and the spot assumes the appearance of a rich verdure. New species of animals also begin to inhabit it: snails and worms abound; and by their remains contribute to the dissolution of the roots of plants, which everywhere penetrate the new soil, and to the decomposition of the stems which periodically fall down. When the soil has acquired sufficient depth, it is sheltered by shrubs; and, lastly, by forest trees, under the shade of which the larger animals exist. The trees shed their leaves every season, and every season consequently gives an additional layer or *stratum* of fertile mould to the soil: and thus while the forest endures, the fertility of the territory on which it stands continues to be augmented by its spoils, and by the bodies of the animals which repair to it for shelter.

Communications to the Board of Agriculture, vol. ii.

76 Process by which nature fertilizes the earth.

This process, by which nature gives fertility to the earth, or creates the rich mould on which vegetables flourish, ought to be imitated by the husbandman; and, in fact, it has been imitated in consequence of a knowledge that is derived from experience and from practice, rather than from the general speculations of science. The imitation of nature upon this point constitutes the art of producing manures, which will be afterwards considered. The principle upon which it proceeds, rests upon this foundation, which is known to be true in fact, that the fermentation of animal and vegetable substances produces that kind of dark rich mould which forms the most fertile soil.

In what way, or by what peculiar operation, this kind of mould or soil becomes so highly conducive and subservient to the growth of plants, is a point of more difficult research, and is fortunately of less importance to be known to the practical agriculturist. It may be observed, however, that this mould possesses, in an eminent degree, all the requisites necessary to the success of vegetation. It retains moisture, which is so necessary to that process, without, at the same time, keeping hold of it with that retentiveness which, in clay, has the effect of injuring the roots of the plants. As this mould consists of the remains both of animal and vegetable life, it necessarily contains an immense variety of ingredients which have different degrees of chemical affinity to each other. By the operation of these affinities in bringing the different substances into new combinations, a great quantity of heat must be continually produced or evolved, as occurs in so many chemical processes. By this heat the roots of the plants will be nourished, especially when assisted by the heat which they themselves throw out or produce when germinating. Thus, by the kind of soil now mentioned, or by the aid of manure, the defects of a cold and ungenial climate may, in some measure, be rectified, and the seeds and roots of vegetables may be supplied with due and seasonable warmth. It is also probable, that what is called the exhausted state of a soil, in consequence of much plowing, and many crops having been taken from it, may chiefly arise from this circumstance, that

77 Conjecture about exhausted soils.

Principles of Cultivation.

that all the chemical affinities having at laſt operated, every particle of the ſoil remains at reſt, and no more heat is produced by the activity of its parts.

That plants growing in fertile mould, like that now mentioned, derive nouriſhment or food from it, cannot be doubted, ſince we ſee, that when taken out of it, or placed in another but leſs favourable ſoil, they ſpeedily go into decay. What the particular ſubſtances are, however, which they take from it, has not been diſcovered. But it appears from the minuteneſs of the extreme fibres of the roots of plants, that the food taken in by them muſt be ſoluble in water, or in a liquid ſtate when taken in by them. Accordingly, their food is actually found to aſcend through their organs in a liquid form. Of this liquor or ſap there are two kinds, the aſcending and the deſcending. The aſcending ſap is that which riſes in the ſpring; and by cutting a ſhort way through the bark into the wood of many trees, large quantities of it may be drawn off, without injury to their health or growth. This ſap aſcends to the leaves, and there undergoes ſome change by the action of the air; for the leaves of vegetables appear to perform to them an office ſimilar to that which is accompliſhed in animals by the organ called the *lungs*. From the leaves the ſap, thus changed, deſcends to every part of the plant, and contributes to its growth by becoming a part of its ſubſtance. It would ſeem, however, that the liquors which circulate in plants, not only undergo a change at the leaves, but alſo at their firſt entrance by the veſſels of the roots; for if ſeveral different kinds of trees are ingrafted upon the ſame common ſtock, each of them is able to derive the ſap peculiar to itſelf from the ſap of the common ſtock. Thus alſo the chemiſts have informed us, that vinegar, called by them the *acetous acid*, is found variouſly combined in the aſcending ſap of various trees; but it has never yet been diſcovered, that vinegar exiſts in any perceptible quantity in vegetable mould. That ſubſtance, therefore, muſt be formed by the root, by bringing together the ingredients of that acid which it finds and ſelects in the earth.

When any plant, whether great or ſmall, is put into a cloſe veſſel, and ſtrongly heated, allowing only the ſmoke to eſcape, the reſidue is in all caſes of the ſame nature, and is called *charcoal*, or by the chemiſts *carbon*. Of this carbonaceous matter a conſiderable quantity is always found in rich garden mould, derived no doubt from the remains of vegetable ſubſtances of which that mould was originally formed. This carbonaceous matter, however, or charcoal, being inſoluble in water, cannot in its ordinary ſtate enter into the veſſels of growing vegetables; but, as it is rendered ſoluble by a variety of combinations, it is no doubt found out in ſuch a ſtate by the fibres of growing roots, and conveyed upwards in the juice. But as all vegetable mould, and the charcoal or carbonaceous matter which it contains, is the reſult of the ruins of vegetation, and as the lichens or vegetables of the coarſeſt and ſimpleſt kind, which originally grow upon the naked ſtone, have no other nouriſhment than water and atmoſpheric air, it is probable, that out of theſe materials they are capable of forming the charcoal, which conſtitutes the baſis of their form, and of the conſtitution of every other vegetable. It is true, that the chemiſts ſtill regard carbon or charcoal as a ſimple and uncompounded ſubſtance; and they have not found it in water, nor in atmoſpheric air, unleſs in the moſt minute degree, reſulting probably from the combuſtion of fires and the breathing of animals in inhabited countries. But although chemiſts have not hitherto been able to find charcoal in the three ſimple ſubſtances, oxygen, hydrogen, and azote, of which atmoſpheric air and water are compoſed, it ſeems evident, that the mighty Chemiſt who contrived this world and the conſtitution of vegetables, finds no difficulty in forming it of thoſe materials by means of their organization. Hence we rather think, that water and air muſt conſtitute the original food of the ſimpleſt and coarſeſt kind of plants; but if this idea be true, it is to be regarded as a fact that is more curious in ſpeculation than uſeful in practice: for it is certain, that the more valuable and larger vegetables, which it is the buſineſs of the huſbandman to cultivate, cannot be reared to perfection without the aid of vegetable mould. Though they may poſſeſs, therefore, the power of deriving a portion of their ſolid ſubſtance, or of the carbonaceous matter which they contain, from common air and water, they cannot obtain the whole by this means, and require the aid of the remains of former vegetation. It is thus that one ſyſtem is ſeen to pervade every part of nature, as through all her works one claſs of animated beings only enjoys life in conſequence of the deſtruction of another. Thus the carnivorous animals conſume thoſe that live upon vegetables; and thus, in like manner, one ſpecies of vegetables only ſubſiſts upon the ruins, and is fed by the ſubſtance, of a former generation of plants.

76 Vegetables are the food of each other.

Beſides animal ſubſtances, there are ſome minerals that have a tendency to accompliſh the decompoſition of vegetables, and thereby to reduce them into a ſtate of mould, poſſeſſing in a great degree the qualities of the garden mould that is produced by the fermentation of the remains of animals and vegetables, the formation of which has now been deſcribed. Of the minerals that have this tendency, lime is the chief, and indeed the one commonly in uſe, either pure or when combined with clay under the form of marl. To the effect of lime, therefore, we ſhall now call the attention of the reader.

Where the ground has been ſuffered to remain uncultivated for many ages, producing all that time ſucculent plants which are eaſily putrefied, and trees, the leaves of which likewiſe contribute to enrich the ground by their falling off and mixing with it, the ſoil will in a manner be totally made up of pure vegetable earth, and be the richeſt, when cultivated, that can be imagined. This was the caſe with the lands of America. They had remained uncultivated perhaps ſince the creation, and were endowed with an extraordinary degree of fertility; nevertheleſs we are aſſured by one who went to America in order to purchaſe lands there, that ſuch grounds as had been long cultivated, were ſo much exhauſted, as to be much worſe than the generality of cultivated grounds in this country. Here, then, we have an example of one ſpecies of poor ſoil; namely, one that has been formerly very rich, but has been deprived, by repeated cropping, of the greateſt part of the vegetable food it contained. The farmer who is in poſſeſſion of ſuch ground, would no doubt willingly reſtore it to its former ſtate; the preſent queſtion is,

79 One ſpecies of poor ſoil deſtroyed by lime.

What

Principles of Cultivation.

What muſt be done in order to obtain this end? We have mentioned ſeveral kinds of manures which long practice has recommended as ſerviceable for improving ground: we ſhall ſuppoſe the farmer tries lime or chalk; for, as we have already ſeen, their operations upon the ſoil muſt be preciſely the ſame. This ſubſtance, being of a ſeptic nature, will act upon ſuch parts of the ſoil as are not putrefied, or but imperfectly ſo; in conſequence of which, the farmer will reap a better crop than formerly. The ſeptic nature of the lime is not altered by any length of time. In ploughing the ground, the lime is more and more perfectly mixed with it, and gradually exerts its power on every putreſcible matter it touches. As long as any matter of this kind remains, the farmer will reap good crops; but when the putreſcible matter is all exhauſted, the ground then becomes perfectly barren; and the cauſtic qualities of the lime are moſt unjuſtly blamed for *burning* the ground, and reducing it to a *caput mortuum*; while it is plain the lime has only done its office, and made the ſoil yield all that it was capable of yielding.

So ſpecies of poor ſoil meliorated by lime.

When ground has been long uncultivated, producing all the time plants, not ſucculent, but ſuch as are very difficultly diſſolved, and in a manner incapable of putrefaction; there the ſoil will be exceſſively barren, and yield very ſcanty crops, though cultivated with the greateſt care. Of this kind are thoſe lands covered with heath, which are found to be the moſt barren of any, and the moſt difficultly brought to yield good crops. In this caſe lime will be as ſerviceable as it was detrimental in the other: for by its ſeptic qualities, it will continually reduce more and more of the ſoil to a putrid ſtate; and thus there will be a conſtant ſucceſſion of better and better crops, by the continued uſe of lime when the quantity firſt laid on has exerted all its force. By the continued uſe of his manure, the ground will be gradually brought nearer and nearer to the nature of garden mould; and, no doubt, by proper care, might be made as good as any: but it will be as great a miſtake to imagine, that, by the uſe of lime, this kind of ſoil may be rendered perpetually fertile, as to think that the other was naturally ſo; for though lime enriches this ſoil, it does ſo, not by adding vegetable food to it, but by preparing what it already contains; and when all is properly prepared, it muſt as certainly be exhauſted as in the other caſe.

81 Poor ſoils, how reſtored.

Here, then, we have examples of two kinds of *poor* ſoils; one of which is totally deſtroyed, the other greatly improved, by lime, and which therefore require very different manures; lime being more proper for the laſt than dung; while dung, being more proper to reſtore an exhauſted ſoil than lime; ought only to be uſed for the firſt. Beſides dunging land which has been exhauſted by long cropping, it is of great ſervice to let it lie fallow for ſome time: for to this it owed its original fertility; and what gave the fertility originally, cannot fail to reſtore it in ſome degree.

By attending to the diſtinction between the reaſons for the poverty of the two ſoils juſt now mentioned, we will always be able to judge with certainty in what caſes lime is to be uſed, and when dung is proper. The mere poverty of a ſoil is not a criterion whereby we can judge; we muſt conſider what hath made it poor. If it is naturally ſo, we may almoſt infallibly conclude, that it will become better by being manured with lime. If it is *artificially* poor, or exhauſted by continual cropping, we may conclude that lime will entirely deſtroy it. —We apprehend, that it is this *natural* kind of poverty only which Mr Anderſon ſays, in his Eſſays on Agriculture, may be remedied by lime; for we can ſcarce think that experience would direct any perſon to put lime upon land already exhauſted. His words are,

82 Mr Anderſon's opinion concerning lime.

"Calcareous matters act as powerfully upon land that is naturally poor, as upon land that is more richly impregnated with thoſe ſubſtances that tend to produce a luxuriant vegetation."

"Writers on agriculture have long been in the cuſtom of dividing manures into two claſſes, viz. *Enriching* manures, or thoſe that tended directly to render the ſoil more prolific, however ſterile it may be; among the foremoſt of which was dung: *Exciting* manures, or thoſe that were ſuppoſed to have a tendency to render the ſoil more prolific, merely by acting upon thoſe enriching manures that had been formerly in the ſoil, and giving them a new ſtimulus, ſo as to enable them to operate anew upon that ſoil which they had formerly fertilized. In which claſs of ſtimulating manures, *lime* was always allowed to hold the foremoſt place.

"In conſequence of this theory, it would follow, that lime could only be of uſe as a manure when applied to rich ſoils;—and, when applied to poor ſoils, would produce hardly any, or even perhaps hurtful, effects.

"I will frankly acknowledge, that I myſelf was ſo far impoſed upon by the beauty of this theory, as to be hurried along with the general current of mankind, in the firm perſuaſion of the truth of this obſervation, and for many years did not ſufficiently advert to thoſe facts that were daily occurring to contradict this theory. —I am now, however, firmly convinced, from repeated obſervations, that lime, and other calcareous manures, produce a much greater *proportional* improvement upon poor ſoils than ſuch as are richer;—and that lime alone, upon a poor ſoil, will, in many caſes, produce a much greater and more laſting degree of fertility than dung."

Thus far Mr Anderſon's experience is exactly conformable to the theory we have laid down, and what ought to happen according to our principles. He mentions, however, ſome facts which ſeem very ſtrongly to militate againſt it; and indeed he himſelf ſeems to proceed upon a theory altogether different.

83 Query concerning the nature of a proper ſoil.

"Calcareous matter alone (ſays he) is not capable of rearing plants to perfection;—mould is neceſſary to be mixed with it in certain proportions, before it can form a proper ſoil. It remains, however, to be determined, what is the due proportion of theſe ingredients for forming a proper ſoil.

"We know that neither chalk, nor marl, nor lime, can be made to nouriſh plants alone; and ſoils are ſometimes found that abound with the two firſt of theſe to a faulty degree. But the proportion of calcareous matter in theſe is ſo much larger than could ever be produced by art, where the ſoil was naturally deſtitute of theſe ſubſtances, that there ſeems to be no danger of erring on that ſide. Probably it would be much eaſier to correct the defects of thoſe ſoils in which calcareous matters

Principles of Cultivation.

ters ſuperabound, by driving earth upon them as a manure, than is generally imagined; as a very ſmall proportion of it ſometimes affords a very perfect ſoil. I ſhall illuſtrate my meaning by a few examples.

84 Examples of ſoil perpetually fertile.

"Near Sandſide, in the county of Caithneſs, there is a pretty extenſive plain on the ſea coaſt, endowed with a moſt ſingular degree of fertility. In all ſeaſons it produces a moſt luxuriant herbage, although it never got any manure ſince the creation; and has been from time immemorial ſubjected to the following courſe of crops.

"1. Bear, after once ploughing from graſs, uſually a good crop.

"2. Bear, after once ploughing, a better crop than the firſt.

"3. Bear, after once ploughing, a crop equal to the firſt.

"4. 5. and 6. Natural graſs, as cloſe and rich as could be imagined; might be cut, if the poſſeſſor ſo inclined, and would yield an extraordinary crop of hay each year.

"After this the ſame courſe of cropping is renewed. The ſoil that admits of this ſingular mode of farming, appears to be a pure incoherent ſand, deſtitute of the ſmalleſt particle of vegetable mould; but, upon examination, it is found to conſiſt almoſt entirely of broken ſhells: the fine mould here bears ſuch a ſmall proportion to the calcareous matter, as to be ſcarce perceptible, and yet it forms the moſt fertile ſoil that ever I yet met with.

"I have ſeen many other links (downs) upon the ſea ſhore, which produced the moſt luxuriant herbage, and the cloſeſt and ſweeteſt pile of graſs, where they conſiſted of ſhelly ſand; which, without doubt, derive their extraordinary fertility from that cauſe.

"A very remarkable plain is found in the iſland of Jir-eye, one of the Hebrides. It has been long employed as a common: ſo that it has never been diſturbed by the plough, and affords annually the moſt luxuriant crop of herbage, conſiſting of white clover and other valuable paſture graſs, that can be met with anywhere. The ſoil conſiſts of a very pure ſhelly ſand.

"From theſe examples, I think it is evident, that a very ſmall proportion of vegetable mould is ſufficient to render calcareous matter a very rich ſoil. Perhaps, however, a larger proportion may be neceſſary when it is mixed with clay than with ſand; as poor chalky ſoils ſeem to be of the nature of that compoſition."

To theſe examples brought by Mr Anderſon, we may add ſome of the ſame kind mentioned by Lord Kames. His lordſhip having endeavoured to eſtabliſh the theory of water being the only food of plants, though he himſelf frequently deviates from that theory, yet thinks it poſſible, upon ſuch a principle, to make a ſoil perpetually fertile.

"To recruit (ſays he), with vegetable food, a ſoil impoveriſhed by cropping, has hitherto been held the only object of agriculture. But here opens a grander object, worthy to employ our keeneſt induſtry, that of making a ſoil perpetually fertile. Such ſoils actually exiſt; and why ſhould it be thought, that imitation here is above the reach of art? Many are the inſtances of nature being imitated with ſucceſs. Let us not deſpair while any hope remains; for invention never was exerciſed upon a ſubject of greater utility. The attempt may ſuggeſt proper experiments: it may open new views: and if we fail in equalling nature, may we not, however, hope to approach it? A ſoil perpetually fertile muſt be endowed with a power to retain moiſture ſufficient for its plants, and at the ſame time muſt be of a nature that does not harden by moiſture. Calcareous earth promiſes to anſwer both ends: it prevents a ſoil from being hardened by water; and it may probably alſo invigorate its retentive quality. A field that got a ſufficient doſe of clay marl, carried above 30 ſucceſſive rich crops, without either dung or fallow. Doth not a ſoil ſo meliorated draw near to one perpetually fertile? Near the eaſt ſide of Fife, the coaſt for a mile inward is covered with ſea ſand, a foot deep or ſo; which is extremely fertile, by a mixture of ſea ſhells reduced to powder by attrition. The powdered ſhells, being the ſame with ſhell marl, make the ſand retentive of moiſture; and yet no quantity of moiſture will unite the ſand into a ſolid body. A ſoil ſo mixed ſeems to be not far diſtant from one perpetually fertile. Theſe, it is true, are but faint eſſays; but what will not perſeverance accompliſh in a good cauſe?"

Having thus in a manner, poſitively determined with Mr Anderſon, that no doſe of calcareous matter can poſſibly be too great, we cannot help owning ourſelves ſurpriſed on finding his lordſhip expreſſing himſelf as follows: "An overdoſe of ſhell marl, laid perhaps an inch, and an inch and an half, or two inches thick, produces, for a time, large crops: but at laſt it renders the ſoil a *caput mortuum*, capable of bearing neither corn nor graſs; of which there are too many inſtances in Scotland. The ſame probably would follow from an overdoſe of clay marl, ſtone marl, or pounded limeſtone."—To account for this, he is obliged to make a ſuppoſition directly contrary to his former one; namely, that calcareous matter renders the ſoil *incapable* of retaining water. This phenomenon, however, we think is ſolved upon the principles above laid down, in a ſatisfactory manner, and without the leaſt inconſiſtency.

85 Inconſiſtency in Lord Kames's theory.

As to rendering ſoils perpetually fertile, we cannot help thinking the attempt altogether chimerical and vain. There is not one example in nature of a ſoil perpetually fertile, where it has no ſupply but from the air and the rain which falls upon it. The above recited examples can by no means be admitted as proofs of perpetual fertility. We know, that the graſs on the banks of a river, is much more luxuriant than what grows at a diſtance: the reaſon is, that the water is attracted by the earth, and communicates its fertilizing qualities to it; but was the river to be dried up, the graſs would ſoon become like the reſt. Why ſhould not the ocean have the ſame power of fertilizing plains near its ſhores, that rivers have of fertilizing ſmall ſpots near their banks? We ſee, however, that it hath not: for the ſea ſhores are generally ſandy and barren. The reaſon of this is, that the waters of the ocean contain a quantity of looſe acid *; and this acid is poiſonous to plants: but abſtracting this acid part, we heſitate not to affirm, that ſea water is more fertilizing than river water. It is impoſſible to know how far the waters of the ocean penetrate under ground through a ſandy ſoil. Where they meet with nothing to abſorb their acid, there the ground is quite barren; but in paſſing through an immenſe quantity of broken ſhells, the calcareous matter, we are very certain, will abſorb all the acid;

86 Perpetual fertility of ſoils chimerical.

* See *Water*.

Principles of Cultivation.

acid; and thus the soil will be continually benefited by its vicinity to the ocean. All the above fields, therefore, are evidently supplied with nourishment from the ocean: for if the salt water has sufficient efficacy to render fields which are in its neighbourhood barren, why should it not render them fertile when the cause of barrenness is removed from its waters?

After all, the field in Caithness, mentioned by Mr Anderson, seems to have been perpetually fertile only in grass; for though the second year it carried a better crop of bear than it did the first, yet the third year the crop was worse than the second, and only equal to the first. Had it been ploughed a fourth time, the crop would probably have been worse than the first. Ground is not near so much exhausted by grass as corn, even though the crop be cut and carried off; and still less if it only feeds cattle, and is manured by their dung; which appears to have been the case with this field. Lord Kames, indeed, mentions fields in Scotland, that, past memory, have carried successive crops of wheat, pease, barley, oats, without a fallow, and without a manure; and particularises one on the river Carron, of nine or ten acres, which had carried 103 crops of oats without intermission and without manure: but as we are not acquainted with any such fields, nor know any thing about their particular situation, we can form no judgement concerning them.

87 Clay and sandy soils.

Besides the two kinds of soils above mentioned, there are others, the principal ingredient of which is clay or sand. The first of these is apt to be hardened by the heat of the sun, so that the vegetables can scarce penetrate it in such a manner as to receive proper nourishment. The second, if it is not situated so as to receive a great deal of moisture, is very apt to be parched up in summer, and the crop destroyed; nor has it sufficient adhesion to support plants that have few roots and grow high. From these opposite qualities, it is evident that these two soils would be a proper manure for one another: the clay would give a sufficient degree of firmness to the sand, and the sand would break the too great tenacity of the clay. According to Dr Home's experiments, however, sand is the worst manure for clay that can be used. He recommends marl most. To reduce clay ground as near as possible to the form of pure vegetable mould, it must first be pulverized. This is most effectually performed by ploughing and harrowing, but care must be taken not to plough it whilst too wet, otherwise it will concrete into hard clots which can scarcely be broken. After it is pulverized, however, some means must be taken to keep it from concreting again into the same hard masses as before. According to Lord Kames, though clay, after pulverization, will concrete into as hard a mass as before, if mixed with water; yet if mixed with dunghill juice, it will not concrete any more. Lime also breaks its tenacity, and is very useful as a manure for this kind of soil.

88 Fertility of the earth limited.

The conclusion we wish the practical farmer to draw from our theory is, That there is a certain limit to the fertility of the earth, both as to duration and to degree, at any particular time: that the nearer any soil approaches to the nature of pure garden mould, the nearer it is to the most perfect degree of fertility; but that there are no hopes of keeping it perpetually in such a state, or in any degree of approximation to it, but by constant and regular manuring with dung. Lime, chalk, marl, &c. may be proper to bring it near to this state, but are absolutely unfit to keep it continually so. They may indeed for several years produce large crops; but the more they increase the fertility for some years, the sooner will they bring on an absolute barrenness; while regular manuring with plenty of dung will always ensure the keeping up the soil in good condition, without any occasion for fallow. What we have said concerning the use of lime, &c. applies likewise to the practice of frequent ploughing, though in a less degree. This tends to meliorate ground that is naturally poor, by giving an opportunity to the vegetable parts to putrefy; but when that is done, it tends to exhaust, though not so much as lime. A judicious farmer will constantly strive to keep his lands always in good condition, rather than to make them suddenly much better; lest a few years should convince him that he was in reality doing almost irreparable mischief, while he fancied himself making improvements. As for the ridiculous notions of stimulating the ground by saline manures, we hope they will never enter the brain of any rational practitioner of agriculture.

Vegetables proper to be raised for Meliorating the Soil.

Sect. V. *Of the different kinds of Vegetables proper to be raised with a view to the Melioration of Soil.*

89 Soil pulverized by certain vegetables.

The methods of meliorating soils, which we have mentioned above, consisting of tedious and laborious operations that yield no return at first, it is natural for a farmer to wish for some method of meliorating his ground, and reaping crops at the same time. One very considerable step towards the melioration of ground is its pulverization. This is accomplished by repeated ploughings (A), as already mentioned; especially if performed in autumn, that the ground may be exposed to the winter's frost; but these ploughings yield no crop as long as the field is not sown. By planting in the field, however, those vegetables whose roots swell to a considerable bulk, the ground must constantly be acted upon by the swelling of their roots in all directions: and thus the growing of the crop itself may be equal, or superior, in efficacy to several ploughings, at the same time that the farmer enjoys the benefit of it. The plant most remarkable for the swelling of its roots is the potato; and by none is the ground meliorated more, or even so much. They are not, however, equally proper for all soils. In clay they do not thrive, nor are palatable; but in hard gravelly or sandy soils, they grow to a large size, and are of an excellent quality. Turnips likewise contribute to meliorate the

(A) This however, must be understood with some limitation; for it appears from experience, that many *light* and *thin* soils receive detriment rather than advantage from frequent ploughings; particularly in summer, when the sun exhales the nutritive particles in great abundance.

Of Deſtroying Weeds.

ground, by the ſwelling of their roots, though not ſo much as potatoes. They have this advantage, however, that they will thrive in almoſt any ſoil. In clay ground, peaſe and beans thrive exceedingly well, and therefore are proper in this kind of ſoil as a preparatory for other kinds of grain. Theſe puſh their roots deep into the ground, and cover it with their leaves more than other crops; ſo that the ſun has not ſo much acceſs as when it is covered with other kinds of grain. Wherever any of theſe kinds of vegetables are raiſed, it is obſervable, that more or leſs blackneſs is communicated to the ſoil: an evident ſign of its melioration; this being the colour of the true vegetable mould, or *loamy ſoil*, as it is called.

Beſides the above-mentioned plants, carrots, parſnips, cabbages, and all thoſe vegetables which ſink their roots deep in the ground, anſwer the ſame purpoſe of looſening and pulverizing the earth: but as they will not thrive but on ground already well cultivated, they cannot be raiſed to any advantage for the purpoſe of meliorating a poor ſoil.

It hath been cuſtomary in many places, particularly in England, to ſow turnip, peaſe, buck-wheat, &c. and then to plough them down for manuring the land. This being ſimilar to that operation of nature by which ſhe renders the uncultivated ſoils ſo exceedingly fertile, cannot fail of being attended with ſingular advantages; and might be looked upon as preferable even to driving dung on the land to fatten it, was it not attended with the entire loſs of a crop for that year.

In addition to this, it may be proper to remark, that an idea has been entertained with regard to the ſucceſſion of vegetables to each other, which ought not to be overlooked, as at ſome future period it may lead to important conſequences. It has been ſuppoſed, that the roots of plants, or at leaſt of ſome plants, poſſeſs a power of throwing out, as excrementitious, a part of the ſubſtances which they have taken in, but which are no longer neceſſary for their ſubſiſtence or growth. It is undoubted, at leaſt, that while by ſome plants the ſoil ſeems to be rendered altogether unfit for the production of certain others, it is rendered by different plants extremely well adapted to their growth. Thus wheat ſucceeds uncommonly well after drilled beans; and theſe two vegetables have even been repeated for a great number of years in rotation, without any deficiency or failure of crop.

90 Some vegetables ſeem to enrich the ſoil.

Sect. VI. *Of deſtroying Weeds.*

What we have already ſaid regarding the cultivation of the ſoil, reſpects only the fitting it for producing all kinds of vegetables indiſcriminately. Experience, however, ſhows, that the ground is naturally much more diſpoſed to produce and nouriſh ſome kinds of vegetables than others; and thoſe which the earth ſeems moſt to delight in, are commonly ſuch as are of very little uſe to man; but if neglected, will increaſe to ſuch a degree, as entirely to deſtroy the plants intended to be raiſed, or at leaſt hinder them from coming to perfection, by depriving them of nouriſhment. The clearing the ground of weeds, therefore, is an article no leſs neceſſary in agriculture, than the diſpoſing it to produce vegetables of any kind in plenty.

Of Deſtroying Weed

The weeds may be divided, according to the time of their duration, into *annual*, or ſuch as ſpring from a ſeed, and die the ſame year; and *perennial*, that is, ſuch as are propagated by the ſeeds, and laſt for a number of years. The firſt kind are the leaſt noxious, and moſt eaſily deſtroyed. For this purpoſe it will be ſufficient to let them ſpring up till near the time of ripening their ſeed, and then plough them down before it comes to maturity. It is alſo of ſervice to deſtroy ſuch weeds as grow in borders or neglected corners, and frequently ſcatter their ſeeds to a great diſtance; ſuch as the thiſtle, dandelion, rag-weed, &c. for theſe are ſufficient to propagate their ſpecies through a deal of ground; as their ſeeds are carried about with the wind to very conſiderable diſtances. A farmer ought alſo to take care, that the ſmall ſeeds of weeds, ſeparated from corn in winnowing, be not ſown again upon the ground; for this certainly happens when they are thrown upon a dunghill; becauſe, being the natural offspring of the earth, they are not eaſily deſtroyed. The beſt method of preventing any miſchief from this cauſe, would be to burn them.

91 Weeds divided into annual and perennial.

Perennial weeds cannot be effectually deſtroyed, but by removing the roots from the ground, which is often a matter of ſome difficulty. Many of theſe roots ſtrike ſo deep in the ground, that they can ſcarcely be got out. The only method that can be depended upon in this caſe, is frequent ploughing, to render the ground as tender as poſſible; and harrowing with a particular kind of harrow, which ſhall hereafter be deſcribed, in order to collect theſe pernicious roots. When collected, they ought to be dried and burnt, as the only effectual method of enſuring their doing no further miſchief.

92 Perennial weeds, how deſtroyed.

There is a particular ſpecies of weed, peculiar only to graſs lands, of a ſoft ſpongy nature, called *fog*, which it is found very difficult to exterminate. Where the land can be conveniently tilled, this weed may be deſtroyed by covering it with a crop of peaſe, potatoes, &c. or, paſſing a heavy roller over the ground will be of great ſervice; for fog owes its origin to too great a laxity of the ſoil, and will not grow on firm ground.

Beſides theſe kinds of weeds which are of an herbaceous nature, there are others which are woody, and grow to a very conſiderable ſize; ſuch as broom, furze or whins, and thorns. *Broom* is an evergreen ſhrub, that thrives beſt in a ſandy ſoil; and there it grows ſo vigorouſly, as ſcarcely to admit any graſs under it. It propagates by ſeed which grows in pods; and theſe, when fully ripe, break with violence, ſcattering the ſeeds all around. Thus, a field which is overgrown with broom, beſides the old plants, always contains an infinite number of young ones: ſo that though the old plants die when cut over, a freſh crop conſtantly ſprings up. It may, however, be deſtroyed by frequent ploughing and harrowing, in the ſame manner as other perennial weeds are; for it does not for ſome time carry any ſeed, and the frequent ploughing encourages the vegetation of all thoſe ſeeds that are already in the ground, which cannot fail of being deſtroyed by frequent repetitions of the operation. Another method of deſtroying broom, is by paſturing the field where it grows with ſheep. A few of the old buſhes may be left as a ſhelter, and theſe will be in a good meaſure prevented from

93 Broom, furze, &c. how deſtroyed.

Diſeaſes of Plants.

from ſpreading by the cropping of the ſheep. Theſe animals are very fond of broom, and greedily devour every young ſhoot: ſo that if any remain after the firſt year, there will not be a veſtige the ſecond. If this method of extirpating broom is equally effectual with that of frequent ploughing, it is certainly much more profitable, as there is no food more nourithing to ſheep than young broom. Broom, however, is ſaid to have a ſingular effect upon ſheep: it makes them drunk ſo effectually, that when heated with a little driving, they tumble over, and lie without motion.

The *whin* is a fine evergreen ſhrub, carrying a ſweet-ſmelling flower all the year round. It propagates both by ſeed and by its roots, which ſpread ſometimes to the diſtance of 10 or 12 feet; and hence, when once eſtabliſhed, it is with difficulty extirpated. The beſt method is to ſet fire to the whins in froſty weather; for froſt has the effect to wither whins, and make them burn readily. The ſtumps muſt then be cut over with a hatchet; and when the ground is well ſoftened by rain, it may be ploughed up, and the roots taken out by a harrow adapted to that purpoſe. If the field is ſoon laid down to graſs, the whins will again ſpring up in great abundance from the ſeeds, and ſmall parts of the roots left in the ground. In this caſe, paſturing with ſheep is an effectual remedy; as they are no leſs fond of young whins than of young broom; and if there are a ſufficient number, they will not leave a ſingle plant above ground. But if graſs is not immediately wanted, the moſt effectual method of clearing a field of whins, is by reiterated ploughings.

The *thorn*, or *bramble*, ſpreads its roots very wide, and at the ſame time ſinks them deep in the earth. Though cut in the winter, it riſes, and comes to ſuch perfection as to carry fruit in ſummer. It can only be extirpated by ploughing up the ground and collecting the roots.

94 Shrubs are deſtroyed by flooding the land.

One effectual plan, which, as will afterwards appear, is practicable in many more ſituations than it has hitherto been applied to, for deſtroying theſe and all other woody ſhrubs and plants, together with a great number of weeds that are of no value upon paſture grounds, conſiſts of flooding the land, by directing over it a ſtream of water. By means of ſuch a device, all whins and other ſhrubs are completely rotted and deſtroyed.

Sect. VII. *Of the Diſeaſes of Plants.*

95 The diſeaſes of vegetables are ill underſtood.

As ſome of the moſt valuable kinds of vegetables are liable to ſuffer much by diſeaſes peculiar to themſelves, it is of much importance to the huſbandman to be aware of this circumſtance, and to adopt every known mode of protecting his crop againſt them. At the ſame time, as the principles of vegetable life are by no means well underſtood, the cauſes and the cure of the moſt ſerious diſeaſes affecting plants ſtill remain under a great degree of obſcurity, and the moſt experienced and intelligent huſbandmen expreſs great uncertainty reſpecting the meaſures to be adopted for preventing their appearance. Hence it appears moſt proper to introduce the conſideration of them in this place before we proceed to the practical part of the ſubject; and as wheat is accounted the moſt valuable kind of grain, we ſhall begin with the diſeaſes to which it is expoſed. Diſeaſes of Plants.

96 Diſeaſes to which wheat is liable.

Wheat chiefly ſuffers from two diſeaſes, the blight and the mildew. Of the blight in wheat we ſhall give an account upon the authority of an eſſay by Robert Somerville, Eſq. ſurgeon, 1ſt Battalion, 8th Fencible Regiment, inſerted in the communications to the Board of Agriculture *, giving a ſtatement of the nature and appearance of the blight which occaſioned the failure of the crop in 1795.—When the crop had juſt ſhaken the flowers, and the grains were beginning to form, moſt of them ſeemingly in a healthy manner, it was obſerved that many of the blades and ſtalks were rather of a dirty green colour, and in two weeks thereafter there appeared upon them great numbers of ſmall red inſects. As the ſeaſon advanced, theſe inſects not only increaſed in ſize, but became more numerous, and in almoſt every field the grain began to manifeſt unequivocal ſymptoms of diſeaſe, which were ſo formidable, that in many inſtances a total loſs was dreaded, and in not a few caſes, one half of the crop was actually deſtroyed. The minute ſymptoms of the blight were theſe:

* Vol. ii.

97 Blight in 1795.

1ſt, In the very early ſtages of the diſeaſe, and before the ear was affected, the blades and ſtalks were marked with black and ruſty ſpots. Theſe ſpots ſeemed to be occaſioned by a glutinous ſubſtance depoſited upon them, eaſily ſoluble in water, and which could be readily waſhed off by rubbing the ſtalks with a wet cloth. Some ſpots, however, were white, and theſe ſeemed to be owing to wounds or punctures made by vermin; the leaf having, to a certain extent, in conſequence of theſe, withered and become white. As the ſeaſon advanced, the black and ruſty-coloured ſpots became larger and more numerous: and when the grain began to ripen, not only the blades but the ſtraw were almoſt entirely coloured with black ſpots.

2d, After the crop had begun to ſhoot, and was in the ear, many of the heads were entirely empty. Where the ſtalk was green, and to appearance tolerably healthy, but the ear at the ſame time withered and without grain, the misfortune ſeemed to have ariſen from an injury done to the neck of the ear, at the place of its junction with the ſtalk. There the outer rind was deſtroyed all round, which muſt have cut off the circulation between the ear and the ſtalk, as happens in trees that have had their bark deſtroyed all round.

3d, Many of the ears were entirely empty in the upper part, while the lower half was well filled. In theſe caſes, the injury ſeemed owing to the rind being deſtroyed about the middle of the ear, at that place which ſeparated the full from the empty part, and was ſimilar to the injury done in the preceding caſe where the whole ear was deſtroyed.

4th, In very many caſes the ears had a plump well-filled pickle and an empty huſk alternately. In theſe the injury ſeemed owing to a wound inflicted at the bottom of the empty grains, where they are joined to the ſtalk, and which had taken place while they were in flower, preventing them from making any farther progreſs.

5th, Many ears, though not entirely empty, contained only ſmall ſhrivelled grains, or what are called hungry

Diſeaſes of Plants.

hungry pickles. Theſe ſeemed to have eſcaped any accident till they had made ſome progreſs in filling, after which they became ſtationary and ripened prematurely. On examination they were found to be injured at the place where they were joined to the ſtalk, in the ſame manner as was already mentioned, in the caſe of thoſe that had empty heads or ears. Like theſe alſo the whole ear was in ſome caſes ill filled. In others only half of it was in that ſtate, and in a very great number the ears conſiſted of a well and ill filled grain alternately. Without a ſingle exception, the whole of the ill filled or hungry grains, were wounded at the place of their inſertion into the ear.

6th, A number of ears, though well filled, were upon opening the huſks found almoſt entirely covered with black and ruſty ſpots, nearly reſembling thoſe already deſcribed, and like them alſo they were eaſily rubbed or waſhed off. The downy part of many of theſe grains, when examined carefully with a good glaſs, appeared to contain ſeveral ſmall white tranſparent globes, reſembling the eggs of inſects.

7th, In many fields, eſpecially ſuch as had been fallowed and well manured for the wheat crop, a great number of plants were entirely withered from top to bottom. The decay, in moſt of theſe caſes, took place when the wheat was beginning to ſhoot. No injury was viſible in theſe caſes upon the blade or ſtalk, but on examining the roots, a worm was found at every one of them.

Laſtly, As the crop began to whiten, the dark or ruſty ſpots on the ſtraw and ears became more numerous, and appeared more conſpicuous. In place of putting on a white or yellow appearance, the whole crop looked as if it had been ſprinkled with ſoot.

The whole of theſe ſymptoms appeared to ariſe from the attack of an inſect, and from the injuries and depredation which it committed upon the plants. This inſect when firſt diſtinguiſhable by the eye, was of a red colour, and ſo ſoft as to be killed by the ſlighteſt preſſure. As it increaſed in ſize the colour gradually changed to a dirty black, at which it became ſtationary. During its growth it loſt its ſoft texture, and in proportion as its colour darkened it became hard, and as it were covered with a cruſt or ſhell upon the back. It is ſaid to be not uncommon, and to be met with at all times, even in the beſt fields of wheat, though its numbers are infinitely increaſed in late wet ſeaſons. From its eggs appearing to lodge upon the well-filled ears of the grain, it might be conſidered as in danger of being propagated to the ſucceeding crop. On this account our author hazards ſome conjectures upon the beſt means of preventing future danger from it. One of theſe conſiſts of the uſe of lime mixed up with all manure, with a view to prevent inſects from being generated in it. It is alſo ſuggeſted that the manure, by means of which ſlugs and worms are chiefly ſuppoſed to be produced, ought not to be plowed into the ground in autumn, but applied as a top-dreſſing in the ſpring; becauſe it is underſtood that manure, expoſed to the ſun and air, has much leſs tendency to foſter inſects, than when it is covered up in the earth.

98 Mildew is red or black, called ſmut.

Another diſeaſe, which is much more deſtructive to wheat, and much more frequently met with, is the mildew. It is of two kinds, the black and the red. In both caſes it conſiſts of a quantity of ſeemingly coarſe powder attached to the grain in the ear, or looſely ſurrounding it; in conſequence of which it is evidently prevented from filling or arriving at perfection. The black kind of mildew is by far the moſt frequent and the moſt pernicious. It is moſt generally known in England by the name of *ſmut*, and in Scotland by that of the *black*, both of which are ſufficiently expreſſive. Concerning the cauſe of this diſeaſe various opinions have been entertained. Dr Home, in his Principles of Agriculture and Vegetation, aſcribes it to an over luxuriancy of growth. He is of opinion, that too great an abundance of juices in a vegetable will produce diſeaſes ſimilar to thoſe occaſioned by repletion in animal bodies, viz. ſtagnations, corruptions, varices, cariofities, &c. along with the too great luxuriancy we have juſt now mentioned, which he expreſſes by "too great an abundance of water ſhoots." Hence he is induced to claſs the ſmut among diſeaſes ariſing from this cauſe, it being a corruption happening moſt in rainy ſeaſons and to weak grain. Like other contagious diſeaſes, he tells us, the ſmut may be communicated from the infected to healthful grain. At a preventive he recommends ſteeping the ſeed in a ſtrong pickle of ſea ſalt. Beſides the effect which this has upon the grain itſelf, it is uſeful for ſeparating the good from the bad; the beſt ſeed falling to the bottom, and the faulty ſwimming on the top of the liquor.

Diſeaſes of Plants.

99 Opinions concerning the cauſe of mildew.

Independent of this notion of an over luxuriancy of growth, it may be obſerved, that two opinions have chiefly been ſupported by perſons who have ſpeculated and written on this ſubject. One opinion is, that the mildew conſiſts of a great multitude of paraſitical plants adhering to the grains of wheat, living upon it, and thereby conſuming its ſubſtance. Another opinion is, that it conſiſts of great numbers of inſects and of eggs of inſects, whoſe form is too ſmall to be diſtinguiſhable by the naked eye. The firſt of theſe opinions has been adopted by the celebrated Italian writer Fontana, and the other by certain writers of our own country.

100 Fontana's opinion.

Fontana endeavours to refute the hypotheſis, that the duſt of the mildew conſiſts of animal eggs, by the following experiment. He cloſely confined the grains of the mildew between two glaſs plates, in ſuch a manner as neceſſarily to break the ſuppoſed eggs. He then, with an accurate microſcope, obſerved them while cruſhed in ſucceſſion. No liquid or glutinous juice proceeded from them, though great force was uſed in cruſhing them; but they appeared wholly to conſiſt of tough reſiſting ſubſtances altogether unlike real animal eggs: their being faſtened to the ſtalk or leaves of the grain, appeared alſo to militate againſt ſuch a ſuppoſition. From a variety of microſcopic obſervations, he is of opinion, that the powder of the black mildew or ſmut conſiſts of a great multitude of ſmall plants attached to the grain by a ſlender fibre. Theſe paraſitical plants, though extremely ſmall, he thinks ſufficiently regular. With regard to the red mildew he admits, that it appears to be compoſed of an immenſe multitude of minute eggs. After a variety of experiments and obſervations, however, he thought he diſcovered, that theſe apparent eggs are in truth the heads or fruit of very fine threads fixed on the ear of corn; that theſe threads or ſtems are exceedingly fine and tranſparent, which gives the appearance of eggs to their outward extremities. Theſe ſtems or tails

are

Diſeaſes of Plants.

are repreſented by him, as infinitely finer than thoſe of the black mildew; and their heads, which reſemble eggs, may be ſeparated from them by the ſlighteſt ſhock. From all his obſervations he concludes, that both the black and the red mildew conſiſt of real plants, though, perhaps, of an imperfect kind; and that they enfeeble and waſte the crop by abſorbing the nutritive juices of the plant. He obſerves, that, if a heavy rain ſpeedily fall on an extenſive mildew, waſhing the leaves and ſtalks affected, it preſently diſappears with hardly any damage to the corn; becauſe the ſmall plants having hardly taken root are eaſily diſperſed before any miſchief is done. He thinks, that the damage occaſioned by this diſeaſe may ſometimes be moderated or diminiſhed by cutting down the grain before it is fully ripe. In this caſe, he ſays, that the crop will be leſs than it ought to be; but ſtill it will be conſiderably greater than if the cuſtomary time of harveſt is waited for, when the diſeaſe will have leiſure to produce greater miſchief.

In our own country, and particularly by Mr Somerville, in the eſſay already quoted, the ſmut in wheat has been regarded as conſiſting of a great variety of inſects. He alſo founds his opinion upon microſcopic obſervations, and apprehends that from them he has clearly aſcertained the exiſtence of the inſects; and he thinks that it is communicated to other grain by contact, in conſequence of the paſſage of the inſects. Hence he endeavours to explain the utility of ſteeping the ſeed in pickles before it is ſown, with a view to the deſtruction of ſuch inſects.

101 Pickles to prevent ſmut or mildew.

It is to be remarked, that in all countries a great variety of theſe pickles has been contrived, with a view to prevent the exiſtence of ſmut in wheat, ſome of which we ſhall now mention. One of the moſt common is the ſalt pickle, conſiſting of a ſolution of common ſalt in water, of ſuch ſtrength as that an egg will ſwim in it. To the wheat, after it has been waſhed in this pickle, and the light grains removed, ſome new ſlaked lime is added, and carefully mixed with it with a wooden ſhovel, till it attain a ſufficient degree of dryneſs, in which ſtate it is committed to the earth. A pickle conſiſting of very ſtale urine has alſo been recommended to be uſed for waſhing wheat that is meant to be uſed as ſeed. It is attended with this diſadvantage, however, that if the urine is very ſtale, and if any length of time is ſuffered to elapſe, in conſequence of rain or other accidents, before the grain is ſown, its vegetative power is ſaid to be greatly injured by the corroſive quality of the volatile alkali with which ſuch urine abounds. This is more particularly the caſe when quicklime is added to the urine; as the alkali is then brought into a cauſtic ſtate.

Another pickle has been propoſed to the Board of Agriculture by an Italian phyſician, J. B. Scandella. It is prepared and uſed in the following manner:—Take of nitre, three pounds; alum, one pound; vitriol, ſix ounces; verdegris, three ounces; wood-aſhes, well ſifted, ſix pounds: Boil the whole in a copper with five pails of water for an hour, then remove them from the fire, and pour them into a large veſſel; then add ſixteen pails of water, in which half a buſhel of quicklime has been previouſly diſſolved: mix the whole intimately, and allow them to ſtand till they are quite cold. In this ſteep two buſhels and a half of wheat are to be plunged, and left for about ſix hours, ſtirring it up frequently with a wooden ſhovel, and ſkimming off what riſes to the ſurface; the wheat is then to be withdrawn, and ſpread out till it is dry enough for ſowing. The proceſs is thus to be continued until the whole quantity of ſeed intended to be ſown is pickled. The above ſteep is generally ſufficient for preparing about twenty-four buſhels of wheat.

Diſeaſes of Plants.

Another pickle has been recommended, conſiſting of a decoction in water of Barbadoes aloes, tobacco, and hellebore powder. A committee of the Royal Society of Agriculture at Paris, in 1786, recommended the following pickle for the ſame purpoſe, contrived by M. Tillet:—Pour upon 50 pounds of wood-aſhes, 900 pints of water; ſtir it well for three days, and then draw off. Waſh the black wheat in ſo many clear waters as not at laſt to dirty it. Heat the lye, ſo as juſt to bear the hand in it; ſlake in the hot lye one pound of lime to every ſeven or eight pints of it. Into the preparation dip the ſeed in baſkets many times. For want of wood-aſhes uſe potaſh, ſeven or eight pounds for 100 pints of water.

Communications to the Board of Agriculture, vol. ii. *Annals of Agricul.* vol. ix.

102 Arſenic uſed to prevent the mildew.

In addition to theſe it may be remarked, that a ſolution of arſenic in water is made uſe of in ſome counties of England, as a pickle in which they waſh or ſteep the grain previous to its being ſown, for the purpoſe of protecting the future crop againſt ſmut.

103 Arthur Young, Eſq. his experiments to prevent mildew.

The moſt complete ſet of experiments, however, which we have met with upon the ſubject, was made by Arthur Young, Eſq. at preſent ſecretary to the Board of Agriculture. December 7. 1787. he ſowed 14 beds with the ſame ſeed wheat as black with the ſmut as any he ever ſaw.

N° 1. Sown dry, nothing done to it.
2. Waſhed well in clean water.
3. Waſhed in lime-water.
4. Waſhed in a lye of wood aſhes.
5. Waſhed in an arſenic and ſalt mixture.
6. Steeped in lime-water four hours.

A propoſal has alſo been made, to deſtroy by means of:

Diſeaſes of Plants.

of heat the inſects which are ſuppoſed to propagate the diſeaſe called *ſmut* from the ſeed wheat to the future crop. The following directions for that purpoſe are

104 Erſkine of Marr's remedy.

extracted from the Agricultural Survey of the County of Clackmannan, by J. F. Erſkine, of Marr, Eſq. "Let the wheat be laid upon the kiln, about three or four inches thick: the kiln to be heated middling ſtrong with blind coal; the wheat to continue on the kiln for 24 hours, but turned frequently. After taking it off the kiln, it muſt be allowed 24 hours to cool; during which time it muſt be frequently turned; then put it through the fanners once or twice. After the wheat has lain a few hours on the kiln, and the fire begins to have effect, a great number of very ſmall worms, formerly undiſcovered by the eye, appear on the top of the grain, and are ſoon deſtroyed by the heat. Theſe come from blacked wheat, or other corns, that could not be ſuſpected to be indifferent; or may lie in or on good wheat; which worms continuing, (when not thus killed) might conſume the corn after it is thrown into the earth, thereby checking the growth entirely, or preventing it from having the ſtrength it otherwiſe would have to bring forth a ſtrong productive ſtalk. This practice is ſaid to have been brought from Ireland, and is recommended as preferable to pickling. It might perhaps be performed with greater ſucceſs by the uſe of a kiln heated by the ſteam of boiling water, in the way already mentioned, as ſuch a kiln would inſtantly afford a fixed and known degree of heat, which could in no caſe be exceeded."

After all, however, both from the reaſon of the thing, and from the concurring opinion of the moſt experienced and intelligent farmers, we think ourſelves authorized to ſay, that the huſbandman will act imprudently if he place entire and complete confidence in any one of the remedies above mentioned. His ſafeſt and beſt plan for procuring crops of wheat free from ſmut is this: In the firſt place, he ought to procure ſeed from a ſituation in which the grain has riſen abſolutely free from this diſeaſe. He ought next to exert the greateſt care in cleaning out, in the moſt anxious manner, his whole barns and their floors, and every place within doors into which his grain may come, and in which diſeaſed grain has formerly been kept: with this view it may probably be neceſſary to whitewaſh the walls with a mixture of quicklime and water, which will prove an effectual remedy. After having adopted theſe precautions, it may ſtill be neceſſary, with a view to ſecure a ſound and full crop, to plunge the ſeed into a ſtrong pickle of ſalt and water, with a view to float the lighter grains, which ought to be ſkimmed off and laid aſide for poultry, to which they may be given after being waſhed in freſh water. No future change of ſeed will be neceſſary. Of the farmers who have adopted this judicious mode of proceeding, there is no inſtance recorded of any one whoſe crop has ſuffered by ſmut; on the contrary, they have uſually derived a conſiderable profit from becoming the furniſhers of grain for ſeed to all their neighbours.

The want of nouriſhment in plants may be eaſily known by their decay; in which caſe, the only remedy

105 Diſeaſes peculiar to ſaffron.

is, to ſupply them with food, according to the methods we have already directed, or to remove from their neighbourhood ſuch other plants as may draw off the nouriſhment from thoſe we wiſh to cultivate.—In the Memoirs of the Academy of Sciences for 1728, Mr Du Hamel mentions a diſeaſe, which he calls *le mort*, that attacks ſaffron in the ſpring. It is owing to another plant, a ſpecies of trefoil, fixing ſome violet-coloured threads, which are its roots, to the roots of the ſaffron, and ſucking out its juice. This diſeaſe is prevented by digging a trench, which ſaves all the unaffected. Diſeaſes of Plants.

106 Vegetables deſtroyed by inſects.

The bad qualities, and unequal diſtribution of the juices of plants, are the occaſion of ſo few of the diſeaſes to which vegetables in this country are ſubject, that we forbear to mention them at preſent. Moſt of the diſeaſes of our plants are owing to external accidents, particularly to the depredations of inſects.—The inſects by which the greateſt devaſtations are committed in this country are, ſnails, caterpillars, grubs, and flies. The ſnails and caterpillars feed on the leaves and young ſhoots; by which means they often totally deſtroy the vegetable. Where the plants are of eaſy acceſs, theſe vermine may be deſtroyed by ſprinkling the vegetable with lime-water; for quicklime is a mortal poiſon to creatures of this kind, and throws them into the greateſt agonies the moment they are touched with it. On trees, however, where this method cannot ſo well be followed, fumigation is the moſt proper; and, for this purpoſe, nothing is better than the ſmoke of vegetables not perfectly dry. In ſome caſes the eggs of theſe deſtroying creatures may be obſerved, and ought without doubt immediately to be taken away. On the fruit trees, as apples, pears, medlars, on ſome foreſt trees, the oak and dwarf maple eſpecially, and the white and black thorn in hedges, a kind of little tufts are to be obſerved, reſembling at firſt ſight withered leaves twiſted by a cobweb, about the uppermoſt twigs or branches. Theſe contain a vaſt number of little black eggs, that in the ſpring produce ſwarms of caterpillars which devour every thing. To prevent this, all the twigs on which theſe cobwebs appear ſhould be taken off and burnt as ſoon as poſſible. This ought to be done before the end of March, that none of the eggs be allowed ſufficient time for hatching.

107 Inſects deſtroyed by lime-water.

108 Grubs.

The grubs are a kind of worms which deſtroy the corn by feeding upon its roots; they are transformed every fourth year into the beetles called *cockchaffers*, *may-bugs*, &c. they are very deſtructive when in their vermicular ſtate, and cannot then be deſtroyed, becauſe they go deep into the ground. When become beetles, they conceal themſelves under the leaves of trees, where they ſeem aſleep till near ſunſet, when they take their flight. It is only now that they can be deſtroyed, and that by a very laborious method; namely, by ſpreading pack-ſheets below the trees in the day-time when the beetles are in their torpid ſtate, then ſhaking them off and burning them. Some time ago they made ſuch devaſtations in the county of Norfolk, that ſeveral farmers were entirely ruined by them; one gathered 80 buſhels of theſe inſects from the trees which grew on his farm. It is ſaid, that in 1574 there fell ſuch a multitude of theſe inſects into the river Severn, that they ſtopped and clogged the wheels of the water-mills.

109 Turnip-fl

Turnips, when young, are apt to be totally deſtroyed by a multitude of little black flies, from thence called the *turnip fly*. As a preventive of theſe, ſome adviſe the ſeed to be mixed with brimſtone; but

this

Diſeaſes of Plants.

110 Prevented by fumigation, &c.

this is improper, as brimſtone is found to be poiſonous to vegetables. The beſt method ſeems to be the fumigation of the fields with ſmoke of half-dried vegetables. For this purpoſe weeds will anſwer as well as any. This fumigation muſt no doubt be often repeated, in order to drive away the innumerable multitudes of theſe inſects which are capable of deſtroying a large field of turnips.

Some have ſuppoſed that the fly is either engendered in new dung, or enticed by it; and have therefore adviſed the manure to be laid on in the autumn preceding, by which it loſes all its noxious qualities, while its nutritive ones are retained, notwithſtanding theſe might be ſuppoſed liable in ſome degree to be exhaled by the ſun. This method is ſaid to have been aſcertained by experiments; and it is added, that another material advantage accruing from autumn manuring for turnips is, that all the ſeeds contained in the dung, and which of courſe are carried on the land with it, vegetate almoſt immediately, are moſtly killed by the ſeverity of the winter, and the few that remain ſeldom avoid deſtruction from the ploughſhare.

111 Various remedies againſt the turnip-fly.

The following method of ſowing has alſo been recommended as a preventive of the fly:—"About Midſummer, take the firſt opportunity, when it rains, or there is an apparent certainty of rain approaching, to ſow your turnip ſeed; if about the full moon, the better. In this caſe, neither harrow, bruſh, nor roll, after ſowing. The natural heat of the ground at that ſeaſon, and the conſequent fermentation occaſioned by copious rain, will give an aſtoniſhingly quick vegetation to the ſeed, which in a few days will be up and out of all danger from the fly. At all events, ſow not till it rains; it is better to wait a month, or even longer, for rain, than to ſow (merely for the ſake of ſowing about the uſual time) when the ground is parched with heat. By the ſcorching of the ſun, the oil and vegetative quality of the ſeed are exhauſted; and the few weak plants that come up will be deſtroyed by the fly before they can attain ſtrength to put forth their rough leaves. The fly infeſts the ground abundantly in dry hot weather, but does no injury in rain. The falling rain will ſufficiently waſh the turnip ſeed into the ground without harrowing it in; which, inſtead of merely covering, too often buries this ſmall ſeed at ſo great a depth, as never afterwards to get above ground."

The following remedies are alſo recommended as having often proved ſucceſsful:—A ſmall quantity of ſoot ſown over the land at their firſt appearance. Branches of elder, with the leaves bruiſed, drawn in a gate over them. Muſk mixed with the ſeed before it is ſown. And ſulphur burnt under it, after moiſtening it with water in which tobacco has been ſteeped.

But ſhowers on the plants, as ſoon as they appear above ground, are eſteemed the beſt preſervatives. They enfeeble and kill the fly, and haſten the plants into the rough leaf, in which ſtate they are out of danger.

The ſweet ſmell of the turnip has been thought to attract the fly; upon which ſuppoſition, the remedy appeared to conſiſt in overpowering that ſmell by one which is ſtrong, fetid, and diſagreeable. Hence it has been recommended, that upon an acre of turnips ſown in the uſual way, a peck or more of dry ſoot be thrown after the ground is finiſhed, and in as regular a way as he ſows the ſeed.

Diſeaſes of Plants.

112 Corn-butterfly.

Some time ago an inſect, called the *corn butterfly*, committed ſuch ravages while in its vermicular ſtate, in France, that upwards of 200 pariſhes were ruined by it; and the miniſtry offered a reward to the diſcoverer of an effectual remedy againſt this deſtroying worm. The cure which was at laſt diſcovered was, to heat the corn in an oven ſo much as not to deſtroy its vegetative power, but ſufficiently to deſtroy the ſmall worms which made their neſt in the ſubſtance of the grain, and at laſt ate out the ſubſtance ſo completely, that nothing could be got from the huſk even by boiling it in water. It is certain, that though inſects can bear a great deal of cold, they are eaſily deſtroyed by a ſlight degree of heat; nor is the vegetative power of corn eaſily deſtroyed, even when kept for a long time in a pretty ſtrong heat. This method muſt therefore be very effectual for deſtroying all kinds of inſects with which grain is apt to be infected: but care muſt be taken not to apply too great a heat; and the adjuſting of the preciſe degree neceſſary to deſtroy the inſect, without hurting the corn, will be attended with ſome difficulty.

113 The curled diſeaſe in potatoes.

The curled diſeaſe in potatoes has long been a ſubject of inveſtigation and experiment among farmers: and the knowledge of its cauſe and cure ſeems yet to remain a deſideratum. The Agricultural Society at Mancheſter, a few years ago, offered a premium for diſcovering by actual experiment the cauſe of the diſeaſe in queſtion; and a great variety of letters were, in conſequence, addreſſed to them upon the ſubject.—As theſe contain many intereſting obſervations both on the diſeaſe itſelf and the beſt methods hitherto adopted for preventing it, the following abſtract of them may not improperly be introduced in this place.

114 Various methods of prevention.

I. According to the writer of the firſt letter, this diſeaſe is cauſed by an inſect produced by froſt or bad keeping before ſetting; and the neweſt kinds, ſuch as have been raiſed within theſe nine or ten years, are moſt apt to curl, becauſe they will not ſtand to be kept in winter and ſpring before ſetting, as the old kinds will. In autumn 1776, he got up a bed of potatoes to lay by in winter, leaving plenty in the ground as regular as poſſible; and, before the ſeverity of winter came on, covered part of the bed with ſtraw and peaſe-haulm, and left the other part of the bed uncovered. That part of the bed which was covered was quite free from curled ones; but the uncovered part produced a great many curled, owing, as the writer ſays, to froſt and ſeverity of the weather.

II. This writer had about a quarter of an acre of potatoes, well manured with cow and horſe dung, and took the greateſt care in picking the fine ſmooth-ſkinned potatoes for ſets; yet nine out of ten parts were curled. He attributes the cauſe of this diſeaſe to a white grub or inſect, which he found near the root, about half an inch long, with eight or ten legs, its head brown and hard; as upon examining a number of the curled roots, he found them all bitten, chiefly from the ſurface to the root, which of courſe ſtopped the progreſs of the ſap, and threw the leaf into a curl. The uncurled roots were not bitten. He tried a few experiments as follow:—Firſt, he put ſoot to the inſects in the rows

Diſeaſes of Plants.

for two days; and after that, he put lime to them for the ſame time, but they ſtill kept lively; next he put a little ſalt, which deſtroyed them in a few hours. From which he infers, that if coarſe ſalt were put into the ground at the time the land is preparing for potatoes, it would effectually cure this diſtemper.

III. In this letter, the cauſe of the diſeaſe is attributed to the method of earthing the ſtems while in cultivation; and the branch, ſtriking root into the new earthed-up ſoil, it is ſaid, produces potatoes of ſuch a nature as the year following to cauſe the diſeaſe complained of.

To prevent the diſeaſe, it is recommended to take the ſets from thoſe potatoes that have not bred any from the branch covered; or, otherwiſe, to dig the part the ſets are to be raiſed from.

IV. According to this writer, the diſorder proceeds from potatoes being in old-tilled or worn-out ground; for though theſe potatoes may look tolerably well, yet their ſets will moſtly, if not all, produce curled potatoes.

Hence he is convinced, that no ſets ought to be uſed from old-tilled or couch-graſs land; and that, in order to have good ſets, they ſhould be procured from land that was purpoſely fallowed for them; from freſh ley land, where they are not curled; or from ley land that was burnt laſt ſpring. He directs to plant them on virgin mould, and the potatoes will have no curled ones amongſt them; and to keep them for winter, from any other kind.

To avoid the uncertainty of getting good ſets, he recommends crabs to be gathered from potatoes growing this year on freſh land free from curl, and the next ſpring to ſow them on freſh ley land; and continue to plant their ſets on freſh ley land yearly, which he is convinced will prevent the curl.

All the good potatoes he ſaw this year, either on freſh ley land or on old tilled land, were raiſed from ſets that grew upon freſh ley land laſt year; and where he has ſeen curled potatoes, he found, upon inquiry, the potato ſets grew upon old-tilled and worn out land laſt year. He gives as a general reaſon for the diſorder, that the land is oftener cropt than it had uſed to be, much more corn being now raiſed than formerly.

V. In 1772, this writer planted ſome potatoes by accident full nine inches deep: when taken up, many of the plants were rotted, and a few curled. He kept the whole produce for ſeed, and planted two acres with it in 1773, not quite ſix inches deep. The crop was amazingly great; and he did not obſerve any curled plants among them. In 1774, many of theſe were planted in different ſoils; yet they were ſo infected with the curled diſeaſe, that not one in twenty eſcaped. In 1775, the complaint of this diſeaſe became general. In 1776, it occurred to him that the good crop of 1773 was owing to the accidental deep ſetting of 1772; and that the reaſon why the ſame ſeed became curled in 1774, was their being ſet ſo near the ſurface in 1773; and attributes the diſeaſe to the practice of ebb ſetting. In 1777, he took ſome potatoes from a crop that was curled the year before, and after cutting the ſets, left them in a dry room for a month. Half were planted in ground dug fourteen days before; the other half, having been ſteeped in a brine made of whitſter's aſhes for two hours, were alſo planted in the ſame land at the ſame time. The ſteeped ones came up ten days before the others, and hardly any miſſed or were curled. The unſteeped ones generally failed, and thoſe few that came up were moſtly curled.

He therefore adviſed as a remedy, 1. That the potatoes intended for next year's ſets be planted nine inches deep. 2. That they remain in the ground as long as the ſeaſon will permit. 3. That theſe ſets be well defended from froſt till the beginning of March. 4. That the ſets be cut a fortnight before planting. 5. That they be ſteeped, as above, two hours in brine or lye. 6. That the dung be put *over* the ſets. And, 7. That freſh ſets be got every year from ſandy ſoils near the coaſt, or on the ſhore.

P. S. At planting, the hard dry ſets ſhould be caſt aſide, for they will probably be curled. Curled potatoes always proceed from ſets which do not rot or putrefy in the ground.

VI. This writer had five drills of the old red potatoes, and four of the winter whites, growing at the ſame time in the ſame field. The drills were prepared exactly alike. Among the red not one was curled; the winter whites were nearly all curled. He ſays he has found by experience, that the red never curl.

VII. Two of the writer's neighbours had their ſets out of one heap of potatoes. They both ſet with the plough, the only early, and the other late, in the ſeaſon. Moſt of thoſe early ſet proved curled, and moſt of thoſe ſet late ſmooth; the latter on clay land.

A few roods of land were alſo planted with ſmall potatoes, which had lain ſpread on a chamber floor all the winter and ſpring till the middle of May. They were ſoft and withered; they proved ſmooth and a good crop. Middle-ſized potatoes, withered and ſoft, which had been kept in a large dry cellar, and the ſprouts of which had been broken off three times, produced alſo a ſmooth good crop.

Hence he was led to think a ſuperfluity of ſap, occaſioned by the ſeed being unripe, might cauſe the diſeaſe. To be ſatisfied in this, he aſked the farmer whether he had ſet any of the ſame potatoes this year, and what was the nature of his land? He told him "he had; that they had been ſet on his farm fourteen years without ever curling; that his ſoil was a poor whitiſh ſand, of little depth; that he let thoſe he deſigned for keeping grow till they were fully ripe."

Hence he concludes, the only ſure way to prevent the curl is, to let potatoes intended for ſeed ſtand till they are fully ripe, and to keep them dry all winter.

VIII. This writer ſet a quantity of the red potatoes, without having a curled one amongſt them. His method is, when the ſets are cut, to pick out ſuch as are reddeſt in the inſide. On digging them up at Michaelmas, he mixes none of the curled ſeed among the others. The curled are eaſily diſtinguiſhed, by their ſtalks withering two months before the reſt of the crop.

The cauſe of the curled diſeaſe he attributes to potatoes being of late years produced from ſeed inſtead of roots, as formerly. Such will not ſtand good more than two or three years, uſe what method you pleaſe. Laſt ſpring, he ſet the old red and white ruſſets, and had not a curled potato amongſt them.

On the limeſtone land about Denbigh, in North Wales,

Diſeaſes of Plants.

Wales, they have no curled potatoes. If this be owing to the nature of that land, perhaps lime might prevent the diſeaſe.

IX. According to this writer, all ſorts of grain wear out and turn wild if ſown too long on the ſame land; the ſame will hold good in all ſorts of pulſe, peaſe, beans, and (as he conceives) potatoes. It generally happens, that thoſe who have moſt curled potatoes plant very ſmall ſets.

Eleven years ago he bought a parcel of freſh ſets, of the golden-dun kind, and has uſed them without change to the preſent year, without any being curled. This he principally attributes to his having always planted good large ſets.

About four years ſince, he thought of changing his ſets, as his potatoes were too ſmooth, too round, and much diminiſhed in ſize. But the curl at that time beginning to be very alarming, he continued his ſets till part of his crop miſſing laſt year, he was obliged to buy new ſets this ſpring, which being ſmall, were curled like other people's.

He allows, that the curl has frequently happened to perſons who have uſed large potatoes for ſets; for, as all roots are not equally affected, ſome curled ones may be mixed with the reſt.

To prevent the evil, cut your ſets from clear and middle-ſized potatoes, gathered from places as clear of the curl as poſſible; preſerve them as uſual till ſpring. If any are harder, or graſh more in cutting than uſual, caſt them aſide. He would alſo recommend the raiſing a freſh ſort from the crab produced on the ſorts leaſt affected, which in Lancaſhire are the long duns.

X. Set potatoes with the ſprits broke off, and they will (ſays the writer of this letter) be curled ones; if ſet with the ſprits on, they will not be curled. Again, take a potato which is ſprit, and cut a ſet off with two ſights; break one ſprit off, and let the other ſtay on, and ſet it; the former will be curled, and the latter will not.

When you have holed your potatoes, take them out before they are ſprit, and lay them dry until you have ſet or ſown them, and you will have no curled potatoes.

XI. This writer was at the expence of procuring ſets at fifty miles diſtance, and where this diſeaſe was not known. The firſt year's trial was ſucceſsful; the year following he procured ſets from the ſame place, but one-fifth of his crop was infected. By way of experiment, he planted ſets from roots which had been infected the year before, and ſome of theſe produced healthy plants, free from all infection.

As every effect muſt have a cauſe, he ſuppoſed it might be ſome inſect, which, living on the leaves, gave them that curled and ſickly appearance, as is the caſe in the leaves of many ſhrubs and trees. But whether the inſect is lodged in the old ſets, and to be deſtroyed at the time of planting, or, proceeding from ſome external cauſe, can only be deſtroyed afterwards, he is not yet certain, although he has made the following experiments.

On a piece of ground that had not been dug for 20 years, he planted four rows of ſets, which he knew to be perfectly clear; the drills were two feet diſtant, the ſets one foot diſtant in each drill. He then planted on the ſame ground four rows with ſets from curled potatoes, at equal diſtances; in each row were about 20 ſets. Diſeaſes of Plants.

Lot 1ſt, The curled ſets.

N° 1. Without manure,
2. In ſalt,
N° 3. In ſoot,
4. In quicklime.

Lot 2d, The clear ſets.

N° 1. Without manure,
2. In ſalt,
N° 3. In ſoot,
4. In quicklime.

Thoſe planted in ſalt and ſoot in both lots were deſtroyed. In Lot 1ſt, N° 1. and 4. all curled. Lot 2d, N° 1. and 4. quite clear.

This experiment was made on a ſuppoſition that the inſect lodged in the ſet, and muſt be deſtroyed on planting. But of that he is not fully ſatisfied. He repeated ſalt, ſoot, and quicklime, on the branches of ſeveral curled potatoes. Salt deſtroyed all he touched with it. Lime and ſoot had, he thought, a partial effect on the plants. After ſome time, they appeared almoſt as healthy as the reſt. Thus, although he had done little towards the cure, he flatters himſelf he has pointed out the cauſe, the inſects on the curled plants being not only very numerous, but viſible to the naked eye.

XII. This writer aſcribes the cauſe of the diſeaſe to the froſt, and bad keeping in winter and ſpring before ſetting. They are liable to be damaged by froſt after they are ſet; but this may be prevented by covering. If it be aſked, why froſt did not injure them formerly? he anſwers, it is only the NEW kinds which are apt to curl. To this may be added, that leſs care is now taken of the ſeed than formerly. To prevent the latter, let them remain in the ground covered with hauim or litter till the time they are wanted for ſetting: and, in caſe no froſt touches them afterwards, they will be free from the diſeaſe.

XIII. This writer ſays, the red potato was as generally planted as the winter white and the Lincolnſhire kidney are now. The firſt, being a later potato, did not ſprout ſo early as the others. The white ſprout very early, and therefore ſhould firſt be moved out of the place where they have been preſerved in the winter. Inſtead of that, they are often let remain till their roots and ſprouts are matted together. On ſeparating them, theſe ſprouts are generally rubbed off, and they are laid by till the ground is ready; during which interval they ſprout a ſecond time: but theſe ſecond ſprouts, being weak and languid, will ſhrink, ſicken, and die; and the fruit at the roots will be ſmall, hard, ill-ſhaped, and of a brown colour.

Now, if putting off the ſprouts once or more, before the ſets are put in the ground, be the cauſe (as he verily believes it is) of the curled diſeaſe, an eaſy remedy is at hand. When the potatoes intended for ſets are dug up, lay them in a weſt aſpect as dry as poſſible: in ſuch a ſituation they will not ſprout ſo ſoon. The beſt time for removing moſt ſorts, is the firſt fine day after the 24th of February. Cut them into ſets as ſoon as poſſible, and let them remain covered with dry ſand till the ground is prepared, which ſhould be a winter fallow. Lay the ſets in without breaking off any of the ſprouts, for the ſecond will not be ſo vigorous. This accounts for one ſprout out of three from the ſame ſet being curled. The two items not curled roſe from two later eyes, and were firſt

Diſeaſes of Plants.

ſprouts. The ſprout curled was a ſecond, the firſt having been rubbed off.

XIV. This writer ſays, that laſt ſpring one of his neighbours cut and ſet, in the uſual way of drilling, ſome loads of the largeſt potatoes he could procure; and more than half of them proved curled. Being a few ſets ſhort of the quantity wanted, he planted ſome very ſmall potatoes which he had laid by for the pigs. Theſe being fully ripe and ſolid, there was not a curled plant among them. He apprehends, the others being curled was owing to their not being fully ripe. A crop of potatoes, ſet this year in rows on ground that had borne a crop of them laſt year, were moſtly curled; but many plants came up from ſeed left in the ground laſt ſeaſon, and there was not a curled one among them.

XV. Of late years, this writer ſays, great improvements have been made in ſetting potatoes and cutting the ſets. The ground is dreſſed cleaner and dunged ſtronger. Many people, in drilling, wrap up the ſets entirely in the dung; by which means, though their potatoes are larger, the diſeaſe ſeems to be increaſed. They alſo cut their ſets out of the richeſt and largeſt potatoes, which is perhaps another cauſe of this evil. In cold countries, where they ſet their own ſeed, which has grown on poor land, with leſs dung, they have no curled plants. On the contrary, when they bought rich and large potatoes for ſeed, they have been curled in great quantities. He believes, the richneſs and largeneſs of the ſeed to be the cauſe of the evil; for he does not remember to have ſeen a curled ſtem which did not ſpring from a ſet of a large potato.

XVI. This writer apprehends the curled diſeaſe in potatoes to proceed from a defect in the *planta ſeminalis*, or ſeed plant; and from comparing curled ones with others, there appeared to be a want of, or inability in, the powers of expanding or unfolding the parts of the former; which, from this defect, forms ſhrivelled, ſtarved, curled ſtems. On examining ſome of the ſets at the time of getting the crop, he found them hard and undecayed; ſo hard, indeed, that ſome of them would not be ſoft with long boiling. This led him to think, that ſome manures might have the ſame effect on them as tanners ooze has on leather, and ſo harden them, that the embryo plant could not come forth with eaſe; but a cloſer examination taught him otherwiſe, and that they grow equally in all manures.

Some have thought that the fermentation is occaſioned by too great quantities being heaped together; but the writer has ſeen an inſtance, wherein a ſingle potato, preſerved by itſelf, when ſet, produced ſtems of the curled kind. He thinks the moſt conſiſtent and rational opinion is, that the diſeaſe is occaſioned by the potatoes being taken from the ground before the ſtamen, or miniature plant, is properly matured and ripened.

For let it be obſerved, that the potato, being a native of a warmer climate, has there more ſun, and a longer continuance in the ground, than in its preſent exotic ſtate; conſequently it has not the ſame natural cauſes here to mature the ſeed plant as in its native ſtate. We ought, therefore, to give all the opportunities our climate will admit for nature to complete her work, and fit the ſtamen for the next ſtate of vegetation, eſpecially in thoſe intended for ſeed. But if the potato be taken up before the ſeed-plant be fully matured, or the air and ſap veſſels have acquired a proper degree of firmneſs or hardneſs, it muſt, when thus robbed of further nutrition, ſhrivel up; and when the veſſels, in this immature ſtate, come to act again in the ſecond ſtate of vegetation, they may produce plants which are curled.

Diſeaſes of Plants.

If it be aſked, why are they more common now than formerly? he anſwers, that before the preſent mode of ſetting them took place, people covered them, while in the ground, with ſtraw, to protect them from froſt.

If it be aſked, why one ſet produces both curled and ſmooth ſtems? he anſwers, we ſuppoſe every eye to contain a *planta ſeminalis*; that all the embryos, or ſeed plants, contained in one potato, are nourished by one root; and that, as in ears of corn, ſome of theſe ſeed plants may be nourished before others.

One of his neighbours, laſt year, ſet two rows of potatoes, which proving all curled, he did not take them up; and this year there is not a curled one among them. Such potatoes, therefore, as are deſigned for ſeed, ſhould be preſerved as long in the ground as poſſible.

XVII. This writer adviſes ſuch ſets to be planted as grow in moſs land; and, he ſays, there will not be a ſingle curled one the firſt year. This is affirmed by the inhabitants of two townſhips, where they grow amazing quantities. A medical gentleman ſowed laſt year two buſhels of ſets from one of the above places, and had not one curled; but on ſowing them again this year, he had a few.

Notwithſtanding there ſeems to be a diverſity of opinions in the above writers, occaſioned by the different appearances of their crops, and the ſeemingly contrary effects of the means uſed to prevent or cure the diſeaſe, we conceive that the following general propoſitions may be fairly drawn from the whole. 1. That ſome kinds of potatoes are (*cæteris paribus*) much more liable to be affected by the diſeaſe than the reſt; and that the old red, the golden dun, and the long-dun, are the moſt free from it.—2. That the diſeaſe is occaſioned by one or more of the following cauſes, either ſingly or combined: 1ſt, By froſt, either before or after the ſets are planted: 2d, From planting ſets out of large unripe potatoes: 3d, From planting too near the ſurface, and in old worn-out ground: 4th, From the firſt ſhoots of the ſets being broken off before planting; by which means there is an incapacity in the *planta ſeminalis* to ſend forth others ſufficiently vigorous to expand ſo fully as they ought.—3. That the moſt ſucceſsful methods of preventing the diſeaſe, are cutting the ſets from ſmooth middle-ſized potatoes, that were fully ripe, and had been kept dry after they were taken out of the ground; and without rubbing off their firſt ſhoots, planting them pretty deep in freſh earth, with a mixture of quicklime, or on limeſtone land.

A correſpondent of the Bath Society is convinced, that, whatever may be its cauſe, the fault itſelf is inherent in the ſeed; and has communicated the following method of avoiding it: "I made a hot-bed in the following manner (which method I have uſed ever ſince):

It

Diſeaſes of Plants.

I laid horſe dung, &c. (as is generally uſed in making hot-beds), about 18 inches thick; over which I ſpread a layer of fine rich mould about four or five inches thick: upon the top of this mould I laid, in different diviſions, a certain number of potatoes of various ſorts, ſome of my own growth, and others bought from different parts, and covered theſe lightly over with more mould; they ſoon came up. I then obſerved which was freeſt from the blight or curl; for if there were not more than one defective in *forty* or *fifty*, I concluded I might ſet of that ſort with ſafety. This method I have now practiſed near twelve years, and never loſt my crop, or any part thereof worth mentioning; whilſt my neighbours, who followed the old method, were frequently diſappointed in their crops; and to the beſt of my knowledge, all thoſe of my neighbours who have of late been perſuaded to take the trouble of uſing the ſame means as myſelf, have never failed of ſucceſs to their utmoſt wiſhes in one inſtance; nor do I ever think it will fail, if duly attended to; the fault being ſome hidden cauſe in the ſeed unknown at preſent, and I believe incurable by any means, at leaſt which have yet come to my knowledge. My reaſon for planting my hot-beds ſo ſoon is, that if the froſt hinder the firſt experiment, or they all prove bad, I may have time to make a ſecond or third, if neceſſary, with different ſorts of ſeed, before the proper ſeaſon arrives for planting in the fields and grounds appointed for the great and general crops."

In addition to the intereſting information upon this ſubject, which has been obtained by means of theſe ſocieties, various other ſpeculations about the cauſe and cure of this diſeaſe have of late been introduced to the notice of the public. In particular it has been ſtrongly urged, that the diſeaſe is almoſt always occaſioned by inſects. It is ſaid, that on looking at the roots of ſuch potatoes as grow up curled, it will uſually be found, that the bearing plant is devoured and excavated by ſnails, centipedes, or beetles. Sometimes alſo, though more rarely, the curl is ſuppoſed to ariſe from the leaves themſelves being infected with minute animalcula. Hence, in rich ſoils in the neighbourhood of cities and well-manured gardens, the potatoes are moſt ſubject to the curl, becauſe ſuch inſects as devour the ſeed abound moſt in theſe ſoils. The inſects are thought to prefer one potato to another. They will hardly touch a yam. A potato from a late part of the country, which has been hardly ripened, the vermin do not ſeem to like; but a potato that has been ſomewhat ſweetened or mellowed by the froſt, is ſuppoſed to be greedily devoured by them.

Farmer's Mag.

An ingenious notion concerning the cauſe of the diſeaſe has been ſuggeſted from attending to the hiſtory of the plant in this country. The potato plant was introduced into the iſland of Great Britain from a climate much warmer than ours, as early as the reign of Queen Elizabeth; but it is a ſingular circumſtance, that the curled diſeaſe did not make its appearance till within leſs than 40 years ago. Indeed, the diſeaſe is ſaid to have firſt occurred in the year 1764, in the very diſtrict of Lancaſhire where potatoes had been firſt cultivated. It is alſo ſaid, that the Surinam potato and ſome other kinds which have been more recently introduced into our climate, have never yet exhibited any ſymptom of the curl. It is farther ſaid, that till within theſe 40 years the potato plant never brought its ſeeds to maturity in this country, though the roots were in full perfection; that the Surinam potato and others lately introduced do not as yet produce perfect ſeeds at the top of their ſtem; and that potatoes, which have been cultivated for a length of time in bleak and mountainous ſituations, are ſtill in the ſame ſtate, and do not bring their ſeeds to maturity. Hence it is endeavoured to be inferred, that there exiſts a connexion in the nature of the plant between this diſeaſe and the ſtate of maturity to which the ſeed is brought. It is ſuppoſed, that the plant is unfit at once to afford mature and perfect ſeed at the ſummit of its ſtem, and alſo roots capable of propagating it in perfection. From theſe premiſes it is ſuggeſted, that, to prevent the curl, it will be neceſſary to procure ſeed potatoes from mountainous ſituations into which the diſeaſe has not yet come, becauſe the plant has never produced perfect fruit at the ſummit of its ſtem; or an attempt may be made to procure more perfect ſeed from the ordinary kind of potatoes, by deſtroying the flowers, which may have the effect to prevent the plant from being exhauſted by bringing to maturity both fruit at its ſummit and roots at its bottom. Laſtly, It has been ſuppoſed, upon theſe principles, that the diſeaſe may be prevented by rearing potatoes from the ſeed produced at the ſummit of the ſtem; the mode of practiſing which will afterwards be explained.

Tranſact. ety for Encouragement of Arts, vol. iii.

In the mean time, it may be obſerved, that the ſubject has been farther diſcuſſed, in a leſs ſpeculative manner, by an anonymous correſpondent of the Board of Agriculture*. This gentleman does not conſider the curl as a ſpecific diſeaſe, but as an accidental debility of thoſe plants in which it occurs; that we are not, therefore, to ſeek for a cure or preventive in a change of ſeed alone, as many have all along done, but in complete attention to all that experience ſhows to be neceſſary to an accurate culture, and to their perfect growth. In this way alone, he thinks, there is reaſon to expect that this very uſeful article of human food may be cultivated with the ſame ſucceſs as before its dreadful enemy the curl made ſuch havock in our crops, as of late years it certainly has done. He deſcribes the diſeaſe as occuring, in Mid Lothian, moſt frequently from the following cauſes: 1ſt, From planting potatoes on ſoils altogether unfit for them. Being unable to penetrate a ſtiff ſoil, potatoes require a light, pervious, or open mould. For a long period after potatoes firſt appeared in the country, this circumſtance was carefully attended to. They were planted entirely with the ſpade, in the lighteſt ſpots upon every farm. Hence, the plants roſe vigorous, and no curl was ſeen; but on farmers wiſhing to extend the culture of potatoes; they were tempted to plant them on every ſoil, without regard to its nature, or tendency to produce this crop. 2dly, Imperfect culture is deſcribed as a frequent cauſe of curling. A crop of potatoes is commonly ſtrong, abundant, and free from curl, in proportion to the previous culture given to the ſoil, and the care taken to keep it clean after they are planted. Hence, it frequently happens, that while a farmer who cultivates this root in a negligent manner, and upon a great ſcale, by means of the plough, finds his crop deficient in conſequence of this diſeaſe, his cottars and ſervants, to whoſe uſe he allows

Communication to the Board, vol. ii.

Diſeaſes of Plants.

allots ſmall portions of potato ground, which they cultivate with the ſpade, obtain crops free from curl, and often double in quantity to his, in proportion to the extent of ground which they occupy. 3dly, Small roots, or too ſmall a portion cut off along with the eye that is to ſerve for ſeed, appears to be a cauſe of curl. In the caſe of grain, it ſeldom happens, unleſs in very fine ſeaſons, that ſmall ſeed produces a large crop; and it is thought that ſomething ſimilar may occur in the caſe of potatoes. As the young plant muſt always derive its earlieſt nouriſhment from the root, out of which it ſprings, before it is capable of ſeeking its food in the ſurrounding ſoil, thoſe plants, whoſe early growth is beſt ſupported and foſtered, muſt be expected to reach the greateſt perfection. To ſubject theſe ideas to the teſt of experiment, 64 ſets were planted; 16 of which were full grown potatoes, 16 from ſmall roots, in which no curl appeared when in the field, 16 from roots raiſed from the ſeeds two years before, and 16 from roots of plants ſtrongly curled. They were all planted in the ſame manner in a light ſoil, in parallel furrows, with a moderate quantity of dung, and covered to the depth of three inches. Of thoſe taken from large potatoes, none were curled, and the plants were ſtrong and healthy. Some good plants appeared in each of the other rows, but nearly a half of the whole were curled. The proportion of curled plants was rather greateſt in thoſe raiſed from the ſeed. 4thly, Sets taken from roots that have ſprouted early, and from which the germs have been rubbed, are ſaid never to fail to produce curl. 5thly, Too much, as well as too little dung, appears to have an influence in producing curl; the firſt probably by corrupting the germ of the young plant, the latter by not being ſufficient to produce vigorous plants. Hence, attention ought to be paid to the regular ſpreading of dung, which ought not to be thrown about in a careleſs and ſlovenly manner, which allows ſome plants to have none, while others are covered with it to the depth of ſeveral inches. 6thly, Too deep, as well as too ſhallow planting, gives riſe to the curl. To aſcertain the proper depth, 12 were planted at 18 inches deep; the ſame number at the depth of 16 inches, and of 14, 12, 10, 8, 7, 6, 5, 4, 3, and 2 inches; and 12 were ſo lightly covered, that they were not, perhaps, at the depth of one inch. The ſets were all from large roots, of the ſame crop, cut as nearly as poſſible of the ſame ſize. They were all planted at the ſame time, in the firſt week of April, in a light dry ſoil, and they all got the ſame quantity of dung. The plants at the depth of 1 and 2 inches appeared firſt; but they were weak, and ſome of them curled. Thoſe at 3, 4, and 5 inches, were all ſtrong, and free from curl. At 6 and 7 inches, they were alſo healthy, and free from curl, but they were three weeks later in getting above the ground than thoſe that were thinly covered, and the plants were neither ſo ſtrong, nor the roots ſo large. Thoſe planted at the depth of 8 inches roſe ſtill later, and were all weak.—Nine out of the 12 were curled. Of thoſe planted at 10 inches deep, only four appeared; and they were ſo weak, that they ſoon withered and died. Of thoſe deeper planted, none ever appeared. On digging them up at the end of two months, thoſe at 16 and 18 inches deep were found unchanged; while ſome of thoſe at the depth of 12 and 14 inches, had put forth ſome feeble germs not exceeding the length of an inch. Thoſe planted at 3 and 4 inches were evidently the ſtrongeſt during the whole ſeaſon, and their roots largeſt. Hence, to procure an early, abundant, and healthy crop, 3 inches appears to be the beſt depth for planting potatoes. 7thly, Whatever injures the new ſets or the germs afterwards may produce curl: ſuch as the trampling of horſes feet at the time of planting; their being partially covered with ſtones or hard clods of earth; deep harrowing, when the young ſhoots are advancing; and grubs, ſnails, or inſects attacking the germs at firſt, or the ſtems afterwards. Hence, 8thly, The curl was produced to an uncommon degree upon a field of ſtiff land, by paſſing a roller over it, about a fortnight after planting. 9thly, The ſtate of the weather when the crop is young may produce the curl. Rain alone will not do ſo, if it be not allowed to lodge; but a long continuance of dry weather, eſpecially with cold winds, when the ſhoots firſt appear, is apt to produce this diſeaſe, and alſo hoar-froſts in this early ſtate of the crop. Hence, it is thought, that the three firſt weeks of April anſwer beſt for planting potatoes in the ſouth of Scotland and north of England, as they do not, in that caſe, appear till the middle or end of May. From all theſe remarks it is concluded, that though with the beſt management the curl can never be completely baniſhed from our fields, yet with due attention to the leading points above mentioned, it may be prevented from being attended with any ſerious miſchief.

As no information upon this intereſting ſubject ought to be overlooked, we think it neceſſary to ſtate, that the following plan for preventing the curl in potatoes has very recently been laid before the public, by an anonymous correſpondent of the publiſhers of the Farmer's Magazine, who aſſerts, that he has adopted it with complete ſucceſs. It conſiſts of uſing for ſeed what are called *potato beans*. Theſe beans are a dark brown excreſcence, larger than a horſe bean, which grows near the ground, on the haulm or ſhaw, generally, it is ſuppoſed, where it has been broken or wounded. They are ſhaped like potatoes, and have a number of eyes, from one of which grow two ſmall leaves. It is ſaid, that eight or ten years ago, ſeveral of theſe potato beans were planted merely to try if they would grow, and that they produced a great number of common ſized potatoes, but of a bad quality. Theſe potatoes, however, being cut and planted next year, produced potatoes of an excellent quality, and in great plenty. Since that time, a number of beans have always been planted ſufficient to produce enough of potatoes for next year's ſeed. They are planted at the ſame diſtance, and treated in every reſpect in the ſame manner with common ſets; and their produce is equally plentiful. No other change of ſeed has ever been neceſſary.

Sect. VIII. *Of the Obſtacles to Agricultural Improvement.*

Diſeaſes of Plants.

115 Moral and political obſtacles to agricultural improvement.

Before proceeding to the practical part of the ſubject, it may be proper to take notice of ſome of the moral and political circumſtances which reſiſt the progreſs of the art of agriculture, and which ought not to be overlooked by perſons engaged, or who have an intention to engage in it.

One

Obſtacles to Agriculture.

One of the firſt and moſt obvious obſtacles to the improvement of this or of any other art conſiſts of the ignorance of its practitioners, or of its being carried on by perſons of an illiterate and unintelligent character, who are unable to take a comprehenſive view of the principles of their profeſſion, or who have not ſufficient curioſity to inquire after the beſt modes of practice, or underſtanding to diſcern the value of any new practices that are explained to them. It ought never to be forgotten, that the art of the huſbandman is an intricate and extenſive one, and that one of the chief circumſtances which has hitherto prevented its improvement has ariſen, as already mentioned, from the ſecluded ſituation of perſons engaged in it. They are ſcattered over the face of the country, inſtead of being collected together like other artiſts in towns, ſo as to be enabled to derive aid from each other's experience. Fortunately this difficulty is paſſing away, in conſequence of the diffuſion of agricultural knowledge, by means of the great number of publications upon that ſubject which are gradually introducing themſelves into the remoteſt corners of the country. Perſons receiving a liberal education, particularly at the univerſity of Edinburgh, have now alſo an eaſier opportunity than formerly of acquiring a knowledge of the principles of this art, in conſequence of the eſtabliſhment of a profeſſorſhip of agriculture, which has been endowed by a private gentleman, Mr Pulteney. Even with all theſe advantages, however, aided as they are by the exertions of the Board of Agriculture, it can never be expected that this art can reach its ultimate degree of perfection, unleſs a conſiderable number of the perſons engaged in it are men of intelligent characters and good education, who will call in the improvements which are making in other ſciences, as well as in this art, in diſtant countries, to the aſſiſtance of their perſonal experience.

A ſecond obſtacle to agricultural improvement conſiſts of the poverty of the huſbandman, or of his want of capital, to enable him fully and completely to labour the ſoil, and provide materials for its amelioration. Complaints have often been made with little reaſon, of the obſtinacy of farmers, and of the tenacious manner in which they adhere to old practices, though demonſtrated to be improper: But a poor man cannot afford to make experiments, or to hazard the loſs of a crop for the chance of obtaining a more valuable one by ſome untried practice. In conſequence of want of capital, large portions of territory remain in ſome parts of the country in a ſtate of nature, and conſequently unproductive, both to the occupier and to the proprietor. Both landlords and tenants, therefore, ought to know, that a man who engages in agriculture without a ſufficient capital takes up a bad trade, in which ſomething may be loſt by both parties by the deterioration both of the ſoil and of the ſtock upon it, but from which neither the public nor themſelves can derive profit.

A third obſtacle to agricultural improvement ſometimes ariſes from the poſſeſſor of the ſoil not having a ſufficient intereſt in it. In barbarous nations, lands are often poſſeſſed by communities as an undivided property, without any individual member having an excluſive right to a particular ſpot. In ſuch caſes, the worſt kind of agriculture muſt always prevail, for the ſame reaſon that public affairs are always worſe managed than the affairs of private perſons, who find their induſtry ſtimulated not merely by a ſenſe of duty, but by the influence of avarice, and of all the other ſelfiſh paſſions. Conſiderable portions of territory in England ſtill remain withheld from the exertions of an improving agriculture by this ſtate of property. But, even where the intereſt which the cultivator has in the ſoil is excluſive, it may ſtill be too limited. Where a landlord is prevented by an entail, or other family ſettlement, or by narrow prejudices and a ſhort-ſighted policy, from granting leaſes of a proper endurance, it is never likely that the ſoil can be well cultivated. Every outgoing farmer will endeavour, during the laſt years of his leaſe, to do as little for the land as poſſible, and to take from it all that he can poſſibly obtain. The firſt years of every new leaſe will therefore be ſpent by every new farmer in repairing the damage done by his predeceſſor. Scarcely, however, has he accompliſhed this object, than he himſelf, if his leaſe be ſhort, muſt ſet about procuring indemnity for the money he has laid out in ameliorating the ſoil, by ſcourging it in his turn, or by taking from it as heavy crops as poſſible, and by beſtowing upon it little or no expence.

Obſtacles to Agriculture.

Under the ſame head of a want of proper intereſt in the ſoil, may be enumerated the payment of tithes, of which in England every farmer ſo grievouſly complains. Whatever money the huſbandman may there lay out in improvements, is not expended for himſelf; as the proprietor of the tithes is entitled to draw a ſhare of the whole additional increaſe, and thus becomes a partner in the profits of the enterpriſe, without running any riſk of loſs by its failure. The odium of this tax, is ſaid to induce great numbers of huſbandmen to continue their lands in paſturage, to the no ſmall detriment of the public, from the comparative unproductiveneſs of human food, which attends that mode of occupying the ſoil. Fortunately, in Scotland this evil hath been removed by the wiſdom of our forefathers, as every landlord poſſeſſes the privilege of obtaining his tithes to be fixed at a ſettled rate of payment for ever; and, in many caſes, of having his lands altogether diſburdened, upon payment of a very moderate price.

The progreſs of the art of agriculture in Europe was long retarded by the want of reſpectability which attended it, when engaged in as a profeſſion or trade from which profit was to be derived. In the feudal times, the military profeſſion was the only employment in which a layman of liberal education could reſpectably engage. Agriculture, the only art which is abſolutely neceſſary to the exiſtence of man, was regarded with contempt, and left in the hands of the meaneſt of the people. Even the moſt ordinary mechanics were conſidered as ſuperior to perſons whoſe employment it was; becauſe the mechanic, reſiding in a town, and uſually under the protection of the prince, was ſafe from the dominion and the inſults of the petty chieftains that ruled in every part of the open country. The ſtate of affairs is now greatly altered in this reſpect. More enlightened views, and a better ſtate of ſociety, have reſtored to the profeſſion of agriculture the reſpectability which naturally belongs to it. It muſt be acknowledged, however, that the recent improvements which have taken place in the art, have contributed not a little to this change in the ſentiments of mankind concerning

Obſtacles to Agriculture.

cerning the perſons occupied in it. It is now found, that a man may become rich by agriculture, and that there are few better ways in which a prudent and induſtrious man can lay out a moderate capital. In a commercial age, the path that leads to wealth is always reſpected and accounted honourable, and accordingly it is now not unuſual for the ſons of Britiſh noblemen and gentlemen, of extenſive fortunes, to become apprentices to farmers.

The laſt obſtacle to agricultural improvements, of which we ſhall take notice, ariſes in ſome countries from the want of judicious legiſlation, or proper arrangements made by the public in its favour. The produce of the art of the huſbandman, and the manures of which his lands have occaſion, are all bulky commodities which cannot be tranſported without labour and expence. Unleſs care is taken, therefore, to prepare and maintain good roads throughout the country, the profits of agriculture muſt always be ſubjected to ſuch deductions as will greatly retard its proſperity. In the ſame manner, if the ſtate, from any narrow policy, ſhall prevent the huſbandman from bringing his goods to the beſt market, by exportation or otherwiſe, it is impoſſible that his art can flouriſh. In former times, nations were afraid to permit the exportation of grain, even in ſeaſons of plenty, leſt they ſhould be left without food, not conſidering that the ſureſt mode of producing abundance of any commodity conſiſts in offering, at all times, a good price for it. This error is now rectified in moſt nations; and at all events, in the preſent ſtate of affairs, the Britiſh huſbandman has no reaſon to complain, as the grain reared in this country is, even in the beſt ſeaſons, underſtood to be inadequate to afford ſubſiſtence to its inhabitants.

Obſtacles to Agriculture.

PRACTICE ON AGRICULTURE.

116 Diviſion of the ſubject.

THE practice of agriculture naturally divides itſelf into three parts; 1ſt, The cultivation of vegetable food for men and animals; 2dly, The cultivation of vegetables, ſuch as flax and hemp, which are more properly articles of commerce; and 3dly, The rearing and management of animals. To theſe we ſhall add, as connected with all the branches of agriculture, a ſhort deſcription of the moſt uſeful modes of fencing and encloſing lands for cattle and other objects of huſbandry.

PART I. OF THE CULTIVATION OF VEGETABLE FOOD.

117 Cultivation of vegetables divided into four branches.

We ſhall conſider this branch of the ſubject under four diviſions. In the firſt we ſhall preſent to the reader a ſtatement of the moſt uſeful inſtruments of agriculture: 2dly, We ſhall ſtate the mode of preparing land for cropping, by removing the phyſical obſtructions to agriculture, and reducing the ſoil into a proper ſtate; 3dly, We ſhall explain the culture of particular plants, and the practices of huſbandry connected with it; and, laſtly, We ſhall ſtate the principles and operations of the horſehoeing or drill huſbandry.

SECT. I. *Inſtruments of Huſbandry.*

THE inſtruments employed in agriculture are various; as the plough, the harrow, the roller, &c. which are again diverſified by various conſtructions adapted to particular uſes.

1. Of PLOUGHS.

118 The plough

The plough, is a machine for turning up the ſoil by the action of cattle, contrived to ſave the time, labour, and expence, which, without this inſtrument, muſt have been employed in digging the ground, and fitting it for receiving all ſorts of ſeed.

Amidſt all the varieties which can occur in the manner of ploughing the ground, ariſing from difference of ſoil, local habits, and other cauſes, there is ſtill a ſameneſs in the taſk which gives a certain uniformity to the chief parts of the inſtrument, and ſhould therefore furniſh principles for its conſtruction. There is not, perhaps, any invention of man that more highly merits our utmoſt endeavours to bring it to perfection; but it has been too much neglected by thoſe perſons who ſtudy machines, and has been conſidered as a rude tool, unworthy of their attention. Any thing appears to them ſufficient for the clumſy taſk of turning up the ground; and they cannot imagine that there can be any nicety in a buſineſs which is ſucceſsfully performed by the ignorant peaſant. Others acknowledge the value of the machine, and the difficulty of the ſubject; but they think that difficulty inſuperable, becauſe the operation is ſo complicated, and the reſiſtances to be overcome ſo uncertain, or ſo little underſtood, that we cannot diſcover any unequivocal principle, and muſt look for improvement only from experience or chance.

119 an inſtrument of the greateſt value,

But theſe opinions are ill founded. The difficulty is indeed great, and it is neither from the ignorant farmer nor the rude artiſt that we can expect improvement. It requires the ſerious conſideration of the moſt accompliſhed mechanician; but from him we *may* expect improvement. We have many data: we know pretty diſtinctly what preparation will fit the ground for being the proper receptacle for the ſeed, and for ſupporting and nouriſhing the plants; and though it is, perhaps, impoſſible to bring it into this ſtate by the operation of any inſtrument of the plough kind, we know that ſome ploughs prodigiouſly excel others in reducing the ſtiff ground to that uniform crumbling ſtate in which it can be left by the ſpade. The imperfections of their performance, or what yet remains to be done to bring the ground into this ſtate, is diſtinctly underſtood. It ſeems, then, a determinate problem (to uſe the language of mathematicians), becauſe the operation depends on the invariable laws of mechanical nature.

120 and may improved

It will therefore be very proper under this article, to aſcertain, if poſſible, what a plough in general ought

121 The taſk it perform

to

Instruments of Husbandry.

to be, by describing distinctly its task. This will surely point out a general form, the chief features of which must be found under every variety that can arise from particular circumstances.

The plough performs its task, not by digging, but by being pulled along. We do not aim at immediately reducing the ground to that friable and uniform state into which we can bring it by the spade; but we wish to bring it into such a state that the ordinary operations of the season will complete the task.

For this purpose, a slice or sod must be cut off from the firm land. This must be shoved to one side, that the plough and the ploughman may proceed in their labour; and the sod must be turned over, so that the grass and stubble may be buried and rot, and that fresh soil may be brought to the surface; and all must be left in such a loose and open condition, that it may quickly crumble down by the influence of the weather, without baking into lumps, or retaining water. The first office is performed by the coulter, which makes a perpendicular cut in the ground. The point of the sock follows this, and its edge gets under the sod, and lifts it up. While lifting it up, it also heels it over, away from the firm land. The mouldboard comes last, and pushes it aside, and gradually turns it over as far as is required.

Plate VI.

122 General form of the plough.

The general form of the body of a plough is that of a wedge, or very blunt chissel, AFEDBC, (fig. 1.), having the lower corner D of its edge considerably more advanced than the upper corner B; the edge BD and the whole back AFDB is the same perpendicular plane; the bottom FDB approaches to a triangular form, acute at D, and square at F; the surface BCED is of a complicated shape, generally hollow, because the angle ABC is always greater than FDE: this consequence will be easily seen by the mathematician. The back is usually called the LAND SIDE by the ploughmen, and the base FDE is called the SOLE, and FE the HEEL, and BCED the MOULDBOARD. Lastly, The angle AFE is generally square, or a right angle, so that the sole has level both as to length and breadth.

123 Advantages of this form.

By comparing this form with attention, the reader will perceive that if this wedge is pulled or pushed along in the direction FD, keeping the edge BD always in the perpendicular cut which has been previously made by the coulter, the point D will both raise the earth and shove it to one side and twist it over; and, when the point has advanced from F to D, the sod, which formerly rested on the triangle DFE, will be forced up along the surface BCED, the line DF rising into the position D*f*, and the line EF into the position E*f*.—Had the bottom of this furrow been covered with a bit of cloth, this cloth would be lying on the mouldboard, in the position D*f*E: the slice, thus deranged from its former situation, will have a shape something like that represented in fig. 2.

In as much as the wedge raises the earth, the earth presses down the wedge; and as the wedge pushes the earth to the right hand, the earth presses the wedge to the left; and in this manner the plough is strongly pressed, both to the bottom of the furrow by its sole, and also to the firm land by its back or land side. In short, it is strongly squeezed into the angle formed along the line FD (fig. 1.) by the perpendicular plane *a b* DF and the horizontal plane FDE; and in this manner the furrow becomes a firm groove, directing the motion of the plough, and giving it a resisting support, by which it can perform all parts of its task. We beg our readers to keep this circumstance constantly in mind. It evidently suggests a fundamental maxim in the construction, namely, to make the land side of the plough an exact plane, and to make the sole, if not plane, at least straight from point to heel. Any projection would tear up the supporting planes, destroy the directing groove, and expend force in doing mischief.

Instruments of Husbandry.

124 A fundamental maxim in the construction of a plough.

This wedge is seldom made of one piece. To give it the necessary width for removing the earth would require a huge block of timber. It is therefore usually framed of several pieces, which we shall only mention in order to have the language of the art. Fig. 3. represents the land side of a plough, such as are made by James Small at Rosebank, near Foord, Mid Lothian. The base of it, CM, is a piece of hard wood, pointed before at C to receive a hollow shoeing of iron CO, called the SOCK, and tapering a little towards the hinder end, M, called the HEEL. This piece is called the HEAD of the plough. Into its fore part, just behind the sock, is mortised a sloping post, AL, called the SHEATH, the front of which is worked sharp, forming the edge of the wedge. Nearer the heel there is mortised another piece, PQ, sloping far back, called the STILT, serving for a handle to the ploughman. The upper end of the sheath is mortised into the long BEAM RH, which projects forward, almost horizontally, and is mortised behind into the stilt. To the fore end of the beam are the cattle attached. The whole of this side of the wedge is fashioned into one plain surface, and the intervals between the pieces are filled up with boards, and commonly covered with iron plates. The COULTER, WFE, is firmly fixed by its shank, W, into the beam, rakes forward at an angle of 45° with the horizon, and has its point E about six inches before the point of the sock. It is brought into the same vertical plane with the land side of the plough, by giving it a knee outward immediately below the beam, and then kneeing it again downward. It is further supported on this side by an iron stay FH, which turns on a pin at F, passes through an eye-bolt I on the side of the beam, and has a nut screwed on it immediately above. When screwed to its proper slope, it is firmly wedged behind and before the shank — Fig. 3. N° 2. represents the same plough viewed from above. ST is the right-hand or small stilt fixed to the inside of the mouldboard LV.

125 The several parts of the plough.

Fig. 4. represents the bottom of the wedge. CM is the head, covered at the point by the sock. Just behind the sock there is mortised into the side of the head a smaller piece DE, called the wrest, making an angle of 16° with the land side of the head, and its outside edge is in the same straight line with the side of the sock. From the point to the heel of the head is about 33 inches, and the extreme breadth of the heel is about nine. The side of the wedge, called the furrow side, is formed by the mouldboard, which is either made of a block or plank of wood, or of a thick iron plate.

126 Socks.

The sock drawn in this figure is called a SPEAR SOCK, and is chiefly used in coarse or stony ground,

Inſtruments of Huſbandry.

which requires great force to break it up. Another form of the ſock is repreſented in the next figure 4. N° 2. This is called a FEATHER SOCK, and has a cutting edge CF on its furrow ſide, extending back about ten inches, and to the right hand or furrow ſide about ſix. The uſe of this is to cut the ſod below, and detach it from the ground, as the coulter detaches it from the unploughed land. This is of great uſe when the ground is bound together by knotted roots, but it is evident that it cannot be uſed to advantage in very ſtony ground. In general, the feather ſock is only fit for ground which has been under tolerable culture; but it greatly facilitates the labour of ſeparating the ſod. It may reaſonably be aſked, why the feather is not much broader, ſo as to cut the whole breadth of the furrow? This is ſometimes done. But we muſt recollect that the ſod is not only to be puſhed aſide, but alſo to be turned over. If it were completely detached by the feather, and chanced at any time to break on the back of the ſock, it would only be puſhed aſide; but by leaving a little of the ſod uncut, it is held faſt below while it is ſhoved aſide above, which cannot fail to twiſt it round. As the wreſt advances, it eaſily deſtroys the remaining connection, which in general is very ſlight and crumbling.

127 Proper breadth of the ſole.

The breadth of the ſole at the heel determines the width of the furrow. Nine inches will give enough of room for a horſe or man to walk in. A greater breadth is of no uſe, and it expends force in puſhing the earth aſide. It is a miſtake to ſuppoſe that a broad ſole gives more room for the turned ſlice to ſtand on; for whatever is the breadth of the furrow, the ſucceſſive ſlices will be left at their former diſtances, becauſe each is ſhoved aſide at the ſame diſtance. When the breadth of a ſlice exceeds its depth, and it is turned on its ſide, it will now ſtand on a narrow baſe, but higher than before, and therefore will ſtand looſer, which the farmers deſire. But in this caſe it generally falls on its back before it has been far enough removed, and is then puſhed aſide, and left with the graſſy ſide down, which is not approved of. On the other hand, when the depth conſiderably exceeds the breadth, the ſods, now turned on their ſides, muſt be ſqueezed home to the ploughed land, which breaks them and toſſes them up, making rough work. In wet clay ſoil, this is alſo apt to knead them together. On the whole, it is beſt to have the breadth and depth nearly equal. But all this is workmanſhip, and has no dependence on the width of the ſole behind.

128 It ſhould be level.

We have already ſaid that the ſole is generally level from right to left at the heel. This was not the caſe formerly, but the wreſt was conſiderably raiſed behind. It reſulted from this form, that the furrow was always ſhallower on the right ſide, or there was left a low ridge of unſtirred earth between the furrows. This circumſtance alone was a bad practice; for one great aim of ploughing is the renewal of the ſuperficial ſoil. In this way of ribbing the furrows, the ſod tumbles over as ſoon as it is puſhed to the top of the rib on the right of the *rut* made by the plough; the firmeſt parts of it fall undermoſt, and the reſt crumbles above it, making the work appear neat; whereas it is extremely unequal, and what moſt needs the influence of the weather to crumble it down is ſheltered from it. Add to theſe circumſtances, that the hollow is a receptacle for water, with a ſurface which can retain it, having been conſolidated by the preſſure of the plough. For all theſe reaſons, therefore, it ſeems adviſable to form the furrow with a flat or level bottom, and therefore to keep the heel of the wreſt as low as the heel of the head. For the ſame reaſon it is proper to hold the plough with the land ſide perpendicular, and not to heel it over to that ſide, as is frequently done, producing the ſame ribbed furrow as an ill-formed ſole.

Inſtrument of Huſbandry

129 Length of the plough

There is great variety of opinions about the length of the plough. If conſidered merely as a pointed inſtrument, or even as a cutting inſtrument acting obliquely on a given length of ſod, there can be no doubt but that it will be more powerful as it is longer: that is, it will require leſs force to pull it through the ground. But it muſt alſo ſhove the earth aſide, and if we double its length we cauſe it to act on twice as much earth at once; for when the plough has entered as far as the heel, the whole furrow ſide is acting together in puſhing the earth to the ſide. Now it is found, that the force neceſſary for puſhing a maſs of earth horizontally along the rough ground is nearly equal to its weight. It would ſeem, therefore, that nothing is to be gained by making the baſe of the plough of a great length, except a greater facility in making the firſt penetration, and this is chiefly performed by the coulter and ſock; and a great length renders the plough heavy and cumberſome; and, by cauſing it to act long on the ſod, tends to knead and cake it.

Nothing very preciſe can be offered on this ſubject. Some ſenſible advantage is derived by making the plough taper, eſpecially forward, where it acts as a boring and cutting inſtrument; and for this purpoſe it is convenient to give the coulter a ſlope of 45 degrees. (This has alſo the advantage of throwing up the ſtones and roots, which it would otherwiſe drive before it through the firm ground.) And for the ſame reaſon the edge of the feather has a great ſlope, it being 10 inches long and only ſix inches broad. But if we purſue this advantage too far, we expoſe ourſelves to another riſk. It is ſometimes neceſſary to heel over the plough to the right, in order to get over ſome obſtruction. In doing this, the coulter is neceſſarily raiſed for a moment, and the ſlanting cut now made by the feather becomes the directing groove for the plough. When the feather has a very long ſlope, this groove has force enough to guide the whole plough; and it is almoſt impoſſible for the ploughman to prevent it from running out of the ground to the land ſide (A). The feather, therefore, ſhould not exceed ten or twelve inches in length.

130 Slope of the coulter and of the feather.

But to return to the length of the plough, from which this obſervation has diverted us a little, we muſt add, that a long plough has a great advantage in the ſteadineſs of its motion, having a much more extenſive ſupport

(A) This is often felt with the excellent plough deſcribed by Mr Arbuthnot of Surry, in the Tranſactions of the Society for the Encouragement of Arts, &c. London.

Instruments of Husbandry.

support both on the land side and below, and being therefore less affected by its inequalities. Accordingly, they are now made considerably longer than formerly; and 33 inches has been assumed as a proportion to 9 inches in breadth, in conformity to the most approved ploughs now in use.

131 The mould-board.

We come now to treat of the mouldboard. This is the most delicate part of the plough, and is to be seen in the greatest variety in the works of different artists, each of whom has a nostrum of great value in his own opinion. It is here indeed that the chief resistances are exerted and must be overcome; and a judicious form of this part of the plough may diminish them considerably, while it performs the work in the best manner. Without pretending to say that the different resistances are susceptible of an accurate determination, we can still draw sufficient information from palpable rules of mechanics to direct us to what would be nearly the best possible form for a mouldboard. The task to be performed is to raise, push aside, and turn over to a certain degree, a slice already cut off from the firm ground. As we cannot provide for every inequality of the cohesion or tenacity of the earth, our safest way is to consider it as uniform: the weight of it is always so. As we cannot provide for every *proportion* between the tenacity and the weight, we must take an average or medium proportion which is not far from that of equality. Conceiving the slice at first as only tenacious, and without weight, it is an easy problem to determine the form which shall give it the intended twist and removal with the smallest force. In like manner we can proceed with a slice that has weight without tenacity. It is equally easy to combine both in any proportion; and it is easiest of all to make this combination on the supposition of equality of weight and cohesion. Supposing the slice like a brick, we know that it requires the greatest force to *begin* to raise it on one edge, and that the strain becomes less as it rises, till its centre of gravity is perpendicularly above the supporting angle. It requires no force to raise it further; for on pushing it beyond this position, it would fall over of itself, unless withheld by the tenacity of what is not yet raised. But on considering the form or plan of the sock, we find that while the weight of the sod resists most strongly, there is less of it in this situation actually rising, and this nearly in the same proportion with the labour of raising it; and we see that after the sod has attained that position in which it is ready to fall over, it has reached the wider part of the wrest, and is now pushed aside, which requires nearly the same force as to raise it: and this continues to the end of the operation.

When we take all these circumstances into consideration, it appears probable, that the compound resistance does not change much from first to last. If this be really the case, it is an undoubted maxim that the whole operation should proceed equably: if it does not, there must be some part of the sod that makes a resistance greater than the medium; and as the resistances in all this class of motions increase nearly as the squares of the velocities with which they are overcome, it is demonstrable that we shall lose power if we render them unequal.

132 low to be rmed.

Hence we deduce this maxim, *That as the plough advances through equal spaces, the twist and the lateral sliding of the sod should increase by equal degrees.* And this determines *à priori* the form of the mouldboard. This principle occurred to Mr James Small, a plough-maker in Berwickshire, and he published a treatise on the subject in 1784. He has given several methods for constructing mouldboards, which he supposes are in conformity to his principle; but being merely a country artist, and unacquainted with science, his rules do not produce mouldboards having this property of equable operation, although they do not deviate far from it. His book is a very useful and instructive performance, and level to the capacity of those for whom it is intended; and we have here availed ourselves of the author's information on many points.

Instruments of Husbandry.

The high character which Small's ploughs have maintained for 25 years is a strong argument for the truth of the maxim. We shall therefore give such instructions as will enable any intelligent workman to construct such a mouldboard without any risk of failure; and if future theory or experience should discover any error in the principles from which this maxim is deduced, by showing that either the weight, the tenacity, or the lateral resistance, is exerted according to a different law from what has been assumed, the directions to be given are of such a nature that they adapt themselves with precision to these changes of principle, and will still produce a perfect and efficacious plough. Our readers will readily acknowledge that this is gaining a great point; because at present the instrument is constructed very much at random, and by a guess of the eye.

Let us now return to the wedge formerly made use of for illustrating the action of the plough. Suppose it placed in a furrow already ploughed, and that the space before the line FE (*fig.* 1.), which is square from the line of motion FD, is covered with a piece of cloth or carpet, and that the point of the wedge enters upon it at F, and advances to D. It will evidently raise the cloth, which will now cover the side of the wedge, forming the triangle *f*DE. The line *f*D is what formerly lay in the angle along the line FD, and *f*E formerly lay on FE. It is this line FE therefore that we are to raise, shove aside, and twist round, by equal degrees, while the plough advances through equal spaces.

Now, if the length DF of the plough-wedge, reckoned from the point of the sock to the heel, be 33 inches, and the breadth FE behind be nine inches, the angle DEF or DE*f* will be nearly 74°. The construction of the furrow side of the plough is therefore reduced to this very simple problem, "To make the angle DE*f* turn equably round the axis DE, while the angular point L advances equably from D to E.

133 Description of an instrument for this purpose.

This will be done by means of the following very simple tool or instrument. Let IHFK (*fig.* 5.) be a piece of hard wood, such as oak, a foot long, three inches broad, and an inch thick. Plant on this another piece BHFC of the same breadth, four inches long, and half an inch thick. This will leave beyond it a flat 8 inches long. We shall call this the *flock* of the instrument. Let ABC be a piece of clean oak, half an inch thick, 20 inches long, and three inches broad at the end BC. Let this be fashioned like the style of a sundial, having its angle ABC 74°. Let it have a part BCE square, to the extent of four inches from C, and the rest EA worked into the form of a straight slender rod.

Inſtruments of Huſbandry.

Let EFG be a ſemicircle of clean plane tree or of metal, four inches radius: faſten this by ſmall ſcrews to the ſquare part of the ſtile CE, ſo that its centre may be at C. Let this ſemicircle be divided into 180 degrees, and numbered from G along the arch GFE, ſo that 0° may be at G, and 180° at E. Let this ſtile and ſemicircle turn round the line BC by means of ſmall hinges. This inſtrument may be called the mouldboard gage, or protractor. When the ſtile is folded down on the ſtock BIK, the point G will be at F; and when it is raiſed up to any angle, the degrees will be pointed out on the ſemicircle by the ſtraight edge CF.

Nothing can be more obvious than the manner of employing this inſtrument once we have determined the moſt proper poſition for the ſod when the work is completed. Now it ſeems to be the opinion of the moſt intelligent framers, that the beſt poſition of the ſod is that repreſented in fig. 6.

134 Proper poſition of the ſod.

Fig. 6. repreſents a ſection of the ground and the working parts of the plough, as viewed by a perſon ſtanding ſtraight before it. ABDC is the unploughed ground, and WB the coulter, kneed in Small's manner. FGKB is the ſection of the plough (or rather of the whole ſpace through which the plough has paſſed, for no part of the plough has this ſection). HOFE is the ſection of a ſlice, puſhed aſide and turned over, ſo as to lean on the next. HE is that ſide of the ſlice which formerly lay on KB. EF is the ſide cut off by the coulter; and FO is the upper or graſſy ſide. The lower corners are ſuppoſed to be a little bruiſed inwards, as muſt generally happen.

The ſod is puſhed 9 inches to the right hand, and it leans with its graſſy ſide on the preceding furrow, in an angle of about 50 degrees. In this poſition the graſs is turned down ſo as to rot; and there is a hollow left below to allow the rain water to run freely off, and to receive the earth as it crumbles down by the weather: and if the harrow is dragged acroſs theſe ridges, it diſtributes along the ſurface the mould which was formerly at the bottom. The ſod has got a twiſt of 130 degrees; but it is evident, that after it has been turned 90 degrees, or even a little before this, it is ready to fall over of itſelf. It is ſufficient therefore that it be turned 90 degrees when the heel of the wreſt has reached it, and the remainder of the twiſt is given to it by the wing or flap of the mouldboard. This, then, dictates to us the manner of applying the inſtrument.

Divide the edge DE (fig. 7.) of the wreſt, or of a lath nailed on it, into 90 equal parts, and continue the diviſions backwards to G in the ſame line to 130. Number the diviſions backwards from the point of the ſock; then place the protractor on the edge of the wreſt, with the point B of fig. 5. at the 90th diviſion (fig. 7.); that is, juſt at the heel, with the ſtock under the wreſt, and the ſtile raiſed to 90°, and preſs it home to the joint, ſo that the ſtock may be ſquare to the edge, and then the ſtile will be in the poſition ſuiting that part of the mouldboard. In like manner ſlide the ſtock forward to the 80th diviſion, and lower the ſtile to 80°, and it will have the poſition which ſuits that part of the mouldboard. In the ſame way ſlide it forward to 70, 60, 50, &c. and lower the ſtile to 70°, 60° 50°, &c. and we ſhall have the poſition for theſe ſeveral parts of the mouldboard; and thus it may be formed to the very point of the ſock, becauſe the ſtraight edge of the wreſt may be continued ſo far. A block of wood may be hewed to fit theſe ſeveral poſitions of the protractor ſtile; and thus, when placed with its ſtraight edge on the outer line of the wreſt, and cut away behind in the land-ſide plane, will be the exact ſhape of the plough-wedge. It would riſe up indeed into a tall piece of ſingular ſhape, gradually tapering down to the point of the ſock; but when cut off parallel to the ground, at the height of about 12 inches, it will form the mouldboard, the front or edge of the ſheath, and the whole back of the ſock except the feather, which is an extraneous piece. The wing or flap of the mouldboard is formed in the ſame manner, by ſliding the ſtock of the protractor to 100, 110, 120, 130, and opening the ſtile to 100°, 110°, 120, 130°. This will extend the top of the mouldboard to about 22 or 23 inches; but the lower part of the wing muſt be cut away, becauſe it would puſh the ſod too far aſide after it has got the proper twiſt. The form of this part ſhould be ſuch as would exactly apply itſelf to a plank ſet at the heel of the wreſt, parallel to the land-ſide of the head, and leaning outward 40 degrees. This will be very nearly the caſe, if it be made a ſweep ſimilar to the edge of the ſheath. Fig. 8. is a reſemblance of the ſurface of the mouldboard; AD being the edge of the ſheath, E the heel of the wreſt, and EBC the wing or flap. When cut through in a perpendicular direction, the ſection is hollow; if cut horizontally it is convex; and if in the direction CE, making an angle of 74° with ED, it is ſtraight. If the protractor be ſet on it at D, and gradually ſlidden backwards, the mouldboard will gradually open the ſtile, and the ſtile will ſkim its whole ſurface without any vacuity between them.

135 How to form the mouldboard.

This form is given to the mouldboard on the authority of the ſuppoſition that the ſum of the reſiſtances ariſing from weight and tenacity remain pretty conſtant in its whole length. This cannot be affirmed with confidence in any caſe, and is by no means true in all. In ſtiff clay ſoils the effects of tenacity prevail, and in light or crumbling ſoils the weight is the chief reſiſtance. The advantage of this mode of conſtruction is, that it can be adapted to any ſoil. If the difficulty of cutting and raiſing the ſod is much greater than that of ſhoving it aſide and turning it over, we have only to make the riſe and twiſt more gentle towards the point of the ſock, and more rapid as we advance; and it is eaſy to do this according to any law of acceleration that we pleaſe. Thus, inſtead of dividing the edge of the wreſt DE (fig. 9.) continued to G into 130 parts, draw a line G*g* perpendicular to it, and draw ſome curve line D*g* convex towards DG, and divide this into equal parts in the points 10, 20, 30, 40, &c; and then draw perpendiculars to the wreſt edge, cutting it in 10, 20, 30, 40, &c. and apply the protractor to theſe points. It is evident that the diviſions of the wreſt line are bigger at D, and grow gradually leſs towards G; and therefore, becauſe each has 10° more twiſt than the preceding, the twiſt will be more rapid as it approaches the end of the mouldboard. This curve may be choſen ſo as to produce any law of acceleration. On the contrary, we produce a retarded or diminiſhed twiſt by making the curve concave towards DG, as repreſented by the dotted curve.

The mathematical reader will obſerve, that this conſtruction

Inſtruments of Huſbandry.

ſtruction aims at regulating the twiſt round the line of the wreſt ED. This does not produce preciſely the ſame regulation round the line FD, which is the line of the plough's motion, and of the ſod's poſition before it is ploughed over. The difference, however, is not worth attending to in a matter ſo little ſuſceptible of preciſion. But the twiſt round the line FD may be regulated according to any law by this inſtrument with equal facility. Inſtead of placing the ſtock of the protractor ſquare with the edge of the wreſt, it may be placed ſquare with the land ſide of the plough. To do this, draw a line BL (fig. 5. No 2.) acroſs the ſtock from the point B, making the angle LBC 16°, and put a braſs pin at L, making a hole in the ſtyle that it may not be prevented from the folding down. Then, in uſing the inſtrument, let the points B and L reſt againſt the edge of the wreſt, and proceed as directed.

A ſtill greater variety of forms, and accommodation to particular views, with the ſame general dependence on principle, will be procured by giving the rod BA a motion round B in the plane of the ſtile, ſo as to form a ſtile of a variable angle.

A tool may even be conſtructed in which the rod BA might be a cutting knife: and the whole may be led along by a ſcrew, while this knife turns round according to any law, and would gradually pare away the mouldboard to the proper form.

Thus have we reduced the faſhioning the operative part of the plough to a rule which is certain. We do not mean by this, that a mouldboard made according to the maxim now given will make the beſt poſſible plough; but we have given a rule by which this part of the plough can be made unequivocally of a certain quality by every workman, whatever this quality may be, and this without being obliged to copy. No deſcription of any curve mouldboard to be met with in books has this advantage; and we ſay that this rule is capable of any ſyſtematic variation, either with reſpect to the width of furrow, or the quantity or variation of its twiſt. We have therefore put it in the power of any intelligent perſon to make ſuch gradual and progreſſive changes as may ſerve to bring this moſt uſeful of all inſtruments to perfection. The angle of the head and wreſt, and the curve for dividing the wreſt-line, can always be expreſſed in writing, and the improvements communicated to the public at large.

136 Mode of the plough's action.

After this deſcription of the working parts of a plough, and directions for giving it the moſt effective form, it will not be improper to conſider a little its mode of action, with the view of attaining a more diſtinct conception of what is done by the ploughman and the cattle, and to direct him in his procedure.

Returning again to the wedge (fig 1.), we ſee that it is preſſed down at the point D, and as far back along the mouldboard as its ſurface continues to look upward, that is, all the way to the heel of the wreſt. Behind this, the perpendicular ſections of the mouldboard overhang, and look downward; and here, while preſſing down the ſod, the plough is preſſed upwards. Theſe two preſſures tend to twiſt the plough round a tranſverſe line ſomewhere between the heel and the point. The plough therefore tends to riſe at the heel, and to run its point deeper into the ground. Upon the whole, the preſſure downwards is much greater than the upward preſſure. It is exerted over a much greater ſpace, and is greater in moſt parts of that ſpace. Behind, very little downward preſſure is neceſſary, the ſod being ready to fall down of itſelf, and only requiring a gentle touch to lay it in a proper poſition.

Inſtruments of Huſbandry.

In like manner the plough is preſſed backward by the reſiſtance made to the coulter and ſock, and part of the reſiſtance made to the ſloping ſide of the mouldboard: and it is preſſed to the left by the other part of the preſſure on the ſock and mouldboard.

All theſe preſſures muſt be balanced by the joint action of the cattle, the reſiſtance of the bottom, and the reſiſtance of the firm ground on the left-hand or land-ſide.

It is the action of the cattle, exerted on that point to which they are attached, which produces all theſe preſſures. It is demonſtrated by the principles of mechanics, that this force muſt not only be equal to the mean or compound force of theſe reſiſting preſſures, but muſt alſo be in the oppoſite direction.

It is further demonſtrated, that if a body be dragged through any reſiſting ſubſtance by a force acting on any point G, and in any direction whatever GH, and really moves uniformly in that direction, the force exerted exactly balances the reſiſtances which it excites, both as to quantity and direction: And if the body advances without turning round the point by which it is dragged, the reſiſtances on one ſide of this point are in equilibrio with thoſe on the oppoſite ſide.

And, laſtly, it is demonſtrated, that when this equilibrium is obtained, it is indifferent to what point in the line GH the force is applied. Therefore, in fig. 3. N° 1. the force acting in the direction HO may either be applied to the point of the beam H, or to the point N of the coulter, or to the point O of the ſock.

When therefore a plough advances ſteadily, requiring no effort of the ploughman to direct it, if the line of draught OM (fig. 10.) be produced backwards to the point G of the mouldboard, that point is the place round which all the reſiſtances balance each other. This point may be called the *centre of reſiſtance* and the *centre of action*.

It would be of importance to determine this point by principle; but this can hardly be done with preciſion even in a plough of a known form: and it is impoſſible to do it in general for all ploughs, becauſe it is different in each. It even varies in any plough by every variation of the proportion between the weight and the coheſion of the ſod. We ſee how it can be found experimentally in any given uniform ſod, viz. by producing backwards the line of draught. Then, if the draught rope, inſtead of being fixed to the muzzle of the beam, were fixed to this point, and if it were pulled in the ſame direction, the plough would continue to perform its work without any aſſiſtance from the ploughman, while the ſod continued uniform. But the ſmalleſt inequality of ſod would derange the plough ſo as to make it go entirely out of its path. Should the reſiſtances between G and D prevail, the plough would go deeper, which would increaſe the reſiſtances on that ſide where they already exceed, and the plough would run ſtill deeper. Should the reſiſtances behind G prevail, the heel would be preſſed down, and the point would riſe, which would ſtill farther deſtroy the equilibrium, and, producing a greater deviation from the

Inſtruments of Huſbandry.

the right path, would quickly throw the plough out of the ground.

For theſe reaſons we muſt not think of attaching the draught to the centre of reſiſtance; but muſt contrive a point of draught, ſuch as ſhall reſtore the plough to its proper poſition when it has been driven out of it by any obſtruction.

137 Muzzle of the beam.

The muzzle or end of the beam is a point which will completely ſuit our purpoſe. For ſuppoſe that the reſiſtance on the back of the ſock has prevailed, and the plough MNFD (fig. 10.) has taken the poſition *m n f d* repreſented by the dotted lines, the draught line GMO is brought down into the poſition *g m o*, diverging a little from GMO, and meeting the mouldboard in a point *g* conſiderably before G. By this means the reſiſtances on the hinder ſide of *g* are increaſed, and thoſe before it are diminiſhed, and the plough quickly regains its former poſition.

138 The point of draught.

From theſe obſervations it is plain, that whatever is the ſituation of the centre of reſiſtance, the point of draught may be ſo choſen that the action of the cattle ſhall be directly oppoſed to the reſiſtance of the ground, and that moreover the plough ſhall have no tendency either to go deeper or to run out. This is the uſe of the apparatus at the point of the beam, called the muzzle, repreſented at H (fig. 3.). It turns round a bolt *i* through the beam, and can be ſtopped at any height by another pin *k* put through the holes in the arch *l m*. A figure is given of the muzzle immediately below, as it appears when looking down on it. The eye to which the draught rope is hooked is ſpread out horizontally, as ſhown by HK, and has ſeveral notches O in it, to either of which the hook can be applied. This ſerves to counteract any occaſional tendency which the plough may have to the right or left.

When the plough goes on ſteadily, without any effort of the ploughman, it is ſaid to be in trim, and to ſwim fair; the preſſure before and behind the centre of action being in equilibrio with each other. In order to learn whether a plough will be in this manner under management, hook the draught ropes as high as poſſible.

139 Of the plough in trim.

In this ſtate the plough ſhould have a continual tendency to riſe at the heel, and even to run a little into the ground. Then hook the rope as low as poſſible. The plough ſhould now preſs hard on the furrow with the heel, and have ſome tendency to run out of the ground. If both theſe are obſerved, the plough is properly conſtructed in this reſpect; if not, it muſt be altered, either by changing the poſition of the ſock or that of the beam. Lowering the end of the beam will correct the tendency of the plough to go deeper; the raiſing the point of the ſock will alſo have the ſame effect. But it is of conſiderable importance not to take the point of the ſock out of the plane of the ſod, and it is much better to make the alteration by the beam. The ſlope of the coulter has a conſiderable effect, but it cannot be placed very far from the inclination of 45° without the riſk of choaking the plough by driving the roots and ſtones before it. It is of great conſequence to have the coulter ſit exactly in the direction of the plough's motion: if it is in any other direction, it will powerfully twiſt the plough into its own track. As it muſt be fixed in the middle of the beam's thickneſs to have ſtrength, it is removed a little from the plane of the land ſide, and it was the uſual practice to point it to the left below to compenſate for this; but this by no means removes the diſpoſition to twiſt, and it expoſes to the riſk of catching a ſtone between its point and that of the ſock, which muſt now be driven forward through the firm ground at a great expence of labour to the cattle. Mr Small has very ingeniouſly remedied this by giving the coulter a ſhort knee to the left immediately below the beam, and thus pointing it downwards in the plumb of the land ſide. See fig. 6.

Inſtrument of Huſbandry

It is not without its uſe to know the abſolute force neceſſary for tilling the ground. This has been frequently meaſured with a ſpring ſteelyard. One of Small's ploughs, worked by two horſes, and employed in breaking up ſtiff land which had been ploughed before winter, and much conſolidated by the rains, required a force of 360lbs. avoirdupois; and we may ſtate this as the ordinary rate of ſuch work; but moderately firm ſod, under good culture, requires at a medium 320lbs.

As we with to embrace every opportunity of rendering this work uſeful to the public, we ſhall conclude this article with an account of a plough which has juſt now been recommended to public notice by the Scots Highland Society as extremely proper for a hilly country. The inventor, the Rev. Alexander Campbell miniſter at Kilcalmonell in Argyleſhire, was honoured with the ſociety's gold medal, value 25l.

140 The Argyleſhire plough.

A, the ſock (fig. 11.); the land-ſide of which ſupplies the place of the coulter, and the ſole of it ſerves for a feather; it is 18 inches long, and is made of a plate of iron 12 inches broad when finiſhed, and ſomewhat under half an inch thick.—B, the head; to be made of iron in a triangular form, 4 inches broad by 2 inches at the thickeſt part. There are 5 inches of the head fixed in the ſock.—C, the beam, 4 inches thick by 5 inches deep, gradually tapered thinner; the length 6 feet.—E, the ſheath, muſt be of the ſame thickneſs with the beam above and the head below, and is five inches broad. An iron ſcrew-bolt connects the beam and head behind the ſheath.—F, the handles are ſo made that the ſlope of the mouldboard, which is fixed to one of them, may be the longer and more gradual. They are 5 feet 8 inches long, and 2 feet 4 inches aſunder at the ends.—G, the mouldboard, conſiſts of 7 rounded ſticks two inches in diameter; the covert of them is in the plane of the ſole, the reſt in ſucceſſion cloſe to each other above it. This makes the mouldboard 14 inches broad. To prevent any earth from getting over the mouldboard, a thin deal 4 or 5 inches broad is fixed above it. The mouldboard, land ſide, and ſole of the plough, are clad with iron.—The length is 20 inches: this added to 18 inches, the length of the ſock, makes the length from point to heel 3 feet 2 inches.—The muzzle or bridle OPH is alſo of a more convenient and better conſtruction than thoſe commonly in uſe. By means of the ſcrew pins at L and M, different degrees of land may be given to the plough; the iron rod LH being thereby moved ſidewiſe in the ſocket LN, and up and down by OP. The rod is 30 inches long, one broad, and half an inch thick. It is hooked into a ſcrewbolt at H. Two inches of the rod project at N, in the form of an eye, before the muzzle, to receive the hook of the croſtree.

The advantages of this plough are ſaid to be: It is not ſo liable to be interrupted or turned out of its courſe by

Inſtruments of Huſbandry.

by ſtones, roots, &c. as other ploughs are; nor does it dip ſo deep as to be liable to be broken by large ſtones or flags. The motion of the muzzle is alſo thought an improvement. Another advantage it has over other ploughs is, its not being ſo liable to be choaked up by ſtubble, &c. This we underſtand to be its chief excellency, and an object much deſired in the conſtruction of the plough. Upon the whole, we are informed that this plough is lighter, leſs expenſive, and leſs liable to go out of trim than the ordinary plough, and that with it two horſes can plough land which require four with any other plough.

141 Objections to its conſtruction.

Such are ſaid to be the advantages of this conſtruction; but we cannot help expreſſing our apprehenſion that the uniting the coulter and feather at the point of the ſock will expoſe the plough to great riſks of being put out of order. When the upright edge ſtrikes a ſtone obliquely, eſpecially on the land-ſide, it muſt be violently twiſted round the point of the head; and, having but a moderate thickneſs at this part, may be broken or permanently twiſted. The plough will then be continually running out of its direction: and we apprehend that this defect cannot be amended without taking off the ſock and putting it in the fire. When a coulter is bent by the ſame cauſe, the ploughman can either rectify it by altering the wedging, or he can ſtraighten it in the field; and it muſt be obſerved, that the plough oppoſes much leſs reſiſtance to the derangement of this ſort of coulter than of the common one. In the common coulter the ſtrain does not ſo much tend to twiſt the plough round the line of its motion, as to preſs it wholly to landward. The reſiſtance to this is great; but a very moderate force will twiſt it round its line of motion. In either caſe, if the blow be given in that point of the coulter where the draught line croſſes it, there will be no twiſt of the whole plough, but the point of the plough will be forced horizontally to or from the land. When the blow is out of this line, the ſtrain tends to twiſt the beam or the plough. Experience will determine which of the two is the moſt hazardous. Theſe ploughs were made by Thomas Lindſay, Abbeyhill, Edinburgh, and models are to be ſeen in the hall of the Highland Society.

142 cots lough.

The plough conſtructed in the following manner is ſtill the moſt common and the moſt generally underſtood in Scotland; and, if properly made, is the beſt for anſwering all purpoſes, when only one is uſed; though others are, perhaps, more proper on ſome particular occaſions.

143 eſcription the Scots ough.

The parts of which this plough is compoſed, are, the head, the beam, the ſheath, the wreſt, the mouldboard, the two handles, the two rungs, the ſock, and the coulter; the two laſt are made of iron, and all the reſt of wood.

late VII. fig. 1.

The HEAD is deſigned for opening the ground below. The length of the head from A to B is about 20 inches, and the breadth from A to D above five inches; C is the point upon which the ſock is driven, and the length from B to C is about ſix inches; *a* is the mortiſe into which the larger handle is fixed, and *b* is the mortiſe into which the ſheath is fixed.

The head is that part of the plough which goes in the ground; therefore the ſhorter and narrower it is, the friction will be the leſs, and the plough more eaſily drawn; but the longer the head is, the plough goes more ſteadily, and is not ſo eaſily put out of its direction by any obſtructions that occur. Twenty inches is conſidered as a mean length; and five inches as the moſt convenient breadth. Inſtruments of Huſbandry.

The SHEATH, E, is driven into the mortiſe *b*, and thus fixed to the head AB. It is not perpendicular to the head, but placed obliquely, ſo as to make the angle formed by the lines AB and EB about 60 degrees. The ſheath is about 13 inches long, beſides what is driven into the mortiſe *b* (fig. 1.); about three inches broad, and one inch thick. Fig. 2.

The ſheath is fixed to the mouldboard, as in fig. 11. E, in the ſame manner as the wreſt is fixed to the head in fig. 7. Fig. 3.

The MOULDBOARD is deſigned to turn over the earth of the furrow made by the plough; and it is obvious, that, according to the poſition of the ſheath, the mouldboard will turn over the earth of the furrow more or leſs ſuddenly. Beſides, when it forms a leſs angle with the head than 60 degrees, the plough is in great danger of being *choked*, as the farmers term it.

The larger HANDLE, FA, is fixed to the head, by driving it into the mortiſe *a* (fig. 1.). It is placed in the ſame plane with the head; and its length from AF is about five feet four inches, and its diameter at the place where it is fixed to the beam is about two inches and a half, and tapers a little to the top F. About ten inches from A, there is a curve in the handle, which, when F is raiſed to its proper height, makes the lower part of it nearly parallel to the ſheath EB. This curve is deſigned to ſtrengthen the handle. The proper poſition of the handle is, when the top F is about three feet two inches higher than the bottom of the head AB. Fig. 3

The longer the handles, the plough is the more eaſily managed, becauſe the levers are more diſtant from the centre of motion. The higher the top of the handles, the plough is more eaſily raiſed out of the ground, provided they be no higher than the lower part of a man's breaſt.

The BEAM is fixed to the larger handle and the ſheath, all of which are placed in the ſame plane with the head. The length of it, from H to I, is about ſix feet; its diameter is about four inches. When the plough is in the ground, the beam ſhould be juſt high enough not to be incommoded by any thing on the ſurface. Fig. 4.

The poſition of the beam depends on the number of cattle in the plough. When two horſes are yoked, the beam ſhould be placed in ſuch a manner as to make the perpendicular diſtance betwixt the bolt-hole of the beam and the plane of the head about 21 inches; when four horſes are yoked, two a-breaſt, this diſtance ſhould only be about 18 inches.

The SOCK, BP, is fixed to the end of the head, and is about two feet long. In fitting the ſock to the head, the point ought to be turned a little to the land or left ſide; becauſe otherwiſe it is apt to come out of the land altogether. When turned to the left, it likewiſe takes off more land; when turned upwards, the plough goes ſhallow; and when downwards, it goes deeper. Fig. 5.

The COULTER is fixed to the beam, and is about two feet ten inches long, two inches and a half broad, ſharp at the point and before, and thick on the back, Fig. 6

like

Instruments of Husbandry.

like a knife. It is fixed and directed by wedges, so as to make the point of it equal to, or rather a little before, the point of the sock, and upon a line with the left side of the head. This oblique position enables it to throw roots, &c. out of the land, which requires less force than cutting or pushing them forward.

Fig. 7. The WREST, BD, is fixed to the head, and is about 26 inches long, two broad, and one thick. It is fixed to the head at B, in such a manner as to make the angle contained between the lines AB and BD about 25 degrees. The wrest is seldom or never placed in the same plane with the head, but gradually raised from the place where it is fixed to it; that is, from B to K, as in fig. 8. The position of the wrest determines the nature of the furrow. When the wrest is wide and low set, the furrow is wide; and when it is narrow and high set, the furrow is narrow.

Fig. 9. represents the two HANDLES, fixed together by the two rungs. The larger handle has already been described; the lesser one is a few inches shorter, and does not require to be quite so strong. The distance of the handles at the little rung depends on the position of the wrest. Their distance at M and P is about two feet six inches. The lesser handle is fixed to the mouldboard at M, fig. 10. and to the wrest KB, at L.

Fig. 11. represents the plough complete, by joining together figures 6. and 10. in the sheath E B. The wrest BK is supposed to make an angle with the head AB as in fig. 7. and the handles joined together as in fig. 9.

After having giving such a particular description of all the parts and proportions of the Scots plough, it will easily appear how it separates, raises, and turns over the earth of the furrow. If it had no coulter, the earth would open above the middle of the sock, and in a line before the sheath; but as the coulter opens the earth in a line with the left side of the head, if the soil has any cohesion, the earth of the furrow will be wholly raised from the left side, and, as the sock moves forward, will be thrown on the right side of the sheath, and by the casting out of the mouldboard, or the raising of the wrest, will be turned over.

Fig. 12. The BRIDLE or MUZZLE, is another article belonging to the plough. It is fixed to the end of the beam, and the cattle are yoked by it. The muzzle commonly used is a curved piece of iron, fixed to the beam by a bolt through it. ABC is the muzzle, AC the bolt by which it is fixed to the beam; D is the swingle-tree or cross-tree, to which the traces are fixed; and B is a hook or *cleek*, as it is commonly called, which joins the muzzle and swingle-tree.

Fig. 13. Some use another kind of muzzle, ABCD. It is fixed to the beam by two bolts, and has notches by which the cleek of the swingle-tree may be fixed either to the right or the left of the beam. There are also different holes for the hind bolt to pass through, by which the draught may be fixed either above or below the beam. AD is the fore bolt upon which the muzzle turns; on BC are four notches, betwixt any two of which the cleek of the swingle-tree may be fixed. When the cleek is fixed at B, the plough is turned towards the firm land, and takes off a broader furrow; and when fixed at C, it is turned towards the ploughed land, and takes off a narrower furrow. E and F are the holes on each side through which the hindmost bolt passes. When the bolt is put through the highest two, these holes being thereby brought to the middle of the beam, the fore part of the muzzle is raised above the beam, and the plough is made to go deeper, and when put through the lowest two, the fore part of the muzzle is sunk below the beam, and the plough is made to go shallower. This muzzle may be so constructed as to have the same play with the common one. A is the end of the beam; B a plate of iron sunk into it, and, with a similar one in the other side, is rivetted into it by bolts; C is the muzzle fixed to these plates of iron by the bolt D, which bolt may be put through any of the holes EE. From the construction of this muzzle it is plain, that it has the same play with the common one, and that by it the land of the plough may be altered at pleasure.

Instruments of Husbandry.

Fig. 16.

144 Properties of the Scots plough.

Of all forms, that of the Scots plough is the fittest for breaking up stiff and rough land, especially where stones abound; and no less fit for strong clays hardened by drought. The length of its head gives it a firm hold of the ground; its weight prevents it from being thrown out by stones; the length of the handles gives the ploughman great command to direct its motion; and by the length of its head, and of its mouldboard, it lays the furrow-slice cleverly over. This plough was contrived during the infancy of agriculture, and was well contrived: in the soils above described it has not an equal.

145 In what soil improper.

But in tender soil it is improper, because it adds greatly to the expence of ploughing, without any counterbalancing benefit. The length of the head and mouldboard increases the friction, and consequently it requires a greater number of oxen or horses than are necessary in a shorter plough. There is another particular in its form that resists the draught: the mouldboard makes an angle with the sock, instead of making a line with it gently curving backward. There is an objection against it no less solid, that it does not stir the ground perfectly: the hinder part of the wrest rises a foot above the sole of the head: and the earth that lies immediately below that hinder part, is left unstirred. This is ribbing land below the surface, similar to what is done by ignorant farmers on the surface.

These defects must be submitted to in a soil that requires a strong heavy plough; but may be avoided in a cultivated soil by a plough differently constructed. Of all the ploughs fitted for a cultivated soil free of stones, that already mentioned, which was introduced into Scotland about 20 years ago, by James Small in Blackadder Mount, Berwickshire, is the best. It is now in great request; and with reason, as it avoids all the defects of the Scots plough. The shortness of its head and of its mouldboard lessens the friction greatly: from the point of the sock to the back part of the head it is only 30 inches; and the whole length, from the point of the beam to the end of the handles, between eight and nine feet. The sock and mouldboard make one line gently curving; and consequently gather no earth. Instead of a wrest, the under edge of the mouldboard is one plane with the sole of the head; which makes a wide furrow, without leaving any part unstirred. It is of late commonly termed the *chain plough*, because it is drawn by an iron chain fixed to the back part of the beam immediately before the coulter. This has two advantages: first, by

146 Chain-plough. Plate VI fig. 1.

means

Inſtruments of Huſbandry.

means of a muzzle, it makes the plough go deep or ſhallow; and, next, it ſtreſſes the beam leſs than if fixed to the point, and therefore a ſlenderer beam is ſufficient.

As we have already ſufficiently explained the ſpeculative principles upon which this plough is formed, we ſhall only remark, that it is proper for loams, for carſe clays, and, in general, for every ſort of tender ſoil free of ſtones. It is even proper for opening up paſture ground, where the ſoil has been formerly well cultivated.

147 The ſock. Plate VII.

A ſpiked ſock is uſed in the Scots plough. The difference between it and the feathered ſock will be beſt underſtood by comparing their figures. Fig. 14. is the common ſock, and fig. 15. the feathered one.

From the conſtruction of the feathered ſock, it is obvious, that it muſt meet with greater reſiſtance than the common ſock. However, when the plough takes off the earth of the furrow broader than that part of the ſock which goes upon the head, it is more eaſily drawn than the plough with the common ſock; for the earth which the common ſock leaves to be opened by the wreſt, is more eaſily opened by the feather of the other ſock. In ley, the feathered ſock makes the plough go more eaſily, becauſe the roots of the graſs, which go beyond the reach of the plough, are more eaſily cut by the feather than they can be torn aſunder by the common ſock. The feathered ſock is alſo of great uſe in cutting and deſtroying root weeds. The common ſock, however, anſwers much better in ſtrong land.

It is proper here to add, that in fitting the feathered ſock to the head, the point of it ſhould be turned a little from the land, or a little to the right hand.

148 Ignorance of farmers in Scotland not a few years ago.

If we look back 40 years, ploughs of different conſtructions did not enter even into a dream. The Scots plough was univerſally uſed, and no other was known. There was no leſs ignorance as to the number of cattle neceſſary for this plough. In the ſouth of Scotland, ſix oxen and two horſes were univerſal; and in the north, 10 oxen, ſometimes 12. The firſt attempt to leſſen the number of oxen was in Berwickſhire. The low part of that county abounds with ſtone and clay marl, the moſt ſubſtantial of all manures, which had been long uſed by one or two gentlemen. About 30 years ago it acquired reputation, and ſpread rapidly. As two horſes and two oxen were employed in every marl cart; the farmer, in ſummer fallowing, and in preparing land for marl, was confined to four oxen and two horſes. And as that manure afforded plenty of ſucculent ſtraw for oxen, the farmer was ſurpriſed to find that four oxen did better now than ſix formerly. Marling, however, a laborious work, proceeded ſlowly, till people were taught by a noted farmer in that country, what induſtry can perform by means of power properly applied. It was reckoned a mighty taſk to marl five or ſix acres in a year. That gentleman, by having plenty of red clover for his working cattle, accompliſhed the marling of 50 acres in a ſummer, and once of 54. Having ſo much occaſion for oxen, he tried with ſucceſs two oxen and two horſes in a plough; and that practice became general in Berwickſhire.

Now here appears with luſtre the advantage of the chain-plough. The great friction occaſioned in the Scots plough by a long head, and by the angle it makes with the mouldboard, neceſſarily requires two oxen and two horſes, whatever the ſoil be. The friction is ſo much leſs in the chain-plough, that two good horſes are found ſufficient in every ſoil that is proper for it. Beſides, the reducing the draught to a couple of horſes has another advantage, that of rendering a driver unneceſſary. This ſaving on every plough, where two horſes and two oxen were formerly uſed, will, by the ſtricteſt computation, be 15l. ſterling yearly; and where four horſes were uſed, no leſs than 20l. ſterling. There is now ſcarce to be ſeen in the low country of Berwickſhire, or in the Lothians, a plough with more than two horſes; which undoubtedly in time will become general. We know but of one further improvement, that of uſing two oxen inſtead of two horſes. That draught has been employed with ſucceſs in ſeveral places; and the ſaving is ſo great, that it muſt force its way everywhere, providing only a breed of oxen with a quick ſtep could be obtained. It may be confidently affirmed, no ſoil ſtirred in a proper ſeaſon, can ever require more than two horſes and two oxen in a plough, even the ſtiffeſt clay. In all other ſoils, two good horſes, or two good oxen abreaſt, may be relied on for every operation of the chain-plough.

149 Advantages of the chain-plough particularly illuſtrated.

A chain-plough of a ſmaller ſize than ordinary, drawn by a ſingle horſe, is of all the moſt proper for horſe-hoeing, ſuppoſing the land to be mellow, which it ought to be for that operation. It is ſufficient for making furrows to receive the dung, for ploughing the drills after dunging, and for hoeing the crop.

150 A ſmall ſingle-horſe plough recommended for various purpoſes.

A ſtill ſmaller plough of the ſame kind may be recommended for a kitchen garden. It can be reduced to the ſmalleſt ſize, by being made of iron; and where the land is properly dreſſed for a kitchen garden, an iron plough of the ſmalleſt ſize drawn by a horſe will ſave much ſpade-work. In Scotland, forty years ago, a kitchen garden was an article of luxury merely, becauſe at that time there could be no cheaper food than oatmeal. At preſent, the farmer maintains his ſervants at double expence, as the price of oatmeal is doubled; and yet he has no notion of a kitchen garden more than he had thirty years ago. He never thinks, that living partly on cabbage, kail, turnip, carrot, would ſave much oatmeal: nor does he ever think, that change of food is more wholeſome, than vegetables alone, or oatmeal alone. We need not recommend potatoes, which in ſcanty crops of corn have proved a great bleſſing; without them, the labouring poor would frequently have been reduced to a ſtarving condition. Would the farmer but cultivate his kitchen garden with as much induſtry as he beſtows on his potato crop, he needed never fear want; and he can cultivate it with the iron plough at a very ſmall expence. It may be held by a boy of 12 or 13; and would be a proper education for a ploughman. But it is the landlord who ought to give a beginning to the improvement. A very ſmall expence would encloſe an acre for a kitchen garden to each of his tenants; and it would excite their induſtry, to beſtow an iron plough on thoſe who do beſt.

Nor is this the only caſe where a ſingle-horſe plough may be profitably employed. It is ſufficient for ſeed-furrowing barley, where the land is light and well-dreſſed.

Instruments of Husbandry.

dreſſed. It may be uſed in the ſecond or third ploughing of fallow, to encourage annual weeds, which are deſtroyed in ſubſequent ploughings.

151 Rotheram Plough, Plate IX. fig. 3.

The *Rotheram plough* is a machine of very ſimple conſtruction, and eaſily worked. AB is the beam, CD the ſheath, EBD the main handle, FR the ſmaller handle, GH the coulter, KI the ſock or ſhare, NP the bridle, S the fly-band, and ML a piece of wood in place of a head. The whole of this plough ſhould be made of aſh or elm; the irons ſhould be ſteeled and well tempered; and that part of the plough which is under ground in tilling ſhould be covered with plates of iron. The difference between this and the common plough ſeems to conſiſt in the bridle at the end of the beam, by which the ploughman can give the plough more or leſs land by notches at N, or make it cut deeper or ſhallower by the holes at P; in the coulter or ſhare, which is ſo made and ſet as to cut off the new furrow without tearing; and in the mouldboard, which is ſo ſhaped at firſt to raiſe a little, and then gradually turn over, the new cut furrow with very little reſiſtance. But the greateſt advantage attending it, is its being ſo eaſy of draught, that it will do double the work of any common plough.

152 The Paring Plough. Plate IX. fig. 4.

The *paring plough* is an inſtrument uſed in ſeveral parts of England for paring off the ſurface of the ground, in order to its being burnt. Mr Bradley has given the following deſcription of a very ſimple inſtrument of this kind: From A to A (fig. 15.) is the plough-beam, about ſeven feet long, mortiſed and pinioned into the block B, which is of clean timber without knots. CC are the ſheaths or ſtandards, made flat on the inſide, to cloſe equally with the paring plate, and faſtened to it with a bolt and key on each ſide, as at D. E is the paring plate of iron laid with ſteel, about four inches wide, and from 12 to 18 inches long. This plate muſt be made to cut on the ſides, which are bolted to the ſtandards as well as at the bottom part. FF are two iron braces to keep the ſtandards from giving way: theſe ſtandards muſt be mortiſed near their outſides and through the block. GG are the plough handles, which muſt be fixed ſlopeways between the beam and the ſtandards. The pin holes in the beam, the uſe of which is to make this plough cut more or leſs deep, by fixing the wheels nearer to or farther from the paring plate, ſhould not be above two inches aſunder.

153 The Four-coultered Plough, Plate IX.

Fig. 1. repreſents the four-coultered plough of Mr Tull. Its beam is ten feet four inches long, whereas that of the common plough is but eight. The beam is ſtraight in the common plough, but in this it is ſtraight only from *a* to *b*, and thence arched; ſo that the line let down perpendicularly from the corner at *a*, to the even ſurface on which the plough ſtands, would be 11¼ inches; and if another line were let down from the turning of the beam at *b* to the ſame ſurface, it would be one foot eight inches and a half; and a third line let down to the ſurface from the bottom of the beam at that part which bears upon the pillow, will ſhow the beam to be two feet ten inches high in that part. At the diſtance of three feet two inches from the end of the beam *a*, at the plough-tail, the firſt coulter, or that next the ſhare, is let through; and at 13 inches from this, a ſecond coulter is let through: a third at the ſame diſtance from that; and, finally, the fourth at the ſame diſtance from the third, that is, 13 inches, and from *a* to *b* is ſeven feet.

Inſtruments of Husbandry.

The crookedneſs of the upper part of the beam of this plough is contrived to avoid the too great length of the three foremoſt coulters, which would be too much if the beam was ſtraight all the way; and they would be apt to bend and be diſplaced, unleſs they were very heavy and clumſy. Aſh is the beſt wood to make the beam of, it being ſufficiently ſtrong, and yet light. The theat in this plough is to be ſeven inches broad. The fixing of the ſhare in this, as well as in the common plough, is the niceſt part, and requires the utmoſt art of the maker; for the well-going of the plough wholly depends upon the placing this. Suppoſing the axis of the beam, and the left ſide of the ſhare, to be both horizontal, they muſt never be ſet parallel to each other; for if they are, the tail of the ſhare bearing againſt the trench as much as the point, would cauſe the point to incline to the right hand, and it would be carried out of the ground into the furrow. If the point of the ſhare ſhould be ſet ſo, that its ſide ſhould make an angle on the right ſide of the axis of the beam, this inconvenience would be much greater; and if its point ſhould incline much to the left, and make too large an angle on that ſide with the axis of the beam, the plough would run quite to the left hand; and if the holder, to prevent its running quite out of the ground, turns the upper part of his plough towards the left hand, the pin of the ſhare will riſe up, and cut the furrow diagonally, leaving it half unploughed. To avoid this and ſeveral other inconveniences, the ſtraight ſide of the ſhare muſt make an angle upon the left ſide of the beam; but that muſt be ſo very acute a one, that the tail of the ſhare may only preſs leſs againſt the ſide of the trench than the point does. This angle is ſhown by the pricked lines at the bottom of fig. 9. where *ef* is ſuppoſed to be the axis of the beam let down to the ſurface, and *gf* parallel to the left ſide of the ſhare: and it is the ſubtenſe *eg* that determines the inclination which the point of the ſhare muſt have towards the left hand. This ſubtenſe, ſays Mr Tull, at the fore-end of an eight-feet beam, ſhould never be more than one inch and a half, and whether the beam be long or ſhort, the ſubtenſe muſt be the ſame.

The great thing to be taken care of, is the placing the four coulters; which muſt be ſo ſet, that the four imaginary places deſcribed by their four edges, as the plough moves forward, may be all parallel to each other, or very nearly ſo; for if any one of them ſhould be very much inclined to, or ſhould recede much from, either of the other, then they would not enter the ground together. In order to place them thus, the beam muſt be carefully pierced in a proper manner. The ſecond coulter-hole muſt be two inches and a half more on the right hand than the firſt, the third muſt be as much more to the right of the ſecond, and the fourth the ſame meaſure to the right hand of the third; and this two inches and a half muſt be carefully meaſured from the centre of one hole to the centre of the other. Each of theſe holes is a mortiſe of an inch and a quarter wide, and three inches and a half long at the top, and three inches at the bottom. The two oppoſite ſides of this hole are parallel to the top and bottom, but the back is oblique, and determines the obliquity

Instruments of Husbandry.

obliquity of the ſtanding of the coulter, which is wedged tight up to the poll. The coulter is two feet eight inches long before it is worn: the handle takes up ſixteen inches of this length, and is allowed thus long, that the coulter may be driven down as the point wears away. As to the wheels, the left hand wheel is 20 inches diameter, and that on the right hand two feet three inches, and the diſtance at which they are ſet from each other is two feet 5½ inches.

154 Patent Sward-cutter, Plate IX.

2. The Patent Sward-cutter.

The different parts of this inſtrument are repreſented by N° 1. 2. 3. of fig. 6. AA, &c. a ſquare frame three feet four inches from the fore to the hind part, by four feet three inches, the breadth of the machine within ſide; the timber (when of fir) four inches ſquare, placed on two wheels BB three feet diameter, a little more or leſs (the old fore-wheels of a chaiſe may anſwer the purpoſe), to ſupport the hind part of the machine.

CC, &c. are ſix ſtrong pieces of wood, called *bulls*, three feet long, five inches and a half broad, the thickneſs ſix inches at E, and tapering to three inches at F. Into theſe bulls are fixed the cutting wheels, which are iron, 13 inches diameter, ¼ths of an inch thick at the centre, about an inch diameter, for piercing holes to fix the iron axles in; from that they are to be of ſuch thickneſs, as to allow the edges to be well ſteeled. The wheels are fixed by two bolts going through the bulls, with eyes on one end for the axles of the wheels to run in, and nuts and ſcrews on the other to make them very firm by being ſunk in the bulls, to prevent their interfering with the weights LL, &c. reſting on them.

GG, &c. are hollow pieces of wood, called *thorles*, each 3½ inches long, which encloſe the bolt MM, and keep the bulls CC, &c. at their proper diſtances, but may be made longer or ſhorter at pleaſure, according as the ſward requires to be cut in larger or ſmaller pieces. They are in two pieces bound together, and jointed by a ſtrap of leather or cord, which allows them to be readily changed when the cutting wheels require to be kept at more or leſs diſtance.

The iron bolt MM goes through two pieces of wood or iron PP, ſeven inches long, clear of the wood, ſupported by iron ſtays fixed to the frame, and through all the bulls. It requires to be ſtrong, as the draught of the horſes terminates there.

HH, N° 2. and 3. a cylinder or ſegment of wood, ſeven inches diameter, called a *rocking tree*, which goes acroſs the frame, and moves on the pivots fixed into it, one at each end, ſupported by an iron bolt or piece of wood mortiſed into the frame, eight inches high, as appears in N° 2. and 3. to which ſix chains or ropes are fixed by hooks, at different diſtances, as you want your cuts, nine, eight, ſeven, or ſix inches from one another, and are joined to the end of each bull in which the cutting wheels run; ſo that when the rocking tree is turned about by the lever I, fixed in the middle of it, all the bulls, with their cutting wheels, are raiſed out of the ground at once, as in N° 3. by which means the machine may be turned, or moved from place to place with great eaſe, without any danger of ſtraining the wheels.

LLL, &c. N° 1. 2. 3. are weights of freeſtone, 26 inches long and ſix inches broad; the under one four inches thick, the upper one three inches thick; weighing about 64lb. the under, and 48 the upper; each of them having two holes, through which iron ſpikes, firmly fixed in the bulls, paſs, in order to keep them ſteady.

When the ground is eaſily cut, the under ſtone may anſwer; when more difficult, the other ſtone may be added; ſo that every wheel may have ſeven ſtone weight upon it, which has been found ſufficient for the ſtiffeſt land and toughеſt ſward the machine has ever been tried on. Caſt iron weights will anſwer fully better, but are more expenſive.

The lever I, N° 2. 3. which ought to be five feet long, muſt have a ſliding rope on it; fixed to the back part of the frame; ſo that when the cutting wheels are all taken out of the ground three or four inches, by the rocking tree's being turned partly round by the lever, the rope may be fixed to it by a loop over the pin R, N° 3. (it ought to be placed three feet four inches from the extremity of the lever I). Thus all the cutting wheels are kept out of the ground till the machine is turned; and then by moving the loop off the pin, it ſlips back towards the frame, and the lever is gently let back to its place, as in N° 2. by which the cutting wheels are put into their former poſture, by the weights fixed on the bulls in which they run. The levers may be made of good tough aſh.

PP, N° 1. a ſmall bolt of iron, with a hook on one end of it (one is ſufficient), to ſtrengthen the bolt MM to be hooked on the centre of it, and joined to the frame by a nut and ſcrew.

The grooves in which the cutting wheels run, may be covered below at the hinder part with a plate of thin black iron, 6 inches long, 3 inches broad, having a ſlit in it where the wheels run, to prevent (if found neceſſary) any graſs, weeds, or ſmall ſtones, from filling the grooves, and clogging the wheels.

To the frame N° 1. are fixed (for a double-horſe ſward-cutter) three ſhafts, as in a waggon, of ſuch length, ſtrength, and diſtance from one another, as any workman may think proper.

For a ſingle-horſe ſward-cutter (which has only four cutting wheels), a pair of ſhafts are uſed, and may make the two ſides of the frame without any joinings. The width of the frame, in proportion to the double-horſe ſward-cutter, is as four to ſix.

It is recommended for a double-horſe ſward cutter to have eight bulls and wheels, in order that when it is uſed to reduce hard clody ſummer-fallow, or land for barley, before the laſt furrow, or even after it, the whole weight (42 ſtone) employed in cutting the ſtiffeſt land and toughеſt ſward, may be applied to the 8 bulls then at 6 inches from one another. The 64lb. weights to be applied to ſix of the bulls, and two of the 48lb. weights to each of the additional bulls, which is a ſufficient weight for the purpoſe, and will effectually prevent a clod of more than ſix inches breadth from eſcaping being broke into pieces.

In the ſame manner, a ſingle-horſe ſward-cutter may have ſix bulls for the above-mentioned purpoſe; the 28 ſtone belonging to it divided thus: The 64lb. weights to four of the bulls, and two of the 48lb. weights to each of the additional bulls.

That the machine may come as cheap as poſſible to

Inſtruments of Huſbandry.

the public, the inventor is of opinion, that the expence of the two wheels and the iron axle (which is conſiderable) may be ſaved, by joining ſtrongly to the frame at S, N° 3. a piece of wood with a little curve at the extremity of it, reſembling the foot of a ſledge formerly much uſed in Scotland to carry in the corn from the field; the part of it reſting on the ground being kept 18 inches (the half diameter of the wheels) from the frame by a ſtrong ſupport of wood.

As the two outer bulls next the frame are apt to get under it, ſo as to prevent the cutting wheels from being taken out of the ground, a thin ſlip of iron fixed to the inſide of the frame, nearly oppoſite to the back end of the bulls, of convenient length, will be found neceſſary.

The original intention of this machine was to prepare old graſs ground for the plough, by cutting it acroſs the ridges, in the beginning of or during winter, when the ground is ſoft, in order to anſwer all the purpoſes that Mr Tull propoſed by his four-coulter plough above deſcribed, and ſo ſtrongly recommended by him for bringing into tilth graſs ground that has been long reſted. This the ſward-cutter has been found to do much more effectually and expeditiouſly: For Mr Tull's machine cuts the ſward in the ſame direction with the plough; and is liable, from every obſtruction any of the coulters meet with, to be thrown out of its work altogether, or the inſtrument broken; to which the ſward-cutter, conſiſting of four, ſix, or more cutting wheels, is never liable, from theſe being entirely independent of one another, cutting the ground acroſs the ridges before ploughing, and rendering that operation eaſier to two horſes than it would be to three, without its being cut. The furrow being cut acroſs, falls finely from the plough in ſquares of any ſize required, not under ſix inches, in place of long ſlips of tough ſward ſeldom and imperfectly broke by the four-coultered plough.

This inſtrument is very fit for preparing ground for burnbating, as it will ſave much hard labour.

It may be properly uſed in croſs-cutting clover of one or two years ſtanding, to prepare the ground for wheat, if the land is ſtiff and moiſt enough.

It may be applied to cutting and croſs-cutting paſture ground, intended to have manure of any kind put upon it to meliorate the graſs. In this it will far exceed the ſcarificator mentioned in one of Mr Young's tours; as that inſtrument is liable, as well as the four-coultered plough, to be thrown out of its work when meeting with a ſtone or other interruption. This the ſward-cutter is proof againſt, which is looked on as its greateſt excellence.

In preparing for barley, the ſward-cutter excels a roller of any kind in reducing the large hard clods in clay land, occaſioned by a ſudden drought, after its being ploughed too wet; and it is likewiſe very proper for reducing ſuch clay land when under a ſummer-fallow. In this operation, the ſward-cutter is greatly to be preferred to the cutting-roller, likewiſe mentioned by Mr Young in one of his tours; for the wheels of the latter being all dependent one on another, when one is thrown out by a ſtone, three or four muſt ſhare the ſame fate. Beſides, the cutting-roller has but ſeven wheels in ſix feet; whereas the ſward-cutter has ſix in four feet three inches, at nine inches diſtant; and, if neceſſary, may have them ſo near as ſix inches.

Inſtrumer of Huſbandr

After old graſs ground is cut acroſs with the ſward-cutter and ploughed, it has a very uncommon and worklike appearance, from each ſquare turned over by the plough being raiſed up an inch or two at the ſide laſt moved by the earthboard; ſo that the field when finiſhed, is all prettily waved, and reſembles a piece of water when blown on by a gentle breeze. By this means a very great deal of the land's ſurface is expoſed to the froſt and other influences of the air, which cannot fail to have a good effect on it.

Two horſes are ſufficient for the draught of a double-horſe ſward-cutter, and one horſe for a ſingle-horſe one. One man manages the machine and drives the horſes. He begins his operation by firſt meaſuring off 20 or 30 paces from the machine, leſs or more as he inclines, and there fixes a pole. He then cuts the field acroſs, as near at right angles with the ridges as he can. When the cutting wheels are paſt the laſt furrow about a yard or ſo, and the machine is upon the utmoſt ridge of the field on which it muſt turn, he muſt ſtop the horſes; then take hold of the lever I, N° 2. and by pulling it to him he raiſes the cutting wheels out of the ground, which are kept ſo by the loop of the rope being put over the pin R, in the lever I, N° 3. till the machine is turned and brought to its proper place, which is done by meaſuring off the ſame diſtance formerly done on the oppoſite ſide of the field. When the cutting wheels are exactly over the outmoſt furrow, then, on the horſes being ſtopped, the rope is ſlipt off the pin R, and the lever returned to its former place, as repreſented N° 2. which allows the weights L L, &c. to force the cutting wheels into the ground again. He then goes on until the interval betwixt the firſt and ſecond ſtroke of the machine is all cut. In this manner the field is to be finiſhed, after which you may begin to plough when you pleaſe. (N. B. There muſt be a pole at each ſide of the field.)

It is of no conſequence whether the land to be ſward-cut is in crooked ridges or ſtraight, in flat ridges or in very high raiſed ones. Be the ſurface ever ſo uneven, the cutting wheels, being all independent of one another, are forced by their weights into every furrow or hollow.

One ſward-cutter will cut as much in one day as ſix ploughs will plough.

The land may lie ſeveral months in winter after being ſward-cut, when there is no vegetation to make the cuts grow together again before it is ploughed; but the ſooner it is ploughed after cutting the better, that it may have the benefit of all the winter's froſt, which makes it harrow better at ſeed time.

When the ground is harrowed, the harrows ought to go with the waves which appear after ploughing, not againſt them, as by that means they are leſs apt to tear up the furrows all cut into ſquares. This, however, need only be attended to the two firſt times of harrowing, as they are called.

Any common wright and ſmith may make the inſtrument. It is very ſtrong, very ſimple, and eaſily managed and moved from place to place; and, if put under cover, will laſt many years.

It was invented ſome time ago, by the Honourable Robert Sandilands; and is repreſented in the Plate as it

Inſtruments of Huſbandry.

it has been lately improved by him, the price being at the ſame time reduced from 15l. or 16l. to 5l. or 6l.

3. The Cultivator.

155 The cultivator described.

This inſtrument was invented by Mr William Leſter of Northampton; and that gentleman received, from the Society for the encouragement of Arts, the ſociety's ſilver medal. The purpoſe of this inſtrument is to pulverize tenacious ſoils that have been once ploughed, in a much more complete and rapid manner than can be accompliſhed by any other inſtrument. It is thus deſcribed, Plate XII.—A, the beam; BB, the handles; CC, a croſs bar of a ſemicircular form, containing a number of holes, which allow the two bars DD to be placed nearer or further from each other.

DD are two ſtrong bars moveable at one end upon a pivot E, and extending from thence in a triangular form to the croſs bar C. In theſe bars are ſquare holes, which allow the ſhares F placed therein to be fixed to any height required.

The ſeven ſhares marked F, are ſhaped at their lower extremities like ſmall trowels; the upper parts of them are ſquare iron bars.

GGG are three iron wheels on which the machine is moved; they may be raiſed or lowered at pleaſure.

H, the iron hook to which the ſwingle-tree and horſes are to be fixed.

When the machine is firſt employed on the land, the bars DD are expanded as much as poſſible. As the ſoil is more looſened, they are brought nearer to the centre; the ſhares then occupy a leſs ſpace, and the ſoil will conſequently be better pulverized.

In working on a rough fallow, therefore, the cultivator ſhould be ſet for its greateſt expanſion, and contracted in proportion as the clods are reduced. The inventor declares himſelf confident that one man, a boy, and ſix horſes, will move as much land in a day, and as effectually, as ſix ploughs, meaning land in a fallow ſtate that has been previouſly ploughed. It is requiſite in ſome ſtates of the ſoil to alter the breadth of the ſhares, but of this it is preſumed that every farmer will be a proper judge. By the expanſion and contraction of the cultivator, the points of the ſhares are in a ſmall degree moved out of the direct line; but this is ſaid to be ſo trifling as to prove no impediment to its working.

A certificate from Mr William Shaw of Cottenend, near Northampton, ſtates, that he had uſed Mr Leſter's cultivator, upon a turnip fallow in ſummer 1800; and that he believes it to be a very uſeful implement for cultivating the land in a fallow ſtate, by its working or ſcuffling off ſeven acres per day with ſix horſes. He adds, that from its property of contracting and expanding, it is calculated to work the ſame land in a rough or fine ſtate, by which means it unites the principles of two implements in one, and by the index on the axis it may be worked at any depth if required.

4. The Brake.

156 Brake deſcribed, Plate VIII. fig. 2.

The brake is a large and weighty harrow, the purpoſe of which is to reduce a ſtubborn ſoil, where an ordinary harrow makes little impreſſion. It conſiſts of four ſquare bulls, each ſide five inches, and ſix feet and a half in length. The teeth are 17 inches long, bending forward like a coulter. Four of them are inſerted into each bull, fixed above with a ſcrew-nut, having 12 inches free below, with a heel cloſe to the under part of the bull, to prevent it from being puſhed back by ſtones. The nut above makes it eaſy to be taken out for ſharping. This brake requires four horſes or four oxen. One of a leſſer ſize will not fully anſwer the purpoſe: one of a larger ſize will require ſix oxen; in which caſe the work may be performed at leſs expence with the plough.

Inſtruments of Huſbandry.

157 Uſes.

This inſtrument may be applied to great advantage in the following circumſtances. In the fallowing ſtrong clay that requires frequent ploughings, a braking between every ploughing will pulverize the ſoil, and render the ſubſequent ploughings more eaſy. In the month of March or April, when ſtrong ground is ploughed for barley, eſpecially if bound with couch-graſs, a croſs-braking is preferable to a croſs-ploughing, and is done at half the expence. When ground is ploughed from the ſtate of nature, and after a competent time is croſs-ploughed, the brake is applied with great ſucceſs, immediately after the croſs-ploughing, to reduce the whole to proper tilth.

Let it be obſerved, that a brake with a greater number of teeth than above mentioned, is improper for ground that is bound together by the roots of plants, which is always the caſe of ground new broken up from its natural ſtate. The brake is ſoon choked, and can do no execution till freed from the earth it holds. A leſs number of teeth would be deficient in pulverizing the ſoil.

4. The Harrow.

Harrows are commonly conſidered as of no uſe but to cover the ſeed; but they have another uſe, ſcarce leſs eſſential, which is to prepare land for the ſeed. This is an article of importance for producing a good crop. But how imperfectly either of theſe purpoſes is performed by the common harrow, will appear from the following account of it.

158 Imperfection of the common harrow.

The harrow commonly uſed is of different forms. The firſt we ſhall mention has two bulls, four feet long and 18 inches aſunder, with four wooden teeth in each. A ſecond has three bulls, and 12 wooden teeth. A third has four bulls, and 20 teeth of wood or iron, 10, 11, or 12 inches aſunder. Now, in fine mould, the laſt may be ſufficient for covering the ſeed; but none of them are ſufficient to prepare for the ſeed any ground that requires ſubduing. The only tolerable form is that with iron teeth; and the bare deſcription of its imperfections will ſhow the neceſſity of a more perfect form. In the firſt place, this harrow is by far too light for ground new taken up from the ſtate of nature, for clays hardened with ſpring drought, or for other ſtubborn ſoils: it floats on the ſurface; and after frequent returns in the ſame track, nothing is done effectually. In the next place, the teeth are too thick ſet, by which the harrow is apt to be choked, eſpecially where the earth is bound with roots, which is commonly the caſe. At the ſame time, the lightneſs and number of teeth keep the harrow upon the ſurface, and prevent one of its capital purpoſes, that of dividing the ſoil: nor will fewer teeth anſwer for covering the ſeed properly. In the third place, the teeth are too ſhort for reducing a coarſe ſoil to proper tilth; and yet it would be in vain to make them longer, becauſe

the

Inſtruments of Huſbandry.

the harrow is too light for going deep into the ground. Further, the common harrows are ſo ill conſtructed, as to ride at every turn one upon another. Much time is loſt in diſengaging them. Laſtly, It is equally unfit for extirpating weeds. The ground is frequently ſo bound with couch-graſs, as to make the furrow ſlice ſtand upright, as when old ley is ploughed: notwithſtanding much labour, the graſs roots keep the field, and gain the victory.

A little reflection, even without experience, will make it evident, that the ſame harrows, whatever be the form, can never anſwer all the different purpoſes of harrowing, nor can operate equally in all different ſoils, rough or ſmooth, firm or looſe. The following, therefore, have been recommended; which are of three different forms, adapted for different purpoſes. They are all of the ſame weight, drawn each by two horſes. Birch is the beſt wood for them, becauſe it is cheap, and not apt to ſplit. The firſt is compoſed of four bulls, each four feet ten inches long, three and a quarter inches broad, and three and a half deep; the interval between the bulls 11 inches and three fourths; ſo that the breadth of the whole harrow is four feet. The bulls are connected by four ſheths, which go thro' each bull, and are fixed by timber nails driven through both. In each bull, five teeth are inſerted, ten inches free under the bull, and ten inches aſunder. They are of the ſame form with thoſe of the brake, and inſerted into the wood in the ſame manner. Each of theſe teeth is three pounds weight: and where the harrow is made of birch, the weight of the whole is ſix ſtone 14 pounds Dutch. An erect bridle is fixed at a corner of the harrow, three inches high, with four notches for drawing higher or lower. To this bridle a double tree is fixed for two horſes drawing abreaſt, as in a plough. And to ſtrengthen the harrow, a flat rod of iron is nailed upon the harrow from corner to corner in the line of the draught.

159 Improved harrows. Plate VIII. fig. 3.

Fig. 4.

The ſecond harrow conſiſts of two parts, connected together by a crank or hinge in the middle, and two chains of equal length, one at each end, which keep the two parts always parallel, and at the ſame diſtance from each other. The crank is ſo contrived, as to allow the two parts to ply to the ground like two unconnected harrows; but neither of them to riſe above the other, more than if they were a ſingle harrow without a joint. In a word, they may form an angle downward, but not upward. Thus they have the effect of two harrows in curved ground, and of one weighty harrow in a plain. This harrow is compoſed of ſix bulls, each four feet long, three inches broad, and three and a half deep. The interval between the bulls nine and a half inches; which makes the breadth of the whole harrow, including the length of the crank, to be five feet five inches. Each bull has five teeth, nine inches free under the wood, and ten inches aſunder. The weight of each tooth is two pounds; the reſt as in the former.

Fig. 5.

The third conſiſts alſo of two parts, connected together like that laſt mentioned. It has eight bulls, each four feet long, two and a half inches broad, and three deep. The interval between the bulls is eight inches; and the breadth of the whole harrow, including the length of the crank, is ſix feet four inches. In each bull are inſerted five teeth, ſeven inches free under the wood, and ten and an half inches aſunder, each tooth weighing one pound. The reſt as in the two former harrows.

Inſtrument of Huſbandry

These harrows are a conſiderable improvement. They ply to curved ground like two unconnected harrows; and when drawn in one plane, they are in effect one harrow of double weight, which makes the teeth pierce deep into the ground. The imperfection of common harrows, mentioned above, will ſuggeſt the advantages of the ſet of harrows here recommended. The firſt is proper for harrowing land that has long lain after ploughing, as where oats are ſown on a winter furrow, and in general for harrowing ſtiff land: it pierces deep into the ſoil by its long teeth, and divides it minutely. The ſecond is intended for covering the ſeed: its long teeth lays the ſeed deeper than the common harrow can do; which is no ſlight advantage. By placing the ſeed conſiderably under the ſurface, the young plants are, on the one hand, protected from too much heat, and, on the other, have ſufficiency of moiſture. At the ſame time, the ſeed is ſo well covered that none of it is loſt. Seed ſlightly covered by the common harrows wants moiſture, and is burnt up by the ſun; beſide, that a proportion of it is left upon the ſurface uncovered. The third harrow ſupplies what may be deficient in the ſecond, by ſmoothing the ſurface, and covering the ſeed more accurately. The three harrows make the ground finer and finer, as heckles do lint; or, to uſe a different compariſon, the firſt harrow makes the bed, the ſecond lays the ſeed in it, the third ſmooths the clothes. They have another advantage not inferior to any mentioned: they mix manure with the ſoil more intimately than can be done by common harrows; and upon ſuch intimate mixture depends greatly the effect of manure, as has already been explained. To conclude, theſe harrows are contrived to anſwer an eſtabliſhed principle in agriculture, That fertility depends greatly on pulverizing the ſoil, and on an intimate mixture of manure with it, whether dung, lime, marl, or any other.

160 Properties of their harrows.

The Chain and Screw harrow. Fig. 8. is the plan of a harrow alſo invented by Mr Sandilands, and to which he has given the name of the *chain and ſcrew harrow*. Its properties are, that if your ridges be high, and you wiſh to harrow them from one end to the other, by lengthening the chain (which the ſcrew commands), the harrow, when drawn along, forms an angle, downwards, and miſſes none of the curve of the ridge, ſo far as it extends (which may be nine feet, the diſtance from A to B. The extent, in the contrary direction, is five feet ſix inches). When the crowns of the ridges have got what is thought a ſufficient harrowing lengthwiſe, you ſhorten the chain by the ſcrew, which forms an angle upwards; the harrow is then drawn by the horſes, one on each ſide of the furrow; which completely harrows it, and the ſide of the ridges, if 18 feet broad. Plate VII.

When you want to harrow even ground or high ridges acroſs with the ſcrew, you can bring the harrow to be horizontal, ſo as to work as a ſolid harrower without a joint.

The teeth are formed and fixed in the common manner, ſquare, not in the faſhion of coulters; and are nine or ten inches below the wood, and of ſuch ſtrength as it is thought the land requires. The teeth cut, or rather

Inſtruments of Huſbandry.

ther tear, the ground at every four inches without variation, though ſeemingly placed irregularly; and this without any riſk of choking, except ſometimes at the extreme angles, where the teeth are neceſſarily near each other: but which may be cleaned with the greateſt eaſe, by raiſing them a little from the ground. The figures 1, 2, &c. point out where the 12 teeth on each ſide of the harrow are placed.

Where a ſtrong brake-harrow is not neceſſary, by making the teeth ſhorter and lighter you may have 48 teeth, which will tear the ground at every two inches, cover the ſeed well, and make a fine mould.

It is recommended, that harrows for every purpoſe, and of any ſize, be made on the above principle; by which no tooth can ever follow the track of another, and all of them will be kept conſtantly acting.

5. The Roller.

161 The roller.

The roller is an inſtrument of capital uſe in huſbandry, though, till of late years, ſcarcely known in ordinary practice; and where introduced, it is commonly ſo ſlight as to have very little effect.

Rollers are of different kinds; ſtone, caſt-iron, wood. Each of theſe has its advantages. We would recommend theſe laſt, conſtructed in the following manner: Take the body of a tree, ſix feet ten inches long, the larger the better, made as near a perfect cylinder as poſſible. Surround this cylinder with three rows of ſtaves, one row in the middle, and one at each end. Line theſe ſtaves with planks of wood equally long with the roller, and ſo narrow as to ply into a circle. Bind them faſt together with iron rings. Beech wood is the beſt, being hard and tough. The roller, thus mounted, ought to have a diameter of three feet ten inches. It has a double pair of ſhafts for two horſes abreaſt. Theſe are ſufficient in level ground; in ground not level, four horſes may be neceſſary. The roller without the ſhafts ought to weigh 200 ſtone Dutch; and the large diameter makes this great weight eaſy to be drawn.

162 Seaſons for rolling.

Rolling wheat in the month of April is an important article in looſe ſoil: as the winter rains preſſing down the ſoil leave many roots in the air. Barley ought to be rolled immediately after the ſeed is ſown; eſpecially where graſs ſeeds are ſown with it. The beſt time for rolling a gravelly ſoil, is as ſoon as the mould is ſo dry as to bear the roller without clinging to it. A clay ſoil ought neither to be tilled, harrowed, nor rolled, till the field be perfectly dry. And as rolling a clay ſoil is chiefly intended for ſmoothing the ſurface, a dry ſeaſon may be patiently waited for, even till the crop be three inches high. There is the greater reaſon for this precaution, becauſe much rain immediately after rolling is apt to cake the ſurface when drought follows. Oats in a light ſoil may be rolled immediately after the ſeed is ſown, unleſs the ground be ſo wet as to cling to the roller. In a clay ſoil, delay rolling till the grain be above ground. The proper time for ſowing graſs ſeeds in an oat field, is when the grain is three inches high; and rolling ſhould immediately ſucceed, whatever the ſoil be. Flax ought to be rolled immediately after ſowing. This ſhould never be neglected; for it makes the ſeed puſh equally, and prevents after-growth; the bad effect of which is viſible in every ſtep of the proceſs for dreſſing flax. The firſt year's crop of ſown graſſes ought to be rolled as early the next ſpring as the ground will bear the horſes. It fixes all the roots preciſely as in the caſe of wheat. Rolling the ſecond and third crops in looſe ſoil is an uſeful work; though not ſo eſſential as rolling the firſt crop.

Inſtruments of Huſbandry.

163 Effects of rolling.

In the firſt place, rolling renders a looſe ſoil more compact and ſolid; which encourages the growth of plants, by making the earth clap cloſe to every part of every root. Nor need we be afraid of rendering the ſoil too compact; for no roller that can be drawn by two or four horſes will have that effect. In the next place, rolling keeps in the moiſture, and hinders drought to penetrate. This effect is of great moment. In a dry ſeaſon, it may have the difference of a good crop, or no crop, eſpecially where the ſoil is light. In the third place, the rolling graſs ſeeds, beſides the foregoing advantages, facilitates the mowing for hay; and it is to be hoped, that the advantage of this practice will lead farmers to mow their corn alſo, which will increaſe the quantity of ſtraw both for food and for the dunghill.

There is a ſmall roller for breaking clods in land intended for barley. The common way is, to break clods with a mell; which requires many hands, and is a laborious work. This roller performs the work more effectually, and at much leſs expence: let a harrowing precede, which will break the clods a little; and after lying a day, or a day and a half, to dry, this roller will diſſolve them into powder. This, however, does not ſuperſede the uſe of the great roller after all the other articles are finiſhed, in order to make the ſoil compact, and to keep out the ſummer drought. A ſtone roller four feet long, and fifteen inches diameter, drawn by one horſe, is ſufficient to break clods that are eaſily diſſolved by preſſure. The uſe of this roller in preparing land for barley is gaining ground daily, even among ordinary tenants, who have become ſenſible both of the expence and toil of uſing wooden mells. But in a clay ſoil, the clods are ſometimes too firm, or too tough, to be ſubdued by ſo light a machine. In that caſe, a roller of the ſame ſize, but of a different conſtruction, is neceſſary. It ought to be ſurrounded with circles of iron, ſix inches aſunder, and ſeven inches deep; which will cut even the moſt ſtubborn clods, and reduce them to powder. Let not this inſtrument be conſidered as a fiſical refinement. In a ſtiff clay it may make the difference of a plentiful or ſcanty crop.

6. The Fallow-cleansing Machine.

164 The fallow-cleanſing machine, Plate IX. fig. 5.

This was invented by Mr Aaron Ogden, a ſmith at Aſhton-under-Line, near Manchester in Lancaſhire. It is intended for cleanſing fallows from weeds, &c. which exhauſt the riches of the ſoil. A, A, is the frame; B, the firſt roller; C, the ſecond ditto; in which laſt are two cranks to move the arms, D, D, which work the rake up the directors fixed on the plank E. The under ſide of the lower ends or ſhares of theſe directors are ſharp, to cut the clods and let them come on the upper ſide. Each alternate heel of the ſhare is longer that the intermediate one, that they may not have more than one-half to cut at once. At the back of the plank E are two ſcrews to let it looſe, that the directors may be ſet higher or lower. The ſhares are to penetrate the ground two or three inches, to raiſe the quicks till the rake I, I, fetches

Inſtruments of Huſbandry.

fetches them into the cart H, where a man muſt be ready with a muck-hook to clear them backward when gathered. In the rake I are two teeth for every ſpace of the directors, that ſtones, &c. may be gathered without damage. K, K, are two ſtaples, by which the machine is drawn: under them at *h* are two hooks, placed low to raiſe the machine in turning, by the help of the traces; and the axletree of the cart ſhould be fixed upon a pin, that it may turn like a waggon. F, F, are the triggers to throw the rake behind the roots. The long teeth at G, G, are to cleanſe the roller C. I, I, is the rake which gathers up the weeds into the cart H, and is drawn above the trigger F by the working of the arms D, expreſſed by the dotted lines at *d d*, *i i*. The triggers F, of which there is one on each ſide, move on the pivots *a*; ſo that when the points *b* of the rake I have been drawn up by the directors E to the part marked *c*, the trigger, giving way, permits the rake to paſs; but immediately falling, the rake returns along the upper ſurface of the trigger marked *e*, *e*, and of courſe falls on the weeds when it comes to the end, a little beyond the pivot *a*. The reader will obſerve, that the boarding is taken away on one ſide, in the Plate, in order to give a more perfect view of the inner parts of the machine; and in fact it would perhaps be better if all the boarding, marked L, L, L, was taken away, and frame-work put in its ſtead. The cart H might undoubtedly alſo be made lighter. The wheels M, M, appear in the Plate to be made of ſolid wood: but there is no neceſſity they ſhould be ſo. At N, is another view of the roller C, by which the diſpoſition of the ſpikes may be eaſily comprehended. Suppoſe the circle O, deſcribed by the end of the roller N, to be divided by four ſtraight lines into eight equal ſegments, as repreſented at P. Let the ſame be done at the other end of the roller, and parallel lines be drawn from one correſponding point to the other the length of the roller; mark the points with figures 1, 2, 3, 4, 5, 6, 7, 8; afterwards draw oblique lines, as from 1, at the end of O, to 2, at the other end, and from 2 to 3, &c. on theſe oblique lines the ſpikes are to be fixed at equal diſtances, in eight circles, deſcribed on the circumference of the roller. The ſpikes of the ſmall roller B are fixed in the ſame manner, except that the diameter being ſmaller, there are only ſix inſtead of eight rows. R is another view of the directors, with the plank E on which they are fixed; and S is a ſection of a part of the plank, with one of the directors as fixed, in which may be ſeen the heel *m*, from whence to the point of the ſhare *n* is a ſharp cutting edge. See the ſame letters in figure R. At T is one of the long teeth to be ſeen at G; it is bent towards the roller C, which it ſerves to cleanſe. When the end of the rake *b*, after riſing above *c*, is puſhed, by the motion of the arms D, D, along the upper part *e*, *e*, of the trigger F, and comes to the end beyond *a*; as it falls, the part of the arm marked *o* reſts in the notch *p*, till it is again raiſed by the motion of the roller C with the rake. The roller C is to be one foot diameter, the ſpikes nine inches long, that they may go through the furrow (if the ſoil ſhould be looſe) into the hard earth, the more effectually to work the rake, which otherwiſe might be ſo overcharged as to cauſe the roller to drag without turning. In the rake-ends *b* there ſhould be pivots, with rollers or pullers on, to go in the groove, to take off the friction; and they would likewiſe take the triggers more ſurely as the rake comes back. The rake ſhould alſo be hung ſo far backward, that when it is fallen, the arms of it may lie in the ſame plane or parallel with the directors, on which it comes up (which will require the frame to be two inches longer in the model). This will cauſe the rake to fall heavier, and drive the teeth into the roots, and bring them up without ſhattering. Theſe teeth muſt be made of ſteel, very fine, and ſo long as to reach down to the plank on which the directors are fixed, that is to ſay, ſix inches long (the directors are alſo to be made ſix inches broad above the plank). The rake-head ſhould alſo fall a little before the crank is at its extremity, which will cauſe the rake to puſh forward to let the teeth come into the roots. The rake-teeth muſt drop in the ſame plane with the roller and wheels, or on the ſurface of the earth. No more ſpace ſhould be given from the roller C to the long teeth at G G, than that the rake may juſt miſs the ſpikes of the roller C and fall on the places before mentioned. As the firſt roller B was intended to cleanſe the ſecond C more than for any other uſe, it may be omitted when the machine is made in large, as Mr Ogden has lately found that the long teeth at G G anſwer the end alone, and this renders the machine about a ſixth part ſhorter. Now, to ſuit any ſort of earth, there ſhould be to each machine three planks, with directors at different ſpaces to uſe occaſionally; in the firſt, the ſpaces between the directors ſhould be eight inches wide, in the ſecond ſix, and in the third four. This will anſwer the ſame end as having ſo many machines.

Inſtrument of Huſbandry

As there may be ſome objections to the rake not leaving the roots when it has brought them up, Mr Ogden has ſeveral methods of cleanſing it; but as he would make it as ſimple as poſſible, he chooſes to let it be without them at preſent; but ſuppoſe it ſhould bring ſome roots back again with it, it will probably loſe them before it gets back to the extremity; whence they will lie light, and be of but little detriment to the others coming up. Mr Ogden would have the firſt machine made four feet ſix inches wide, the teeth divided into equal ſpaces, the outſides into half ſpaces.

7. The new-invented Patent Univerſal SOWING *Machine*.

165 Univerſal ſowing machine, Plate X. fig. 1. 2. 1

This machine, whether made to be worked by hand, drawn by a horſe, or fixed to a plough, and uſed with it, is extremely ſimple in the conſtruction, and not liable to be put out of order; as there is but one movement to direct the whole, nor does it require any ſkill in working. It will ſow wheat, barley, oats, rye, clover, cole-ſeed, hemp, flax, canary, rape, turnip, beſides a great variety of other kinds of grain and ſeeds broad-caſt, with an accuracy hitherto unknown. It is equally uſeful in the new huſbandry, particularly when fixed to a plough; it will then drill a more extenſive variety of grain, pulſe and ſeed, through every gradation, with regard to quantity, and deliver each kind with greater regularity than any drill-plough whatever. When uſed in this manner, it will likewiſe be found of the utmoſt ſervice to farmers who are partial to the old huſbandry, as, among many other very valuable and peculiar properties, it will not only ſow

in

Inſtruments of Huſbandry.

in the broad-caſt way with the moſt ſingular exactneſs, but ſave the expence of a ſeedſman; the ſeed being ſown (either over or under furrow at pleaſure), and the land ploughed, at the ſame operation.

Perhaps a fair and deciſive experiment for aſcertaining the ſuperior advantage of broad-caſting or drilling any particular crop, was never before ſo practicable; as the ſeed may now be put in with the utmoſt degree of regularity, in both methods of culture, by the ſame machine; conſequently the ſeed will be ſown in both caſes with equal accuracy, without which it is impoſſible to make a juſt deciſion.

The excellence of this machine conſiſts in ſpreading any given quantity of ſeed over any given number of acres with a mathematical exactneſs, which cannot be done by hand; by which a great ſaving may be made in ſeeding the ground, as well as benefiting the expected crop.

There has always been a difficulty in ſowing turnip ſeed with any degree of exactneſs, both from the minuteneſs of the ſeed, and the ſmallneſs of the quantity required to be ſown on an acre. Here the machine has a manifeſt advantage, as it may be ſet to ſow the leaſt quantity ever required on an acre; and with an accuracy the beſt ſeedſman can never attain to.

It will alſo ſow clover, cole, flax, and every other kind of ſmall ſeed, with the utmoſt degree of regularity.

It will likewiſe broad-caſt beans, peaſe, and tares, or drill them with the greateſt exactneſs, particularly when conſtructed to be uſed with a plough.

Another advantage attending the uſe of this machine is, that the wind can have no effect on the falling of the ſeed.

Of the Machine when made to be uſed without a Plough, and to be drawn by a Horſe.—It may in this caſe be made of different lengths at the deſire of the purchaſer. The upper part AAAA, contains the hoppers from which the grain or ſeed deſcends into the ſpouts. The ſeveral ſpouts all reſt upon a bar, which hangs and plays freely by two diagonal ſupporters BB; a trigger fixed to this bar bears a catch-wheel; this being fixed on the axle, occaſions a regular and continual motion, or jogging of the ſpouts, quicker or ſlower in proportion to the pace the perſon ſowing with it drives; and of courſe, if he quickens his pace, the bar will receive a greater number of ſtrokes from the catch-wheel, and the grain or ſeed will feed the faſter. If he drives ſlower, by receiving fewer ſtrokes, the contrary muſt take place. In going along the ſide of a hill, the ſtrength of the ſtroke is corrected by a ſpring which acts with more or leſs power, in proportion as the machine is more or leſs from a horizontal poſition, and counteracts the difference of gravity in the bar, ſo that it preſſes, in all ſituations, with a proper force againſt the catch-wheel. The ſpring is unneceſſary if the land be pretty level. At the bottom of the machine is placed an apron or ſhelf in a ſloping poſition; and the corn or ſeed, by falling thereon from the ſpouts above, is ſcattered about in every direction under the machine, and covers the ground in a moſt regular and uniform manner.

Fig. 2.

To ſow the corn or ſeed in drills, there are moveable ſpouts (ſee fig. 10.), which are fixed on or taken off at pleaſure, to direct the ſeed from the upper ſpout to the bottom of the furrow.

The machine is regulated for ſowing any particular quantity of ſeed on an acre by a braſs ſlider, A, fig. 7. fixed by ſcrews againſt a braſs bridge on each of the ſpouts. The machine is prevented from ſeeding while turning at the ends, by only removing the lever E, fig. 2. out of the channel G, to another at H, on the right hand of it, which carries back the bar from the catch-wheel, and occaſions the motion of the ſpouts to ceaſe, and at the ſame time brings them upon a level by the action of the diagonal ſupporters; ſo that no corn or ſeed can fall from them.

Inſtruments of Huſbandry.

The machine in this form is particularly uſeful for broad-caſting clover upon barley or wheat; or for ſowing any other kind of ſeed, where it is neceſſary that the land ſhould firſt be harrowed exceedingly fine and even.

Manner of uſing the Machine, when drawn by a Horſe.—Place the machine about two feet from the ends of the furrows where you intend it ſhall begin to ſow. Fill the hoppers with ſeed, and drive it forwards with the outſide wheel in the firſt furrow. When you are at the end of the length, at the oppoſite ſide of the field, lift the lever E, fig. 2. into the channel H, and the machine will inſtantly ſtop ſowing. Drive it on about two feet, and then turn. Fill the hoppers again if neceſſary; then remove the lever back again into the channel G, and in returning, let the outſide wheel of the machine go one furrow within the track which was made by it, in paſſing from the oppoſite end; as for example, if the wheel paſſed down the eighth furrow from the outſide of the field, let it return in the ſeventh; and in every following length let the outſide wheel always run one furrow within the track made by the ſame wheel: becauſe the breadth ſown is about nine inches leſs than the diſtance between the wheels.

Let the machine be kept in a perpendicular ſituation. If the farmer wiſhes to ſow more or leſs ſeed on any one part of the field than the other, it is only raiſing the handles a little higher, or ſinking them a little lower than uſual, and it will occaſion a ſufficient alteration; and ſhould the laſt turn be leſs in breadth than the machine, thoſe ſpouts which are not wanted may be taken up from the bar, and prevented from feeding, by turning the knob above them.

Alſo, when the land required to be ſown has what is called a *vent*, that is, when the ſides of the field run in an oblique line to the furrows, which by this means are unequal in length; the ſpouts muſt be taken up or let down in ſucceſſion by turning the knobs, as that part of the machine where they are placed arrives at the ends of the furrows. This is done while the machine is going forwards.

If the land be tolerably level, the machine may be fixed by the ſcrew in the front, and the machine may then be uſed by any common harrow boy.

Method of regulating the Machine.—In each ſpout is fixed a bridge (ſee fig. 7.), with an aperture in it, B, for the grain or ſeed to paſs through. This aperture is enlarged or contracted by a ſlider, A, which paſſes over it; and, when properly fixed for the quantity of ſeed deſigned to be ſown on an acre, is faſtened by means of two ſtrong ſcrews firmly againſt the bridge. This is made uſe of in ſowing all kinds of ſeed, where it is required to ſow from one buſhel upwards on an acre. To ſow one, two, three gallons, or any of the inter-

Inſtruments of Huſbandry.

mediate quantities, as of clover, cole-ſeed, &c. the braſs plate, fig. 6. is placed between the bridge and the ſlider, with the largeſt aperture B downwards, which aperture is enlarged or contracted by the ſlider as before. To ſow turnips, the ſame plate is placed between the bridge and the ſlider, with its ſmalleſt aperture A downwards, and the hollow part about the ſame aperture inwards.

Fig. 8. is a view of the regulator, by which the apertures in the ſeveral ſpouts are all ſet exactly alike, with the utmoſt eaſe, to make them feed equally. The extreme height of the largeſt aperture is equal to the breadth AB, and the breadth at C is equal to the height of the ſmalleſt aperture uſed, viz. that for turnips. The ſide AC is divided into 60 equal parts, and on it moves the ſlider or horſe D; which being placed at any particular degree, according to the quantity of ſeed required to be ſown on an acre, is fixed upon it, by a ſcrew on the ſide of the ſlider or horſe. When this is done, the end of the regulator is put through the aperture in the bridge or plate (whichever is intended to be uſed), and the ſlider againſt the bridge in the ſpout, raiſed by it, till it ſtops againſt the horſe on the regulator: then the ſlider is faſtened againſt the bridge firmly by the two ſcrews; care being taken at the ſame time that it ſtand nearly ſquare.

By this means the ſpouts (being all fixed in the ſame manner) will feed equally.

It is eaſy to conceive that the ſize of the apertures, and conſequently the quantity of ſeed to be ſown on an acre, may be regulated with a far greater accuracy than is required in common practice.

The ſpouts may be regulated with the utmoſt nicety, in five minutes, to ſow each particular ſeed, for the whole ſeaſon. But a little practice will enable any perſon, who poſſeſſes but a very moderate capacity, to make the ſpouts feed equally, even without uſing the regulator (A).

Of the Machine, when made to be uſed by Hand.—The difference of the machine in this caſe is, that it is made lighter, with but three ſpouts, without ſhafts, and is driven forwards by the handles. It hath alſo a bolt in front, which being puſhed in by the thumb, releaſes the machine; ſo that it can then eaſily be placed in a perpendicular poſition. This alteration is neceſſary to keep the handles of a convenient height, in ſowing up and down a hill, where the ſlope is conſiderable; and is done while the machine is turning at the end of the length. The method of regulating and uſing it is the ſame as when made to be drawn by a horſe.

Of the Machine, when conſtructed to be uſed with a Plough.—This is, without doubt, the moſt uſeful application of the machine; and it can be fixed without difficulty to any kind of plough, in the ſame manner as to that repreſented in fig. 1. Inſtrument of Huſbandry

The advantages ariſing from the uſe of it are great and numerous; for, beſide the increaſe in the crop, which will be enſured by the ſeeds being broad-caſt with a mathematical nicety, a large proportion of ſeed (the value of which alone, in a few months, will amount to more than the price of the machine) and the ſeedsman's labour will be ſaved. The ſeed may likewiſe be ſown either under or over furrow; or one caſt each way, as is practiſed by ſome farmers. The ſeeds alſo, being caſt by the machine upon the freſh ploughed land, may be immediately harrowed in, before the mould has loſt any part of its moiſture; which in a dry ſeaſon will greatly promote the crop. In drilling any kind of grain, pulſe, or ſeed, it poſſeſſes every property that can be wiſhed for in the beſt drill-plough, nor will it (as moſt of them do) bruiſe the ſeed, or feed irregularly. The conſtruction of the machine is the ſame as the large ones, except being made with one hopper and ſpout inſtead of ſeveral, and the apron moveable inſtead of being fixed, as may be ſeen by inſpecting fig. 4. The only alteration neceſſary to make the machine broad-caſt or drill is, in the former caſe to place the apron B, fig. 1. at the bottom of the machine, upon the hooks FF, ſloping either towards the furrows or the unploughed land, according as it is intended to ſow the ſeed either over or under furrow. Whenever the apron is required to be ſhifted, it is done in leſs than a ſecond of time; as it only requires to be moved up or down with the hand, when a catch fixes it.

To prepare it for drilling, inſtead of the apron, place the long ſpout, fig. 10. upon the brackets, on the front of the machine, by the ears AA, to receive the ſeed from the upper ſpout, and faſten the lower end of it, by a ſmall cord, to that hook upon which the apron is hung for broad-caſting which is next the plough (ſee fig. 3.); the ſeed will then be directed by the long ſpout, to the centre of the furrow, near the heel of the plough. The ſpring for correcting the ſtrength of the ſtroke, is neceſſary only when they are required to go along the ſide of a conſiderable declivity. The machine, when fixed to a plough, does not require the ſmalleſt degree of ſkill in uſing, as nothing is neceſſary but to keep the hopper filled, which will contain a ſufficient quantity of ſeed to go upwards of 140 rods, before it will want refilling, when three buſhels and a half

---

(A) Proper directions are given with each machine for uſing it, as alſo for fixing the ſliders to ſow any particular quantity of corn or ſeed on an acre, ſo as to enable any perſon to ſet the ſpouts.

The prices of the machine (excluſive of the packing caſes) are as follow. If conſtructed to be uſed with a ſingle furrow plough; the wheel, with the axle and cheeks ſteeled, ſtrap, regulator, braſs-plates for broad-caſting or drilling turnips, lucerne, tares, wheat, barley, &c. &c. &c. and every article neceſſary for fixing it included, three guineas and a half. If made with a ſpring (for ſowing on the ſide of a hill, where the ſlope is conſiderable), but which is very rarely neceſſary, five ſhillings more. If made to be fixed to any double-furrow plough, four guineas and a half.

The large machine, fig. 2. when made to broad-caſt ſeven furrows at a time and to be drawn by a horſe, eight guineas and a half. If conſtructed to ſow five furrows at a time, and to be uſed by hand, ſix guineas. Theſe are alſo five ſhillings more if made with a ſpring.

Inſtruments of Huſbandry.

half are ſown on an acre. The accuracy with which it will broad-caſt, may in ſome meaſure be conceived, by conſidering that the ſeed regularly deſcends upon the apron or ſhelf, and is from thence ſcattered upon the ground, in quantity exactly proportioned to the ſpeed of the plough: alſo that each caſt ſpreads to the third furrow: and by this means ſhuts upon the laſt. In this manner it is continually filling up till the whole field is completely covered; ſo that it it impoſſible to leave the ſmalleſt ſpace without its proper quantity of ſeed.

When the plough is wanted for any other purpoſe, the machine, with the wheel at the heel of the plough for giving it motion, can be removed or replaced at any time in five minutes.

Fig. 11. repreſents the machine fixed to a double-furrow creaſing plough, and prepared for drilling. As this plough may not be generally known, it will not be improper to obſerve, that it is chiefly uſed for creaſing the land with furrows (after it has been once ploughed and harrowed); which method is neceſſary when the ſeed is to be ſown broad-caſt upon land that has been a clover ley, &c. becauſe, if the ſeed be thrown upon the rough furrows, a conſiderable part of it will fall between them, and be unavoidably loſt, by lying too deep buried in the earth. This mode anſwers extremely well, and partakes of both methods of culture; the ſeed, though ſown broad-caſt, falling chiefly into the furrows.

The machine is very uſeful for ſowing in this manner; as the ſeed is broad-caſt, with an inconceivable regularity, at the time the land is creaſed. The advantages it likewiſe poſſeſſes for drilling all ſorts of grain or ſeed with this plough, are too evident to need mentioning.

The machine, when conſtructed to be uſed with a double-furrow plough, is made with two upper and two long ſpouts for drilling, two aprons for broad-caſting, and with a double hopper; but in other reſpects the ſame as when intended for a ſingle furrow plough: it is uſed in all caſes with the greateſt eaſe imaginable.

The interval between the points of the two ſhares of a creaſing plough is uſually ten inches; the beam about nine feet long; and the whole made of a light conſtruction.

Plate XI.

A more particular explanation of the figures.—Fig. 1. The machine fixed to a Kentiſh turn-wreſt plough. A, The machine. B. The apron upon which the ſeed falls and rebounds upon the land, in broad-caſting. C, Lid to cover the hopper. D, Wheel at the heel of the plough. E, Scrap. FF, Hooks, upon which the apron turns by a pivot on each. G, Stay, to keep the machine ſteady, H, Lever, to prevent it from ſowing.

Sect. II. *Of preparing Land for cropping, by removing obſtructions and bringing the Soil into a proper ſtate.*

1. Of Removing Stones.

166 Importance of removing ſtones.

It is of the utmoſt importance to have land effectually cleared of ſtones, before undertaking any agricultural operation upon in; for by means of them there is frequently more expence incurred in one ſeaſon, by the breaking of ploughs and the injury ſuffered by the cattle and harneſs, than would remuve the evil. It has alſo been obſerved that the ſoil round a large ſtone is commonly the beſt in the field. It may be conſidered as purchaſed at a low rate by removing the ſtone. At any rate, ſuch ſtones muſt be removed before the ground can be properly cultivated. For whether a large ſtone occupy the ſurface, or lie beneath it, but within reach of the plough, a conſiderable ſpace around it cannot be ſtirred by that inſtrument, and is therefore uſeleſs. Even the reſt of the field where

Preparation of Land.

ſtones abound muſt be laboured in a more ſlow and tedious manner, on account of the caution neceſſary to avoid the danger which they produce.

The ſtones which impede the improvement of land are, 1ſt, looſe ſtones, or ſuch as are thrown up to the ſurface by the plough; and, 2dly, ſitfaſt ſtones, which are either upon or immediately below the ſurface, but are of ſuch magnitude that they cannot be ſtirred by the plough. The firſt kind of ſtones may uſually be eaſily removed by being gathered and carried off. When land is laid down for hay, ſuch ſtones are often improperly thrown in heaps into the furrows, where they ever after continue to interrupt the plough, or are dragged again by the harrows over the land. Inſtead of proceeding in this manner, they ought to be carried wholly off the field in carts at the dryeſt ſeaſon of the year, and placed in ſituations in which they may be rendered uſeful to the farm. In this point of view, ſtones are ſometimes of conſiderable value for making concealed drains, or for making and repairing the roads through a farm, and alſo for the repairs of ſome kinds of fences.

167 Modes of removing ſtones.

The only writer upon agriculture who has in any caſe objected to the propriety of clearing land of ſmall ſtones, is probably Lord Kames. In ſome parts of the of the ſouth of Scotland, and particularly in Galloway, the ſoil is ſaid to be compoſed in a great meaſure of gravel, and of ſtones of a ſmooth ſurface, as if worn by the running of water. After being ploughed, the whole ſurface of every field appears to be compoſed of looſe ſtones lying almoſt in contact with each other. Some induſtrious farmers, with great labour, collected and removed the ſtones from a few of their fields with a view to their improvement; and the reſult is ſaid to have been, that the ſucceeding crops were wholly blighted in the tender blade, and never came to maturity. The ſtones upon the ſurface were ſuppoſed to have prevented the exhalation of the moiſture from the ſhallow and extremely porous and open ſoil which they covered: and they were alſo ſuppoſed to have contributed to foſter the young plants, by reflecting powerfully from their ſmooth ſurfaces the ſun's rays in every direction around them: but when they were removed, the ſoil, in that bleak climate, became at once too cold and too dry for any purpoſe of agriculture. The farmers, therefore, who had with ſo much toil and coſt removed the ſtones from part of their lands, could think of no better remedy than, with equal toil, to bring them all back again, and carefully replace them upon their fields. It is added, that the ſoil immediately reſumed its wonted fertility. The truth of this anecdote has never been conteſted; and there is no doubt that it has long been current in the ſouth of Scotland, both previous to its publication by Lord Kames, and after that period, among a claſs of perſons who are very unlikely to have been acquainted with his writings. It is poſſible that the replacing the ſtones was the beſt remedy for the want of fertility in the ſoil which its cultivators had within their reach: but it is probable that they might have found it of more importance to have covered the ſurface of their land with a ſubſtantial coat of clay marl, or even with almoſt any kind of earth or clay obtained from the bogs and ſwamps that uſually abound in theſe countries, providing only they could obtain a quantity of lime to add to it. In this way, poſſeſſing land whoſe bottom was very pervious to moiſture, they might have obtained a ſoil ſuited to every purpoſe of agriculture; whereas, in its preſent ſtate, it muſt remain for ever unfit to be touched with the ſcythe.

Preparation of Land.

With regard to large or ſitfaſt ſtones which cannot be removed by any ordinary effort, they uſually either appear fully above the ſurface or are concealed immediately under it. For the ſake of diſcovering concealed ſtones, it is ſaid to be a cuſtom in Yorkſhire, when they intend to reduce waſte and rude land under the plough, in the firſt place, carefully to go over the whole ſurface with ſharp prongs, which at the diſtance of every twelve or fourteen inches they thruſt into the ground to the depth of above a foot, and wherever a ſtone meets the prong, they mark the ſpot with a twig, a bit of wood, or ſome other object. They afterwards trace all the marks, and remove every ſtone before they touch the land with the plough.

Concerning the modes which have been adopted for removing large ſtones out of the way of the plough; one of the ſimpleſt is the following: A pit or hole is dug beſide the ſtone, 16 or 18 inches deeper than the height or thickneſs of the ſtone. A number of men are then aſſembled, who tumble it into the pit. It is immediately covered up with a part of the earth that came out of the hole; and the reſt of the earth is ſcattered over the field, or employed in bringing to a level with the reſt of the ſoil the ſpot where the ſtone formerly lay. As the ſtone now remains at a greater depth than the plough can reach, it is no longer an impediment to agriculture. In performing this operation, however, the workmen muſt attend to the nature of the ſoil, and take care that the weight of the ſtone do not bring down the ſide of the pit, which might be attended with dangerous conſequences. To obviate any hazard of this kind, it is always proper to have at hand a ſtout plank, which ought to be laid acroſs the pit or hole, immediately under the neareſt corner or edge of the ſtone. With this precaution, a ſingle man may uſually perform the whole operation of burying ſtones or pieces of rock of very great ſize and weight.

By the above operation, however, the ſtones are utterly loſt; whereas they may ſometimes be of conſiderable value for fences or other buildings. When this is the caſe, they muſt be broken to pieces before they are removed. With this view it is to be obſerved, that a great variety of ſtones have ſome thin veins, which being found, wedges can be driven into them by large hammers, ſo that they may be eaſily broken. For ſuch operations ſpades and pick axes are neceſſary to clear away the earth, and a large and a ſmall lever to turn the ſtones out of the ground. Hammers and wedges are alſo requiſite, with carts, to remove the fragments from the field. In the Statiſtical Account of Scotland, vol. xix. p. 565. pariſh of Maderty, we are told that "the Rev. Mr Ramſay, the preſent incumbent, who occupies a piece of land full of ſitfaſt ſtones, conſtructed a machine for the purpoſe of raiſing them. It operates on the principles of the pulley and cylinder, or wheel and axis, and has a power as one to 24; it is extremely ſimple, being a triangle, on two ſides of which the cylinder is fixed; it can be eaſily wrought and carried from place to place by three men. A low four-wheeled machine of a ſtrong conſtruction is made to go under the arms of the triangle, to receive

the

Preparation of Land.

the ſtone when raiſed up. This machine has been already of great uſe in clearing ſeveral fields of large ſtones in this place and neighbourhood."

It is evident, that the machine here deſcribed is only valuable for getting ſtones out of the way in the groſs and unbroken; and, accordingly, we learn that ſtone fences are almoſt unknown in the parith of Maderty.

Where ſtones are valuable, therefore, and the operation of breaking them with hammers and wedges is found impracticable or too laborious, it will be neceſſary to blaſt them with gunpowder. To perform this operation properly, however, conſiderable experience is requiſite; for it is ſaid, that a ſkilful workman can in moſt inſtances, by the depth and poſition of the bore, contrive to rend ſtones into three equal pieces without cauſing their fragments to fly about. In time of war, however, the expence of gunpowder is apt to become very great. With a view to diminiſh the coſt of that article, it has been ſuggeſted, that it is proper to perform the operation not with gunpowder alone, but with that article of a good quality, mixed up with about one-third of its bulk of quicklime in fine powder. It is ſaid that this compoſition poſſeſſes as much force as an equal quantity of pure gunpowder, and it is even alleged, that the proportion of quicklime may be increaſed with advantage. How the ſtrength of gunpowder ſhould be ſo much augmented by the addition of quicklime, we do not know. Perhaps it may add to the force of the exploſion by undergoing a chemical decompoſition of its parts, as it has of late been ſuſpected, that this mineral is by no means a ſimple or uncompounded body.

Where a field is very greatly overrun with concealed ſtones, the moſt effectual method of getting quit of them, and of rendering it permanently arable, conſiſts of trenching it wholly by the ſpade. Nor is this always the moſt expenſive mode of proceeding. The trenching can be done at the rate of from 3l. to 4l. *per* Scots acre, which is one-ſixth larger than an Engliſh acre, allowing at the ſame time the ſtones or their price at the quarry to the labourers. In this way, the expence of ploughing the field is ſaved. The ſoil is deepened to the utmoſt extent of which it is capable, and can be laid out in the form moſt convenient for cultivation. In Dr Anderſon's report of the ſtate of agriculture in Aberdeenſhire, it is ſaid that the expence of trenching an acre to the depth of from 12 to 14 inches, where the ſtones are not very large and numerous, runs from 4d. to 6d. a fall, which is from 2l. 13s. to 4l. *per* Scots acre. Ground that has been formerly trenched, is ſometimes done as low as 2d. *per* fall, or 1l. 6s. 6d. *per* acre. Hence, in conſequence of the practice of trenching ground by the ſpade being not unfrequent in Aberdeenſhire, workmen have become expert, and by competition have rendered the price extremely moderate. It is to be wiſhed that the ſame practice were more frequent in other parts of the country, as it would have a tendency to introduce a taſte for the moſt correct and perfect of all modes of labouring the ſoil, and would alſo occupy a conſiderable part of the population of the country, in the moſt innocent and healthful of all employments, that of agriculture.

2. Of Draining.

Imp. rtance of draining.

168 It has already been remarked, that the preſence of moiſture is of the utmoſt importance to the ſucceſs of vegetation. At the ſame time, as muſt neceſſarily happen with every powerful and active agent, the too great abundance of water is no leſs pernicious to many plants, than an entire want of it. When it ſtagnates upon the ſoil, it decompoſes or rots the roots and ſtems of the moſt valuable vegetables. Even when it does not remain on a ſpot round the whole year, its temporary ſtagnation during the winter renders the land unproductive. Seaſons of tillage are often loſt, and in wet years the crop muſt always be ſcanty and precarious. When in graſs, the land can only produce the coarſeſt and moſt hardy vegetables, which can reſiſt the chill or cold ſtate of the ſoil, or the fermentation which is often produced by ſudden warmth while the water remains upon the ground. Hence ariſes the importance of draining, by which arable land is rendered manageable, is made to dry gradually and early in the ſpring, and the corn is increaſed in quantity and weight; and by which, in paſture lands, the graſſes are made to change their colour and to loſe their coarſe appearance, and the finer kinds of plants are enabled to flouriſh. Even the climate is, by means of draining, very conſiderably improved. It is rendered leſs cold during the winter, and by diminiſhing in hot weather the exhalations from the ſoil, its ſalubrity both to animal and vegetable life is greatly increaſed. Every kind of grain comes earlier to maturity. The harveſt is leſs precarious, and the diſeaſes are baniſhed which aroſe from a damp ſoil and a humid atmoſphere.

Land is rendered wet by rain or by ſprings.

169 The water which ſtagnates upon the ſurface of a ſoil may originate from two cauſes. It may deſcend upon it in the form of rain, or it may aſcend from ſprings or reſervoirs of water in the bowels of the earth. The rules for draining land which is rendered too wet for the purpoſes of agriculture are different, according to the cauſes which occaſion the wetneſs. We ſhall firſt take notice of the moſt approved modes of draining, when the exceſſive moiſture is occaſioned by rain water ſtagnating upon the land; and we ſhall afterwards take notice of the plan of draining to be adopted, when the wetneſs ariſes from ſprings or water ariſing out of the earth.

Drains are open or hollow.

170 To relieve land from rain water that is apt to ſtagnate upon it, two kinds of drains have been adopted. One of theſe is called *open drains*, from their being expoſed to view in their whole length. The other kind receives the appellation of *hollow drains*, from their being covered, ſo that their exiſtence is not apparent to a ſtranger, nor is any part of the land loſt in conſequence of their being made. Hollow draining is ſometimes avoided on account of the great immediate expence with which it is attended, and in ſome ſituations it is altogether inadequate to the object in view. There are ſome ſoils that being chiefly compoſed of a ſtiff clay, poſſeſs ſo great a degree of tenacity as to retain water upon every trifling depreſſion of their ſurface, till evaporation carries it off. It is in vain to attempt to drain ſuch ſoils by hollow channels below ground, as the water will never be able to filtrate through the ſoil ſo as to reach the drain. In ſuch ſituations, therefore,

Hollow drains, when inapplicable.

171

Preparation of Land.

fore, open draining is the only mode that can be adopted for clearing the ſoil of ſurface water.

It alſo ſometimes happens that, on ordinary ſoils, hollow drains would ſpeedily be rendered uſeleſs. This muſt take place where the admiſſion of ſurface water cannot be avoided, and, from the figure of the adjoining lands, muſt be very greatly augmented in time of heavy rains. In ſuch caſes, a cloſe or hollow drain would ſpeedily be choked up by the ſand and ſoil brought down by ſudden and violent torrents. In theſe ſituations, therefore, open drains can alone prove uſeful.

172 Draining of clay ſoils.

Soils formed of a tenacious clay can only be drained by being laid up properly in ridges which are high in the middle, and have furrows at each ſide for carrying off the water. The great art of preſerving land of this deſcription, therefore, free from ſuperfluous moiſture, conſiſts of laying out every field in ſuch a direction as that all the furrows between the ridges may have a gradual deſcent to a common ditch or drain for carrying off the water. Where at any particular ſpot the regularity of the deſcent is interrupted, croſs furrows muſt be kept open with the ſame view. The ridges muſt alſo be laid up in ſuch a form as to allow the water to deſcend from the ſummit in the middle to the furrows on each ſide. If the ridges, however, are too high in the centre, there will be a danger that in heavy rains the ſoil may be waſhed from the ſummit down into the furrows, which would produce the double evil of impoveriſhing the centre of every ridge, and of choking up the furrows, and rendering them unfit to drain the land.

The diſtinguiſhed ſucceſs of the Flemiſh huſbandmen, and alſo of the farmers in the central counties of England where this kind of ſoil abounds, ſufficiently demonſtrates the practicability of preſerving it in a due degree of dryneſs for the moſt valuable purpoſes of agriculture. In theſe Engliſh counties, and in Flanders, the general mode of drying land conſiſts of ploughing it up in high and broad ridges, from 20 to 30, and even 40 feet wide, with the centre or crown three or four feet higher than the furrows. By attentively preſerving the furrows in good order, and free from ſtagnating water, the land is kept in a dry ſtate, and all kinds of crops flouriſh.

173 Draining in the Carſe of Gowrie.

The mode of ridging and croſs-furrowing the clay ſoil of the Carſe of Gowrie, Perthſhire, has been thus deſcribed by George Paterſon, Eſq. of Caſtlehuntly in that county. There are certain large common drains which paſs through the diſtrict in different directions, ſufficiently capacious to receive the water drained from the fields by the ditches which ſurround them, and of ſuch a level as to carry it clear off, and to empty their contents into the river Tay. There are alſo ditches which ſurround every farm, or paſs through them as their ſituation may require, but in ſuch manner as to communicate with every field upon the farm. Theſe ditches are made from two to four feet wide at top, and from one and a half to one foot at bottom; a ſhape which prevents their ſides from falling in: but even then they muſt be cleanſed and ſcoured every year at a conſiderable expence. If the fields be of an uniform level ſurface, the common furrows between the ridges, provided they be ſufficiently deepened at their extremities, will ſerve to lay the grounds dry; but, as it ſeldom happens that any field is ſo completely free of inequalities, the laſt operation, after it is ſown and harrowed in, is to draw a furrow with the plough through every hollow in the field which lies in ſuch a direction, that it can be guided through them, ſo as to make a free communication with any of the ditches which ſurround the farm, or with any of the furrows between the ridges which may ſerve as a conductor to carry the water off to the ſurrounding ditches. When this track is once opened with the plough, it is widened, cleared out, and ſo ſhaped with the ſpade, that it may run no riſk of filling up. Its width is from ſix inches to a foot according to its depth, which muſt depend upon the level of the field; but the breadth of a ſpade at bottom is a good general rule. It frequently happens that there are inequalities in ſeveral parts of the ſame field, which do not extend acroſs it, or which do not paſs through it in any direction that a plough can follow; but which may extend over two ridges, or one ridge, or even part of a ridge. Such require an open communication to be made with any furrow, which may ſerve as a conductor to carry off the water, which is always made with the ſpade. All theſe open communications are here called *gaas*, and to keep them perfectly clear is a very eſſential object of every Carſe farmer's attention.

Preparati of Land

It is the general practice in the Carſe to have headridges, as they are called, at the two extremities of each field; that is the ground upon which the plough turns, is laid up as a croſs ridge higher in the middle and falling off at each ſide, ſo that a gaa is made in the courſe of the inner furrow with which the whole furrows between the longitudinal ridges communicate, and into which they pour all their ſurface water, which is carried off by gaas or openings cut through the head ridges, and emptied into the adjoining ditches which convey the water to the main drain. Beſides all this, an experienced Carſe farmer takes care that his lands be carefully ploughed, and laid up equally without inequalities that can hold water, and that the ridges be gradually rounded, ſo that the ſurface water may neither lodge nor run ſo rapidly off as to injure the equal fertility of the field.

174 Rules for making open drains.

With regard to the general rule for making open drains, it may be obſerved, that their depth and wideneſs muſt always in ſome meaſure be left to the judgement of each particular huſbandman, that they may be varied according to the variety of ſoils and ſituations. Upon the whole, however, the width at bottom ought to be one-third of that at top, that, by being ſufficiently ſloped, the ſides may be in no danger of falling in. The fall or declivity alſo ſhould be ſuch as may carry off the water without ſtagnation, and along with it any graſs and other looſe and light ſubſtances that may get into the ditch. At the ſame time, care ought to be taken to lead the drain in ſuch a direction down any ſteep declivity that may occur in an oblique manner, that the water may not have too rapid a motion, as it would otherwiſe be apt to form inequalities in the bottom, and to wear down the ſides. In moſs and very ſoft ſoils drains require to be of conſiderable width, on account of their tendency to fill up; and their breadth at top muſt exceed that at the bottom in a greater degree than the proportion already mentioned. In all caſes in which a ditch is intended for a drain only,

and

eparation of Land.

and not to be uſed as a fence, none of the earth thrown out of it ought to be allowed to remain upon the ſides, but ſhould be ſpread abroad upon the land, or uſed in filling up the neareſt holes. When this is not done, the utility of the drain is injured by the ſurface water being prevented from reaching it, and by the tendency which this weight of earth has to cauſe the ſides to fall in; the difficulty of ſcouring or cleaning it is thus alſo much increaſed. If it be neceſſary, however, to uſe the ditch, and the earth thrown out of it, as a fence, a deep furrow ought to be made along the back of the mound of earth, with openings in convenient places into the ditch for tranſmitting to it the water collected in the furrow.

In plantations, open drains are the only kind that can be uſed, as the roots of the trees would be apt to choke up covered drains. In paſtures, ſmall and narrow open cuts, made with the plough or otherwiſe, are often extremely uſeful, to carry off ſtagnating water and a part of the rain as it falls. The only objection to them is, that they are eaſily ſtopt by the trampling of the cattle; but, on the other hand, they are eaſily reſtored. Concerning all open drains, indeed, it muſt be remembered, that they require to be cleaned out at leaſt once a-year; and when this proceſs is neglected for any length of time, it becomes more difficult, and the drains loſe their effect. Hence, though open drains are originally cheaper, yet, by the neceſſity of annual repairs, they ſometimes become ultimately more expenſive than covered or hollow drains, to the conſideration of which we ſhall next proceed.

175 ature and ſtory of ollow rains.

Hollow drains, in which the water is allowed to flow along a bed of looſe ſtones, or other porous materials, while they are covered with a bed of earth in which the operations of the plough can proceed, bear a near reſemblance to that part of the conſtitution of nature by which water flows in various channels along beds of porous ſtrata in the bowels of the earth, and coming to the ſurface in various ſituations, ſupplies ſprings and the conſtant flow of rivulets and of the largeſt ſtreams. The practice of hollow draining was known in a very remote antiquity. It is ſaid that the preſent Perſians are ſupplied by means of hollow drains with water in their moſt fertile fields, though they know not from whence the water is brought, and are unacquainted with the arts by which a more ingenious people in former times contrived to deprive one part of the ſoil of its ſuperfluous moiſture with a view to enrich another. The ancient Roman writers, Cato, Palladius, Columella, and Pliny, particularly mention the practice of hollow draining. They knew the kind of ſoils in which theſe drains are uſeful, and the propriety of directing them obliquely acroſs the ſlope of the field. They filled them half way up with ſmall ſtones, and for want of theſe with willow poles, or even with any coarſe twigs or other ſimilar materials twiſted into a rope. They alſo fortified the heads of their drains with large ſtones, and their mouths or outlets with a regular building; and they carried the whole drain to the depth of three or four feet.

As already mentioned, hollow drains are of little value in a ſoil that conſiſts of a ſtiff clay, and are chiefly uſeful where, from whatever cauſe the wetneſs may reſult, the ſoil is ſufficiently porous to allow the moiſture to percolate to an internal drain.

If the field propoſed to be drained lie on a declivity, great care ſhould be taken to make hollow drains in a direction ſufficiently horizontal to prevent a too rapid fall of the water, which might wear the bottom uneven, and have the effect to choak, or, as it is ſometimes called, to *blow up* the drain, whereby in certain ſpots in the field artificial ſprings would be formed. Preparation of Land. 176 Rules for making hollow drains.

Concerning the ſeaſon for executing drains, diſcordant opinions are entertained. Some prefer winter, others ſummer. Where much work is to be accompliſhed, a choice of ſeaſons may not indeed be left to the huſbandman. Some farmers, however, when they have the choice of time, always prefer ſummer for this employment, being then able to execute the cuts in a neater manner without that kneading of the ſoil which takes place in winter, which they think hurts the uſefulneſs of the drain, by ever after preventing the water from eaſily finding its way to it; beſides, that it is eaſier to bring the ſtones or other materials to the ſpot in ſummer than in winter. Others, however, prefer draining in winter, becauſe in the caſe of a clay ſoil the labour is at that ſeaſon much eaſier; and alſo becauſe labourers are then uſually moſt eaſy to be obtained.

The depth and width uſually adopted for hollow draining is very various, according to the nature of the ſoil and the ſituation of the field. When the practice firſt came into general uſe, three feet is ſaid to have been the common depth; but, for many years paſt, it is ſaid that hollow drains ſeldom exceed 30 or 32 inches, and that more drains are of two feet, or 26 inches deep, than of any other. One general rule, however, cannot be neglected with ſafety, that the depth muſt be ſufficient to prevent the materials with which the drain is filled from being affected by the feet of horſes in a furrow while ploughing; twenty-four inches is perhaps too little for this purpoſe. A horſe's foot in a furrow is uſually at the depth of four inches or more. If ten inches additional be allowed for the materials employed in filling the drain, there will remain only nine or ten inches to ſupport the foot of a horſe exerting his ſtrength in the act of ploughing, which upon a porous ſoil ſeems ſcarcely ſufficient. What are called *main drains*, which are thoſe intended to receive the water of ſeveral other drains, muſt always be ſomewhat deeper than the reſt, having more water to convey. As to the wideneſs of hollow drains, moſt farmers have of late been ſolicitous to render them as narrow as poſſible, becauſe by this means a great ſaving takes place of the materials uſed for filling them. If the ſtones are coupled at the bottom of the drain, that is, made to lean towards each other, ſo as to conſtitute a triangle, of which the bottom of the drain forms the baſe, the width need not be greater than one foot; nor perhaps is it even neceſſary to exceed this breadth where large ſtones are thrown in promiſcuouſly. That the ditches or cuts which are meant to be converted into hollow drains may be executed with neatneſs and care, a point of much importance to their uſefulneſs, it is thought prudent that the workmen ſhould not be paid according to the extent of ground which they open, but as day labourers. This, however, is more particularly the caſe with regard to filling the drains, an operation in which a ſtill greater degree of attention is neceſſary.

The

Preparation of Land.

177 Materials with which hollow drains may be filled.

The materials uſed for filling drains have been various, according to the ſubſtances which different farmers have been able to obtain. Stones, however, are the moſt common, and alſo the beſt of all materials, on account of their permanency. If ſtones from quarries are to be uſed, and the drain formed like a conduit at the bottom, the trench muſt be made at the loweſt part 16 inches wide, containing two ſide ſtones about ſix inches aſunder, and the ſame in height, with a cap or flat ſtone laid over, which ſecures the cavity. Such hollow drains are commonly uſed for permanent currents of water from ſprings, and are more expenſive than where no ſuch ſteady current exiſts, and the ſtones are either thrown in promiſcuouſly, or laid down ſo as to form triangular cavities. Small ſtones, however, ought not to be uſed for the bottom of a drain. Whether the ſtones are large or ſmall, they ought to be very clean, having no clay or earth adhering to them, and of the moſt hard and permanent quality that can be procured, with as little tendency as poſſible to moulder or decay in conſequence of alternate changes from wet to dry. They ought alſo to be laid in carefully, ſo as not to tumble down any earth, which might choke up their interſtices. The whole ſubject, however, will be better underſtood by a ſtatement of the way in which drains have been filled with ſucceſs by intelligent perſons.

The following directions are given by T. B. Bayley, Eſq. of Hope, near Mancheſter: "Firſt make the main drains down the ſlope or fall of the field. When the land is very wet, or has not much fall, there ſhould in general be two of theſe to a ſtatute acre; for the ſhorter the narrow drains are, the leſs liable they will be to accidents. The width of the trench for the main drains ſhould be 30 inches at top, but the width at the bottom muſt be regulated by the nature and ſize of the materials intended to be uſed. If the drain is to be made of bricks, 10 inches long, 3 inches thick, and 4 inches in breadth, then the bottom of the drain muſt be 12 inches; but if the common ſale bricks are uſed, then the bottom muſt be proportionably contracted. In both caſes there muſt be an interſtice of one inch between the bottom brick and the ſides of the trench, and the vacuity muſt be filled up with ſtraw, ruſhes, or looſe mould. For the purpoſe of making theſe drains, I order my bricks to be moulded ten inches long, four broad, and three thick; which dimenſions always make the beſt drain."

The method which this gentleman purſues in conſtructing his main drains is ſtated by him to be the following: When the ground is ſoft and ſpungy, the bottom of the drain is laid with bricks placed acroſs. On theſe, on each ſide, two bricks are laid flat, one upon the other, forming a drain ſix inches high, and four broad, which is covered with bricks laid flat.—When the bottom of the trench is found to be a firm and ſolid body, ſuch as clay or marl, he formerly thought that it might not be neceſſary to lay the bottom with brick; but in this he has candidly acknowledged that he was quite wrong. By the runs of water, the alternate changes from wet to dry, and the acceſs of air, theſe hard bottoms were rendered friable, crumbled away, and let in all the drains, and allowed them to choke up, that were not ſupported by a bottom laid with brick or ſtone. When ſtones are uſed inſtead of bricks, Mr Bayley thinks that the bottom of the drain ſhould be about eight inches in width; and in all caſes the bottom of main drains ought to be ſunk four inches below the level of the narrow ones, whoſe contents they receive, even at the point where the latter fall into them. Prepara of Lan

The main drains ſhould be kept open or uncovered till the narrow ones are begun from them, after which they may be finiſhed; but before the earth is returned upon the ſtones or bricks, it is adviſable to throw in ſtraw, ruſhes, or bruſhwood, to increaſe the freedom of the drain. The ſmall narrow drains ſhould be cut at the diſtance of 16 or 18 feet from each other, and ſhould fall into the main drain at very acute angles, to prevent any ſtoppage. At the point where they fall in, and eight or ten inches above it, they ſhould be made firm with brick or ſtone. Theſe drains ſhould be 18 inches wide at the top, and 16 at bottom.

A mode of draining clay ſoils wet by rain or ſurface water, practiſed by Sir Henry Fletcher, Bart. with great ſucceſs, ſeems worthy of being here ſtated. The upper ſoil is of good quality, but being ſituated in a mountainous part of the country, the frequent rains kept the upper ſoil ſo full of water, that it produced only a coarſe graſs worth 3s. per acre. The inferior ſoil of clay was of great depth. The mode of draining which has been ſucceſsfully practiſed upon it is the following: "On graſs lands he digs 22 inches, or 2 feet deep; the firſt ſpadeful is of the turf, taken ſo deep, as where it ſeparates from the clay, which is dug carefully out, and preſerved unbroken graſs ſide up, and laid on one ſide of the cut; then, with a very ſtrong ſpade, 18 inches long, 6 inches wide at top, and 2 at the bottom, he digs a ſpadeful in the clay, which the men ſpread about the land, on the ſide of the drain oppoſite to where the turfs were laid, as far as poſſible from the drain, ſo as none may get in again. A ſcoop, to clear out the fragments in the bottom, follows, which are alſo ſpread in like manner. They are then ready for filling; and in doing this, he takes three ſtones of a thin flat form, two of which are placed againſt the ſides of the drain, meeting at bottom; and the third caps the other two. Thus, a hollow triangular ſpace is left to convey the water, which is ſubject to no accidents that can fill it up or impede the current. Stones always ſink deeper in the ground; in the common method, this frequently cauſes ſtoppages by their being partly buried in the clay: but the triangle, when it ſubſides, does it regularly, and keeps its form and the paſſage for the water clear. One cart load of ſtones, in this way, will do a conſiderable length of drain. They are carefully laid down by the ſide of the cut, with a ſhovel or baſket, and if there are any ſmall refuſe ſtones left on the ground after the drain is ſet, they are thrown in above. The ſtones being thus fixed, the ſods are then trimmed to the ſhape of the drain, and laid on them, with the graſs ſide downwards, and none of the clay uſed in filling up.

The expence is a halfpenny per yard, the men earning 2s. and 2s. 6d. per day, at 10 yards diſtance from drain to drain. At 6 yards diſtance they anſwered well, but would not operate a cure, if more than 7 yards aſunder. At this laſt diſtance, therefore, the expence of draining an Engliſh acre, at ½d. per yard, would amount to 1l. 9s. 2d. the ſtones being not more than half a mile diſtant.

Preparation of Land.

Not only ſtones and bricks, but alſo wood and other materials have been uſed for filling drains. Upon this point, Lord Petre expreſſes himſelf thus: "The drains filled with wood, and covered as uſual with ſtraw or ruſhes, are, preferable to ſtones or any other kind of materials; the reaſon is, as the wood decays, the water continues to paſs. When filled with ſtones, and the drains ſtop up, which muſt be expected to take place in time, the earth becomes quite ſolid round the ſtones, and as they do not decay, the filtering of the water is for ever obſtructed: not ſo when buſhes or wood are uſed; continual filtering and draining are then for ever to be perceived; and by repeating the operation a ſecond time, cutting the drains tranſverſely of the old ones, the benefit of the filterings through the rotten wood is ſecured, and the ſpewing up of old, broken, and damaged drains corrected and carried off. Moreover, as buſhes form a much greater number of cavities than either ſtones or poles, they are leſs liable to ſtop up, and encourage filtering more than larger and more ſolid bodies. A load of buſhes containing 120 faggots, will do about 360 rods; and a load of ſtraw containing 120 bottles, the ſame: the load of buſhes is generally worth about 14s. and the ſtraw 18s. per load. I therefore calculate this expence about 12s. per acre, ditches a rod apart."

Richard Preſton, Eſq. of Blackmore, preſers, on twenty years experience, black thorns to every other material for filling drains. Wood is ſometimes uſed with this view, in the following manner: Two billets are placed at oppoſite ſides of the drain, and each is made to reſt under the oppoſite ſide to that on which its lower part ſtands, ſo as to form with each other a St Andrew's croſs. The upper part of the croſs is filled with bruſhwood, laid longitudinally, above which ſtraw is placed croſs-ways, and the mould is thrown in over all. This kind of drain is ſaid to have continued running in Berwickſhire for 30 years, and it is recommended by the author of the Agricultural Report of the county of Caermarthen, in Wales. He ſays, "The completeſt method I have yet known, is to cut the ſtrongeſt willows, or other aquatic bruſhwood, into lengths of about 20 inches, and place them alternately in the drain, with one end againſt one ſide of the bottom, and the other leaning againſt the oppoſite ſide. Having placed the ſtrong wood in this manner, I fill the ſpace left between them on the upper ſide with the ſmall bruſhwood, upon which a few ruſhes or ſtraw being laid, as before mentioned, the work is done. Willow, alder, aſp, or beech boughs, are exceedingly durable if put into the drain green, or before the ſap is dried; but if they are ſuffered to become dry, and then laid under ground, a rapid decay is the conſequence. I have ſeen willow taken out of a bog, after lying there thirty years, and its bark was as freſh and ſappy as if it had been recently cut from the hedge; and it is well known that beech laid green in the water will continue ſound for any length of time."

Another method of uſing wood conſiſts of fixing at every foot diſtance in the drain, a ſtick in the form of a ſemicircular arch, and of laying upon theſe longer branches or twigs longitudinally. Thus is a curved cavity, or arch, formed beneath, capable of ſupporting any weight of earth. For this purpoſe young wood is recommended, and in particular the prunings of larch.

Inſtead of wood or ſtone, in many places, it has of late become cuſtomary to fill the loweſt part of drains with ſtraw, and with that view to make uſe of wheat ſtubble as the cheapeſt kind of ſtraw. On this ſubject, Mr Vancouver, in his Report of the Eſſex huſbandry, remarks, that when the ſoil is a very cloſe and retentive clay, the drains ſhould be made proportionally near to each other, ſhallow, and filled with ſtraw only, it being totally unneceſſary to uſe wood or any more durable material upon land where the ſides of the drains are not likely to crumble in. He aſſerts that drains formed in this manner, through the tough and retentive clays, will be found in a ſhort time after the work is finiſhed, to afford over the ſtraw, with which the drain was filled, an arch of ſufficient ſtrength to ſupport the incumbent weight of the ſoil, and the caſual traffic of the field. "In 12 or 18 months it may be obſerved that the ſtraw, being of one uniform ſubſtance, is all rotted, and carried away, leaving a clear pipe through the land in every drain, into which the paſſage of the water may have been much facilitated, by a due attention to the filling of the drains with the moſt friable and porous parts of the ſurface the field might have afforded."

An improvement in filling hollow drains with ſtraw, conſiſts of twiſting the ſtraw into a rope, ſaid to have been deviſed by Mr Bedwell, of Eſſex. The rope of ſtraw is formed as large as a man's arm, and is placed at the bottom of the drain. The expence of draining an Engliſh acre of land with this material in Eſſex, is ſaid to ſtand thus:

For cutting and raking together an acre of wheat ſtubble, generally ſufficient for an acre of drains, - -	L.0	2	0
Digging eight ſcore rods of drains, -	0	13	4
Filling them up with ſtubble, -	0	2	8
Extra work with the common ſpade, on an average a day's work for a man, -	0	1	4
	L.0	19	4

As in ſome ſituations it is an object of great importance to ſave the expence of materials commonly uſed in filling drains, a variety of devices have with that view been adopted. One of theſe is of the following nature. A drain is firſt dug to the neceſſary depth, narrow at bottom. Into the trench is laid a ſmooth tree, or cylindrical piece of wood, 12 feet long, 6 inches diameter at the one end, and 5 at the other, having a ring faſtened into the thickeſt end. After ſtrewing a little ſand upon the upper ſide of the tree, the clay or toughest part of the contents of the trench, is firſt thrown in upon it, and thereafter the remainder of the earth is fully trod down. By means of a rope through the ring the tree is then drawn out to within a foot or two of the ſmall or hinder end, and the ſame operation is repeated till the whole drain is complete. Such a drain is ſaid to have conducted a ſmall run of water a conſiderable way under ground for more than 20 years without any ſign of failure.

176 Sod or pipe drains.

What is called the ſod or pipe drain conſiſts of a trench dug to a proper depth; after which a laſt ſpadeful is taken out in ſuch a way as to leave a narrow channel, which can be covered by a ſod or turf dug in graſs land and laid over it, the graſs ſide downwards. Such

Preparation of Land.

drains are said to continue hollow, and to discharge well for a great number of years. Mosses are said to be drained in Lancashire nearly in the same manner, by leaving shoulders about a foot and a half from the bottom of the trench, and laying across these pieces of dryed peat or turf, cut into lengths of 16 inches, and 8 or 9 inches in breadth.

In Buckinghamshire, in grass lands, the sod drain is thus made: When the line of drain is marked out, a sod in form of a wedge is cut, the grass side being the narrowest, and the sods being from 12 to 18 inches in length. The drain is then cut to the depth required, but is contracted to a very narrow bottom. The sods are then set in with the grass side downwards, and pressed as far as they will go. As the figure of the drain does not suffer them to go to the bottom, a cavity is left, which serves as a water course; and the space above is filled with the earth thrown out.

Another invention for draining land is described in the agricultural report of the county of Essex. It consists of a draining wheel of cast iron, that weighs about 4 cwt. It is 4 feet in diameter, the cutting edge or extremity of the circumference of the wheel is half an inch thick, and it increases in thickness towards the centre. At 15 inches deep it will cut a drain, one half of an inch wide at the bottom, and 4 inches wide at the top. The wheel is so placed in a frame, that it may be loaded at pleasure, and made to operate to a greater or less depth, according to the resistance made by the ground. It is used, in winter, when the soil is soft; and the wheel tracks are either immediately filled with straw ropes and lightly covered over with earth, or they are left to crack wider and deeper till the ensuing summer; after which the fissures are filled with ropes of straw or of twisted twigs, and lightly covered with the most porous earth that is at hand. Thus, upon grass or ley lands, hollow drains are formed at a trifling expence, which answer extremely well. It is said that 12 acres may be fully gone over with this draining wheel in one day, so as to make cuts at all necessary distances.

On sheep pastures a still simpler mode of removing surface water is said to be practised in some places. Wherever the water is apt to stagnate, a deep furrow is turned up with a stout plough. Thereafter, a man with a spade pares off the loose soil from the inverted sod, and scatters it over the field, or casts it into hollow places. The sod thus pared and rendered thin, or brought to the thickness of about three inches, is restored to its original situation, with the grassy side uppermost, as if no furrow had been made. A pipe or opening is thus formed beneath it two or three inches deep in the bottom of the furrow, which is sufficient to discharge a considerable quantity of surface water which readily sinks into it. These furrows, indeed, are easily choked up by any pressure, or by the growth of the roots of the grass; but they are also easily restored, and no surface is lost by means of them.

179 Duration of hollow drains.

With regard to the duration of hollow drains, or the length of time that the water will continue to flow in them, and thereby to preserve the soil in a proper state of dryness, it must necessarily depend, in a great degree, upon the nature of the materials with which they are filled, and the care that has been taken to prevent their being choked up by any accession of soft soil. Independent of this last circumstance, a drain filled with stones, like the channel which supplies a natural spring, may endure for ever. Wood, with which many drains have of late years been filled, perishes at certain periods according to its nature; but it does by no means follow, that the drain should lose its effect in consequence of the destruction of the wood. If the earth over it form itself into an arch, the water will still continue to flow. Accordingly, it is said, that drains filled with bushes and straw have been known to run well after 40 years.

Preparation of Land.

180 Drains when the wetness is caused by springs.

Having thus stated the various modes that have been most successfully adopted for draining lands of a superabundant moisture caused by rain or surface water, we shall proceed to consider the way in which a soil may be drained when its undue wetness is the consequence of natural springs, or of water arising out of the bowels of the earth; and also when the soil, whether injured by spring or rain water, is so completely surrounded by higher grounds, as to prevent the possibility, at a moderate expence, of obtaining a level by which the water may be conducted away, either by open or by artificial hollow drains.

181 Nature of springs.

To understand the principles upon which land, rendered wet by springs, may be drained for the purposes of agriculture, it is necessary to attend to the materials of which the globe we inhabit is composed, and to the manner in which large quantities of water find their way into its bowels. The earth upon which we tread is by no means an uniform mass of matter. It consists of various layers or strata of different substances, one placed over the other. These layers or strata are seldom situated horizontally, but almost always descend towards one side or the other. One part of a stratum or layer often ascends and appears on the surface, while the other end or side of it descends obliquely to a great depth into the earth. Having done so, it frequently again bends upwards towards the surface; and indeed assumes almost all the variety of irregular forms and bearings that the imagination can conceive; sometimes suddenly breaking off and giving place to other strata or layers, and sometimes continuing at one corner while the greater part of it ceases. These strata or layers, of which the earth is composed, may be considered, with a view to the explanation of our present subject, as of two kinds. Some of them are porous, and allow water to pass through their substance, and to fill up all their cavities and interstices, such as sand, gravel, some marls, and various kinds of porous rocks. Other layers, on the contrary, do not suffer water to enter into them; such as clay, or gravel with much clay mixed with it, and rocks of a close and compact nature, without any fissures or clefts in them.

It is next to be remarked, that it is chiefly upon high mountains that water exills, or is formed, in very great abundance. Not only do they catch and break the passing clouds, which deposite upon them the greatest portion of their watery contents, but they would seem to have a power, when neither rain nor clouds appear in the sky, of condensing, attracting, or somehow forming water from the atmosphere. In the great burning deserts of Africa rain is scarcely known. The inhabitants build their houses of clods of earth or of lumps of salt. A drizzling shower, which is apt to come once in several years, endangers every dwelling; and

Preparation of Land.

and two hours of heavy rain would lay a whole city in ruins; yet even there, wherever mountains exiſt, that is to ſay, naked rocks, which abound in a few diſtricts of this wilderneſs, water is almoſt always found in their vicinity; and, in conſequence of the water, ſpots covered with the moſt luxuriant verdure are ſeen like iſlands amidſt the dreary tracts of moveable and unproductive ſand.

The upper part of mountains is very frequently covered with a layer of gravel, or looſe and open rock, into which water readily penetrates. Theſe porous layers or ſtrata deſcend gradually into the bowels of the earth, and convey along with them the water which they contain, and have received from the clouds. Under the porous ſtratum or layer of gravel are uſually layers of clay or of ſolid rock, through which the water cannot paſs, but along the upper part of which it flows. After deſcending, however, a certain length obliquely down towards the plain country, layers or ſtrata of clay and other impervious materials uſually come to be placed above the layers of porous gravel. Thus, as the water in the gravel is confined between clay above and clay or rock below, and muſt deſcend along the gravelly channel which is pervious to it, ſtreams of water are formed in the bowels of the earth, which have their origin in high gravelly ſoils, and their outlets at any place in the low country, where any part of the beds of gravel or porous rock, along which they flow, happens to approach the ſurface, forming ſprings and rivulets, and, by their union or conflux, mighty rivers, which continue ſteadily to water the ſurface of the earth. Hence alſo, in very many ſituations, by digging pits into the earth, we at laſt reach a layer of pervious gravel or rock, containing a ſtream of water, brought, perhaps, from the ſummit of a diſtant mountain; and ſuch pits can be uſed as wells for ſupplying water for every domeſtic purpoſe.

We have ſaid that the upper part of the face of a mountain is often covered with a bed of porous or gravelly ſubſtances capable of taking in water. Upon the ſurface, at a certain diſtance down the hill, a bed of clay begins. The water received above into the layer of gravel continues to deſcend with that layer for a conſiderable ſpace below the bed of clay; and thereafter the gravel ſuddenly ſtops, and the clay above unites with the clay beneath, or with ſome other impervious ſtrata upon which the gravel all the way reſted. In this ſituation, as the water contained in the gravel can proceed no farther, it hangs within the ſide of the hill as in a bag of clay; and a reſervoir is formed of water within the earth. When this bag or natural reſervoir is full, the water contained in it is preſſed upwards againſt the clay by which it is covered. It moiſtens this clay, and finds its way by chinks through all its weaker parts or pores. Thus a belt of ſoft and ſpouty land is formed upon the ſide of the hill;

182 Principle on which land made wet by ſprings drained.

the mode of draining which is very eaſy. If a hole is dug into the earth near the bottom of the bag or reſervoir of water, ſo as to reach the layer of gravel, the water will inſtantly flow freely out, and, being no longer reſtrained, it will ceaſe to preſs upon the layer or ſtratum of clay that covers it, or to force a paſſage through its chinks; and the ſoil will conſequently be drained.

Let it be ſuppoſed, that the porous ſtratum or layer of gravel, inſtead of ſtopping on the ſide of a hill, deſcends into the plain or level country, the water all the while paſſing along in its bowels; and that the gravel has a layer of clay below and another layer of clay above it. After it has reached and paſſed to a conſiderable diſtance along the valley, if the layer of gravel either ſuddenly ſtop and allow the layers of clay to come together, or if the gravel have too little thickneſs and capacity to allow the water which flows within it to paſs eaſily along, it will neceſſarily, from the new ſupplies of water which are continually deſcending, be preſſed upwards againſt the layer of clay which covers it: as in the former caſe, the clay will be ſoftened, and the water will filtrate through all its weaker parts till it reach the ſurface, which it will keep conſtantly wet, and where it will ſtagnate in conſequence of the flat and level form of the country. Over the ſofteſt places, a coarſe verdure will ſpread, and the roots of the parts intertwining, will form ſhaking quagmires. In other places, the moſs plants, being the only ones which can thrive in the moiſt and ungenial ſoil which is thus produced, will rapidly ſpring up, and a moſs will be formed altogether unfit for any purpoſe of agriculture. To drain ſuch a ſoil, it is evidently only neceſſary to dig a pit or hole through the upper ſtratum of clay into the gravel, to give a free vent or iſſue to the water; which having thus found an eaſy paſſage to the open air, will ceaſe to preſs upon the incumbent layer of clay, or to render it moiſt. This clay will therefore ſpeedily become dry and collapſe; the moſs plants will wither, provided the ſurface is properly drained; and the whole ſoil will become ſolid and fit to be cultivated.

It ſometimes happens, as already noticed, that a piece of territory which lies low, is rendered extremely wet by rain and ſpring water coming from adjacent high grounds, and lodging upon its ſurface, while, at the ſame time, it is ſo completely ſurrounded by eminences, or land-locked, that it cannot be drained at a moderate coſt; the conſequence of which is, that the water ſtagnates, and a moſs or bog is formed. The principles which we have already ſtated concerning the manner in which the globe is made up of various ſtrata, indicate the way in which ſuch a bog may be drained at a cheap rate. It is only neceſſary to dig a pit at the loweſt part of it, down through the clay, or other impervious layer that holds up the water, till a porous ſtratum is reached, capable of conveying away the ſurface water down the country below ground to the ſea, or to ſuch rivers as it may chance to be connected with.

The whole art of draining land, where the wetneſs is occaſioned by water preſſing upwards from the bowels of the earth, depends upon theſe principles. It is an art whoſe importance is not yet ſufficiently appretiated, becauſe imperfectly underſtood, and becauſe it has not yet been carried into practice to its full extent. It is probable, however, that at no remote period it will be held in univerſal eſtimation, on account of the command of thoſe hidden ſtreams that are contained in the bowels of the earth, which it will give to mankind for the purpoſes of an improved agriculture, and for the ſervice of commerce in filling canals and giving motion to every kind of machinery. A diſpute exiſts about the original diſcoverer of this art. The celebrated writer upon agriculture, Dr James Anderſon of Aber-

183 Diſpute about the firſt diſcoverer of the mode of draining land made wet by ſprings.

deen,

Preparation of Land.

deen, in his "Eſſays on Agriculture and Rural Affairs," publiſhed in 1775, was undoubtedly the firſt perſon who explained to the world the nature of the art of draining land rendered wet by ſprings, and the principles upon which it ought to proceed; having been led to the inveſtigation many years before, by his having fortunately ſucceeded in draining a bog by ſinking a pit in it through the clay, till an opening was made into the gravel or porous ſtratum, from which the water ruſhed up vehemently. In the mean while, it had happened that Mr Joſeph Elkington, poſſeſſor of a farm in England called Princethorp, in the pariſh of Stretton upon Dunſmore, and county of Warwick, almoſt as early as Dr Anderſon, had accidentally diſcovered that land might be drained in many ſituations by making a ſmall hole into the earth. Being a man of conſiderable natural ingenuity, though, it is ſaid, of little literature, he had the addreſs to take advantage of the diſcovery he had made, with a view to the improvement of his affairs. He therefore commenced the trade of a drainer of lands; and by the novelty of draining land by a ſmall hole bored often at a conſiderable diſtance from the wetteſt part of it, and by conducting himſelf in a myſterious manner, he acquired great reputation, and was extenſively employed. This employment he appears to have merited, as his operations were attended with very great ſucceſs. After the eſtabliſhment of the Board of Agriculture, its members, who appear to have been unacquainted with Dr Anderſon's publication, ſuppoſed Mr Elkington to be the only diſcoverer and poſſeſſor of the art of draining land wet by ſprings in the way now mentioned; and upon their recommendation, parliament beſtowed a reward of 1000l. upon him. It was ſurely an unfortunate circumſtance, that the firſt premium granted upon the recommendation of this board, ſhould have proceeded upon an error, as it undoubtedly did; for, although Mr Elkington had the merit of being the firſt who introduced this art extenſively into practice, there is no doubt that Dr Anderſon, by whom alſo it was diſcovered, was the firſt who explained its principles to the public, and that at a period when Mr Elkington's ſecret remained with himſelf. After all, however, it is not to be ſuppoſed that the theory of this art was abſolutely unknown, although theſe perſons appear to have been the firſt who propoſed to apply it extenſively to the purpoſes of agriculture. It is ſaid that the practice is very ancient in Italy, when a well is dug, to avoid the expence of going to a great depth, by boring with an auger in the bottom of the pit, in the hope of reaching the porous ſtratum which contains the water. And in Germany it appears, as will be afterwards noticed, that the practice has long exiſted of draining land-locked bogs, by letting down the water by means of a pit through the impervious clay, to a porous ſubſtratum. We ſhall now proceed to ſtate the moſt approved modes of draining land that is rendered wet by ſprings, or water aſcending out of the earth; and as the Board of Agriculture inſtructed Mr John Johnſton, land ſurveyor, to inſpect Mr Elkington's principal drainings of this ſort, and to give an account of them, we ſhall give all due attention to the contents of the report made out by that gentleman, which is underſtood to have been executed with much fidelity and accuracy; though we ſhall alſo exhibit, at the ſame time, the practice of other intelligent perſons upon the ſame ſubject. Preparation of Land.

In the practice of this art it will readily occur, that it is of the utmoſt importance to obtain a knowledge of the internal ſtructure of the earth, and of the manner in which its various layers or ſtrata ſucceed, and are uſually intermingled with each other. This object, however, can only be attained in any conſiderable degree of perfection by obſervation and experience. There are ſeveral ways, however, by which a man of ſagacity and reflection may greatly abridge the difficulty of this ſtudy, ſo as in a ſhort time to enable himſelf to practiſe the art of draining with conſiderable ſucceſs. The ſureſt way of aſcertaining the inclination of the different ſtrata, or the way in which they lie upon each other, and the direction in which they deſcend into the earth, conſiſts of examining the bed of the neareſt rivers, and the appearance of their banks when ſteep and broken, ſo as to lay bare the different ſtrata of earth adjoining to them. Pits, quarries, and wells, that may have been dug in the neighbourhood, may alſo be examined with the ſame view. Ruſhes, ſmall elder buſhes, and other plants which grow on the wetteſt ſoils, alſo frequently afford ſymptoms of the line under which an internal reſervoir of water is placed, and is preſſing upwards from wanting a free paſſage below ground. 184 Practical rules for draining land made wet by ſprings.

It is often of much importance, even in ſheep countries, to drain the ſide of a hill, not only becauſe wet land is more unproductive than that which is properly drained, but becauſe the ſuperabundance of moiſture is apt to introduce and to keep up among the flock that deſtructive and incurable diſeaſe, the *rot*, for which draining is an almoſt infallible preventive. It is cheaply executed in ſuch ſituations, becauſe the drains for collecting and leading off the water, may uſually be left uncovered. Let it be ſuppoſed then, that in conſequence of internal ſprings at a certain diſtance down the declivity of a hill, or upon any other deſcending ſurface, the ground becomes wet and ſpouty, and unwholeſome for ſheep, and unfit for agriculture; the beſt mode of proceeding with a view to drain it is this. It ought to be recollected, that the reaſon of the wetneſs is this: The rain water at the ſummit of the high ground is received into a porous ſtratum of gravel, with which it deſcends down the ſide of the hill, till it comes to be covered with a clayey ſoil. After deſcending under the covering of clay to ſome diſtance, the gravel or porous under ſoil ſuddenly ceaſes; the clay becomes deeper, and touches the rock or another inferior bed of clay. In this ſituation, the water, unable to deſcend farther, regorges and preſſes upwards upon the clayey ſoil which covers it, rendering it moiſt and ſwampy in every part, and oozing through all its weaker crannies. Thus it forms a belt of moiſt ground along the face of the hill, from which the water perhaps deſcends and damages every part. To drain this declivity, begin at the bottom and carry up a ditch towards the wet ground. As the object is to let out the water at the loweſt point of the reſervoir or natural bag in which it is contained, by making an opening into the gravel there, it will be proper, as the ditch proceeds upwards, frequently to bore holes with an auger of about two inches diameter to a conſiderable depth, 185 To drain the ſide of a hill.

Preparation of Land.

depth, that is, about 15 feet, though ſometimes it is neceſſary to go to twice that depth. As long as the water is not found by boring, the ditch muſt be carried upwards, and new auger holes formed; when at laſt the auger by boring reaches the loweſt part of the gravel or reſervoir of water, the water will immediately ruſh forth with conſiderable violence at the hole formed by it, and will continue ever after to run without any danger of choking up. When the bottom of the reſervoir of water or layer of gravel is thus found, another ditch ought to be drawn acroſs the head of the former along the face of the hill, ſo as to form the figure of the latter T. In the upper ditch or drain that runs along the face of the hill, auger holes ought to be bored at ſhort diſtances, to let out the whole water from the interior reſervoir or ſtratum of gravel. The whole proceſs will be eaſily underſtood from conſidering the figure 3. Care ought always to be taken in digging the upper drain along the face of the hill, to form it in ſuch a way as that the water may deſcend in it towards the ditch firſt formed, which is intended to convey it down the hill to the neareſt brook. The old practice or mode of draining ground in this ſituation before the uſe of the auger was underſtood, and before men had reflected upon the way in which water is often confined in the earth, conſiſted of digging a trench wherever the ſpouty land commenced. As this was not deep enough to reach the level, that is, to penetrate to the reſervoir of water, it produces only a partial remedy. Other parallel ditches of the ſame kind were therefore cut the whole way down the declivity, and being filled with looſe ſtones and connected with a deſcending ditch, each carried off only a portion of ſurface water, leaving the ſoil ſtill cold in conſequence of the wetneſs of the bottom.

Plate XII.

In performing the operation already deſcribed, ſome difficulties are apt to occur, in conſequence of the irregularities with which the ſtrata are often placed in the earth. In boring in the aſcending trench, in the firſt part of the operation, with a view to diſcover the loweſt point at which the water may be let out from the internal reſervoir, the operator is ſometimes apt to be miſled by finding water before he has come high enough to reach the place at which the porous ſtratum ſtops. This ariſes from its ſometimes happening that at the bottom of the reſervoir ſmall leakages occur, and a portion of the water finds its way downwards through crannies in the earth to ſome diſtance from the main reſervoir. When the auger in boring meets theſe leakages, they are apt to be miſtaken for the main body of water, and the operator can only guard himſelf againſt ſuch errors, by forming an eſtimate of the quantity of water which the adjoining high grounds ought to afford. If the quantity of water that follows the auger be very trifling, while the extent of high ground is great, he may be aſſured that he has not yet reached the great cauſe of the wetneſs of the ſoil. It alſo ſometimes happens that the croſs drain carried along the face of the hill, may in ſome places be below the level of the reſervoir of water, while it is upon it at other places. In this caſe, when the auger by boring in the croſs trench brings no water, it will be neceſſary to bore above it, and to conduct the water that is there obtained by a ſmall cut into the general croſs trench.

It ſometimes happens that hills are compoſed of alternate ſtrata, of ruck and ſand and clay, which reſt horizontally or nearly ſo upon each other, and penetrate and form the maſs of the hill. In ſuch caſes the ſoil above the ſand or rock is often dry and productive, while the clay is wet and ſwampy. In this caſe, the higheſt part of the hill being generally porous, receives the rain water, which deſcends through it till it meets the impervious clay, which forces it to flow to the ſurface, which it renders wet. Having overflowed the upper clay ſurface, it is immediately abſorbed by the next porous ſtratum; and deſcending into it in like manner, again iſſues at the lower ſide of it, and injures the ſurface of the next bed of clay, as it did that of the firſt. To drain a hill ſide of this deſcription, it is neceſſary to make a trench along the upper ſide of every belt of ruſhy or boggy ſoil to receive the water from the ſuperior porous ſoil, and to lead the whole water thus obtained by one or more ditches downwards to the bottom.

Preparation of Land.

Where a ſoil is compoſed of intermixed varieties, with clay predominating, it is ſometimes very difficult to drain, as it is apt to form itſelf into a variety of hollow reſervoirs, each of which holds water like a cup, while, at the ſame time, theſe hollows being full of porous materials, the ſurface of the ſoil is ſufficiently regular. Thus in wet ſeaſons, patches of moiſt unwholeſome ſoil are formed, not by ſprings for which they may be miſtaken, but by rain water held up by clay in theſe diſjoined cavities. They can only be drained by ſeparate covered cuts, communicating in the ſhorteſt way poſſible with one or more main drains.

186 To drain a bog by letting the water aſcend freely.

With regard to the drainage of bogs, it has already been remarked, that they are either ſuch as can have their water carried off by a communication, at a tolerable expence, with ſome adjoining lower ground; or they are land-locked, ſo as not to admit of being drained in this way. With regard to the former, or thoſe which can be drained by trenches for conducting the water to an adjoining low country or river, they may be rendered wet in two ways: 1ſt, By ſprings oozing out of the adjoining higher ground, in a regular line along the upper ſide of the wet ſurface, which afford water that ſtagnates upon the ſurface of the inferior ground, forming it into a bog. To render free from water a bog of this kind, nothing more is neceſſary than merely to drain the upper adjoining ſwampy ground in the way that has been already ſtated, and to convey away to a diſtance the water produced by it, in regular, open, or hollow drains.—The ſecond claſs of bogs rendered wet by ſprings, conſiſts of thoſe in which the many ſprings that appear are not confined to one regular direction along the upper ſide, but burſt out everywhere, forming ſhaking quagmires, over which it is dangerous for cattle to paſs. The upper part of ſuch bogs uſually conſiſts of peat-earth. Below that is found a bed of clay, extremely wet and ſoft, through the crannies of which ſmall quantities of water are continually oozing. When the loweſt part of ſuch a bog it found, or the place in which it will be moſt convenient to convey away the water, little more is uſually neceſſary than to dig proper trenches, and to bore with the auger through the ſtratum of clay to the porous ſtratum containing the water. To drain an extenſive bog, it will uſually be neceſſary to dig a trench from end to end of it, with croſs trenches at conſiderable diſtances, the

Preparation of Land.

the bottom of the whole being frequently penetrated with the auger, ſo as to allow a free paſſage for the water to aſcend; the effect of which will be, that the nature of the ſurrounding ſoft ſoil will ſpeedily be altered, in conſequence of the water being removed from beneath it. It will become dry and ſolid, and ſoon fit for bearing the plough. The ſame effect would follow, although only a ſingle perforation were made through the inferior ſtratum of the bog; and accordingly Mr Elkington is ſaid ſometimes to have ſucceeded, while he drained a bog, in raiſing the water from it conſiderably above its own level, for any purpoſe for which it may be required. This was done by rearing around the perforation, a building of brick, puddled around and within with clay, to the top of which the water roſe, and was from thence conveyed away in pipes or otherwiſe.

187 Dr Anderſon's rules for draining ſpouty land.

That the whole of this important ſubject, of draining land rendered wet by ſprings, may be better underſtood, we ſhall give an account of it as deſcribed by Dr Anderſon, in his Eſſays publiſhed in 1775, already mentioned. Suppoſing, ſays he, a deſcending ſtratum of ſand or gravel ſhould be diſcontinued, and that the ſtratum above it ſhould be of a coherent clayey nature; in this caſe, the water being pent in on every ſide, and being accumulated in great quantities, muſt at length force a paſſage for itſelf in ſome way, and preſſing ſtrongly upon the upper ſurface, if any one part is weaker than the reſt, it would burſt forth, and form a ſpring: but if the texture of every part of this ſtratum were equally ſtrong, the water would ſquecze through many ſmall crannies, and would ooze out in numberleſs places, ſo as to occaſion that kind of wetneſs that is known by the name of ſpouting clayey ſoil.

The cure in this caſe is eaſily effected.—For if a ditch of a conſiderable ſize is opened towards the lowermoſt part of the ſpouting ground, ſo deep as to penetrate through the upper ſtratum of clay, and reach to the gravel, the water will riſe up through it at firſt with very great violence, which will gradually decreaſe as the preſſure from the water behind is diminiſhed; and when the whole of the water accumulated in the ſubterraneous reſervoir is run off, there being no longer any preſſure upon the clay above it, the whole ſoon becomes as dry as could be deſired, and continues ſo ever afterwards, if the ditch is always kept open. This the doctor ſays he can aſſert from experience, having rendered ſome fields of this kind that were very wet quite dry by this method of treating them. The attentive obſerver, he adds, will readily perceive, that if any field that is wet from this cauſe admits of being ploughed, it will be in equal danger of being hurt by being raiſed into high ridges, with the other kind of damp ground before mentioned. For as the depth of earth above the reſervoir would be ſmaller in the deep furrows than anywhere elſe, there would of conſequence be leſs reſiſtance to the water in that place, ſo that it would ariſe there in greater abundance. And if, in this caſe, a farmer ſhould dig a drain in each furrow, as a conſiderable quantity of water would riſe into them, in ſome caſes the ground might be improved, or even quite drained thereby, eſpecially if they ſhould have accidentally reached the gravel in any one place: although at an expence much greater than was neceſſary. "I take notice of this circumſtance, ſays he, in ſome meaſure to prevent the prejudice that ſome inattentive obſervers might entertain againſt what was ſaid before of this method of draining, from their having accidentally ſeen ſome fields that may have been bettered by it.

Preparation of Land.

"Bogs are only a variety of this laſt-mentioned kind of wet ground; and, therefore ought in general to be drained after the ſame manner with them. Clay is a ſubſtance that ſtrongly reſiſts the entrance of water into it: but when it is long drenched with it, it is, in proceſs of time, in ſome meaſure diſſolved thereby; loſes its original firmneſs of texture and conſiſtence; and becomes a ſort of ſemi-fluid maſs, which is called a *bog*; and as theſe are ſometimes covered with a ſtrong ſcurf of a particular kind of graſs, with very matted roots, which is ſtrong enough to bear a ſmall weight without breaking, although it yields very much, it is in theſe circumſtances called a *ſwaggle*. But, whatever be the nature of the bog, it is invariably occaſioned by water being forced up through a bed of clay, as juſt now deſcribed, and diſſolving or ſoftening, if you will, a part thereof. I ſay only a part; becauſe whatever may be the depth of the bog or ſwaggle, it generally has a partition of ſolid clay between it and the reſervoir of water under it, from whence it originally proceeds: for if this were not the caſe, and the quantity of water were conſiderable, it would meet with no ſufficient reſiſtance from the bog, and would iſſue through it with violence, and carry the whole ſemi-fluid maſs along with it. But this would more inevitably be the caſe, if there was a cruſt at the bottom of the bog, and if the cruſt ſhould ever be broken, eſpecially if the quantity of water under it were very conſiderable: and as it is probable, that, in many caſes of this ſort, the water ſlowly diſſolves more and more of this under cruſt, I make no doubt but that, in the revolution of many ages, a great many eruptions of this kind may have happened, although they may not have been deemed of importance enough to have the hiſtory of them tranſmitted to poſterity. Of this kind, although formed of a different ſubſtance, I conſider the flow of the Solway moſs in Northumberland to have been; which, upon the 16th of November 1771, burſt its former boundaries, and poured forth a prodigious ſtream of ſemi-fluid matter, which in a ſhort time covered ſeveral hundred acres of very fine arable ground. Nor will any one, who is acquainted with the nature of moſs,—who knows its reſemblance to clay in its quality of abſorbing and retaining water, and its very eaſy diffuſibility therein, be ſurpriſed at this; as from all theſe properties, it is much better adapted for forming an extenſive bog, and therefore in greater danger of producing an extenſive devaſtation by an irruption of the water into it, than thoſe that are formed of any kind of clay whatever.

"If the bog, or ſwampy ground, is upon a declivity, the ditch ought to be carried acroſs the field about the place where the loweſt ſprings ariſe. But if the ſurface of the ground is level or nearly ſo, ſo as to form ſoft quagmires, interſperſed through the whole of the field, it will be of little conſequence in what part the drain is opened; for if it is dug up ſo deep as to allow the water to riſe in it with freedom, it will iſſue through that opening, and the field will be left perfectly dry.

"But as it may frequently happen that the ſtratum of gravel ſhould be at a conſiderable depth beneath the

Preparation of Land.

furface of the earth, and as it may be fometimes even below the level of the place into which the drain muſt be emptied, it might fometimes be extremely difficult to make a ditch ſo deep as to reach the bed of ſand or gravel. But it is lucky for us that this is not abſolutely neceſſary in the preſent caſe; as a drain of two or three feet deep, will be equally effectual with one that ſhould go to the gravel. All that is neceſſary, in this caſe, is to ſink pits in the courſe of the drain, at a moderate diſtance from one another, which go ſo deep as to reach the gravel; for as the water there meets with no reſiſtance, it readily flows out at theſe openings, and is carried off by the drain without being forced up through the earth; ſo that the ground is left entirely dry ever after.

"I have likewiſe drained ſeveral fields in this way: and as I have generally found the appearances pretty much alike, I ſhall, for the information of the inexperienced reader, give a ſhort account of them.

"If you attempt to make your pit in one of theſe ſoft quaggy places where the water is found in great abundance, you will meet with very great difficulty in forming it; for as the ſubſtance of which it is compoſed is ſoft, it will always flow into the hole as faſt as you dig it; on which account I would adviſe, not to attempt to make the pit in the ſwaggle, but as near it in the ſolid earth as you conveniently can. However, if it is pretty firm, and of no great extent, it is ſometimes practicable to make a pit in the ſoft bog at the drieſt time of the year. This I have ſometimes practiſed, which gave me an opportunity of obſerving the nature of theſe bogs more perfectly than I otherwiſe would have had. In the trials of this kind that I have made, this ſoft quaggy ground has ſeldom been above three or four feet deep; below which I have always found a ſtratum of hard tough clay uſually mixed with ſtones, and ſo firm that nothing but a mattock or pickaxe could penetrate it: and as this is comparatively ſo much drier than the ground above it, an inexperienced operator is very apt to imagine that this is the bottom that he is in ſearch of. In digging through this ſtratum, you will frequently meet with ſmall ſprings oozing out in all directions; ſome of them that might fill the tube of a ſmall quill, and others ſo ſmall as to be ſcarce perceptible: but without regarding theſe, you muſt continue to dig on without intermiſſion till you come to the main body of the reſervoir, if I may ſo call it, that is contained in the rock, gravel, or ſand; which you will generally find from two to four feet below the bottom of the ſwaggle, and which you will be in no danger of miſtaking when you come to it: for, if there has been no opening made before that in the field, as ſoon as you break the crull immediately above the gravel or rock, the water burſts forth like a torrent, and on ſome occaſions riſes like a *jet d'eau*, to a conſiderable height above the bottom of the ditch; and continues to flow off with great impetuoſity for ſome time, till the pent-up water being drained off, the violent boiling up begins to ſubſide, and the ſtrength of the current to abate; and, in a ſhort time, it flows gently out like any ordinary ſpring; —allowing it to remain in this ſtate, the quaggy earth begins to ſubſide, and gradually becomes firmer and firmer every day; ſo that, in the ſpace of a few months, thoſe bogs which were formerly ſo ſoft as hardly to ſupport the weight of a ſmall dog, become ſo firm that oxen and horſes may tread upon them without any danger of ſinking, at the very wetteſt ſeaſon of the year. I have had a field of this nature, that, by having only one ſuch pit as I have now deſcribed opened in it, was entirely drained to the diſtance of above a hundred yards around it in every direction. But as it is poſſible that the ſtratum in which the water runs may be in ſome places interrupted, it will be in general expedient to make ſeveral of theſe pits, if the field is of great extent; always carrying the drain forward through the lowermoſt part of the field, or as near the quag as you conveniently can; and ſinking a pit wherever you may judge it will be moſt neceſſary. But if the ſtratum of gravel is not interrupted, there will be no violent burſt of water at opening any of theſe after the firſt, as I have frequently experienced. To keep theſe wells from cloſing up after they are made, it is always expedient to fill them up with ſmall ſtones immediately after they are made, which ought to riſe to the height of the bottom of the drain.

Preparation of Land.

"I have often imagined that the expence of digging theſe pits might be ſaved by boring a hole through this ſolid ſtratum of clay with a large wimble made on purpoſe; but as I never experienced this, I cannot ſay whether or not it would anſwer the deſired end exactly.

"If the whole field that is to be drained conſiſts of one extenſive bog, it will require a long time before the whole work can be entirely finiſhed, as it will be impoſſible to open a drain through it till one part of it is firſt drained and become ſolid ground. In a ſituation of this kind, the undertaker, after having opened a drain to convey the water from the loweſt part of the bog, muſt approach as near to the ſwampy ground as he can, and there make his firſt pit; which will drain off the water from the neareſt parts of the bog. When this has continued open for ſome time, and that part of the bog is become ſo ſolid as to admit of being worked, let him continue the ditch as far forward through it as the ſituation it is in will admit of, and there ſink another pit; and proceed gradually forward in the ſame manner; making croſs cuts where neceſſary, till the whole be finiſhed.

"In this manner may any bog or tract of ſpouting ground of this nature be rendered dry at a very inconſiderable expence; and as there can be no other method of draining ground of this ſort effectually, I recommend the ſtudy of it to the attention of every diligent farmer who may have occaſion for it. Let him firſt be extremely cautious in examining all the circumſtances of his particular fields, that he may be certain which of the claſſes above enumerated it may be ranked with; and when he is perfectly ſure of that, he may proceed without fear, being morally certain of ſucceſs.

We ſhall add the ſubſtance of a paper on this ſubject, for which the author received the ſilver medal of the Society inſtituted for the encouragement of Arts, Manufactures, and Commerce. That author is Mr John Wedge of Bickenhill, near Coventry, who is not only a great farmer himſelf, but had likewiſe been employed by the earl of Aylesford in the management of ſeveral eſtates. Encouraged by his lordſhip's liberality, Mr Wedge informs the ſociety, that he had

155 Mr Wedge's mode of draining.

been

Preparation of Land.

been employed for some years in draining large portions of land, of which part was in the earl's occupation, and part in his own, as tenant to his lordship. The principles upon which he proceeded, as well as his mode of procedure, he states in the following terms:

In every country there are large portions of land that, in wet seasons, have always what may be called a *dry surface*, and other portions of land that have always a *moist* or *wet surface;* the former of these admitting all the water which falls upon them to sink freely through their pores to various depths, till falling on clay, or some other unctuous earth, whose pores will not permit it to pass through, it is there held up to a height proportioned to the quantity of water which comes upon it, and the facility with which that water is discharged. Thus, held up to various heights, it serves as a fountain to distribute its water (either by veins of sand, pebbles, or rock, according to the formation of the different under strata) on the neighbouring lands; and there forms bogs and other varieties of wet surface, on a basis that will be always found to consist of marl or clay, or some mixture thereof. The effect of water thus distributed may be divided into two classes. The first class, where the water is thrown out by a body of marl or clay, &c. upon the surface of descending ground, and in the valley (there held up by clay also) forms bogs or swamps. The second class, where the water is held up by marl or clay, as before, having above that marl or clay a stratum of sand, or pebbles, through which the water passes; and above those sands or pebbles another stratum of marl or clay, through the weakest parts of which the water, by a continual pressure from its fountain, forces a passage upwards; and thus, through the weakest parts of the marl or clay, furnishes a continual supply of water on the surface, for the formation or growth of bogs, &c. in proportion as this water is more or less abundantly supplied by its fountain or head, namely, the higher lands, into which rain-water freely passes, as before described. There are also different soils, under different circumstances, which may form a third class of land for draining; such as strong deep soils, or open light soils, having near the surface a body of marl or clay. In either of these cases, the water which falls on the surface must, for reasons which are self-evident, keep such lands, in rainy seasons, constantly wet and cold; and it should be observed, that a mixture of all the three before described classes of wet land sometimes occurs in one field, by sudden alterations of the under strata, and thereby perplexes the operator, by requiring all the different modes of draining in the same field.

If it be admitted that bogs are thus formed and fed, their cure may be effected with certainty: The first class, by cutting through the stratum (be it sand, pebbles, or rock), that conveys the water to the bog, and carrying off that water by a close drain to some proper place, where the level admits of its discharge: The second class, by sinking a drain to any convenient depth in the upper clay; and then digging or boring with a large auger, at a small distance on one side of this drain, through the remaining part, be it (the upper clay) ever so deep, into the under stratum of sand, pebbles, or rock, through which the water passes; which will then rush up into the drain so made, with a velocity proportioned to the height of the land or fountain whence it is supplied. As this drain advances through the land, holes must be dug or bored, as before, every seven yards, or at such distance as the strength of the springs may require; and the whole of the water thus brought up by tapping the springs, is carried off by the drain made in the upper clay, which must be a close one, to its proper level, and there discharged.

Prepar. tio of Land.

By both these methods of draining, large tracts of land, under favourable circumstances, may be cured with one drain. The best place for fixing these drains is where the stratum that conveys the water comes nearest to the surface; and the best method of ascertaining that, is to bore or dig in different parts through the different under strata.

The third class may be easily cured by close drains, at such distances and depths as will best carry off the surface-water. It may not be improper to observe, that where the different strata or measures crop out, that is, become gradually more and more shallow in some certain direction (as is often the case, till, one after the other, they all present themselves in succession on the surface of the earth), draining may often be much more easily and better effected by crossing with the drain the different strata or measures, where the levels and other circumstances will admit.

Some of the land drained was part of a common, in the parish of Church Bickenhill, in the county of Warwick; part of it was covered with moss and ling, had a peaty surface, about six inches deep, and produced little or no grass: in all wet seasons it was filled quite to the surface, and often overflowed, with water. Some of the land was much more unsound, deeper of peat, and covered with moss, in most parts nine inches long; another part was an absolute bog in all seasons.

Having dug or bored with a large auger into several parts of the land, Mr Wedge found peat, gravel, and sand mixed, and a quicksand almost uniformly. The quicksand in every part, after getting an inch or two into it, seemed almost as fluid as water, Judging from this, that no materials for a drain could be laid in the quicksand, but what it would immediately bury, he dug a trench almost to the quicksand, leaving gravel, &c. of sufficient strength to bear up the materials for a hollow drain; these materials were two sides and a cover of stone, with a peat-turf on the top to keep out the soil. At every seven yards forward, by the side of this drain, he dug a hole in the quicksand as deep as it would permit. From these holes the water rose freely into the hollow drain, and was by it discharged at a proper level. It may be proper to remark, that the stone made use of for this drain, and all others here mentioned, was a red sand and rag-stone, which easily split into proper sizes for the purpose, and is very durable; it cost about sixpence per ton getting, exclusive of carriage. The drain thus formed ran on the whole rather freely, and made the land dry for a few yards on each side thereof, but was far from having the effect he improperly expected; for it evidently appears that the drain could only take a very small portion of the water from so large a quicksand, which it did not penetrate more than two inches; and that it could drain only to its own depth, or, at most, to that depth in the fountain which supplied the quicksand. His purpose was then defeated; and his motive for mentioning this error cannot, he hopes, be mistaken.

Preparation of Land.

He now did what he says he ought to have done before, that is, he examined the different strata to a greater depth, particularly on the bog, and at the upper edges thereof, and found the bog to be what has been described under the first class. He therefore determined to attempt the cure in the manner before prescribed for that class, namely, to cut through the whole of the stratum (in this instance, of quicksand), through which he found the water pass. This he effected as follows: The summer being dry, and favourable for the purpose, and having previously made his main open drain, he began his main close drain the first week in June 1791, three feet wide, on the declivity near the edge of the great bog. In the first operation he dug through the peat, the hard sand, and gravel, and one spade's graft (about nine inches deep and seven inches wide) into the quicksand, the whole length of this drain, which was 73 perches, of eight yards to the perch, in length. The drain thus dug ran copiously, not less than 60 gallons per minute. In this state he left it about nine days: the effect of it was rapid, both above the drain and on the bog below. Upon examination, he now found about three inches on the top of the spade's graft which had been made into the quicksand, perfectly dry. He then dug out these three inches of dry sand, to nearly the whole width of the drain, three feet; and at the same time dug out, as before, another spade's graft, from the top of the quicksand, as near the middle of the drain as possible. This was left to run a few days, as before, and had the same effect, namely, three or four inches more of the top of the quicksand became dry and hard. The same operation was repeated again and again with the same effect, till the purpose of getting through this quicksand was completed, so far at least as the level of the main open drain would permit. The stream of water continued increasing during the whole operation; the bog below the drain was quite dry, and the land above perfectly so. The drain which was first made, and continued running for some time during the progress of the main close drain, became gradually dry; and has not, since that drain was finished, discharged one single drop of water. Great care was necessary, in making the main close drain, to keep the stream of water in the middle of it, otherwise the current would have undermined the sides, as it sometimes had done, and caused them to fall in. For this reason it was necessary, when the dry sand was taken from the top of the quicksand, immediately to take out a spade's graft from the middle thereof, in order to divert the current from the sides.

The main close drain thus made was three feet wide at top, about nine feet deep on the average, and, bevelling a little from the top, it was about one foot ten inches wide at the bottom. The stone and other materials were put into this drain in the following manner: 1. Where the drain went through the quicksand into the stratum of clay below it, as in most places it did, the bottom, and in some instances the sides, wanted no particular security; but where it did not go quite through the quicksand, which the level of his main open drain in some places would not admit, the bottom of the drain was covered half an inch thick with ling; then peat turfs, one foot wide and three or four inches thick, were cut in convenient lengths, and placed on their edges on each side of the bottom of the drain, forming two sides of a trough of peat; then side stones about eight inches high, and a stone coverer, were put in upon the ling between the peat turfs; a large peat-turf, near two feet wide and four inches thick, was then cut and firmly placed over the whole: this left in the bottom of the drain an open space, of more than six inches square, for the water to pass. The whole was then completed by filling in the upper part of the drain.

In this way the author drained for about 80l. thirty acres of land, which from being of no value whatever, became worth at least 14 shillings per acre of yearly rent. He likewise hollow-drained nine acres by the method prescribed for the third class of wet land. These drains were made a few yards below that part of each field where the dry and wet land separate, about 22 inches deep, with sides and a coverer of stone, and ling on the top of it, to keep the earth from running in. The length of these drains was 880 yards, and the expence of labour and materials three halfpence per yard. The drains, in wet weather, discharge a large quantity of water; and will, he has no doubt, answer the intended purpose. Thus far relates to land in his own occupation.

Nine acres of the land in the earl of Aylesford's occupation was almost an entire pulp. This bog was of the second class, namely, water passing through a quicksand, and confined by a stratum of clay below, and another stratum of clay above it. The water thus confined, being pressed by its fountain, and forced up through the weakest parts of the clay, had formed a bog of irregular thickness on the surface, in some places six feet deep, in others not more than two. As there is a considerable fall in this land from east to west, he thought it expedient to put two drains into it; and this appears to him to have been necessary, from a consideration that both these drains continue to run in the same proportions as when first opened. The manner in which these drains were executed was, by digging through the different upper strata, and as deep into the clay as the main open drain would admit; then digging or boring through the remaining part of that clay into the quicksand, at the distance of about six yards, in a progressive manner.

The water rising rapidly through these holes into the close drains, has effected a complete cure of this land, every part of which will now bear a horse to gallop upon it. These drains discharge 3660 gallons an hour; which is much less than they did at first, as must be the case in all bogs. This land will be worth 20s. per acre. The draining cost 25l.; and the length of the under-ground drains is eight hundred and fourteen yards.

Mr Wedge had just finished (January 1792) draining another piece of land, about forty-three acres. As this was intended to answer two purposes, one, to drain the land, the other to give an additional supply of water to a mill-pool, and as a circumstance arose in the execution of the work which frequently happens in draining land, namely, a sudden alteration in the position of the under strata; a description thereof will not probably be thought tedious. This draining was begun at the level of a mill-pool, and continued, without any great difficulty, to the distance of about thirty-two chains, in the manner before described as a cure

Preparation of Land.

for the ſecond claſs of boggy land: but at or near that place the under ſtrata altered their poſition; the quickſand which conveyed the water now became of twice its former thickneſs; and the clay, which had hitherto been above that quickſand, for ſome diſtance diſappeared. From the quickſand thus becoming ſo much deeper, he could not, with the level of the mill-pool, cut through it; nor indeed, from the wetneſs of the ſeaſon, would ſuch an operation have been proper. He therefore continued a ſhallow drain to ſome diſtance, making ſide-holes into the quickſand, which ran freely; but as this could not cure the whole of the bog below, he branched out another drain (which was made by the method deſcribed for curing the ſecond claſs of wet or boggy land), by ſinking a cloſe drain through the upper ſtrata into the upper clay, and then, at a ſmall diſtance on one ſide of this cloſe drain, boring a hole with an auger through the remaining part of that clay into the quickſand; and at every eight yards, as this cloſe drain advanced, ſtill boring other holes, in the manner before deſcribed: through many of theſe holes the water ruſhed with great rapidity. The water diſcharged by theſe drains into the mill-pool is 168 gallons per minute, or 3780 hogſheads in a day; which is after the rate of 1,379,700 hogſheads in a year.

About ſix acres of this land were always ſound; about twelve acres on the north ſide were an abſolute pulp, and the remaining twenty-ſix acres very unſound. The whole is now ſound, and will when cultivated be worth 16s. per acre. This land would have been drained at a much leſs expence into the main open drain; but then the water, which was much wanted for the mill, would have been loſt. Theſe cloſe drains are in length 1452 yards, and coſt 100l. of which about 30l. ought to be charged to the mill.

189 Draining of land-locked bogs.

With regard to the drainage of land-locked bogs, which are often ſituated ſo much lower than the ground around them, that the cutting a main drain would coſt more than the value of the land when drained; the mode of proceeding, with a view at once cheaply and effectually to relieve them from the ſuperfluous moiſture which renders them uſeleſs to agriculture, is the following: A ſpot in the middle or loweſt part of the bog muſt be ſelected, towards which all the drains muſt be conducted, as radii to a common centre. When this central ſpot is properly cleared out to the top of the clay, or retentive ſubſtratum, which in this caſe muſt not be affected by water from below, but only by ſurface or rain water, a number of perforations muſt be made with the auger, to give an outlet downwards for the water, which will be abſorbed by the porous ſtratum below. A conduit ſhould be formed over the auger holes, by looſe ſtones, placed in ſuch a manner as to prevent their being afterwards filled up by any rubbiſh: or rather auger holes may not be ſufficient; and it may be a preferable plan to make a large pit, or well, in the loweſt part of the bog, dug through into the porous ſubſtrata. This pit ought to be filled with large ſtones, and the drains from the reſt of the field conducted to that ſpot, as mentioned in the following quotation from the Agricultural Report of Hertfordſhire.—"If a pit is ſunk 20 or 30 feet deep in the middle of a field, through the Hertfordſhire red, flinty, and impervious clay, into the chalk below; when the uſual quantity of chalk is taken out, the pit ſhaft is filled up with the flint taken out of the chalk and clay, and the top drainage of this part of the field is much ſhortened for ever afterwards, by making principal drains from the part of the field above the level of the top of the pit terminate therein, as the ſuperabundant moiſture will eſcape through the flints in the pit ſhaft to the chalk below. And if a drain is carried into a limeſtone quarry, it is ſeldom neceſſary to carry it further.

Preparation of Land.

"In dells or hollows, of conſiderable extent, covered with an impervious ſtratum, and from which there is no natural drainage, ſuch as the valley between Mold, the ſhire-town of Flintſhire, and the adjoining high land, a pit about four feet diameter, and 15 feet deep, more or leſs, as the caſe may require, is ſunk through the impervious ſuperſtratum, into a pervious ſtratum of gravel, and the rain water, and that of ſome adjoining ſprings, are carried from the ſurface thereby; the pit is railed round to prevent cattle from falling into it. I muſt here remark, that though in this, as well as in many other inſtances that may be given, the top water eſcaped through the pervious ſubſtratum, the effect might have been directly the contrary. I therefore recommend the impervious ſuperſtratum, in all ſuch caſes, to be perforated by bore-rods, as the hole made by them is eaſily ſtopped up."

190 German mode of draining land-locked bogs.

In Dr Nugent's travels through Germany, publiſhed in 1768, a mode of draining marſhes upon ſimilar principles is deſcribed, as having been practiſed in that country. He had only ſeen it performed on moor grounds, though it is alſo ſucceſsful with regard to lakes. "It is the nature, ſays he, of moors in general, that beneath the turf or moſs there is a loam which hinders the moiſture from penetrating; and this indeed is what makes the marſh, and cauſes the luxuriant growth of the turf or moſs; but this loam or clay is only a ſtratum, and far from being of an immenſe depth; under it is generally a ſand, or ſome other ſtony or looſe ſoil.

"Here reaſon readily informs us, that a middling moraſs may be drained by perforating the clay, and thus making way for the moiſture to penetrate. In order to this, a pit is dug in the deepeſt part of the moor, till they come below the obſtructing clay, and meet with ſuch a ſpongy ſtratum as, in all appearance, will be ſufficient to imbibe the moiſture of the marſh above it. Into this pit the ebbing of the moraſs is conveyed through a trench, and both the trench and the pit are filled up after the firſt drain with large broad ſtones, ſetting them edgewiſe, ſo as to leave interſtices for carrying off the water; then ſuch ſtones are laid over breadthwiſe, and theſe covered with looſe earth like that on the ſurface: when no ſuch ſtones are to be had, ſtrong piles are rammed down the ſides of the trench, and broad boards laid acroſs; and theſe are covered with earth to a height fit for culture. This is a matter of no great expence, the pit being as near the moraſs as the water will admit, and the trenches but ſhort; then they have a drain unperceived, which leaves the ſurface of the trenches for the plough; and in middling marſhes, eſpecially in ſuch moors as are only wet and damp, this method, though ſometimes ſlow, never fails taking effect; and many tracts are thereby made ſerviceable to the farmer or grazier."

191 Draining Roxburgſhire.

The writer of the Roxburghſhire Agricultural Report repreſents

Preparation of Land.

represents himself as having successfully adopted a similar mode of draining. In that part of the country, such of the waste lands, as are capable of being drained so as to become arable, have, at the distance of from one to six feet below the surface, a large stratum or seam of a black slaty or metallic substance, generally from 20 to 25 feet in thickness. Below this is a layer of whinstone rock of unknown depth. The black slaty or metallic substance has no chinks or fissures, and is impenetrable to water; but the whinstone rock beneath it abounds with chinks and fissures, and will swallow up any quantity of water poured into its bosom. The uppermost surface of the soil is of a light mossy nature, upon which the water stagnates in winter, so as to swell and enlarge it to a considerable degree. In the spring months, when dried by the sun and the wind, the moss becomes tolerably firm, and produces a coarse unprofitable grass, mixed with short heather; neither of which are of any value as food for sheep or cattle. In the year 1784 the writer of the Report ploughed up 20 acres of the waste lands of the above description, a part of them being situated on a level. This last part was gathered in small ridges, and ploughed pretty deep, and the stones removed. Thus it lay till midsummer 1785; but, during the spring, the sheep and cattle were frequently driven upon it to tread it to a firm consistence. At midsummer it was gathered up again; and, to get the water out of the hollows of the ridges, a pair of boring rods were obtained, which were put down through the slaty substance to the whinstone rock at sundry places. This effectually answered the purpose. The tops of the holes were kept open with baskets of loose stones over them, which were allowed to remain or removed at pleasure, as the weather proved more or less wet. In spring 1786 the land was in a condition to sow almost as early as any other part of the farm, the winter rains having found their way down into the whinstone rock through the slaty substance, and the land speedily became and continued very valuable.

192 Draining of quarries and mines.

We may here add, that the modes of draining now stated are also valuable for other purposes than those of agriculture. Quarries, for example, and marl pits may often be cleared of water, by cutting off the springs by which they are incommoded, or by letting down the water into the next porous stratum. The same may be often done, with regard to deep mines, the working of which may frequently be thus greatly facilitated. A colliery, for example, in Yorkshire had been wrought for several years, and the water was raised from it about 60 yards by a steam engine. The proprietors having bored about ten yards farther, to ascertain the thickness of a seam of coals; as soon as the boring rods were withdrawn, the water from the works, which usually ran across that place, began to sink into the holes made by the rods; and continuing to do so, the steam engine became useless, as its pump had no longer any water to draw. It must be observed, that the situation was higher than the nearest valleys, or the level of the sea; but this example shows of what extensive importance a knowledge of the principles upon which the above modes of draining proceed may hereafter become.

3. Of rendering Mosses fit for Cultivation.

In many parts of the country a very serious obstruction to the cultivation of large portions of territory arises from the existence of mosses. It is, therefore, of much importance to consider their nature, and how they are to be rendered fertile. Preparation of Land.

193 Nature and origin of mosses.

With regard to the nature and origin of moss, the celebrated Dr Anderson, whose works we have already frequently quoted, advances this opinion, that moss is a vegetable, or an assemblage of vegetables, growing or living below, while at the top it is dead. Hence, he distinguishes moss into two kinds; quick moss from which peats are dug, on which no vegetables grow, and in which no animals exist, while in its natural situation; and dead moss, which frequently covers the former, and upon which heath and fog and coarse grasses grow, and insects and other animals are found. Mr Headrick states various objections to this opinion, some of which appear to have great force. Thus, it is observed, that the moss here supposed to be alive below the soil, has every mark of utter deadness and partial dissolution. When tossed about in a very dark night, it emits light like half rotten wood, giving rise to frequent terrors in those who live in the vicinity of peat bogs. It also seems a strange circumstance, and contrary to the whole analogy of nature, to suppose that a vegetable should grow, should form ligneous fibres, and acquire inflammability, without the influence of the sun, or contact with the air, during any period of its growth. The true history of the origin of mosses seems to be this: What are called the moss plants, amount to about three hundred in number. They are extremely hardy, and are capable of flourishing in the most cold and bleak situations, providing only they are surrounded by abundance of stagnating water. Accordingly, wherever water stagnates in a moderate quantity, they grow up, and, by spreading themselves around, they increase the stagnation. When they have arisen in this manner, with the water around them, to a considerable height, the lower part of their stems being continually soaked or macerated in water, cease to vegetate, and give forth their juices to the surrounding fluid. As the moss plants are extremely astringent, and contain large quantities of the gallic acid and tanning principle, the moss water acquires these qualities, or becomes astringent, in a great degree, and prevents any process of putrefaction from taking place, or the stems of the moss plants from suffering any proper process of rottenness or chemical decomposition. Hence it is, that moss water has sometimes been used for tanning leather, in the same manner as the liquor of oak bark. In the mean time, while the stems of the moss plants remain in this manner dead, but prevented from rotting, or becoming the habitation of animals which cannot live in a vegetable astringent liquor, the tops of the plants that are at the surface of the water continue to grow, or new plants rise upon the summits of the dead ones, and continue their ascending progress; the whole being perhaps a sort of parasitical plants, which can grow upon each other. *Communications to the Board of Agriculture*, vol. ii.

In this way, a moss proceeds, rising higher and higher, till from the nature of the adjoining country, and the declivities in it, the water cannot stagnate to any greater depth. After the moss has come to this height, its farther growth is prevented, its plants, unable to live or grow without abundance of water, wither and die; the upper part of them being exposed to the action of the air, suffers an ordinary process of decomposition,

Preparation of Land.

like other vegetable remains, and is converted into a ſort of ſoil, upon which a few plants and reptiles are ſometimes found; while at a ſmall depth, that is to ſay, below the ſurface of the ſtagnating water, the whole ſtems of the ancient moſs plants continue macerated in their own liquor, and preſerved from putrefaction by it.

194 Black and yellow moſs.

There are, however, two general kinds of moſſes; black moſs, and whitiſh or yellow moſs. The black moſs is originally of a mahogany colour, but ſpeedily becomes black upon expoſure to the air. The yellowiſh, or foggy moſs, is much leſs compact than the former, and retains a light or yellowiſh colour after it is dried. It does not appear to be in ſuch a perfect ſtate of maceration as the black moſs, has leſs variety of plants, and is never ſo ſolid. It is uſually produced in low warm ſituations, and appears to have grown rapidly; whereas, the black moſs is moſt commonly found in cold elevated lands, and ſeems to have conſiſted of a greater number of leſs luxuriant plants. Thus, moſs may be regarded as bearing ſome reſemblance to timber, which is always of a compact grain, and cloſe texture, in proportion to the ſeverity of the climate of which it is the product, or rather in proportion to the length of time which it has taken to grow.

From what has been here ſtated, it will not be difficult to underſtand the mode in which moſſes come originally to find an exiſtence, or to cover a piece of territory in any country. When a pool of water is ſpeedily, or in a ſhort time, formed to a great depth, no moſs appears; but when a gradual ſtagnation to a ſmall depth takes place, upon any ſpot, eſpecially in a cold and expoſed ſituation, there the moſs plants (being the only ones capable of ſubſiſting on ſuch a ſoil) ſpeedily grow up, and occupy the place of every other. Though the quantity of water that originally ſtagnated there might not be great, it is increaſed by degrees, in conſequence of the additional obſtruction produced by the roots, ſtems, and leaves of the moſs plants, till at laſt it forms a bog of very great depth.—We have already mentioned the nature and cauſe of the ſtagnation of water. It may either occur in conſequence of the figure and quality of the ſoil making it tenaciouſly to retain the falling rains, or it may be the conſequence of ſprings or reſervoirs of water pent up or confined in the bowels of the earth by an incumbent maſs of clay. Struggling to riſe up through this clay, it will wet every part of it, and will ſlowly ooze through all its leſs adheſive parts, and will form a ſoil fit only for the reception of moſs plants, which will there, by obſtructing the departure of the moiſture, which is conſtantly riſing, in the courſe of years rear up the ſurface into a complete and perfect peat-bog.

195 Moſſes produced by cutting down foreſts.

But moſſes not only ariſe in particular ſituations, in conſequence of theſe operations of nature: They are alſo produced as the reſult of certain exertions of human induſtry. In almoſt all our moſſes in this country great numbers of trees of various ſorts are found. They remain, like the inferior parts or roots of moſs plants, infuſed and macerated in the moſs water, but not rotted. The trees and ſhrubs found at the bottom of moſſes in Scotland, exhibit, perhaps the whole variety of the native trees and ſhrubs. Of trees, are found the oak, the elm, the birch, the willow, the alder, and fir. Of ſhrubs, we find the hazel, the dwarf willow, the gall plant, and laſtly, the heath plant. This laſt is of ſo hardy a nature, that it often continues to riſe upon the moſs during the whole period of its exiſtence. Now, if it ſhould be ſuppoſed, that at any time extenſive foreſts of theſe trees were ſuddenly cut down by the exertions of man, they would undoubtedly produce a ſtagnation of water, and a bleakneſs of climate, that would render the ſituation fit only to be inhabited by moſs plants, which would therefore ſpeedily riſe up, and form a peat-bog, in which multitudes of trees and ſhrubs would be found ſoaked in their own juice, and in the aſtringent liquor reſulting from the maceration of the ſtems of the moſs plants. That in ancient times old foreſts were thus deſtroyed by the efforts of man, we have every reaſon to believe. Not only in this country, but alſo in England and Ireland, there are found in moſſes vaſt numbers of trees ſtanding with their ſtumps erect, and their roots piercing the ground in a natural poſture as when growing. Many of thoſe trees are broken or cut off near the roots, and lie along, and this uſually in a north-eaſt direction. People who have been willing to account for this, have uſually reſolved it into the effect of the deluge in the days of Noah; but this is a very wild conjecture, and is proved falſe by many unanſwerable arguments. The waters of this deluge might indeed have waſhed together a great number of trees, and buried them under loads of earth; but then they would have lain irregularly and at random; whereas, in this caſe, the trees all lie lengthwiſe from ſouth-weſt to north-eaſt, and the roots all ſtand, in their natural perpendicular poſture, as cloſe as the roots of trees in a foreſt.

Preparation of Land.

Beſides, theſe trees are not all in their natural ſtate, but many of them have the evident marks of human workmanſhip upon them, ſome being cut down with an axe; ſome ſplit, and the wedges ſtill remaining in them; ſome burnt in different parts, and ſome bored through with holes. Theſe things are alſo proved to be of a later date than the deluge, by other matters found among them, ſuch as utenſils of ancient people, and coins of the Roman emperors.

It appears from the whole, that all the trees which we find in this foſſil ſtate, originally grew in the very places where we now find them, and have only been thrown down and buried there, not brought from elſewhere. It may appear indeed an objection to this opinion, that moſt of theſe foſſil trees are of the fir kind; and that Cæſar ſays expreſsly, that no firs grew in Britain in his time: but this is eaſily anſwered by obſerving that theſe trees, though of the fir kind, yet are not the ſpecies uſually called the *fir*, but pitch tree; and Cæſar has nowhere ſaid that pitch trees did not grow in England. Norway and Sweden yet abound with theſe trees; and there are at this time whole foreſts of them in many parts of Scotland, and a large number of them wild upon a hill at Wareton in Staffordſhire to this day.

In Hatfield marſh, where ſuch vaſt numbers of the foſſil trees are now found, there has evidently once been a whole foreſt of them growing. The laſt of theſe was found alive, and growing in that place, within 70 years laſt paſt, and cut down for ſome common uſe.

It is alſo objected by ſome to the ſyſtem of the firs growing where they are found foſſil, that theſe countries

Preparation of Land.

tries are all bogs and moors, whereas theſe ſorts of trees grow only in mountainous places. But this is founded on an error; for though in Norway and Sweden, and ſome other cold countries, the fir kinds all grow upon barren and dry rocky mountains, yet in warmer places they are found to thrive as well on wet plains. Such are found plentifully in Pomerania, Livonia, Courland, &c.; and in the weſt parts of New England there are vaſt numbers of fine ſtately trees of them in low grounds. The whole truth ſeems to be, that theſe trees love a ſandy ſoil; and ſuch as is found at the bottoms of all the moſſes where theſe trees are found foſſil. The roots of the fir kind are always found fixed in theſe; and thoſe of oaks, where they are found foſſil in this manner, are uſually found fixed in clay: ſo that each kind of tree is always found rooted in the places where they ſtand in their proper ſoil; and there is no doubt to be made but that they originally grew there. When we have thus found that all the foſſil trees we meet with once grew in the places where they are now buried, it is plain that in theſe places there were once noble foreſts, which have been deſtroyed at ſome time; and the queſtion only remains how and by whom they were deſtroyed. This we have reaſon to believe, by the Roman coins found among them, was done by the people of that empire, and that at the time when they were eſtabliſhed or eſtabliſhing themſelves here.

Their own hiſtorian tells us, that when their armies purſued the wild Britons, theſe people always ſheltered themſelves in the miry woods and low watery foreſts. Cæſar expreſsly ſays this; and obſerves, that Caſſibelan and his Britons, after their defeat, paſſed the Thames, and fled into ſuch low moraſſes and woods that there was no purſuing them: and we find that the Silures ſecured themſelves in the ſame manner when attacked by Oſtorius and Agricola. The ſame thing is recorded of Venutius king of the Brigantes, who fled to ſecure himſelf into the boggy foreſts of the midland part of this kingdom: and Herodian expreſsly ſays, that in the time of the Romans puſhing their conqueſts in theſe iſlands, it was the cuſtom of the Britons to ſecure themſelves in the thick foreſts which grew in their boggy and wet places, and when opportunity offered, to iſſue out thence and fall upon the Romans. The conſequence of all this was the deſtroying all theſe foreſts; the Romans finding themſelves ſo plagued with parties of the natives iſſuing out upon them at times from the foreſts, that they gave orders for the cutting down and deſtroying all the foreſts in Britain which grew on boggy and wet grounds. Theſe orders were punctually executed; and to this it is owing that at this day we can hardly be brought to believe that ſuch foreſts ever grew with us as are now found buried.

The Roman hiſtories all join in telling us, that when Suetonius Paulinus conquered Angleſea, he ordered all the woods to be cut down there, in the manner of the Roman generals in England: and Galen tells us, that the Romans, after their conqueſt in Britain, kept their ſoldiers conſtantly employed in cutting down foreſts, draining of marſhes, and paving of bogs. Not only the Roman ſoldiers were employed in this manner, but all the native Britons made captives in the wars were obliged to aſſiſt in it: and Dion Caſſius tells us, that the emperor Severus loſt no leſs than 50,000 men in a few years time in cutting down the woods and draining the bogs of this iſland. It is not to be wondered at, that ſuch numbers executed the immenſe deſtruction which we find in theſe buried foreſts. One of the greateſt ſubterranean treaſures of wood is that near Hatfield; and it is eaſy to prove, that theſe people, to whom this havock is thus attributed, were upon the ſpot where theſe trees now lie buried. The common road of the Romans out of the ſouth into the north, was formerly from Lindum (Lincoln) to Segelochum (Little Burrow upon Trent), and from thence to Danum (Doncaſter), where they kept a ſtanding garriſon of Criſpinian horſe. A little off on the eaſt, and north-eaſt of their road, between the two laſt named towns, lay the borders of the greateſt foreſt, which ſwarmed with wild Britons, who were continually making their ſallies out, and their retreats into it again, intercepting their proviſions, taking and deſtroying their carriages, killing their allies and paſſengers, and diſturbing their garriſons. This at length ſo exaſperated the Romans, that they were determined to deſtroy it; and to do this ſafely and effectually, they marched againſt it with a great army, and encamped on a great moor not far from Finningly: this is evident from their fortifications yet remaining.

Preparation of Land.

There is a ſmall town in the neighbourhood called *Oſterfield;* and as the termination *field* ſeems to have been given only in remembrance of battles fought near the towns whoſe names ended with it, it is not improbable that a battle was fought here between all the Britons who inhabited this foreſt and the Roman troops under Oſtorius. The Romans ſlew many of the Britons, and drove the reſt back into this foreſt, which at that time overſpread all this low country. On this the conquerors taking advantage of a ſtrong ſouth-weſt wind, ſet fire to the pitch-trees, of which this foreſt was principally compoſed; and when the greater part of the trees was thus deſtroyed, the Roman ſoldiers and captive Britons cut down the remainder, except a few large ones which they left ſtanding as remembrances of the deſtruction of the reſt. Theſe ſingle trees, however, could not ſtand long againſt the winds, and theſe falling into the rivers which ran through the country, interrupted their currents; and the water then overſpreading the level country, made one great lake, and gave origin to the moſſes or moory bogs, which were afterwards formed there, by the workings of the waters, the precipitation of earthy matter from them, and the putrefaction of rotten boughs and branches of trees, and the vaſt increaſe of water moſs and other ſuch plants which grow in prodigious abundance in all theſe ſorts of places. Thus were theſe burnt and felled trees buried under a new formed ſpongy and watery earth, and afterwards found on the draining and digging through this earth again.

Hence it is not ſtrange that Roman weapons and Roman coins are found among theſe buried trees; and hence it is that among the buried trees ſome are found burnt, ſome chopped and hewn; and hence alſo it is that the bodies of the trees all lie by their proper roots, and with their tops lying north-eaſt, that is, in that direction in which a ſouth-weſt wind would have blown them down: hence alſo it is, that ſome of the trees

are

Preparation of Land.

are found with their roots lying flat, these being not cut or burned down, but blown up by the roots afterwards when left single; and it is not wonderful, that such trees as these should have continued to grow even after their fall, and shoot up branches from their sides which might easily grow into high trees. (*Phil. Trans.* N° 275.).

By this system it is also easily explained why the moor soil in the country is in some places two or three yards thicker than in others, or higher than it was formerly, since the growing up of peat earth or bog ground composed of moss plants is well known, and the soil added by overflowing of waters is not a little.

As the Romans were the destroyers of this great and noble forest, so they were probably also of the several other ancient forests; the ruins of which furnish us with the bog wood of Staffordshire, Lancashire, Yorkshire, and other counties. But as the Romans were not much in Wales, in the Isle of Man, or in Ireland, it is not to be supposed that forests cut down by these people gave origin to the fossil wood found there; but though they did not cut down these forests, others did; and the origin of the bog wood is the same with them and with us. Holinshead informs, that Edward I. being not able to get at the Welsh because of their hiding themselves in boggy woods, gave orders at length that they should all be destroyed by fire and by the axe; and doubtless the roots and bodies of trees found in Pembrokeshire under ground, are the remains of the execution of this order. The fossil wood in the bogs of the island of Man is doubtless of the same origin, though we have not any accounts extant of the time or occasion of the forests there being destroyed; but as to the fossil trees of the bogs of Ireland, we are expressly told, that Henry II. when he conquered that country, ordered all the woods to be cut down that grew in the low parts of it, to secure his conquests, by cutting away the places of resort of rebels.

The tendency of our climate to produce in cold and damp situations moss plants, which gradually form around themselves a liquor which is the enemy of all putrefaction, may be considered as a fortunate circumstance, upon the whole, for the preservation of the health of men and animals, as well as contributing to other valuable purposes. In considering the nature of moss, "I cannot dismiss the subject (says Mr Headrick) without suggesting my admiration at the beneficence of Providence, in having provided the moss plants for the situations in which they grow: they afford an immediate supply of fuel, and are the source from which pit-coal derives its origin, though trees, and all the plants which abound in oils and carbon also contribute to the supply of pit-coal. Were the places now occupied by mosses divested of vegetables, or stored with vegetables of a different character, they would become noisome fens, which, by the emission of putrid gasses, would spread all around them pestilence and death. Mosses emit no noxious gasses, but rather, by growing at the surface, where the plants are acted upon by the sun's rays, they perpetually throw out oxygen, and thus contribute to the salubrity of the atmosphere. The only defect with which they are chargeable is forming magazines of moisture, which by its exhalation generates cold, and spreads rheumatism and intermitting fevers among all the animals within its reach. The perpetual evaporation of this moisture not only tends to chill the moss, but it descends in hoar-frost and mildews upon all the lands that are lower in point of situation. These last mentioned disadvantages are more than amply compensated by the consideration that moss is not only an inexhaustible magazine of manure for other soils, but may be converted into a most fertile soil itself. After it is so converted, none of the defects already stated are any longer applicable to it."

Preparation of Land.

This gentleman analyzed chemically some specimens of moss. He found that a small portion of Berkshire peat of great hardness exhibited, when pounded in a mortar and infused in warm water, a liquor that had some slight marks of acidity by test paper. Gypsum and sulphat of magnesia appeared to exist in it. A purified potash produced an abundant precipitation of various substances. A portion of this peat being burned, gave forth at the close of the operation a sulphureous smell and flame. The white ashes, after some days, assumed a rusty colour, from iron contained in them. Being washed, the liquor appeared to contain sulphates of lime, magnesia, alumine, and iron. Black hard peat of Swinridgemuir, in Ayrshire, when burned, gave brown ashes which were attracted by the magnet. An infusion of them in water exhibited no mark of acid or of alkali, and the ingredients contained in it appeared to be the same as in the Berkshire peat. Foggy or yellow peat yielded a smaller quantity of ashes, which were white, and did not obey the magnet.

Moss water, obtained by squeezing light peats, contained gallic acid and tanning principle in great quantities. Quicklime appeared to be the most powerful agent in precipitating every substance from the moss water, and in rendering moss a compact and solid substance; a fact which, as will be afterwards noticed, has been successfully taken advantage of in practice.

There are two ways in which a tract of territory that is covered by moss may be reduced under the dominion of the plough, or rendered fit for the purposes of agriculture. The one consists of altogether removing the mossy substance, or the whole wrecks of the moss plants that have been accumulating for ages, and endeavouring thereafter to cultivate the subsoil. The other mode consists of converting the substance of the moss into vegetable mould fit for bearing crops of grain.

The first of these plans has been adopted with regard to the moss of Kincardine, and the other has been successfully practised by Mr Smith of Swinridgemuir, in Ayrshire; and in imitation of him by various other persons in different districts of the country. To each of these we shall give attention.

196 The moss of Kincardine removed by human labour

The moss of Kincardine is a remarkable tract of ground in the shire of Perth, in Scotland, which deserves particular notice, both as a topographical curiosity or subject of natural history, and for the information, equally uncommon and important, which it affords, respecting agricultural improvements, and the promotion of industry and population.

The moss of Kincardine is situated in the parish of the same name, comprehended between the rivers Forth and Teith, and in that district of Perthshire called *Monteith*. The moss begins about a mile above the confluence of these rivers; from thence it extends in length

Preparation of Land.

length about four miles, and from one to two in breadth; and before the commencement of the operations (an account of which is to be given), comprehended near 2000 Scots acres, of which about 1500 belong to the eſtate of Blair Drummond, the property of the late Lord Kames, by his marriage with Mrs Drummond of Blair Drummond.

As moſſes are extremely various in their nature; before entering upon the improvements made in Kincardine moſs, it will be proper to give a ſhort deſcription of that moſs, and of the ſubjacent ſoil which is the object of theſe improvements.

The moſs lies upon a field of clay, which is a continuation of thoſe rich extenſive flats in the neighbourhood of Falkirk and Stirling, diſtinguiſhed by the name of *carſes*. This clay, which is one uniform homogeneous maſs ſinking to a great depth, is found near the ſurface, conſiſts of different colours, and is diſpoſed in layers. The uppermoſt is gray; the next is reddiſh; and the loweſt, which is the moſt fertile, is blue. Through the whole maſs not a pebble is to be found. The only extraneous bodies it contains are ſea-ſhells, which occur in all the varieties peculiar to the eaſtern coaſt of Scotland. They are diſpoſed ſometimes in beds, ſometimes ſcattered irregularly at different depths. By attending to theſe circumſtances, it cannot be doubted that the ſea has been the means of the whole accumulation, and that it was carried on in a gradual manner by the ordinary ebb and flow of the tide. Upon any other ſuppoſition, why ſhould there not have been a congeries of all the different materials that compoſe the ſurface of the ſurrounding heights? But to whatever cauſe the origin of this accumulation may be aſcribed, certain it is that no ſoil whatever is more favourable to vegetation, or carries more abundant crops of every kind.

The ſurface of the clay, which, upon the retreat of the ſea, had been left in an almoſt level plane, is everywhere thickly covered with trees, chiefly oak and birch, many of them of a great ſize. Theſe trees ſeem to have been the firſt remarkable produce of the carſe; and it is probable they were propagated by diſſemination from the ſurrounding eminences. They are found lying in all directions beſide their roots, which ſtill continue firm in the ground in their natural poſition; and from impreſſions ſtill viſible, it is evident they have been cut with an axe or ſome ſimilar inſtrument. For the cutting of wood, the two common purpoſes are, either to apply it to its proper uſe, or that the ground it occupies may be cultivated. In the preſent caſe, however, neither of theſe ends had been propoſed, ſince the trees, by being juſt left as they were cut, were not only entirely loſt, but the ground was rendered totally unfit for cultivation. Hence it is evident, that the downfal of this wood muſt be aſcribed to ſome more extraordinary cauſe; and to none more probably than to that expedient, which, as we learn from Dion Caſſius and other hiſtorians, the Romans put ſo extenſively in practice to diſlodge from their foreſts the ancient inhabitants of the Britiſh iſlands, as already explained.

This hypotheſis acquires no ſmall degree of force from a circumſtance that occurred in May 1768, when a large round veſſel of thin braſs and curious workmanſhip, 25 inches in diameter, and 16 inches in height, was diſcovered upon the ſurface of the clay buried under the moſs. This veſſel, found upon the eſtate of John Ramſay, Eſq. of Ochtertyre, was by that gentleman preſented to the Antiquarian Society of Edinburgh; in whoſe muſeum it remains depoſited for preſervation. And in a liſt of the various donations preſented to that ſociety, publiſhed by them in 1782, it is there denominated a *Roman camp kettle*.

Between the clay and the moſs is found a ſtratum nine inches thick, partly dark brown and partly of a colour approaching to black. This is a vegetable mould, accumulated probably by the plants that covered the ground previous to the growth of the wood, and by leaves from the trees thereafter. The difference of colour muſt be owing to a difference in the vegetable ſubſtances that compoſe it. The brown mould is highly fertile; the other, eſpecially in a dry ſeaſon, is very unproductive. The crop that had occupied this mould when the trees were felled is found ſtill entire. It conſiſts chiefly of heath; but ſeveral other ſmaller plants are alſo very diſtinguiſhable.

Immediately above this ſtratum lies the moſs, to the height, upon an average, of ſeven feet. It is compoſed of different vegetables arranged in three diſtinct ſtrata. Of theſe the firſt is three feet thick. It is black and heavy, and preferable to the others for the purpoſe of fuel. It conſiſts of bent graſs (*agroſtis*), which ſeems to have grown up luxuriantly among the trees after they were felled. The ſecond ſtratum alſo is three feet thick. It is compoſed of various kinds of moſſes, but principally of bog-moſs (*ſphagnum*). It is of a fallow or iron colour, and remarkably elaſtic. It is commonly called *white peat*; and for fuel is conſidered as much inferior to that above mentioned. The third ſtratum is compoſed of heath and a little bent graſs, but chiefly of the deciduous parts of the former. It is about a foot thick, and black.

By far the greateſt part of the moſs in queſtion is, upon an average, full ſeven feet deep, and has in all probability lain undiſturbed ſince its formation: this is called the *High Moſs*. The remainder, called the *Low Moſs*, lies to a conſiderable breadth around the extremities of the high; and is, upon an average, not above three feet in depth, to which it has been reduced by the digging of peats. Theſe are formed of that ſtratum of the moſs only that lies four feet below the ſurface and downwards; the reſt is improper for the purpoſe, and is thrown aſide.

Before the introduction of the plan which is now purſued, two methods chiefly were employed to gain land from the moſs. 1ſt, The ſurrounding farmers marked off yearly a portion of the low moſs next to their arable land, about 15 feet broad. This they removed with carts and ſpread upon their fields, ſome acres of which they for that end left unſown. Here it lay till May or June; when, being thoroughly dry, it was burnt to aſhes to ſerve as a manure. By this means they added to their farms about half a rood of land yearly. But this plan proved unſucceſsful; for by the repeated application of theſe aſhes, the ſoil was rendered ſo looſe that the crops generally failed. 2dly, Many farmers were wont to *trench down* the low moſs, and to cover it *furrow deep* with clay taken out of the trench. This, though commendable as an attempt to improve,

Preparation of Land.

improve, proved likewiſe an unavailing method; becauſe in a dry ſeaſon the ſuperficial covering of clay retains ſo little moiſture that the crop commonly fails.

It has been attempted to cover the moſs with clay brought from the adjacent grounds. But what from the neceſſary impoveriſhment of the ground from which the clay was carried, and the ſoftneſs of the moſs, this was ſoon found to be impracticable.

Draining has alſo been propoſed as another mode of improvement: and it muſt be acknowledged, that, by means of draining, many moſſes have been converted both into arable and meadow grounds, which in the end became intereſting improvements. But in a moſs, ſuch as that of Kincardine, this method would be ineffectual; as for ſeveral feet deep it is of ſuch a nature, that upon being dry, and divided into parts, it would blow with the wind like chaff; and when thrown aſide in the operation of digging peats, it lies for years without producing a ſingle vegetable, except only a few plants of ſorrel.

Hence it was thought evident, that all attempts to *improve* this moſs muſt ever prove abortive; and that the object to be had in view was the acquiſition of the valuable ſoil lying underneath; to which end nothing leſs was requiſite than the total abolition of the moſs.

By the methods above deſcribed from 100 to 200 acres of moſs had been removed. When the preſent plan was introduced, there ſtill remained covered with moſs from 1300 to 1400 acres of carſe clay—a treaſure for which it muſt be ever intereſting to dig.

In the year 1766 Lord Kames entered into poſſeſſion of the eſtate of Blair Drummond. Long before that period he was well acquainted with the moſs, and often lamented that no attempt had ever been made to turn it to advantage. Many different plans were now propoſed; at length it was reſolved to attempt, by means of water as the moſt powerful agent, entirely to ſweep off the whole body of moſs.

That moſs might be floated in water, was abundantly obvious; but to find water in ſufficient quantity was difficult, the only ſtream at hand being employed to turn a corn mill. Convinced of the ſuperior conſequence of dedicating this ſtream to the purpoſe of floating off the moſs, Lord Kames having made an agreement with the tenant who farmed the mill, and the tenants thirled conſenting to pay the rent, he immediately threw down the mill, and applied the water to the above purpoſe.

In order to determine the beſt manner of conducting the operation, workmen were now employed for a conſiderable time upon the low moſs both by the day and by the piece, to aſcertain the expence for which a given quantity of moſs could be removed. It was then agreed to operate at a certain rate per acre; and in this manner ſeveral acres were removed.

But this was to be a very expenſive proceſs. The ground gained might, indeed, be afterwards let to tenants; but every acre would require an expenditure from 12l. to 15l. before it could be ready for ſowing; ſo that the acquiſition of the whole, computing it at a medium to be 1350 acres, would ſink a capital of nearly 20,000l. ſterling.

One other method ſtill remained; namely, to attempt letting portions of the moſs, as it lay, for a term of years ſufficient to indemnify tenants for the expences incurred in removing it. For ſome time both theſe plans were adopted; but ſeveral reaſons made the latter preferable: 1. The quantity of water to be had was ſmall; and being alſo uncertain, it was very inconvenient for an undertaker; neither were there any houſes near the ſpot, which occaſioned a great loſs of time in going and coming: but when a man ſhould live upon the ſpot, then he could be ready to ſeize every opportunity. 2. The moſs was an uſeleſs waſte. To let it to tenants would increaſe the population of the eſtate, and afford to a number of induſtrious people the means of making to themſelves a comfortable livelihood.

Preparation of Land

In the mean time it was determined, till as many tenants ſhould be got as could occupy the whole water, to carry on the work by means of undertakers.

But before proceeding farther, it will be neceſſary to deſcribe the manner of applying water to the purpoſe of floating the moſs.

A ſtream of water ſufficient to turn a common corn-mill will carry off as much moſs as 20 men can throw into it, provided they be ſtationed at the diſtance of 100 yards from each other. The firſt ſtep is to make in the clay, alongſide of the moſs, a drain to convey the water: and for this operation the carſe clay below the moſs is peculiarly favourable, being perfectly free from ſtones and all other extraneous ſubſtances, and at the ſame time, when moiſt, ſlippery as ſoap; ſo that not only is it eaſily dug, but its lubricity greatly facilitates the progreſs of the water when loaded with moſs. The dimenſions proper for the drain are found to be two feet for the breadth and the ſame for the depth. If ſmaller, it could not conveniently receive the ſpadefulls of moſs; if larger, the water would eſcape, leaving the moſs behind. The drain has an inclination of one foot in 100 yards; the more regularly this inclination is obſerved throughout, the leſs will the moſs be liable to obſtructions in its progreſs with the water. The drain being formed, the operator marks off to a convenient extent alongſide of it a ſection of moſs, 10 feet broad; the greateſt diſtance from which he can heave his ſpadeful into the drain. This he repeatedly does till the entire maſs be removed down to the clay. He then digs a new drain at the foot of the moſs bank, turns the water into it, and proceeds as before, leaving the moſs to purſue its courſe into the river Forth, a receptacle equally convenient and capacious; upon the fortunate ſituation of which, happily forming for ſeveral miles the ſouthern boundary of the eſtate, without the interpoſition of any neighbouring proprietor, depended the very exiſtence of the whole operations.

When the moſs is entirely removed, the clay is found to be encumbered with the roots of different kinds of trees ſtanding in it as they grew, often very large: their trunks alſo are frequently found lying beſide them. All theſe the tenants remove, often with great labour. In the courſe of their operations they purpoſely leave upon the clay a ſtratum of moſs ſix inches thick. This, in ſpring, when the ſeaſon offers, they reduce to aſhes, which in a great meaſure enſures the firſt crop. The ground thus cleared is turned over, where the dryneſs admits, with a plough, and, where too ſoft, with a ſpade. A month's expoſure to the ſun, wind, and froſt, reduces the clay to a powder fitting

Preparation of Land.

fitting it for the ſeed in March and April. A crop of oats is the firſt, which ſeldom fails of being plentiful, yielding from eight to ten bolls after one.

In the year 1767 an agreement was made with one tenant for a portion of the low moſs. This, as being the firſt ſtep towards the intended plan, was then viewed as a conſiderable acquiſition. The ſame terms agreed upon with this tenant have ever ſince been obſerved with all the reſt. They are as follow:

The tenant holds eight acres of moſs by a tack of 38 years; he is allowed a proper quantity of timber, and two bolls of oatmeal to ſupport him while employed in rearing a houſe; the firſt ſeven years he pays no rent; the eighth year he pays one merk Scots; the ninth year two merks; and ſo on with the addition of one merk yearly till the end of the firſt 19 years; during the laſt five years of which he alſo pays a hen yearly. Upon the commencement of the ſecond 19 years, he begins to pay a yearly rent of 12s. for each acre of land cleared from moſs, and 2s. 6d. for each acre not cleared, alſo two hens yearly: A low rent indeed for ſo fine a ſoil; but no more than a proper reward for his laborious exertions in acquiring it.

In the year 1768 another tenant was ſettled. Theſe two were tradeſmen; to whom the preference was always given, as having this great advantage to recommend them, that even when deprived of water they need never want employment. The motives that induced theſe people to become ſettlers were, 1ſt, The proſpect of an independent eſtabliſhment for a number of years. 2dly, The moſs afforded them great abundance of excellent fuel; to which was added the comfortable conſideration, that, while buſied in providing that neceſſary article, they had the double advantage of promoting, at the ſame time, the principal object of their ſettlement.

Notwithſtanding theſe inducements, ſtill ſettlers offered ſlowly: to which two circumſtances chiefly contributed: 1ſt, The whole farmers ſurrounding the moſs threw every poſſible obſtruction in their way. 2dly, By people of all denominations the ſcheme was viewed as a chimerical project, and became a common topic of ridicule. The plan, however ſupported itſelf; and in the year 1769 five more tenants agreed for eight acres each; and thus 56 acres of low moſs were diſpoſed of. From the progreſs made by the firſt ſettlers, and the addition of theſe, the obloquy of becoming a moſs tenant gradually became leſs regarded; ſo that in the year 1772 two more were added; in 1773, three; and in 1774, one; in all 13: which diſpoſed of 104 acres; all the low moſs to which water could then be conveyed. As water is the mainſpring of the operation, every tenant, beſides the attention neceſſary to his ſhare of the principal ſtream, collected water by every poſſible means, making ditches round his portion of the moſs, and a reſervoir therein to retain it till wanted.

The tenants in the low moſs having now begun to raiſe good crops, in the year 1774 ſeveral perſons offered to take poſſeſſions in the high moſs, upon condition that acceſs to it ſhould be rendered practicable. The high moſs wanted many advantages that the low poſſeſſed. To the low moſs, lying contiguous to the ſurrounding arable lands, the acceſs was tolerably good; but from the arable lands the high moſs was ſeparated by 300 or 400 yards of the low, which even to a man, affords but indifferent footing, and to horſes is altogether impracticable. The low moſs is in general only three feet deep; the high moſs is from ſix to twelve feet in depth.

Preparation of Land.

It will appear at firſt ſight, that without a road of communication the high moſs muſt forever have proved unconquerable. Without delay, therefore, a road was opened to the breadth of 12 feet, for ſeveral hundred yards in length, by floating off the moſs down to the clay.

This being effected, and at the ſame time an opening given to admit water, in the year 1775 twelve tenants agreed for eight acres of high moſs each. In conſideration of the greater depth of this part of the moſs, it was agreed, that during the firſt 19 years they ſhould pay no rent; but for the ſecond 19 years the terms of agreement were the ſame as thoſe made with the tenants in the low moſs. To the above-mentioned tenants every degree of encouragement was given; as upon their ſucceſs depended, in a great meaſure, the diſpoſal of the great quantity of moſs ſtill remaining. But their ſucceſs, however problematical, was ſuch, that next year, 1776, ſix more took eight acres each; in 1777, one; in 1778, four; in 1779, three; in 1780, one; in 1781, one; in 1782, one:—In all, including thoſe upon the low moſs, 42 tenants, occupying 336 acres.

Though for ſome time the diſpoſal of the high moſs went but ſlowly on, it was not for want of tenants; but the number of operators was already ſufficient for the quantity of water; to have added more would evidently have been imprudent.

In the year 1783 Mr Drummond entered into the poſſeſſion of the eſtate of Blair Drummond, and went fully into the plan adopted by his predeceſſor for ſubduing the moſs. At this time there ſtill remained undiſpoſed of about 1000 acres of high moſs. As water was the great deſideratum, it was determined, that to obtain that neceſſary article neither pains nor expence ſhould be wanting. Steps were accordingly taken to aſcertain in what manner it might be procured to moſt advantage.

Meanwhile, to prepare for new tenants, a ſecond road parallel to the former, at the diſtance of half a mile, was immediately begun and cut, with what water could be got, down to the clay, 12 feet broad and 2670 yards long, quite acroſs the moſs. This opening was previouſly neceſſary, that operators might get a drain formed in the clay to direct the water; and it was to remain as a road that was abſolutely neceſſary, and which relieved ſettlers from an expence they were unable to ſupport. Theſe preparations, the progreſs of the former tenants, and the proſpect of a farther ſupply of water, induced 10 more to take poſſeſſions in the year 1783: in the year 1784, 18 more took poſſeſſions; and in 1785 no fewer than 27:—in all 55 tenants in three years: which diſpoſed of 440 acres more of the high moſs.

As the introduction of an additional ſtream to the moſs was to be a work both of nicety and expence, it was neceſſary to proceed with caution. For this reaſon ſeveral engineers were employed to make ſurveys and plans of the different modes by which it might be procured. In one point they all agreed, that the pro-

Preparation of Land.

per ſource for furniſhing that ſupply was the river Teith, a large and copious ſtream that paſſes within a mile of the moſs; but various modes were propoſed for effecting that purpoſe.

To carry a ſtream from the river by a cut or canal into the moſs was found to be impracticable; and Mr Whitworth (B) gave in a plan of a pumping machine, which he was of opinion would anſwer the purpoſe extremely well.

Soon after this Mr George Meikle of Alloa, a very ſkilful and ingenious millwright, gave in a model of a wheel for raiſing water entirely of a new conſtruction, of his own and his father's invention jointly. This machine is ſo exceedingly ſimple, and acts in a manner ſo eaſy, natural, and uniform, that a common obſerver is apt to undervalue the invention: But perſons ſkilled in mechanics view machinery with a very different eye; for to them ſimplicity is the firſt recommendation a machine can poſſeſs. Accordingly, upon ſeeing the model ſet to work, Mr Whitworth, with that candour and liberality of mind that generally accompany genius and knowledge, not only gave it the greateſt praiſe, but declared that, for the purpoſe required, it was ſuperior to the machine recommended by himſelf, and adviſed it to be adopted without heſitation.

The better to explain this machine, two ſketches are annexed, to the firſt of which the following letters refer. The explanation of the ſecond will be found upon the ſketch.

Plate XIII.

a, Sluice through which is admitted the water that moves the wheel.

b, *b*, Two ſluices through which is admitted the water raiſed by the wheel.

c, *c*, A part of one of two wooden troughs and an aperture in the wall, through which the above water is conveyed into the buckets. [The other trough is hid by two ſtone walls that ſupport the wheel.]

d, *d*, *d*, Buckets, of which 80 are arranged on each ſide of the arms of the wheel=160.

e, *e*, *e*, A ciſtern, into which the water raiſed by the buckets is diſcharged.

f, *f*, *f*, Wooden barrel pipes, through which the water deſcends from the ciſtern under ground to avoid the high road from Stirling, and the private approach to the houſe.

Sketch ſecond contains a plan of the ciſtern, and exhibits the manner in which the water is filled into the buckets.

The diameter of the wheel to the extremities of the float-boards is 28 feet; the length of the float-boards 10 feet. The wheel makes nearly four revolutions per minute; in which time it diſcharges into the ciſtern 40 hogſheads of water. But this is not all the wheel is capable of performing; for by ſeveral accurate trials by Meſſrs Whitworth and Meikle, in the reſult of which, though made ſeparately, they perfectly agreed, it was found that the wheel was able to lift no leſs than 60 hogſheads per minute; but that the diameter of the pipes through which the water deſcends from the ciſtern would not admit a greater quantity than what they already receive.

Preparation of Land.

To a perſon at all converſant in hydraulics, the reſemblance of this to the Perſian wheel muſt be obvious: and indeed it is probable, that from the Perſian wheel the firſt idea of this machine was derived. But admitting this, ſtill the ſuperiority of the preſent wheel is, in moſt reſpects, ſo conſpicuous, as to entitle it to little leſs praiſe than the firſt invention. For, 1ſt, In the Perſian wheel, the buckets being all moveable, muſt be conſtantly going out of order: in this wheel they are all immoveable, conſequently never can be out of order. 2dly, Inſtead of lifting the water from the bottom of the fall, as in the Perſian wheel, this wheel lifts it from the top of the fall, being from four to five feet higher; by which means ſome additional power is gained. 3dly, By means of the three ſluices (*a*, and *b*, *b*, fig. 1.) in whatever ſituation the river may be, the quantity of the water to be raiſed is ſo nicely adjuſted to that of the moving power, as conſtantly to preſerve the wheel in a ſteady and equable motion. In ſhort, as a regulator is to a watch, ſo are theſe ſluices to this wheel, whoſe movements would otherwiſe be ſo various, as ſometimes to carry the water clear over the ciſtern, ſometimes to drop it entirely behind, but ſeldom ſo as fully to diſcharge the whole contents of the buckets into the ciſtern.

It is however but candid to remark, that this machine labours under a ſmall defect, which did not eſcape the obſervation of Mr Whitworth; namely, that by raiſing the water about $3\frac{1}{2}$ feet higher than the ciſtern where it is ultimately delivered, a ſmall degree of power is loſt. To this, indeed, he propoſed a remedy; but candidly confeſſed, that as it would render the machine ſomewhat more complex, and would alſo increaſe the friction, he thought it more adviſable to keep it in its preſent ſtate. At the ſame time he juſtly obſerved, that as the ſtream by which the wheel is moved is at all times copious and powerful, the ſmall loſs of power occaſioned by the above circumſtance was of little or no avail.

This ſtream is detached from the Teith at the place where that river approaches neareſt to the moſs. The ſurface of the latter is about 15 feet higher than that of the former; the ciſtern is therefore placed 17 feet above the ſurface of the ſtream, ſo as to leave a declivity ſufficient to deliver the water upon the ſurface of the moſs.

The pipes through which the water deſcends from the ciſtern are compoſed of wooden barrels hooped with iron, 4 feet long and 18 inches in diameter within.

In theſe pipes, having been conveyed under ground for 354 yards from the ciſtern, the water at once emerges into an open aqueduct. This aqueduct, which was formed according to a plan by Mr Whitworth, is conſtructed wholly of earth or clay; and in order to keep the water on a level with the ſurface of the moſs, it is for nearly two-thirds of its courſe elevated from 8 to 10 feet above the level of the adjacent grounds; the baſe being 40 feet broad, the ſummit 18 feet, and the water

(B) This gentleman was ſuperintendant of the London water-works, and an engineer of great reputation in England. He was ſeveral years employed in Scotland in completing the great canal.

Preparation of Land.

water courſe 10 feet broad. It commences at the termination of the pipes; from whence extending above 1400 yards, it diſcharges the water into a canal formed for its reception on the ſurface of the moſs.

For raiſing the water to this height there were two reaſons: 1ſt, That not only where it was delivered on the moſs, but even after being conveyed to the moſt diſtant corners, it might ſtill retain ſufficient power to tranſport the moſs to the river Forth. 2dly, That reſervoirs of a ſufficient height might be formed in the moſs to retain the water delivered during night.

In conſequence of Mr Whitworth's advice, a contract was entered into with Mr Meikle in ſpring 1787; and by the end of October in that year, the wheel, pipes, and aqueduct, were all completely finiſhed; and what, in ſo complex and extenſive an undertaking, is by no means common, the different branches of the work were ſo completely executed, and ſo happily adjuſted to each other, that upon trial the effect anſwered the moſt ſanguine expectations. The total expence exceeded 1000l. ſterling.

To induce the proprietor to embark in this undertaking, the moſs tenants had of their own accord previouſly come under a formal engagement to pay the intereſt of any ſum that might be expended in procuring a ſupply of water. But he was determined they ſhould not enjoy by halves the ſweets of this long wiſhed for acquiſition. With a view, therefore, not only to reward their paſt induſtry, but to rouſe them to future exertion, he at once ſet them free from their engagement; nor has any intereſt ever been demanded.

This new ſupply was a moſt acceptable boon to the moſs tenants. In order to make an equitable diſtribution, the water raiſed through the day was allotted to one diviſion of operators; that raiſed during the night to another. To retain the latter, a canal was formed, extending almoſt three miles through the centre of the moſs. From place to place along the ſides are inſerted ſluices to admit water to the reſervoirs of the poſſeſſors; each ſluice having an aperture proportioned to the number of operators to be ſupplied from the reſervoir which it fills. For the water raiſed through the day no reſervoirs are neceſſary; as it is immediately uſed by the diviſion to which it is allotted.

This additional ſtream, though highly beneficial, yet is not more than ſufficient to keep 40 men at conſtant work. But ſuch a quantity as would give conſtant work is not neceſſary: the operators muſt be often employed in making and repairing their drains, grubbing up roots of trees, &c.; ſo that a quantity ſufficient to give five or ſix hours work per day to the whole inhabitants is as much as would be wanted. But as the quantity procured was ſtill inſufficient for this purpoſe, a ſmall ſtream that deſcended from the higher grounds was diverted from its courſe and brought into the moſs. From want of level this ſtream could not be delivered to the greateſt advantage; namely, upon the ſurface of the moſs. Yet by making, at a conſiderable expence, a drain half a mile long, and a reſervoir for the night water, it was rendered of much importance: and during the whole winter months, as well as in ſummer, after every fall of rain, it keeps 15 perſons fully employed.

In the year 1787, two more tenants agreed for eight acres each; in 1788, four; in 1789, eight; in 1790, four tenants, all agreed for the ſame number of acres. Preparation of Land.

The whole moſs was now diſpoſed of, except that part called *Flow Moſs*, which comprehended about 400 acres. Here it is twice the uſual breadth, ſo fluid that a pole may be thruſt with one hand to the bottom; and the interior part, for near a mile broad, is three feet above the level of all the reſt of the moſs. Hitherto the many and various difficulties that preſented themſelves had been overcome by perſeverance and expence. But here the extraordinary elevation of the moraſs, joined to its great fluidity, ſeemed to exclude all poſſibility of admitting a ſtream of water; and it was the general opinion that the moſs operations had now arrived at their *ne plus ultra*, and that this moraſs was doomed to remain a nuiſance for ages to come.

But the proprietor had now advanced ſo far that he could not ſubmit to retreat: and he conſidered himſelf as in ſome meaſure pledged to the country for the completion of this undertaking. To detail the various methods practiſed to introduce a ſtream of water into that moraſs, would prove tedious. It is ſufficient to ſay, that after a thouſand unſucceſsful efforts, attended with much trouble and conſiderable expence, the point at laſt was gained, and a ſtream of water was brought in, and carried fairly acroſs the centre of the moraſs.

The greateſt obſtacle was now indeed overcome; but ſtill another remained of no ſmall moment, namely, the diſcouragement given to ſettlers from the total impoſſibility of erecting habitations upon the ſurface of this moraſs. To find a remedy for this evil was difficult. Happily a reſource at laſt occurred. This was to bargain with a certain number of the old tenants, whoſe habitations were neareſt, to take leaſes of portions of the moraſs. But as ſome additional aid was here neceſſary, it was agreed that 12l. ſterling ſhould be gradually advanced to each tenant till he ſhould accompliſh the clearing of an acre, for which he or his ſucceſſor is bound to pay 12s. of yearly rent, equal to five per cent. upon the ſum advanced. When this point ſhall be gained, they are bound to diſpoſe, as moſt agreeable to themſelves, either of their old or of their new poſſeſſion; for which, when once an acre is cleared, purchaſers will not be wanting.

In conſequence of the above arrangement, during the year 1791 no fewer than 35 of the old tenants agreed, upon the foreſaid conditions, for eight acres each of the flow moſs. Thus 1200 acres are now diſpoſed of to 115 tenants. But when theſe 35 tenants ſhall each have cleared their acre, then, according to agreement, 35 additional tenants will ſpeedily be acquired; and the moſs will then contain in all 150 families.

To the leaſes at firſt granted to the tenants in the high moſs, it was afterwards determined to add a further period of 19 years (making in all 57 years), during which they are to pay one guinea per acre; a rent not greater than the land is worth even at preſent, but greatly below its probable value at that diſtant period. This, it is hoped, will prove to the tenants a ſufficient incite-

Preparation of Land.

ment to continue their operations till their poſſeſſions are completely cleared from moſs.

Having now gone through, in detail, the whole progreſs of the colony for many years after its firſt ſettlement in the year 1767, it ſtill remains to take a general view of the effects produced by that eſtabliſhment.

For ſeveral years, at firſt, the water was uſed chiefly to carry off moſs, in the forming of new roads, and preparing reſervoirs; which conſiderably retarded the principal object, of gaining land. Nevertheleſs there have been cleared full 300 acres of excellent land, producing wheat, barley, oats, and clover, yielding from ſix to twelve bolls after one.

From the nature of the undertaking, there is good reaſon to ſuppoſe that the operations will yearly advance with greater rapidity; eſpecially as the greater number of the ſettlers have only of late begun to operate. Many, beſides maintaining their families otherwiſe by occaſional employments, have in the high moſs cleared in a year one rood of land; ſome have cleared two, ſome three roods, and in the low moſs an acre.

It was a remark often made, even by perſons of ſome obſervation, that by collecting together ſuch a number of people, Kincardine would be overſtocked; and the conſequence would be their becoming a burden on the pariſh: for as the bulk of them were labourers not bred to any trade, and poſſeſſed of little ſtock, it was foreſeen, that, for ſome time, they could not afford to confine themſelves ſolely to the moſs, from which the return muſt be ſlow; but behoved, for immediate ſubſiſtence, to work for daily hire. Happily theſe predictions have proved entirely groundleſs; for ſuch is the growing demand for hands in this country, that not only do the whole of theſe people find employment whenever they chooſe to look for it, but their wages have been yearly increaſing from the time of their firſt eſtabliſhment. In ſhort, they have proved to the corner where they are ſet down a moſt uſeful nurſery of labourers; and thoſe very farmers who, at firſt, ſo ſtrongly oppoſed their ſettlement, now fly to them as a ſure reſource for every purpoſe of agriculture. Still they conſider the moſs operations as their principal buſineſs; none pay them ſo well; and when they do leave it to earn a little money, they return with cheerfulneſs to their proper employment. Many of them already raiſe from 10 to 60 bolls of grain, and have no occaſion to go off to other work; which will ſoon be the caſe with the whole. Their original ſtock, indeed, did not often exceed 25l. and ſome had not even 10l.; but what was wanting in ſtock is compenſated by induſtry.

Of the whole inhabitants full nine tenths are Highlanders, from the neighbouring pariſhes of Callander, Balquhidder, &c.; a ſober, frugal, and induſtrious people, who, inured to hardſhips in their own country, are peculiarly qualified to encounter ſo arduous an undertaking. From this circumſtance, too, ariſes a very happy conſequence; that wearing a different garb and ſpeaking a different language from the people amongſt whom they are ſettled, they conſider themſelves in a manner as one family tranſported to a foreign land: and hence upon all occaſions of difficulty, they fly with alacrity to each others relief. Neither ought it to be forgotten, that, from their firſt ſettlement to the preſent day, not a ſingle inſtance has occurred amongſt them of theft, bad neighbourhood, or of any other miſdemeanour, that required the interpoſition of the civil magiſtrate. Nor, however poor in circumſtances, has any one of them ever ſtooped to ſolicit aſſiſtance from the funds of the pariſh appropriated to that purpoſe.

Preparation of Land.

Though few of the tenants entered with a large ſtock, one only has been obliged to leave the moſs from incapacity to proceed. Many indeed have ſpent their ſmall ſtocks, and even run a little in debt: but in this caſe they have been permitted to ſell their tacks upon the following conditions: 1ſt, That the purchaſer ſhall be a good man; 2dly, That the ſeller ſhall take another poſſeſſion. By this manœuvre a new inhabitant is gained; while the old one, relieved from debt, and aided by paſt experience, recommences his operations with double ſpirit upon a new poſſeſſion. The moneyed man again has at once a houſe and a piece of ground, the want of which chiefly ſtartled new beginners.

Some have even made a kind of trade of ſelling; inſomuch, that from the year 1774 to the year 1792, no fewer than fifty ſales have taken place, producing in all the ſum of 849l. ſterling. This proved from time to time a moſt ſeaſonable recruit to the colony, and gave new vigour and ſpirits to the whole.

The number of the ſettlers is productive of an excellent effect; that although ſome are generally abſent, enough ſtill remain to occupy the water conſtantly. In a favourable day, there may be ſeen hundreds, men, women, and children, labouring with the utmoſt aſſiduity. The women declare they can make more by working at the moſs than at their wheel; and ſuch is the general attachment to that employment, that they have frequently been diſcovered working by moonlight.

Another happy conſequence ariſing from their numbers is the great quantity of moſs they conſume for fuel. There are in all 115 families. Each family requires at an average 10 dargues (c) of peats yearly. Each dargue uncovers a ſpace equal to 10 ſquare yards of clay; ſo that, by caſting peats, the moſs tenants gain yearly about 6 roods of land.

The advantage, too, of providing their fuel with ſo little trouble, is very great. They require yearly 1150 dargues of peats; which, as each dargue when dried and ſtacked is valued at five ſhillings, are worth 287l. 10s. ſterling; a ſum which otherwiſe muſt have been expended on the prime coſt and carriage of coals.—Many of them caſt peats for ſale; and 100l. worth are yearly diſpoſed of in the town of Stirling, the village of Down, &c.

Though moſs work be laborious, it is at the ſame time amuſing. The operator moves the moſs five feet only at a medium; and the water, like carts in other caſes,

(c) A dargue (or darg) of peats, is the quantity that one man can caſt and two can wheel in a day to the field where they are ſpread out to dry.

Preparation of Land.

caſes, carrying it off as faſt as it is thrown in, excites him to activity. Still he muſt ſubmit to be wet from morning to night. But habit reconciles him to this inconvenience; while his houſe and arable land fill his eye and cheer his mind. Nor is it found that the health of the inhabitants is in the ſmalleſt degree injured either by the nature of the work or the vicinity of the moſs.

The quantity of moſs that one man can move in a day is ſurpriſing; when he meets with no interruption, ſeldom leſs than 48 cubic yards, each weighing 90 ſtones. The weight, then, of moſs moved per day is no leſs than 4320 ſtones. A cubic yard is moved into the water, and of courſe carried into the river Forth for one farthing. It follows, that the expence of moving 48 cubic yards is one ſhilling. But the ſame quantity moved to the ſame diſtance by carts would coſt 24 ſhillings. Hence the advantage derived from the poſſibility of floating moſs in water, and the great importance of having water for that purpoſe.

The moſs, when contraſted with the rich lands ſurrounding, appeared, eſpecially before the improvements, a very dreary ſpot; one wide unvaried wild, totally unproductive, unfit even to furniſh ſuſtenance to any animal, except here and there a few wretched ſtraggling ſheep. Beſides, it entirely cut off all connexion betwixt the farms on either ſide; among which no intercourſe was practicable but by a circuit of ſeveral miles.

The ſcene is already greatly changed. The following are the numbers of the inhabitants who ſome years ago reſided in the moſs; alſo of their cows and horſes, and of the acres gained by them from the moſs, together with their produce.

Men - - - -	115
Women - - -	113
Boys - - -	199
Girls - - - -	193
Total	620
Number of cows, at leaſt, -	115
Ditto of horſes and carts, - -	34
Ditto of acres cleared from moſs, -	300

The produce in bolls cannot be exactly aſcertained: out, conſidering the goodneſs of the ſoil, may be fairly ſtated at 8 bolls per acre. *Inde* 2400 bolls.

As oats are the ſtaple commodity, the calculation ſhall be confined to that grain. According to the fiars of Stirlingſhire, crop 1790, carſe oats are valued at 14s. per boll. *Inde* 2400 bolls at 14s. is 1680l. Of late this price has at times been doubled.

A tract of ground ſo conſiderable, formerly a nuiſance to the country, thus converted into a fertile field, filled with inhabitants, comfortable and happy, cannot ſurely be ſurveyed with an eye of indifference by any perſon whoſe mind is at all ſuſceptible of feeling or of public ſpirit.

An excellent gravelled road, 20 feet wide and a mile and a half long, is now carried quite acroſs the moſs. By this means, in the firſt place, a ſhort and eaſy intercourſe is eſtabliſhed between two conſiderable parts of the eſtate, formerly as little connected as if ſeparated by a lake or an arm of the ſea. Secondly, The inhabitants of the moſs, to whom, hitherto, all paſſage with carts or horſes was impracticable for at leaſt one half of the year, have now obtained the eſſential advantage of being able, with eaſe, to tranſport all the different commodities at every ſeaſon of the year. This road was entirely formed by the hands of the moſs tenants, and gravelled by their own carts and horſes: a work which, it will not be doubted, they performed with much alacrity; when it is conſidered that, to the proſpect of procuring a laſting and material benefit to themſelves, there was joined the additional inducement of receiving an immediate ſupply of money, the whole being done at the proprietor's expence.

The poſſeſſions are laid off in the manner beſt fitted for the operations; and are divided by lanes running in ſtraight lines parallel to each other. Parallel to theſe again the drains are carried; and this ſtraight direction greatly facilitates the progreſs of the water with its load of moſs. Upon the bank of moſs fronting the lanes, the operation of floating is begun; and twenty or thirty people are ſometimes ſeen heaving moſs into the ſame drain. That the water may be the more conveniently applied, the lanes include between them the breadth of two poſſeſſions only. The new houſes are erected upon each ſide of theſe lanes at the diſtance of 100 yards from each other.

Before the formation of lanes and roads, and while yet no ground was cleared, the firſt ſettlers were obliged to erect their houſes upon the ſurface of the moſs. Its ſoftneſs denied all acceſs to ſtones; which, at any rate, are at ſuch a diſtance as would render them too expenſive. Settlers, therefore, were obliged to conſtruct their houſes of other materials. Upon the low moſs there is found for this purpoſe great plenty of ſod or turf, which accordingly the tenants uſe for the walls of their houſes. For the rudeneſs of the fabric nature in ſome meaſure compenſates, by overſpreading the outſide with a luxuriant coating of heath and other mooriſh plants, which have a very picturesque appearance.

But upon the high moſs there is no ſod to be found. There the tenant muſt go differently to work. Having choſen a proper ſituation for his houſe, he firſt digs four trenches down to the clay, ſo as to ſeparate from the reſt of the moſs a ſolid maſs, containing an oblong rectangular area, ſufficiently large for his intended houſe. This being done, he then ſcoops out the middle of the maſs, leaving on all ſides the thickneſs of three feet for walls; over which he throws a roof, ſuch as that by which other cottages are commonly covered.

Upon the ſofteſt parts of the moſs, even theſe walls cannot be obtained. In ſuch places the houſes are built with peat dug out of the moſs, and cloſely compreſſed together while in a humid ſtate (D). It is neceſſary

(D) This does not apply to the *moraſs*, upon the ſurface of which, it has already been obſerved, it is impoſſible to erect houſes in any ſhape.

Preparation of Land.

ceſſary even to lay upon the ſurface a platform of boards to prevent the walls from ſinking; which they have frequently done when that precaution was neglected. After all, to ſtamp with the foot will ſhake the whole fabric as well as the moſs for fifty yards around. This, at firſt, ſtartled the people a good deal; but cuſtom ſoon rendered it familiar.

The coloniſts have now made conſiderable advancement in rearing better habitations for their comfort and convenience. Their huts of turf are but temporary lodgings. As ſoon as they have cleared a little ground, they build houſes of brick: when the proprietor a ſecond time furniſhes them with timber gratis. It has alſo been found neceſſary to relieve them entirely from the payment of the burdenſome tax upon brick; a tax which ſurely was never intended to fall on ſuch poor induſtrious adventurers; and which, without this aſſiſtance, would have proved a moſt effectual bar to the employment of theſe materials.

There are now erected in the moſs 69 brick houſes, ſubſtantially built with lime. The total expence amounted to 1033l. ſterling. And it is a very comfortable circumſtance, that the money expended upon theſe houſes is moſtly kept in circulation among the inhabitants themſelves; for as a number of them have learned not only to manufacture but alſo to build bricks, and as others who have horſes and carts furniſh the carriage of lime and coals, they thus interchange ſervices with each other.

With a view to excite the exertion of the coloniſts, the following premiums were alſo offered: 1. To the perſon who ſhall in the ſpace of one year remove the greateſt quantity of moſs down to the clay, a plough of the beſt conſtruction. 2. To the perſon who ſhall remove the next greateſt quantity, a pair of harrows of the beſt kind. 3. For the next greateſt quantity, a ſpade of the beſt kind, and 10lb. of red clover ſeed. But as theſe premiums, if conteſted for by the whole inhabitants, could reach but a very few of the number, they were therefore divided into ſix diſtricts according to their ſituation; and the above premiums were offered to each diſtrict.

The eſtabliſhment of this colony was no doubt attended with a very conſiderable ſhare of expence and difficulty; for the undertaking was altogether new, and there were many prejudices againſt it, which it was neceſſary to overcome. At the ſame time it was noble and intereſting; it was to make a valuable addition to private property: it was to increaſe the population of the country, and to give bread to a number of people; many of whom having been turned out of their farms and cottaries in the Highlands, might otherwiſe, by emigration, have been loſt to their country; and that too, at a time when, owing to the great enlargement of farms, depopulation prevails but too much even in the low countries. And it was to add to the arable lands of the kingdom, making many thouſand bolls of grain to grow where none ever grew before.

Theſe conſiderations have hitherto preponderated with the proprietors againſt the various obſtacles that preſent themſelves to the execution of ſo extenſive an undertaking. Should their example tend in any degree to ſtimulate others, who both in Scotland and in England poſſeſs much ground equally uſeleſs to the country, to commence ſimilar improvements, it would be a moſt grateful conſideration ſuperadded to the pleaſure already ariſing from the progreſs of the infant colony.

Preparation of Land.

After all, it will probably hereafter be thought, that the great efforts of ingenuity, and of perſevering induſtry, which were requiſite in the above operation, might all have been avoided, and the work much eaſier performed, had the art been found out of converting moſs into fruitful ſoil, according to the plan practiſed, and undoubtedly brought to great perfection in Ayrſhire, by the gentleman already mentioned, John Smith, Eſq. of Swinridgemuir, near Beith. On a part of moſs in this gentleman's property, a quantity of lime had been ſpread in conſequence of the miring of ſome carts in wet weather; to relieve which, their load was laid over the ground in their neighbourhood, though this was accounted at that period an abſurd operation, as it was believed that lime would have the effect of conſuming and rendering moſſy ground uſeleſs for ever. The proprietor, Mr Smith, was then in the army, towards the cloſe of the American war. On returning home the ſucceeding ſummer, and being informed of the accident, he was ſurpriſed to find that as good a crop grew upon the patch of moſs on which the lime had been ſcattered, as upon another ſpot that had been pared and burned, in conſequence of inſtructions that he had tranſmitted home for that purpoſe, from having peruſed ſome treatiſes in which burning of moſs was recommended. He alſo remarked, that upon the places which had neither been burned nor limed, nothing grew, and that the crop upon the burned ſoil was inferior to that where the lime had been laid, being almoſt choked with ſorrel. Mr Smith purſued the hint thus obtained: He reclaimed by means of lime every portion of moſs in his own poſſeſſion, and having ſatisfied his tenants of the utility of the practice, he allowed them to dig limeſtone gratis, and gave them the refuſe of his coal at prime coſt to burn it. Thus, in a ſhort time, every part of the moſs upon his eſtate was reduced under cultivation, and rendered highly valuable.

197 Mr Smith mode of improving moſs.

When Mr Smith began his operations, he met the fate of innovators in agriculture, that is, he was ridiculed by all his neighbours. His ſucceſs, however, at length made ſome converts, and though the new ſyſtem at firſt advanced ſlowly, it was at laſt univerſally approved of, and extenſively imitated. The reſult has been, that what was once the worſt land in the country, is now become the moſt productive and fertile.

The following is a conciſe ſtatement of Mr Smith's practice, and conſequently of the Ayrſhire practice, of actually converting moſs into vegetable mould, capable of bearing rich crops of corn, hay, potatoes, &c. which we ſhall give in the words of Mr Headrick.

"1. When they enter upon the improvement of a moſs in its natural ſtate, the firſt thing to be done is, to mark and cut main or maſter drains, eight feet in width, by four and a half in depth, and declining to two and a half at bottom; theſe coſt 1s. per fall of ſix Scots ells. In ſome inſtances, it will be found neceſſary to cut thoſe drains much deeper, conſequently at a greater expence. Theſe drains almoſt in every inſtance can be, and are ſo conducted, as to divide the field into regular and proper incloſures. They always make it a rule to finiſh off as much of a drain as they have broken

Communication to the board of agriculture, vol.

Preparation of Land.

broken up, before they leave it at night; becauſe, if a part is left dug, ſuppoſe half way, the oozing of water from the ſides would render the bottom ſo ſoft, that they could neither ſtand upon it nor lift it with the ſpade. When the moſs is ſo very ſoft, that the preſſure of what is thrown out of the drain may cauſe its ſides to fall in again, they throw the clods from the drain a conſiderable way back, and ſometimes have a man to throw them ſtill further back, by a ſpade or the hand; for this reaſon too, they always throw the ſtuff taken from a drain as equally as poſſible on each ſide of it. In digging the drains, the workmen ſtand upon ſmall boards to prevent them from ſinking, and move them forward as the work advances.

"When the moſs lies in a hollow, with only one outlet, it is neceſſary to lead up a drain, ſo as to let the water paſs this outlet, and then conduct it along the loweſt or wetteſt part of the moſs: this middle drain is afterwards ſloped, and the ſtuff thrown back into the hollows that may occur; upon it the ridges are made to terminate on each ſide, while a ring drain, ſerving the purpoſe of a fence, is thrown round the moſs at the line where the riſing ground commences. This can generally be ſo managed as to divide the moſs into a ſquare field, leaving ſtraight lines for the ſides of the contiguous fields. The ring drain intercepts the ſurface water from the higher grounds, and conducts it into the lower part of the outlet, while the ſloped drain in the centre receives and diſcharges all the water that falls upon the moſs.

"After the moſs collapſes in conſequence of liming and culture, it is often neceſſary to clean out theſe drains a ſecond time, and to dig them to a greater depth: their ſides become at laſt like a wall of peat, which few animals will venture to paſs.

"2. The drains being thus completed, they mark out the ridges, either with a long ſtring or with three poles ſet in a line. Mr Smith has tried ſeveral breadths of ridges, but now gives a decided preference to thoſe that are ſeven yards in breadth. The ridges are formed with the ſpade in the following manner: In the centre of each intended ridge, a ſpace of about two feet is allowed to remain untouched; on each ſide of that ſpace a furrow is opened, which is turned over ſo as completely to cover that ſpace, like what is called *veering* or *ſeering* of a gathered ridge; the work, thus begun, is continued by cutting furrows with the ſpade, and turning them over from end to end of the ridge on each ſide, until they arrive at the diviſion furrows. The breadth of the ſlices thus cut, may be about 12 inches, and each piece is made as long as it may ſuit to turn over: the ridge, when finiſhed, has the appearance of having been done with a plough. The diviſion furrow is two feet in breadth, which, if neceſſary to draw off ſuperfluous water, is partly cut and thrown upon the ſides, or into hollows in the ridges on each ſide. The depth of the diviſion furrows is regulated by circumſtances, ſo as not to lay the ridges at firſt too dry, but at the ſame time, to bleed, as it were, the moſs, and conduct the ſuperfluous water into the maſter drains.

"3. The next operation is to top-dreſs the ridges with lime. The ſooner this is done after the ridges are formed, the better. When the moſs appears dry, experienced farmers throw on the lime, but do not clean out the diviſion furrows until the enſuing winter. When it is ſoaked in water, they clean the diviſion furrows as ſoon as the lime is ready, and after the water has run off apply the lime immediately. It is of great importance to have the lime applied while the moſs is ſtill moiſt, and the lime in as cauſtic a ſtate as poſſible. For this purpoſe, they have the lime conveyed from the kiln in parcels, ſlaked and laid on as faſt as the ridges are formed. Being dropped from carts, and ſlaked at the neareſt acceſſible ſtation, it is carried to the moſs by two men on light handbarrows, having a hopper and bottom of thin boards, and there ſpread with ſhovels as equally as poſſible. During the firſt and ſecond years, the crop is generally carried off in the ſame way. In ſome places where a moſs is covered with coarſe herbage, and acceſſible by carts in dry weather, I ſaw them give a good doſe of lime to the moſs before it was turned up with the ſpade, and another after the ridges were formed. It is ſurpriſing how quickly they execute theſe operations with the handbarrows. In other places where coarſe boards can be procured, they lay a line of them along the crown of a ridge, and convey the lime upon them in wheelbarrows."

Preparation of Land.

"The proportion of lime allowed to the acre is various, being from three to eight chalders. Improvers are much leſs ſparing of this ingredient now than formerly, and much greater proportions have been applied with good effect. Suppoſe 120 bolls, or 480 Wincheſter buſhels, of ſlaked or powdered lime allowed to every Scots acre, this would coſt at the ſale kilns 40s.; and thus the reader may be enabled to calculate the expence of lime in this diſtrict at every given proportion: But moſt of the farmers here burn lime for themſelves in vaſt kilns of ſod, and think they have it much cheaper than it could be got from a ſale kiln. In many places, limeſtone abounds ſo much, that houſes, fences, and roads are conſtructed with it; and when a farmer burns the limeſtone within his premiſes, he at leaſt ſaves the expence of carriage.

"In ſome caſes, after the limeſtone is laid on, they go over the ground with hoes, or with ſpades, hacking and mangling the clods, and mixing the lime more completely with the ſuperficial ſoil; but where there is much to do, and hands are ſcarce, they never think of theſe operations.

"4. The field thus prepared is ready to receive the ſeed, which is ſown at the proper ſeaſon whether it be *wet* or *dry*, and harrowed in with a ſmall harrow drawn by two men. Four men will with eaſe harrow at leaſt five or ſix roods per day, two and two dragging the harrow by turns, and two breaking and dividing the mould with ſpades. When the lime has been applied early the preceding ſummer, a good crop of oats may generally be expected; but if it has been recently applied, the firſt crop of oats frequently miſgives, as the lime has not time to combine with the moſs, and form it into a ſoil.

"The early Dutch or Poliſh oats are always preferred by moſs improvers, as the common Scots or late oats are too apt to run into ſtraw, and lodge before the grain arrives at maturity. The ſame proportion of ſeed is allowed per acre that is uſual in other places. The great deſideratum is, to procure plants which will throw up a ſufficient quantity of herbage, ſo as to ſhield the

Preparation of Land. the ſurface from the winds and ſun's rays, and thus to keep it moiſt during the firſt ſummer after a moſs is reclaimed.

" This deſideratum is effectually ſupplied by the potato, which thrives well on moſs at all times, whether recently opened up and limed, or at any future period of its cultivation; only it requires a proportion of ſtable dung. It is now become the general practice in Ayrſhire, to plant potatoes on thoſe moſſes which have been but recently turned up and limed; and where dung can be procured, it is generally the firſt crop on all their moſſes.

" The method of planting potatoes, whether they be the firſt crop or ſucceed the firſt crop of oats, is by lazy beds. If they be the firſt crop, the moſs having been delved into ridges, and limed as before directed, ſpaces of from five to ſix feet in breadth are marked out acroſs the ridges, having intervals of about two feet, from which the moſs is taken to cover the ſets. Theſe ſpaces or beds are covered over with a thin *ſtratum* of dung, laid upon the ſurface of the lime at the rate of about ſixteen tons to the Scots acre. The cuttings of the potatoes are laid or placed upon the ſaid beds, about ten or twelve inches aſunder; and the whole are covered over with moſs, taken from the intervals which are thus converted into ditches, to be followed by another covering about the time the potato plants begin to make their appearance, the covering in the whole amounting to about four or five inches: at the ſame time, the diviſion furrows are cleaned out to cover the ſets that are contiguous to them. The whole field is thus divided into ſpaces or lazy beds, like a chequered board. During ſummer, they cut the moſs with hoes, and draw it up a little towards the ſtems of the plants. Few weeds appear, except what are conveyed by the dung. This is the practice univerſally followed when potatoes are planted on moſs for the firſt time; but after the moſs is finely pulverized and reduced, they either plant them in rows acroſs the ridges, or plant and dreſs them with the plough in the uſual manner.

" Potatoes planted as the firſt crop never miſgive, and they are the beſt and moſt certain method at once to reclaim a moſs, not owing ſo much perhaps to the dung aiding the putrid fermentation which the lime has already excited, as to their roots puſhing and dividing the moſs, while their leaves ſhelter it from the ſun, cauſe a ſtagnation of air, and thus keep it in that degree of moiſture which is moſt favourable to the action of lime upon moſs. The practice of making potatoes the firſt crop is now univerſally followed, in ſo far as the farmers can command dung. The produce is from 40 to 60 bolls per acre, the potato meaſure being eight Wincheſter buſhels a little heaped to the boll. Moſſes that are fully reclaimed yield from 60 to 70 bolls of potatoes at an average, and in ſome places where manures are abundant, they have been known to yield from 80 to 100 bolls per acre, of the above meaſure.

" Mr Smith is about to try yams upon his moſſes, from the opinion that prevails among ſome of the Mid-Lothian farmers, where this plant is much cultivated, that they require little or no dung, and that the ſuperior breadth of their leaves, will prove more favourable than thoſe of potatoes, for ſheltering the ground.

" When the potato crop is removed, the ridges are again put into their original form; in doing which, care is taken to preſerve the mould that is acquired uppermoſt; this is done by moving the ſubfurrow on each ſide with a ſtrong ſpade, half way into the intermediate ditch from which the lazy beds were covered, and ſcattering the mould equally over the whole ſurface. This operation coſts 18s. per acre. It is not eaſy to calculate the expence of planting the potatoes forming the lazy beds, &c. as this is ſeldom executed by contract; but the lazy beds being thus reduced, the land is ready for a crop of corn. Preparat of Lanc

" Though a crop of oats frequently miſgives upon moſs that has been but recently limed, yet in other caſes, when the lime has lain ſeveral months upon the land, it proves a good crop, and is ſufficient to cover all the expence with a little profit. The crops of ſucceeding years are ſufficient to afford from their ſtraw putreſcent manure for ſuch land in order that it may be cleaned with potatoes, and prepared for graſs ſeeds.

" But after potatoes of the firſt year, with the ſlight operation of reducing the lazy-beds, from 10 to 12 bolls of oats are at an average produced per acre. The oats are excellent, and yield from 18 to 20 pecks of meal per boll; they would ſell upon the ground for 10l. or 12l. per acre. The ground continues to yield oats of the ſame quality for ſeveral years, without any apparent diminution of fertility, and without receiving any additional manure: the only apparent bar to the continuance of this crop is, the ſoil becoming graſſy. When the graſs begins to contend with the crop for pre-eminence, the land is thrown into paſture, and would let ever after in that ſtate at from 20s. to 25s. per acre. Daiſies, white clover, &c. &c. now ſpring up in moſſes, where their exiſtence was never before ſuſpected; at the ſame time, thiſtles and other weeds for ſome time infeſt the paſture.

" The better practice is, to take another crop of potatoes with a little dung and lime, and give it a trench-delving, to bury the weeds and bring up new ſoil; after the potatoes, to ſow barley and graſs ſeeds.

" Rye-graſs is univerſally ſown here, and it attains amazing perfection upon moſs properly prepared; along with this, white and yellow clover are ſometimes ſown, and thrive remarkably well. Red clover has been tried, but did not ſucceed, and is hence diſcredited for moſs-lands: perhaps it may have been unjuſtly cenſured, becauſe it is certain that the ſeaſons in which it was tried, proved very unfavourable to red clover in all parts of the country, moſt of it having died during winter.

" 5. We have already deſcribed the levelling of the lazy beds. All future delvings of the moſs are performed from one end of the ridge to the other; by this method the ſlices that had been cut and turned over in the firſt operation of forming the ridge, are again cut acroſs, and conſtantly reduced into ſmaller pieces, till they moulder into earth.

" The expence of delving a moſs for the firſt time, where the ſurface is tolerably ſmooth, is 2½d. per fall, or 1l. 13s. 4d. per Scots acre; but where inequalities occur, which muſt be thrown down by the ſpade into hollows, it coſts about 2l. per acre. If there be eminences, which muſt be removed into hollows by wheelbarrows running upon boards, the firſt expence is great-

eparation of Land.

er according to circumſtances. The ſecond delving, where potatoes have not intervened, coſts from 1l. to 1l. 6s. per Scots acre, the diviſion-furrows being at the ſame time cleaned out. The third delving and cleaning of the diviſion-furrows coſts 1l. per acre; but the moſs is now ſo friable, that it may be wrought with the greateſt eaſe and rapidity. At the above rates, an ordinary workman will earn 1s. 6d. per day, and an able and experienced one, from that to 2s. 6d. per day. They uſe a ſtrong ſpade, edged with ſteel, and have always a gritſtone near them for ſharpening the ſpade. In the evening they repair its edge upon a grindſtone; and when the ſteel is worn away, they lay it again with new ſteel. Sometimes the moſs is ſo ſoft that they walk upon boards while they are turning it over.

"Mr Smith has found, by long experience, that it is improper to make the ridges too high or too narrow: when they are too high, they throw the water off from their ſides without admitting it to penetrate their ſubſtance; the top of courſe gets too dry: when too narrow, there is a loſs of ſurface from too many diviſion-furrows; the breadth already mentioned is found to be the beſt: and when the improvement is completed, the ridges appear like ſegments of wide circles, with a clean well defined diviſion-furrow between each of them. The moiſture is thus cauſed ſlowly to filtrate through the moſs rendered friable by lime until it reaches the diviſion-furrows, and is diſcharged. As the moſs ſubſides for ſome time, and cloſes in towards the furrows, it is generally neceſſary to clean theſe out before winter, and at the time the crop is ſown, until the moſs acquire ſolidity.

"Some moſſes may be ploughed the ſecond year to within two bouts or four ſlices of the diviſion-furrows, and every operation performed by the force of horſes, except turning over with the ſpade the narrow ſtripes next to the diviſion-furrows. In other moſſes it requires three years before this can be done; and it ſeldom happens but every moſs may be wrought by the plough after it has been wrought four years by the ſpade. When moſs is wrought by the ſpade, it ſeems of no conſequence whether it be wrought wet or dry; but when it is wrought by the plough, opportunities muſt be watched, as horſes cannot walk upon it for ſome years during wet weather.

"6. With reſpect to the quality of the potatoes thus produced upon moſſes, I do not ſcruple to pronounce it moſt excellent. Potatoes have been tried with dung alone; but they are always watery, and frequently hollow or rotten in the heart: thoſe raiſed upon moſſes that have been well limed, are frequently ſo dry and farinaceous, that it is difficult to boil them without reducing them to powder; and they are often obliged to lift them with ſpoons: they come clean out of the ground; keep remarkably well in heaps covered with moſs in the field; and are remarkably well flavoured.

"No ſuch diſeaſe as the curl was ever known among moſs potatoes; and, indeed, if Dr Coventry's opinion be true, that the curl is cauſed by overloading the ſets with too much earth, or from the earth becoming too hard around them; no ſuch thing can take place in moſs. But to whatever cauſe the curl may be owing, it is certainly propagated by diſeaſed ſeed; it would, therefore, appear advantageous to transfer the potatoes raiſed upon moſs as ſeed for ſolid land. They have a remarkably good ſpecies of potato in this diſtrict, which was brought from Virginia to Largs about eight years ago; and whether it be owing to the beneficial nature of a moſſy ſoil, or to its own intrinſic merits, this potato has long been ſo much diſtinguiſhed by the good quality and large quantity of its produce, that it has ſuperſeded the uſe of every other ſpecies. There ſeems to be no occaſion for moſs improvers to change their ſeed. Some perſons in this diſtrict, who have but ſmall patches of moſs, have kept them conſtantly in potatoes more than ten years, without changing the ſeed, and without any ſenſible diminution either in the quantity or quality of the crop."

Preparation of Land.

4. Of bringing LAND into CULTURE from a State of Nature.

198
A moor, how to be cultivated.

To improve a moor, let it be opened, if poſſible, in winter, when it is wet, which has one convenience, that the plough cannot be employed in any other work. It is always ſuppoſed, however, that the moiſture has been ſufficiently removed by draining, to render this practicable. In ſpring, after the froſt is over, a ſlight harrowing will fill up the interſtices with mould, to keep out the air and rot the ſod. Thus it may be ſuffered to lie during the following ſummer and winter, which will tend more to rot the turf than if laid open to the air by ploughing. Next April, let it be croſs-ploughed, braked, and harrowed, till it be ſufficiently pulverized for turnip-ſeed, to be ſown broadcaſt, or in drills, after being manured, and the manure mixed with the ſoil by repeated harrowings.

It ſometimes happens, however, that the heath which grows upon a mooriſh ſoil, is ſo ſtrong and vigorous as to be ſubdued with great difficulty. It has been obſerved, that after land is drained and the heath burnt upon the ſurface, this plant is in time extirpated by ſheep. Theſe animals are extremely fond of the tender ſhoots and flowers of heath, but they will not taſte it after it runs into ſeed, unleſs compelled by extreme hunger. For ſubduing it by a ſhorter proceſs, lime is the beſt remedy, as it ſeems a mortal enemy to heath. A ſtrong doſe of cauſtic lime therefore laid upon the ſurface of the land after it is firſt ploughed, is attended with the beſt effect in conſuming the roots of heath and of coarſe graſſes, and rendering the ſoil friable, which it accompliſhes in about ſix months. Economy in the uſe of this ingredient, therefore, at the firſt breaking up of moor land, is extremely miſapplied. Accordingly ſome ſkilful farmers lay one doſe of lime upon the land before it is ploughed, and another after it, that the furrow ſlices, being wholly ſurrounded by it, may be ſooner brought into a friable ſtate. But, although a very conſiderable doſe of lime is abſolutely neceſſary, when ſuch land is newly reduced from a ſtate of nature, it ought not to be ſolely truſted to. To render the land permanently fertile, it ſoon becomes neceſſary to aid the ſoil, by vegetable or putreſcent manure.

The turnip crop may be conſumed upon the ground by ſheep, which affords an excellent preparation for laying down the field with graſs ſeeds; a point which every improver ought to have in view, on account of the command of dung which it gives him. It is even ſaid to be an improvement upon this method, to take two or even three ſucceſſive crops of turnips, all con-

Preparation of Land.

fumed in the ſame way. No dung will be neceſſary for the two laſt crops, and the ſoil will be greatly thickened and enriched.

199 Swampy lands, how to be cultivated.

With regard to ſwampy lands and a ſoil covered with ruſhes, ant hills, and coarſe graſſes; after draining, the beſt procedure which can be adopted, conſiſts of paring and burning. When land is pared, a thin ſod is taken off, either by a paring ſpade or paring plough, over the whole ſurface. The ſods being dried, are collected into ſmall heaps and burned, and the aſhes are ſcattered over the field. Swampy land that is overrun with ruſhes and coarſe graſſes, and lands that are covered with heath and other coarſe plants, ſuit beſt for paring and burning. In this way theſe coarſe plants are deſtroyed at once, and the land may be ploughed and cropped immediately, without waiting for the rotting of the turf, as in the former caſe. It is alſo ſaid, that this practice deſtroys all ſlugs and other vermin that infeſt the ſoil. It is more eſpecially valuable in ſituations where lime and other manures cannot be procured. Where lime is to be found in abundance, however, it might probably be a better practice, inſtead of burning the turf that has been cut from the ſurface of the coarſe land, to collect it all into heaps in different parts of the field, and make it up into compoſt with lime. The whole heaps in ſuch caſes ought to be thoroughly moiſtened, and the maſs to be frequently turned and mixed. In this way, by uſing lime in place of fire, the whole roots and coarſe herbage would be deſtroyed, and reduced at once into a moſt valuable manure for enriching the ſoil. In the mean time it is to be obſerved, that paring and burning is ſo evidently advantageous to the immediately ſucceeding crops, that it has ſometimes been abuſed by overcropping after it, and by extending it, perhaps unneceſſarily, to all ſoils, upon breaking them up from graſs, though formerly cultivated and in good order: though even in ſuch caſes it may be found valuable, where lime cannot eaſily be obtained. The following remarks upon the ſubject, in the Report of the Agriculture of the county of Northumberland, by J. Bayley and G. Culley, are worthy of attention. "Paring and burning is not much practiſed in the eaſtern and northern parts of the county: in the middle and ſouthern parts it is moſt prevalent; but, even there, it is confined to old ſwards, and coarſe, rough, ruſhy, and heathy lands. For the firſt breaking up of ſuch ground, it is certainly very convenient, and preferable to any other mode we have ever ſeen; but though we are fully convinced of its beneficial effects in ſuch ſituations, yet we have our doubts whether it could be uſed with advantage upon lands that have lain a few years in graſs, and that would produce good crops of grain immediately on being ploughed out, which is not the caſe with coarſe rough heathy lands, or even very old ſwards on rich fertile ſoils; it being found that crops on the latter are frequently very much injured by *leaping* for two or three years, which paring and burning entirely obviate, and enſure full crops to the farmer, who need not be under any apprehenſion of his ſoil being ruined by it, provided he purſue the following courſe: 1. Turnips; 2. Oats; 3. Fallow well limed for turnips; 4. Barley ſown up with clover and graſs ſeeds, and depaſtured with ſheep for three or four years. It is the injudicious cropping, more than the ill effects derived from paring and burning, that has been the chief cauſe of bringing ſuch an odium on this practice, which is certainly an excellent one in ſome ſituations, and when properly conducted; but, like the fermented juice of the grape, may be too often repeated and improperly applied.

200 Paring and burning, how far uſeful.

Preparation of Land.

"The popular clamour againſt this practice, "that it deſtroys the ſoil," we can by no means admit; and are inclined to believe, that not a ſingle atom of ſoil is abſtracted, though the bulk of the ſod or turf be diminiſhed. This ariſes from the burning of the roots or vegetable ſubſtances, which, by this proceſs, afford a conſiderable portion of alkaline ſalts, phlogiſtic or carbonic matter, and probably other principles friendly to vegetation; as we find thoſe aſhes produce abundant crops of turnips, which fatten ſtock much quicker than thoſe after any other dreſſing or manure we have ever ſeen; and the ſucceeding crops of corn are ſo very luxuriant as to tempt the injudicious cultivator to purſue it too far; who, for the ſake of a temporary gain, may be ſaid to rip it up, as the boy did his gooſe that laid golden eggs."

But where the ground is dry, and the ſoil ſo thin as that the ſurface cannot be pared, the beſt way of bringing it into tilth from the ſtate of nature, as mentioned above, is to plough it with a feathered ſock, laying the graſſy ſurface under. After the new ſurface is mellowed with froſt, fill up all the ſeams by harrowing croſs the field, which by excluding the air will effectually rot the ſod. In this ſtate let it lie ſummer and winter. In the beginning of May after, a croſs ploughing will reduce all to ſmall ſquare pieces, which muſt be pulverized with the brake, and make it ready for a May or June crop. If theſe ſquare pieces be allowed to lie long in the ſap without breaking, they will become tough, and not be eaſily reduced.

5. Forming Ridges.

201 Of ridges.

The firſt thing that occurs on this head, is to conſider what grounds ought to be formed into ridges, and what ought to be tilled with a flat ſurface. Dry ſoils, which ſuffer by lack of moiſture, ought to be tilled flat, which tends to retain moiſture. And the method for ſuch tilling, is to go round and round from the circumference to the centre, or from the centre to the circumference. This method is advantageous in point of expedition, as the whole is finiſhed without once turning the plough. At the ſame time, every inch of the ſoil is moved, inſtead of leaving either the crown or the furrow unmoved, as is commonly done in tilling ridges. Clay ſoil, which ſuffers by water ſtanding on it, ought to be laid as dry as poſſible by proper ridges. A loamy ſoil is the middle between the two mentioned. It ought to be tilled flat in a dry country, eſpecially if it incline to the ſoil firſt mentioned. In a moiſt country, it ought to be formed into ridges, high or low according to the degree of moiſture and tendency to clay.

In grounds that require ridging, an error prevails, that ridges cannot be raiſed too high. High ridges labour under ſeveral diſadvantages. The ſoil is heaped upon the crown, leaving the furrows bare: the crown is too dry, and the furrows too wet: the crop, which is always beſt on the crown, is more readily ſhaken with the wind, than where the whole crop is of an equal

Preparation of Land.

equal height: the half of the ridge is often covered from the ſun, a diſadvantage which is far from being ſlight in a cold climate. High ridges labour under another diſadvantage, in ground that has no more level than barely ſufficient to carry off water: they ſink the furrows below the level of the ground; and conſequently retain water at the end of every ridge. The furrows ought never to be ſunk below the level of the ground. Water will more effectually be carried off by leſſening the ridges both in height and breadth: a narrow ridge, the crown of which is but 18 inches higher than the furrow, has a greater ſlope than a very broad ridge where the difference is three or four feet.

Next, of forming ridges where the ground hangs conſiderably. Ridges may be too ſteep as well as too horizontal: and if to the ridges be given all the ſteepneſs of a field, a heavy ſhower may do irreparable miſchief. To prevent ſuch miſchief, the ridges ought to be ſo directed croſs the field, as to have a gentle ſlope for carrying off water ſlowly, and no more. In that reſpect, a hanging field has greatly the advantage of one that is nearly horizontal; becauſe, in the latter, there is no opportunity of a choice in forming the ridges. A hill is of all the beſt adapted for directing the ridges properly. If the ſoil be gravelly, it may be ploughed round and round, beginning at the bottom and aſcending gradually to the top in a ſpiral line. This method of ploughing a hill requires no more force than ploughing on a level; and at the ſame time removes the great inconvenience of a gravelly hill, that rains go off too quickly; for the rain is retained in every furrow. If the ſoil be ſuch as to require ridges, they may be directed to any ſlope that is proper.

In order to form a field into ridges that has not been formerly cultivated, the rules mentioned are eaſily put in execution. But what if ridges be already formed, that are either crooked or too high? After ſeeing the advantage of forming a field into ridges, people were naturally led into an error, that the higher the better. But what could tempt them to make their ridges crooked? Certainly this method did not originate from deſign; but from the lazineſs of the driver ſuffering the cattle to turn too haſtily, inſtead of making them finiſh the ridge without turning. There is more than one diſadvantage in this ſlovenly practice. Firſt, the water is kept in by the curve at the end of every ridge, and ſours the ground. Next, as a plough has the leaſt friction poſſible in a ſtraight line, the friction muſt be increaſed in a curve, the back part of the mouldboard preſſing hard on the one hand, and the coulter preſſing hard on the other. In the third place, the plough moving in a ſtraight line, has the greateſt command in laying the earth over. But where the ſtraight line of the plough is applied to the curvature of a ridge in order to heighten it by gathering, the earth moved by the plough is continually falling back, in ſpite of the moſt ſkilful ploughman.

The inconveniences of ridges high and crooked are ſo many, that one would be tempted to apply a remedy at any riſk. And yet, if the ſoil be clay, it would not be adviſeable for a tenant to apply the remedy upon a leaſe ſhorter than two nineteen years. In a dry gravelly ſoil, the work is not difficult nor hazardous. When the ridges are cleaved two or three years ſucceſſively in the courſe of cropping, the operation ought to be concluded in one ſummer. The earth, by reiterated ploughings, ſhould be accumulated upon the furrows, ſo as to raiſe them higher than the crowns: they cannot be raiſed too high, for the accumulated earth will ſubſide by its own weight. Croſs ploughing once or twice, will reduce the ground to a flat ſurface, and give opportunity to form ridges at will. The ſame method brings down ridges in clay ſoil: only let care be taken to carry on the work with expedition; becauſe a hearty ſhower, before the new ridges are formed, would ſoak the ground in water, and make the farmer ſuſpend his work for the remainder of that year at leaſt. In a ſtrong clay, we would not venture to alter the ridges, unleſs it can be done to perfection in one ſeaſon. On this ſubject Mr Anderſon has the following obſervations *.

Preparation of Land.

* *Eſſays on Agriculture*, vol. i. p. 146.

202 Inconveniences in the common methods of levelling.

"The difficulty of performing this operation properly with the common implements of huſbandry, and the obvious benefit that accrues to the farmer from having his fields level, has produced many new inventions of ploughs, harrows, drags, &c. calculated for ſpeedily reducing the fields to that ſtate; none of which have as yet been found fully to anſwer the purpoſe for which they were intended, as they all indiſcriminately carry the earth that was on the high places into thoſe that were lower; which, although it may in ſome caſes render the ſurface of the ground tolerably ſmooth and level, is uſually attended with inconveniences far greater, for a conſiderable length of time, than that which it was intended to remove.

203 Vegetable mould becomes inert by being long buried.

"For experience ſufficiently ſhows, that even the beſt vegetable mould, if buried for any length of time ſo far beneath the ſurface as to be deprived of the benign influences of the atmoſphere, loſes its *vis vitæ*, if I may be allowed that expreſſion; becomes an inert, lifeleſs maſs, little fitted for nouriſhing vegetables; and conſtitutes a ſoil very improper for the purpoſes of the farmer. It therefore behoves him, as much as in him lies, to preſerve, on every part of his fields, an equal covering of that vegetable mould that has long been uppermoſt, and rendered fertile by the meliorating influence of the atmoſphere. But, if he ſuddenly levels his high ridges by any of theſe mechanical contrivances, he of neceſſity buries all the good mould that was on the top of the ridges in the old furrows; by which he greatly impoveriſhes one part of his field, while he too much enriches another; inſomuch that it is a matter of great difficulty, for many years thereafter, to get the field brought to an equal degree of fertility in different places; which makes it impoſſible for the farmer to get an equal crop over the whole of his field by any management whatever: and he has the mortification frequently, by this means, to ſee the one half of his crop rotted by an over-luxuriance, while other parts of it are weak and ſickly; or one part ripe and ready for reaping, while the other is not properly filled; ſo that it were, on many occaſions, better for him to have his whole field reduced at once to the ſame degree of poorneſs as the pooreſt of it, than have it in this ſtate. An almoſt impracticable degree of attention in ſpreading the manures may indeed in ſome meaſure get the better of this: but it is ſo difficult to perform this properly, that I have frequently ſeen fields that had been thus levelled, in which, after thirty years of continued culture and repeated dreſſings, the marks of the old

Preparation of Land.

ridges could be diſtinctly traced when the corn was growing, although the ſurface was ſo level that no traces of them could be perceived when the corn was off the ground.

" But this is a degree of perfection in levelling that cannot be uſually attained by following this mode of practice, and therefore is but ſeldom ſeen. For all that can be expected to be done by any levelling machine, is to render the ſurface perfectly ſmooth and even in every part, at the time that the operation is performed: but as, in this caſe, the old hollows are ſuddenly filled up with looſe mould to a great depth, while the earth below the ſurface upon the heights of the old ridges remains firm and compact, the new raiſed earth after a ſhort time ſubſides very much, while the other parts of the field do not ſink at all; ſo that in a ſhort time the old furrows come to be again below the level of the other parts of the field, and the water of courſe is ſuffered in ſome degree to ſtagnate upon them; inſomuch that, in a few years, it becomes neceſſary once more to repeat the ſame levelling proceſs, and thus renew the damage that the farmer ſuſtains by this pernicious operation.

204 Levelling ſometimes not to be attempted.

" On theſe accounts, if the farmer has not a long leaſe, it will be found in general to be much his intereſt to leave the ridges as he found them, rather than to attempt to alter their direction; and, if he attends with due caution to moderate the height of theſe old ridges, he may reap very good crops, although perhaps at a ſomewhat greater expence of labour than he would have been put to upon the ſame field, if it had been reduced to a proper level ſurface, and divided into ſtraight and parallel ridges.

" But, where a man is ſecure of poſſeſſing his ground for any conſiderable length of time, the advantages that he will reap from having level and well laid out fields, are ſo conſiderable as to be worth purchaſing, if it ſhould even be at a conſiderable expence. But the loſs that is ſuſtained at the beginning, by this mechanical mode of levelling ridges, if they are of conſiderable height, is ſo very great, that it is perhaps doubtful if any future advantages can ever fully compenſate it. I would therefore adviſe, that all this levelling apparatus ſhould be laid aſide; and the following more efficacious practice be ſubſtituted in its ſtead: A practice that I have long followed with ſucceſs, and can ſafely recommend as the very beſt that has yet come to my knowledge.

205 Beſt method of levelling.

" If the ridges have been raiſed to a very great height, as a preparation for the enſuing operations, they may be firſt *cloven*, or *ſcalded* out, as it is called in different places; that is, ploughed ſo as to lay the earth on each ridge from the middle towards the furrows. But if they are only of a moderate degree of height, this operation may be omitted. When you mean to proceed to level the ground, let a number of men be collected, with ſpades, more or fewer as the nature of the ground requires, and then ſet a plough to draw a furrow directly acroſs the ridges of the whole field intended to be levelled. Divide this line into as many parts as you have labourers, allotting to each one ridge or two, or more or leſs, according to their number, height, and other circumſtances. Let each of the labourers have orders, as ſoon as the plough has paſſed that part aſſigned him, to begin to dig in the bottom of the furrow that the plough has juſt made, about the middle of the ſide of the old ridge, keeping his face towards the old furrow, working backwards till he comes to the height of the ridge; and then turn towards the other furrow, and repeat the ſame on the other ſide of the ridge, always throwing the earth that he digs up into the deep old furrow between the ridges, that is directly before him; taking care not to dig deep where he firſt begins, but to go deeper and deeper as he advances to the height of the ridge, ſo as to leave the bottom of the trench he thus makes acroſs the ridge entirely level, or as nearly ſo as poſſible. And when he has finiſhed that part of the furrow allotted to him that the plough has made in going, let him then go and finiſh in the ſame manner his own portion of the furrow that the plough makes in returning. In this manner, each man performs his own taſk through the whole field, gradually raiſing the old furrows as the old heights are depreſſed. And, if an attentive overſeer is at hand, to ſee that the whole is equally well done, and that each furrow is raiſed to a greater height than the middle of the old ridges, ſo as to allow for the ſubſiding of that looſe earth, the operation will be entirely finiſhed at once, and never again need to be repeated.

Preparation of Land.

" In performing this operation, it will always be proper to make the ridges, formed for the purpoſe of levelling, which go acroſs the old ridges, as broad as poſſible; becauſe the deep trench that is thus made in each of the furrows is an impediment in the future operations, as well as the height that is accumulated in the middle of each of theſe ridges; ſo that the fewer there are of theſe, the better it is. The farmer, therefore, will do well to advert to this in time, and begin by forming a ridge by always turning the plough to the right hand, till it becomes of ſuch a breadth as makes it very inconvenient to turn longer in that manner; and then, at the diſtance of twice the breadth of this new-formed ridge from the middle of it, mark off a furrow for the middle of another ridge, turning round it to the right hand, in the ſame manner as was done in the former, till it becomes of the ſame breadth with it; and then, turning to the left hand, plough out the interval that was left between the two new-formed ridges. By this mode of ploughing, each ridge may be made of 40, 50, or 60 yards in breadth, without any great inconvenience; for although ſome time will be loſt in turning at the ends of theſe broad ridges, yet as this operation is only to be once performed in this manner, the advantage that is reaped by having few open furrows, is more than ſufficient to counterbalance it. And, in order to moderate the height that would be formed in the middle of each of theſe great ridges, it will always be proper to mark out the ridges, and draw the furrow that is to be the middle of each, ſome days before you collect your labourers to level the field; that you may, without any hurry or loſs of labour, clear out a good trench through the middle of each of the old ridges; as the plough, at this time, going and returning nearly in the ſame track, prevents the labourers from working properly without this precaution.

" If theſe rules are attended to, your field will be at once reduced to a proper level, and the rich earth that formed the ſurface of the old ridges be ſtill kept upon the

Preparation of Land.

the ſurface of your field; ſo that the only loſs that the poſſeſſor of ſuch ground can ſuſtain by this operation, is merely the expence of performing it."

He afterwards makes a calculation of the different expences of levelling by the plough and by the ſpade, in which he finds the latter by far the cheapeſt method.

206 Proper direction of the ridges.

Let it be a rule to direct the ridges north and ſouth, if the ground will permit. In this direction, the eaſt and weſt ſides of the ridges, dividing the ſun equally between them, will ripen at the ſame time.

207 Narrow ridges an advantage.

It is a great advantage in agriculture, to form ridges ſo narrow, and ſo low, as to admit the crowns and furrows to be changed alternately every crop. The ſoil neareſt the ſurface is the beſt; and by ſuch ploughing, it is always kept near the ſurface, and never buried. In high ridges, the ſoil is accumulated at the crown, and the furrows left bare. Such alteration of crown and furrow is eaſy where the ridges are no more but ſeven or eight feet broad. This mode of ploughing anſwers perfectly well in ſandy and gravelly ſoils, and even in loam; but it is not ſafe in clay ſoil. In that ſoil, the ridges ought to be 12 feet wide, and 20 inches high; to be preſerved always in the ſame form by caſting, that is, by ploughing two ridges together, beginning at the furrow that ſeparates them, and ploughing round and round till the two ridges be finiſhed. By this method, the ſeparating furrow is raiſed a little higher than the furrows that bound the two ridges. But at the next ploughing, that inequality is corrected by beginning at the bounding furrows, and going round and round till the ploughing of the two ridges be completed at the ſeparating furrow.

6. Clearing Ground of Weeds.

208 Cleaning harrow. Plate VIII. fig. 6.

For this purpoſe a new inſtrument, termed a *cleaning harrow*, has been introduced by Lord Kames, and is ſtrongly recommended (E). It is one entire piece like the firſt of thoſe mentioned above, conſiſting of ſeven bulls, four feet long each, two and one-fourth inches broad, two and three-fourths deep. The bulls are united together by ſheths, ſimilar to what are mentioned above. The intervals between the bulls being three and three-fourths inches, the breadth of the whole harrow is three feet five inches. In each bull are inſerted eight teeth, each nine inches free below the wood, and diſtant from each other ſix inches. The weight of each tooth is a pound, or near it. The whole is firmly bound by an iron plate from corner to corner in the line of the draught. The reſt as in the harrows mentioned above. The ſize, however, is not invariable. The cleaning harrow ought to be larger or leſs, according as the ſoil is ſtiff or free.

To give this inſtrument its full effect, ſtones of ſuch a ſize as not to paſs freely between the teeth ought to be carried off, and clods of that ſize ought to be broken. The ground ought to be dry, which it commonly is in the month of May.

In preparing for barley, turnip, or other ſummer-crop, begin with ploughing and croſs ploughing. If the ground be not ſufficiently pulverized, let the great brake be applied, to be followed ſucceſſively with the 1ſt and 2d harrows. In ſtiff ſoil, rolling may be proper, once or twice between the acts. Theſe operations will looſen every root, and bring ſome of them to the ſurface. This is the time for the 3d harrow, conducted by a boy mounted on one of the horſes, who trots ſmartly along the field, and brings all the roots to the ſurface: there they are to lie for a day or two, till perfectly dry. If any ſtones or clods remain, they muſt be carried off in a cart. And now ſucceeds the operation of the cleaning harrow. It is drawn by a ſingle horſe, directed by reins, which the man at the oppoſite corner puts over his head, in order to have both hands free. In this corner is fixed a rope, with which the man from time to time raiſes the harrow from the ground, to let the weeds drop. For the ſake of expedition, the weeds ought to be dropt in a ſtraight line croſs the field, whether the harrow be full or not; and ſeldom is a field ſo dirty, but that the harrow may go 30 yards before the teeth are filled. The weeds will be thus laid in parallel rows, like thoſe of hay raked together for drying. A harrow may be drawn ſwiftly along the rows, in order to ſhake out all the duſt; and then the weeds may be carried clean off the field in carts. But we are not yet done with theſe weeds: inſtead of burning, which is the ordinary practice, they may be converted into uſeful manure, by laying them in a heap with a mixture of hot dung to begin fermentation. At firſt view, this way of cleaning land will appear operoſe; but, upon trial, neither the labour nor expence will be found immoderate. At any rate, the labour and expence ought not to be grudged; for if a field be once thoroughly cleaned, the ſeaſons muſt be very croſs, or the farmer very indolent, to make it neceſſary to renew the operation in leſs than 20 years. In the worſt ſeaſons, a few years paſture is always under command; which effectually deſtroys triennial plants, ſuch as thiſtles and couch graſs.

Preparation of Land. Plate VIII. fig. 3, 4. fig. 5.

7. On the Nature of different Kinds of Soils, and the Plants proper to each.

209 Clay ſoil.

1. Clay, which is in general the ſtiffeſt of all ſoils, and contains an unctuous quality. But under the terms *clays*, earths of different ſorts and colours are included. One kind is ſo obſtinate, that ſcarcely any thing will ſubdue it; another is ſo hungry and poor, that it abſorbs whatever is applied, and turns it into its own quality. Some clays are fatter than others, and the fatteſt are the beſt; ſome are more ſoft and ſlippery. But all of them retain water poured on their ſurface, where it ſtagnates, and chills the plants without ſinking into the ſoil. The cloſeneſs of clay prevents the roots and fibres of plants from ſpreading in ſearch of nouriſhment. The blue, the red, and the white clay, if ſtrong, are unfavourable to vegetation. The ſtony and looſer ſorts are leſs ſo; but none of them are worth any thing till their texture is ſo looſened by a mixture of other ſubſtances, and opened, as to admit the influence of the ſun, the air, and froſts. Among the manures recommended for clay, ſand is of all

(E) In his *Gentleman Farmer*; to which performance the practical part of this article is materially indebted.

Preparation of Land.

all others to be preferred; and ſea ſand is the beſt of all where it can be obtained: This moſt effectually breaks the coheſion.

The reaſon for preferring ſea ſand is, that it is not formed wholly (as moſt other ſands are) of ſmall ſtones; but contains a great deal of calcareous matter in it, ſuch as ſhells grated and broken to pieces by the tide, and alſo of ſalts. The ſmaller the ſand is, the more eaſily it penetrates the clay; but it abides leſs time in it than the larger.

The next beſt ſand is that waſhed down by rains on gravelly ſoils. Thoſe which are dry and light are the worſt. Small gritty gravel has alſo been recommended by the beſt writers on agriculture for theſe ſoils; and in many inſtances we have found it to anſwer the purpoſe.

Shell marl, aſhes, and all animal and vegetable ſubſtances, are very good manures for clay; but they have been found moſt beneficial when ſand is mixed with them. Lime has been often uſed; but the writer of this ſection would not recommend it, for he never found any advantage from it ſingly, when applied to clays.

The crops moſt ſuitable for ſuch lands are, wheat, beans, cabbages, and rye-graſs. Clover ſeldom ſucceeds, nor indeed any plants whoſe roots require depth and a wide ſpread in the earth.

210 Chalky ſoil.

2. Chalk. Chalky ſoils are generally dry and warm, and if there be a tolerable depth of mould, fruitful; producing great crops of barley, rye, peaſe, vetches, clover, trefoil, burnet, and particularly ſainfoin. The latter plant flouriſhes in a chalky ſoil better than any other. But if the ſurface of mould be very thin, this ſoil requires good manuring with clay, marl, loam, or dung. As theſe lands are dry, they may be ſown earlier than others.

When your barley is three inches high, throw in 10lb. of clover, or 15lb. of trefoil, and roll it well. The next ſummer mow the crop for hay: feed off the aftermath with ſheep; and in winter give it a top-dreſſing of dung. This will produce a crop the ſecond ſpring, which ſhould be cut for hay. As ſoon as this crop is carried off, plough up the land, and in the beginning of September ſow three buſhels of rye per acre, either to feed off with ſheep in the ſpring or to ſtand for harveſt. If you feed it off, ſow winter vetches in Auguſt or September, and make them into hay the following ſummer. Then get the land into as fine tilth as poſſible, and ſow it with ſainfoin, which, with a little manure once in two or three years, will remain and produce good crops for 20 years together.

211 Light poor ſoil.

3. Light poor land, which ſeldom produces good crops of any thing till well manured. After it is well ploughed, ſow three buſhels of buck-wheat per acre, in April or May: When in bloom, let your cattle in a few days to eat off the beſt, and tread the other down; this done, plough in what remains immediately. This will ſoon ferment and rot in the ground; then lay it fine, and ſow three buſhels of rye per acre. If this can be got off early enough, ſow turnips; if not, winter vetches to cut for hay. Then get it into good tilth, and ſow turnip-rooted cabbages, in rows three feet apart. This plant ſeldom fails, if it has ſufficient room, and the intervals be well horſe-hoed; and you will find it the beſt ſpring feed for ſheep when turnips are over.

Preparation of Land.

The horſe-hoeing will clean and prepare the land for ſainfoin; for the ſowing of which April is reckoned the beſt ſeaſon. The uſual way is to ſow it broad-caſt, four buſhels to an acre; but the writer prefers ſowing it in drills two feet aſunder; for then it may be horſe-hoed, and half the ſeed will be ſufficient.

The horſe-hoeing will not only clean the crop, but earth up the plants, and render them more luxuriant and laſting.

If you ſow it broad-caſt, give it a top-dreſſing in December or January, of rotten dung or aſhes, or, which is ſtill better, of both mixed up in compoſt.

From various trials, it is found that taking only one crop in a year, and feeding the after-growth, is better than to mow it twice. Cut it as ſoon as it is in full bloom, if the weather will permit. The hay will be the ſweeter, and the ſtrength of the plants leſs impaired, than if it ſtand till the ſeed is formed.

212 Light rich land.

4. Light rich land, being the moſt eaſy to cultivate to advantage, and capable of bearing moſt kinds of grain, pulſe, and herbage, little need be ſaid upon it. One thing however is very proper to be obſerved, that ſuch lands are the beſt adapted to the drill huſbandry, eſpecially where machines are uſed, which require ſhallow furrows to be made for the reception of the ſeed. This, if not prone to couch graſs, is the beſt of all ſoils for lucerne; which, if ſown in two feet drills, and kept clean, will yield an aſtoniſhing quantity of the moſt excellent herbage. But lucerne will never be cultivated to advantage where couch graſs and weeds are very plentiful; nor in the broad-caſt method, even where they are not ſo; becauſe horſe-hoeing is eſſential to the vigorous growth of this plant.

213 Coarſe rough land.

5. Coarſe rough land. Plough deep in autumn; when it has lain two weeks, croſs-plough it, and let it lie rough through the winter. In March give it another good ploughing; drag, rake, and harrow it well, to get out the rubbiſh, and ſow four buſhels of black oats per acre if the ſoil be wet, and white oats if dry. When about four inches high, roll them well after a ſhower: This will break the clods; and the fine mould falling among the roots of the plants will promote their growth greatly.

Some ſow clover and rye-graſs among the oats, but this appears to be bad huſbandry. If you deſign it for clover, ſow it ſingle, and let a coat of dung be laid on in December. The ſnow and rain will then dilute its ſalts and oil, and carry them down among the roots of the plants. This is far better than mixing the crops on ſuch land, for the oats will exhauſt the ſoil ſo much that the clover will be impoveriſhed. The following ſummer you will have a good crop of clover; which cut once, and feed the after-growth. In the winter plough it in, and let it lie till February: Then plough and harrow it well; and in March, if the ſoil be moiſt, plant beans in drills of three feet, to admit the horſe-hoe freely. When you horſe-hoe them a ſecond time, ſow a row of turnips in each interval, and they will ſucceed very well. But if the land be ſtrong enough for ſowing wheat as ſoon as the beans are off, the turnips may be omitted.

SECT. III.

Culture of particular Plants.

Sect. III. *Culture of particular Plants.*

The articles hitherto inſiſted on, are all of them preparatory to the capital object of a farm, that of raiſing plants for the nouriſhment of man and of other animals. Theſe are of two kinds; culmiferous and leguminous; differing widely from each other. Wheat, rye, barley, oats, rye-graſs, are of the firſt kind: of the other kind are, peaſe, beans, clover, cabbage, and many others.

214 Culmiferous plants.

Culmiferous plants, ſays Bonnet, have three ſets of roots. The firſt iſſue from the ſeed, and puſh to the ſurface an upright ſtem; another ſet iſſue from a knot in that ſtem; and a third from another knot, nearer the ſurface. Hence the advantage of laying ſeed ſo deep in the ground as to afford ſpace for all the ſets.

215 Leguminous plants.

Leguminous plants form their roots differently. Peaſe, beans, cabbage, have ſtore of ſmall roots, all iſſuing from the ſeed, like the undermoſt ſet of culmiferous roots; and they have no other roots. A potato and a turnip have bulbous roots. Red clover has a ſtrong tap-root. The difference between culmiferous and leguminous plants with reſpect to the effects they produce in the ſoil, will be inſiſted on afterward, in the ſection concerning rotation of crops. As the preſent ſection is confined to the propagation of plants, it falls naturally to be divided into three articles; firſt, Plants cultivated for fruit; ſecond, Plants cultivated for roots; third, Plants cultivated for leaves.

I. Plants Cultivated for Fruit.

1. Wheat and Rye.

216 Fallowing for wheat.

Any time from the middle of April to the middle of May, the fallowing for wheat may commence. The moment ſhould be choſen, when the ground, beginning to dry, has yet ſome remaining ſoftneſs: in that condition, the ſoil divides eaſily by the plough, and falls into ſmall parts. This is an eſſential article, deſerving the ſtricteſt attention of the farmer. Ground ploughed too wet, riſes, as we ſay, *whole-fur*, as when paſture-ground is ploughed: where ploughed too dry, it riſes in great lumps, which are not reduced by ſubſequent ploughings; not to mention, that it requires double force to plough ground too dry, and that the plough is often broken to pieces. When the ground is in proper order, the farmer can have no excuſe for delaying a ſingle minute. This firſt courſe of fallow muſt, it is true, yield to the barley-ſeed; but as the barley-ſeed is commonly over the firſt week of May, or ſooner, the ſeaſon muſt be unfavourable if the fallow cannot be reached by the middle of May.

As clay ſoil requires high ridges, theſe ought to be cleaved at the firſt ploughing, beginning at the furrow, and ending at the crown. This ploughing ought to be as deep as the ſoil will admit: and water-furrowing ought inſtantly to follow; for if rain happen before water-furrowing, it ſtagnates in the furrow, neceſſarily delays the ſecond ploughing till that part of the ridge be dry, and prevents the furrow from being mellowed and roaſted by the ſun. If this firſt ploughing be well executed, annual weeds will riſe in plenty.

About the firſt week of June, the great brake will looſen and reduce the ſoil, encourage a ſecond crop of annuals, and raiſe to the ſurface the roots of weeds moved by the plough. Give the weeds time to ſpring, which may be in two or three weeks. Then proceed to the ſecond ploughing about the beginning of July; which muſt be croſs the ridges, in order to reach all the ſlips of the former ploughing. By croſs-ploughing the furrows will be filled up, and water-furrowing be ſtill more neceſſary than before. Employ the brake again about the 10th of Auguſt, to deſtroy the annuals that have ſprung ſince the laſt ſtirring. The deſtruction of weeds is a capital article in fallowing: yet ſo blind are people to their intereſt, that nothing is more common than a fallow field covered with charlock and wild muſtard, all in flower, and 10 or 12 inches high. The field having now received two harrowings and two brakings is prepared for manure, whether lime or dung, which without delay ought to be incorporated with the ſoil by a repeated harrowing and a gathering furrow. This ought to be about the beginning of September, and as ſoon after as you pleaſe the ſeed may be ſown.

Culture of particular Plants.

217 Dreſſing loam for wheat.

As in ploughing a clay ſoil it is of importance to prevent poaching, the hinting furrows ought to be done with two horſes in a line. If four ploughs be employed in the ſame field, to one of them may be allotted the care of finiſhing the hinting furrows.

Loam, being a medium between ſand and clay, is of all ſoils the fitteſt for culture, and the leaſt ſubject to chances. It does not hold water like clay; and when wet, it dries ſooner. At the ſame time, it is more retentive than ſand of that degree of moiſture which promotes vegetation. On the other hand, it is more ſubject to couch graſs than clay, and to other weeds; to deſtroy which, fallowing is ſtill more neceſſary than in clay.

Beginning the fallow about the firſt of May, or as ſoon as barley ſeed is over, take as deep a furrow as the ſoil will admit. Where the ridges are ſo low and narrow as that the crown and furrow can be changed alternately, there is little or no occaſion for water-furrowing. Where the ridges are ſo high as to make it proper to cleave them, water-furrowing is proper. The ſecond ploughing may be at the diſtance of five weeks. Two crops of annuals may be got in the interim, the firſt by the brake and the next by the harrow; and by the ſame means eight crops may be got in the ſeaſon. The ground muſt be cleared of couch graſs and knot-graſs roots, by the cleaning harrow deſcribed above. The time for this operation is immediately before the manure is laid on. The ground at that time being in its looſeſt ſtate, parts with its graſs roots more freely than at any other time. After the manure is ſpread, and incorporated with the ſoil by braking or harrowing, the ſeed may be ſown under furrow, if the ground hang ſo as eaſily to carry off the moiſture. To leave it rough without harrowing has two advantages: it is not apt to cake with moiſture, and the inequalities make a ſort of ſhelter to the young plants againſt froſt. But if it lie flat, it ought to be ſmoothed with a ſlight harrow after the ſeed is ſown, which will facilitate the courſe of the rain from the crown to the furrow.

218 Dreſſing a ſandy ſoil.

A ſandy ſoil is too looſe for wheat. The only chance for a crop is after red clover, the roots of which bind the ſoil; and the inſtructions above given for loam are applicable

Culture of particular Plants.

applicable here. Rye is a crop much fitter for ſandy ſoil than wheat; and like wheat, it is generally ſown after a ſummer fallow.

219 Time for ſowing.

Laſtly, Sow wheat as ſoon in the month of October as the ground is ready. When ſown a month more early, it is too forward in the ſpring and apt to be hurt by froſt: when ſown a month later, it has not time to root before froſt comes on; and froſt ſpews it out of the ground.

220 Setting of wheat,

Setting of wheat, a method which by ſome is reckoned one of the greateſt improvements in huſbandry that has taken place this century. It ſeems to have been firſt ſuggeſted by planting grains in a garden from mere curioſity, by perſons who had no thought or opportunity of extending it to a lucrative purpoſe. Nor was it attempted on a larger ſcale, till a little farmer near Norwich began it, about 25 years ſince, upon leſs than an acre of land. For two or three years only a few followed his example; and theſe were generally the butt of their neighbours merriment for adopting ſo ſingular a practice. They had, however, conſiderably better corn and larger crops than their neighbours: this, together with the ſaving in ſeed, engaged more to follow them: while ſome ingenious perſons, obſerving its great advantage, recommended and publiſhed its utility in the Norwich papers. Theſe recommendations had their effect. The curioſity and inquiry of the Norfolk farmers particularly round Norwich were excited, and they found ſufficient reaſon to make general experiments. Among the reſt was one of the largeſt occupiers of lands in that county, who ſet 57 acres in one year. His ſucceſs, from the viſible ſuperiority of his crop, both in quantity and quality, was ſo great, that the following autumn he ſet 300 acres, and has continued the practice ever ſince. This noble experiment eſtabliſhed the practice, and was the means of introducing it generally among the intelligent farmers in a very large diſtrict of land; there being few who now ſow any wheat, if they can procure hands to ſet it. It has been generally obſerved, that although the ſet crops appear very thin during the autumn and winter, the plants ſide-ſhoot and ſpread prodigiouſly in the ſpring. The ears are indiſputably larger, without any dwarfiſh or ſmall corn; the grain is of a larger bulk, and ſpecifically heavier *per* buſhel than when ſown.

221 a capital improvement in agriculture.

222 Method.

The lands on which this method is particularly proſperous, are either after a clover ſtubble, or on which trefoil and graſs ſeed were ſown the ſpring before the laſt. Theſe grounds, after the uſual manuring, are once turned over by the plough in an extended flag or turf, at ten inches wide; along which a man, who is called a *dibbler*, with two ſetting irons, ſomewhat bigger than ramrods, but conſiderably bigger at the lower end, and pointed at the extremity, ſteps backwards along the turf, and makes the holes about four inches aſunder every way, and an inch deep. Into theſe holes the droppers (women, boys, and girls) drop two grains, which is quite ſufficient. After this, a gate buſhed with thorns is drawn by one horſe over the land, and cloſes up the holes. By this mode, three pecks of grain is ſufficient for an acre; and being immediately buried, it is equally removed from vermin or the power of froſt. The regularity of its riſing gives the beſt opportunity of keeping it clear from weeds, by weeding or hand-hoeing.

Culture of particula Plants.

Wheat-ſetting is a method peculiarly beneficial when corn is dear; and, if the ſeaſon be favourable, may be practiſed with great benefit to the farmer. Sir Thomas Beevor of Hethel-Hall in Norfolk, found the produce to be two buſhels per acre more than from the wheat which is ſown; but having much leſs ſmall corn intermixed with it, the ſample is better, and always fetches a higher price, to the amount generally of two ſhillings per quarter.

223 Peculiar advantage

This method, too, ſaves to the farmer and to the public ſix pecks of ſeed wheat in every acre; which, if nationally adopted, would of itſelf afford bread for more than half a million of people.

Add to theſe conſiderations, the great ſupport given to the poor by this *ſecond* harveſt, as it may be called, which enables them to diſcharge their rents and maintain their families without having recourſe to the pariſh.—The expence of ſetting by hand is now reduced to about ſix ſhillings per acre; which, in good weather, may be done by one dibbler, attended by three droppers, in two days. This is five ſhillings per day; of which if the dibbler gives to the children ſixpence each, he will have himſelf three ſhillings and ſixpence for his day's work, which is much more than he can poſſibly earn by any other labour ſo eaſy to himſelf. But put the caſe, that the man has a wife who dibbles with him, and two or three of his own children to drop to him, you ſee his gains will then be prodigious, and enough to enſure a plenty of candidates for that work, even in the leaſt populous parts of the country.

It is, however, to be obſerved with regard to this method, that in ſeaſons when ſeed-corn is very cheap, or the autumn particularly unfavourable to the practice, it muſt certainly be leſſened. In light lands, for inſtance, a very dry time prevents dibbling; as the holes made with the inſtruments will be filled up again by the mould as faſt as the inſtrument is withdrawn. So, again, in a very wet ſeaſon, on ſtrong and ſtiff clays, the ſeeds in the holes cannot be well and properly covered by the buſhes drawn over them. But theſe extremes of dry and wet do not often happen, nor do they affect lands of a moderately conſiſtent texture, or both light and heavy ſoils at the ſame time; ſo that the general practice is in fact never greatly impeded by them.

224 Propagating of wheat by dividing the roots

Propagating of wheat by dividing and tranſplanting its roots. In the Philoſophical Tranſactions for 1768, we meet with a very important experiment, of which the following is an abſtract. On the 2d of June 1766, Mr C. Miller ſowed ſome grains of the common red wheat; and on the 8th of Auguſt a ſingle plant was taken up and ſeparated into 18 parts, and each part planted ſeparately. Theſe plants having puſhed out ſeveral ſide-ſhoots, by about the middle of September; ſome of them were then taken up and divided, and the reſt of them between that time and the middle of October. This ſecond diviſion produced 67 plants. Theſe plants remained through the winter, and another diviſion of them, made between the middle of March and the 12th of April, produced 500 plants. They were then divided no further, but permitted to remain. The plants were in general ſtronger than any of the wheat in the fields. Some of them produced upwards of

Culture of particular Plants.

of 100 ears from a ſingle root. Many of the ears meaſured ſeven inches in length, and contained between 60 and 70 grains.

The whole number of ears which, by the proceſs above mentioned, were produced from one grain of wheat, was 21,109, which yielded three pecks and three quarters of clean corn, the weight of which was 47lb. 7 ounces; and from a calculation made by counting the number of grains in an ounce, the whole number of grains was about 386,840.

By this account we find, that there was only one general diviſion of the plants made in the ſpring. Had a ſecond been made, Mr Miller thinks the number of plants would have amounted to 2000 inſtead of 500, and the produce thereby been much enlarged.

The ground was a light blackiſh ſoil, upon a gravelly bottom; and, conſequently, a bad ſoil for wheat. One half of the ground was well dunged, the other half had no manure. There was, however, not any difference diſcoverable in the vigour, or growth, or produce, of the plants.

It muſt be evident, that the expence and labour of ſetting in the above manner by the hand, will render it ſcarcely practicable upon a large ſcale ſo as to be productive of any utility. A correſpondent of the Bath Society, therefore, (Robert Bogle, Eſq. of Daldowin, near Glaſgow), with a view to extend the practice, has propoſed the uſe of the harrow and roller until ſome better implements be invented. This method occurred to him from attending to the practice uſual with farmers on certain occaſions, of harrowing their fields after the grain is ſprung up. Upon inveſtigating the principles upon which theſe practices are founded, he found them confined merely to that of pulverizing the earth, without any attention to Mr Miller's doctrine. They ſaid, "that after very heavy rains, and then exceſſive dry weather, the ſurface of their lands was apt to be caked, the tender fibres of the young roots were thereby prevented from puſhing, and of courſe the vegetation was greatly obſtructed; in ſuch inſtances, they found very great benefit from harrowing and rolling."

225 Method propoſed by Mr Bogle.

Theſe principles he acknowledges to be well founded, ſo far as relates to pulverizing; but contends, that the benefit ariſing from harrowing and rolling is not derived from pulverizing entirely, but alſo from ſubdividing and enabling the plants to tiller (as it is termed). "The harrow (he obſerves) certainly breaks the incruſtation on the ſurface, and the roller crumbles the clods; but it is alſo obvious, that the harrow removes a great many of the plants from their original ſtations; and that if the corn has begun to tiller at the time it is uſed, the roots will be, in many inſtances, ſubdivided, and then the application of my ſyſtem of diviſibility comes into play. The roller then ſerves to plant the roots which have been torn up by the harrow."

226 Objections.

But on this the Society obſerve, that the teeth of a harrow are too large to divide roots ſo ſmall and tenacious as are thoſe of grain; and whenever ſuch roots (however tillered) ſtand in the line any tooth makes, they will, if ſmall, be only turned on one ſide by the earth yielding to their lateral preſſure, or, if large, the whole root will probably be drawn out of the ground. The principal uſes, therefore, derived from harrowing and rolling theſe crops are, opening the ſoil between the plants, earthing them up, breaking the clods, and cloſing the earth about their roots.

Culture of particular Plants.

In a ſubſequent letter, Mr Bogle, without conteſting theſe points, further urges the ſcheme of propagating wheat by dividing and tranſplanting its roots. "I have converſed (ſays he) much with many practical farmers, who all admit that my plan has the appearance not only of being practical, but advantageous. I have alſo ſeen, in the ninth number of Mr Young's Annals of Agriculture, the account of an experiment which ſtrongly corroborates my theory. It was made by the Rev. Mr Pike of Edmonton. From this, and other experiments which have been made under my own eye, I foreſee clearly, that the ſyſtem is practicable, and will certainly be productive of great benefit, ſhould it become general. Beſides the ſaving of nine-tenths of ſeed in the land ſown broad-caſt, other very important advantages will attend the ſetting out of wheat from a feed-bed: ſuch as an early crop; the certainty of good crops; rendering a ſummer-fallow unneceſſary; ſaving dung; and having your wheat perfectly free from weeds without either hand or horſe-hoeing. Five hundred plants in April produced almoſt a buſhel of grain. My gardener ſays, he can ſet one thouſand plants in a day, which is confirmed by the opinion of two other gardeners. Mr Miller found no difference in the produce of what was planted on lands that had dung, and on what had none, except where the land was improper for wheat at all."

227 Practicability of the ſcheme of ſetting.

On this letter we have the following note by the ſociety: "Mr Bogle will ſee, by the ſociety's premium book this year, that by having offered ſeveral premiums for experiments of the kind he ſo earneſtly recommends, we wiſh to have his theory brought to the teſt of practice. Our reaſon for this, as well as for printing Mr B's letter, was rather to excite deciſive trials by ingenious perſons, than from any expectation of the practice ever becoming a general one. General, indeed, it never can be. A ſufficient number of hands could not be found to do it. Unkindly ſeaſons at the time of tranſplanting and dividing the roots would frequently endanger and injure, if not deſtroy, the crops. But admitting the mode generally practicable, we very much doubt whether all the advantages he has enumerated would be derived from this mode of culture. Why ſhould dividing and tranſplanting the roots of wheat cauſe the crop to be early, or afford a *certainty* of its being *a good one?* We cannot think that *leſs manure* is neceſſary in this method than either in drilling or broad-caſt; nor can we by any means admit, ſuch crops would 'be perfectly free from weeds without either hand or horſe-hoeing.' We readily agree with Mr Bogle, that by this mode of culture on a general ſcale, an immenſe quantity of ſeed-corn would be annually ſaved to the nation; and in this, we believe, the advantage, were it practicable, would principally conſiſt."

228 Bath Society's obſervations.

Upon the ſame ſubject, and that of harrowing all kinds of corn, we are informed, Mr Bogle afterwards communicated to the Society his thoughs more at large, together with authentic accounts which were made at his inſtance, and which were attended with very great ſucceſs. Theſe muſt undoubtedly be regarded as of very great importance, and accordingly the ſociety, conceiving his ſyſtem may be attended with

229 Further obſervations of Mr Bogle.

Culture of particular Plants.

with conſiderable advantages if brought into general practice, have given, at the end of their third volume a few of his leading principles. Mr Bogle ſtates, 1. That he has known many inſtances of very great crops having been obtained by harrowing fields of corn after they were ſprouted; and therefore recommends the practice very warmly.

2. That he has alſo received an authentic account of one inſtance where the ſame good effects were produced by ploughing the field.

3. On the ſyſtem of tranſplanting, he ſtates, that a very great proportion of the ſeed will be ſaved, as a farmer may have a nurſery, or ſmall patch of plants, from which his fields may be ſupplied; he calculates that one acre will yield plants ſufficient for 100 acres.

4. That a very great increaſe of crops may be obtained by this method, probably a double crop, nay perhaps a triple quantity of what is reaped either by drilling or by the broad-caſt huſbandry.

5. That a great part of the labour may be performed by infirm men and women, and alſo by children, who are at preſent ſupported by the pariſh charity; and that of courſe the poor's rates may be conſiderably reduced.

6. That the expence will not exceed from 20s. to 30s. per acre, if the work be performed by able-bodied men and women; but that it will be much lower, if that proportion of the work which may be done by employing young boys and girls ſhould be allotted to them.

7. That in general he has found the diſtance of nine inches every way a very proper diſtance for ſetting out the plants at; but recommends them to be tried at other ſpaces, ſuch as 6, 8, or even 12 inches.

8. That he conceives an earlier crop may be obtained in this manner that can be obtained by any other mode of cultivation.

9. That a clean crop may alſo be procured in this way, becauſe if the land be ploughed immediately before the plants are ſet out, the corn will ſpring much quicker from the plants than the weeds will do from their ſeeds; and the corn will thereby bear down the growth of the weeds.

10. That ſuch lands as are overflowed in the winter and ſpring, and are of courſe unfit for ſowing with wheat in the autumn, may be rendered fit for crops of wheat by planting them in the ſpring, or even in the ſummer.

11. That he has known inſtances of wheat being tranſplanted in September, October, November, February, March, April, and even as late as the middle of May, which have all anſwered very well.

12. That he has known an early kind of wheat ſown as late as the middle of May, which has ripened in very good time; and from that circumſtance he conceives, if the plants ſhould be taken from that early kind, the ſeaſon of tranſplanting might be prolonged at leaſt till the 1ſt of July, perhaps even later.

13. That he has reaſon to think wheat, oats, and barley, are not annuals, but are perennials, provided they are eaten down by cattle and ſheep, or are kept low by the ſcythe or ſickle; and are prevented from ſpindling or coming to the ear.

14. That one very prevalent motive with him in proſecuting this plan, is, that he is of opinion it may enable government to deviſe means of ſupporting the vagrant poor, both old and young, who are now to be met with everywhere, both in towns and in the country, and who are at preſent a burden on the community: but if ſuch employment could be ſtruck out for them, a comfortable ſubſiſtence might be provided for them by means of their own labour and induſtry; and not only ſave the public and private charitable contributions, but may alſo render that claſs of people uſeful and profitable ſubjects; inſtead of their remaining in a uſeleſs, wretched, and perhaps a profligate and vicious courſe of life.

Culture of particular Plants.

Laſtly, Mr Bogle has hinted at a ſecondary object which he has in view, from this mode of cultivation, which he apprehends may in time, with a ſmall degree of attention, prove extremely advantageous to agriculture.—It is, that, in the firſt place, the real and intrinſic value of different kinds of grain may be more accurately aſcertained by making a compariſon of it with a few plants of each kind ſet out at the ſame time, than can be done when ſown in drills or broad-caſt; and when the moſt valuable kinds of wheat, oats, or barley, are diſcovered, he ſtates, that in a very ſhort time (not exceeding four or five years) a ſufficient quantity of that valuable kind may be procured to ſupply the kingdom with ſeed from a ſingle grain of each kind; for he calculates, that 47,000 grains of wheat may be produced by diviſibility in two years and three months.

230 Obſervation of the Bath Society.

Upon theſe propoſitions the Society obſerves, "That although Mr Bogle appears to be too ſanguine in his expectations of ſeeing his plan realized in *general practice*, it certainly merits the attention of gentlemen farmers. We wiſh them to make fair experiments, and report their ſucceſs. Every grand improvement has been, and ever will be, progreſſive. They muſt neceſſarily originate with gentlemen; and thence the circle is extended by almoſt imperceptible degrees over provinces and countries. At all events, Mr Bogle is juſtly entitled to the thanks of the Society, and of the public for the great attention he has paid to the ſubject."

231 Culture of wheat in Norfolk.

There is perhaps no part of Great Britain where this ſpecies of grain is cultivated to more perfection than in Norfolk. Mr Marſhall informs us, that the ſpecies raiſed in that country is called the *Norfolk red*, and weighs heavier than any other which has yet been introduced, though he owns that its appearance is much againſt the aſſertion, it being a long thin grain, reſembling rye more than well-bodied wheat. About 15 or 20 years ago a new ſpecies was introduced, named the *Kentiſh coſh*; againſt which the millers were at firſt very much prejudiced, though this prejudice is now got over. A remarkable circumſtance reſpecting this grain is, that though upon its introduction into the county the *coſh* or huſk be perfectly white, yet ſuch is the power either of the ſoil or of the mode of cultivation to produce what the botaniſts call *varieties*, that the grain in queſtion is ſaid to loſe every year ſomewhat of the whiteneſs of its huſks, until they become at laſt equally red with thoſe of the former kind. The ſouthern and ſouth-eaſtern parts of the county generally enjoy a ſtronger and richer ſoil than the more northerly, and therefore are more proper for the cultivation of that ſpecies of grain. In the northern parts are ſome farms of very light ſoil, where the farmers ſow

only

Culture of particular Plants.

only a ſmall quantity of wheat; and theſe light lands are called *barley farms*.

The greateſt part of the wheat in Norfolk is ſown upon a ſecond year's ley; ſometimes it is ſown upon a firſt year's ley; ſometimes on a ſummer fallow; after peaſe, turnips, or buck harveſted or ploughed under. The practice adopted by thoſe who are looked upon as ſuperior huſbandmen in the county of Norfolk is as follows: The ſecond year's leys having finiſhed the bullocks, and brought the ſtock cattle and horſes through the fore part of ſummer, and the firſt year's leys having been made ready to receive his ſtock, the farmer begins to break up his old land or ley ground by a peculiar mode of cultivation named *rice-balking*, in which the furrow is always turned toward the unploughed ground, the edge of the coulter paſſing always cloſe by the edge of the flag laſt turned. This is done at firſt with an even regular furrow; opportunity being taken for performing the operation after the ſurface has been moiſtened by a ſummer ſhower. In this ſtate his ſummer leys remain until towards the end of harveſt, when he harrows and afterwards ploughs them acroſs the balks of the former ploughing, bringing them now up to the full depth of the ſoil. On this ploughing he immediately harrows the manure, and ploughs it in with a ſhallow furrow. The effects of this third ploughing are to mix and effectually pulverize the ſoil and manure; to cut off and pulverize the upper ſurfaces of the furrows of the ſecond ploughing; and thus, in the moſt effectual manner, to eradicate or ſmother the weeds which had eſcaped the two former ones. Thus it lies until the ſeed time, when it is harrowed, rolled, ſown, and gathered up into ridges of ſuch width as the farmer thinks moſt proper. Thoſe of ſix furrows are moſt common, though ſome very good farmers lay their wheat land into four-furrow and others into ten-furrow ridges; "which laſt (ſays our author) they execute in a ſtyle much ſuperior to what might be expected from wheel ploughs." They excel, however, in the ſix-furrow ploughing; of which Mr Marſhall gives a particular account. When ploughing in this manner, they carry very narrow furrows; ſo that a ſix-furrow ridge, ſet out by letting the off-horſe return in the firſt-made furrows, does not meaſure more than three feet eight or nine inches.

232 Succeſſion of crops, &c.

233 Rice-balking, a particular mode of culture, explained.

When wheat is cultivated after the firſt year's ley, the ſeed is generally ſown upon the flag or furrow turned over. After peaſe, one or two ploughings are given; the other parts of the management being the ſame with that after the ſecond year's ley already mentioned. After buck harveſted he ſeldom gives more than two, and ſometimes but one, ploughing. In the former caſe he ſpreads his manure on the ſtubble, and ploughs it in with a ſhallow furrow; harrows, rolls, ſows, and gathers up the ſoil into narrow work. The manure is in like manner ſpread on the ſtubble after once ploughing; and the ſeed is then ſown among the manure, the whole ploughed in together, and the ſoil gathered up into narrow ridges, as if it had undergone the operations of a fallow. An inconvenience attending this practice is, that the buck which is neceſſarily ſhed in harveſting ſprings up among the wheat, and becomes a weed to it, at the ſame time that the rooks, if numerous, pull up both buck and wheat, leaving ſeveral patches quite bare. This is obviated in a great meaſure by firſt ploughing in the manure and ſelf-ſown buck with a ſhallow furrow; in conſequence of which the buck vegetates before the wheat.

Culture of particular Plants.

It is likewiſe a favourite practice with the Norfolk farmers to raiſe wheat after buck ploughed under. They plough under the buck by means of a broom made of rough buſhes fixed to the ſure tackle of the plough between the wheels, which bears down the plant without lifting the wheels from the ground. Sometimes, when the buck is ſtrong, they firſt break it down with a roller going the ſame way that the plough is intended to go; afterwards a good ploughman will cover it ſo effectually that ſcarce a ſtalk can be ſeen. Sometimes the ſurface of the ground is left rough, but it is more eligible to harrow and roll it. The practice of ſummer fallowing ſeldom occurs in Norfolk; though ſometimes, when the ſoil has been much worn down by cropping, and overrun by weeds, it is eſteemed a judicious practice by many excellent huſbandmen, and the practice ſeems to be daily gaining ground. After turnips the ſoil is ploughed to a moderate depth, and the ſeed ſown over the firſt ploughing: but if the turnips be got in early, the weeds are ſometimes firſt ploughed in with a ſhallow furrow, and the ſeed ploughed under with a ſecond ploughing, gathering the ſoil into narrow ridges.

234 Manuring the ground in Norfolk.

With regard to the manuring of the ground for wheat in Norfolk, that which has been recently clayed or marled is ſuppoſed to need no other preparation any more than that which has received 15 or 20 loads of dung and mould for turnips; the firſt year's ley having been teathed in autumn, and the ſecond fed off. Where the ſoil is good, and the wheat apt to run too much to ſtraw, it is the practice of ſome judicious farmers to ſet their manure upon the young clover, thereby depriving the wheat in ſome degree of its rankneſs; but it is moſt common to ſpread it upon the broken ground; or if the ſeed be ſown upon the turned furrow, to ſpread it on the turf and plough it under; or to ſpread it on the ploughed ſurface, and harrow it in with the ſeed as a top-dreſſing. A ſmaller quantity of manure is generally made uſe of for wheat than for turnips. From eight to ten cart loads (as much as three horſes can conveniently draw) are reckoned ſufficient for an acre; three or four chaldrons of lime to one acre, or 40 buſhels of ſoot to the ſame quantity of ground; or about a ton of rape-cake to three acres.

235 Time of ſowing.

In this county they never begin to ſow wheat till after the 17th of October, and continue till the beginning of December, ſometimes even till Chriſtmas. They give as a reaſon for this late ſowing, that the wheat treated in this manner is leſs apt to run to ſtraw than when ſown earlier. The ſeed is generally prepared with brine, and candied in the uſual manner with lime. The following method of preparing it is ſaid to be effectual in preventing the ſmut. "The ſalt is diſſolved in a very ſmall quantity of water, barely ſufficient for the purpoſe. The lime is ſlaked with this ſolution, and the wheat candied with it in its hotteſt ſtate, having been previouſly moiſtened with pure water." According to our author's obſervation, the crops of thoſe farmers who uſe this preparation are in general more free from ſmut than thoſe who make uſe of any other.

236 Of preparing the ſeed.

Culture of particular Plants.

The practice of dibbling or ſetting of wheat has not as yet become general throughout Norfolk, the common broad-caſt method being uſually followed, except on the Suffolk ſide of the county. Some few make uſe of dibbling and flating rollers; but drilling is almoſt entirely unknown, notwithſtanding the great aptitude of ſoil for the practice. Ploughing in the ſeed under furrow is the favourite mode of the Norfolk farmers, and is performed in the following manner: "The land having been harrowed down level, and the ſurface rendered ſmooth by the roller, the head ploughman (it at leiſure) marks out the whole piece in narrow ſlips of about a ſtatute rood in width. This he does by hanging up the plough in ſuch a manner, that no part of it except the heel touches the ground; and this makes a ſure mark for the ſeedſman, which he cannot by any means miſtake. In caſe the ploughs are all employed, the ſeedſman himſelf marks the ground, by drawing a piece of wood or other heavy body behind him." Mr Marſhall prefers this to the Kentiſh method of ſetting up ſticks in the form of a lane, as being leſs liable to produce miſtakes.

237 Method of ſowing.

238 Ploughing the ſeed under furrow deſcribed.

239 Inſtruments for dibbling wheat deſcribed.

In thoſe places where wheat is dibbled, they make uſe of iron inſtruments for the purpoſe. The acting part is an egg-ſhaped knob, ſomewhat larger than a pigeon's egg; the ſmaller end is the point of the dibble, the larger having a rod of iron riſing from it about half an inch ſquare, and two feet and a half long; the head being received into a croſs piece of wood reſembling the crutch of a ſpade or ſhovel, which forms the handle. The dibbler uſes two of theſe inſtruments, one in each hand; and, bending over them, walks backward upon the turned furrows, making two rows of holes in each of them. Thoſe rows are uſually made at the diſtance of four inches from each other; the holes being two and a half or three inches diſtant, viz. four in each length of the foot of the dibbler. The great art in making theſe lies in leaving them firm and ſmooth in the ſides, ſo that the looſe mould may not run in to fill them up before the ſeeds are depoſited. This is done by a circular motion of the hand and wriſt; making a ſemi-revolution every ſtroke; the circular motion beginning as the bit enters, and continuing until it is entirely diſengaged from the mould. The operation is not perfect unleſs the dibbles come out clean and wear bright. It is ſomewhat difficult to make the holes at equal diſtances; but more eſpecially to keep the two ſtraight and parallel to each other, ſome practice being required to guide the inſtruments in ſuch a manner as to correſpond exactly with each other; but though couples have been invented to remedy this inconvenience to keep them at a proper diſtance, the other method is ſtill found to be preferable. A middling workman will make four holes in a ſecond. One dibbler is ſufficient for three droppers; whence one man and three children are called a *ſet*. The dibbler carries on three flags or turned furrows; going on ſome yards upon one of the outſide furrows, and returning upon the other, after which he takes the middle one; and thus keeps his three dibblers conſtantly employed, and at the ſame time is in no danger of filling up the holes with his feet. The droppers put in two or three grains of wheat into each hole; but much time and patience is neceſſary to teach them to perform the buſineſs properly and quickly. An expert dibbler will hole half an acre in a day; though one third of an acre is uſually reckoned a good day's work. The ſeed is covered by means of a buſh harrow; and from one buſhel to ſix pecks is the uſual quantity for an acre. Notwithſtanding the advantages of ſaving ſeed, as well as ſome others which are generally reckoned undeniable, it is here aſſerted by ſome very judicious farmers, that dibbling of wheat on the whole is not really a profitable practice. It is particularly ſaid to be productive of weeds unleſs dibbled very thick: which indeed may probably be the caſe, as the weeds are thus allowed a greater ſpace to vegetate in. Mr Marſhall himſelf is of opinion, that "the dibbling of wheat appears to be peculiarly adapted to rich deep ſoils, on which three or four pecks dibbled early may ſpread ſufficiently for a full crop; whereas light, weak, ſhallow ſoils, which have lain two or three years, and have become graſſy, require an additional quantity of ſeed, and conſequently an addition of labour, otherwiſe the plants are not able to reach each other, and the graſſes of courſe find their way up between them, by which means the crop is injured and the ſoil rendered foul."

Culture of particular Plants.

240 Objections againſt the practice of dibbling.

241 Culture of wheat in the midland diſtrict.

The ſame author has likewiſe given an account of the method of cultivating wheat practiſed in other Engliſh counties. In the midland diſtrict, including part of Staffordſhire, Derbyſhire, Warwick, and Leiceſterſhire, we are informed that the ſpecies uſually ſown is that called *Red Lammas*, the ordinary red wheat of the kingdom: but of late a ſpecies named the *Eſſex dun*, ſimilar to the *Kentiſh white coſh* of Norfolk, and the *Hertfordſhire brown* of Yorkſhire, has been coming into vogue. Cone-wheat, formerly in uſe in this diſtrict, is now out of faſhion. Spring wheat is cultivated with remarkable ſucceſs, owing principally to the time of ſowing; viz. the cloſe of April. Our author was informed by an excellent farmer in theſe parts, that by ſowing early, as in the beginning of March, the grain was liable to be ſhrivelled, and the ſtraw to be blighted; while that which was ſown towards the end of April, or even in the beginning of May, produced clean plump corn. At the time he viſited this county, however, it ſeemed to be falling into diſrepute; though he looks upon it, in ſome ſituations, eſpecially in a turnip country, to be eligible. In the ordinary ſucceſſion in this part of the kingdom, wheat comes after oats; and there is perhaps nine-tenths of the wheat in this diſtrict ſown upon oat-ſtubble. Our author has alſo ſeen a few examples of wheat being ſown upon turf of ſix or ſeven years leying; and ſeveral others on clover ley once ploughed, as well as ſome after turnips. The beſt crops, however, produced in this, or perhaps in any other diſtrict, are after ſummer fallow. The time of ſowing is the month of October, little being ſown before Michaelmas; and in a favourable ſeaſon, little after the cloſe of the month. Much ſeed is ſown here without preparation. When any is made uſe of, it is the common one of brine candied with lime. The produce is very great, the medium being full three quarters per acre, ſometimes four or five; and one farmer, in the year 1784, had on 50 acres of land together, no leſs than 45 buſhels per acre.

242 In the v of Glouc ſter.

In the Vale of Glouceſter, the *cone-wheat*, a variety of the *triticum turgidum*, is cultivated, as well as the lammas

Culture of particular Plants.

mas and ſpring wheats. It is not, however, the true cone wheat which is cultivated here, the ears being nearly cylindrical; but our author met with the true ſpecies in North-Wiltſhire. Beans in this country are the common predeceſſors of wheat, and ſometimes peaſe; but here the farmers cultivate wheat upon every ſpecies of ſoil. The time of ſowing is in November and December, and the ſeed is thought to be ſown in ſufficient time if it is done before Chriſtmas. In this country it is thought that late ſown crops always produce better than thoſe which are ſown early; but Mr Marſhall accounts for this by the vaſt quantity of weeds the latter have to encounter, and which the late ſown crops eſcape by reaſon of the weakneſs of vegetation at that time of the year. The produce, however, throughout the Vale of Glouceſter, is but very indifferent.—Setting of wheat is not practiſed, but hoeing univerſally.—In harveſting, Mr Marſhall obſerves, that the grain is allowed to ſtand until it be unreaſonably ripe, and that it is bound up into very ſmall ſheaves.

243 Remarkably ſmall ſheaves.

The practice of making double bands is unknown in this diſtrict; ſo that the ſheaves are no bigger than can be contained in the length of ſingle ſtraw. The inconveniences of this method are, that the crop requires more time to ſtook, load and unload, and ſtack: the advantages are, that the trouble of making bands is avoided; and that if rainy weather happens to intervene, the ſmall ſheaves dry much ſooner than the large ones. Here the crop is cut very high, the ſtubble and weeds being mown off in ſwaths for litter ſoon after the crop is cut; and ſometimes ſold as high as 5s. per acre.—Mr Marſhall is at a loſs to account for the little quantity produced in this country: it being hardly poſſible to derive it from the nature of the ſoil, almoſt all of it being proper for the cultivation of the grain.

244 In the Cotſwold hills.

Among the Cotſwold hills of Glouceſter the lammas and cone wheats are ſown; and a new variety of the latter was raiſed not long ago by picking out a ſingle grain of ſeed from among a parcel. The body is very long and large, but not ſightly.—The Cotſwold hills are almoſt proverbial for early ſowing of wheat. The general rule is to begin ploughing in July, and ſowing the firſt wet weather in Auguſt; ſo that here the ſeed-time and harveſt of wheat coincide. If, in conſequence of this early ſowing the blade becomes rank in autumn, it is ſuppoſed to be proper to eat it down by putting a large flock of ſheep upon it at once. Eating it in ſpring is conſidered as pernicious. It is uſually weeded with ſpud-hooks; not hoed, as in the

245 Inſtance of the good effects of hoeing wheat.

Vale. One inſtance, however, is mentioned by our author, in which a very thin crop full of ſeed-weeds hoed in autumn with uncommon ſucceſs, occurred in the practice of a ſuperior manager in this diſtrict; as well as others in which wheat has been weeded in autumn with great advantage. He alſo met with another well authenticated inſtance of the good effect of

246 Of cutting mildewed wheat very green.

cutting mildewed wheat while very green. "A fine piece of wheat being lodged by heavy rains, and being ſoon after perceived to be infected with the mildew, was cut, though ſtill in a perfectly green ſtate; namely, about three weeks before the uſual time of cutting. It lay ſpread abroad upon the ſtubble until it became dry enough to prevent its caking in the ſheaf; when it was bound and ſet up in ſhocks. The reſult of this treatment was, that the grain, though ſmall, was of a fine colour, and the heavieſt wheat which grew upon the ſame farm that ſeaſon; owing, no doubt, to the thinneſs of its ſkin. What appears much more remarkable, the ſtraw was perfectly bright, not a ſpeck upon it.—In this part of the country, the produce of wheat is ſuperior to that in the Vale; but Mr Marſhall is of opinion, that the ſoil is much more fit for barley than wheat.

Culture of particular Plants.

247 Cultivation of wheat in Yorkſhire.

In Yorkſhire, though generally a graſs land country, and where of conſequence corn is only a ſecondary concern, yet ſeveral kinds of wheat are cultivated, particularly *Zealand*, *Downy Kent*, *Common White*, *Hertfordſhire Brown*, *Yellow Kent*, *Common Red*. All theſe are varieties of winter wheat; beſides which they cultivate alſo the *ſpring* or *ſummer wheat*. Here our author makes ſeveral curious obſervations concerning the raiſing of *varieties* of plants. "It is probable, ſays he, that time has the ſame effect upon the varieties of wheat and other grains as it has on thoſe of cultivated fruits, potatoes, and other vegetable productions. Thus to produce an early pea, the gardener marks the plants which open firſt into bloſſom among the moſt early kind he has in cultivation. Next year he ſows the produce of thoſe plants, and goes over the coming crop in the manner he had done the preceding year, marking the earlier of this early kind. In a ſimilar manner new varieties of apples are raiſed, by chooſing the broadeſt leaved plants among a bed of ſeedlings riſing promiſcuouſly from pippins. Huſbandmen, it is probable, have heretofore been equally induſtrious in producing freſh varieties of corn; or whence the endleſs variety of winter wheats? If they be naturally of one ſpecies, as Linnæus has deemed them, they muſt have been produced by climature, ſoil, or induſtry; for although nature ſports with individuals, the induſtry of man is requiſite to raiſe, eſtabliſh, and continue a permanent variety. The only inſtance in which I have had an opportunity of tracing the *variety* down to the *parent individual*, has occurred to me in this diſtrict. A man of acute obſervation, having, in a piece of wheat, perceived a plant of uncommon ſtrength and luxuriance, diffuſing its branches on every ſide, and ſetting its cloſely-ſurrounding neighbours at defiance; marked it; and at harveſt removed it ſeparately. The produce was 15 ears, yielding 604 grains of a ſtrong-bodied liver-coloured wheat, different, in general appearance, from every other variety he had ſeen. The chaff was ſmooth, without awns, and of the colour of the grain; the ſtraw ſtout and reedy. Theſe 604 grains were planted ſingly, nine inches aſunder, filling about 40 ſquare yards of ground, on a clover ſtubble, the remainder of the ground being ſown with wheat in the ordinary way; by which means extraordinary trouble and deſtruction by birds were avoided. The produce was two gallons and a half, weighing 20¼ lb. of prime grain for ſeed, beſides ſome pounds of ſeconds. One grain produced 35 ears, yielding 1235 grains; ſo that the ſecond year's produce was ſufficient to plant an acre of ground. What deters farmers from improvements of this nature is probably the miſchievouſneſs of birds: from which at harveſt it is ſcarcely poſſible to preſerve a ſmall patch of corn, eſpecially in a garden or other ground ſituated near a habitation; but by carrying on the improvement in a field of corn of the ſame nature, that inconvenience is

248 Obſervations on raiſing varieties of plants.

Culture of particular Plants.

got rid of. In this ſituation, however, the botaniſt will be apprehenſive of danger from the floral farina of the ſurrounding crop. But from what obſervations I have made, I am of opinion his fears will be groundleſs. No evil of this kind occurred, though the cultivation of the above variety was carried on among *white* wheat. But this need not be brought as an evidence; it is not uncommon here to ſow a mixture of red and white wheats together; and this, it is confidently aſſerted, without impairing even the colour of either of them. The ſame mode of culture is applicable to the improvement of varieties; which perhaps would be more profitable to the huſbandman than raiſing new ones, and more expeditious."

249 Preparation of wheat with arſenic.

In Yorkſhire the very ſingular preparation of ſeed wheat prevails which we formerly mentioned, viz. the ſteeping it in a ſolution of *arſenic*, as a preventive of ſmut. Marſhall was informed by one farmer, that he had made uſe of this preparation for 20 years with ſucceſs, having never during that long ſpace of time ſuffered any ſenſible injury from ſmut. Our author ſeems inclined to believe the efficacy of this preparation; but thinks there may be ſome reaſon to apprehend danger in the uſe of ſuch a pernicious mineral, either through the careleſſneſs of ſervants, or handling of the ſeed by the perſon who ſows it. The farmer above mentioned, however, during all the time he uſed it, never experienced any inconvenience either to himſelf, the ſeedſman, or even to the poultry; though theſe laſt, we ſhould have thought, would have been peculiarly liable to accidents from arſenicated ſeed. The preparation is made by pounding the arſenic extremely fine, boiling it in water, and drenching the ſeed with the decoction. "In ſtrictneſs, ſays Mr Marſhall, the arſenic ſhould be levigated ſufficiently fine to be taken up and waſhed over with water, reducing the ſediment until it be fine enough to be carried over in the ſame manner. The uſual method of preparing the liquor is to boil one ounce of white arſenic, finely powdered, in a gallon of water, from one to two hours: and to add to the decoction as much water or ſtale urine as will increaſe the liquor to two gallons. In this liquor the ſeed is, or ought to be, immerged, ſtirring it about in ſuch a manner as to ſaturate effectually the downy end of each grain. This done, and the liquor drawn off, the ſeed is conſidered as fit for the ſeed baſket, without being candied with lime, or any other preparation. A buſhel of wheat has been obſerved to take up about a gallon of liquor. The price of arſenic is about 6d. per pound; which, on this calculation, will cure four quarters of ſeed. If no more than three quarters be prepared with it, the coſt will be only a farthing per buſhel; but to this muſt be added the labour of pounding and boiling. Nevertheleſs, it is by much the cheapeſt, and perhaps, upon the whole, adds Mr Marſhall, the beſt preparation we are at preſent acquainted with. In this county it is believed, that a mixture of wheat and rye, formerly a very common crop in theſe parts, is never affected with mildew; but our author does not vouch for the truth of this aſſertion.

250 Wheat and turnips ſown together.

We muſt not here omit to take notice of a new mode of cultivating wheat contrived by Mr E. Walker of Harpley, Norfolk; which mode of culture we ſhall alſo afterwards have occaſion to notice when we come to treat of the culture of turnips. Mr Walker thus explains his mode of procedure in a letter addreſſed to the publiſher of the Annals of Agriculture. "I ſow in broad-caſt, after the turnips have been once hoed, two buſhels of wheat or two buſhels of rye per acre; and then hoe the ſame in with the ſecond hoeing: if it be hoed by the day it may be beſt, as it will be better done by the ſhort ſtrokes or cuts with the hoes than otherwiſe. It is recommended to be done ſoon after the firſt hoeing, for many reaſons: It becomes a fine herbage, and keeps the land very clean, without any injury to the turnips, or to the wheat or rye. I began to feed in laſt September, the turnips, &c. the firſt of the mouth, and ſhall continue till all are done. I have fed off with all ſorts of ſtock mixed, and have drawn out the turnips in lines to ſet the hurdles, as is uſual, and fed off the turnips and growing corn in wet and dry weather; but find that dry weather, and ſheep, is the propereſt time and ſtock; and that ſheep and light beaſts are the beſt for light lands, which, on the whole, this method will greatly improve.

Culture of particular Plants.

Vol. ix.

"All my experiments have been made without mucking, or any manure, for the turnip and wheat crop; and on thoſe parts where I have fed off at the time it has been dry weather, though with all ſorts of ſtock mixed, and drawing as above, I have grown at the rate of one coomb of wheat per acre, and at the rate of eight coomb of rye per acre; and ſome was almoſt totally deſtroyed by feeding off in wet weather, as I was determined not to deſiſt, that I might know the bad or good effects from feeding off the turnips with the corn in different weather, as well as the different months; all which I ſhall be able to give information of next year, to thoſe who wiſh to know. I find the ſeed nearly worth the coſt of the ſeed corn, which is a material conſideration in caſe you plough the land for barley or other ſummer corn; but if the wheat or rye ſtands a crop to your mind, it will do better to harrow it in the ſpring, at which time you may ſow your graſs ſeeds, which I find anſwer very well; or plough the ſtubble early in the autumn, and ſow with clover or other ſeeds."

The well-known author of the Annals of Agriculture has given a farther account of this method of cultivation. The idea which led to Mr Walker's experiments was this: Wheat requires a certain degree of ſtiffneſs and compactneſs in the ſoil upon which it is reared. Of this compactneſs, ſandy ſoils are apt to be deficient in proportion to the degree of tillage they receive. Hence it occurred to Mr Walker, that if wheat could be ſown without any ploughing at all, there would be a better chance of a crop upon certain ſoils, than after the moſt expenſive ſyſtem of tillage. Accordingly, in 1784, he executed his ſcheme on ſix acres of turnips, which were fed during the ſucceeding winter by bullocks and ſheep, like the reſt of his turnip fields, without making the leaſt diſtinction on account of the wheat that had been ſown and was growing among them. It is known, that turnip-land, when fed off, is left highly manured and much trodden; and the queſtion was, whether the firſt of theſe circumſtances would not counterbalance the laſt? and, whether even the treading itſelf might not prove advantageous. The ſucceſs juſtified the project, and, in 1785, Mr Walker extended it to 35 acres, a part of which was ſown with

Culture of particular Plants.

rye. The management was the ſame as before; the wheat did better than the rye, and the beſt crop was where the turnips were eaten in the drieſt weather. In 1786, the ſame culture was extended to 70, and in 1797 to 100 acres, with complete ſucceſs; but the crop was not better than that raiſed in the common way, though in general as good. The effect of this mode of culture, or the profit ariſing from it, conſiſted chiefly in this, that upon a farm of 600 acres, the labour of five horſes was ſaved, and at the time of the barley-ſowing, when all his neighbours were in the greateſt hurry, he was at his eaſe quietly ſtirring his turnip fallows. The chief difficulty attending this mode of cultivating wheat aroſe from the wetneſs of the ſeaſon at the time of feeding, as the ground was apt to be too much trodden and poached, particularly when the crop of turnips was very large, ſo as to keep the cattle long upon them. On the contrary, in dry or froſty weather nothing of this kind happened. The greater the crop of turnips, and the more treading that occurred, the crop of wheat ſeemed afterwards to proſper the better. In a wet ſeaſon, however, the evil ariſing from the treading was diminiſhed when ſheep alone without bullocks were introduced to conſume the turnips. Under this huſbandry, the following rotation was uſed: Two years graſs put in among the wheat-ſtubble, ploughed once, and harrowed both in autumn and ſpring with the whole dung of the farm; Third year, oats; Fourth, turnips; Fifth, wheat.

2. Oats.

251 Effect of froſt upon tilled land.

As winter-ploughing enters into the culture of oats, we muſt remind the reader of the effect of froſt upon tilled land. Providence has neglected no region intended for the habitation of man. If in warm climates the ſoil be meliorated by the ſun, it is no leſs meliorated by froſt in cold climates. Froſt acts upon water, by expanding it into a larger ſpace. Froſt has no effect upon dry earth; witneſs ſand, upon which it makes no impreſſion. But upon wet earth it acts moſt vigorouſly; it expands the moiſture, which requiring more ſpace puts every particle of the earth out of its place, and ſeparates them from each other. In that view, froſt may be conſidered as a plough ſuperior to any that is made, or can be made, by the hand of man: its action reaches the minuteſt particles; and, by dividing and ſeparating them, it renders the ſoil looſe and friable. This operation is the moſt remarkable in tilled land, which gives free acceſs to froſt. With reſpect to clay ſoil in particular, there is no rule in huſbandry more eſſential than to open it before winter in hopes of froſt. It is even adviſable in a clay ſoil to leave the ſtubble rank; which, when ploughed in before winter, keeps the clay looſe, and admits the froſt into every cranny.

To apply this doctrine, it is dangerous to plough clay ſoil when wet; becauſe water is a cement for clay, and binds it ſo as to render it unfit for vegetation. It is, however, leſs dangerous to plough wet clay before winter than after. A ſucceeding froſt corrects the bad effects of ſuch ploughing; a ſucceeding drought increaſes them.

252 Culture of Oats.

The common method is, to ſow oats on new-ploughed land in the month of March, as ſoon as the ground is tolerably dry. If it continues wet all the month of March, it is too late to venture them after. It is much better to ſummer-fallow, and to ſow wheat in the autumn. But the preferable method, eſpecially in clay ſoil, is to turn over the field after harveſt, and to lay it open to the influences of froſt and air, which leſſen the tenacity of clay, and reduce it to a free mould. The ſurface-ſoil by this means is finely mellowed for reception of the ſeed; and it would be a pity to bury it by a ſecond ploughing before ſowing. In general, the bulk of clay ſoils are rich; and ſkilful ploughing without dung, will probably give a better crop, than unſkilful ploughing with dung.

Culture of particular Plants.

Hitherto of natural clays. We muſt add a word of carſe clays which are artificial, whether left by the ſea, or ſweeped down from higher grounds by rain. The method commonly uſed of dreſſing carſe clay for oats, is, not to ſtir it till the ground be dry in the ſpring, which ſeldom happens before the 1ſt of March, and the ſeed is ſown as ſoon after as the ground is ſufficiently dry for its reception. Froſt has a ſtronger effect on ſuch clays than on natural clay. And if the field be laid open before winter, it is rendered ſo looſe by froſt as to be ſoon drenched in water. The particles at the ſame time are ſo ſmall, as that the firſt drought in ſpring makes the ſurface cake or cruſt. The difficulty of reducing this cruſt into mould for covering the oat-ſeed, has led farmers to delay ploughing till the month of March. But we are taught by experience, that this ſoil ploughed before winter, is ſooner dry than when the ploughing is delayed till ſpring; and as early ſowing is a great advantage, the objection of the ſuperficial cruſting is eaſily removed by the firſt harrow above deſcribed, which will produce abundance of mould for covering the ſeed. The ploughing before winter not only procures early ſowing, but has another advantage: the ſurface-ſoil that had been mellowed during winter by the ſun, froſt, and wind, is kept above.

The dreſſing a loamy ſoil for oats differs little from dreſſing a clay ſoil, except in the following particular, that being leſs hurt by rain, it requires not high ridges, and therefore ought to be ploughed crown and furrow alternately.

Where there is both clay and loam in a farm, it is obvious, from what is ſaid above, that the ploughing of the clay after harveſt ought firſt to be deſpatched. If both cannot be overtaken that ſeaſon, the loam may be delayed till the ſpring with leſs hurt.

Next of a gravelly ſoil; which is the reverſe of clay, as it never ſuffers but from want of moiſture. Such a ſoil ought to have no ridges; but be ploughed circularly from the centre to the circumference, or from the circumference to the centre. It ought to be tilled after harveſt: and the firſt dry weather in ſpring ought to be laid hold of to ſow, harrow, and roll; which will preſerve it in ſap.

The culture of oats is the ſimpleſt of all. That grain is probably a native of Britain: it will grow on the worſt ſoil with very little preparation. For that reaſon, as already noticed, before turnip was introduced, it was always the firſt crop upon land broken up from the ſtate of nature.

Upon ſuch land, may it not be a good method, to build upon the crown of every ridge, in the form of a wall, all the ſurface-earth, one ſod above another, as in a fold for ſheep? After ſtanding in this form

all

Culture of particular Plants.

all the ſummer and winter, let the walls be thrown down, and the ground prepared for oats. This will ſecure one or two good crops; after which the land may be dunged for a crop of barley and graſs-ſeeds. This method may anſwer in a farm where manure is ſcarce.

253 Norfolk cultivation of oats.

In Norfolk this kind of grain is much leſs cultivated than barley; and the only ſpecies obſerved by Mr Marſhall is a kind of white oat, which grows quickly, and ſeems to be of Dutch extraction. Oats are cultivated occaſionally on all kinds of ſoils, but more eſpecially on cold heavy land, or on very light, unproductive, heathy ſoils. They may frequently ſucceed wheat, or ley ground barley: "but (ſays our author) there are no eſtabliſhed rules reſpecting any part of the culture of this time-ſerving crop." The culture of the ground is uſually the ſame with that of barley; the ground generally undergoing a winter fallow of three or four ploughings, though ſometimes they are ſown after one ploughing. They are more commonly ſown above furrow than barley. The ſeed-time is made ſubſervient to that of barley, being ſometimes ſooner and ſometimes later than barley ſeed-time: and Mr Marſhall obſerves, that he has ſometimes ſeen them ſown in June; it being obſervable, that oats ſown late ripen earlier than barley ſown at the ſame time. The quantity of ſeed in Norfolk is from four to five buſhels per acre; but he does not acquaint us with the produce. He mentions a very ſingular method of culture ſometimes practiſed in this county, viz. ploughing down the oats after they begin to vegetate, but before they have got above ground; which is attended with great ſucceſs, even though the ground is turned over with a full furrow. By this method weeds of every kind are deſtroyed, or at leaſt checked in ſuch a manner as to give the crop an opportunity of getting above them; and the poroſity communicated to the ſoil is excellently well adapted to the infant plants of barley; which probably might frequently receive benefit from this operation.

254 Method of ploughing down oats.

255 Wild oats a weed in the Vale of Glouceſter.

In the Vale of Glouceſter, Mr Marſhall obſerves, that the wild oat is a very troubleſome weed, as well as in Yorkſhire; and he is of opinion, that it is as truly a native of Great Britain as any other arable weed, and is perhaps the moſt difficult to be extirpated. It will lie a century in the ſoil without loſing its vegetable quality. Ground which has lain in a ſtate of graſs time immemorial, both in Glouceſter and Yorkſhire, has produced it in abundance on being broken up. It is alſo endowed with the ſame ſeemingly inſtinctive choice of ſeaſons and ſtate of the ſoil as other ſeeds of weeds appear to have. Hence it is exceſſively difficult to be overcome; for as it ripens before any crop of grain, it ſheds its ſeed on the ſoil, where the roughneſs of its coat probably ſecures it from birds. The only methods of extirpating this plant are fallowing, hoeing, and handweeding, where the laſt is practicable, after it has ſhot its panicle.

256 Oats not cultivated in the Vale of Glouceſter.

No oats are cultivated in the Vale of Glouceſter; though the wild oat grows everywhere as already ſaid. Mr Marſhall is of opinion that it is better adapted to oats than to barley. The reaſon he aſſigns for the preference given to the latter is, that in this part of the country the monks were formerly very numerous, who probably preferred *ale* to oaten cake.—He now, however, recommends a trial of the grain on the ſtronger cold lands in the area of the Vale, as they ſeldom can be got ſufficiently fine for barley. The fodder from oats he accounts much more valuable than that from barley to a dairy country; and the grain would more than balance in quantity the comparative difference in price.

Culture of particular Plants.

257 Cultivation in the Midland diſtrict.

In the midland diſtrict the *Poland oat*, which was formerly in vogue, has now given place to the *Dutch* or *Frieſland* kind. It is conſtantly ſown after turf; one ploughing being given in February, March, or April. The ſeed-time is the latter end of March and beginning of April, from four to ſeven buſhels an acre; the produce is in proportion to the ſeed, the medium being about ſix quarters.

258 In Yorkſhire.

In Yorkſhire the Frieſland oats are likewiſe preferred to the Poland, as affording more ſtraw, and being thinner ſkinned than the latter. The *S.berian* or *Tartarian* oat, a ſpecies unnoticed by Linnæus, is likewiſe cultivated in this country: the *reed* oat is known, but has not yet come into any great eſtimation. The grain is light, and the ſtraw too ready to be affected by cattle.

Oats are particularly cultivated in the weſtern diviſion of the Vale of Yorkſhire; where the ſoil is chiefly a rich ſandy loam, unproductive of wheat. Five or ſix buſhels, or even a quarter of oats, are ſometimes ſown upon an acre; the produce from ſeven to ten quarters. In this country they are threſhed in the open air, and frequently even upon the bare ground, without even the ceremony of interpoſing a cloth. The reaſons aſſigned for this ſeemingly ſtrange practice are, that if pigs and poultry be employed to eat up the grain which eſcapes the broom, there will be little or no waſte. Here the market is always very great for new oats, the manufacturing parts of Weſt Yorkſhire uſing principally oat-bread. The only objection to this practice is the chance of bad weather; but there is always plenty of ſtraw to cover up the threſhed corn, and it is found that a little rain upon the ſtraw does not make it leſs agreeable to cattle.

259 Singular method of threſhing

In an experiment made by Mr Bartley near Briſtol, upon black oats, we are informed that he had the prodigious increaſe of 98½ Wincheſter buſhels from four on the acre: the land was a deep, mellow, ſandy loam. It had caried potatoes the former year, and received one ploughing for a winter fallow. Another ploughing was given it in February, and the ſeed was ſown on the 27th and 28th of the month. The ſucceſs of the experiment was ſuppoſed to be owing partly to the early ſowing and partly to a good deep tillage.

Bath Papers vol.

260 Experiment on black oats.

3. Barley.

261 Culture of barley.

This is a culmiferous plant that requires a mellow ſoil. Upon that account, extraordinary care is requiſite where it is to be ſown in clay. The land ought to be ſtirred immediately after the foregoing crop is removed, which lays it open to be mellowed with the froſt and air. In that view, a peculiar ſort of ploughing has been introduced, termed *ribbing*; by which the greateſt quantity of ſurface poſſible is expoſed to the air and froſt. The obvious objection to this method is, that half of the ridge is left unmoved. And to obviate that objection, the following method is offered, which moves the whole ſoil, and at the ſame time expoſes the ſame quantity of ſurface to the froſt and air.

262 Ribbing

As

Culture of particular Plants.

As ſoon as the former crop is off the field, let the ridges be gathered with as deep a furrow as the ſoil will admit, beginning at the crown and ending at the furrows. This ploughing looſens the whole ſoil, giving free acceſs to the air and froſt. Soon after, begin a ſecond ploughing in the following manner: Let the field be divided by parallel lines croſs the ridges, with intervals of thirty feet or ſo. Plough once round an interval, beginning at the edges, and turning the earth toward the middle of the interval; which covers a foot or ſo of the ground formerly ploughed. Within that foot plough another round ſimilar to the former; and, after that, other rounds, till the whole interval be finiſhed, ending at the middle. Inſtead of beginning at the edges, and ploughing toward the middle, it will have the ſame effect to begin at the middle, and to plough toward the edges. Plough the other intervals in the ſame manner. As by this operation the furrows of the ridges will be pretty much filled up, let them be cleared and water-furrowed without delay. By this method, the field will be left waving like a plot in a kitchen garden, ridged up for winter. In this form, the field is kept perfectly dry; for beſide the capital furrows that ſeparate the ridges, every ridge has a number of croſs furrows that carry the rain inſtantly to the capital furrows. In hanging grounds retentive of moiſture, the parallel lines above mentioned ought not to be perpendicular to the furrows of the ridges, but to be directed a little downward, in order to carry rain water the more haſtily to theſe furrows. If the ground be clean, it may lie in that ſtate winter and ſpring, till the time of ſeed-furrowing. If weeds happen to riſe, they muſt be deſtroyed by ploughing, or braking, or both; for there cannot be worſe huſbandry, than to put the ſeed into dirty ground.

263 A better method.

This method reſembles common ribbing in appearance, but is very different in reality. As the common ribbing is not preceded by a gathering furrow, the half of the field is left untilled, compact as when the former crop was removed, impervious in a great meaſure to air or froſt. The common ribbing at the ſame time lodges the rain-water on every ridge, preventing it from deſcending to the furrows; which is hurtful in all ſoils, and poiſonous in a clay ſoil. The *ſtitching* here deſcribed, or *ribbing*, if you pleaſe to call it ſo, prevents theſe noxious effects. By the two ploughings the whole ſoil is opened, admitting freely air and froſt; and the multitude of furrows lays the ſurface perfectly dry, giving an early opportunity for the barley-ſeed.—

264 Advantages of this method.

But further, as to the advantage of this method: When it is proper to ſow the ſeed, all is laid flat with the brake, which is an eaſy operation upon ſoil that is dry and pulverized; and the ſeed-furrow which ſucceeds, is ſo ſhallow as to bury little or none of the ſurface earth: whereas the ſtirring for barley is commonly done with the deepeſt furrow; and conſequently buries all the ſurface ſoil that was mellowed by the froſt and air. Nor is this method more expenſive; becauſe the common ribbing muſt always be followed with a ſtirring furrow, which is ſaved in the method recommended. Nay, it is leſs expenſive; for after common ribbing, which keeps in the rain-water, the ground is commonly ſo ſoured, as to make the ſtirring a laborious work.

265 Management of ſeed in a dry ſeaſon.

It is well known that barley is leſs valuable when it does not ripen equally; and that barley which comes up ſpeedily in a duſky ſoil, muſt gain a great advantage over ſeed-weeds. Therefore, firſt take out about one-third of the contents of the ſacks of ſeed barley or bear, to allow for the ſwelling of the grain. Lay the ſacks with the grain to ſteep in clean water; let it lie covered with it for at leaſt 24 hours. When the ground is ſo dry as at preſent, and no likelihood of rain for 10 days, it is better to lie 36 hours. Sow the grain wet from ſteeping, without any addition of powdered quicklime, which, though often recommended in print, can only poiſon the ſeed, ſuck up part of its uſeful moiſture, and burn the hands of the ſower. The ſeed will ſcatter well, as clean water has no tenacity; only the ſower muſt put in a fourth or a third more ſeed in bulk than uſual of dry grain, as the grain is ſwelled in that proportion: harrow it in as quickly as poſſible after it is ſown; and though not neceſſary, give it the benefit of freſh furrow, if convenient. You may expect it up in a fortnight at fartheſt.

Culture of particular Plants.

The following experiment by a correſpondent of the Bath Society being conſidered as a very intereſting one, is here ſubjoined.

266 Important experiments on ſeed-barley.

"The laſt ſpring (1783) being remarkably dry, I ſoaked my ſeed-barley in the black water taken from a reſervoir which conſtantly receives the draining of my dung heap and ſtables. As the light corn floated on the top, I ſkimmed it off, and let the reſt ſtand 24 hours. On taking it from the water, I mixed the ſeed grain with a ſufficient quantity of ſifted wood-aſhes, to make it ſpread regularly, and ſowed three fields with it. I began ſowing the 16th, and finiſhed the 23d of April. The produce was 60 buſhels per acre, of good clean barley, without any *ſmall* or *green* corn, or weeds, at harveſt. No perſon in this country had better grain.

I ſowed alſo ſeveral other fields with the ſame ſeed dry, and without any preparation; but the crop, like thoſe of my neighbours, was very poor; not more than twenty buſhels per acre, and much mixed with *green* corn and weeds when harveſted. I alſo ſowed ſome of the ſeed dry on one ridge in each of my former fields, but the produce was very poor in compariſon of the other parts of the field."

267 Time of ſowing.

Where the land is in good order, and free of weeds, April is the month for ſowing barley. Every day is proper, from the firſt to the laſt.

The dreſſing loamy ſoil and light ſoil for barley, is the ſame with that deſcribed; only that to plough dry is not altogether ſo eſſential as in dreſſing clay ſoil. Loam or ſand may be ſtirred a little moiſt: better, however, delay a week or two, than to ſtir a loam when wet. Clay muſt never be ploughed moiſt, even though the ſeaſon ſhould eſcape altogether. But this will ſeldom be neceſſary; for not in one year of 20 will it happen, but that clay is dry enough for ploughing ſome time in May. Froſt may correct clay ploughed wet after harveſt; but when ploughed wet in the ſpring, it unites into a hard maſs, not to be diſſolved but by very hard labour.

268 Miſcellaneous obſervations concerning the cultivation of barley.

On the cultivation of this grain we have the following obſervations by a Norfolk farmer.

The beſt ſoil, he obſerves, is that which is dry and healthy, rather light than ſtiff, but yet of ſufficient tenacity and ſtrength to retain the moiſture. On this kind

Culture of particular Plants.

kind of land the grain is always the beſt bodied and coloured, the nimbleſt in the hand, and has the thinneſt rind. Theſe are qualities which recommend it moſt to the maltſter. If the land is poor, it ſhould be dry and warm; and when ſo, it will often bear better corn than richer land in a cold and wet ſituation.

In the choice of your ſeed, it is needful to obſerve, that the beſt is of a pale lively colour, and brightiſh caſt, without any deep redneſs or black tinge at the tail. If the rind be a little ſhrivelled, it is the better; for that ſlight ſhrivelling proves it to have a thin ſkin, and to have ſweated in the mow. The neceſſity of a change of ſeed by not ſowing two years together what grew on the ſame ſoil, is not in any part of huſbandry more evident than in the culture of this grain, which, if not frequently changed, will grow coarſer and coarſer every ſucceeding year.

It has generally been thought, that ſeed-barley would be benefited by ſteeping; but liming it has, in many inſtances, been found prejudicial. Sprinkling a little ſoot with the water in which it is ſteeped has been of great ſervice, as it will ſecure the ſeed from inſects. In a very dry ſeed time, barley that has been wetted for malting, and begins to ſprout, will come up ſooner, and produce as good a crop as any other.

If you ſow after a fallow, plough three times at leaſt. At the firſt ploughing, lay your land up in ſmall ridges, and let it remain ſo during the winter, for the froſt to mellow it; the ſecond ploughing ſhould be the beginning of February. In March ſplit the ridges, and lay the land as flat as poſſible, at the ſame time harrowing it fine. But in ſtrong wet lands (if you have no other for barley) lay it round, and make deep furrows to receive the water.

"I have often (continues he), taken the following method with ſucceſs: On lands tolerably manured, I ſowed clover with my barley, which I reaped at harveſt; and fed the clover all the following winter, and from ſpring to July, when I fallowed it till the following ſpring, and then ſowed it with barley and clover as before. Repeating this method every year, I had very large crops, but would not recommend this practice on poor light land.

"We ſow on our lighteſt lands in April, on our moiſt lands in May; finding that thoſe lands which are the moſt ſubject to weeds produce the beſt crops when ſown late.

"The common method is to ſow the barley-ſeed broad-caſt at two ſowings; the firſt harrowed in once, the ſecond twice; the uſual allowance from three to four buſhels per acre. But if farmers could be prevailed on to alter this practice, they would ſoon find their account in it. Were only half the quantity ſown equally, the produce would be greater, and the corn leſs liable to lodge: For when corn ſtands very cloſe, the ſtalks are drawn up weak; and on that account are leſs capable of reſiſting the force of winds, or ſupporting themſelves under heavy rains.

"From our great ſucceſs in ſetting and drilling wheat, ſome of our farmers tried theſe methods with barley; but did not find it anſwer their expectations, except on very rich land.

"I have myſelf had 80 ſtalks on one root of barley, which all produced good and long ears, and the grain was better than any other; but the method is too expenſive for general practice. In poor land, ſow thin, or your crop will be worth little. Farmers who do not reaſon on the matter will be of a different opinion; but the fact is indiſputable." Culture of particular Plants.

When the barley is ſowed and harrowed in, he adviſes that the land be rolled after the firſt ſhower of rain, to break the clods. This will cloſe the earth about the roots, which will be a great advantage to it in dry weather.

When the barley has been up three weeks or a month, it is a very good way to roll it again with a heavy roller, which will prevent the ſun and air from penetrating the ground to the injury of the roots. This rolling, before it branches out, will alſo cauſe it to tiller into a greater number of ſtalks; ſo that if the plants be thin, the ground will be thereby filled, and the ſtalks ſtrengthened.

If the blade grows too rank, as it ſometimes will in a warm wet ſpring, mowing is a much better method than feeding it down with ſheep; becauſe the ſcythe takes off only the rank tops, but the ſheep being fond of the ſweet end of the ſtalk next the root, will often bite ſo cloſe as to injure its future growth.

269 Cultivation of barley in Norfolk.

The county of Norfolk, according to Mr Marſhall, is peculiarly adapted to the cultivation of this grain, the ſtrongeſt ſoil not being too heavy, and the lighteſt being able to bear it; and ſo well verſed are the Norfolk farmers in the cultivation of it, that the barley of this country is deſired for ſeed throughout the whole kingdom. It is here ſown after wheat or turnips, and in ſome very light lands it is ſown after the ſecond year's ley. After wheat, the ſeed time of the latter being finiſhed, and the ſtubble trampled down with bullocks, the land is ploughed with a ſhallow furrow for a winter fallow for barley. In the beginning of March the land is harrowed and croſs-ploughed; or if it be wet, the ridges are reverſed. In April it receives another ploughing lengthwiſe; and at ſeed time it is harrowed, rolled, ſowed, and the ſurface rendered as ſmooth and level as poſſible. After turnips the ſoil is broken up as faſt as the turnips are taken off; if early in winter by *rice-balking*, a practice already explained; but if late, by a plain ploughing. It is common, if time will permit, to plough three times; the firſt ſhallow, the ſecond full, and the third a mean depth; with which laſt the ſeed is ploughed in. Sometimes, however, the ground is ploughed only once, and the ſeed ſown above, but more frequently by three ploughings, though, perhaps, the farmer has not above a week to perform them in. After ley, the turf is generally broken by a winter fallow, and the ſoil treated as after wheat.

This grain is ſeldom manured for, except when ſown after ley, when it is treated as wheat. No manure is requiſite after turnips or wheat, if the latter has been manured for. If not, the turnip crop following immediately, the barley is left to take its chance, unleſs the opportunity be embraced for winter marling.

Little barley is ſown by the Norfolk farmers before the middle of April, and the ſeed time generally continues till the middle of May; though this muſt in ſome meaſure depend on the ſeaſon; which, ſays Mr Marſhall, is more attended to in Norfolk than perhaps in all the world beſides." In the very backward ſpring

Culture of particular Plants.

spring of 1782, barley was sown in June with success. No preparation is used. It is all sown broadcast, and almost all under furrow; that is, the surface having been smoothed by the harrow and roller, the seed is sown and ploughed under with a shallow furrow; but if the season be wet, and the soil cold and heavy, it is sometimes sown above; but, if the spring be forward, and the last piece of turnips eaten off late, the ground is sometimes obliged to be ploughed only once, and to be sown above: though in this case Mr Marshall thinks it the most eligible management, instead of turning over the whole thickness of the soil, to *two-furrow* it, and sow between. This is done by only skimming the surface with the first plough, sowing the seed upon this, and then covering it with the bottom furrow brought up by the second plough. Three bushels are usually sufficient for an acre.

The barley, as well as the wheat, in Norfolk, is allowed to stand till very ripe. It is universally mown into swath, with a small bow fixed at the heel of the scythe. If it receive wet in the swath in this county, it is not turned, but *lifted*; that is, the heads or ears are raised from the ground, either with a fork or the teeth of a rake, thereby admitting the air underneath the swaths; which will not fall down again to the ground so close as before, so that the air has free access to the under side; and this method of lifting is supposed not to be inferior to that of turning, which requires more labour, besides breaking and ruffling the swaths.

270 In the Vale of Gloucester.

In the Vale of Gloucester the quantity of barley cultivated is very inconsiderable; the only species is the common long-eared barley, *hordeum zeocriton*. In this county the grain we speak of is used, on the every year's lands, as a cleansing crop. It is sown very late, viz. in the middle or end of May; sometimes the beginning or even the middle of June. The reason of this is, that the people of the Vale think, that if a week or ten days of fine weather can be had for the operation of harrowing out couch, and if after this a full crop of barley succeed, especially if it should fortunately take a reclining posture, the business of fallowing is effectually done, insomuch that the soil is cleaned to a sufficient degree to last for a number of years. A great quantity of seed is made use of, viz. from three to four bushels to an acre; under the idea, that a full crop of barley, especially if it lodge, smothers all kinds of weeds, couch-grass itself not excepted. Our author acknowledges this effect in some degree, but does not recommend the practice. "If the land, says he, be tolerably clean, and the season favourable, a barley fallow may no doubt be of essential service. But there is not one year in five in which even land which is tolerably clean can be sown in season, and at the same time be much benefited by it for future crops." The barley in this county is all hand-weeded. It is harvested loose, mown with the naked scythe, lies in swath, till the day of carrying, and is cocked with common hay forks. The medium produce is three quarters per acre. Its quality is preferable to that of the hill-barley.

271 Lots-ord.

The common long-eared species is sown among the Cotswold hills. It is sown in the latter end of March and beginning of April, in the quantity of three bushels to an acre, producing from 20 bushels to four quarters to an acre; "which, says our author, is a low produce. It must be observed, however, that this produce is from land deficient in tillage; and that barley delights in a fine pulverous tilth."

Culture of particular Plants.

272 In the midland district.

In the midland district they cultivate two species of barley, viz. the *zeocriton* or common long-eared, and the *distichon* or sprat barley; the latter not being of more than 50 years standing, but the former of much older date. The sprat is the more hardy, and requires to be more early sown; but the long-ear yields the better produce. It succeeds wheat and turnips; but on the strong lands of this district, the crop after wheat is much less productive, as well as less certain, than after turnips: which circumstance is likewise observed in Norfolk. It is sometimes also sown with success upon turf. When sown after wheat, the soil is winter fallowed by three ploughings; the first lengthwise in November; the second across in March; the last, which is the seed-ploughing, lengthwise. Between the two last ploughings the soil is harrowed, and the twitch shaken out with forks; after which it is left loose and light to die upon the surface, without being either burnt or carried off. After turnips the soil has commonly three ploughings; the reason of which is, that the turnips being commonly folded off with sheep, the soil, naturally of a close texture, receives a still greater degree of compactness, which it is proper to break down, to render it porous. The seed time is the two last weeks of April and the first of May; from two bushels and a half to three bushels an acre, sometimes even as much as four bushels: the produce very great, sometimes as high as seven or even eight quarters an acre; but the medium may be reckoned from four to four and a half quarters. Mr Marshall remarks, that the culture of barley is extremely difficult. "Something, says he, depends on the nature of the soil, much on the preparation, much on the season of sowing, and much on harvesting. Upon the whole, it may be deemed, of corn crops, the most difficult to be cultivated with certainty.

273 Culture of barley difficult.

274 In Yorkshire.

In Yorkshire there are four kinds of barley cultivated, viz. the *zeocriton* or long-eared; the *distichon* or sprat; the *vulgare*, big, four-rowed or spring barley; and the *hexastichon*, six-rowed or spring barley. The first and third sorts are principally cultivated; the winter barley is as yet new to the district. Battledoor barley was formerly very common, but is now almost entirely disused. Mr Marshall observes, that less than a century ago, barley was not saleable until it was malted; there were neither maltsters nor public houses, but every farmer malted his own grain, or sold it to a neighbour who had a malt kiln. Brakes cut from the neighbouring commons were the fuel commonly used upon this occasion; and a certain day for cutting them was fixed, in order to prevent any one from taking more than his share. The case is now totally reversed, even public malt-houses being unknown, and the business of malting entirely performed by maltsters, who buy the barley from the farmer, and sell him what malt he may want for his family.

275 Importance of barley to the revenue.

To give some idea of the importance of this grain, we shall here state the amount of the revenue which the public draws from an acre of land when cultivated for barley, independent altogether of the profits reaped from it by the landlord and tenant. Supposing an

Culture of particular Plants.

acre to produce eight bolls of barley, and the whole to be made into ordinary ſmall beer, the taxes paid by it ſtand thus in 1802.

	L.	s.	d.
8 bolls of barley made into malt, allowing 7 buſhels per boll, at 1s. 7¾d. per buſhel of malt duty	4	12	2
The whole may produce 40 barrels of ſmall beer, the duty upon each of which is 2s.	4	0	0
Borough impoſt, which is impoſed in Scotland, but not in England, at 1s. 3d. per barrel	2	10	0
	L. 11	2	2

4. Buck-Wheat.

276 Culture of buck-wheat.

The uſes of this plant have already been ſufficiently noticed. It delights in a mellow ſandy ſoil; but ſucceeds well in any dry looſe healthy land, and moderately ſo in a free loamy ſtone braſh. A ſtiff clay is its averſion, and it is entirely labour loſt to ſow it in wet poachy ground. The proper ſeaſon for ſowing is from the laſt week of May or the beginning of June. It has been ſown, however, ſo early as the beginning of April, and ſo late as the 22d of July, by way of experiment; but the latter was rather extreme to be choſen, and the former was in danger from froſt. In an experiment upon a ſmall piece of ground, the grain of two different crops was brought to maturity in the ſummer 1787.—After ſpring feedings, a crop of turnip-rooted cabbage, or vetches, there will be ſufficient time to ſow the land with buck-wheat. Probably, in hot dry ſummers, a crop of vetches might even be mown for hay early enough to introduce a crop of this grain after it.

In the year 1780, about ſeven acres of a ſandy ſoil on Briſſington common (F), having been firſt tolerably well cleanſed from brambles, furze, &c. received one ploughing. To reduce the irregularities of the ſurface, it was rolled; and on the 9th of June in that year, two buſhels and a half of buck-wheat per acre ſown, the ground rolled again without harrowing.

277 Advantages of this cropping.

The vegetation appeared in five or ſix days, as is conſtantly the caſe, be the weather wet or dry. The growth was ſo rapid, that the fern, with which this land greatly abounded, was completely kept under. About the middle of September the crop was mown; but by reaſon of a great deal of rain about that time, it was not ſecured until the beginning of October; hence a loſs of a great part of the grain by ſhedding, as well as ſome eaten by birds. However, there were ſaved about 24 Wincheſter buſhels per acre; and, notwithſtanding its long expoſure to the weather, received no ſort of damage, only perhaps that the fineſt and moſt perfect grain was the firſt to fall from the plant. The ground after this had almoſt the appearance of a fallow, and was immediately ploughed.

When it had lain a moderate time to meliorate, and to receive the influences of the atmoſphere, it was harrowed, ſown with Lammas wheat, and ploughed in under furrow, in a contrary direction to the firſt ploughing. Thus a piece of land, which in the month of April was altogether in a ſtate of nature, in the following November was ſeen under a promiſing crop of what is well ſtyled the king of grain, and this without the aid of manure, or of any very great degree of tillage. Nor was the harveſt by any means deficient; for ſeveral perſons converſant in ſuch things eſtimated the produce from 26 to 30 buſhels per acre. As ſoon as the wheat crop was taken off, the ground had one ploughing, and on the firſt of September following was ſown with turnip ſeed. The turnips were not large, but of an herbage ſo abundant as in the following ſpring to ſupport 120 ewes with their lambs, which were fed on it by folding four weeks. After this it was manured with a compoſition of rotten dung and natural earth, about 20 putt loads per acre, and planted with potatoes. The crop ſold for 138l. beſides a conſiderable number uſed in the family, and a quantity reſerved with which ten acres were planted the following ſeaſon. The enſuing autumn it was again ſown with wheat, and produced an excellent crop. In the ſpring of 1784, it was manured and planted with potatoes, as in the preceding inſtance; the crop, (though tolerably good) by no means equal to the former, producing about 100 ſacks per acre only. In ſpring 1785, the land was now for a third time under a crop of wheat, it being intended to try how far this mode of alternate cropping, one year with potatoes and another with wheat, may be carried.

Culture of particular Plants.

From the ſucceſs of the preceding and other experiments, by Nehemiah Bartley, Eſq. of Briſtol, as detailed in the Bath Society Papers, it would ſeem, that the culture of this plant ought in many caſes to be adopted inſtead of a ſummer fallowing: for the crop produced appears not only to be ſo much clear gain in reſpect to ſuch practice, but alſo affords a conſiderable quantity of ſtraw for fodder and manure; beſide that a ſummer fallowing is far from being ſo advantageous a preparation for a ſucceeding crop.

5. Pease.

278 Culture of peaſe.

Peaſe are of two kinds; the white and the gray. The cultivation of the latter only belongs to this place.

There are two ſpecies of the gray kind, diſtinguiſhed by their time of ripening. One ripens ſoon, and for that reaſon is termed *hot ſeed:* the other, which is ſlower in ripening, is termed *cold ſeed.*

Peaſe, a leguminous crop, is proper to intervene between two culmiferous crops; leſs for the profit of a peaſe crop than for meliorating the ground. Peaſe, however, in a dry ſeaſon, will produce ſix or ſeven bolls each acre; but, in an ordinary ſeaſon, they ſeldom reach above two, or two and a half. Hence, in a moiſt climate, which all the weſt of Britain is, red clover ſeems a more beneficial crop than peaſe; as it makes as good winter food as peaſe, and can be cut green thrice during ſummer.

A field intended for cold ſeed ought to be ploughed in October or November; and in February, as ſoon as the ground is dry, the ſeed ought to be ſown on the winter furrow. A field intended for hot ſeed ought to be

(F) A very rough piece of land, at that time juſt encloſed.

Culture of particular Plants.

be ploughed in March or April, immediately before ſowing. But if infeſted with weeds, it ought to be alſo ploughed in October or November.

Peaſe laid a foot below the ſurface will vegetate; but the moſt approved depth is ſix inches in light ſoil, and four inches in clay ſoil; for which reaſon, they ought to be ſown under furrow when the ploughing is delayed till ſpring. Of all grain, beans excepted, they are the leaſt in danger of being buried.

Peaſe differ from beans, in loving a dry ſoil and a dry ſeaſon. Horſe-hoeing would be a great benefit, could it be performed to any advantage; but peaſe grow expeditiouſly, and ſoon fall over and cover the ground, which bars ploughing. Horſe-hoeing has little effect when the plants are new ſprung; and when they are advanced to be benefited by that culture, their length prevents it. Faſt growing at the ſame time is the cauſe of their carrying ſo little ſeed: the ſeed is buried among the leaves; and the ſun cannot penetrate to make it grow and ripen. The only practicable remedy to obtain grain, is thin ſowing; but thick ſowing produces more ſtraw, and mellows the ground more. Half a boll for an Engliſh acre may be reckoned thin ſowing; three firlots thick ſowing.

Notwithſtanding what is ſaid above, Mr Hunter, a noted farmer in Berwickſhire, began ſome time ago to ſow all his peaſe in drills; and never failed to have great crops of corn as well as of ſtraw. He ſowed double rows at a foot interval, and two feet and a half between the double rows, which admit horſe-hoeing. By that method, he had alſo good crops of beans on light land.

Peaſe and beans mixed are often ſown together, in order to catch different ſeaſons. In a moiſt ſeaſon, the beans make a good crop; in a dry ſeaſon, the peaſe.

The growth of plants is commonly checked by drought in the month of July; but promoted by rain in Auguſt. In July, graſs is parched; in Auguſt, it recovers verdure. Where peaſe are ſo far advanced in the dry ſeaſon as that the ſeed begins to form, their growth is indeed checked, but the ſeed continues to fill. If only in the bloſſom at that ſeaſon, their growth is checked a little; but they become vigorous again in Auguſt, and continue growing without filling till ſtopped by froſt. Hence it is, that cold ſeed, which is early ſown, has the beſt chance to produce corn: hot ſeed, which is late ſown, has the beſt chance to produce ſtraw.

The following method is practiſed in Norfolk, for ſowing peaſe upon a dry light ſoil, immediately opened from paſture. The ground is pared with a plough extremely thin, and every ſod is laid exactly on its back. In every ſod a double row of holes is made. A pea dropt in every hole lodges in the flay'd ground immediately below the ſod, thruſts its roots horizontally, and has ſufficient moiſture. This method enabled Norfolk farmers, in the barren year 1740, to furniſh white peaſe at 12s. per boll.

279 In ſetting peaſe in drills.

In the Bath Papers, vol. i. p. 148. we have an account of the ſucceſs of an experiment by Mr Pavier near Taunton, on ſowing peaſe in drills. The ſcale on which this experiment was made, however, being ſo ſmall, it would perhaps be raſh to infer from it what might be the event of planting a large piece of ground in the ſame manner. The ſpace was only 16 ſquare yards, but the produce ſo great, that by calculating from it, a ſtatute acre would yield 600, or at the leaſt 500 pecks of green peaſe at the firſt gathering; which, at the high price they bore at that time in the country about Taunton, viz. 16d. per peck, would have amounted to 33l. 6s. 8d. On this the ſociety obſerve, that though they doubt not the truth of the calculation, they are of opinion, that ſuch a quantity as 500 or 600 pecks of green peaſe would immediately reduce the price in any country market. "If the above-mentioned crop (ſay they) were ſold only at ninepence per peck, the farmer would be well paid for his trouble." In a letter on the drill huſbandry by Mr Whitmore, for which the thanks of the ſociety were returned, he informs us, that drilled peaſe muſt not be ſown too thin, or they will always be foul: and in an experiment of this kind, notwithſtanding careful hoeing, they turned out ſo foul, that the produce was only eight buſhels to the acre.—From an experiment related in the 5th volume of the ſame work, it appears that peaſe, however meliorating they may be to the ground at firſt, will at the laſt totally exhauſt it, at leaſt with regard to themſelves. In this experiment they were ſown on the ſame ſpot for ten years running. After the firſt two years the crop became gradually leſs and leſs, until at laſt the ſeed would not vegetate, but became putrid. Strawberries were then planted without any manure, and yielded an excellent crop.

280 Peaſe muſt not be ſown too often on the ſame ſpot.

281 Mr Marſhall's obſervations.

On the Norfolk culture of peaſe, Mr Marſhall makes two obſervations. "Leys are ſeldom ploughed more than once for peaſe; and the ſeed is in general dibbled in upon the flag of this one ploughing But ſtubbles are in general broken by a winter-fallow of three or four ploughings; the ſeed being ſown broadcaſt and ploughed in about three inches deep with the laſt ploughing."—In the Vale of Glouceſter they are planted by women, and hoed by women and children, once, twice, and ſometimes thrice; which gives the crop, when the ſoil is ſufficiently free from root-weeds, the appearance of a garden in the ſummer time, and produces a plentiful crop in harveſt. The diſtance between the rows varies from 10 to 14 inches, but 12 may be conſidered as the medium; the diſtance in the rows two inches. In the Cheltenham quarter of the diſtrict, they ſet the peaſe not in continued lines, but in clumps; making the holes eight or ten inches diſtant from one another, putting a number of peaſe into each hole. Thus the hoe has undoubtedly greater freedom; all the diſadvantage is, that in this caſe the ſoil is not ſo evenly and fully occupied by the roots as when they are diſpoſed in continued lines.—In Yorkſhire it is common to ſow beans and gray peaſe together, under the name of *blendings*; and ſometimes fitches (probably, ſays Mr Marſhall, a gigantic variety of the *ervum lens*) are ſown among beans. Such mixtures are found to augment the crop, and the different ſpecies are eaſily ſeparated by the ſieve.

6. Beans.

The propereſt ſoil for beans is a moiſt and deep clay, but they may alſo be raiſed upon all heavy ſoils. They are cultivated in two ways, either in the old way by broad-caſt, or, according to the more recent practice, they

Culture of particular Plants.

they are drilled in distinct rows. Of each of these we shall give a very short account.

282 Culture of beans by broad-cast.

When the mode of cultivating beans by broad-cast is adopted, it is to be observed, that as this grain is early sown, the ground intended for it should be ploughed before winter, to give access to the frost and air; beneficial in all soils, and necessary in a clay soil. Take the first opportunity after January, when the ground is dry, to loosen the soil with the harrow first described, till a mould be brought upon it. Sow the seed, and cover it with the second harrow. The third will smooth the surface, and cover the seed equally. These harrows make the very best figure in sowing beans: which ought to be laid deep in the ground, not less than six inches. In clay soil, the common harrows are altogether insufficient. The soil, which has rested long after ploughing, is rendered compact and solid: the common harrows skim the surface: the seed is not covered; and the first hearty shower of rain lays it above ground. Where the farmer overtakes not the ploughing after harvest, and is reduced to plough immediately before sowing, the plough answers the purpose of the first harrow; and the other two will complete the work. But the labour of the first harrow is ill saved; as the ploughing before winter is a fine preparation, not only for beans, but for grain of every kind. If the ground ploughed before winter happen by superfluity of moisture to cake, the first harrow going along the ridges, and crossing them, will loosen the surface, and give access to the air for drying. As soon as the ground is dry, sow without delaying a moment. If rain happen in the interim, there is no remedy but patience till a dry day or two come.

Carse clay, ploughed before winter, seldom fails to cake. Upon that account, a second ploughing is necessary before sowing: which ought to be performed with an ebb furrow, in order to keep the frost-mould as near the surface as possible. To cover the seed with the plough is, with regard to this as well as other grain, expressed by the phrase *to sow under furrow*. The clods raised in this ploughing are a sort of shelter to the young plants in the chilly spring months.

The foregoing method will answer for loam. And as for a sandy or gravelly soil, it is altogether improper for beans.

283 Culture of beans in drills.

Previous to the year 1770, beans were seldom sown in Scotland, unless upon the very rich clays; but since that time, by adopting the plan of raising them in drills, or distinct rows, they have been successfully cultivated upon all the heavy loams, and in many farms they now constitute a regular branch of rotation. With very few exceptions, beans are constantly drilled at intervals of from 20 to 27 inches. Of these modes, the last is the most prevalent, because it admits the ground to be ploughed with a horse, in the most sufficient manner. Very little hand-hoeing is given; nor is it required, as the kind of land which is best adapted for their growth, and upon which they are commonly sown, has not naturally a tendency to the production of annual weeds, and fine crops of wheat generally follow, provided due attention has been given to working the bean crop. The necessity of summer fallow, which the present high price of labour, and the loss of a year's crop, render an expensive affair to the farmer, is consequently much lessened: for if land is once thoroughly cleaned, and afterwards kept in an alternate course of leguminous and culmiferous crops, it will remain in good order for a considerable number of years. Culture of particular Plants.

As beans delight in a moist soil, and have no end of growing in a moist season, they cover the ground totally when sown broad-cast, keep in the dew, and exclude the sun and air: the plants grow to a great height; but carry little seed, and that little not well ripened. This displays the advantage of drilling; which gives free access to the sun and air, dries the ground, and affords plenty of ripe seed.

II. Plants Cultivated for Roots.

1. Potatoes.

These, next to the different kinds of grain, may be looked upon as the crop most generally useful for the husbandman; affording not only a most excellent food for cattle, but for the human species also; and they are perhaps the only substitute that could be used for bread with any probability of success. In the answer by Dr Tillot to M. Linguet already mentioned, the former objects to the constant use of them as food; not because they are pernicious to the body, but because they hurt the faculties of the mind. He owns, that those who eat maize, potatoes, or even millet, may grow tall and acquire a large size; but doubts if any such ever produced a literary work of merit. It does not, however, by any means appear, that the very general use of potatoes in our own country has at all impaired either the health of body or vigour of mind of its inhabitants. The question then, as they have already been shown to be an excellent food for cattle, comes to be merely with regard to the profit of cultivating them; and this seems already to be so well determined by innumerable experiments, as well as by the general practice of the country, that no room appears left for doubt. 284 Are not prejudicial to mankind.

285 General culture.

The choice of soil is not of greater importance in any other plant than in a potato. This plant in clay soil, or in rank black loam lying low without ventilation, never makes palatable food. In a gravelly or sandy soil, exposed to the sun and free air, it thrives to perfection, and has a good relish. But a rank black loam, though improper to raise potatoes for the table, produces them in great plenty; and the product is, as already observed, a palatable food for horned cattle, hogs, and poultry.

The spade is a proper instrument for raising a small quantity, or for preparing corners or other places inaccessible to the plough; but for raising potatoes in quantities, the plough is the only instrument.

As two great advantages of a drilled crop are, to destroy weeds, and to have a fallow at the same time with the crop, no judicious farmer will think of raising potatoes in any other way. In September or October, as soon as that year's crop is removed, let the field have a rousing furrow, a cross-braking next, and then be cleared of weeds by the cleaning harrow. Form it into three-feet ridges, in that state to lie till April, which is the proper time for planting potatoes. Cross-brake it, to raise the furrows a little. Then lay well digested horse-dung along the furrows, upon which lay the roots at eight inches distance. Cover up these roots with the plough, going once round every row. This makes a warm bed for the potatoes; hot dung below, and

Culture of particular Plants.

a looſe covering above, that admits every ray of the ſun. As ſoon as the plants appear above ground, go round every row a ſecond time with the plough, which will lay upon the plants an additional inch or two of mould, and at the ſame time bury all the annuals; and this will complete the ploughing of the ridges. When the potatoes are ſix inches high, the plough, with the deepeſt furrow, muſt go twice along the middle of each interval in oppoſite directions, laying earth firſt to one row, and next to the other. And to perform this work, a plough with a double mouldboard will be more expeditious. But as the earth cannot be laid cloſe to the roots by the plough, the ſpade muſt ſucceed, with which four inches of the plants muſt be covered, leaving little more but the tops above ground; and this operation will at the ſame time bury all the weeds that have ſprung ſince the former ploughing. What weeds ariſe after muſt be pulled up with the hand. A hoe is never to be uſed here: it cannot go ſo deep as to deſtroy the weeds without cutting the fibres of the plants; and if it ſkim the ſurface, it only cuts off the heads of the weeds, and does not prevent their puſhing again.

286 Particular methods.

In the Bath Society Papers, we have the following practical obſervations on the culture and uſe of potatoes, given as the reſult of various experiments made for five years ſucceſſively on that valuable root, the growth of which cannot be too much encouraged.

When the potato crop has been the only object in view, the following method is the moſt eligible.

The land being well pulverized by two or three good harrowings and ploughings, is then manured with 15 or 20 cart loads of dung per acre, before it receives its laſt earth. Then it is thrown into what the Suffolk farmers call the *trench balk*, which is narrow and deep ridge-work, about 15 inches from the centre of one ridge to the centre of the other. Women and children drop the ſets in the bottom of every furrow 15 inches apart; men follow and cover them with large hoes, a foot in width, pulling the mould down ſo as to bury the ſets five inches deep; they muſt receive two or three hand-hoeings, and be kept free from weeds; always obſerving to draw the earth as much as poſſible to the ſtems of the young plants. By repeated trials, the firſt or ſecond week in April is found the moſt advantageous time for planting.

In the end of September or the beginning of October, when the haulm becomes withered, they ſhould be ploughed up with a ſtrong double-breaſted plough. The workman muſt be cautioned to ſet his plough very deep, that he may ſtrike below all the potatoes, to avoid damaging the crop. The women who pick them up, if not carefully attended to, will leave many in the ground, which will prove detrimental to any ſucceeding corn, whether wheat or barley. To avoid which inconvenience, let the land be harrowed, and turn the ſwine in to glean the few that may be left by their negligence.

By this method, the ſets will be 15 ſquare inches from each other; it will take 18 buſhels to plant an acre; and the produce, if on a good mixed loamy ſoil, will amount to 300 buſhels.

If the potatoes are grown as a preparation for wheat, it is preferable to have the rows two feet two inches from each other, hand-hoeing only the ſpace from plant to plant in each row; then turning a ſmall furrow from the inſide of each row by a common light plough, and afterwards, with a double-breaſted plough with one horſe, ſplit the ridge formed by the firſt ploughing thoroughly to clean the intervals. This work ſhould not be done too deep the firſt time, to avoid burying the tender plants; but the laſt earth ſhould be ploughed as deep as poſſible; and the cloſer the mould is thrown to the ſtems of the plants, the more advantageous it will prove. Thus 15 buſhels will plant an acre, and the produce will be about 300 buſhels; but the land, by the ſummer ploughings, will be prepared to receive ſeed wheat immediately, and almoſt enſure a plentiful crop.

Culture of particular Plants.

287 To prevent the grub.

The potato ſets ſhould be cut a week before planting, with one or two eyes to each, and the pieces not very ſmall; two buſhels of freſh-ſlaked lime ſhould be ſown over the ſurface of the land as ſoon as planted, which will effectually prevent the attacks of the grub.

The expence attending an acre of potatoes well cultivated in the firſt method, ſuppoſing the rent 20 ſhillings, tithe and town charges rather high (as in Suffolk), taking up, and every thing included, will be about ſix pounds. In the laſt method, it would be ſomewhat reduced.

"When predilections for old cuſtoms are ſubdued (adds the author), I hope to ſee the potato admitted in the conſtant courſe of crops by every ſpirited huſbandman. The moſt beneficial effects will, I am certain, accrue from ſuch a ſyſtem. The advantages in my neighbourhood are apparent; I cultivated and fed my own children upon them, and my poorer neighbours ſenſibly followed the example. A great proportion of every cottager's garden is now occupied by this root, and it forms a principal part of their diet. Potatoes are cheap and excellent ſubſtitutes for peaſe in ſoups and broths, allowing double the quantity.

288 A cheap preparation for the poor.

"Although it is nearly a tranſcript of the directions given by a very ingenious author, yet I ſhall take the liberty of inſerting a receipt for making a potato-ſoup, which I have weekly diſtributed among the poor to their great relief.

	s.	d.
An ox's head - - - -	2	9
Two pecks of potatoes - -	0	6
Quarter of a peck of onions - -	0	3
Three quarters of a pound of ſalt -	0	1
An ounce and a half of pepper -	0	3
Total	3	10

Ninety pints of water to be boiled with the above ingredients on a ſlow fire until reduced to 60, which requires one peck of coals, value threepence. I have added the expence of every article according to their prices with me, that gentlemen may clearly perceive at how eaſy a rate they can feed 60 of their poor neighbours. I find from experience, a pint of this ſoup, with a ſmall piece of the meat, is ſufficient to ſatisfy a hearty working man with a good meal. If vegetables are plentiful, ſome of every ſort may be added, with a few ſweet herbs.

"I hope my inſerting the above will not be eſteemed improper; though ſomewhat deviating from the culture of potatoes, it may poſſibly be a means of rendering them more extenſively uſeful."

At

Culture of particular Plants.

A premium having been offered by the above-mentioned ſociety for the cultivation of potatoes by farmers, &c. whoſe rent does not exceed 40l. per annum, the following methods were communicated, by which thoſe who have only a ſmall ſpot of ground may obtain a plentiful crop.

289 Methods of cultivating potatoes on ſmall ſpots.

Firſt, then, the earth ſhould be dug 12 inches deep, if the ſoil will allow of it; after this, a hole ſhould be opened about ſix inches deep, horſe dung or long litter ſhould be put therein about three inches thick; this hole ſhould not be more than 12 inches in diameter; upon this dung or litter a potato ſhould be planted whole, upon which a little more dung ſhould be caſt, and then earth muſt be put thereon. In like manner the whole plot of ground muſt be planted, taking care that each potato be at leaſt 16 inches apart; and when the young ſhoots make their appearance, they ſhould have freſh mould drawn round them with a hoe; and if the tender ſhoots are covered, it will prevent the froſt from injuring them: they ſhould again be earthed when the ſhoots make a ſecond appearance, but not be covered, as in all probability the ſeaſon will then be leſs ſevere. A plentiful ſupply of mould ſhould be given them, and the perſon who performs this buſineſs ſhould never tread upon the plant, or the hillock that is raiſed round it; as the lighter the earth is, the more room the potato will have to expand. From a ſingle root thus planted, very near 40 pounds weight of large potatoes were obtained, and from almoſt every other root upon the ſame plot of ground from 15 or 20 pounds weight; and except the ſoil be ſtony or gravelly, 10 pounds or half a peck of potatoes may almoſt always be obtained from each root, by purſuing the foregoing method. But note, cuttings or ſmall ſets will not do for this purpoſe.

290 Methods of culture adapted to ſmall farms.

The ſecond method will ſuit the indolent, or thoſe who have not time to dig their ground; and that is, where weeds much abound and have not been cleared in the winter, a trench may be opened in a ſtraight line the whole length of the ground, and about 6 inches deep: in this trench the potatoes ſhould be planted about ten inches apart; cuttings or ſmall potatoes will do for this method. When they are laid in the trench, the weeds that are on the ſurface may be pared off on each ſide about ten inches from it, and be turned upon the plants; another trench ſhould then be dug, and the mould that comes out of it turned carefully on the weeds. It muſt not be forgot, that each trench ſhould be regularly dug, that the potatoes may be throughout the plot 10 or 12 inches from each other. This ſlovenly method will in general raiſe more potatoes than can be produced by digging the ground twice, and dibbling in the plants; and the reaſon is, that the weeds lighten the ſoil, and give the roots room to expand. They ſhould be twice hoed, and earthed up in rows. And here note, that if cut potatoes are to be planted, every cutting ſhould have two eyes, for though fewer ſets will be obtained, there will be a greater certainty of a crop, as one eye often fails or is deſtroyed by grubs in the earth.

Where a crop of potatoes fails in part (as will ſometimes be the caſe in a dry ſeaſon), amends may ſtill be made by laying a little dung upon the knots of the ſtraw or haulm of thoſe potatoes that do appear, and covering them with mould: each knot or joint thus ordered will, if the weather prove wet afterwards, produce more potatoes than the original roots.

Culture of particular Plants.

From the ſmalleſt potatoes planted whole, from four to ſix pounds at a root were obtained, and ſome of the ſingle potatoes weighed near two pounds. Theſe were dug in as before mentioned, in trenches where the ground was covered with weeds, and the ſoil was a ſtiff loamy clay.

A good crop may be obtained by laying potatoes upon turf at about 12 or 14 inches apart, and upon beds of about ſix feet wide; on each ſide of which a trench ſhould be opened about three feet wide, and the turf that comes from thence ſhould be laid with the graſſy ſide downwards upon the potatoes; a ſpit of mould ſhould next be taken from the trenches, and be ſpread over the turf; and in like manner the whole plot of ground that is deſigned to be planted muſt be treated. And remark, that when the young ſhoots appear, another ſpit of mould from the trenches ſhould be ſtrewed over the beds ſo as to cover the ſhoots; this will prevent the froſt from injuring them, encourage them to expand, and totally deſtroy the young weeds; and when the potatoes are taken up in the autumn, a careful perſon may turn the earth again into the trenches, ſo as to make the ſurface level; and it will be right to remark, that from the ſame ground a much better crop of potatoes may be obtained the following year.

For field planting, a good (if not the beſt) method is to dung the land, which ſhould be once ploughed previous thereto; and when it is ploughed a ſecond time, a careful perſon ſhould drop the potato plants before the plough in every third furrow at about eight or ten inches apart. Plants that are cut with two eyes are beſt for this purpoſe. The reaſon for planting them at ſo great a diſtance as every third furrow, is, that when the ſhoots appear, a horſe-hoe may go upon the two vacant furrows to keep them clean; and after they are thus hoed, they ſhould be moulded up in ridges; and if this crop be taken up about October or November, the land will be in excellent condition to receive a crop of wheat. Lands that are full of twitch or couch-graſs may be made clean by this method, as the horſe-hoeing is as good as a ſummer fallow; and if, when the potatoes are taken up, women and children were to pick out ſuch filth, not any traces of it would remain; and by laying it on heaps and burning it, a quantity of aſhes would be produced for manure.

After ploughing, none ſhould ever dibble in potatoes, as the perſons who dibble, plant, or hoe them, will all tread the ground; by which means it will become ſo bound, that the young fibres cannot expand, as has been already obſerved. Good crops have indeed been obtained by ploughing the land twice, and dropping the plants in every other furrow, and by hand-hoeing and earthing them up afterwards as the gardeners do peaſe; but this method is not equal to the other.

Vacant places in hedge-rows might be grubbed and planted with potatoes, and a good crop might be expected, as the leaves of trees, thorns, &c. are a good manure, and will ſurpriſingly encourage their growth, and gratify the wiſhes of the planter; who by cultivating ſuch places, will then make the moſt of his ground, and it will be in fine order to receive a crop of corn the following year.

The field on which the above experiment was made, was an out-stubble in the autumn of 1783. In October it was ploughed, and left in a rough state during the winter. In April it was cross-ploughed and harrowed. On the 8th of May the field was marked out into beds or ridges eight feet wide, leaving a space of two feet wide for an alley between every two ridges. The manure (a compost of stable dung, virgin earth, and scrapings of a turnpike road) was then brought on the land, and deposited in small heaps on the centre of each ridge, in the proportion of about thirty cart-loads to each acre. A trench was then opened with a spade, breadth-way of the ridge, about four inches deep; in this trench the potato sets were placed, at the distance of nine inches from each other; the dung was then spread in a trench on the sets, and a space or split of 14 inches in breadth dug in upon them. When the plants were about six inches high, they were carefully hoed, and soon after the two feet intervals between the ridges were dug, and the contents thrown around the young plants. This refreshment, added to the ample manuring previously bestowed, produced such a luxuriance and rapidity of growth, that no weed could show its head.

292 Best method of taking them up

The shortest and most certain method of taking up potatoes, is to plough once round every row at the distance of four inches, removing the earth from the plants, and gathering up with the hand all the potatoes that appear. The distance is made four inches, to prevent cutting the roots, which are seldom found above that distance from the row on each side. When the ground is thus cleared by the plough, raise the potatoes with a fork having three broad toes or claws; which is better than a spade, as it does not cut the potatoes. The potatoes thus laid above ground must be gathered with the hand. By this method scarce a potato will be left.

Culture of particular Plants.

293 Of preserving them.

As potatoes are a comfortable food for the common people, it is of importance to have them all the year round. For a long time, potatoes in Scotland were confined to the kitchen garden; and after they were planted in the field, it was not imagined at first that they could be used after the month of December. Of late years, they have been found to answer even till midsummer; which has proved a great support to many a poor family, as they are easily cooked, and require neither kiln nor mill. But there is no cause for stopping there. It is easy to preserve them till the next crop: When taken out of the ground, lay in the corner of a barn a quantity that may serve till April, covered from frost with dry straw pressed down: bury the remainder in a hole dug in dry ground, mixed with the husks of dried oats, sand, or the dry leaves of trees, over which build a stack of hay or corn. When the pit is opened for taking out the potatoes, the eyes of what have a tendency to push must be cut out; and this cargo will serve all the month of June. To be still more certain of making the old crop meet the new, the setting of a small quantity may be delayed till June, to be taken up at the ordinary time before frost. This cargo, having not arrived at full growth, will not be so ready to push as what are set in April.

If the old crop happen to be exhausted before the new crop is ready, the interval may be supplied by the potatoes of the new crop that lie next the surface, to be picked up with the hand; which, far from hurting the crop, will rather improve it.

In the Transactions of the Society for the encouragement of Arts, a number of experiments are related by Mr Young on that kind called the *clustered* or *hog potato*, which he strongly recommends as food for the poor, in preference to the kidney or other more expensive kinds. The following is the result of the most remarkable of his experiments.

294 Mr Young's experiments on the clustered potato.

In the first week of March 1780, two acres and a quarter of barley stubble were sown with the cluster potato, which appeared on the 23d of May. A sharp frost on the 7th of June turned them as black as they usually are by the frosts of November and December. In time, however, they recovered; and by the end of October produced 876 bushels from the 2¼ acres; which, when cleaned, were reduced to 780, or 350 bushels per acre; thus affording, when only valued at 6d. per bushel, a clear profit of 7l. 14s. 4d. per acre. The experiment, however, in his opinion, would have been still more profitable, had it not been for the following circumstances: 1. The soil was not altogether proper. 2. The crop was grievously injured by the frost already mentioned, which, in our author's opinion, retarded the growth for about six weeks. 3. The dung was not of his own raising, but purchased; which cannot but be supposed to make a great difference, not only on account of the price, but likewise of the quality,

Culture of particular Plants.

lity, as happened to be the caſe at preſent. He is of opinion, however, that potatoes, at leaſt this kind of them, are an exhauſting crop. Having ſown the field after this large crop of potatoes with wheat, his neighbours were of opinion that it would be too rank; but ſo far was this from being the caſe, that the wheat ſhowed not the leaſt ſign of luxuriance, nor the leaſt ſuperiority over the parts adjacent which were ſown without dung. He was willing to account for this by the poverty of the dung, and the ſevere cropping which the ground had undergone while in the poſſeſſion of the former tenant. In another experiment, however, in which the ground had been likewiſe exhauſted by ſevere cropping, the ſucceeding crop of wheat ſhowed no luxuriance; ſo that the former ſuſpicion of the exhauſting quality of the cluſter potato was rather confirmed. The ground was a fine turnip loam; but though the produce was even greater than in the former caſe, viz. 356 buſhels from an acre, the profit was much leſs, viz. only 4l. 15s. 6d. An acre of ley ground was ſown at the ſame time with the turnip loam, but the produce from it was only 200 buſhels. Mr Young ſuppoſes that the produce would have been greater if the potatoes had been planted with an iron dibble, as the turf, in ploughing, lay too heavy upon the ſeed. A few rows of other potatoes, planted along with the cluſtered kind, did not vegetate at all; which ſhows that the latter have a more powerful vegetative faculty.

295 Experiments on a larger ſcale.

Having ſucceeded ſo well with his experiments on this kind of potato hitherto, Mr Young determined to try the culture of them upon a larger ſcale: and therefore, in the year 1782, ſowed 11 acres: but being obliged to commit the care of ſowing them to an ignorant labourer, his unſkilfulneſs, together with the exceſſive cold and moiſture of that ſeaſon, ſo diminiſhed the produce, that he had only a ſingle acre out of the whole. This produced 180 buſhels, which yielded of clear profit 4l. 2s. 6d. From this experiment he draws the following concluſions: 1. "That the poor loam, on which theſe potatoes were ſown, will yield a crop of cluſter-potatoes, though not of any other kind. 2. That the manure for potatoes ought to be carted and ſpread upon all ſoils inclinable to wet before the planting ſeaſon, either in autumn preceding, or elſe during a hard froſt." In 1783 he ſucceeded till worſe; for having that year ſown three acres and a half, the profit did not exceed 11s. 4d. per acre. The produce was about 224 buſhels per acre. He gives two reaſons for the failure of this crop: 1. The cluſtered potato thrives beſt in wet years; but the ſummer of 1783 was dry and hot. 2. The ſpring froſt, by interrupting the hoeing, not only greatly raiſed the expences, but very much injured the crop by encouraging the growth of weeds. Barley was ſown after the laſt crop, and produced well: ſo that our author thinks the potatoes ſeem to be a better preparation for ſpring corn than wheat. His experiment in 1784 produced a clear profit of 2l. 0s. 4d.; the produce being 250 buſhels per acre. Still, however, an error was committed, by employing an old man and woman to cut the ſets, by whoſe unſkilfulneſs there were many great gaps among the potatoes as they came up; ſo that, on the whole he reckons that he thus loſt from 500 to 800 buſhels. On the whole, however, his opinion is favourable to the cluſter potato. "With ſmall crops (ſays he), and at the low rate of value which is produced by conſuming them at home, they are clearly proved to be a crop which will pay the expence of manuring, and very ample tillage and hoeing. This is, after all, the chief object of modern huſbandry; for if a man can rely upon this potato for the winter conſumption for his yard in fattening or keeping hogs, in feeding his horſes, and fattening his bullocks, he has made one of the greateſt acquiſitions that can be deſired; ſince he can do all this upon land much too ſtiff and wet for turnips; houſes his crops before the winter rains come on; and conſequently without doing any of that injury to his land which the turnip culture is known to entail, and from which even cabbages are not free. Thoſe who know the importance of winter food on a turnip farm, cannot but admit the magnitude of this object on wet ſoils."

Culture of particular Plants.

297 Mr Marſhall's remarks

Mr Marſhall, in his Rural Economy of Yorkſhire, has ſeveral very intereſting remarks on the potato. Its varieties, he ſays, are endleſs and tranſitory. The rough ſkinned Ruſſian potato, which was long a favourite of the Yorkſhire farmers, he is of opinion, has now no longer an exiſtence, more than many others which flouriſhed for a time. "There is ſome reaſon to believe (ſays he) that the diſeaſe which has of late years been fatal to the potato crop in this and in other diſtricts, under the name of CURLED TOPS, has ariſen from too long a continuance of declining varieties. Be this as it may, it appears to be an eſtabliſhed opinion here, that *freſh varieties*, raiſed from ſeed, are not liable to that diſeaſe." Our author, however, does not look upon this to be a fact abſolutely eſtabliſhed: though one inſtance fell under his obſervation, in which its removal was in all probability owing to the introduction of new varieties. It made its appearance between 40 and 50 years ago, and ſpread in ſome degree over the whole kingdom. In ſome places it continued but a ſhort time, ſo that its effects are almoſt forgotten. It is ſeldom obvious at the firſt coming up of the plants; but attacks them as they increaſe in ſize; the entire top becoming dwarfiſh and ſhrivelled as if affected by drought or loaded with inſects: they nevertheleſs live and increaſe, though ſlowly, in ſize; but the roots are unproductive. Some crops have been almoſt wholly deſtroyed by this diſeaſe. In Yorkſhire the Morelands are in a manner free from it, but the Vale is in ſome meaſure infected. Plants procured from the Morelands remain free from it in the Vale the firſt year; but, being continued, become liable to the diſeaſe. Where the attack has been partial, weeding out the diſeaſed plants as they failed, is ſaid to have had a good effect; and it is ſaid the Morelanders got rid of the diſeaſe by this means.

298 on the cur

299 Method of raiſing varieties from ſeed.

In Yorkſhire ſome intelligent huſbandmen are acquainted with the method of raiſing potatoes from ſeed; which is as follows: "In autumn when the apples are beginning to fall ſpontaneouſly, they are gathered by hand, and preſerved among ſand until the ſpring, when they are maſhed among the ſand or among freſh mould; ſeparating the ſeeds and mixing them evenly with the mould. As ſoon as the ſpring froſts are judged to be over, they are ſown in fine garden mould; and as faſt as the plants get into rough leaf, and are ſtrong enough to be handled without injury, they

296 Concluſion favourable to the cultivation of this kind.

Culture of particular Plants.

they are transplanted into another bed of rich mould in rows, which are kept clean during summer. In autumn, bunches of small potatoes are found at the roots of these plants; varying in size, the first year, from a hazel nut to that of a crab. These being planted next spring, produce potatoes of the middle size; but they do not arrive at their fullest bulk until the third or fourth year. Where the use of the stove or the garden frame can be had, this process may be shortened. The seeds being sown within either of these early in the spring, the plants will be fit to be planted out as soon as the frosts are gone; by which means the size of the roots will be much increased the first year, and will in the second rise early to perfection."

Another account of the mode of raising potatoes from seed is given by Mr Henry Doby of Woodside Chapel, Allerton, near Leads. "Take the largest potato apples, of the kind you wish to renew, and string them on a very strong coarse thread, and hang them in a dry warm place till the latter end of February; when breaking them very small, and washing them in several waters, the seed is to be separated from the fleshy part and skins; this done, it should be spread on brown paper; and when dry, sow it in the beginning of March, or sooner, on a hot-bed, in lines about nine inches asunder, and one-third of an inch deep, and very thin: water between the lines frequently, and when the plants are risen a little height, introduce fine rich earth between the lines to strengthen them. They should have air admitted frequently, the better to enable them to bear being removed into the open air as soon as the weather shall be sufficiently temperate. Before they are transplanted they should be plentifully watered, to make them rise with a large ball at their roots; old rotten horse-dung and yellow moss are the best manures; plant them in trenches, as celery was formerly, with a space of four feet between the trenches, and 12 or 14 inches between each plant; as they grow up, draw the earth between the trenches to the stalks, but do not cover their tops. The ground, when brought to a level, should be dug, and the plants earthed until there are pretty deep trenches formed between the lines. With this treatment they will produce the first season from a pound weight to five pounds a plant; and many of the plants considerably more than a hundred potatoes a-piece; the produce of which for ten or twelve years after will be prodigious."

nnals of griculture, ol. xix.

300 Anderson's experiments.

In the 4th volume of the Bath Papers, Dr Anderson relates some experiments made on potatoes raised from seed. The first year they were of different sizes, from a pigeon's egg to that of a small pea. On planting these next year, it was invariably found, that the largest potatoes yielded the largest crop; and the same happened the third, when a few showed blossom; but not even these had bulbs equal to what would have been produced by very large potatoes. Whence he concludes, that it is impossible to assign any time in which these seedling potatoes will arrive at what is called *perfection*; but that it must depend very much on the nature of the soil and the culture bestowed upon them. From the practice of the Yorkshire farmers, however, and even from the experiments of the Doctor himself, it is evident, that potatoes raised in this way will at last grow to the usual size, as during the three years in which his experiments were continued they constantly increased in bulk. Dr Anderson likewise contends, that there is no reason for supposing that potatoes raised from bulbs in the ordinary way degenerate, or require to be renewed by seminal varieties; and he instances the universal practice of Britain and Ireland for a great number of years past. But this may be accounted for from an observation of Mr Marshall's, that varieties of potatoes, like those of corn, are partial to particular soils and situations. Hence, by transplanting all the different varieties of potatoes into all possible soils and situations, as has been done within this last century in the islands of Britain and Ireland, these varieties have continued for a much longer time than they would otherwise have done. In Yorkshire, Mr Marshall tells us, that "the old favourite sorts were driven until some of the individual plants barely produced their seed again." It is evident, therefore, that there is a necessity from time to time of renewing them from seed; though it deserves well to be considered whether it would not be more eligible to choose the seed from a plant in full vigour than from that which is so far degenerated that it can scarce produce its seed. "Potatoes raised from seed (says Mr Marshall) are a miscellany of endless varieties. Sometimes these varieties are planted miscellaneously; sometimes particular varieties are selected. In selecting varieties from seedling potatoes, two things are to be attended to; the intrinsic quality of the potato, and its productiveness. If these two desirable properties can be found in one plant, the choice is determined. To this species of attention and industry we are indebted for the many valuable kinds which have been and now are distributed throughout the island. It is observable, however, that varieties of potatoes, like those of corn, are partial to particular soils and situations. Hence the propriety of husbandmen raising potatoes from seed; as by this means, they obtain, with a degree of moral certainty, a sort adapted to their own particular soils and situations. Whoever has attended closely to the work of taking up potatoes, must have observed the great inequality in the productiveness of individual plants. The difference in the produce of adjoining roots, where no disparity of soil can influence, will sometimes be three or four fold. Hence it is evident, that each variety has its *sub-varieties*; through whose means it can hardly be doubted the parent variety may be improved, and its continuance be prolonged. Thus the farmer has another mean in his power of improving the quality and productiveness of his potato crop, by improving varieties; or, in other words, selecting sub-varieties, superiorly adapted to his soil and situation."

Culture of particular Plants.

301 Whether potatoes degenerate.

Sir Archibald Grant, Bart. of Monymusk, in a letter to the conductors of the Farmer's Magazine, has recently made known a mode practised by him with a view to the saving of seed, and the obtaining an early crop of potatoes. "In spring 1800, (says that gentleman), from a scarcity of seed, I followed a method sometimes used by gardeners, for forcing early potatoes, pease, and beans, viz. that of planting them out upon a small dunghill, in order to make them come sooner forward, and afterwards transplanting them into the ground. This I did, after they had upon the dunghill risen to be good plants, and the leaves about an inch

Farmer's Magazine, 1802.

302 How to obtain an early crop.

Culture of particular Plants.

long. The dunghill was about three feet broad and 18 inches high, with from 2 to 3 inches of earth upon the top of it, and as long as held about a peck and three quarters of a peck of Aberdeenſhire meaſure (or 32lb. Dutch to the peck) of ſmall potatoes, cut into ſets, ſtuck as cloſe to each other as poſſible in the rows, and each row about two inches aſunder. On the 17th of April, they were put upon the dunghill; on the 2d of May they were in leaf; and on the 14th and 15th of May were planted out into the field; each plant 3 feet aſunder each way. On the 12th June, they were earthed up with the plough, and were afterwards dreſſed in the ordinary method. On the 1ſt Monday of October, being taken up, they produced from 14 to 16 bolls Aberdeen meaſure. In June I obſerved, that potatoes which had been planted in the ordinary way in other parts of the pariſh, in the middle of April, were ſcarcely appearing above ground when theſe were ſo high as to require being earthed up with the plough; ſo that ſix weeks were gained in growth by this method."

303 Potatoes planted by ſcooping out the eyes.

During the late great dearth of all kinds of proviſions, a plan was adopted with a view to ſave for food a part of the potatoes uſed as ſeed, which conſiſted of not cutting them into pieces with one or more eyes in each piece, as uſual, but of ſlightly ſcooping out the eyes, which in that ſtate were planted while the greater part of the potato was preſerved for the uſe of man or cattle. This mode of planting potatoes was ſucceſsful with a great number of perſons; but in ſome inſtances, where the ground was not in an excellent ſtate of preparation, the crop is underſtood to have been more defective than when the uſual mode was adopted of cutting off large pieces of the potato along with the eye. The point, however, about the utility of this mode of practice muſt ſtill be conſidered as doubtful or worthy of farther inveſtigation. We are rather diſpoſed to think that the practice of ſlightly ſcooping out the eye will not ultimately prove beneficial, becauſe in ordinary caſes the plant will be left deſtitute of due nouriſhment from the parent root at too early a period of its growth, and before it is completely capable of deriving its ſubſiſtence from the ſoil around it; in the ſame manner, and for the ſame reaſon, that light ſeed is apt to produce a light crop of grain. This objection may not indeed hold good with regard to potatoes planted on a very fine ſoil, or upon a hot-bed, for tranſplanting after the manner adopted by Sir Archibald Grant above mentioned. But on poor lands, where the ſtrength of the young plants is more ſeverely tried, any defect in the ſize of the root planted will probably always be productive of bad effects.

2. Turnip.

304 Culture of turnip.

Turnip delights in a gravelly ſoil; and there it can be raiſed to the greateſt perfection, and with the leaſt hazard of miſcarrying. At the ſame time, there is no ſoil but will bear turnip when well prepared.

No perſon ever deſerved better of a country, than he who firſt cultivated turnip in the field. No plant is better fitted for the climate of Britain, no plant proſpers better in the coldeſt part of it, and no plant contributes more to fertility. In a word, there has not for two centuries been introduced into Britain a more valuable improvement.

Of all roots, turnip requires the fineſt mould; and to that end, of all harrows froſt is the beſt. In order to give acceſs to froſt, the land ought to be prepared by ribbing after harveſt, as above directed in preparing land for barley. If the field be not ſubject to annuals, it may lie in that ſtate till the end of May; otherwiſe, the weeds muſt be deſtroyed by a braking about the middle of April, and again in May, if weeds ariſe. The firſt week of June, plough the field with a ſhallow furrow. Lime it if requiſite, and harrow the lime into the ſoil. Draw ſingle furrows with intervals of three feet, and lay dung in the furrows. Cover the dung ſufficiently, by going round it with the plough, and forming the three feet ſpaces into ridges. The dung comes thus to lie below the crown of every ridge.

Culture of particular Plants.

305 Seaſon and method of ſowing.

The ſeaſon of ſowing muſt be regulated by the time intended for feeding. Where intended for feeding in November, December, January, and February, the ſeed ought to be ſown from the firſt to the 20th of June. Where the feeding is intended to be carried on to March, April, and May, the ſeed muſt not be ſown till the end of July. Turnip ſown earlier than above directed, flowers that very ſummer, and runs faſt to ſeed; which renders it in a great meaſure unfit for food. If ſown much later, it does not apple, and there is no food but from the leaves.

Though by a drill plough the ſeed may be ſown of any thickneſs; the ſafeſt way is to ſow thick. Thin ſowing is liable to many accidents, which are far from being counterbalanced by the expence that is ſaved in thinning. Thick ſowing can bear the ravage of the black fly, and leave a ſufficient crop behind. It is a protection againſt drought, gives the plants a rapid progreſs, and eſtabliſhes them in the ground before it is neceſſary to thin them.

The ſowing turnip broad-caſt is almoſt univerſal in England, and common in Scotland, though a barbarous practice. The eminent advantage of turnip is, that, beſides a profitable crop, it makes a moſt complete fallow; and the latter cannot be obtained but by horſe-hoeing. Upon that account, the ſowing turnip in rows at three feet diſtance is recommended. Wider rows anſwer no profitable end, ſtraiter rows afford not room for a horſe to walk in. When the turnip is about four inches high, annual weeds will appear. Go round every interval with the ſlighteſt furrow poſſible, at the diſtance of two inches from each row, moving the earth from the rows toward the middle of the interval. A thin plate of iron muſt be fixed on the left ſide of the plough, to prevent the earth from falling back and burying the turnip. Next, let women be employed to weed the rows with their fingers; which is better, and cheaper done, than with the hand-hoe. The hand-hoe, beſide, is apt to diſturb the roots of the turnip that are to ſtand, and to leave them open to drought by removing the earth from them. The ſtanding turnip are to be at the diſtance of twelve inches from each other: a greater diſtance makes them ſwell too much; a leſs diſtance affords them not ſufficient room. A woman ſoon comes to be expert in finger-weeding. The following hint may be neceſſary to a learner. To ſecure the turnip that is to ſtand, let her cover it with the left hand; and with the right pull up the turnip on both ſides. After thus freeing the ſtanding turnip, ſhe may ſafely uſe both hands. Let the field remain in this ſtate till the appearance of new annuals make a ſecond

ploughing

Culture of particular Plants.

ploughing neceſſary; which muſt be in the ſame furrow with the former, but a little deeper. As in this ploughing the iron plate is to be removed, part of the looſe earth will fall back on the roots of the plants; the reſt will fill the middle of the interval, and bury every weed. When weeds begin again to appear, then is the time for a third ploughing in an oppoſite direction, which lays the earth to the roots of the plants. This ploughing may be about the middle of Auguſt; after which, weeds riſe very faintly. If they do riſe, another ploughing will clear the ground of them. Weeds that at this time riſe in the row, may be cleared with a hand-hoe, which can do little miſchief among plants diſtant 12 inches from each other. It is certain, however, that it may be done cheaper with the hand (G). And after the leaves of turnips in a row meet together, the hand is the only inſtrument that can be applied for weeding.

In ſwampy ground, the ſurface of which is beſt reduced by paring and burning, the ſeed may be ſown in rows with intervals of a foot. To ſave time, a drill-plough may be uſed that ſows three or four rows at once. Hand-hoeing is proper for ſuch ground; becauſe the ſoil under the burnt *ſtratum* is commonly full of roots, which digeſt and rot better under ground than when brought to the ſurface by the plough. In the mean time, while theſe are digeſting, the aſhes will ſecure a good crop.

306 Properties of different ſorts of turnip.

In cultivating turnips to advantage, great care ſhould be taken to procure a good, bright, nimble, and well-dried ſeed, and of the beſt kinds.

The Norfolk farmers generally raiſe the oval white, the large green-topped, and the red or purple topped kinds, which from long experience they have found to be the moſt profitable.

The roots of the green-topped will grow to a large ſize, and continue good much longer than others. The red or purple-topped will alſo grow large, and continue good to the beginning of February; but the roots become hard and ſtringy ſooner than the former.

The green-topped growing more above ground, is in more danger of ſuſtaining injury from ſevere froſts than the red or purple, which are more than half covered by the ſoil; but it is the ſofteſt and ſweeteſt, when grown large, of any kind. We have ſeen them brought to table a foot in diameter, and equally good as garden turnips.

Turnips delight in a light ſoil, conſiſting of ſand and loam mixed; for when the ſoil is rich and heavy, although the crop may be as great in weight, they will be rank, and run to flower earlier in ſpring.

307 Obſervations with regard to ſeed.

Turnip-ſeed, like that of grain, will not do well without frequent changing. The Norfolk ſeed is ſent to moſt parts of the kingdom, and even to Ireland: but after two years it degenerates; ſo that thoſe who with to have turnips in perfection ſhould procure it freſh every year from Norwich, and they will find their account in ſo doing. For, from its known reputation, many of the London ſeedſmen ſell, under that character, ſeed raiſed in the vicinity of the metropolis, which is much inferior in quality.

Culture of particular Plants.

When the plants have got five leaves, they ſhould be hoed, and ſet out at leaſt ſix inches apart. A month afterward, or earlier if it be a wet ſeaſon, a ſecond hoeing ſhould take place, and the plants be left at leaſt 14 inches diſtant from each other, eſpecially if intended for feeding cattle; for where the plants are left thicker, they will be proportionably ſmaller, unleſs the land is very rich indeed.

308 Methods of culture in Norfolk.

Some of the beſt Norfolk farmers ſow turnips in drills three feet aſunder, and at a ſecond hoeing leave them a foot apart in the rows. By this means the trouble and expence of hoeing is much leſſened, and the crop is of equal weight as when ſown in the common method. The intervals may eaſily be cleared of weeds by the horſe-hoe.

Communications to the Board of Agriculture, vol. ii.

There has been laid before the Board of Agriculture, the reſult of ſome intereſting experiments, which we ſhall here ſtate, that were made by Mr W. Jobſon of Turvelaws, with a view to aſcertain the comparative merits of the two modes of rearing turnips by drill or broad-caſt. The trial was made upon a part of a field of 15 acres ſown in the month of June 1797. "The whole field, ſays Mr Jobſon, was in equal tilth, was manured as equally as poſſible immediately before ſowing with rotted fold-yard dung, at the rate of 17 cart loads per acre, each load containing about 28 Wincheſter buſhels; and in order to make the experiment perfectly fair, there were breadths of land of 20 yards each, ſown in broad-caſt and drills alternately, throughout the whole field. Part of the drills on one-bout ridges of 27 inches each, with the dung laid immediately underneath, where the row of ſeed was depoſited; the reſt of the drills upon a level ſurface, were ſown by Mr Bayley's machine at 21 inches diſtance. The produce per acre is calculated from the weight of four ſquare perches, or the fortieth part of a ſtatute acre of each, having firſt cut off the tails, or fibrous part of the root, and thrown them aſide, as unfit for food, and then taken the weight of the tops and roots ſeparately.

309 Culture of turnip by drill and broad-caſt compared.

"It is neceſſary to obſerve, that this field of turnip was but a middling crop, having been much hurt immediately after the firſt hoeing, by the *grub* (a ſmall worm which deſtroys the root), particularly the drilled part of the field, which, having had the plants ſet out, at the diſtances at which they were intended to remain before the grub ſeized them, was on that account rendered too thin and otherwiſe much injured; notwithſtanding which, it was found that thoſe on the one-bout ridges exceeded the others in weight; alſo, that theſe parcels of turnips were taken from an inferior (though not the worſt) part of the field, and may therefore be deemed to be a pretty fair average of the whole:

(G) Children under thirteen may be employed to weed turnips with the fingers. We have ſeen them go on in that work with alacrity; and a ſmall premium will have a good effect. For boys and girls above thirteen, a hand-hoe adapted to their ſize is an excellent inſtrument: it ſtrengthens the arms amazingly. In driving the plough, the legs only are exerciſed; but as the arms are chiefly employed in huſbandry, they ought to be prepared beforehand by gentle exerciſe.

Culture of particular Plants.

whole: there were alſo three other portions weighed, which were taken from a part of the field where the roots were larger, and a fuller crop, with a view to aſcertain what might have been expected, had not the grub ſeized them in the manner deſcribed; but unfortunately the paper containing their weight has been loſt or miſlaid, which puts it out of my power to furniſh you with it. There was alſo an account taken of the number (but not the weight) of loads which were produced upon a few acres of the worſt part of the field, which was in favour of the broad-caſt, in the proportion of ten of broad-caſt to nine of thoſe drills on one-bout ridges, and eight of Mr Bayley's drill.

"From this experiment (though defective from the reaſons aſſigned) we have reaſon to conjecture, though not to form a concluſion, that a heavier crop may be raiſed by ſowing in drills at 27 inches diſtance with the dung immediately beneath the plants, than in broad-caſt or in drills at 21 inches on a level ſurface: but whether the advantage ariſes from the ſituation in which the dung is depoſited, or from their having a freer circulation of air, or from both theſe united, it remains for future and repeated experiments to decide. Notwithſtanding this, it will be found, that each of theſe methods poſſeſſes peculiar advantages and diſadvantages, according to ſituations and circumſtances; the reaſons for which I deduce from the obſervations I have made reſpecting this as well as former crops. In the firſt place, the one-bout ridges I think preferrable for early ſowing, and eating off, through the winter months, even ſo late as the month of February, as they are more eaſily procured for food for cattle in deep ſnows; alſo in ſituations where it is difficult to procure a ſufficient number of experienced hoers, thoſe under the drill ſyſtem can be more eaſily managed and at leſs expence, as boys and girls may be readily taught to ſet out the plants with great regularity in very little time; but turnips under this ſyſtem are liable to the inconvenience of being more apt to be injured by ſevere froſts from their high expoſure. Another inconvenience I have alſo obſerved on wet and heavy lands, more eſpecially with little declivity, that although there ſhould, and poſſibly may, be a larger crop produced thereby, yet the land will unavoidably be ſo much poached by carrying them off, that the ſucceeding crop of corn will be leſſened more than the extra value of the turnips will compenſate. When it is attempted to raiſe turnips upon land of this deſcription, it will be found more advantageous to form it into ridges of ſufficient height to carry off the water with eaſe into the water furrows, and of ſufficient breadth (ſuppoſe fifteen feet) to allow a cart to paſs along them freely, without forcing the earth in to choke up theſe furrows. The turnips may be ſown either in broad-caſt or in drills, upon the ſurface of theſe ridges. If the land is addicted to annual weeds, they will be beſt in drills, which will expedite the hoeing; but if not, or if they be late in ſowing, or if the land be ſubject to the grub, broad-caſt will generally be found to produce a more certain crop, as they can be left ſo near to each other at the firſt hoeing as to admit of being thinned, and thereby give the opportunity of taking out unhealthy plants at the ſubſequent hoeings, and alſo that they grow more vigorouſly between the firſt and ſecond hoeings."

Culture of particular Plants.

The reſult of the experiment here alluded to, is ſtated in the following manner:

COMPARATIVE WEIGHT of ſix portions of Turnips, which were part of a Field of fifteen Acres: the whole of which was Sown in the Month of June 1797, as an experiment between the Drill and Broad-caſt ſyſtems.

	Time of weighing.	Number upon four ſquare perches.	Weight on four ſquare perches, or the 40th part of an acre. ROOTS. Cwt. qr. lib.	TOPS. cwt. qr. lb.	Weight per ſtatute acre. Tons cwt. qr. lib.	Average weight of each turnip. lb. oz.	Average diſtance of each turnip.
No I. Drilled on one-bout ridges, at 27 inches diſtance.	January	354	8 1 1	1 1 3	19 1 0 20	3 0¼	16½ in. by 27 in.
II. Drilled with Mr Bayley's machine, on a level ſurface, at 21 inches diſtance.	ditto	428	7 1 15½	1 1 5½	17 7 1 8	2 4¾	17 in. by 21 in.
III. Broad-caſt.	do.	568	7 2 12½	1 0 11½	17 8 1 26	1 11½	16¾ each way.
IV. Drilled on one-bout ridges, at 27 inches diſtance.	Mar. 2.	334	8 3 0	1 1 22	20 7 3 12	3 6½	17 by 27 in.
V. Broad-caſt. Theſe and the preceding were round white turnips.	do.	628	8 2 22	1 1 8	20 0 2 24	1 12½	16 each way.
VI. Broad-caſt (Red.)	do.	561	6 3 26½	2 3 5	19 11 1 0	1 15½	16½ each way.

"By noting the average diſtance of each turnip, as is done in the laſt column, is intended to ſhow, at one view, how many plants there were wanting in the drills to have made them a full crop; for, if 550 be ſtated as a medium number in a full crop, upon the 40th part of an acre, they will be found to occupy a ſpace of 17 inches each way in broad-caſt, 10½ by 27 inches on the one-bout ridges, and 13½ by 21 inches of thoſe drilled

Culture of particular Plants.

drilled on the level ſurface; from whence may be eaſily ſeen, how much thoſe were wider in the rows than they ought to have been."

Great quantities of turnips are raiſed in Norfolk every year for feeding black cattle, which turn to great advantage.

310 Value as food for cattle.

It is well known, that an acre of land contains 4840 ſquare yards, or 43,560 ſquare feet; ſuppoſe then that every ſquare foot contains one turnip, and that they weigh only two pounds each on an average, here will be a maſs of food, excellent in kind, of 46 tons per acre, often worth from four to five guineas, and ſometimes more.

Extraordinary crops of barley frequently ſucceed turnips, eſpecially when fed off the land. In feeding them off, the cattle ſhould not be ſuffered to run over too much of the ground at once, for in that caſe they will tread down and ſpoil twice as many as they eat. In Norfolk, they are confined by hurdles to as much as is ſufficient for them for one day. By this mode the crop is eaten clean, the ſoil is equally trodden, which if light is of much ſervice, and equally manured by the cattle.

A notion prevails in many places, that mutton fattened with turnips is thereby rendered rank and ill taſted; but this is a vulgar error. The beſt mutton in Norfolk (and few counties have better) is all fed with turnips. It is by rank paſtures, and marſhy lands, that rank mutton is produced.

If the land be wet and ſpringy, the beſt method is to draw and carry off your turnips to ſome dry paſture; for the treading of the cattle will not only injure the crop, but render the land ſo ſtiff, that you muſt be at an additional expence in ploughing.

311 Method of preſerving turnips.

To preſerve turnips for late ſpring feed, the beſt method, and which has been tried with ſucceſs by ſome of the beſt Engliſh farmers, is, To ſtack them up in dry ſtraw; a load of which is ſufficient to preſerve 40 tons of turnips. The method is eaſy, and is as follows:—

After drawing your turnips in February, cut off the tops and tap roots (which may be given to ſheep), and let them lie a few days in the field, as no weather will then hurt them.

Then, on a layer of ſtraw next the ground, place a layer of turnips two feet thick; and then another layer of ſtraw, and ſo on alternately, till you have brought the heap to a point. Care muſt be taken to turn up the edges of the layers of ſtraw, to prevent the turnips from rolling out; cover the top well with long ſtraw, and it will ſerve as a thatch for the whole.

In this method, as the ſtraw imbibes the moiſture exhaled from the roots, all vegetation will be prevented, and the turnips will be nearly as good in May as when firſt drawn from the field. If ſtraw be ſcarce, old haulm or ſtubble will anſwer the ſame purpoſe.

But to prevent this trouble and expence, perhaps farmers in all counties would find it moſt to their intereſt to adopt the method uſed by our neighbours the Norfolk farmers, which is, to continue ſowing turnips to the latter end of Auguſt; by which means their late crops remain good in the field till the latter end of April, and often till the middle of May.

The advantages of having turnips good till the ſpring feed is generally ready, are ſo obvious, and ſo great, that many of the moſt intelligent farmers (although at firſt prejudiced againſt the practice) are now come into it, and find their account in ſo doing.

Culture of particular Plants.

312 Their culture ſaid to be generally attended with no profit.

Turnips have long been in ſuch general uſe as food for cattle, that the profit on raiſing them might be reaſonably thought to be altogether certain; nevertheleſs, Mr Young, in the paper already quoted, informs us, that "turnips dunged for are univerſally a loſing crop; for if they are ſtated from 30s. to 40s. an acre, their value does not amount to the dung alone which is ſpread for potatoes; yet the latter pays that dung, all other expences, and leaves a profit ſometimes conſiderable. I admit that turnips fed upon the land will prepare better for corn; but that is by no means the queſtion. Would not the dung raiſed in the farmyard by the conſumption of the potatoes, ſuppoſing it ſpread on the potato acre, make that produce more than the turnip one? I have no doubt but it would give a ſuperiority. But turnips are liable to great failures, and cannot be relied on late in the ſpring: potatoes may; and are applicable to uſes to which the other root cannot be applied."—In the ſecond volume of the Bath Papers, p. 101. we have a comparative account of the value of turnips, turnip-rooted cabbage, and lucerne, as food for cattle. The reſult of this writer's obſervations is, that "when ſheep are allowed as many turnips as they can eat (which ſhould always be the caſe when they are fattening), they will, on an average, eat near 20 pounds each in 24 hours. An acre of turnips, twice hoed, will, if the land be good, produce about fifty tons; which will, on the above calculation, maintain 100 ſheep 52 days. The ſheep mentioned weigh 20 pounds per quarter. An acre of turnip-rooted cabbage will maintain 100 ſheep for a month, and ſometimes five weeks; but an acre of Scots cabbages will maintain 200 ſheep a full month." The number fed by lucerne is not determined.

313 Compared with other vegetables as food for cattle.

The greateſt diſadvantage which attends a crop of turnips, is their being ſo ready to be damaged by the fly, which ſometimes deſtroys them ſo completely, that they muſt be ſown over again two or three times the ſame ſeaſon, and even this without any certainty of ſucceſs. Innumerable methods of avoiding this evil have been projected, which may all be reduced to the following claſſes: 1. Steeping the ſeed in certain liquids. 2. Fumigation of the fields with the ſmoke of certain herbs. 3. Rolling. 4. Strewing ſoot, lime, aſhes, &c. on the ſurface of the ground. It is very difficult, however, to determine, with any degree of certainty, whether remedies of this kind are effectual or not; becauſe ſometimes the turnips are not injured though no precaution has been made uſe of: and when this happens to be the caſe, after the uſe of any ſuppoſed preventive, the preſervation of the crop is aſcribed to the uſe of that preventive, whether it be really efficacious or not. The virtues of ſteeps ſeem to have been fully aſcertained by Mr Winter Charlton near Briſtol, of whoſe experiments an account is given in the Tranſactions of the Society for Encouraging Arts, vol. v. The ſeeds were of the Dutch kind, ſowed on beds in the kitchen garden in drills, about twelve inches diſtant, an inch and a half deep, on the 11th of May 1786. The beds had been prepared with rotten dung in May 1785, and afterwards ſown with cabbages. The quality of the turnips is exhibited in the following table; the

314 The fly occaſions the great inconvenience in turnip culture.

315 Whether ſteeps for turnip-ſeed be of any uſe.

Culture of particular Plants.

the beſt being marked 1; and theſe of inferior quality, 2, 3, &c. The obſervations were taken on the 26th of June.

Seed without any preparation,	1
ſteeped in train oil, flouriſhed extremely,	
ſteeped in linſeed oil, ſomewhat inferior,	1
Seed mixed with foot and water,	2
with drainings of a dunghill,	2
with elder and barton draining,	2
with foot,	3
with elder leaf juice,	3
with elder and barton draining, foot being ſowed over the covered drills,	3
with ditto, and lime ſowed over the drills,	3
ſowed with foot ſcattered over, and then covered,	3
with barton draining,	4
an elder buſh drawn over when the plants appeared,	4
with ſtale human urine, very few plants appeared,	
with ſlaked lime ſcattered over, and then covered, very few plants appeared,	
with elder, barton-draining, and ſlaked lime, very few plants appeared,	
with lime and barton-draining did not vegetate.	

Another ſet of experiments was made with the green Norfolk turnip, drilled an inch and a half deep, the rows one foot diſtant, on beds eight feet three inches long, and two feet wide; half a drachm of ſeed allowed for each bed, ſteeped and mixed with various ſubſtances like the former. The ſeeds were drilled upon unmanured ground on the 20th of June 1786, and the obſervation made on the 17th of July. None of the beds were found free from the ravages of the fly; but the ſeed which had been ſteeped in train oil and linſeed oil were much more free from this injury than the others. The linſeed oil, as in the former experiment, was found inferior to the train oil, which was ſuppoſed to have been owing to its being kept in a bottle that had formerly held oil of turpentine. The leaves of the ſteeped ſeeds were of a much darker green than the others, appeared twice as thick in bulk and luxuriancy, and the plants were conſiderably larger than thoſe of the other kinds. The ſubſtances mixed with the reſt were ſoapers aſhes, wood aſhes, pounded gunpowder, brimſtone, ſlaked lime, ſoot, barton-draining; ſometimes mixed together in various proportions, and ſometimes with the addition of a portion of ſifted mould.

Theſe experiments ſhow, that no dependence can be had on ſteeps or mixtures of any kind with the turnip-ſeed; though the train oil and linſeed oil ſeem greatly to have forwarded the vegetation of the plant. It does not appear that fumigation has ever been tried; nor indeed does it ſeem eaſy to be tried in ſuch a manner as might enſure ſucceſs.—In the fourth volume of the Bath Papers, Mr Gullet of Devonſhire gives ſuch directions for performing the operation as he thinks would be productive of ſucceſs.—In a preceding paper he had explained the good effects of fumigating orchards; but the caſe with theſe muſt be very conſiderably different from a field of turnips. The trees in an orchard are elevated above the ground, and the ſmoke naturally aſcends, and is blown along their tops: but in fumigating a large field of turnips, it muſt creep along the ground in ſuch a manner as is by no means agreeable to its nature; and without an exceſſive degree of labour, as well as a vaſt quantity of burning materials, there cannot be the leaſt hope of ſucceſs. Mr Gullet's directions are as follow: "If the turnip-ground be ſpaded and burnt, or the weeds, &c. burnt without ſpading, the fumigation thereby may ſuffice to chaſe ſuch of the winged tribe from thence as are then there; but in all caſes, when the field is ploughed and ready for ſowing, let heaps be made at different places and intervals round by the hedges and boundaries of the turnip-ground, and ſome few ſcattered through the field; then, as ſoon as the ſeed is ſown, let the heaps on the windward ſide and the ſcattered ones be lighted and kept ſmothering during the continuance of the wind in that quarter; the leſs the fire, and the more the ſmoke, the better. Should the wind happen to ſhift, thoſe heaps on the quarter it ſhifts to muſt then be lighted and kept ſmothering in like manner; ſo that during the growth of the tender turnip leaf, and until it becomes rough and out of all danger, this fumigation and ſmoke, over and acroſs the field, muſt be continued from one quarter to the other; which I venture to aſſert, will effectually deter and prevent any winged inſect tribe from approaching the turnip-ground: nay more, if there already, it would moſt completely drive them from thence, as ſuch delicately formed inſects (which can only feed on the moſt tender leaf) would be ill able to continue long in ſuch a ſmother of fire and ſmoke. The conſequence is obvious and certain, that if the fly be kept from approaching the field, the turnip-crop is ſafe; and few, I believe, will diſagree with me, that *prevention is better than remedy*."

316 Mr Gullet's directions for fumigation.

Our author does not ſay that he has ever tried this method with turnips; but lays great ſtreſs upon his ſucceſs in a ſimilar experiment with cabbages, in order to preſerve them from the caterpillar. To make the matter more ſure, however, he recommends the trailing of a buſh of elder over the turnip field at the time of harrowing or bruſhing in the ſeed: but this remedy has by numberleſs experiments been found inſignificant, and by thoſe above related ſeems even to be pernicious: ſo that whatever good effects we can expect from this method, muſt depend on the fumigation alone; and even this is attended with very great uncertainties, as has already been obſerved.

317 Of rolling

Rolling promiſes to be of ſervice when the young turnips are attacked by ſnails, which frequently deſtroy them; but it cannot be ſuppoſed to have much effect in deſtroying flies, theſe being too numerous and too minute to be effectually cruſhed by the roller: and indeed, though this has been frequently recommended, we have no deciſive proofs of its having ever been attended with any good effect.

The ſtrewing of ſoot, lime, aſhes, &c. upon the ground, have been determined ineffectual by the experiments already related, at leaſt when applied before the turnips come up; and there ſeems to be little hope of their proving more effectual even when applied after the crop has appeared above ground. We may argue indeed

Culture of particular Plants.

indeed *à priori* about the taſte or ſmell of ſoot, lime, &c. being diſagreeable to inſects; but of this we have no proof; and even though this were the caſe, the leaf ſoon emerges from under this covering, or the inſects will feed on the under part of the leaves, where theſe ſubſtances cannot lie. It is evident, therefore, that very little can be expected from any of the methods hitherto propoſed either by way of cure or prevention. The more probable methods are,

318 Early ſowing recommended.

1. To ſow the turnips at ſuch a ſeaſon of the year that they may be well grown before the fly makes its appearance. In the Bath Papers, vol. iv. p. 132. Mr Wimpey obſerves, that in order to procure food for their cattle in the ſpring before the graſs is grown, farmers are obliged to poſtpone the ſowing of turnips beyond the natural time of vegetation: but were turnips to be ſown in April, as ſoon as the ſeaſon would permit, it is very probable that there would be as great a crop of them as of other vegetables uſually ſown in theſe months. On account of the delay in ſowing, however, for the reaſon already mentioned, the ſucceſs of the farmer becomes exceedingly precarious, unleſs he is ſo fortunate as to have a few rainy days, or cloudy weather and frequent ſhowers, ſoon after the ſeed is ſown: and this our author ſuppoſes to be the true reaſon why the turnip is a more uncertain article than any other. But though ſpeculations of this kind have a great ſhow of probability, there is not any experiment hitherto publiſhed, even by our author himſelf, by which the truth of the above conjecture can be abſolutely aſcertained. Our author, however, is of opinion, that none of the common methods propoſed can anſwer any good purpoſe, farther than as by means of them the vegetation of the plant may be invigorated. Mr Wimpey recommends aſhes, ſoot, or a rich compoſt of lime and dung, uſed in ſufficient quantities; but the method of uſing them is, either to ſow them with the ſeed, or rather by themſelves immediately before, and to harrow them well in, that they may be completely incorporated with the ſoil. This for the moſt part would ſo invigorate and encourage the growth of the plants, as to be an overmatch for the moſt vigorous attacks of the fly.

319 Sowing a great quantity of ſeed.

2. Another method propoſed for ſecuring turnips from the fly, is by ſowing ſuch a quantity of ſeed as will be more than ſufficient for the conſumpt of the inſects. This we find recommended in a letter to the Bath Society, by a gentleman-farmer in Eſſex, vol. ii. p. 238. His method is to make the land clean and fine as ſoon as the ſeaſon will permit, and to ſow four pints per acre. It may be objected, that if the fly does not take them, the plants will ſtand ſo thick, that they cannot eaſily be hoed; but this may be obviated by harrowing them firſt, which will make them fit for the hoe. There can be no expectation of a crop if the fly takes them when only a pint of ſeed is ſown per acre; but this gentleman remarks, that he has not in any one inſtance miſſed of a crop when he ſowed four pints; becauſe, though the fly has ſometimes deſtroyed more than one half, and much damaged the other, ſtill there was a ſufficient number left behind. He alſo agrees with other of the Society's correſpondents, that the ground ſhould be well dunged and manured previous to the ſowing of turnips, as this makes them grow vigorouſly, ſo that they quirkly get into the rough leaf, in which ſtate the fly will not touch them.

In the ſame volume, a gentleman of Norfolk remarks, that manuring the ground in autumn for turnips is preferable to the doing ſo in ſpring. This diſcovery he made in conſequence of the following accident.—"A neighbouring farmer, not having a ſufficient quantity of manure for all his turnip land, was under the neceſſity of ſowing four acres unmanured. The effect was, that the turnips on the manured part of the land were moſtly eaten off by the fly, while four acres unmanured eſcaped without injury." In conſequence of having obſerved this, the gentleman made a ſimilar experiment, by manuring five acres well for turnips, and tilling three acres and a half in the uſual way without any manure. The manured crops were almoſt all deſtroyed by the fly, ſo that he was obliged to ſow moſt of the land over again. The three acres and a half which had no manure were entirely free from injury, though the plants were much ſmaller than thoſe of the manured ground which came up. Not content with this trial, however, he repeated the experiment by manuring ſix acres of wheat ſtubble in autumn, ploughing it in immediately, and leaving it to incorporate with the earth during the winter: the turnips which grew upon this were as large as if the ground had been manured in the ſpring. This experiment was repeated with ſurpriſing ſucceſs in two ſucceeding years; whence he infers, that the fly is either engendered in the new dung or enticed by it. But when the manure is laid on in autumn it loſes its noxious qualities, though it ſtill retains its nutritive ones.—This concluſion, however, does not appear to be well founded; for it is certain from undoubted experience, that turnips which have been well manured in the common way, have ſometimes eſcaped any injury; while others, which have got no manure at all, have been almoſt totally deſtroyed. Another material advantage, however, which this correſpondent obſerves is to be derived from manuring in autumn is, that all the ſeeds contained in the manure, and which are of courſe carried to the land with it, vegetate almoſt immediately, and are moſtly killed by the cold of the ſucceeding winter, while the few that remain can ſcarce eſcape deſtruction from the ploughſhare.

Culture of particular Plants.

320 Manuring in autumn preferable to ſpring manure.

Mr Wimpey is alſo of opinion, that it is proper to ſow a large quantity of ſeed; but thinks two pounds will be ſufficient for an acre. A few ounces indeed would be ſufficient to ſtock the land; but as the article is ſo precarious, he thinks it by far the ſafeſt way to allow ſeed in plenty, and reduce the plants afterwards by harrowing. He obſerves alſo, that it is of great conſequence to have ſeed both good in quality and of the beſt ſpecies. He prefers the large and green topped, as being the moſt ſweet and juicy; others give the preference to the red or purple-topped, as being hardier: but at any rate, the ſeed from the largeſt and fineſt tranſplanted turnips, of whatever ſort, is greatly to be preferred, even though it ſhould coſt double or treble the price. Such as is ſold by the ſeedſmen in London he found generally of a mixed kind, and often in great part not worth cultivating. "Whether plants from new or old ſeed are moſt ſecure from the depredations of the fly (ſays he), is perhaps a queſtion which cannot be eaſily determined even by experiments; for concomitant circumſtances are frequently ſo much more operative and powerful, as to render the difference be-

321 Mr Wimpey's opinion of ſowing a great quantity of ſeed.

322 Of the quality of the ſeed.

Culture of particular Plants.

tween them, if there be any, imperceptible. It is, however, known to every practical man, that new feed ſprouts or vegetates ſeveral days before old; and I think more vigorouſly: and it is equally well known, that the healthy and vigorous plants eſcape the fly, when the ſtinted and ſickly ſeldom or never eſcape it. Hence it would ſeem, that new ſeed, *cæteris paribus*, is more ſecure from the fly than old; and for my own uſe I would always prefer it."

323 Of ſowing turnips with grain.

3. The ſowing of turnips along with grain.—This, of all others, ſeems to be the moſt eligible and efficacious. In the ſecond volume of Bath Papers, p. 210. a Hertfordſhire correſpondent gives an account of the ſucceſs of an experiment of drilling turnips with wheat. A ſmall field of ſpring-wheat was drilled in rows two feet apart; and in the month of May turnips were ſown by hand in the intervals. They came up very well, and were thinned once by the hoe. The crop of wheat turned out better than another field of the ſame ſoil ſown broad-caſt in autumn, though it ripened ſomewhat later. The turnips were no other way injured by cutting it, than having ſome of the large leaves trodden down by the reapers. After harveſt the weeds were cut up round the turnips with a hand-hoe, and they grew very large and vigorous. They were of the purple and white long kind, and the crop proved nearly as good as the ſame land produced in common. An excellent crop of barley and clover was got from the ſame field afterwards.

324 With wheat.

325 Mr Anderdon's experiments of ſowing them with beans.

In the third volume of the ſame work we find an account of ſeveral ſucceſsful experiments in ſowing turnips between rows of beans. The advantages of this method are ſtrongly ſet forth by R. P. Anderdon, Eſq; who made ſome of the experiments, and are as follow: "1. You may have a crop of beans and turnips on the ſame field the ſame year. 2. The bean crop being well horſe-hoed, no ploughing is wanted for turnips, for which the beſt Norfolk farmers give five ploughings. 3. It is hoed cheaper, more effectually, and conſequently more profitably, than in any other way. 4. The ground is kept clean from weeds. 5. It is in order for a Lent crop the ſucceeding year with one earth. 6. The ground is kept in heart, if not improved, by fallowing your alleys. 7. It brings the plant to perfection in poor ground, where it would not become ſo otherwiſe. 8. It doubles the crop in any ground which Mr Anderdon has had experience of. 9. You have the crops more within your own power in this than in any other method, let the ſeaſons turn out as they will. 10. You may have on the ſame ground a bean and turnip crop annually, if the land be ſuitable, and you think proper. 11. The clay farmer, by this mode, renders land which is naturally unfit for turnips, ſo free and open by ſeaſonable horſe-hoeings, that it will bring this uſeful plant to great perfection.

326 Objections by the Bath Society.

On this paper the ſociety made ſome remarks, and ſtated the following objections: 1. That the ſame ſoil cannot be proper for both crops. Scotch cabbages are more adapted for a bean ſoil; and they wiſhed him to repeat the experiment with cabbages inſtead of turnips betwixt his beans. 2. The Norfolk farmers rarely uſe more than three ploughings for turnips, inſtead of five, as Mr Anderdon repreſents, unleſs the ground be full of couch-graſs. 3. They think him too ſanguine in his expectations of having double crops on the ſame field. 4. Nothing renders a clay ſoil ſo free and open as to have it expoſed to froſts and ſnow by being laid up in high ridges in January and February; but, on Mr Anderdon's plan, this cannot be done, unleſs the turnips are leſſened in value by being fed off in autumn.

Culture of particular Plants.

327 Mr Anderdon's reply.

Theſe ſtrictures were ſent to Mr Anderdon before the papers were printed, but did not make any alteration in his opinion; and he replied to the following purpoſe.

1. *The ſame ſoil cannot be proper for beans and turnips*, &c.—Granted.—But had Mr Anderdon adhered rigorouſly to this rule, he would have ſowed no turnips at all, not having on his farm any ſoil altogether proper for that crop; "but (ſays he) while I can get in ſingle rows, four feet aſunder or more, from half a dozen to half a ſcore tons of turnips per acre, after, or rather between, a crop of beans in my heavy lands, I ſhall feel that product here more beneficial than to drop the mode. I believe the medium of the two, ſo far as I can judge by the eye or get information, to be ſuperior to the average produce of prepared fallow turnip crops in 10 miles round me."—On this the Society make the following remarks: "The queſtion here is, Whether, it inſtead of turnips, Mr Anderdon had planted his beans two feet diſtance only, the extra produce of his crop would not have exceeded in value that of his turnips? We think they would, as theſe intervals would freely admit his horſe-hoe between the beans."

Mr Anderdon then proceeds to acquaint the committee, that he had tried the experiment as they wiſhed with Scotch cabbages inſtead of turnips betwixt the rows of beans; but the crop of the turnips was ſo much preferable, that he found himſelf inclined to ſuppoſe the cabbage would not get to ſo great perfection there as to be profitably introduced on a large ſcale, for want of the great quantity of dung neceſſary for that crop, and which could not be procured in that part of the country. He further remarks in favour of turnips, that they have an abundance of very ſmall lateral fibrous roots, which run as far in ſearch of food, and feed as ravenouſly where they can penetrate, as thoſe of almoſt any other vegetable; and the plant certainly derives more nouriſhment from thoſe than from its tap-root (H). Thoſe fine fibrous roots, almoſt imperceptible to the eye, iſſue chiefly from the apple or body of the turnip, and get into the richeſt part of the ſoil near the ſurface, and will bring the plants to a conſiderable magnitude in heavy lands adapted to beans, when mellowed by the horſe-hoe. Some of his turnips weighed ten pounds each: and if he could have only two ſuch turnips on every ſquare yard, it would be at the rate of 43 tons per acre.

2. *The Committee doubt of the poſſibility of doubling the crop.* Mr Anderdon gives the following explanation.

"I

(H) Here the ſociety remark, that this is not the caſe with thoſe kinds of turnips which grow chiefly above ground, and which are generally the beſt crops, and moſt capable of reſiſting the froſts.

Culture of particular Plants.

" I have made many comparative trials on turnips between this mode and broad-caſt ſowing, and always found on *my ground* the horſe-hoed crops the beſt. But here, in denoting the benefits of the horſe-hoe by its *doubling* a crop, I wiſh to be underſtood, that if, *in ſoils like mine*, a crop be drilled, leaving proper intervals for horſe-hoeing, and one part be horſe-hoed the other not, the horſe-hoed part will double the other in product."

Mr Anderdon, in the courſe of his reply to the commitee, gives an account of another experiment he made in conſequence of being deficient in winter fodder for his cattle. By this neceſſity he was induced to ſow turnips wherever he could; and on the 18th of July drilled a ſingle row between his drilled wheat. On the 20th and 22d of Auguſt he drilled four rows of winter vetches in each interval between the turnips, at the rate of leſs than one peck and three quarters of ſeed to an acre. " The turnip crop (ſays he) is very acceptable, and my vetches ſucceed beyond my warmeſt expectation; are thick enough, and give me the pleaſing proſpect and hope, that I ſhall not, when my dry meat is gone, want a ſeaſonable ſuppy of early green fodder that will laſt me till my lucerne comes on."

328 Mr Pavier's opinion.

This ſubject is farther conſidered in the ſame volume by Mr Pavier, who viewed Mr Anderdon's turnips, and gave in a report of them to the commitee. He ſuppoſes a crop of beans drilled in ſingle rows at four feet diſtance, and the turnips drilled in the intervals, according to Mr Anderdon's method, there will then be four rows of 17 feet in length to make a ſquare perch; whereas Mr Anderdon's rows were only 15 feet 8 inches in length; and this diſparity in length will make a difference of weight on a perch from 230 to 249 pounds, and on an acre from 16 tons 8 cwt. 2 qrs. 8 lb. Mr Anderdon's produce, to 17 tons 15 cwt. 2 qrs. 24 lb.—Each turnip at this diſtance (viz. four feet from row to row, and nine inches in the rows) muſt occupy a ſpace of three ſquare feet; conſequently the greateſt number produced on an acre muſt be 14,520; but if ſown in broad-caſt, twice hoed, and the diſtance on an average 15 inches, each turnip will then occupy little more than one foot and an half, and the number produced on an acre may be about 27,920; an exceſs which may reaſonably be ſuppoſed to overbalance the value of the beans, let us ſuppoſe the crop as great as we can reaſonably do. Thus far the argument ſeems to lie againſt this method of cultivating beans and turnips together: but on the other hand, Mr Pavier conſiders it probable that the expence of drilling and horſe-hoeing the beans, together with drilling the turnips in the manner Mr Anderdon did, muſt be conſiderably leſs than that of fallowing and preparing the ground, and ſowing the turnips in broad-caſt; to which we muſt likewiſe add the facility of hoeing the drills in compariſon of the broad-caſt. But beſides theſe, the great advantage ariſing from this method, and which, if certain, gives it a decided ſuperiority, is, " the great chance, if not an almoſt certainty, of preſerving the turnips from the depredations of the fly." Mr Pavier was inclined to think that this muſt be the caſe, as Mr Anderdon had ſuch crops repeatedly without any damage of that kind; but the committee differ from him, and think that this muſt have proceeded from ſome other cauſe; though they do not aſſign any reaſon for this opinion. " The principal point (ſays Mr Pavier), in determining this queſtion, ſeems to me to be this; if the crop of beans drilled as above after deducting the ſeed, and ſome additional expence in taking the crop off the ground without injuring the turnips, can be, one year with another, ſuppoſed to be as valuable as the quantity of turnips that might be reaſonably expected in the broad-caſt method more than in the other, I ſhall not heſitate to declare in favour of drilling between the beans."

Culture of particular Plants.

Thus far the argument ſeems to be carried on *a priori*. Mr Wimpey, in the letter already quoted, inclines to the practice of ſowing turnips between beans planted in rows. " It exactly correſponds (ſays he) with all my obſervations on the ſucceſsful vegetation of that root. A conſiderable degree of moiſture is neceſſary to the rapid vegetation of that very juicy root, and nothing retains moiſture equal to ſhade: and ſhade can be obtained and ſecured by no means ſo effectually on a large ſcale as in the intervals of tall growing plants, as beans or wheat planted in drills." The ſucceſs of Mr Bult of Kingſton near Taunton, leaves little room to doubt of the propriety of the method, and its ſucceſs in preventing the fly. The beans were planted in drills not quite two feet aſunder, on two ploughings, horſe-hoed three times, and the turnips ſown in the intervals at the laſt-hoeing. The field meaſured ſix acres and a quarter, and was a very good clayey ſoil, but had not been manured, nor had any dreſſing laid upon it for ſix years before. It produced this year three quarters of beans per acre, and 37 tons 5 cwt. of turnips. This field was alſo viewed by Mr Pavier, who makes the following obſervations upon it. 1. The turnips were ſown promiſcuouſly among the beans at the laſt hoeing, which was given about midſummer; from which time nothing was done but drawing off the beans and carrying them off the land. 2. The crop of beans was believed to be conſiderably above 20 buſhels per acre, which is much more than was produced by any other method that ſeaſon in the neighbouring part of the country: and as Mr Pavier had this account before he ſaw the turnip crop, he did not expect any thing conſiderable from the latter; but as it turned out, the produce muſt be accounted highly profitable, when we conſider that there was no crop loſt, no preparation, dreſſing, nor any expence whatever, excepting the price of the ſeed and ſowing it. 3. This he conſiders as one of the ſtrongeſt recommendations of the drill huſbandry he ever knew or heard of; but he is of opinion that it never can anſwer, except where the ground is perfectly clean and free from weeds, by the crops having been horſe-hoed for a few years before. 4. He thinks the beans ought to have been planted at wider intervals, by which the ſun and air would be freely admitted, and the plants would alſo be leſs damaged by the operation of the hoe.

329 Other experiments on ſowing turnips among beans.

Mr Pavier likewiſe informs the Society of two other experiments on a ſimilar plan; but with this difference, that the turnips were ſown among the beans at the ſecond horſe-hoeing. The turnip crops were very good, and the beans more than *double* the value of thoſe raiſed in the uſual mode of huſbandry. " I think it is very evident (ſays he), that the beans preſerve the turnips from the fly; and as no expence or trouble attends

Culture of particular Plants.

of the practice, I apprehend it will ſoon become more general." The Society own, that the uncommon ſucceſs of Mr Bult's experiment *ſeems to militate* at leaſt againſt what they ſaid on Mr Anderdon's letter; but they inſiſt that the caſes are by no means ſimilar. "Though the land (ſay they), in both inſtances, is called a *heavy clay*, they are very different. Mr Anderdon's is poor, wet, and cold; the other a good rich clay; and we apprehend naturally mixed with a kind of marl, which is called clay by perſons not thoroughly acquainted with the nice diſtinction of ſoils apparently alike, but very different in their nature. Our principle therefore, that cold wet clay lands are unſuitable for turnips remains unaffected by this experiment; and general practice confirms the truth of the theory."

In another letter, Mr Pavier gives a more particular account of the two other crops of beans and turnips raiſed upon Mr Bult's plan. The beans were drilled in rows about 22 inches diſtance, twice horſe-hoed, and the produce from about 25 to 30 buſhels the computed acre, or from 30 to 36 buſhels the ſtatute acre. The preceding ſummer had been very unfavourable to beans, and the produce per acre in the common huſbandry did not, on an average, equal a third part of this quantity. One of theſe crops was ſuperior to that of Mr Bult: they were ſown upon a field of nine computed acres on the 10th of June, after the ſecond horſe-hoeing; but whether the ſecond hoeing was performed too ſoon, the ground not clear, or, whatever might be the cauſe, the beans were weeded twice by hand afterwards; and he is of opinion, that the turnips were ſomewhat benefited by it. Mr Pavier was aſſured by a very intelligent farmer, that this was the beſt crop of turnips he had ever ſeen. The turnip ſeed in the other crop was put in between the rows of beans by a hand drill; but the work was badly performed, the plants coming up in ſome places vaſtly too thick, and in others as much too thin; but wherever they happened to be of a proper thickneſs, the farmer told him it was one of the moſt profitable crops he ever had. The ſoil was wet, heavy, and not very favourable for turnips. Hence Mr Pavier deduces the following concluſion: 1. That with reſpect to beans in particular, the drilling and hoeing is vaſtly ſuperior to the common mode of huſbandry. 2. That the beans are undoubtedly a good preſervative of the turnips from the depredations of the fly. 3. That as by this method no crop is loſt, and conſequently no rent, but a mere trifle of expence (if any) chargeable to the turnip crop, it muſt be one of the moſt profitable as well as the moſt certain methods of propagating that uſeful root ever yet practiſed.—He ſtill inſiſts, however, that if he had an opportunity of trying this method, he would drill the beans in rows at a greater diſtance, that the turnips might be hand-hoed eaſily; and that he ſhould prefer the London tick-beans to any other, by reaſon of their ſhortneſs and being ſuch bearers; that he ſhould alſo take off their tops as ſoon as the under bloſſoms began to decay; which, he ſuppoſes, would be of great ſervice.

330 Inſtrument for tranſplanting turnips.

In this diſſertation on the culture of turnips, we cannot avoid taking notice of an inſtrument uſed in Norfolk for tranſplanting them, and thus filling up the gaps which frequently happen in fields from the failure of the plants in particular ſpots. It is repreſented on the margin; and the conſtruction and mode of uſing are obvious from the figure.—When the turnips are to be tranſplanted, the workman holds the long handle with the left hand, and the ſhort one with the right hand drawn up. Put the inſtrument then over the plant that is to be taken up, and with your foot force it into the ground; then give it a twiſt round, and by drawing it gently up, the earth will adhere to the roots of the plant in a ſolid body; then with another inſtrument of the ſame ſize take the earth out where the plant is to be put, and bringing the inſtrument with the plant in it, put it into the hole which has been made by the other; then keep your right hand ſteady, and draw up your left, and the earth and plant will be left in the hole with the roots undiſturbed. In this operation two men will be employed, each of them having an inſtrument of the form repreſented on the margin. One man takes up a plant, while the other fills his inſtrument with earth only, thereby making room for the depoſition of the plant; ſo that the hole which is made by taking up the plant is filled with the earth taken out where the plant is to be put; which being depoſited, he takes up a plant, and returns to the place he firſt ſet out from, the former man at the ſame time returning with the earth only; ſo that each man is alternately the planter, and each being employed both ways, the work goes on briſkly.—This inſtrument was the invention of Mr Cubitt Gray of Southrepps, Norfolk.

Culture of particular Plants.

Bath Papers, vol. iv. p. 126.

Turnips being the grand baſis of the Norfolk huſbandry, Mr Marſhall gives a very particular account of their culture in that county.—The ſpecies cultivated are, 1. The common *white ſtock*, called in many places the Norfolk turnip. 2. The *purple ſtock* is ſimilar to the former, but its rind is of a dark red or purple colour; its ſize in general ſmaller, and its texture cloſer and firmer than that of the common white-ſtock; it alſo ſtands the winter better, and is more ſucculent in the ſpring, but it is not ſo well reliſhed by cattle as the former; whence it is leſs generally cultivated. 3. The *pudding-ſtock*, the *tankard-turnip* of the midland counties, is in ſhape ſo perfectly different from the common ſort, that it might be ranked as a diſtinct ſpecies. It riſes in a cylindrical form, eight, ten, or twelve inches high, ſtanding in a manner wholly above ground; generally taking a rough irreguiar outline, and a ſomewhat reclining poſture. It very much reſembles the common turnip, and is by much its moſt formidable rival. In many reſpects it ſeems to be ſuperior, particularly in being readily drawn, and eaten off by ſheep with much leſs waſte than the common turnip.—The diſadvantage is, that they are liable to the attacks of froſt, by reaſon of their ſtanding ſo high above the ſurface of the ground; ſo that on the whole, Mr Marſhall concludes, that the common white turnip is to be preferred to every other.

331 Norfolk cultivation of turnips.

In Norfolk, turnips are ſown upon every ſpecies of arable land. Marl is found to be highly beneficial; and by means of this manure, a ſoil naturally unfit for turnips may be rendered proper for it. They ſucceed barley better than any other crop; ſome few are ſown on wheat or pea ſtubble after harveſt; but this is not a general practice. The manures in greateſt reputation for turnips are dung, with a greater or ſmaller

332 Advantage of uſing marl.

admixture

Culture of particular Plants.

admixture of mould; *malt-coombs* are alſo in good repute, and oil-cake is uſed by a few individuals; "but it may be ſaid that nine acres of ten of the turnips grown in eaſt Norfolk are manured with muck."—The quantity of dung ſet on for a crop of turnips generally depends on the quantity on hand, and the quantity of turnip ground to be manured. From 10 to 15 cart loads of muck are conſidered as a good dreſſing; and about a ton of oil cake to three acres; 50 or 60 buſhels of malt-coombs, and 40 or 50 buſhels of ſoot, to an acre.

333 Manures of different kinds.

334 Cultivation of turnips for early conſumption.

When the turnips are intended for early conſumption, the ſooner they can be got into the ground the better; but when they are intended to ſtand the winter, the beginning of July is thought ſoon enough. The moſt general rule is to begin ſowing about a week before midſummer, and continue till about a fortnight after, viz. from the 17th or 18th of June to the 7th or 8th of July.—Broad-caſt ſowing is univerſal, in the quantity of two pints to an acre. The ſeed is covered by two lines of a pair of light harrows drawn backward, in order to prevent the tines, which uſually point ſomething forward, from tearing up the clods, and burying the ſeed too deep. The horſes are univerſally *walked* one way, and *trotted* back again in the ſame place. This is an excellent cuſtom; the quick zig-zag motion of the harrows at once aſſiſting to level the ſurface, and to diſtribute the ſeeds more evenly.—They are univerſally hoed; and unleſs they be ſown very late, are generally hoed twice. The diſtance of time between the ſowing and the firſt hoeing depends upon the ſoil and ſeaſon; the ſize of the plants being the only guide. When turnips are ſuffered to grow too large before they are hoed, the plants are difficult to be ſet out ſingly, and are liable to be drawn up by weeds, thereby acquiring a ſlender upright tendency; whereas their natural growth, in their infant ſtate, is procumbent, ſpreading their firſt leaves on the ground, and taking the form of a roſe.—If the hoe be put in too ſoon, the plants which are ſet out are liable to be buried, and their tender roots diſturbed in the act of ſetting out the neighbouring plants. The time for hoeing, as directed by the moſt judicious huſbandmen, is when the plants, as they lie ſpread upon the ground, are about the ſize of the palm of the hand: if, however, ſeed-weeds be numerous and luxuriant, they ought to be checked before the turnips arrive at that ſize, leſt by being drawn up tall and ſlender they ſhould acquire a weak and ſickly habit. The proper diſtance depends upon the nature of the ſoil and the time of ſowing; ſuch as are ſown early, in a rich productive ſoil, require to be ſet out wider than thoſe ſown late on a ſoil of a contrary nature. If the ſoil be at par, the diſtance ought to be regulated by the time of ſowing: if this be at par, the nature or ſtate of the ſoil ſhould be the regulator.—Mr Marſhall complains of the conduct of the Norfolk farmers in general in this reſpect, who "hack out their turnips 14, 15, or perhaps 18 inches aſunder, without any regard to the ſtate of the ſoil, or time of ſowing. This practice was eſtabliſhed while the Norfolk ſoil was full of marl, and new to turnips; and when, it is probable, 11 or 12 inches in diameter was no uncommon ſize, with tops proportionally large and ſpreading; and 14 or 15 inches might then be a proper diſtance. But now, when the efficacy of marl is leſſened, and the ſoil no longer the favourite of turnips, which ſeldom reach more than ſeven or eight inches in diameter, it is ruinous and abſurd to continue the practice."

335 Method of ſowing, and culture.

Turnips are cultivated either for ſeed, for ſale, or for conſumption. When cultivated for ſeed, it is ſuppoſed in moſt parts of the kingdom that it ought always to be taken from tranſplanted roots; but in Norfolk they are frequently raiſed from ſuch as are untranſplanted. "It is a fact (ſays Mr Marſhall) well underſtood by every huſbandman here, that if the ſeed be gathered repeatedly from untranſplanted roots, the plants from this ſeed will become coarſe-necked and foul-rooted; and the fleſh of the root itſelf will become rigid and unpalatable. On the contrary, if it be gathered year after year from tranſplanted roots, the necks will become too fine, and the fibres too few; the entire plant acquiring a weak delicate habit, and the produce, though ſweet, will be ſmall. For the neck, or onſet of the leaves, being reduced to the ſize of the finger (for inſtance), the number and ſize of the leaves will be reduced in proportion; and in a ſimilar proportion will the number and ſize of the fibrils be reduced. From a parity of reaſoning, it may perhaps be inferred, that when the neck acquires a thickneſs equal to that of the wriſt, the ſize of the root will be in proportion.

336 Cultivation of turnips for ſeed.

"With reſpect to the fibres or rootlings, this is a juſt inference; but with reſpect to the bulb, it is in a great meaſure erroneous. For a few generations the ſize of the bulb will keep pace with the increaſe of leaves and fibres; but after having once reached the limits which nature has ſet to its magnitude, it begins to revert to its original ſtate of wildneſs, from which to its preſent ſtate it has undoubtedly been raiſed by tranſplantation. The farmer has therefore two extremes to avoid. The one is diſcoverable by the thickneſs and coarſeneſs of the neck, the ſcaly roughneſs of the bulb, the thickneſs of the rind in general, the foulneſs of its bottom, and the forkedneſs of its main or tap-root: the other by the ſlenderneſs of the neck, the fineneſs of the leaf, and the delicacy of the root. The former are unpalatable to cattle, and are therefore creative of waſte: The latter are unproductive, are difficult to be drawn, and do not throw out ſuch ample tops in the ſpring, as do thoſe which are, by conſtitution or habit, in a middle ſtate between theſe two extremes. There is not, however, any general rule reſpecting how many years turnips ought to be tranſplanted ſucceſſively, and how often they ought to be ſuffered to run up from the ſeed-bed: the ſoil and ſituation have, and other circumſtances may have, influence on the habit and conſtitution of vegetables as of animals; and the farmer muſt attend alone to the ſtate of the turnips themſelves. Whenever he judges, that, by repeated tranſplantation, they have paſſed the acme of perfection, then it is his duty and intereſt to let them run up to ſeed without tranſplantation. In Norfolk it has been found, by long experience, that tranſplanting two, three, or four years, and letting the plants run up the third, fourth, or fifth, will keep the ſtock in the deſired ſtate. The time of tranſplanting is from Old Chriſtmas to Old Candlemas. In the choice of plants, the farmer is not guided by ſize, but picks the cleaneſt plants without regard to ſize; or, more

Culture of particular Plants.

more accurately ſpeaking, he makes choice of ſuch as are near, but not at or above the ſtate of perfection. In almoſt every turnip-field there are plants in various ſtates: much judgement, therefore, is requiſite in the choice of plants. A piece of good ground near a habitation is generally choſen for this purpoſe; but the method of planting is various: the plants are generally ſet in rows, at uncertain diſtances from one another." Theſe diſtances our author has obſerved to be 16 or 18 inches, and the diſtance of the plants in them nine or ten inches; but the practice of a man who, he tells us, is indiſputably near the head of his profeſſion, is to plant them in rows two feet aſunder, the plants in the rows being contiguous. The only culture required, is to keep the intervals clean hoed; but when the ſeed begins to ripen, much care is requiſite to keep it from birds. If the plot be large, it is neceſſary to employ a boy to ſcare them; but if it be ſmall, and near the houſe, Mr Marſhall has known the following expedient uſed with ſucceſs. "On a ſlender poſt, riſing in the midſt of the patch of ſeed, was fixed a bell; from which a line paſſed into the kitchen: in the moſt frequented part of this hung the pull. Whoever paſſed the pull rung the bell; ſo that in a farm-houſe kitchen, where a miſtreſs and two or three maids were ſome of them almoſt always on the foot, an inceſſant peal was kept up; and the birds, having no reſpite from alarm, forſook their prey."

337 Method of planting.

338 Method of ſcaring away birds.

339 Of drawing the turnips.

The time of drawing commences about Michaelmas, and continues until the plants be in blow. The proceſs of drawing, he ſays, "is ſevere weather is an employment which nothing but cuſtom could reconcile to thoſe whoſe lot it is to go through it, namely, ſtout lads and youths; whoſe hands are frequently ſwelled until the joints are diſcernible only by the dimples they form;" nevertheleſs he never heard of any inſtance of bad effects from this circumſtance. When the tops will bear it, their method of pulling is very expeditious: they pull with both hands at once; and having filled each hand, they bring the two together with a ſmart blow to diſengage the ſoil from the roots, and with the ſame motion throw them into the cart. If the tops be cut off by the froſt, or if this be in the ground, the turnips are raiſed with two-tined forks named *crooms*. If the roots are buried under deep ſnow, it is removed by means of an implement called the *ſnow-ſledge*. This conſiſts of three deal-boards from one to two inches thick, 10 or 12 inches deep, and from ſeven to nine feet long, ſet upon their edges in the form of an equilateral triangle, and ſtrongly united with nails or ſtraps of iron at the angles; at one of which is faſtened, by means of a double ſtrap, a hook or an eye, to faſten the horſes to. This being drawn over a piece of turnips covered with ſnow, forces up the latter into a ridge on each ſide, while between the ridges a ſtripe of turnips is left bare, without having received any material injury from the operation. Though it is cuſtomary, in drawing, to clear the ground entirely, our author met with one inſtance in which the ſmall ones were left by a very good huſbandman on the ground, both to increaſe in ſize, and to throw out tops in the ſpring; it being obſervable, that a ſmall turnip ſends up a top nearly equal to one whoſe bulb is larger. There is one inconvenience, however, ariſing from this practice: the plough is prevented from entering upon the ſoil until late in the ſpring; which upon ſome ſoils is an unſurmountable objection; though it may be very proper upon land which will bring good barley with one ploughing after turnips.

340 Snow-ſledge deſcribed.

Culture of particul. Plants.

341 Method o preſerving turnips.

Mr Marſhall relates the following ſimple method, by which a Norfolk farmer preſerved turnips through a conſiderable part of the winter ſeaſon. Having cut off their tops with a ſpade, he gave them to his cows, and carried the bulbs to a new-made ditch, into which he threw them, and then covered them up with ſtraw, laying over it a quantity of bramble kids. Here they lay until wanted in a froſt. They were then again carted by means of a fork, and given to the cattle, who ate them as well, or rather better than freſh drawn turnips; and in general they came out as freſh as they went in. Our author is of opinion, that this method might be extended to the preſervation of turnips till the ſpring.

3. Carrot.

342 Culture of carrot.

Of all roots, a carrot requires the deepeſt ſoil. It ought at leaſt to be a foot deep, all equally good from top to bottom. If ſuch a ſoil be not in the farm, it may be made artificially by trench-ploughing, which brings to the ſurface what never had any communication with the ſun or air. When this new ſoil is ſufficiently improved by a crop or two with dung, it is fit for bearing carrots. Beware of dunging the year when the carrots are ſown; for with freſh dung they ſeldom eſcape rotten ſcabs.

The only ſoils proper for that root are a loam and a ſandy ſoil.

The ground muſt be prepared by the deepeſt furrow that can be taken, the ſooner after harveſt the better; immediately upon the back of which, a ribbing ought to ſucceed, as directed for barley. At the end of March, or beginning of April, which is the time of ſowing the ſeed, the ground muſt be ſmoothed with a brake. Sow the ſeed in drills, with intervals of a foot for hand-hoeing; which is no expenſive operation where the crop is confined to an acre or two: but if the quantity of ground be greater, the intervals ought to be three feet, in order for horſe-hoeing.

In flat ground without ridges, it may be proper to make parallel furrows with the plough, ten feet from each other, in order to carry off any redundant moiſture.

At Parlington in Yorkſhire, from the end of September to the firſt of May, 20 work horſes, four bullocks, and ſix milk cows, were fed on the carrots that grew on three acres; and theſe animals never taſted any other food but a little hay. The milk was excellent: and, over and above, 30 hogs were fattened upon what was left by the other beaſts. We have this fact from undoubted authority.

Carrots have been greatly recommended as food for cattle, and, in this reſpect, bid fair to rival the potato; though, with regard to the human ſpecies, they are far inferior. The profit attending the cultivation of them, however, appears to be much more doubtful than that of potatoes. Mr Arthur Young informs us, that from Norden's Surveyor's Dialogue, publiſhed in 1600, it appears, that carrots were commonly cultivated at that time about Orford in Suffolk, and Norwich in Norfolk; *Bath Papers*, vol. p. 1.

ulture of ious other Plants.

343 uch cul- ated in folk and rt of orfolk.

344 hy the lture has t extend- itself.

folk; and he remarks, that the tract of land between Orford, Woodbridge, and Saxmundum, has probably more carrots in it than all the reſt of the kingdom put together." In 1779, few farmers in theſe parts had leſs than five or ſix acres; many from 10 to 20; and one had 36 acres: the ſtraight, handſome, and clean roots were ſent at 6d. per buſhel to London; the reſt being uſed at home, principally as food for horſes. In other counties, he obſerves, the culture of carrots has not extended itſelf; that ſome have begun to cultivate them in place of turnips, but have ſoon deſiſted; ſo that the culture ſeems in a manner ſtill confined to the angle of Suffolk, where it firſt began. In attempting to inveſtigate the cauſe of this general neglect, he obſerves, that "the charge of cultivation is not ſo great as is commonly imagined, when managed with an eye to an extenſive culture, and not a confined one for one or two particular objects." Two acres which our author had in carrots coſt 3l. 17s. 6d. per acre, including every expence; but had not the ſummer been dry, he obſerves, that his expences might have been higher; and when he tried the experiment 15 years before, his expences, through inadvertence, ran much higher. His difficulty this year aroſe chiefly from the *polygonum aviculare*, the predominant weed, which is ſo tough that ſcarcely any hoe can cut it. Some acres of turnips which he cultivated along with the carrots were all eaten by the fly; but had they ſucceeded, the expence of the crop would have been 18s. 5d. leſs per acre than the carrots. "But (adds our author) if we call the ſuperiority of expence 20s. an acre, I believe we ſhall be very near the truth: and it muſt at once be apparent that the expence of 20s. per acre cannot be the cauſe of the culture ſpreading ſo little; for, to anſwer this expence, there are favourable circumſtances, which

345 periority carrots turnips.

muſt not be forgotten. 1. They (the carrots) are much more impenetrable to froſt, which frequently deſtroys turnips. 2. They are not ſubject to the diſtempers and accidents which frequently affect turnips; and they are ſown at a ſeaſon when they cannot be affected by drought, which frequently alſo deſtroys turnips. 3. They laſt to April, when ſtock, and eſpecially ſheep farmers are ſo diſtreſſed, that they know not what reſource to provide. 4. The culture requiſite for turnips on a ſandy ſoil, in order to deſtroy the weeds, deſtroys alſo its tenacity, ſo that the crop cannot thrive; but with carrots the caſe is otherwiſe. Hence it appears, that the reaſon why the cultivation of carrots is ſtill ſo limited, does not ariſe from the expence, but becauſe the

346 fficulty aſcer- ning the lue.

value is not aſcertained. In places where theſe roots can be ſent to London, or ſold at a good price, the tops being uſed as food for cattle, there is not the leaſt doubt that they are profitable; and therefore in ſuch places they are generally cultivated: but from the experiments as yet laid before the public, a ſatisfactory deciſive knowledge of the value is not to be gained. The moſt conſiderable practice, and the only one of common farmers upon a large ſcale, is that of the ſands of Woodbridge; but here they have the benefit of a London market, as already mentioned. Amongſt thoſe whoſe experiments are publiſhed, Mr Billingſley ranks foremoſt. Here again the value of carrots is rather depreciated than advanced; for he raiſed great crops, and had repeated experience upon a large ſcale of their excellence in fattening oxen and ſheep; feeding cows, horſes, and hogs; and keeping ewes and lambs in a very ſuperior manner, late in the ſpring, after turnips were gone: but notwithſtanding theſe great advantages, he gave the culture up; from which we may conclude a deficiency in value. "In ſeveral experiments (though not altogether determinate), I found the value, upon an average of all applications, to be 13d. a buſhel, heaped meaſure; eſtimating which at 70lb. weight, the ton is 1l. 14s." The following are the valuations of ſeveral gentlemen of the value of carrot in the way of fattening cattle:

Culture of particular Plants.

	per ton.
Mr Meiſh of Elyth, a general valuation of horſes, cows, and hogs, -	L.1 0 0
Mr Stovin of Doncaſter, hogs bought lean, fatted, and ſold off,	4 0 0
Mr Moody of Ratford, oxen fatted, and the account accurate, - - -	1 0 0
Mr Taylor of Biſrons, ſaving of hay and corn in feeding horſes, - -	1 0 0
Mr Le Grand of Ath, fattening wethers,	0 13 9
Sir John Hobby Miſl of Biſhan, fattening hogs, - - - - -	1 6 0
Mr Billingſley, for fattening hogs, -	1 13 6

Some other gentlemen whom our author conſulted, could not make their carrots worth any thing: ſo that, on the whole, it appears a matter of the utmoſt doubt, ſo contradictory are the accounts, whether the culture of carrots be really attended with any profit or not. Thus Sir John Miſl, by fattening hogs, makes 1l. 6s. and Mr Stovin 4l.; but others could not fatten hogs upon them at all: and ſome of Mr Young's neighbours told him, that carrots were good for nothing except to *ſcour* hogs to death. The experiment of Mr Le Grand upon wethers appeared to be made with the greateſt accuracy; yet two circumſtances ſeem to militate againſt it. 1. The ſheep were put lean to them; whereas it is a fact well known, that if they are not half fat when put to turnips, no profit will reſult; and it is poſſible that the caſe may be the ſame with carrots. 2. He gave them alſo as much fine hay as they would eat.

347 New expe- riments re- commend- ed.

In this uncertain ſtate of the matter, the only thing that can be done is to make a number of experiments with as much accuracy as poſſible, in order to aſcertain the real value per ton: and our author endeavours to ſhow, that there is no danger of loſing much by experiments of this kind. "I have ſhown (ſays he), that they are to be cultivated for 4l. per acre, left on the ground for ſheep. Suppoſe the crop only two buſhels at 70lb. each per rood, 320 per acre, or ten tons; it will readily be agreed, that ſuch a produce is very low to calculate upon, ſince 20 tons are common among carrot-cultivators. It appears from Mr Le Grand's experiments, that a wether worth 2l. 5s. eats 16lb. of carrots, and four pounds of hay per day: dropping the hay, and calculating for ſheep of leſs than half that ſize (which are much more common), it will be perhaps an ample allowance to aſſign them 12lb. of carrots a day. If they are, as they ought to be, half fat when put up, they will be completely fattened in 100 days. At this rate, 20 wethers will, in 100 days, eat 11 tons, or very little more than one moderate acre. Now, let it be remembered, that it is a good acre of turnips which will fatten eight ſuch wethers, the common No folk calculation:

Culture of particular Plants.

calculation: from which it appears, that one acre of carrots is, for this purpoſe, of more value than two of turnips. Further, let us ſuppoſe horſes fed with them inſtead of oats: to top, cart and pack up, 10 tons of carrots, I know may be done for 20s.—An acre therefore (other expences included) coſts 5l. Fifty pounds weight of carrots are an ample allowance for a horſe a day: ten tons, at that rate, laſt three horſes for five months. But this 5l. laid out in oats at 16s. per quarter, will purchaſe little more than ſix quarters; which will laſt three horſes, at two buſhels each per week, no more than two months; a moſt enormous inferiority to the carrots."

348 Experiment on feeding lambs with them.

In the ſame volume, p. 187. Mr Young gives an account of another experiment made by himſelf on the feeding of lambs with carrots. The quantities they eat varied exceſſively at different times; thirty-ſix of them conſumed from five to ten buſhels per day; but on an average, he rates them at four buſhels of 56 pounds per day. In all, they conſumed 407 buſhels from November to April, when they were ſold and killed fat. At putting upon the carrots, the lambs were valued only at 18l. but were ſold in April at 25l. 4s.; ſo that the value of the carrots was exactly 7l. 4s. or about 4d. per buſhel. This price he ſuppoſes to be ſufficient to induce any one to attempt the culture of carrots, as thus he would have a clear profit of 40s. per acre; "which (ſays he) is greater than can attend the beſt wheat crops in this kingdom." The land on which the carrots grew was ſown next year with barley, and produced the cleaneſt in the pariſh; which contradicts an aſſertion our author had heard, that carrots make land foul. The graſs upon which the ſheep were fed with the carrots, and which amounted to about an acre, was very little improved for the crop of hay in 1781, owing to the dryneſs of the ſeaſon but in 1782 was greatly ſuperior to the reſt of the field, and more improved in quantity: "for, inſtead of an indifferent vegetation, ſcattered thick with the centaurea ſcabioſa, ſilago, rhinanthus, criſta galli, and linum catharticum, with other plants of little value, it encouraged a very beautiful ſheet of the beſt plants that can appear in a meadow, viz. the lathyrus pratenſis, achillea millefolium, trifolium repens, trifolium ochroleucrum, trifolium alpeſtie, and the plantago lanceolata.

349 Carrots compared with cabbages.

In the ſame volume of the Bath papers, p. 227, Mr Billingſley gives an account of the comparative profit of carrots and cabbages. Of the former, however, he obtained only ſeven tons, 15 cwt. per acre; the cabbages produced 36 tons: nevertheleſs, according to him, the profit of the former was 5l. 8s.; of the latter, only 3l. 11s. In a paper on the culture of carrots by Mr Kirby of Ipſwich, vol. iii. p. 84. he informs us that he never determined the weight of an acre, but reckons the produce from 200 to 500 buſhels; which, at 56lb. to the buſhel, is from five to ten tons and an half.

350 Culture of carrots preferred to potatoes.

In the ſame volume, p. 320, the Rev. Mr Onley ſeems to prefer the culture of carrots to potatoes. "However valuable (ſays he), from eaſe of culture, and greatneſs of produce to the poor, eſpecially in all ſmall ſpots, I doubt, unleſs near great towns, whether, on a farming plan, potatoes be ſo eligible as other herbage or roots, eſpecially as carrots, which I cannot but *furmiſe* (for my trial are too trivial to venture bolder language), deſerve every encouragement, even on ſoils hitherto thought too heavy for them.—I am from experience convinced, that an acre of carrots will double in the quantum, of equally hearty provender, the product of an acre of oats; and from the nature of their vegetation, the nice mode of cultivation, and even of taking them up (all of which, expenſive as they are, bear a very inferior proportion to the value of a medium crop), muſt leave the land, eſpecially if taken off it in an early period, ſo mellow for the plough, as to form a ſeed-bed for barley equally to any fallow-tilth."

Culture of particular Plants.

Mr Onley's deſideratum was a ſubſtitute for oats to feed horſes; of which great numbers are kept in his county (Eſſex). Potatoes, he obſerves, are excellent for *ſmall* pork, when baked or boiled, mixed with a little barley meal; but for large hogs, they are moſt profitably given raw, if theſe have at the ſame time the ſhack of the barn door in threſhing ſeaſon, &c. In the 5th volume he reſumes the ſubject, and acquaints us, that he applied a ſingle acre in his bean field to the culture of carrots, which generally produced 400 buſhels; and this he conſiders as a ſmall produce. "I am, however, ſenſible (ſays he) that they will amply repay every expence of the fineſt culture; and ſhould, from their extenſive utility on ſound, deep, and friable land, be everywhere attempted. Some of my neighbours, who have been induced to try them on rather a larger ſcale, with finer culture, and freſher ſoil, have raiſed from 600 to 900 buſhels per acre, and applied them more profitably, as well as more generally, than any other winter herbage, to deer, ſheep, bullocks, cows, and horſes. At the loweſt calculation, from our little trials, they are computed to exceed turnips in value one-third, as to quantity of food; but are far ſuperior in what ariſes from convenience for the ſtable; where to us they ſeem to be a ſubſtitute for corn to all horſes, at leaſt ſuch as are not uſed in any quick work; and partially ſo with corn for thoſe that are."

351 Superior to turnips and oats.

In making a compariſon betwixt the profit on oats and carrots, Mr Onley found the latter exceed by no leſs than 2l. 15s. 8d. per acre. His method of cultivation is to ſow them in March or April; to hoe them three times, harrowing after each hoeing. Sometimes he left them in the ground till after Chriſtmas, taking them up as wanted; but afterwards he took them up in October, in dry days, putting them directly into ſmall upright cocks of 10 buſhels each, covered entirely, with the tops cut off.—Thus, they appear to dry better than in any other way, and bear the weather with very little loſs. If, after being thus dried, they are carried into any barn or ſhed, it will be better, if they are in large quantities, not to pack them cloſe, on account of the danger of heating, but rather to throw them promiſcuouſly into heaps, with a little ſtraw over them. When perfectly dry, they do not in general require any waſhing, except for horſes regularly kept in the ſtable.

This root has been found ſo generally valuable as a ſubſtitute for grain in feeding horſes, that its uſe in that way is rapidly ſpreading into various parts of the country. By the quantity of ſaccharine matter which it contains, it is probably rendered extremely rich and ſtimulating to the ſtomach of that delicate animal, ſo that a leſs quantity of it goes to waſte than of any other food. We may remark that the gentleman already mentioned, Mr Onley, who had the merit of

Culture of particular Plants.

preſſing upon the public attention the importance and utility of this root, mentions an uſe to which we believe it is not unfrequently applied in the dairy. "In our dairies (ſays he) as many carrots are bruiſed before churning, as produce, ſqueezed through a cloth into as much cream as makes eight or ten pounds of butter, a half pint of juice; this adds ſomewhat to the colour, richneſs, and flavour of winter butter; and we think, where hay is allowed beſides, contributes much to counteracting the flavour from the ſeed of turnips. At preſent (our carrot ſeed being exhauſted) from turnips and hay, with this juice, our butter is equal to that of the Epping dairies."

Annals of Agriculture, vol. xii.

352 Carrots uſed to colour butter.

353 Carrots advantageouſly cultivated in young plantations.

We may conclude by taking notice here of an advantageous mode of cultivating carrots by making uſe of them with a view to ſtir the ground in young plantations. It was adopted by Thomas Walford, Eſq. of Birdbrooke, Eſſex, who gives the following account of it:—"It has been my conſtant practice for theſe laſt five years, wherever I made a plantation of firs, or deciduous trees, to ſow the ground in the ſpring with carrots, which I have found not only pay part of my expences, and frequently the whole, but much more beneficial to the trees than any other method I had before adopted.

"When I make a plantation of deciduous trees, the ground is dug two ſpits deep in October, and planted immediately, leaving it in that ſtate until the middle or latter end of March, or beginning of April; then, if neceſſary, chop it over with a hoe, and ſow my carrots; if for firs, I do not dig the ground until March, at which time I plant my trees, and ſow the carrots, having found my crop more luxuriant and productive upon ground freſh dug than that which was dug in the autumn.—I give for digging 8d. per rod; hoe only twice; the produce is generally four buſhels of clean carrots, which I ſell at 6d. per buſhel, the buyer to fetch them from their place of growth.

"The ſoil in ſome places looſe and hollow; the under ſtratum clay; in others a fine vegetable mould upon a red loam.

"I find, in taking up the carrots, leſs damage is done to the young fibres of the trees, than by digging between them; for it is impoſſible, with the greateſt care of your ſervants, not to cut off ſome of them by digging, and thereby injure the trees, beſides leaving the ground in no better ſtate than it is after carrots; for when the carrot is drawn, the cavity is filled immediately with looſe mould, through which the young fibres will ſtrike with great freedom, and very much accelerate the growth of the trees."

4. Parsnips.

354 The cultivation of parſnips too much neglected.

Parſnips have never in this country received from huſbandmen that attention to which they are well entitled from the eaſe with which they are cultivated, and the great quantity of ſaccharine or nouriſhing matter they are known to contain, which certainly abounds in them, in a much greater proportion than in almoſt any other vegetable with which we are at preſent acquainted.

Smith Parſ. vol. iv. 344.

To cultivate this root (ſays Mr Hazard) ſo as to make it advantageous to the farmer, it will be right to ſow the ſeed in the autumn immediately after it is ripe; by which means the plants will appear early the following ſpring, and get ſtrong before the weeds can riſe to injure them. Neither the ſeeds nor young plants are ever materially injured by froſts; on which account, as well as many others, the autumn is preferable to the ſpring ſowing. The beſt ſoil for them is a rich deep loam, and next to this ſand. They will thrive well in a black gritty ſoil, but not in ſtone-braſh, gravel, or clay; and they are always largeſt in the deepeſt earth. If the ſoil be proper, they do not require much manure. Mr Hazard obtained a very good crop for three years upon the ſame piece of ground without uſing any; but when he laid on about 40 cart loads of ſand per acre upon a ſtiff loam, and ploughed it in, he found it anſwer very well; whence he concludes, that a mixture of ſoils may be proper for this root. The ſeed may be ſown in drills at about 18 inches diſtance from one another, that the plants may be the more conveniently hand or horſe-hoed; and they will be more luxuriant if they undergo a ſecond hoeing, and are carefully earthed, ſo as not to cover the leaves. Such as have not ground to ſpare, or cannot get it in proper condition in autumn, may at that time ſow a plot in their garden, and tranſplant from thence in the latter end of April, or early in the month of May following. The plants muſt be carefully drawn, and the ground well pulverized by harrowing and rolling; after which a furrow ſhould be opened with the plough, about ſix or eight inches deep, in which the plants ſhould be regularly laid at the diſtance of about ten inches from each other, taking care not to let the root be bent, but for the plant to ſtand perpendicular after the earth is cloſed about it, which ought to be done immediately by means of perſons who ſhould for this purpoſe follow the planter with a hoe. Another furrow muſt be opened about 18 inches from the former, in the ſame direction, and planted as before; and ſo on in like manner until all the plants are depoſited, or the field be completely cropped; and when the weeds appear, hoeing will be neceſſary, and it will afterwards be proper to earth them; but if the leaves of the plants be covered with earth, the roots will be injured. Parſnips ought not to be planted by dibbling, as the ground thus becomes ſo bound, as ſeldom to admit the ſmall lateral fibres with which theſe roots abound to fix in the earth, by which they are prevented from expanding themſelves, and never attain a proper ſize. When circumſtances are properly attended to, there is little doubt that a crop of parſnips would anſwer much better than a crop of carrots. They are equal, if not ſuperior, in fattening pigs, as they make their fleſh whiter, and the animals themſelves are more fond of theſe roots than of carrots. Horſes eat them greedily when clean waſhed and ſliced among bran, and thrive very well upon them; and black cattle are ſaid likewiſe to approve of them.

Though parſnips are little uſed in Britain, they are highly eſteemed in France. In Britanny they are thought, as food for cattle, to be little inferior to wheat; and cows fed with them are ſaid to give as much milk, and of as good quality, as in the ſummer months. In the iſland of Jerſey they have long been conſidered as of the higheſt importance; and as the mode of cultivating them there ſeems worthy of attention, we ſhall here give an account of it, from a paper tranſmitted by

Culture of particular Plants.

355 Mr Hazard's method of cultivation.

Culture of particular Plants.

the Agricultural Society of Jerſey to the Britiſh Board of Agriculture.

" It is impoſſible, ſay theſe gentlemen, to trace the period when the cultivation of this plant was firſt introduced amongſt us. It has been known for ſeveral centuries, and the inhabitants have reaped ſuch benefit therefrom, that, for fattening their cattle and pigs, they prefer it to all the known roots of both hemiſpheres. The cattle fed therewith yield a juicy and exquiſite meat. The pork and beef of Jerſey are inconteſtably equal, if not ſuperior, to the beſt in Europe. We have obſerved, that the beef in ſummer is not equal to that in the autumn, winter, and ſpring periods, when the cattle are fed with parſnips; which we attribute to the excellency of that root.

356 Culture of parſnips with beans in Jerſey and Guernſey.

" All animals eat it with avidity, and in preference to potatoes. We are ignorant of the reaſon, having never made any analyſis of the parſnip. It would be curious, intereſting, and uſeful, to inveſtigate its characteriſtic principles: it is certain that animals are more fond of it than of any other root, and fatten more quickly. The parſnip poſſeſſes, without doubt, more nutritious juices than the potato. It has been proved that the latter contains eleven ounces and a half of water, and one groſs of earthy ſubſtance, French weight; therefore, there only remain four ounces and five gros of nutritive matter. Probably the parſnip does not contain near ſo much watery particles; nevertheleſs, they digeſt very eaſily in the animal's body. The cows fed with hay and parſnips during winter yield butter of a fine yellow hue, of a ſaffron tinge, as excellent as if they had been in the moſt luxuriant paſture."

Theſe gentlemen proceed to ſtate, that, in the iſland of Jerſey, parſnips are not cultivated alone, but along with beans, among which laſt peaſe are ſometimes mixed. There are three modes of cultivation: 1ſt, With the ſpade; 2d, With the plough and ſpade; and 3d, With two ploughs, the one called the ſmall and the other the great plough. This laſt method, as being the moſt economical and advantageous to the huſbandman, is the only one deſcribed. In the month of September, a ſlight ploughing and preparation is ſometimes given to the field deſtined for beans and parſnips in the enſuing year; but more generally the whole work is performed in high grounds about the middle of February, and in the middle of March in low land. A light plough cuts and turns the earth about four or five inches deep; then follows it a large plough conſtructed on purpoſe, and only uſed for this operation, which elevates the earth on the furrow laid open, and turns it over that which the ſmall plough turned up. The eſſential point is to plough deep and to cover the clods over again.

The field thus prepared, is ſuffered to remain 15 days, after which it is very lightly harrowed. On the ſame day, or on the enſuing, the beans are planted in the following manner. Straight lines muſt be drawn from north to ſouth with a gardeners rake at $4\frac{1}{2}$ feet diſtance. On theſe ſtraight lines, 19 inches in breadth, women plant four or five beans in rows 4 inches diſtant from each other, or the beans are planted in double rows all over the field, at the uſual depth, and 12 feet diſtance from each other, with the beans ſpaced out 18 inches from each other. When all this is done, the parſnips are ſown in broad-caſt over the field, after which it is well harrowed. In 15 days after, if the weather has been warm and rainy, or in three weeks if it has been cold and dry, the ground is harrowed again to cut up the weeds. In five or ſix weeks the beans ſhoot out, and the ground ſoon appears as if covered by hedges or laid out in paths for walking; for in the ſpaces between the lines where the beans were planted are as many alleys, where women and children weed with great facility. They generally weed the ground twice, and the operation is performed with a two-pronged fork, ſuch as is uſed in gardens. The firſt weeding is performed at the end of April or beginning of May, when the plants muſt be cleared out if they are too thick. When the beans are ripe, which is in Auguſt or September, they are immediately plucked up, not to incommode the parſnips. The crop of beans is not always certain. If high winds or fogs prevail when they are in flower, the produce will be ſcanty; but the parſnips in a manner never fail. They neither dread the inclemency of the weather, nor are affected by the hardeſt froſt, nor by any of thoſe accidents which at times will inſtantly deſtroy a whole crop.

Culture of particular Plants.

Parſnips grow till the end of September, but ſome give them to cattle they wiſh to fatten in the beginning of September. The people of theſe iſlands conſider the parſnip as the moſt juicy and nutritious of all roots known. Its cultivation is an excellent preparation for wheat, which is ſown there without manure after parſnips, and yields a plentiful crop. It muſt be obſerved, that though this cultivation of parſnips is expenſive where the price of labour is high, no dung or manure is neceſſary either for the parſnips or the wheat. They reckon 30 perches of parſnips, with a little hay, will fatten an ox of three or four years old, though ever ſo lean; he eats them in the courſe of three months as follows: they are given at ſix in the morning, at noon, and at eight at night, in rations of 40lb. each; the largeſt are ſlit into three or four pieces; but not waſhed unleſs very much covered with earth. In the intermediate hours, at nine in the morning, two in the afternoon, and nine at night, a little hay is given. Experience has ſhewn, that when cattle, pigs, or poultry, are fed with parſnips, they are ſooner fattened and are more bulky than with any other root or vegetable whatever. The meat of ſuch is moſt delicate and ſavoury. In ſpring the markets are furniſhed with the beſt and fatteſt beef from their feeding on parſnips. The crops of parſnips raiſed in Jerſey and Guernſey are very great. On an extent of 1000 feet, the produce of a field of beans and parſnips is about 1200lb. weight of parſnips, Rouen meaſure, and 30 cabots or half buſhels of beans, and three cabots and a half of peaſe; which altogether, according to the price at which theſe articles are actually ſold there, amount to the ſum of 256 livres French currency. The following information was alſo received from the preſident of the Jerſey Society on 1ſt March 1796, viz. " Since writing concerning the crop of beans and parſnips together, we have found that an individual who cultivates parſnips without ſowing either peaſe or beans along with them had a crop of 14,760lb. weight Rouen meaſure per vergee." The vergee is 40 perches in length and one perch in breadth.

Culture of particular Plants.

III. Plants cultivated for Leaves, or for both Leaves and Root.

I. Turnip-rooted Cabbage.

357 Cultivation of the turnip-rooted cabbage.

This plant may deſervedly be reckoned next in value to the turnip itſelf. Its advantages, according to Sir Thomas Beevor, are, "that it affords food for cattle late in the ſpring, and reſiſts mildew and froſt, which ſometimes deſtroy the common turnip;" whence he is of opinion that every farmer who cultivates the common turnip ſhould always have part of his farm laid out in the cultivation of this root. The importance and value of turnip-rooted cabbages ſeem only to have been lately aſcertained. In the Bath Society papers we have the following account of Sir Thomas Beevor's method of cultivating them; which from experience he found to be cheaper and better than any other.

"In the firſt or ſecond week of June, I ſow the ſame quantity of ſeed, hoe the plants at the ſame ſize, leave them at the ſame diſtance from each other, and treat them in all reſpects like the common turnip. In this method I have always obtained a plentiful crop of them; to aſcertain the value of which I need only inform you, that on the 23d day of April laſt, having then two acres left of my crop, ſound, and in great perfection, I divided them by fold hurdles into three parts of nearly equal dimenſions. Into the firſt part I put 24 ſmall bullocks of about 30 ſtone weight each (14lb. to the ſtone), and 30 middle-ſized fat wethers, which, at the end of the firſt week, after they had eaten down the greater part of the leaves, and ſome part of the roots, I ſhifted into the ſecond diviſion, and then put 70 lean ſheep into what was left of the firſt; theſe fed off the remainder of the turnips left by the fat ſtock; and ſo they were ſhifted through the three diviſions, the lean ſtock following the fat as they wanted food, until the whole was conſumed.

358 Their utility and value.

"The 24 bullocks and 30 fat wethers continued in the turnips until the 21ſt of May, being exactly four weeks: and the 70 lean ſheep until the 29th, which is one day over four weeks: ſo that the two acres kept me 24 ſmall bullocks and 110 ſheep four weeks (not reckoning the overplus day of keeping the lean ſheep); the value, at the rate of keeping at that ſeaſon, cannot be eſtimated in any common year at leſs than 4d. a-week for each ſheep, and 1s. 6d. per week for each bullock, which would amount together to the ſum of 14l. 10s. 8d. for the two acres.

"You will hardly, I conceive, think I have ſet the price of keeping the ſtock at too high a rate; it is beneath the price here in almoſt every ſpring, and in this laſt it would have coſt double, could it have been procured; which was ſo far from being the caſe, that hundreds of ſheep and lambs here were loſt, and the reſt greatly pinched, for want of food.

"You will obſerve, gentlemen, that in the valuation of the crop above mentioned I have claimed no allowance for the great benefit the farmer receives by being enabled to ſuffer his graſs to get into a forward growth, nor for the ſuperior quality of theſe turnips in fattening his ſtock; both which circumſtances muſt ſtamp a new and a great additional value upon them. But as their continuance on the land may ſeem to be injurious to the ſucceeding crop, and indeed will deprive the farmer totally of either oats or barley; ſo to ſupply that loſs I have always ſown buck-wheat on the firſt earth upon the land from which the turnips were thus fed off; allowing one buſhel of ſeed per acre, for which I commonly receive from five to ſix quarters per acre in return. And that I may not throw that part of my land out of the ſame courſe of tillage with the reſt, I ſow my clover or other graſs ſeeds with the buck-wheat, in the ſame manner as with the oat or barley crops, and have always found as good a *layer* (ley) of it afterwards.

"Thus you ſee, that in providing a moſt incomparable vegetable food for cattle, in that ſeaſon of the year in which the farmer is generally moſt diſtreſſed, and his cattle almoſt ſtarved, a conſiderable profit may likewiſe be obtained, much beyond what is uſually derived from his former practice, by the great produce and price of a crop raiſed at ſo eaſy an expence as that of buck-wheat, which with us ſells commonly at the ſame price as barley, oftentimes more, and but very rarely for leſs.

"The land on which I have uſually ſown turnip-rooted cabbages is a dry mixed ſoil, worth 15s. per acre."

359 Recommendation by the Bath Society.

To the preceding account the ſociety have ſubjoined the following note: "Whether we regard the importance of the ſubject, or the clear and practical information which the foregoing letter conveys, it may be conſidered as truly intereſting as any we have ever been favoured with: and therefore it is recommended in the ſtrongeſt manner to farmers in general, that they adopt a mode of practice ſo deciſively aſcertained to be in a high degree judicious and profitable."

360 To raiſe the turnip-rooted cabbage for tranſplanting.

To raiſe the turnip-rooted cabbage for tranſplanting, the beſt method yet diſcovered is, to breaſt-plough and burn as much old paſture as may be judged neceſſary for the ſeed bed; two perches well ſtocked with plants will be ſufficient to plant an acre. The land ſhould be dug as ſhallow as poſſible, turning the aſhes in; and the ſeed ſhould be ſown the beginning of April.

The land intended for the plantation to be cultivated and dunged as for the common turnip. About midſummer (or ſooner if the weather will permit) will be a proper time for planting, which is beſt done in the following manner: the land to be thrown into *one-bout* ridges, upon the tops of which the plants are to be ſet, at about 18 inches diſtance from each other. As ſoon as the weeds riſe, give a hand-hoeing; afterwards run the ploughs in the intervals, and fetch a furrow from each ridge, which, after lying a fortnight or three weeks, is again thrown back to the ridges; if the weeds riſe again, it is neceſſary to give them another hand-hoeing.

If the young plants in the ſeed-bed ſhould be attacked by the fly, ſow wood-aſhes over them when the dew is on, which will effectually prevent the ravages they would otherwiſe make.

In another letter from Sir Thomas Beevor, Bath Papers, vol. viii. p. 489. he expreſſes his hope that the turnip-rooted cabbages he had would laſt until he ſhould have plenty of graſs for all his ſtock. To make a comparative eſtimation of the quantity of food yielded by the turnip-rooted cabbage and the common turnip, he ſelected ſome of each kind, and having girted them with as much accuracy as poſſible, he found, that

361 Compariſon of the quantity of food in the and in the common turnip.

Culture of particular Plants.

a turnip-rooted cabbage of 18 inches in circumference weighed 5¼lb. and a common turnip of the same size only 3¼lb.; on trying others, the general result was found to be in that proportion. Had they been weighed with the tops, the superiority of the turnip-rooted cabbage would have been greater, the tops of them being remarkably bushy. They were weighed in the month of March; but had this been done at Christmas, our author is of opinion that the difference would not have been so great; though he reckons this very circumstance of their continuing so long to afford a nourishing food, an instance of their excellency above almost every other vegetable whatever.

362 Other experiments.

In the fourth volume of the same work, Sir Thomas gives an account of another experiment on five acres of turnip rooted cabbage, four of which were eaten upon the field, the other was pulled up and carried to the stables and ox-houses. They were sown and cultivated as other turnips; the beasts were put to them on the 12th of April, and continued feeding upon them till the 11th of May. The cattle fed for this space of time were, 12 Scotch bullocks weighing 40 stone each; eight homebreds, two years old; fifteen cows full-sized; 40 sheep; 18 horses; besides 40 store-hogs and pigs, which lived upon the broken pieces and offal, without any other allowance, for the whole four weeks. The whole value of the plant, exclusive of the feeding of the pigs, amounted, according to our author's calculation, to 18l.; and he says that the farmers would willingly give this sum in the spring for feeding as many cattle; "because it enables them to save the young shooting grass (which is so frequently injured by the tread of the cattle in the frosty nights) until it gets to such a length and thickness as to be afterwards but little affected by the summer's drought. Besides this, the tops or leaves are in the spring much more abundant, and much better food than those of the common turnip, as already observed; and they continue in full perfection after all the common turnips are rotten or worthless.

363 Disadvantages attending the cultivation of this plant.

The disadvantages attending the cultivation of turnip-rooted cabbages are, that they require a great deal of time and pains to take them up out of the ground, if they are to be carried off the field; and if fed where they grow, it requires almost an equal labour to take up the pieces left by the cattle. A great deal of earth is also taken up along with the root; and the substance of the latter is so firm and solid, that they must be cut in two in order to enable the cattle to eat them. To obviate some of these objections, it will be proper to sow the plants on rich and very light land; and as they are longer in coming to the hoe than the common turnip, it will be proper to sow them about the beginning of June.

364 Why every farmer ought to cultivate this plant.

In another experiment upon this plant by the same gentleman, the cabbages held out during the long and severe frost of 1788 without the least injury, though it destroyed three-fourths of all the common turnips in the neighbourhood. On the 21st of April 1789, the average produce of an acre was found to be somewhat more than 24½ tons, though the tops had not sprouted above three inches. Considering the precariousness of turnips and other crops, Sir Thomas is decisively of opinion, that all farmers ought to have as many turnip-rooted cabbages as would afford and ensure them a full provision for their cattle for about three or four weeks during the latter part of the spring. This quantity he reckons sufficient, as the consumption, particularly when drawn and carried off the land, is attended with more trouble and expence than that of common turnips, especially if the soil be wet and heavy. In another letter, dated May 3. 1790, Sir Thomas Beevor once more sets forth the advantages of having a crop of these vegetables during the spring season. "In consequence (says he) of the very cold weather we have had here, the grass is but just springing; as the turnips are wholly eaten up, it occasions much distress among the farmers for want of some green vegetable food for their sheep and cattle; whereas, by the assistance of my turnip-rooted cabbages, I have abundance of the best and most nutritive food that can be found them." He then proceeds to recommend their culture "for the support of almost all live stock for the three last weeks of April, or first week of May, when the grass shoots late."

Culture of particular Plants.

In the 4th volume of the Transactions of the Society for encouraging Arts, Mr Robins, who received a premium for raising the greatest quantity of this plant, informs us, that the soil on which it grew was a *stone brash*, inclining to sand, not worth more than 10s. per acre; the preparation the same as for turnips. The manure was a compost of earth and dung, which he finds to answer better than dung. The seed was sown about the beginning of April on a clean spot of ground; and he commonly uses an old pasture where the sheep-fold has been in the winter, after taking away the dung, and digging it very shallow; "as the roots of the young plants (says he) might soon reach the dung or salts, which must consequently be left, in order to force them out of the fly's way." These insects, our author observes, are extremely fond of the turnip-rooted cabbage; much more so, he believes, than of common turnips. About the middle of June they should be planted out upon one-bout ridges raised by a double plough made for the purpose. Seven thousand plants are sufficient for one acre; but if only six are used, the roots will be the larger.

365 Number of sheep fed by an acre of turnip-rooted cabbages.

To determine how many sheep might be kept upon an acre of turnip-rooted cabbage, our author shut up 200 ewes with their lambs upon a piece of poor pasture land of no great extent; the whole not exceeding ten acres. One ton was found sufficient for keeping them in sufficient health for a day. On giving them a larger piece of ground to run over, though it had been eaten all winter and late in the spring, yet, with this trifling assistance, 13 tons of turnip-cabbage were made to serve 18 days; at the end of which the ewes and lambs were found very much improved, which could not have been expected from four acres of turnips in the month of April, the time that these were fed.

366 Experiments at Cullen-house.

From some trials made on the turnip-rooted cabbage at Cullen House in the north of Scotland, it appears that the plant is adapted to the climate of every part of our island. The first trial was made in the year 1784. The seeds were sown about the middle of March in garden ground properly prepared. The cabbages were transplanted about the middle of March that year into a dry light soil, well cleaned and dunged with rotten cow-dung, in rows three feet distant from each other, and at the distance of 20 inches in the

Culture of particular Plants.

the rows. They were kept very clean, and the earth was hoed up to the roots of the plants; by which means they were probably prevented from attaining the hardneſs they would otherwiſe have arrived at; though, after all, it was neceſſary to cut the roots in two before the ſheep could eat them. When thus cut, the animals ate them greedily, and even preferred them to every other food. The roots continued good for at leaſt a month after the common turnips were unfit for uſe: ſome of them weighed from eight to ten pounds, and a few of them more. Other trials have ſince been made; and it now appears that the plant will thrive very well with the ordinary culture of turnips in the open fields, and in the uſual manner of ſowing broad-caſt. From a comparative trial made by the earl of Fife upon this root with ſome others, the quantities produced upon 100 ſquare yards of ground were as follows:

	ſtone.	lb.
Common turnips -	92	4
Turnip-rooted cabbage -	88	0
Carrots - -	95	0
Root of ſcarcity -	77	0

The turnip-rooted cabbage was planted in lines 20 inches aſunder; the common turnips ſown broad-caſt, and hand-weeded, ſo that they came up very thick, being not more than three or four inches aſunder when full grown. Two cows were fed for ſix weeks with the turnips, two with the turnip-rooted cabbage, and two with the root of ſcarcity for an equal time: the two fed with turnips gave moſt milk, and thoſe with the root of ſcarcity the leaſt. His lordſhip obſerves, however, that carrots thrive better on his farm than any other crop: that his horſes had been fed on them at the rate of two pecks a-day, with no corn, and little more than half the uſual quantity of hay. "They were kept at work every day from ſeven to eight hours, and were never in better order."

2. Swedish Turnip, or Roota Baga.

367 Of the Roota baga.

The roota baga, or Swediſh turnip, is a plant from which great expectations have been formed. It is ſaid to be hardier than the common turnip, and of greater ſweetneſs and ſolidity. It alſo preſerves its freſhneſs and ſucculence till a very late period of its growth, even after it has produced ſeed; on account of which property it has been recommended to the notice of farmers as an excellent kind of ſucculent food for domeſtic animals in the ſpring of the year, when common turnips and moſt other winter crops have failed, and before graſs has got up to furniſh an abundant bite for feeding beaſts. This peculiarity, ſo valuable, yet ſo ſingular as to have led many at firſt to doubt the fact, ſeems to be ſufficiently aſcertained by experiment. Dr J. Anderſon * in particular informs us, that it "begins to ſend out its flower-ſtems in the ſpring, nearly about the ſame time with the common turnip; but that the root, in conſequence of that change of ſtate, ſuffers very little alteration. I continued to uſe theſe turnips at my table every day till towards the middle of May; and had I never gone into the garden myſelf, I ſhould not even then have ſuſpected, from the taſte or appearance of the bulb itſelf, that it had been ſhot at all. The ſtems, however, at the ſeaſon I gave over uſing them, were from four to five feet high, and in full flower. I ſhould have continued the experiment longer, had not the quantity I had left for that purpoſe been exhauſted, and a few only left for ſeed.

The *Bee*, vol. iii. p. 71.

"This experiment, however, fully proves, that this kind of turnip may be employed as a ſucculent food for cattle till the middle of May at leaſt, in an ordinary year; and I have not the ſmalleſt doubt but it will continue perfectly good for that purpoſe till the end of May in any ſeaſon; at which time graſs and other ſpring crops can eaſily be had for bringing beaſts forward in fleſh. I can therefore, without heſitation, recommend this plant to the farmer as a moſt valuable ſpring feeding for cattle and ſheep; and for this purpoſe, I think no wiſe farmer ſhould be without a proportion of this kind of turnip to ſucceed the other ſorts after they fail. The profitable method of conſuming it, where it is to be kept very late, is, I am convinced, to cut off the tops with a ſcythe or ſickle when from one foot to eighteen inches high, to induce it to ſend out freſh ſtems, that will continue ſoft and ſucculent to the end; whereas, without this proceſs, the ſtems would become ſticky and uſeleſs.

"I cannot, however, recommend this kind of turnip, from what I have yet ſeen, as a general crop; becauſe I think it probable, that unleſs in particular circumſtances, the common field turnips grow to a much larger ſize, and afford upon the whole a more weighty crop. Theſe, therefore, ſhould ſtill continue to be cultivated for winter uſe, the other being reſerved only for ſpring conſumption.

"Experiments are ſtill wanting to aſcertain with certainty the peculiar ſoil and culture that beſt agree with this plant; but from the few obſervations I have hitherto had an opportunity of making upon it, it ſeems to me probable, that it thrives better, and grows to a larger ſize, on damp clayey ſoil, than on light ſandy land. But I would not wiſh to be underſtood as here ſpeaking poſitively, I merely throw it out as a hint for future obſervation: on ſpongy ſoil it proſpers.

"Though the uſes of this as a garden plant are of much ſmaller conſequence than thoſe above ſpecified, it may not be improper to remark, that its leaves form a very ſweet kind of greens at any time; and merely for the ſake of the experiment, I cauſed ſome of theſe to be picked off the ſtems of the plants coming to ſeed, on the 4th of June, the king's birth day, which, on being readied, were found perfectly ſweet, without the ſmalleſt tendency to bitterneſs, which moſt, if not all, other kinds of greens that have been hitherto cultivated are known to acquire after their ſtems are conſiderably advanced; no family, therefore, can ever be at a loſs for greens when they have any of this plant in ſeed.

"A root of this kind of turnip was taken up this day (June 15.); the ſeed-ſtalks were firm and woody, the pods full formed, and in ſome of them the ſeeds were nearly ripe. The root, however, was as ſoft and ſucculent as at any former period of its growth; nor was the ſkin, as I expected, hard or woody. It was made ready and brought to the table: ſome perſons there thought the taſte as good, if not better, than at any former period of its growth; but I myſelf, perhaps through prejudice, thought it had not quite ſo high a reliſh as in winter. At any rate, however, there

can

Culture of particular Plants.

can be no doubt, that if ever it could be neceſſary, it might, even now, be employed very properly as a feeding for cattle."

368 Culture of the roota baga in Nottinghamſhire.

This vegetable, from its obvious utility, is gradually coming to be much uſed in various quarters of the iſland. In the Agricultural Survey of Nottinghamſhire, the following deſcription of the modes in which it has been ſucceſsfully cultivated, is well worthy of attention. "The roota baga, or Swediſh turnip, is now cultivated by a few farmers in the diſtrict. It appears to be ſuperior to the common turnip in many reſpects, particularly in hardineſs, as it ſtood the laſt ſevere winter without the leaſt injury. It is eaten with greedineſs by all animals, from the horſe to the ſwine. Sheep prefer it to all others; but the material advantage that has been made of it, is the ſubſtituting it for corn in the food of draught horſes; in which it has been found to anſwer the wiſh of every perſon who has yet tried it. The turnips are put into a tub or barrel, and cut ſmall with an inſtrument like a hoe, with the blade put perpendicularly into the ſhaft; a man will cut in one hour as much as ſix horſes can eat in twenty-four. The tops and bottoms are previouſly cut off and given to the pigs. Horſes that are hard worked, look full as well when fed with this turnip and very little hay, as they formerly did when very high fed with corn. The Swediſh turnip ſhould be ſowed early, from the 15th of May to the 10th of June."—The following information on the culture of the roota baga, is given in the ſame Survey, upon the authority of J. Daiken, Eſq. of Nottingham.

Mr Daiken, about the 10th of May 1794, ſowed about four acres with the ſeed of roota baga, about 2lbs. per acre, on good ſand land, worth 20s. an acre, manured as for turnips, and having been ploughed four or five times; the reſt of the field, to the amount of nine acres in all, with common turnip and turnip-rooted cabbage, all broad-caſt. They were not tranſplanted, but hoed out nine inches aſunder, at three hocings, at 7s. 6d. an acre; no other culture. In November began to uſe them for horſes, giving at firſt clover and rye-graſs hay, oats and beans; but finding that the horſes did well upon them, left off all corn, and continued them on hay and the roots only; fifteen were thus fed for about two months, were conſtantly hard worked, and preſerved themſelves in very good condition. Mr Daiken is well convinced, that in this application they were worth 30l. an acre, that he would in future, if he could not get them otherwiſe, rather give that ſum per acre for one or two acres, than not have them for this uſe. They loſt their leaves entirely when the froſt ſet in; but the roots were not the leaſt affected, though the common turnips in the ſame field were totally deſtroyed. Paſſengers paſſing through the field, cut holes in them, which did not let the froſt injure them; nor were thoſe hurt which were damaged by cattle biting them. Some came to the weight of 16lbs. and Mr Daiken thinks the average of the crop 8lbs. and much to exceed in tonnage per acre common turnips.

Mr Daiken gave them alſo to hogs, cattle and ſheep. They are excellent for hogs; and ſheep being let into the field before the common turnips were deſtroyed, gave ſo decided a preference to the roota baga that they would not ſettle on the common turnips while the others were to be had.

Culture particul Plants

The method of giving them to horſes is to cut off the top-root, to waſh them, and to cut them roughly with a perpendicular hoe, and then given directly, without keeping them to dry. The horſes ate them with avidity, and ſeemed even to prefer them to corn. Their qualities appear to be ſingular, as they bind horſes inſtead of relaxing them as other roots do. One mare was kept entirely upon them and ſtraw, worked every day, did well, and never looked better; this mare was more bound by them than the reſt. They have a ſtrong effect upon making the coats fine, and one or two affected by the greaſe, were cured by them, as they act as a ſtrong diuretic. In this mode of application, one acre maintained fifteen about two months: and Mr Daiken is ſo well convinced of the utility of the plant, as well as many of his neighbours, that he intends, and they alſo, to increaſe the cultivation much.

Mr Daiken ſuſpects there are two ſorts of the roota baga, becauſe ſome, upon cutting, are white within, but in general yellow; otherwiſe of the ſame external appearance. The yellow is the beſt.

3. Turnip Cabbage.

This plant is as yet but little known. The ſeed is ſaid to have been brought from the Cape of Good Hope by Mr Haſtings, where it is very common, as well as in Holland. It has alſo had an exiſtence in Britain for many years, though not generally known. It has a much greater affinity to the cabbage than to the turnip; and is very hardy, bearing the winter as well, if not better, than common brocoli, and may therefore be conſidered as a valuable acquiſition to the kitchen garden as well as for cattle. The beſt time for ſowing it for the garden is the end of May or beginning of June, though none of the plants have ever been obſerved to run to ſeed though ſown ever ſo early. Even though ſown in Auguſt at the cauliflower ſeaſon, the greater part ſtood throughout the following ſummer, and did not ſeed till the ſecond ſpring. The plants require nearly the ſame management with brocoli as to diſtance, tranſplanting, &c. and are uſually moſt eſteemed when young, and about the ſize of a moderate garden turnip; thoſe ſown in June will continue all winter. The bulb muſt be ſtripped clean of its thick fibrous rind; after which it may be uſed as a common turnip. The crown or ſprout is very good, but eſpecially in the ſpring, when they begin to run to ſeed. Mr Broughton, from whoſe account in the Bath Papers, vol. v. this article is taken, thinks that the turnip-cabbage is more nutritious than the common turnip. The largeſt bulb he meaſured was 23 inches circumference; but the thickneſs of the rind is ſo great, that ſome farmers imagined that the bulb would be too hard for ſheep. The objection, however, was obviated by Mr Broughton, who gave ſome of the oldeſt and toughеſt bulbs to his ſheep, and found that they not only penetrated through the rind, but even devoured the greateſt part of it.

369 Method cultivat

4. Cabbage.

The cabbage has been recommended by long experience

Culture of particular Plants.

rience as an excellent food for cattle. Its uſes as part of human food are alſo well known. It is therefore an intereſting article in huſbandry. It is eaſily raiſed, is ſubject to few diſeaſes, reſiſts froſts more than turnip, is palatable to cattle, and ſooner fills them than turnip, carrot, or potatoes.

370 Culture of cabbage.

The ſeaſon for ſetting cabbage depends on the uſe it is intended for. If intended for feeding in November, December, and January, plants procured from ſeed ſown the end of July the preceding year muſt be ſet in March or April. If intended for feeding in March, April, and May, the plants muſt be ſet the firſt week of the preceding July, from ſeed ſown in the end of February or beginning of March the ſame year. The late ſetting of the plants retards their growth; by which means they have a vigorous growth the following ſpring. And this crop makes an important link in the chain that connects winter and ſummer green food. Where cabbage for ſpring food happens to be neglected, a few acres of rye, ſown at Michaelmas, will ſupply the want. After the rye is conſumed, there is time ſufficient to prepare the ground for turnip.

And now to prepare a field for cabbage. Where the plants are to be ſet in March, the field muſt be made up after harveſt in ridges three feet wide. In that form let it lie all winter, to be mellowed with air and froſt. In March, take the firſt opportunity, between wet and dry, to lay dung in the furrows. Cover the dung with a plough, which will convert the furrow into a crown, and conſequently the crown into a furrow. Set the plants upon the dung, diſtant from each other three feet. Plant them ſo as to make a ſtraight line croſs the ridges, as well as along the furrows, to which a gardeners line ſtretched perpendicularly croſs the furrows will be requiſite. This will ſet each plant at the diſtance preciſely of three feet from the plants that ſurround it. The purpoſe of this accuracy is to give opportunity for ploughing not only along the ridges, but croſs them. This mode is attended with three ſignal advantages: it ſaves hand-hoeing, it is a more complete dreſſing to the ſoil, and it lays earth neatly round every plant.

If the ſoil be deep and compoſed of good earth, a trench ploughing after the preceding crop will not be amiſs; in which caſe, the time for dividing the field into three-feet ridges, as above, ought to be immediately before the dunging for the plants.

If weeds happen to riſe ſo cloſe to the plants as not to be reached by the plough, it will require very little labour to deſtroy them with a hand-hoe.

Unleſs the ſoil be much infeſted with annuals, twice ploughing after the plants are ſet will be a ſufficient dreſſing. The firſt removes the earth from the plants: the next, at the diſtance of a month or ſo, lays it back.

Where the plants are to be ſet in July, the field muſt be ribbed as directed for barley. It ought to have a ſlight ploughing in June before the planting, in order to looſen the ſoil, but not ſo as to bury the ſurface-earth; after which the three-feet ridges muſt be formed, and the other particulars carried on as directed above with reſpect to plants that are to be ſet in March.

In a paper already quoted from thoſe of the Bath Society, Scots cabbages are compared, as to their utility in feeding cattle, with turnips, turnip-rooted cabbage, and carrots. In this trial the cabbages ſtand next in value to the carrots; and they are recommended as not liable to be affected by froſt, if they be of the true flat-topped firm kind. Fifty-four tons have been raiſed upon an acre of ground not worth more than 12 ſhillings. There is likewiſe an advantage attending the feeding of cattle with cabbages, viz. that their dung is more in proportion than when fed with turnips or with hay; the former going off more by urine, and the latter having too little moiſture. They alſo impoveriſh the ground much leſs than grain. Mr Billingſley accounts 46 tons per acre a greater crop than he ever read of; but Mr Vagg, in the 4th volume of Bath Papers, gives an account of a crop for which he received a premium from the Society, which was much ſuperior to that of Mr Billingſley. Its extent was 12 acres; the produce of the worſt was 42, and of the beſt 68 tons. They were manured with a compoſt of lime, weeds, and earth, that lay under the hedges round the field, and a layer of dung, all mixed and turned together. About 25 cart loads of this were ſpread upon an acre with the uſual ploughing given to a common ſummer fallow; but for this, he ſays, "admitting ſuch crop to exhauſt the manure in ſome degree by its growth, an ample reſtoration will be made by its refuſe ploughed in, and by the ſtirring and cleaning of the ground." The whole expence of an acre, excluſive of the rent, according to Mr Vagg's calculation, amounts to 11. 14s. 1d. only four ounces of ſeed being requiſite for an acre. The 12 acres, producing as above mentioned, would feed 45 oxen, and upwards of 60 ſheep, for three months; improving them as much as the graſs in the beſt months of the year, May, June, and July. He recommends ſowing the ſeed about the middle of Auguſt, and tranſplanting the young cabbages where they may be ſheltered from the froſt; and to the neglect of this he aſcribes the partial failure, or at leaſt inferiority of one part of his ground in the crop juſt mentioned, the young plants not being removed till near midſummer, and then in ſo dry a time, that they were almoſt ſcorched up.

Culture of particular Plants.

371 Quantity raiſed on an acre, &c.

372 Of watering cabbages.

In the Farmer's Magazine, vol. ii. p. 217. we have ſeveral pertinent remarks upon the culture of this uſeful plant, particularly with regard to watering. "It is a rule (ſays this correſpondent) never to water the plants, let the ſeaſon be as dry as it may; inſiſting that it is entirely uſeleſs. If the land is in fine tilth and well dunged, this may be right, as the expence muſt be conſiderable; but it is probable, in very dry ſeaſons, when the new ſet plants have nothing but a burning ſun on them, that watering would ſave vaſt numbers, and might very well anſwer the expence, if a pond is near, and the work done with a water-cart." He takes notice alſo of another uſe of cabbages, which has not met with the attention it merits, viz. the planting of lands where turnips have failed. A late ſown crop of theſe ſeldom turns to any account; but cabbages planted on the ground without any ploughing would prove very beneficial for ſheep late in the ſpring; in all probability (unleſs on light, ſandy, or limeſtone ſoils) of greater value than the turnips, had they ſucceeded.

Mr Marſhall obſerves, that in the midland diſtrict, a valuable

Culture of particular Plants.

valuable ſort of large green cabbage " is propagated, if not raiſed, by Mr Bakewell, who is not more celebrated for his breed of rams than for his breed of cabbages. Great care is obſerved here in raiſing the ſeed, being careful to ſuffer no other variety of the braſſica tribe to blow near ſeed cabbages; by which means they are kept true to their kind. To this end, it is ſaid that ſome plant them in a piece of wheat; a good method, provided the ſeed in that ſituation can be preſerved from birds."

373 Cabbages cultivated in the midland diſtrict.

374 Diſtance at which they ought to be placed.

The advantage of having large cabbages is that of being able to plant them wide enough from each other, to admit of their being cleaned with the plough, and yet to afford a full crop. The proper diſtance depends in ſome meaſure on the natural ſize of the ſpecies and the ſtrength of the ſoil; the thinner they ſtand, the larger they will grow: but our author is of opinion that cabbages, as well as turnips, are frequently ſet out too thin. Four feet by two and a half, according to Mr Marſhall, are a full diſtance for large cabbages on a rich ſoil.

375 Method of tranſplanting and earthing them.

Annals of Agriculture, vol. xv.

We think it of importance to take notice of the following mode of tranſplanting cabbages, or earthing them, as being conſiſtent with the beſt mode of practice, and coming from the moſt reſpectable practical authority, Mr George Cully of Fenton. " We plant the cabbages, ſays he, not only in right lines but equidiſtant every way, ſo that we can plough between the rows, both long-ways and croſs over; which, by looſening the earth ſo effectually on all ſides, very much promotes their growth. But the matter I wiſhed to inform you of, is the taking them up by the roots in the autumn whenever they have completed their growth, and putting them into the neareſt ſtubble field you have, where a plough is ready to draw a ſtraight furrow in the moſt convenient place; and at twenty yards diſtance, more or leſs, the ploughman makes another furrow parallel to the firſt. The cabbages are now turned out of the carts as conveniently as may be for a ſufficient number of women to lay them along theſe furrows as cloſe one to another as poſſible. The ploughman begins again where he firſt ſtarted, and turns a large furrow upon the cabbages which is trodden down and righted by one, two or more as occaſion requires, with each a ſpade in his hand to aſſiſt where the plough has by chance or accident not thrown earth enough. Thus the work goes on till all is finiſhed."

" We think we derive two advantages by the above proceſs. In the firſt place the cabbages keep ſufficiently well through the winter in their new ſituation, while they do not draw or exhauſt the land ſo much where they were growing: and, ſecondly, that land is at liberty to be ſown with wheat as ſoon as cleared of the cabbages; which grain, in general, anſwers well after that green crop."

376 How protected from caterpillars.

Cabbages and greens in general are apt to be infeſted by caterpillars. They may uſually however be protected againſt thoſe vermin by pulling off the large undermoſt leaves, which may be given to cows in the month of Auguſt, or when the common white butterflies begin to appear in numbers. Theſe butterflies lay their eggs, which produce the cabbage caterpillar on the under ſide of the largeſt leaves of the cabbage plants. There is alſo ſaid to be another remedy. It conſiſts of ſowing beans among the cabbages, which will greatly prevent the breeding of theſe worms; for it is ſaid that the butterflies have an antipathy to the flavour of beans.

Culture Graſs.

5. The Root of Scarcity.

377 Culture o the root c ſcarcity.

The *racine de diſette*, or root of ſcarcity (*Betacia*), delights in a rich loamy land well dunged. It is directed to be ſown in rows, or broad-caſt, and as ſoon as the plants are of the ſize of a gooſe quill, to be tranſplanted in rows of 18 inches diſtance, and 18 inches apart, one plant from the other: care muſt be taken in the ſowing, to ſow very thin, and to cover the ſeed, which lies in the ground about a month, an inch only. In tranſplanting, the root is not to be ſhortened, but the leaves cut at the top; the plant is then to be planted with a ſetting ſtick, ſo that the upper part of the root ſhall appear about half an inch out of the ground: this laſt precaution is very neceſſary to be attended to. Theſe plants will ſtrike root in twenty-four hours, and a man a little accuſtomed to planting will plant with eaſe 1800 or 2000 a-day. In the ſeed-bed, the plants, like all others, muſt be kept clear of weeds: when they are planted out, after once hoeing, they will take care of themſelves, and ſuffocate every kind of weed near them.

The beſt time to ſow the ſeed is from the beginning of March to the middle of April: it is, however, adviſed to continue ſowing every month until the beginning of July, in order to have a ſucceſſion of plants. Both leaves and roots have been extolled as excellent both for man and beaſt. This plant is ſaid not to be liable, like the turnip, to be deſtroyed by inſects; for no inſect touches it, nor is it affected by exceſſive drought, or the changes of ſeaſons. Horned cattle, horſes, pigs, and poultry, are exceedingly fond of it when cut ſmall. The leaves may be gathered every 12 or 15 days; they are from 30 to 40 inches long, by 22 to 25 inches broad. This plant is excellent for milch cows, when given to them in proper proportions, as it adds much to the quality as well as quantity of their milk; but care muſt be taken to proportion the leaves with other green food, otherwiſe it would abate the milk, and fatten them too much, it being of ſo exceeding a fattening quality. To put all theſe properties beyond doubt, however, further experiments are wanting.

Sect. IV. *Culture of Graſs.*

378 Of laying down fiel to graſs.

The latter end of Auguſt, or the beginning of September, is the beſt ſeaſon for ſowing graſs ſeeds, as there is time for the roots of the young plants to fix themſelves before the ſharp froſts ſet in. It is ſcarce neceſſary to ſay, that moiſt weather is beſt for ſowing; the earth being then warm, the ſeed will vegetate immediately; but if this ſeaſon prove unfavourable, they will do very well the middle of March following.

If you would have fine paſture, never ſow on foul land. On the contrary, plough it well, and clear it from the roots of couch-graſs, reſt-harrow, fern, broom, and all other noxious weeds. If theſe are ſuffered to remain, they will ſoon get above and deſtroy your young graſs. Rake theſe up in heaps, and burn them on the land, and ſpread the aſhes as a manure. Theſe ploughings and harrowings ſhould be repeated in dry weather.

Culture of Grafs.

weather. And if the ſoil be clayey and wet, make ſome under-drains to carry off the water, which, if ſuffered to remain, will not only chill the graſs, but make it ſour. Before ſowing, lay the land as level and fine as poſſible. If your graſs ſeeds are clean (which ſhould always be the caſe), three buſhels will be ſufficient per acre. When ſown, harrow it in gently, and roll it in with a wooden roller. When it comes up, fill up all the bare ſpots by freſh ſeed, which, if rolled to fix it, will ſoon come up and overtake the reſt.

In Norfolk they ſow clover with their graſſes, particularly with rye-graſs; but this ſhould not be done except when the land is deſigned for graſs only three or four years, becauſe neither of theſe kinds will laſt long in the land. Where you intend it for a continuance, it is better to mix only ſmall white Dutch clover, or marl graſs, with your other graſs ſeed, and not more than eight pounds to an acre. Theſe are abiding plants, ſpread cloſe on the ſurface, and make the ſweeteſt feed of any for cattle. In the following ſpring, root up thiſtles, hemlock, or any large plants that appear. The doing this while the ground is ſoft enough to permit your drawing them up by the roots, and before they ſeed, will ſave you infinite trouble afterwards.

The common method of proceeding in laying down fields to graſs is extremely injudicious. Some ſow barley with their graſſes, which they ſuppoſe to be uſeful in ſhading them, without conſidering how much the corn draws away the nouriſhment from the land.

Others take their ſeeds from a foul hay rick; by which means, beſides filling the land with rubbiſh and weeds, what they intend for dry ſoils may have come from moiſt, where it grew naturally, and *vice verſa*.

379 Different kinds of graſs.

The conſequence is, that the ground, inſtead of being covered with a good thick ſward, is filled with plants unnatural to it. The kinds of graſs moſt eligible for paſture lands are, the annual meadow, creeping, and fine bent, the fox's tail, and the creſted dog's tail, the poas, the feſcues, the vernal oat-graſs, and the ray or rye-graſs. We do not, however, approve of ſowing all theſe kinds together; for not to mention their ripening at different times, by which means you can never cut them all in perfection and full vigour, no kind of cattle are fond of all alike.

Horſes will ſcarcely eat hay which oxen and cows will thrive upon; ſheep are particularly fond of ſome kinds, and refuſe others. The darnel-graſs, if not cut before ſeveral of the other kinds are ripe, becomes ſo hard and wiry in the ſtalks, that few cattle care to eat it.

As the ſubject of paſtures is very important, we ſhall firſt take notice of the general mode of improving ordinary paſtures, and of the particular graſs plants that ought to be cultivated in them. After which we ſhall mention the celebrated modern improvements upon graſs lands, by flooding them artificially with water.

Paſture land is of ſuch advantage to huſbandry, that many prefer it even to corn land, becauſe of the ſmall hazard and labour that attends it; and as it lays the foundation for moſt of the profit that is expected from the arable land, becauſe of the manure afforded by the cattle which are fed upon it. Paſture ground is of two ſorts: the one is meadow land, which is often overflowed; and the other is upland, which lies high and dry. The firſt of theſe will produce a much greater quantity of hay than the latter, and will not require manuring or dreſſing ſo often: but then the hay produced on the upland is much preferable to the other; as is alſo the meat which is fed in the upland more valued than that which is fatted in rich meadows; though the latter will make the fatter and larger cattle, as is ſeen by thoſe which are brought from the low rich lands in Lincolnſhire. But where people are nice in their meat, they will give a much larger price for ſuch as hath been fed on the downs, or in ſhort upland paſture, than for the other, which is much larger. Beſides this, dry paſtures have an advantage over the meadows, that they may be fed all the winter, and are not ſo ſubject to poach in wet weather; nor will there be ſo many bad weeds produced; which are great advantages, and do in a great meaſure recompenſe for the ſmallneſs of the crop.

Culture of Grafs.

380 How to improve upland paſtures.

The firſt improvement of upland paſture is, by fencing it, and dividing it into ſmall fields of four, five, ſix, eight, or ten acres each, planting timber trees in the hedge-rows, which will ſcreen the graſs from the dry pinching winds of March, which will prevent the graſs from growing in large open lands; ſo that if April proves a dry month, the land produces very little hay; whereas in the ſheltered fields, the graſs will begin to grow early in March, and will cover the ground, and prevent the ſun from parching the roots of the graſs, whereby it will keep growing, ſo as to afford a tolerable crop if the ſpring ſhould prove dry. But in fencing of land, the incloſure muſt not be made too ſmall, eſpecially where the hedge rows are planted with trees; becauſe, when the trees are advanced to a conſiderable height, they will ſpread over the land; and where they are cloſe, will render the graſs ſo ſour, that inſtead of being of an advantage, it will greatly injure the paſture.

The next improvement of upland paſture is, to make the turf good, where, either from the badneſs of the ſoil, or for want of proper care, the graſs hath been deſtroyed by ruſhes, buſhes, or mole-hills. Where the ſurface of the land is clayey and cold, it may be improved by paring it off, and burning it; but if it is a hot ſandy land, then chalk, lime, marl, or clay, are very proper manures to lay upon it; but theſe ſhould be laid in pretty good quantities, otherwiſe they will be of little ſervice to the land.

If the ground is overrun with buſhes or ruſhes, it will be of great advantage to the land to grub them up towards the latter part of ſummer, and after they are dried to burn them, and ſpread the aſhes over the ground juſt before the autumnal rains; at which time the ſurface of the land ſhould be levelled, and ſown with graſs ſeed, which will come up in a ſhort time, and make good graſs the following ſpring. So alſo, when the land is full of mole-hills, theſe ſhould be pared off, and either burnt for the aſhes, or ſpread immediately on the ground when they are pared off, obſerving to ſow the bare patches with graſs ſeed juſt as the autumnal rains begin.

Where the land has been thus managed, it will be of great ſervice to roll the turf in the months of February and March with a heavy wooden roller; always obſerving to do it in moiſt weather, that the roller may make an impreſſion; this will render the ſurface level

Culture of Grafs.

level, and make it much eaſier to mow the graſs than when the ground lies in hills; and will alſo cauſe the turf to thicken, ſo as to have what people uſually term a *good bottom*. The graſs likewiſe will be the ſweeter for this huſbandry, and it will be a great help to deſtroy bad weeds.

Another improvement of upland paſtures is, the feeding of them; for where this is not practiſed, the land muſt be manured at leaſt every third year; and where a farmer hath much arable land in his poſſeſſion, he will not care to part with his manure to the paſture. Therefore every farmer ſhould endeavour to proportion his paſture to his arable land, eſpecially where manure is ſcarce, otherwiſe he will ſoon find his error; for the paſture is the foundation of all the profit which may ariſe from the arable land.

Whenever the upland paſtures are mended by manure, there ſhould be a regard had to the nature of the ſoil, and a proper ſort of manure applied: as for inſtance, all hot ſandy land ſhould have a cold manure; neats dung and ſwines dung are very proper for ſuch lands; but for cold lands, horſe dung, aſhes, and other warm manures, are proper. And when theſe are applied, it ſhould be done in autumn, before the rains have ſoaked the ground, and rendered it too ſoft to cart on; and it ſhould be carefully ſpread, breaking all the clods as ſmall as poſſible, and then harrowed with buſhes, to let it down to the roots of the graſs. When the manure is laid on at this ſeaſon, the rains in winter will waſh it down, ſo that the following ſpring the graſs will receive the advantage of it.

There ſhould alſo be great care taken to deſtroy the weeds in the paſture every ſpring and autumn: for, where this is not practiſed, the weeds will ripen their ſeeds, which will ſpread over the ground, and thereby fill it with ſuch a crop of weeds as will ſoon overbear the graſs, and deſtroy it; and it will be very difficult to root them out after they have gotten ſuch poſſeſſion, eſpecially ragwort, and ſuch other weeds as have down adhering to their ſeeds.

The graſs which is ſown in theſe upland paſtures ſeldom degenerates, if the land is tolerably good: whereas the low meadows, on which water ſtagnates in winter, in a few years turn to a harſh ruſhy graſs, though the upland will continue a fine ſweet graſs for many years without renewing.

There is no part of huſbandry of which the farmers are in general more ignorant than that of the paſture: moſt of them ſuppoſe, that when old paſture is ploughed up, it can never be brought to have a good ſward again; ſo their common method of managing their land after ploughing, is to ſow with their crop of barley ſome graſs ſeeds as they call them; that is, either the red clover, which they intend to ſtand two years after the corn is taken off the ground, or rye-graſs mixed with trefoil; but as all theſe are at moſt but biennial plants, whoſe roots decay ſoon after their ſeeds are perfected, ſo the ground, having no crop upon it, is again ploughed for corn; and this is the conſtant round which the lands are employed in by the better ſort of farmers.

But whatever may have been the practice of theſe people, it is certainly poſſible to lay down lands which have been in tillage with graſs, in ſuch a manner as that the ſward ſhall be as good, if not better, than any natural graſs, and of as long duration. But this is never to be expected in the common method of ſowing a crop of corn with the graſs ſeeds; for, whenever this has been practiſed, if the corn has ſucceeded well, the graſs has been very poor and weak; ſo that if the land has not been very good, the graſs has ſcarcely been worth ſaving; for the following year it has produced but little hay, and the year after the crop is worth little, either to mow or feed. Nor can it be expected to be otherwiſe, for the ground cannot nouriſh two crops; and if there were no deficiency in the land, yet the corn, being the firſt and moſt vigorous of growth, will keep the graſs from making any conſiderable progreſs; ſo that the plants will be extremely weak, and but very thin, many of them which come up in the ſpring being deſtroyed by the corn; for wherever there are roots of corn, it cannot be expected there ſhould be any graſs. Therefore the graſs muſt be thin; and if the land is not in good heart to ſupply the graſs with nouriſhment, that the roots may branch out after the corn is gone, there cannot be any conſiderable crop of clover; and as their roots are biennial, many of the ſtrongeſt plants will periſh ſoon after they are cut; and the weak plants, which had made but little progreſs before, will be the principal part of the crop for the ſucceeding year; which is frequently not worth ſtanding.

Culture of Graſs.

381 How to ſow upland paſtures.

Therefore, when ground is laid down for graſs, there ſhould be no crop of any kind ſown with the ſeeds; or at leaſt the crop ſhould be ſown very thin, and the land ſhould be well ploughed and cleaned from weeds, otherwiſe the weeds will come up the firſt, and grow ſo ſtrong as to overbear the graſs, and if they are not pulled up, will entirely ſpoil it. The beſt ſeaſon to ſow the graſs ſeeds upon dry land, when no other crop is ſown with them, is about the middle of September or ſooner, if there is an appearance of rain: for the ground being then warm, if there happen ſome good ſhowers of rain after the ſeed is ſown, the graſs will ſoon make its appearance, and get ſufficient rooting in the ground before winter: ſo will not be in danger of having the roots turned out of the ground by froſt, eſpecially if the ground is well rolled before the froſt comes on, which will preſs it down, and fix the earth cloſe to the roots. Where this hath not been practiſed, the froſt has often looſened the ground ſo much, as to let in the air to the roots of the graſs, and done it great damage; and this has been brought as an objection to the autumnal ſowing of graſs; but it will be found to have no weight if the above direction is practiſed: nor is there any hazard of ſowing the graſs at this ſeaſon, but that of dry weather after the ſeeds are ſown; for if the graſs comes up well, and the ground is well rolled in the end of October, or the beginning of November, and repeated again the beginning of March, the ſward will be cloſely joined at bottom, and a good crop of hay may be expected the ſame ſummer. But where the ground cannot be prepared for ſowing at that ſeaſon, it may be performed the middle or latter end of March, according to the ſeaſon's being early or late; for, in backward ſprings, and in cold land, we have often ſowed the graſs in the middle of April with ſucceſs; but there is danger, in ſowing late, of dry weather, and eſpecially if the land is light and dry; for we have ſeen many

times

Culture of Grafs.

times the whole furface of the ground removed by ftrong winds at that feafon; fo that the feeds have been driven in heaps to one fide of the field. Therefore, whenever the feeds are fown late in the fpring, it will be proper to roll the ground well foon after the feeds are fown, to fettle the furface, and prevent its being removed.

The forts of feeds which are the beft for this purpofe, are, the beft fort of upland hay feeds, taken from the cleaneft paftures, where there are no bad weeds; if this feed is fifted to clean it from rubbifh, three bufhels will be fufficient to fow an acre of land. The other fort is the *trifolium pratenfe album*, which is commonly known by the names *white Dutch clover*, or *white honeyfuckle grafs*. Eight pounds of this feed will be enough for one acre of land. The grafs feed fhould be fown firft, and then the Dutch clover feed may be afterwards fown; but they fhould not be mixed together, becaufe the clover feeds being the heavieft will fall to the bottom, and conſequently the ground will be unequally fown.

When the feeds are come up, if the land fhould produce many weeds, thefe fhould be drawn out before they grow fo tall as to overbear the grafs; for where this has been neglected, the weeds have taken fuch poffeffion of the ground as to keep down the grafs, and ftarve it; and when thefe weeds have been fuffered to remain until they have fhed their feeds, the land has been fo plentifully ſtocked with them as entirely to deſtroy the grafs; therefore it is one of the principal parts of huſbandry never to ſuffer weeds to grow on the land.

382 Ivantages of rolling grafs.

If the ground is rolled two or three times at proper diſtances after the grafs is up, it will preſs down the grafs, and cauſe it to make a thicker bottom; for, as the Dutch clover will put out roots from every joint of the branches which are near the ground, ſo, by preſſing down of the ſtalks, the roots will mat ſo cloſely together, as to form a ſward ſo thick as to cover the whole ſurface of the ground, and form a green carpet, and will better reſiſt the drought. For if we do but examine the common paſtures in ſummer, in moſt of which there are patches of this white honeyſuckle graſs growing naturally, we ſhall find theſe patches to be the only verdure remaining in the fields. And this, the farmers in general acknowledge, is the ſweeteſt feed for all ſorts of cattle; yet never had any notion of propagating it by ſeeds, nor has this been long practiſed in England.

As the white clover is an abiding plant, ſo it is certainly the very beſt ſort to ſow, where paſtures are laid down to remain; for as the hay-ſeeds, which are taken from the beſt paſtures will be compoſed of various ſorts of graſs, ſome of which may be but annual, and others biennial; ſo, when thoſe go off, there will be many and large patches of ground left bare and naked, if there is not a ſufficient quantity of the white clover to ſpread over and cover the land. Therefore a good ſward can never be expected where this is not ſown; for in moſt of the natural paſtures, we find this plant makes no ſmall ſhare of the ſward; and it is equally good for wet and dry land, growing naturally upon gravel and clay in moſt parts of England: which is a plain indication how eaſily this plant may be cultivated to great advantage in moſt ſorts of land throughout this kingdom. Culture of Grafs.

Therefore the true cauſe why the land which has been in tillage is not brought to a good turf again, in the uſual method of huſbandry, is, from the farmers not diſtinguiſhing which graſſes are annual from thoſe which are perennial: for if annual or biennial graſſes are ſown, theſe will of courſe ſoon decay; ſo that, unleſs where ſome of their ſeeds may have ripened and fallen, nothing can be expected on the land but what will naturally come up. Therefore this, with the covetous method of laying down the ground with a crop of corn, has occaſioned the general failure of increaſing the paſture in many parts of Britain, where it is now much more valuable than any arable land.

After the ground has been ſown in the manner before directed, and brought to a good ſward, the way to preſerve it good is, by conſtantly rolling the ground with a heavy roller, every ſpring and autumn, as hath been before directed. This piece of huſbandry is rarely practiſed by farmers; but thoſe who do, find their account in it, for it is of great benefit to the graſs. Another thing ſhould alſo be carefully performed, which is, to cut up docks, dandelion, knapweed, and all ſuch bad weeds, by their roots every ſpring and autumn; this will increaſe the quantity of good graſs, and preſerve the paſtures in beauty. Dreſſing of theſe paſtures every third year is alſo a good piece of huſbandry; for otherwiſe it cannot be expected the ground ſhould continue to produce good crops. Beſides this, it will be neceſſary to change the ſeaſons of mowing, and not to mow the ſame ground every year, but to mow one ſeaſon and feed the next; for where the ground is every year mown, it muſt be conſtantly dreſſed, as are moſt of the graſs grounds near London, otherwiſe the ground will be ſoon exhauſted.

383 Culmiferous graſſes.

Culmiferous graſſes might be divided into two general claſſes for the purpoſes of the farmer, that it might be of uſe for him to attend to; viz. 1ſt, Thoſe which, like the common annual kinds of corn, run chiefly to ſeed-ſtalks; the leaves gradually decaying as they advance towards perfection, and becoming totally withered, or falling off entirely, when the ſeeds are ripe. Rye-graſs belongs to this claſs in the ſtricteſt ſenſe. To it likewiſe may be aſſigned the vernal graſs, dogs-tail graſs, and fine bent graſs. 2dly, Thoſe whoſe leaves continue to advance even after the ſeed-ſtalks are formed, and retain their verdure and ſucculence during the whole ſeaſon, as is the caſe with the feſcue and poa tribes of graſſes, whoſe leaves are as green and ſucculent when the ſeeds are ripe and the flower-ſtalks fading, as at any other time.

† *Tranſ. relating to Nat. Hiſt. &c.*

384 Culpable negligence of farmers about the proper kinds of graſſes.

"It is wonderful, Mr Stillingfleet ‡ remarks, to ſee how long mankind have neglected to make a proper advantage of plants of ſuch importance, and which, in almoſt every country, are the chief food of cattle. The farmer, for want of diſtinguiſhing and ſelecting graſſes for ſeed, fills his paſtures either with weeds or bad or improper graſſes; when, by making a right choice, after ſome trials, he might be ſure of the beſt graſs, and in the greateſt abundance that his land admits of. At preſent, if a farmer wants to lay down his land to graſs, what does he do? he either takes

Culture of Grafs.

his ſeeds indiſcriminately from his own foul hay rack, or ſends to his next neighbour for a ſupply. By this means, beſides a certain mixture of all ſorts of rubbiſh, which muſt neceſſarily happen, if he chances to have a large proportion of good ſeeds, it is not unlikely but that what he intends for dry land may come from moiſt, where it grew naturally, and the contrary. This is ſuch a ſlovenly method of proceeding, as one would think could not poſſibly prevail univerſally: yet this is the caſe as to all graſſes except the darnel-graſs, and what is known in ſome few counties by the name of the *Suffolk-graſs*; and this latter inſtance is owing, I believe, more to the ſoil than any care of the huſbandman. Now, would the farmer be at the pains of ſeparating once in his life half a pint or a pint of the different kinds of graſs ſeeds, and take care to ſow them ſeparately, in a very little time he would have wherewithal to ſtock his farm properly, according to the nature of each ſoil, and might at the ſame time ſpread theſe ſeeds ſeparately over the nation, by ſupplying the ſeed ſhops. The number of graſſes fit for the farmer is, I believe, ſmall; perhaps half a dozen or half a ſcore are all he need to cultivate; and how ſmall the trouble would be of ſuch a taſk, and how great the benefit, muſt be obvious to every one at firſt ſight. Would not any one be looked on as wild who ſhould ſow wheat, barley, oats, rye, peaſe, beans, vetches, buck-wheat, turnips, and weeds, of all ſorts together? yet how is it much leſs abſurd to do what is equivalent in relation to graſſes? Does it not import the farmer to have good hay and graſs in plenty? and will cattle thrive equally on all ſorts of food? We know the contrary. Horſes will ſcarcely eat hay that will do well enough for oxen and cows. Sheep are particularly fond of one ſort of graſs, and fatten upon it faſter than any other, in Sweden, if we may give credit to Linnæus. And may they not do the ſame in Britain? How ſhall we know till we have tried?"

385 Kinds of graſs commonly ſown.

The graſſes commonly ſown for paſture, for hay, or to cut green for cattle, are red clover, white clover, yellow clover, rye-graſs, narrow-leaved plantane, commonly called *ribwort*, ſainfoin, and lucerne.

Red clover is of all the moſt proper to be cut green for ſummer food. It is a biennial plant when ſuffered to perfect its ſeed; but when cut green, it will laſt three years, and in a dry ſoil longer. At the ſame time the ſafeſt courſe is to let it ſtand but a ſingle year: if the ſecond year's crop happen to be ſcanty, it proves, like a bad crop of peaſe, a great encourager of weeds, by the ſhelter it affords them.

Here, as in all other crops, the goodneſs of ſeed is of importance. Chooſe plump ſeed of a purple colour, becauſe it takes on that colour when ripe. It is red when hurt in the drying, and of a faint colour when unripe.

386 Of red clover.

Red clover is luxuriant upon a rich ſoil, whether clay, loam or gravel: it will grow even upon a moor, when properly cultivated. A wet ſoil is its only bane; for there it does not thrive.

To have red clover in perfection, weeds muſt be extirpated, and ſtones taken off. The mould ought to be made as fine as harrowing can make it; and the ſurface be ſmoothed with a light roller, if not ſufficiently ſmooth without it. This gives opportunity for diſtributing the ſeed evenly; which muſt be covered by a ſmall harrow with teeth no larger than thoſe of a garden rake, three inches long, and ſix inches aſunder *. In harrowing, the man ſhould walk behind with a rope in his hand fixed to the back part of the harrow, ready to diſentangle it from ſtones, clods, turnip or cabbage roots, which would trail the ſeed, and diſplace it.

Culture of Graſs.

* Plate VIII. fig.

Nature has not determined any preciſe depth for the ſeed of red clover more than of other ſeed. It will grow vigorouſly from two inches deep, and it will grow when barely covered. Half an inch may be reckoned the moſt advantageous poſition in clay ſoil, a whole inch in what is light or looſe. It is a vulgar error, that ſmall ſeed ought to be ſparingly covered. Miſled by that error, farmers commonly cover their clover ſeed with a buſhy branch of thorn; which not only covers it unequally, but leaves part on the ſurface to wither in the air.

The proper ſeaſon for ſowing red clover, is from the middle of April to the middle of May. It will ſpring from the firſt of March to the end of Auguſt; but ſuch liberty ought not to be taken except from neceſſity.

There cannot be a greater blunder in huſbandry than to be ſparing of ſeed. Ideal writers talk of ſowing an acre with four pounds. That quantity of ſeed, ſay they, will fill an acre with plants as thick as they ought to ſtand. This rule may be admitted where grain is the object; but it will not anſwer with reſpect to graſs. Graſs ſeeds cannot be ſown too thick: the plants ſhelter one another; they retain all the dew; and they muſt puſh upward, having no room laterally. Obſerve the place where a ſack of peaſe, or of other grain, has been ſet down for ſowing: the ſeed dropt there accidentally grows more quickly than in the reſt of the field ſown thin out of hand. A young plant of clover, or of ſainfoin, according to Tull, may be raiſed to a great ſize where it has room; but the field will not produce half the quantity. When red clover is ſown for cutting green, there ought not to be leſs than 24 pounds to an acre. A field of clover is ſeldom too thick: the ſmaller a ſtem be, the more acceptable it is to cattle. It is often too thin; and when ſo, the ſtems tend to wood.

387 Of ſowing clover with grain.

Grain may be ſown more ſafely with red clover than with almoſt any other graſs; and the moſt proper grain has been found to be flax. The ſoil muſt be highly cultivated for flax as well as for red clover. The proper ſeaſon of ſowing is the ſame for both; the leaves of flax being very ſmall, admit of free circulation of air; and flax being an early crop, is removed ſo early as to give the clover time for growing. In a rich ſoil it has grown ſo faſt, as to afford a good cutting that very year. Next to flax, barley is the beſt companion to clover. The ſoil muſt be looſe and free for barley; and ſo it ought to be for clover: the ſeaſon of ſowing is the ſame; and the clover is well eſtabliſhed in the ground before it is overtopped by the barley. At the ſame time, barley commonly is ſooner cut than either oats or wheat. In a word, barley is rather a nurſe than a ſtepmother to clover during its infancy. When clover is ſown in ſpring upon wheat, the ſoil which has lain five or ſix months without being ſtirred, is an improper bed for it; and the wheat, being in the vigour of growth,

overtops

Culture of Grafs.

overtops it from the beginning. It cannot be ſown along with oats, becauſe of the hazard of froſt; and when ſown as uſual among the oats three inches high, it is overtopped, and never enjoys free air till the oats be cut. Add, that where oats are ſown upon the winter furrow, the ſoil is rendered as hard as when under wheat.—Red clover is ſometimes ſown by itſelf without other grain: but this method, beſide loſing a crop, is not ſalutary; becauſe clover in its infant ſtate requires ſhelter.

As to the quantity of grain proper to be ſown with clover: In a rich ſoil well pulverized, a peck of barley on an Engliſh acre is all that ought to be ventured; but there is not much ſoil in Scotland ſo rich. Two Linlithgow firlots make the proper quantity for an acre that produces commonly ſix bolls of barley; half a firlot for what produces nine bolls. To thoſe who are governed by cuſtom, ſo ſmall a quantity will be thought ridiculous. Let them only conſider, that a rich ſoil in perfect good order, will from a ſingle ſeed of barley produce 20 or 30 vigorous ſtems. People may flatter themſelves with the remedy of cutting barley green for food, if it happen to oppreſs the clover. This is an excellent remedy in a field of an acre or two; but the cutting an extenſive field for food muſt be ſlow; and while one part is cutting, the clover is ſmothered in other parts.

388 White and yellow clover, ribwort, and rye-graſs.

The culture of white clover, of yellow clover, of ribwort, of rye-graſs, is the ſame in general with that of red clover. We proceed to their peculiarities. Yellow clover, ribwort, rye-graſs, are all of them early plants, blooming in the end of April or beginning of May. The two latter are evergreens, and therefore excellent for winter paſture. Rye-graſs is leſs hurt by froſt than any of the clovers, and will thrive in a moiſter ſoil: nor in that ſoil is it much affected by drought. In a rich ſoil, it grows four feet high: even in the dry ſummer 1775, it roſe to three feet eight inches; but it had gained that height before the drought come on. Theſe graſſes are generally ſown with red clover for producing a plentiful crop. The proportion of ſeed is arbitrary; and there is little danger of too much. When rye-graſs is ſown for procuring ſeed, five firlots wheat meaſure may be ſown on an acre; and for procuring ſeed of ribwort, 40 pounds may be ſown. The roots of rye-graſs ſpread horizontally: they bind the ſoil by their number; and though ſmall, are yet ſo vigorous as to thrive in hard ſoil. Red clover has a large tap-root, which cannot penetrate any ſoil but what is open and free; and the largeneſs of the root makes the ſoil ſtill more open and free. Rye-graſs, once a great favourite, appears to be diſcarded in many parts of Britain. The common practice has been, to ſow it with red clover, and to cut them promiſcuouſly the beginning of June for green food, and a little later for hay. This indeed is the proper ſeaſon for cutting red clover, becauſe at that time the ſeed of the rye-graſs is approaching to maturity, its growth is ſtopped for that year, as much as of oats or barley cut after the ſeed is ripe. Oats or barley cut green before the ſeed forms, will afford two other cuttings; which is the caſe of rye-graſs, of yellow clover, and of ribwort. By ſuch management, all the profit will be drawn that theſe plants can afford.

When red clover is intended for ſeed, the ground ought to be cleared of weeds, were it for no other purpoſe than that the ſeed cannot otherwiſe be preſerved pure; what weeds eſcape the plough ought to be taken out by the hand. In England, when a crop of ſeed is intended, the clover is always firſt cut for hay. This appears to be done, as in fruit trees, to check the growth of the wood, in order to encourage the fruit. This practice will not anſwer in Scotland, as the ſeed would often be too late for ripening. It would do better to eat the clover with ſheep till the middle of May, which would allow the ſeed to ripen. The ſeed is ripe when, upon rubbing it between the hands, it parts readily from the huſk. Then apply the ſcythe, ſpread the crop thin, and turn it carefully. When perfectly dry, take the firſt opportunity of a hot day for threſhing it on boards covered with a coarſe ſheet. Another way, leſs ſubject to riſk, is to ſtack the dry hay, and to threſh it in the end of April. After the firſt threſhing, expoſe the huſks to the ſun, and threſh them over and over till no ſeed remain. Nothing is more efficacious than a hot ſun to make the huſk part with its ſeed; in which view it may be expoſed to the ſun by parcels, an hour or two before the flail is applied.

Culture of Grafs.

White clover, intended for ſeed, is managed in the ſame manner. No plant ought to be mixed with rye-graſs that is intended for ſeed. In Scotland, much rye-graſs ſeed is hurt by tranſgreſſing that rule. The ſeed is ripe when it parts eaſily with the huſk. The yellowneſs of the ſtem is another indication of its ripeneſs; in which particular it reſembles oats, barley, and other culmiferous plants. The beſt manner to manage a crop of rye-graſs for ſeed, is to bind it looſely in ſmall ſheaves, widening them at the bottom to make them ſtand erect; as is done with oats in moiſt weather. In that ſtate they may ſtand till ſufficiently dry for threſhing. By this method they dry more quickly, and are leſs hurt by rain, than by cloſe binding and putting the ſheaves in ſhocks like corn. The worſt way of all is to ſpread the rye-graſs on the moiſt ground, for it makes the ſeed malten. The ſheaves, when ſufficiently dry, are carried in cloſe carts to where they are to be threſhed on a board, as mentioned above for clover. Put the ſtraw in a rick when a hundred ſtone weight or ſo is threſhed. Carry the threſhing board to the place where another rick is intended; and ſo on till the whole ſeed be threſhed, and the ſtraw ricked. There is neceſſity for cloſe carts to ſave the ſeed, which is apt to drop out in a hot ſun; and, as obſerved above, a hot ſun ought always to be choſen for threſhing. Carry the ſeed in ſacks to the granary or barn, there to be ſeparated from the huſks by a fanner. Spread the ſeed thin upon a timber floor, and turn it once or twice a-day till perfectly dry. If ſuffered to take a heat, it is uſeleſs for ſeed.

339 Culture of ſainfoin.

The writers on agriculture reckon ſainfoin preferable to clover in many reſpects: They ſay, that it produces a larger crop; that it does not hurt cattle when eaten green; that it makes better hay; that it continues four times longer in the ground; and that it will grow on land that will bear no other crop.

Sainfoin has a very long tap-root, which is able to pierce very hard earth. The roots grow very large; and the larger they are, they penetrate to the greater depth; and hence it may be concluded, that this graſs, when

Culture of Grafs.

when it thrives well, receives a great part of its nouriſhment from below the *ſtaple* of the ſoil: of courſe, a deep dry ſoil is beſt for the culture of ſainfoin. When plants draw their nouriſhment from that part of the ſoil that is near the ſurface, it is not of much conſequence whether ther number be great or ſmall. But the caſe is very different when the plants receive their food, not only near, but alſo deep below, the ſurface. Beſides, plants that ſhoot their roots deep are often ſupplied with moiſture, when thoſe near the ſurface are parched with drought.

To render the plants of ſainfoin vigorous, it is neceſſary that they be ſown thin. The beſt method of doing this is by a drill; becauſe, when ſown in this manner, not only the weeds, but alſo the ſupernumerary plants, can eaſily be removed. It is ſeveral years before ſainfoin comes to its full ſtrength; and the number of plants ſufficient to ſtock a field, while in this imperfect ſtate, will make but a poor crop for the firſt year or two. It is therefore neceſſary that it be ſown in ſuch a manner as to make it eaſy to take up plants in ſuch numbers, and in ſuch order, as always to leave in the field the proper number in their proper places. This can only be done, with propriety, by ſowing the plants in rows by a drill. Suppoſing a field to be drilled in rows at ten inches diſtance, the partitions may be hand-hoed, and the rows dreſſed in ſuch a manner as to leave a proper number of plants. In this ſituation the field may remain two years; then one-fourth of the rows may be taken out in pairs, in ſuch a manner as to make the beds of fifty inches, with ſix rows in each, and intervals of thirty inches, which may be ploughed. Next year, another fourth of the rows may be taken out in the ſame manner, ſo as to leave double rows with partitions of ten inches, and intervals of thirty: All of which may be hoed at once or alternately, as it may be found moſt convenient.

The great quantity of this graſs which the writers on this ſubject aſſure us may be raiſed upon an acre, and the excellency and great value of the hay made of it, ſhould induce farmers to make a complete trial of it, and even to uſe the ſpade in place of the hoe, or hoe-plough, if neceſſary.

The plants taken up from a field of ſainfoin may be ſet in another field; and if the tranſplanting of this graſs ſucceeds as well as the tranſplanting of lucerne has done with M. Lunin de Chateauvieux, the trouble and expence will be ſufficiently recompenſed by the largeneſs of the crops. In tranſplanting, it is neceſſary to cut off great part of the long tap-root: this will prevent it from ſtriking very deep into the ſoil, and make it puſh out large roots in a ſloping direction, from the cut end of the tap-root. Sainfoin managed in this manner, will thrive even on ſhallow land that has a wet bottom, provided it be not overſtocked with plants.

Whoever inclines to try the culture of this graſs in Scotland, ſhould take great pains in preparing the land, and making it as free from weeds as poſſible.

In England, as the roots ſtrike deep in that chalky ſoil, this plant is not liable to be ſo much injured by drought as other graſſes are, whoſe fibres ſtrike horizontally, and lie near the ſurface. The quantity of hay produced is greater and better in quality than any other. But there is one advantage attending this graſs, which renders it ſuperior to any other; and that ariſes from feeding with it milch cows. The prodigious increaſe of milk which it makes is aſtoniſhing, being nearly double that produced by any other green food. The milk is alſo better, and yields more cream than any other; and the butter procured from it is much better coloured and flavoured.

Culture of Grafs.

The following remarks by an Engliſh farmer are made from much experience and obſervation.

390 Remarks on the culture of ſainfoin in England.

Sainfoin is much cultivated in thoſe parts where the ſoil is of a chalky kind. It will always ſucceed well where the roots run deep; the worſt ſoil of all for it is where there is a bed of cold wet clay, which the tender fibres cannot penetrate. This plant will make a greater increaſe of produce, by at leaſt 30 times, than common graſs or turf on poor land. Where it meets with chalk or ſtone, it will extend its roots through the cracks and chinks to a very great depth in ſearch of nouriſhment. The dryneſs is of more conſequence than the richneſs of land for ſainfoin; although land that is both dry and rich will always produce the largeſt crops.

It is very commonly ſown broad-caſt; but it is found to anſwer beſt in drills, eſpecially if the land be made fine by repeated ploughing, rolling, and harrowing. Much depends on the depth at which this ſeed is ſown. If it be buried more than an inch deep, it will ſeldom grow; and if left uncovered, it will puſh out its roots above ground, and theſe will be killed by the air. March and the beginning of April are the beſt ſeaſons for ſowing it, as the ſeverity of winter and the drought of ſummer are equally unfavourable to the young plants. A buſhel of ſeed ſown broad-caſt, or half that quantity in drills, if good, is ſufficient for an acre. The drills ſhould be 30 inches apart, to admit of horſe-hoeing between them. Much, however, depends on the goodneſs of the ſeed, which may be beſt judged of by the following marks:

The huſk being of a bright colour, the kernel plump, of a gray or bluiſh colour without, and if cut acroſs, greeniſh and freſh withinſide; if it be thin and furrowed, and of a yellowiſh caſt, it will ſeldom grow. When the plants ſtand ſingle, and have room to ſpread, they produce the greateſt quantity of herbage, and the ſeed ripens beſt. But farmers in general, from a miſtaken notion of all that appears to be waſte ground being unprofitable, plant them ſo cloſe, that they choke and impoveriſh each other, and often die in a few years. Single plants run deepeſt and draw moſt nouriſhment; they are alſo eaſieſt kept free from weeds. A ſingle plant will often produce half a pound of hay, when dry. On rich land this plant will yield two good crops in a year, with a moderate ſhare of culture. A good crop muſt not be expected the firſt year; but, if the plants ſtand not too thick, they will increaſe in ſize the ſecond year prodigiouſly.

No cattle ſhould be turned on the field the firſt winter after the corn is off with which it was ſown, as their feet would injure the young plants. Sheep ſhould not come on the following ſummer, becauſe they would bite off the crown of the plants, and prevent their ſhooting again. A ſmall quantity of ſoapers aſhes as a top-dreſſing will be of great ſervice, if laid on the firſt winter.

Culture of Grafs.

If the fainfoin be cut juft before it comes into bloom, it is admirable food for horned cattle; and if cut thus early, it will yield a fecond crop the fame feafon. But if it proves a wet feafon, it is better to let it ftand till its bloom be perfected; for great care muft be taken, in making it into hay, that the flowers do not drop off, as cows are very fond of them; and it requires more time than any other hay in drying. Sainfoin is fo excellent a fodder for horfes, that they require no oats while they eat it, although they be worked hard all the time. Sheep will alfo be fattened with it fafter than with any other food.

If the whole feafon for cutting proves very rainy, it is better to let the crop ftand for feed, as that will amply repay the lofs of the hay; becaufe it will not only fetch a good price, but a peck of it will go as far as a peck and a half of oats for horfes.

The beft time of cutting the feeded fainfoin is, when the greateft part of the feed is well filled, the firft blown ripe, and the laft blown beginning to open. For want of this care fome people have loft moft of their feed by letting it ftand too ripe. Seeded fainfoin fhould always be cut in a morning or evening, when the dews render the ftalks tender. If cut when the fun fhines hot, much of the feed will fall out and be loft.

301 excellence as a fodder.

An acre of very ordinary land, when improved by this grafs, will maintain four cows very well from the firft of April to the end of November; and afford, befides, a fufficient ftore of hay to make the greater part of their food the four months following.

If the foil be tolerably good, a field of fainfoin will laft from 15 to 20 years in prime; but at the end of feven or eight years, it will be neceffary to lay on a moderate coat of well-rotted dung; or, if the foil be very light and fandy, of marl. By this means the future crops, and the duration of the plants in health and vigour, will be greatly increafed and prolonged. Hence it will appear, that for poor land there is nothing equal to this grafs in point of advantage to the farmer.

Clover will laft only two years in perfection; and often, if the foil be cold and moift, near half the plants will rot, and bald patches be found in every part of the field the fecond year. Befides, from our frequent rains during the month of September, many crops left for feeding are loft. But from the quantity and excellent quality of this grafs (fainfoin), and its ripening earlier, and continuing in vigour fo much longer, much rifk and certain expence are avoided, and a large annual profit accrues to the farmer.

302 Culture of lucerne.

The writers on agriculture, ancient as well as modern, bellow the higheft encomiums upon lucerne as affording excellent hay, and producing very large crops. Lucerne remains at leaft 10 or 12 years in the ground, and produces about eight tons of hay upon the Scots acre. There is but little of it cultivated in Scotland. However, it has been tried in feveral parts of that country; and it is found, that, when the feed is good, it comes up very well, and ftands the winter froft. But the chief thing which prevents this grafs from being more ufed in Scotland, is the difficulty of keeping the foil open and free from weeds. In a few years the furface becomes fo hard, and the turf fo ftrong, that it deftroys the lucerne before the plants have arrived at their greateft perfection: fo that lucerne can fcarce be cultivated with fuccefs there, unlefs fome method be fallen upon of deftroying the natural grafs, and preventing the furface from becoming hard and impenetrable. This cannot be done effectually by any other means than horfe-hoeing. This method was firft propofed by Mr Tull, and afterwards practifed fucceffully by M. de Chateauvieux near Geneva. It may be of ufe therefore to give a view of that gentleman's method of cultivating lucerne.

Culture of Grafs.

He does not mention any thing particular as to the manner of preparing the land; but only obferves, in general, that no pains fhould be fpared in preparing it. He tried the fowing of lucerne both in rows upon the beds where it was intended to ftand, likewife the fowing it in a nurfery, and afterwards tranfplanting it into the beds prepared for it. He prefers tranfplanting; becaufe, when tranfplanted, part of the tap-root is cut off, and the plant fhoots out a number of lateral branches from the cut part of the root, which makes it fpread its roots nearer the furface, and confequently renders it more eafily cultivated: befides, this circumftance adapts it to a fhallow foil, in which, if left in its natural ftate, it would not grow.

The tranfplanting of lucerne is attended with many advantages. The land may be prepared in the fummer for receiving the plants from the nurfery in autumn; by which means the field muft be in a much better fituation than if the feed had been fown upon it in the fpring. By tranfplanting, the rows can be made more regular, and the intended diftances more exactly obferved; and confequently the hoeing can be performed more perfectly, and with lefs expence. M. Chateauvieux likewife tried the lucerne in fingle beds three feet wide, with fingle rows; in beds three feet nine inches wide, with double rows; and in beds four feet three inches wide, with triple rows. The plants in the fingle rows were fix inches afunder, and thofe in the double and triple rows were about eight or nine inches. In a courfe of three years he found, that a fingle row produced more than a triple row of the fame length. The plants of lucerne, when cultivated by tranfplantation, fhould be at leaft fix inches afunder, to allow them room for extending their crowns.

He further obferves, that the beds or ridges ought to be raifed in the middle; that a fmall trench, two or three inches deep, fhould be drawn in the middle; and that the plants ought to be fet in this trench, covered with earth up to the neck. He fays, that if the lucerne be fown in fpring, and in a warm foil, it will be ready for tranfplanting in September; that, if the weather be too hot and dry, the tranfplanting fhould be delayed till October; and that, if the weather be unfavourable during both thefe months, this operation muft be delayed till fpring. He further directs, that the plants fhould be carefully taken out of the nurfery, fo as not to damage the roots; that the roots be left only about fix or feven inches long; that the green crops be cut off within about two inches of the crown; that they be put into water as foon as taken up, there to remain till they are planted; and that they fhould be planted with a planting ftick, in the fame manner as cabbages.

He does not give particular directions as to the times of horfe-hoeing; but only fays, in general, that the

Culture of Grafs.

the intervals ſhould be ſtirred once in the month during the whole time that the lucerne is in a growing ſtate. He likewiſe obſerves, that great care ought to be taken not to ſuffer any weeds to grow among the plants, at leaſt for the firſt two or three years; and for this purpoſe, that the rows, as well as the edges of the intervals where the plough cannot go, ſhould be weeded by the hand.

393 Culture of burnet.

Burnet is peculiarly adapted to poor land; beſides, it proves an excellent winter-paſture when hardly any thing elſe vegetates. Other advantages are, It makes good butter; it never blows or ſwells cattle; it is fine paſture for ſheep; and will flouriſh well on poor, light, ſandy, or ſtony ſoils, or even on dry chalk hills.

The cultivation of it is neither hazardous nor expenſive. If the land is prepared as is generally done for turnips, there is no danger of its failing. After the firſt year, it will be attended with very little expence, as the flat circular ſpread of its leaves will keep down, or prevent the growth of weeds.

On the failure of turnips, either from the fly or the black worm, ſome of our farmers have ſown the land with burnet, and in March following had a fine paſture for their ſheep and lambs. It will perfect its ſeed twice in a ſummer; and this ſeed is ſaid to be as good as oats for horſes; but it is too valuable to be applied to that uſe.

It is ſometimes ſown late in the ſpring with oats and barley, and ſucceeds very well; but it is beſt to ſow it ſingly in the beginning of July, when there is a proſpect of rain, on a ſmall piece of land, and in October following tranſplant it in rows two feet apart, and about a foot diſtant in the rows. This is a proper diſtance, and gives opportunity for hoeing the intervals in the ſucceeding ſpring and ſummer.

After it is ſed down with cattle, it ſhould be harrowed clean. Some horſes will not eat it freely at firſt, but in two or three days they are generally very fond of it. It affords rich pleaſant milk, and in great plenty.

A gentleman farmer near Maidſtone, ſome years ſince, ſowed four acres as ſoon as the crop of oats was got off, which was the latter end of Auguſt. He threw in 12 pounds of ſeed per acre, broaſt-caſt; and no rain falling until the middle of September, the plants did not appear before the latter end of that month. There was however a good crop; and in the ſpring he ſet the plants out with a turnip hoe, leaving them about a foot diſtant from each other. But the drill method is preferable, as it ſaves more than half the ſeed. The land was a poor dry gravel, not worth three ſhillings an acre for any thing elſe.

The ſevereſt froſt never injures this plant; and the oftener it is fed the thicker are its leaves, which ſpring conſtantly from its root.

We ſhall here enumerate a few more of the graſſes which have been accounted valuable, or are likely to become ſo.

394 Bulbous foxtail-graſs.

Alopecurus bulboſus, BULBOUS FOXTAIL GRASS, is recommended by Dr Anderſon *, as promiſing on ſome occaſions to afford a valuable paſture-graſs. It ſeems chiefly, he obſerves, to delight in a moiſt ſoil, and therefore promiſes to be only fit for a meadow paſture-graſs. The quality that firſt recommended it to his notice, was the unuſual firmneſs that its matted roots gave to the ſurface of the ground, naturally ſoft and moiſt, in which it grew; which ſeemed to promiſe that it might be of uſe upon ſuch ſoils, chiefly in preventing them from being much poached by the feet of cattle which might paſture upon them. Moſſy ſoils eſpecially are ſo much hurt by poaching, that any thing that promiſes to be of uſe in preventing it deſerves to be attended to.

* *Eſſays on Agriculture*, &c.

Culture Graſs.

395 Great Meadow-graſs.

Poa pratenſis, GREAT MEADOW-GRASS, ſeems to approach in many reſpects to the nature of the purple feſcue; only that its leaves are broader, and not near ſo long, being only about a foot or 16 inches at their greateſt length. Like it, it produces few ſeed ſtalks and many leaves, and is an abiding plant. It affects chiefly the dry parts of meadows, though it is to be found on moſt good paſtures. It is very retentive of its ſeeds, and may therefore be ſuffered to remain till the ſtalks are quite dry. It bloſſoms the beginning of June, and its ſeeds are ripe in July.

396 Creeping meadow graſs.

Poa compreſſa, CREEPING MEADOW-GRASS, according to Dr Anderſon, ſeems to be the moſt valuable graſs of any of this genus. Its leaves are firm and ſuculent, of a dark Saxon-green colour; and grow ſo cloſe upon one another, as to form the richeſt pile of paſture-graſs. The flower-ſtalks, if ſuffered to grow, appear in ſufficient quantities: but the growth of theſe does not prevent the growth of the leaves, both advancing together during the whole ſummer; and when the ſtalks fade, the leaves continue as green as before. Its leaves are much larger and more abundant than the common meadow-graſs, *poa trivialis*; and therefore it better deſerves to be cultivated.

397 Vernal graſs.

Anthoxanthum odoratum, VERNAL GRASS, grows very commonly on dry hills, and likewiſe on found rich meadow-land. It is one of the earlieſt graſſes we have; and from its being found on ſuch kinds of paſtures as ſheep are fond of, and from whence excellent mutton comes, it is moſt likely to be a good graſs for ſheep paſtures. It gives a grateful odour to hay. In one reſpect, it is very eaſy to gather, as it ſheds its ſeeds upon the leaſt rubbing. A correſpondent of the Bath Society, however, mentions a difficulty that occurs in collecting them, owing to its being ſurrounded with taller graſſes at the time of its ripening, and being almoſt hid among them. If it be not carefully watched when nearly ripe, he obſerves, and gathered within a few days after it comes to maturity, great part of the ſeed will be loſt. The twiſted elaſtic awns, which adhere to the ſeed, lift them out of their receptacles with the leaſt motion from the wind, even while the ſtraw and ear remain quite erect. It is found moſtly in the moiſt parts of meadows; very little of it on dry paſtures. It flowers about the beginning of May, and is ripe about the middle of June.

398 Creſted dog's-tail graſs.

Cynoſurus criſtatus, CRESTED DOG'S TAIL GRASS. Mr Stillingfleet imagines this graſs to be proper for parks, from his having known one, where it abounds, that is famous for excellent veniſon. He recommends it alſo, from experience, as good for ſheep; the beſt mutton he ever taſted, next to that which comes from hills where the purple and ſheep's feſcue, the fine bent, and the ſilver hair graſſes abound, having been from ſheep fed with it. He adds, that it makes a very fine turf upon dry ſandy or chalky ſoils: but unleſs ſwept over with the ſcythe, its flowering-ſtems will look brown;

Culture of Grafs.

brown; which is the caſe of all graſſes which are not fed on by variety of animals. For that ſome animals will eat the flowering ſtems is evident from commons, where ſcarcely any parts of graſſes appear but the radical leaves. This graſs is ſaid to be the eaſieſt of the whole group to collect a quantity of ſeeds from. It flowers in June, and is ripe in July.

309 Cock's-tail, or feather graſs.

Stipa pennata, COCK'S-TAIL, or FEATHER GRASS.

400 Fine bent.

Agroſtis capillaris, FINE BENT, is recommended by Mr Stillingfleet, from his having always found it in great plenty on the beſt ſheep paſtures in the different counties of England that are remarkable for good mutton. This graſs flowers and ripens its ſeed the lateſt of them all. It ſeems to be loſt the former part of the year, but vegetates luxuriantly towards the autumn. It appears to be fond of moiſt grounds. It retains its ſeed till full ripe; flowers the latter end of July, and is ripe the latter end of Auguſt.

401 Mountain hair.

Aira flexuoſa, MOUNTAIN HAIR.

402 Silver hair.

—— *caryophillea*, SILVER HAIR.

The ſame may be ſaid of theſe two graſſes as of the preceding one.

403 Flote feſcue.

Feſtuca fluitans, FLOTE FESCUE. In a piece publiſhed in the Amœnitates Academicæ, vol. iii. entitled *Plantæ Eſculentæ*, we are informed, that "the ſeeds of this graſs are gathered yearly in Poland, and from thence carried into Germany, and ſometimes into Sweden, and ſold under the name of *manna ſeeds*.—Theſe are much uſed at the tables of the great, on account of their nouriſhing quality and agreeable taſte. It is wonderful (adds the author), that amongſt us theſe ſeeds have hitherto been neglected, ſince they are ſo eaſily collected and cleanſed." There is a clamminess on the ear of the flote feſcue, when the ſeeds are ripe, that taſtes like honey; and for this reaſon perhaps they are called *manna ſeeds*.

Linnæus (*Flor. Suec.* art. 95.) ſays that the bran of this graſs will cure horſes troubled with botts, if kept from drinking for ſome hours.

Concerning this graſs we have the following information by Mr Stillingfleet. "Mr Dean, a very ſenſible farmer at Ruſcomb, Berkſhire, aſſured me that a field, always lying under water, of about four acres, that was occupied by his father when he was a boy, was covered with a kind of graſs, that maintained five farm horſes in good heart from April to the end of harveſt, without giving them any other kind of food, and that it yielded more than they could eat. He, at my deſire, brought me ſome of the graſs, which proved to be the flote feſcue with a mixture of the marſh-bent; whether this laſt contributes much towards furniſhing ſo good paſture for horſes, I cannot ſay. They both throw out roots at the joints of the ſtalks, and therefore are likely to grow to a great length. In the index of dubious plants at the end of Ray's Synopſis, there is mention made of a graſs, under the name of *gramen caninum ſupinum longiſſimum*, growing not far from Saliſbury, 24 feet long. This muſt by its length be a graſs with a creeping ſtalk; and that there is a graſs in Wiltſhire growing in watery meadows, ſo valuable that an acre of it lets from 10 to 12 pounds, I have been informed by ſeveral perſons. Theſe circumſtances incline me to think it muſt be the flote feſcue; but whatever graſs it be, it certainly muſt deſerve to be inquired after.

Alopecurus pratenſis, MEADOW FOXTAIL. Linnæus ſays that this is a proper graſs to ſow on grounds that have been drained. Mr Stillingfleet was informed, that the beſt hay which comes to London is from the meadows where this graſs abounds. It is ſcarce in many parts of England, particularly Hereforddhire, Berkſhire, and Norfolk. It might be gathered at almoſt any time of the year from hay-ricks, as it does not ſhed its ſeeds without rubbing, which is the caſe of but few graſſes. It is among the moſt grateful of all graſſes to cattle. It is ripe about the latter end of June.

Culture of Grafs.

404 Meadow foxtail.

405 Annual meadow graſs.

Poa annua, ANNUAL MEADOW GRASS. "This graſs (ſays Mr Stillingfleet) makes the fineſt of turfs. It grows everywhere by way ſides, and on rich ſound commons. It is called in ſome parts the *Suffolk graſs*. I have ſeen whole fields of it in High Suffolk without any mixture of other graſſes; and as ſome of the beſt ſalt butter we have in London comes from that county, it is moſt likely to be the beſt graſs for the dairy. I have ſeen a whole park in Suffolk covered with this graſs; but whether it afford good veniſon, I cannot tell, having never taſted of any from it. I ſhould rather think not, and that the beſt paſture for ſheep is alſo the beſt for deer. However, this wants trial. I remarked on Malvern-hill ſomething particular in relation to this graſs. A walk that was made there for the convenience of the water drinkers, in leſs than a year was covered in many places with it, though I could not find one ſingle plant of it beſides in any part of the hill. This was no doubt owing to the frequent treading, which above all things makes this graſs flouriſh; and therefore it is evident that rolling muſt be very ſerviceable to it. It has been objected, that this graſs is not free from *bents*, by which word is meant the flowering-ſtems. I anſwer, that this is moſt certainly true, and that there is no graſs without them. But the flowers and ſtems do not grow ſo ſoon brown as thoſe of other graſſes; and being much ſhorter, they do not cover the radical leaves ſo much; and therefore this graſs affords a more agreeable turf without mowing than any other whatever that I know of." The ſeeds of this ſpecies drop off before they are dry, and to appearance, before they are ripe. The utmoſt care is therefore neceſſary in gathering the blades, without which very few of the ſeeds will be ſaved. It ripens from the middle of April, to ſo late, it is believed, as the end of October; but moſtly diſappears in the middle of the ſummer. It grows in any ſoil and ſituation, but rather affects the ſhade.

406 Agroſtis cornucopiæ.

A new graſs from America (named *Agroſtis cornucopiæ*), was ſome time ago much advertiſed and extolled, as poſſeſſing the moſt wonderful qualities, and the ſeeds of it were ſold at the enormous rate of 68l. the buſhel. But we have not heard that it has at all anſwered expectation. On the contrary, we are informed by Dr Anderſon, in one of his publications*, that "it has upon trial been found to be good for nothing. Of the ſeeds ſown, few of them ever germinated: but enough of plants made their appearance, to aſcertain, that the graſs, in reſpect of quality, is among the pooreſt of the tribe; and that it is an *annual* plant, and altogether unprofitable to the farmer."

* *Bee*, vol. i. p. 38.

Chicorum Intybus, Chicory.

407 Chicory.

Mr Arthur Young has anxiouſly endeavoured to diffuſe a knowledge of this plant, and he appears to

Culture of Grafs.

have been the firſt perſon that introduced it into the agriculture of England from France, where it grows naturally on the ſides of the roads and paths, and is ſometimes cultivated as a ſalad. When it has been ſown by itſelf, in ground prepared by good tillage, it has yielded two crops the ſame year. When ſown amongſt oats, no crop is expected till the following year. This plant defies the greateſt droughts, and reſiſts every ſtorm. Being of very early growth, its firſt leaves, which are large and tufted, ſpread ſidewiſe, and cover the ground ſo as to retain the moiſture and preſerve its roots from the heat which ſo often dries up every other vegetable production: it has not any thing to fear from ſtorms, for its thick and ſtiff ſtalks ſupport themſelves againſt the winds and heavieſt rains. The moſt ſevere cold and froſts cannot injure it. The quickneſs of its growth, above all, renders it moſt valuable, becauſe it furniſhes an abundance of ſalutary fodder in a ſeaſon, when the cattle, diſguſted with their dry winter food, greedily devour freſh plants.

This plant is greedily eaten by all ſorts of cattle, but it is difficult to make into hay. It is very voluminous, and drys ill, unleſs the weather be very favourable for it. The dry fodder, however, which it does yield, is eaten with pleaſure by the cattle. The following is the reſult of an experiment made with it by Mr Young upon an acre of ground

Annals of Agriculture, vol. xv.

The following Engliſh graſſes are recommended to attention by Mr Curtis, author of the *Flora Londinenſis*; and he has given directions for making experiments with graſs ſeeds in ſmall quantities.

408 Tall oat-graſs.

"*Avena elatior*, *tall oat graſs*; common in wet meadows, and by the ſides of hedges; early, and very productive, but coarſe.

409 Yellow oat-graſs.

"*Avena flaveſcens*, *yellow oat-graſs*; affects a dry ſoil, is early and productive, bids fair to make a good ſheep paſture.

410 Rough oat-graſs.

"*Avena pubeſcens*, *rough oat-graſs*; ſoil and ſituation nearly ſimilar to that of the meadow feſcue; hardy, early, and productive.

411 Upright broom-graſs.

"*Bromus erectus*, *upright broom-graſs*; peculiar to chalky ſoils; early and productive; promiſes to be a good graſs for chalky lands, and thrives indeed very well on others.

412 Blue dogs-tail

"*Cynoſurus cæruleus*, *blue dogs-tail graſs*; earlieſt of all the graſſes; grows naturally on the tops of the higheſt limeſtone rocks in the northern part of Great Britain: not very productive, yet may perhaps anſwer in certain ſituations, eſpecially as a graſs for ſheep; bears the drought of ſummer remarkably well: at all events ſeems more likely to anſwer than the *ſheeps feſcue graſs*, on which ſuch encomiums have, moſt unjuſtly, been laviſhed.

Culture of Graſs.

413 Rough cock's-foot graſs.

"*Dactylis glomeratus*, *rough cock's-foot graſs*; a rough coarſe graſs, but extremely hard and productive: ſoil and ſituation the ſame as the *meadow feſcue*.

414 Tall feſcue graſs.

"*Feſtuca elatior*, *tall feſcue graſs*; tall and coarſe, but very productive; affects wet ſituations.

415 Hard feſcue graſs.

"*Feſtuca duriuſcula*, *hard feſcue graſs*; affects ſuch ſituations as the *ſmooth-ſtalked meadow graſs*; is early and tolerably productive: its foliage is fine, and of a beautiful green; hence we have ſometimes thought it was of all others the fitteſt for a graſs-plat or bowling-green; but we have found, that though it thrives very much when firſt ſown or planted, it is apt to become thin, and die away after a while.

416 Meadow cat's-tail graſs.

"*Phleum pratenſe*, *meadow cats-tail graſs*; affects wet ſituations; is very productive, but coarſe and late."

To ſow graſs ſeeds in ſmall quantities, this author gives the following directions:—

417 Rules for making experiments with graſs ſeeds.

"If a piece of ground can be had, that is neither very moiſt nor very dry, it will anſwer for ſeveral ſorts of ſeed: they may then be ſown on one ſpot; but if ſuch a piece cannot be obtained, they muſt be ſown on ſeparate ſpots according to their reſpective qualities, no matter whether in a garden, a nurſery, or in a field, provided it be well ſecured and clean. Dig up the ground, level and rake it, then ſow each kind of ſeed thinly in a ſeparate row, each row about a foot apart, and cover them over lightly with the earth; the latter end of Auguſt or beginning of September will be the moſt proper time for this buſineſs. If the weather be not uncommonly dry the ſeeds will quickly vegetate, and the only attention they will require will be to be carefully weeded. In about a fortnight from their coming up, ſuch of the plants as grow thickly together may be thinned, and thoſe which are taken up tranſplanted ſo as to make more rows of the ſame graſs.

"If the winter ſhould be very ſevere, though natives, as ſeedlings, they may receive injury; therefore it will not be amiſs to protect them with mats, fern, or by ſome other contrivance.

"Advantage ſhould be taken of the firſt dry weather in the ſpring, to roll or tread them down, in order to faſten their roots in the earth, which the froſt generally looſens: care muſt ſtill be taken to keep them perfectly clear from weeds. As the ſpring advances, many of them will throw up their flowering ſtems, and ſome of them will continue to do ſo all the ſummer. As the ſeed in each ſpike or pannicle ripens, it muſt be very carefully gathered and ſown in the autumn, at which time the roots of the original plants, which will now bear ſeparating, ſhould be divided, and tranſplanted, ſo as to form more rows; the roots of the ſmooth-ſtalked meadow-graſs, in particular, creeping like couch-graſs, may readily be increaſed in this way; and thus by degrees a large plantation of theſe graſſes may be formed and much ſeed collected.

"While the ſeeds are thus increaſing, the piece or pieces

Culture of Grafs. pieces of ground, which are intended to be laid down, ſhould be got in order. If very foul, perhaps the beſt practice (if paſture land) will be to pare off the ſward and burn it on the ground: or if this ſhould not be thought adviſable, it will be proper to plough up the ground and harrow it repeatedly, burning the roots of couch-graſs and other noxious plants till the ground is become tolerably clean; to render it perfectly ſo, ſome cleanſing crop, as potatoes or turnips, ſhould be planted or ſown.

"By this means, the ground we propoſe laying down will be got into excellent order without much loſs; and being now ready to form into a meadow or paſture, ſhould be ſown broad-caſt with the following compoſitions:

Meadow fox-tail, one pint;
Meadow feſcue, ditto;
Smooth-ſtalked meadow, half a pint;
Rough-ſtalked meadow, ditto;
Creſted dog's-tail, a quarter of a pint;
Sweet ſcented vernal, ditto;
Dutch clover (trifolium repens), half a pint;
Wild red clover (trifolium pratenſe), or in its ſtead,
Broad clover of the ſhops, ditto;
For wet land, the *creſted dog's-tail* and *ſmooth-ſtalked meadow* may be omitted, eſpecially the former.

"Such a compoſition as this, ſown in the proportion of about three buſhels to an acre on a ſuitable ſoil, in a favourable ſituation, will, I am bold to aſſert, form in two years a moſt excellent meadow; and, as all the plants ſown are ſtrong, hardy perennials, they will not eaſily ſuffer their places to be uſurped by any noxious plants, which by manure or other means, in ſpite of all our endeavours, will be apt to inſinuate themſelves; if they ſhould, they muſt be carefully extirpated; for ſuch a meadow is deſerving of the greateſt attention: but if that attention cannot be beſtowed on it, and in proceſs of time weeds ſhould predominate over the crop originally ſown, the whole ſhould be ploughed up, and freſh ſown with the ſame ſeeds, or with a better compoſition, if ſuch ſhall be diſcovered; for I have no doubt but at ſome future time, it will be as common to ſow a meadow with a compoſition ſomewhat like this as it now is to ſow a field with wheat or barley.

"One of the moſt important improvements in agriculture that has occurred of late years, is the practice of overflowing or flooding graſs lands, which is now coming greatly into uſe, not only on level grounds, but in all ſituations in which a command of water can be obtained. In the Monthly Review for October 1788, the editors acknowledge the favour of a correſpondent, who informed them, that watering of meadows was practiſed during the reigns of Queen Elizabeth and James I. A book was written upon the ſubject by one Rowland Vaughan, who ſeems to have been the inventor of this art, and who practiſed it on a very extenſive plan in the Golden Valley in Herefordſhire. Till this note to the Reviewers appeared, the inhabitants of a village called South Cerney in Glouceſterſhire had aſſumed the honour of the invention to themſelves, as we are informed in a treatiſe upon the ſubject by the Rev. Mr Wright curate of the place. According to a received tradition in that village, watering of meadows has been practiſed there for about a century, and was introduced by one *Welladviſe*, a wealthy farmer in South Cerney. His firſt experiment was by cutting a large ditch in the middle of his ground, from which he threw the water over ſome parts, and allowed it to ſtagnate in others: but finding this not to anſwer his expectations, he improved his method by cutting drains and filling up the hollows; and thus he ſucceeded ſo well, that his neighbours, who at firſt called him a madman, ſoon changed their opinion, and began to imitate his example.

418 Then the watering of meadows as firſt practiſed in England.

Culture of Graſs.

419 Advantages of watering.

"The advantages which attend the watering of meadows are many and great; not only as excellent crops of graſs are thus raiſed, but as they appear ſo early, that they are of infinite ſervice to the farmers for food to their cattle in the ſpring before the natural graſs riſes. By watering we have plenty of graſs in the beginning of March, and even earlier when the ſeaſon is mild. The good effects of this kind of graſs upon all ſorts of cattle are likewiſe aſtoniſhing, eſpecially upon ſuch as have been hardly wintered; and Mr Wright informs us, that the farmers in his neighbourhood, by means of watering their lands, are enabled to begin the making of cheeſe at leaſt a month ſooner than their neighbours who have not the ſame advantage. Graſs raiſed by watering is found to be admirable for the nurture of lambs; not only thoſe deſigned for fattening, but ſuch as are to be kept for ſtore: For if lambs when very young are ſtopped and ſtinted in their growth, they not only become contracted for life themſelves, but in ſome meaſure communicate the ſame diminutive ſize to their young. The beſt remedy for preventing this evil is the ſpring feed from watered meadows; and Mr Wright is of opinion, that if the young of all kinds of farmer's ſtock were immediately encouraged by plenty of food, and kept continually in a growing ſtate, there would in a few years be a notable change both in the ſize and ſhape of cattle in general. Such indeed is the forwardneſs of graſs from watered meadows, that the feed between March and May is worth a guinea per acre; and in June an acre will yield two tons of hay, and the after-math is always worth twenty ſhillings; and nearly the ſame quantity is conſtantly obtained whether the ſummer be dry or wet. In dry ſummers alſo, ſuch farmers as water their meadows have an opportunity of ſelling their hay almoſt at any price to their neighbours.

420 Land conſtantly improves by watering.

"Land treated in this manner is continually improving in quality, even though it be mown every year: the herbage, if coarſe at firſt, becomes finer; the ſoil, if ſwampy, becomes ſound; the depth of its mould is augmented, and its quality meliorated every year.

"To theſe advantages (ſays Mr Boſwell in his treatiſe upon this ſubject) another may be addreſſed to the gentleman who wiſhes to improve his eſtate, and whoſe benevolent heart prompts him to extend a charitable hand to the relief of the induſtrious poor, and not to idleneſs and vice: almoſt the whole of the expence in this mode of cultivation is the actual manual labour of a claſs of people who have no genius to employ their bodily ſtrength otherwiſe for their own ſupport and that of their families; conſequently when viewed in this light, the expence can be but comparatively ſmall, the improvement great and valuable."

Culture of Grafs.

421 Example of the produce of a watered meadow.

As a proof of the above doctrine, Mr Wright adduces an inſtance of one year's produce of a meadow in his neighbourhood. It had been watered longer than the eldeſt perſon in the neighbourhood could remember; but was by no means the beſt meadow upon the ſtream, nor was the preceding winter favourable for watering. It contains ſix acres and a half. The ſpring feed was let for ſeven guineas, and ſupported near 200 ſheep from the 1ſt of March till the beginning of May: the hay being ſold for 30 guineas, and the after-math for ſix. Another and ſtill more remarkable proof of the efficacy of watering, is, that two of the moſt ſkilful watermen of that place were ſent to lay out a meadow of ſeven acres, the whole crop of which was that year ſold for two pounds. Though it was thought by many impoſſible to throw the water over it, yet the ſkill of the workmen ſoon overcame all difficulties; and ever ſince that time the meadow has been let at the rent of three pounds per acre. From manifold experience, our author informs us, that the people in that part of the country are ſo much attached to the practice of watering, that they never ſuffer the ſmalleſt ſpring or rivulet to be unemployed. Even thoſe temporary floods occaſioned by ſudden ſhowers are received into proper ditches, and ſpread equally over the lands until their fertilizing property be totally exhauſted. "Neceſſity (ſays he) indeed compels us to make the moſt of every drop: for we have near 300 acres in this pariſh, that muſt all, if poſſible, be watered; and the ſtream that affords the water ſeldom exceeds five yards in breadth and one in depth: therefore we may ſay, that a ſcarcity of water is almoſt as much dreaded by us as by the celebrated inhabitants of the banks of the Nile."

422 The practice of watering ought to be more generally extended.

Conſidering the great advantages to be derived from the practice of watering meadows, and the many undoubted teſtimonies in its favour, Mr Wright expreſſes his ſurpriſe, that it has not come into more general uſe, as there is not a ſtream of water upon which a mill can be erected but what may be made ſubſervient to the enriching of ſome land, perhaps to a great quantity. "I am confident (ſays he), that there are in each county of England and Wales 2000 acres upon an average which might be thus treated, and every acre increaſed at leaſt one pound in annual value. The general adoption therefore of watering is capable of being made a national advantage of more than 100,000l. per annum, beſides the great improvement of other land ariſing from the produce of the meadows and the employment of the induſtrious poor. Such an improvement, one would think, is not unworthy of public notice; but if I had doubled the ſum, I believe I ſhould not have exceeded the truth, though I might have gone beyond the bounds of general credibility. In this one pariſh where I reſide there are about 300 acres now watered: and it may be eaſily proved that the proprietors of the land reap from thence 1000l. yearly profit."

In Mr Boſwell's treatiſe upon this ſubject, publiſhed in 1790, the author complains of the neglect of the practice of improving the wet, boggy, and ruſhy lands, which lie at the banks of rivers, and might be meliorated at a very ſmall expence, when much larger ſums are expended in the improvement of barren uplands and large tracts of heath in various parts of the kingdom: and he complains likewiſe of the little information that is to be had in books concerning the method of performing this operation. The only author from whom he acknowledges to have received any information is Blyth; and even his method of watering is very different from that practiſed in modern times; for which reaſon he propoſes to furniſh an original treatiſe upon the ſubject; and of this we ſhall now give the ſubſtance.

Culture Graſs.

423 Land capable of being watered.

The firſt thing to be conſidered is, what lands are capable of being watered. Theſe, according to Mr Boſwell, are all ſuch as lie low, near the banks of rivulets and ſprings, eſpecially where the water courſe is higher than the lands, and kept within its bounds by banks. If the rivulet has a quick deſcent, the improvement by watering will be very great, and the expences moderate. On level lands the water runs but ſlowly, which is alſo the caſe with the large rivers; and therefore only a ſmall quantity of ground can be overflowed by them in compariſon of what can be done in other caſes: but the water of large rivers is generally poſſeſſed of more fertilizing properties than that of rivulets. In many caſes, however, the rivers are navigable, or have mills upon them; both of which are ſtrong objections to the perfect improvement of lands adjacent to them. From theſe conſiderations, our author concludes, that the watering of lands may be performed in the beſt and leaſt expenſive manner by ſmall rivulets and ſprings.

There are three kinds of ſoils commonly found near the banks of rivers and rivulets, the melioration of which may be attempted by watering. 1. A gravelly or ſound warm firm ſoil, or a mixture of the two together. This receives an almoſt inſtantaneous improvement; and the faſter the water runs over it the better. 2. Boggy, miry, and ruſhy ſoils, which are always found by the banks of rivers where the land is nearly level. Theſe alſo are greatly improved by watering; perhaps equally ſo with thoſe already deſcribed, if we compare the value of both in their unimproved ſtate, this kind of ground being ſcarce worth any thing in its unimproved ſtate. By proper watering, however, it may be made to produce large crops of hay, by which horned cattle may be kept through the winter and greatly forwarded; though, in its uncultivated ſtate, it would ſcarce produce any thing to maintain ſtock in the winter, and very little even in ſummer. Much more ſkill, as well as expence, however, is requiſite to bring this kind of land into culture than the former. 3. The ſoils moſt difficult to be improved are ſtrong, wet, and clay ſoils; and this difficulty is occaſioned both by their being commonly on a dead level, which will not admit of the water running over them; and by their tenacity, which will not admit of draining. Even when the utmoſt care is taken, unleſs a ſtrong body of water is thrown over them, and that from a river the water of which has a very fertilizing property, little advantage will be gained; but wherever ſuch advantages can be had in the winter, and a warm ſpring ſucceeds, theſe lands will produce very large crops of graſs.

424 Springs rivulets preferable to large rivers.

The advantage of uſing ſprings and rivulets for watering inſtead of large rivers is, that the expence of raiſing wares acroſs them will not be great; nor are they liable to the other objections which attend the

uſe

Culture of Grafs.

uſe of large rivers. When they run through a cultivated country alſo, the land floods occaſioned by violent rains frequently bring with them ſuch quantities of manure as contribute greatly to fertilize the lands, and which are totally loſt where the practice of watering is not in uſe.

Springs may be uſeful to the coarſe lands that lie near them, provided the water can be had in ſufficient quantity to overflow the lands. "By ſprings (ſays our author), are not here meant ſuch as riſe out of poor heath or boggy lands (for the water iſſuing from them is generally ſo ſmall in quantity, and always ſo very lean and hungry in quality, that little if any advantage can be derived from it); but rather the head of rivulets and brooks riſing out of a chalky and gravelly ſound firm ſoil, in a cultivated country. Theſe are invaluable; and every poſſible advantage ſhould be taken to improve the ground near them. The author knows a conſiderable tract of meadow-land under this predicament; and one meadow in particular that is watered by ſprings iſſuing immediately out of ſuch a ſoil, without any advantage from great towns, &c. being ſituated but a ſmall diſtance below the head of the rivulet, and the rivulet itſelf is fed all the way by ſprings riſing out of its bed as clear as cryſtal. The ſoil of the meadow is a good loam ſome inches deep, upon a fine ſpringy gravel. Whether it is from the heat of the ſprings, or whether the friction by the water running over the ſoil raiſes a certain degree of warmth favourable to vegetation, or from whatever cauſe it ariſes, the fecundity of this water is beyond conception; for when the meadow has been properly watered and well drained, in a warm ſpring, the graſs has been frequently cut for hay within five weeks from the time the ſtock was taken out of it, having eat it bare to the earth: almoſt every year it is cut in ſix weeks, and the produce from one to three waggon loads to an acre. In land thus ſituated, in the mornings and evenings in the months of April, May, and June, the whole meadow will appear like a large furnace: ſo conſiderable is the ſteam or vapour which ariſes from the warmth of the ſprings acted upon by the ſun-beams: and although the water is ſo exceeding clear, yet upon its being thrown over the land only a few days in warm weather, by dribbling through the graſs, ſo thick a ſcum will ariſe and adhere to the blades of the graſs, as will be equal to a conſiderable quantity of manure ſpread over the land, and (it may be preſumed from the good effects) ſtill more enriching.

"It is inconceivable what 24 hours water properly conveyed over the lands will do in ſuch a ſeaſon: a beautiful verdure will ariſe in a few days where a parched ruſty ſoil could only be ſeen; and one acre will then be found to maintain more ſtock than ten could do before."

425 Explanation of the terms uſed in watering.

Mr Boſwell next proceeds to an explanation of the terms uſed in this art; of the inſtruments neceſſary to perform it; and of the principles on which it is founded. The terms uſed are:

1. A WARE. This is an erection acroſs a brook, rivulet, or river, frequently conſtructed of timber, but more commonly of bricks or ſtones and timber, with openings to let the water paſs, from two to ten in number according to the breadth of the ſtream: the height being always equal to the depth of the ſtream compared with the adjacent land. The uſe of this is occaſionally to ſtop the current, and to turn it aſide into the adjacent lands.

Culture of Grafs.

2. A SLUICE is conſtructed in the ſame manner as a ware; only that it has but a ſingle paſſage for the water, and is put acroſs ſmall ſtreams for the ſame purpoſe as a ware.

3. A TRUNK is deſigned to anſwer the ſame purpoſes as a ſluice; but being placed acroſs ſuch ſtreams as either cattle or teams are to paſs over, or where it is neceſſary to carry a ſmall ſtream at right angles to a large one to water ſome lands lower down, is for theſe reaſons made of timber, and is of a ſquare figure. The length and breadth are various, as circumſtances determine.

4. A CARRIAGE is made of timber or of brick. If of timber, oak is the beſt; if of brick, an arch ought to be thrown over the ſtream that runs under it, and the ſides bricked up: But when made of timber, which is the moſt common material, it is conſtructed with a bottom and ſides as wide and high as the main in which it lies. It muſt be made very ſtrong, cloſe, and well jointed. Its uſe is to convey the water in one main over another, which runs at right angles to it; the depth and breadth are the ſame with thoſe of the main to which it belongs: and the length is determined by that which it croſſes. The carriage is the moſt expenſive inſtrument belonging to watering.

5. A DRAIN-SLUICE, or *Drain-Trunk*, is always placed in the lower part of ſome main, as near to the head as a drain can be found; that is, ſituated low enough to draw the main, &c. It is made of timber, of a ſquare figure like a trunk, only much ſmaller. It is placed with its mouth at the bottom of the main, and let down into the bank; and from its other end a drain is cut to communicate with ſome trench-drain that is neareſt. The dimenſions are various, and determined by circumſtances. The uſe of it is, when the water is turned ſome other way, to convey the leaking water that oozes through the hatches, &c. into the drain, that otherwiſe would run down into the tails of thoſe trenches which lie loweſt, and there poach and rot the ground, and probably contribute not a little to the making it more unſound for ſheep. This operation is of the utmoſt conſequence in watering; for if the water be not thoroughly drained off the land, the ſoil is rotted; and when the hay comes to be removed, the wheels of the carriages ſink, the horſes are mired, and the whole load ſometimes ſticks faſt for hours together. On the other hand, when the drain trunks are properly placed, the ground becomes firm and dry, and the hay is ſpeedily and eaſily removed.

7. HATCHES are beſt made of oak, elm, or deal; the uſe of them is to fit the openings of wares, trunks, or ſluices; and to keep back the water when neceſſary, from paſſing one way, to turn it another. They ought to be made to fit as cloſe as poſſible. When hatches belong to wares that are erected acroſs large ſtreams, or where the ſtreams fall quickly with heavy rains, when the hatches are in their places to water the meadows, they are ſometimes made ſo, that a foot or more of the upper part can be taken off, ſo that vent may be given to the ſuperfluous water, and yet enough retained for the purpoſe of watering the meadows. In

this

Culture of Grafs.

this caſe, they are called *flood-hatches*: but Mr Boſwell entirely diſapproves of this conſtruction, and recommends them to be made entire, though they ſhould be ever ſo heavy, and require the aſſiſtance of a lever to raiſe them up. For when the water is very high, and the hatches are ſuddenly drawn up, the water falls with great force upon the bed of the ware, and in time greatly injures it: but when the whole hatch is drawn up a little way, the water runs off at the bottom, and does no injury.

8. A HEAD MAIN, is a ditch drawn from the river, rivulet, &c. to convey the water out of its uſual current, to water the lands laid out for that purpoſe, by means of leſſer mains and trenches. The head-main is made of various dimenſions, according to the quantity of land to be watered, the length or deſcent of it, &c. Smaller mains are frequently taken out of the head one; and the only difference is in point of ſize, the ſecondary mains being much ſmaller than the other. They are generally cut at right angles, or nearly ſo with the other, though not invariably. The uſe of the mains, whether great or ſmall, is to feed the trenches with water, which branch out into all parts of the meadow, and convey the water to float the land. By ſome, theſe ſmaller mains are improperly called *carriages*.

9. A TRENCH is a ſmall ditch made to convey the water out of the mains for the immediate purpoſe of watering the land. It ought always to be drawn in a ſtraight line from angle to angle, with as few turnings as poſſible. It is never deep, but the width is in proportion to the length it runs, and the breadth of the plane between that and the trench-drain. The breadth tapers gradually to the lower end.

10. A TRENCH-DRAIN is always cut parallel to the trench, and as deep as the tail-drain water will admit, when neceſſary. It ought always, if poſſible, to be cut down to a ſtratum of ſand, gravel, or clay. If into the latter, a ſpade's depth into it will be of great advantage. The uſe of it is to carry away the water immediately after it has run over the panes from the trench. It need not be drawn up to the head of the land by five, ſix, or more yards, according to the nature of the ſoil. Its form is directly the reverſe of the trench; being narrower at the head, and growing gradually wider and wider until it empties itſelf into the tail drain.

11. The TAIL-DRAIN is deſigned as a receptacle for all the water that flows out of the other drains, which are ſo ſituated that they cannot empty themſelves into the river. It ſhould run, therefore, nearly at right angles with the trenches, though generally it is thought moſt eligible to draw it in the loweſt part of the ground, and to uſe it to convey the water out of the meadows at the place where there is the greateſt deſcent; which is uſually in one of the fence-ditches: and hence a fence-ditch is uſually made uſe of inſtead of a tail drain, and anſwers the double purpoſe of fencing a meadow, and draining it at the ſame time.

12. A PANE of ground is that part of the meadow which lies between the trench and the trench-drain; and in which the graſs grows for hay. It is watered by the trenches, and drained by the trench-drains; whence there is a pane on each ſide of every trench.

13. A WAY-PANE is that part of the ground which lies in a properly watered meadow, on the ſide of the main where no trenches are taken out, but is watered the whole length of the main over its banks. A drain for carrying off the water from this pane runs parallel to the main. The uſe is to convey the hay out of the meadows, inſtead of the teams having to croſs all the trenches. Culture Graſs

14. A BEND is made in various parts of thoſe trenches which have a quick deſcent, to obſtruct the water. It is made, by leaving a narrow ſtrip of green ſward acroſs the trench where the bend is intended to be left; cutting occaſionally a piece of the ſhape of a wedge out of the middle of it. The uſe is to check the water, and force it over the trench into the panes; which, were it not for theſe bends, would run rapidly on in the trench, and not flow over the land as it paſſes along. The great art in watering conſiſts in giving to each part of the panes an equal proportion of water.

15. A GUTTER is a ſmall groove cut out from the tails of theſe trenches where the panes run longer at one corner than the other. The uſe is to carry the water to the extreme point of the pane. Thoſe panes which are interſected by the trench and tail-drains, meeting in an obtuſe angle, require the aſſiſtance of gutters to convey the water to the longeſt ſide. They are likewiſe uſeful, when the land has not been ſo well levelled, but ſome part of the panes lie higher than they ought: in which caſe, a gutter is drawn from the trench over that high ground, which otherwiſe would not be overflowed. Without this precaution, unleſs the flats be filled up (which ought always to be done when materials can be had to do it) the water will not riſe upon it; and after the watering ſeaſon is paſt, thoſe places would appear ruſty and brown, while the reſt is covered with beautiful verdure. Our author, however, is of opinion, that this method of treating water meadows ought never to be followed; but that every inequality in water meadows ſhould either be levelled or filled up. Hence the waterman's ſkill is ſhown in bringing the water over thoſe places to which it could not naturally riſe, and in carrying it off from thoſe where it would naturally ſtagnate.

16. A CATCH-DRAIN is ſometimes made uſe of when water is ſcarce. When a meadow is pretty long, and has a quick deſcent, and the water runs quickly down the drains, it is cuſtomary to ſtop one or more of them at a proper place, till the water flowing thither riſes ſo high as to ſtrike back either into the tail drains ſo as to ſtagnate upon the ſides of the panes, or till it flows over the banks of the drains, and waters the grounds below, or upon each ſide. It is then to be conveyed over the land in ſuch quantity as is thought proper, either by a ſmall main, out of which trenches are to be cut with their proper drains, or by trenches taken properly out of it. In caſe of a ſtagnation, the deſign will not ſucceed; and it will then be neceſſary to cut a paſſage to let the ſtagnating water runs off. Even when the method ſucceeds beſt, Mr Boſwell is of opinion, that it is not by any means eligible; the water having been ſo lately ſtrained over the ground, that it is ſuppoſed by the watermen not to be endowed with ſuch fertilizing qualities as at firſt; whence nothing but abſolute neceſſity can juſtify the practice.

17. A POND is any quantity of water ſtagnating upon

upon the ground, or in the tail-drain, trench-drains, &c. ſo as to annoy the ground near them. It is occaſioned ſometimes by the flats not having been properly filled up; at others, when the ware not being cloſe ſhut, in order to water ſome grounds higher up, the water is thereby thrown back upon the ground adjacent.

18. A TURN of water ſignifies as much ground as can be watered at once. It is done by ſhutting down the hatches in all thoſe wares where the water is intended to be kept out, and opening thoſe that are to let the water through them. The quantity of land to be watered at once muſt vary according to circumſtances; but Mr Boſwell lays down one general rule in this caſe, viz. that no more land ought to be kept under water at one time than the ſtream can ſupply regularly with a ſufficient quantity of water; and if this can be procured, water as much ground as poſſible.

19. The HEAD of the meadow, is that part of it into which the river, main, &c. firſt enter.

20. The TAIL is that part out of which the river, &c. laſt paſſes.

21. The UPPER SIDE of a main or trench, is that ſide which (when the main or trench is drawn at right angles, or nearly ſo, with the river) fronts the part where the river entered. The lower ſide is the oppoſite.

22. The UPPER PANE in a meadow, is that which lies on the upper ſide of the main or trench that is drawn at right angles with the river: where the river runs north and ſouth, it enters in the former direction, and runs out in the ſouthern, the main and trenches running eaſt and weſt. Then all thoſe panes which lie on the north ſide of the mains are called *upper* panes; and thoſe on the ſouth ſide the *lower* panes. But when the mains, trenches, &c. run parallel to the river, there is no diſtinction of panes into upper and lower.

The inſtruments uſed in watering meadows are:

1. A *Water level*. The uſe of this is to take the level of the land at a diſtance, and compare it with that of the river, in order to know whether the ground can be overflowed by it or not. This inſtrument, however, is uſed only in large undertakings; for ſuch as are on a ſmaller ſcale, the workmen diſpenſe with it in the following manner: In drawing a main, they begin at the head, and work deep enough to have the water follow them. In drawing a tail drain, they begin at the lower end of it and work upwards, to let the tail water come after them. By this method we obtain the moſt exact level.

2. The *Line*, *Reel*, and *Breaſt-Plough*, are abſolutely neceſſary. The line ought to be larger and ſtronger than that uſed by gardeners.

3. *Spades*. Thoſe uſed in watering meadows are made of a particular form, on purpoſe for the work: having a ſtem conſiderably more crooked than thoſe of any other kind. The bit is iron, about a foot wide in the middle, and terminating in a point: a thick ridge runs perpendicularly down the middle, from the ſtem almoſt to the point. The edges on both ſides are drawn very thin, and being frequently ground and whetted, the whole ſoon becomes narrow; after which the ſpades are uſed for trenches and drains; new ones being procured for other purpoſes. The ſtems being made crooked, the workmen ſtanding in the trench or drains are enabled to make the bottoms quite ſmooth and even.

4. *Wheel* and *Hand-barrows*. The former are uſed for removing the clods to the flat places, and are quite open, without any ſides or hinder part. The latter are of ſervice where the ground is too ſoft to admit the uſe of wheel-barrows, and when clods are to be removed during the time that the meadow is under water.

5. *Three-wheeled Carts* are neceſſary when large quantities of earth are to be removed; particularly when they are to be carried to ſome diſtance.

6. Short and narrow *Scythes* are made uſe of to mow the weeds and graſs, when the water is running in the trenches, drains, and mains.

7. *Forks*, and long *Crooks* with four or five tines, are uſed for pulling out the roots of ſedges, ruſhes, reeds, &c. which grow in the large mains and drains. The crooks ſhould be made light, and have long ſtems to reach wherever the water is ſo deep that the workmen cannot work in it.

8. Strong *Water-boots*, the tops of which will draw up half the length of the thigh, are indiſpenſably neceſſary. They muſt alſo be large enough to admit a quantity of hay to be ſtuffed down all round the legs, and be kept well tallowed to reſiſt the running water for many hours together.

426 Principles on which the practice of watering depends.

The principles on which the practice of watering meadows depend are few and eaſy.

1. Water will always riſe to the level of the receptacle out of which it is originally brought.

2. There is in all ſtreams a deſcent greater or ſmaller; the quantity of which is in ſome meaſure ſhown by the running of the ſtream itſelf. If it run ſmooth and ſlow, the deſcent is ſmall; but if rapidly and with noiſe, the deſcent is conſiderable.

3. Hence if a main be taken out of the river high enough up the ſtream, water may be brought from that river to flow over the land by the ſide of the river, to a certain diſtance below the head of the main, although the river from whence it is taken ſhould, oppoſite to that very place, be greatly under it.

4. Water, ſunk under a carriage which conveys another ſtream at right angles over it, one, two, or more feet below its own bed, will, when it has paſſed the carriage, riſe again to the level it had before.

5. Water conveyed upon any land, and there left ſtagnant for any length of time, does it an injury; deſtroying the good herbage, and filling the place with ruſhes, flags, and other weeds.

6. Hence it is abſolutely neceſſary, before the work is undertaken, to be certain that the water can be thoroughly drained off.

427 Wright's method

In Mr Wright's treatiſe upon this ſubject, the author conſiders a ſolution of the three following queſtions as a neceſſary preliminary to the operation of watering. 1. Whether the ſtream of water will admit of a temporary dam or ware acroſs it? 2. Can the farmer raiſe the water by this means a few inches above its level, without injuring his neighbour's land? 3. Can the water be drawn off from the meadow as quick as it is brought on? If a ſatisfactory anſwer can be given

to

Culture of Graſs.

to all theſe queſtions, he directs to proceed in the following manner.

Having taken the level of the ground, and compared it with the river, as directed by Mr Boſwell, cut a deep wide nich as near the dam as poſſible, and by it convey the water directly to the higheſt part of the meadow; keeping the ſides or banks of the ditch of an equal height, and about three inches higher than the general ſurface of the meadow. Where the meadow is large, and has an uneven ſurface, it will ſometimes be neceſſary to have three works in different directions, each five feet wide, if the meadow contains 15 acres, and if the higheſt part be fartheſt from the ſtream. A ditch of 10 feet wide and three deep will commonly water 10 acres of land. When there are three works in a meadow, and flood hatches at the mouth of each, when the water is not ſufficient to cover the whole completely at once, it may be watered at three different times, by taking out one of the hatches, and keeping the other two in. In this caſe, when the water has run over one diviſion of the land for 10 days, it may then be taken off that and tumbled over to another, by taking up another hatch and letting down the former; by which means the three diviſions will have a proper ſhare of the water alternately, and each reap equal benefit. The bottom of the firſt work ought to be as deep as the bottom of the river, when the fall of the meadow will admit of it; for the deeper the water is drawn, the more mud it carries along with it. From the works, cut at right angles, ſmaller ditches or troughs, having a breadth proportioned to the diſtance to which ſome part of the water is to be carried, their diſtance from each other being about 12 yards. A trough two feet wide and one foot deep, will water a ſurface 12 yards wide and 40 feet long. In each trough as well as ditch place frequent ſtops and obſtructions, eſpecially when the water is rapid, to keep it high enough to flow through the notches or over the ſides. Each ditch and trough is gradually contracted in width, as the quantity of water conſtantly decreaſes the farther they proceed. Between every two troughs, and at an equal diſtance from both, cut a drain as deep as you pleaſe parallel to them, and wide enough to receive all the water that runs over the adjacent lands, and to carry it off into the maſter-drain with ſuch rapidity as to keep the whole ſheet of water in conſtant motion; and if poſſible, not to ſuffer a drop to ſtagnate upon the whole meadow. "For a ſtagnation, ſays he, (though it is recommended by a Mr D. Young for the improvement of arable land), is what we never admit in our ſyſtem of watering; for we find that it rots the turf, ſoaks and ſtarves the land, and produces nothing but coarſe graſs and aquatic weeds.

"When a meadow lies cold, flat, and ſwampy, the width of the bed, or the diſtance between the trough and drain, ought to be very ſmall, never exceeding ſix yards: indeed, in this caſe, you can ſcarcely cut your land too much, provided the water be plentiful; for the more you cut, the more water you require. The fall of the bed in every meadow ſhould be half an inch in a foot: leſs will do, but more is deſirable; for when the draught is quick, the herbage is always fine and ſweet. The water ought never to flow more than two inches deep, nor leſs than one inch, except in the warm months."

Culture of Graſs.

Mr Wright proceeds now to anſwer ſome objections made by the Reviewers in their account of the firſt edition of his work. 1. That the Glouceſterſhire farmers uſe more works for their lands than is neceſſary. To this it is anſwered, That where water is plentiful, they find it advantageous to uſe even more water than he recommends; and when water is ſcarce, they chooſe rather to water only one half, or even a ſmaller portion of a meadow at a time, and to give that a plentiful covering, than to give a ſcanty one to the whole. 2. The Reviewers likewiſe recommend a repeated uſe of the ſame water upon different and lower parts of the ſame meadow, or to make each drain ſerve as a trough to the bed which is below it. But though this method is in ſome degree recommended by the celebrated Mr Bakewell, and taught by a ſyſtematic waterer in Staffordſhire, he entirely diſapproves of it; excepting where the great declivity of the land will not admit of any other plan. "This cannot (ſays he) be a proper mode of watering graſs-land in the winter time; for it can be of no ſervice to the loweſt parts of the meadow, unleſs as a wetting in ſpring or ſummer. The firſt or higheſt part of a meadow laid out according to this plan will indeed be much improved; the ſecond may reap ſome benefit; but the third, which receives the exhauſted thin cold water, will produce a very unprofitable crop. Our farmers never chooſe more than a ſecond uſe in the ſame meadow, and that very ſeldom; they call even the ſecond running by the ſignificant name of *ſmall beer*; which, they ſay, may poſſibly ſatisfy thirſt, but can give very little life or ſtrength to land. It is a much better method to have a meadow laid out ſo as to be watered at ſeveral times, and to be at the expence of ſeveral ſmall flood-hatches, than to water the whole of it at once by means of catch-drains.

428 Objection to his method anſwered.

429 A repeated uſe of the ſame water is not eligible.

"Sometimes it is neceſſary, in a large meadow, to convey the water that has been uſed under the works and troughs; and then the water above is ſupported by means of boards and planks, which we call a *carry-bridge*. Sometimes, the better to regulate the courſe of the water on the ſurface, eſpecially in the ſpring, narrow trenches are dug, and the mould laid by the ſide of them, in order to be reſtored to its former place when the watering is finiſhed. The earth and mud thrown out in cleanſing and paring the ditches ſhould be carried to fill up the low hollow parts of the meadow, and be trodden down with an even ſurface; which will eaſily be done when the water is on, the waterman being always provided with a ſtrong pair of water-proof boots. If the mould thus uſed has upon it a turf that is tolerably fine, place it uppermoſt; but if it is ſedgy and coarſe, turn it under, and the water if it runs quick will ſoon produce a fine herbage upon it.

"The grounds that are watered in the eaſieſt and moſt effectual manner, are ſuch as have been ploughed and ridged up in lands about twelve yards wide. Here the water is eaſily carried along the ridge by means of a ſmall ditch or trough cut along its ſummit, and then, by means of the ſtops in it, is made to run down the ſides or beds into the furrows, by which it is carried into

Culture of Grafs.

into the maſter-drain, which empties itſelf into the river. Every meadow, before it is well watered, muſt be brought into a form ſomething like a field that has been thus left by the plough in a ridged ſtate. Each ſide of the ridge ſhould be as nearly as poſſible an exact inclined plane, that the water may flow over it as equally as may be." Mr Wright does not, like Mr Boſwell, diſapprove of the uſe of flood-hatches; he only gives the following hint, viz. that their baſis ſhould be deep and firmly fixed, well ſecured with ſtone and clay, that it be not blown up. The following directions are given for each month of watering.

430 Of cleaning and repairing the works.

In the beginning of November, all the ditches, troughs, and drains, are to be thoroughly cleanſed by the ſpade and breaſt-plough, from weeds, graſs, and mud; and well repaired, if they have received any injury from cattle.

431 Thick and muddy water to be uſed when it can be done.

After a ſhower, when the water is thick and muddy, turn over the meadow as much water as you can without injuring the banks of the works, eſpecially if the land be poor; as in this month, according to our author, the water contains many more fertilizing particles, which he calls *ſalts* and *richneſs*, than later in the winter. In defence of this poſition, of which it ſeems the Monthly Reviewers have doubted, our author urges, that though he is not able to prove it by any chemical analyſis, yet it ſeems evident, that "after the firſt waſhing of farm yards, various ſinks, ditches, and the ſurface of all the adjoining fields, which have lain dry for ſome time, the common ſtream ſhould then contain much more fatneſs than when the ſame premiſes have been repeatedly waſhed." This is confirmed by the experience of the Glouceſterſhire farmers; who, if they can at this ſeaſon of the year procure plenty of muddy water to overflow their grounds for one week, look upon it to be equally valuable with what is procured during all the reſt of the winter. In ſupport of this, he quotes the followings words of Mr Forbes, in a treatiſe on watering: "The water ſhould be let in upon the meadow in November, when the firſt great rains make it muddy, for then it is full of a rich ſediment, brought down from the lands of the country through which it runs, and is waſhed into it by the rain; and as the ſediment brought by the firſt floods is the richeſt, the carriages and drains of the meadow ſhould all be ſcoured clean and in order, before theſe floods come."

"In oppoſition (adds Mr Wright) to the opinion of practical waterers, that the muddineſs of the water is of little conſequence, I heſitate not to affirm, that the mud is of as much conſequence in winter-watering, as dung is in the improvement of a poor upland field. For each meadow in this neighbourhood is fruitful in proportion to the quantity of mud that it collects from the water. And, indeed, what can be conceived more enriching than the abundant particles of putrid matter which float in the water, and are diſtributed over the ſurface of the land, and applied home to the roots of the graſs. It is true, that any the moſt ſimple water thrown over a meadow in proper quantity, and not ſuffered to ſtagnate, will ſhelter it in winter, and in the warmth of ſpring will force a crop; but this unuſual force muſt exhauſt the ſtrength of the land, which will require an annual ſupply of manure in ſubſtance, or, in a courſe of years, the ſoil will be impaired rather than improved. The meadows in this county, which lie next below a market town or village, are invariably the beſt; and thoſe which receive the water after it has been two or three times uſed, reap proportionably leſs benefit from it: For every meadow that is well laid out, and has any quantity of graſs upon its ſurface, will act as a fine ſieve upon the water, which, though it flow in ever ſo muddy, will be returned back to the ſtream as clear as it came from the fountain. This circumſtance, when there is a range of meadows to be watered, the property of different perſons, when water is ſcarce, creates vehement contentions and ſtruggles for the firſt uſe of it. The proprietors are therefore compelled to agree among themſelves, either to have the firſt uſe alternately, or for the higher meadows to dam up, and uſe only one half or a leſs portion of the river. Our farmers know the mud to be of ſo much conſequence in watering, that whenever they find it collected at the bottom of the river, or the ditches, they hire men whole days to diſturb and raiſe it with rakes made for the purpoſe, that it may be carried down by the water, and ſpread upon their meadows. One meadow in South Cerney, I think, is an inconteſtible proof of the conſequence of muddy water. It is watered by a branch of the common ſtream that runs for about half a mile down a public road. This water, by the mud on the road being continually diſturbed by carriages and the feet of cattle, becomes very thick, and when it enters the meadow is almoſt as white as milk. This field, which conſiſts of ſeven acres, was a few years ago let for 10s. an acre, but is already become the richeſt land in the pariſh, and has produced at one crop eighteen loads of hay, and each load more than 25 hundred weight."

Culture of Graſs.

432 Inſtance of the good effects of muddy water.

In further confirmation of what our author aſſerts, he quotes, from the Annals of Agriculture, the following words of Mr Wimpey: "As to the ſorts of water, little is to be found, I believe, which does not encourage and promote vegetation, even the moſt ſimple, elementary, and uncompounded fluid: heat and moiſture, as well as air, are the *ſine qua non* of vegetation as well as animal life. Different plants require different proportions of each to live and flouriſh; but ſome of each is abſolutely neceſſary to all. However, experience as well as reaſon univerſally ſhows, that the more turbid, feculent, and replete with putreſcent matter the water is, the more rich and fertilizing it proves. Haſty and impetuous rains, of continuance ſufficient to produce a flood, not only diſſolve the ſalts, but waſh the manure in ſubſtance off the circumjacent land into the rapid current. Such turbid water is both meat and drink to the land; and, by the unctuous ſediment and mud it depoſits, the ſoil is amazingly improved and enriched. The virtue of water from a ſpring, if at all ſuperior to pure elementary water, is derived from the ſeveral ſtrata or beds of earth it paſſes through, which, according to the nature of ſuch ſtrata, may be friendly or otherwiſe to vegetation. If it paſſes through chalk, marl, foſſil ſhells, or any thing of a calcareous nature, it would in moſt ſoils promote the growth of plants; but if through metallic ores, or earth impregnated with the vitriolic acid, it would render the land unfertile, if not wholly barren. In general the water that has run far is ſuperior to that which immediately flows from the ſpring, and more eſpecially that which is feculent and muddy, con-

433 Mr Wimpey's opinion upon the ſubject.

Culture of Graſs.

434 Confirmed by Mr Forbes.

435 Mr Boſwell's opinion.

436 Advantag of land-floods.

437 Of conver ing arable land into paſture.

ſifting chiefly of putrid animal ſubſtances waſhed down the ſtream."

To the ſame purpoſe alſo ſays Mr Forbes: "There is great difference in the quality of water, ariſing from the particles of different kinds of matter mixed with them. Thoſe rivers that have a long courſe through good land, are full of fine particles, that are highly fertilizing to ſuch meadows as are uſually overflowed by them; and this chiefly in floods, when the water is fulleſt of a rich ſediment: for when the water is clear, though it may be raiſed by art high enough to overflow the adjoining lands, and be of ſome ſervice to them, the improvement thus made is far ſhort of what is obtained from the ſame water when it is thick and muddy."

Mr Boſwell, though quoted by Mr Wright as an advocate for the doctrine juſt now laid down, ſeems, in one part of his work at leaſt, to be of a contrary opinion. This is in the 14th chapter of his book, where he remarks upon another publication on the ſame ſubject, the name of which he does not mention: "In page 4. of that pamphlet (ſays Mr Boſwell), the writer informs us, 'if the water uſed be always pure and ſimple, the effect will by no means be equal to the above; that is, of a ſtream that is ſometimes thick and muddy. We have a ſtriking inſtance of this in two of our meadows, which are watered immediately from ſprings that ariſe in the grounds themſelves. Their crops are early and plentiful, but not of a good quality, and the land remains unimproved after many years watering.'

"The writer of this treatiſe (Mr Boſwell), in a former edition, had aſſerted, and in this repeated, the contrary effects from a ſtream very near the ſpring-head, as clear as cryſtal.

"The gentleman (Mr Beverly of Keld) whom that writer mentions in his preface, made a ſhort viſit laſt ſpring into Dorſetſhire, to ſatisfy himſelf of the fact. The editor had the pleaſure to ſhow him the ſtream alluded to, which he traced almoſt to the fountain-head. It was perfectly clear, and the water was then immediately conveyed out of the ſtream upon the lands adjoining, ſome of which it was then running over; others it had been upon, and the verdure was then appearing. The gentleman expreſſed himſelf perfectly ſatisfied with the fact. To him the editor wiſhes to refer, &c. Mr George Culley of Fenton near Wooler in Northumberland, with a truly noble and public ſpirit that does him great honour as a friend to his country, ſent a very ſenſible young man from thence into Dorſetſhire, to learn the art of watering meadows, and to work the whole ſeaſon in thoſe meadows under different watermen. This man was often over thoſe meadows, and worked in ſome juſt below that were watered by the ſame ſtream. Might the editor preſume to offer his opinion upon this ſeeming contradiction, it is very probable that the ſoils, both the upper and under ſtrata, are very diffrent, as well as thoſe through which the different ſprings run."

From this paſſage, the latter part of which is not very intelligible, we might conclude that Mr Boſwell prefers clear to muddy water for overflowing meadows. In his chapter on land-floods, however, he expreſſes himſelf as follows: "They will (ſays he) always be found of great uſe where the ſweepings of towns, farm-yards, &c. are carried down by them; feldom any other erection is wanting beſides a ſluice or ſmall ware to divert and convey them over the lands. If the ſituation of the land happen to be on the ſide of a hill, catch-drains are abſolutely neceſſary for watering the lower part of the hill, after the water has been uſed upon the upper. In many parts of the kingdom, where there are large hills or extenſive riſing lands, great quantities of water run from them into the valleys after heavy rains: Theſe might with proper attention be collected together before they get to the bottom or flat ground, and from thence be diverted to the purpoſe of watering thoſe lands that lie below, with great advantage to the occupier, and at a ſmall expence. And ſhould the land thus ſituated be arable, yet it would be found a beneficial exchange to convert it into paſture; particularly if paſture-ground ſhould be a deſirable object to the occupier. The method of performing it is thus recommended. Obſerve the piece of land or field beſt adapted to the purpoſe, both for ſituation and ſoil. If it ſhould be arable, make it firſt very level; and with the crop of corn ſow all ſorts of hay ſeeds; and as ſoon as it has got a green ſward it may be laid out. In the loweſt part of the ground draw a deep ditch for the current to run in through it; and continue it into ſome ditch or low part in the lands below, that the water may be freely carried off, after it has been and while it is in uſe. Draw ditches above the field intended to be watered aſlant the ſides of the hill, in ſuch a manner that they may all empty themſelves into the head of the ditch above mentioned, juſt where it enters the field to be watered; then erecting a ware acroſs this ditch, the field will be capable of being watered, according to the ſituation of the ditch in the middle or on the ſide of the field. It muſt then be conveyed by ſmall mains or trenches, and ſubdivided again by branch-trenches, according to the ſite of the field and quantity of water that can be collected; trench-drains muſt be drawn, and the water conveyed into the ditch by means of tail-drains. A perſon unacquainted with water-meadows cannot conceive the advantage ariſing from water thus collected, and conveyed over this ſpecies of water-meadow (if it may be ſo called), being generally a firm good ſoil; but the water running down from rich cultivated hills, eminences, &c. ſweeps away with it, when the rain falls very heavy, vaſt quantities of dung dropped by ſheep and other cattle, and the manure carried upon arable lands; all which being now diverted, and carried over the meadow with an eaſy deſcent, gives time for the particles of manure to ſubſide upon the ground at one ſeaſon, or of being filtered from it as it dribbles through the graſs at another; after which the warm weather puſhes on vegetation amazingly. Meadows thus ſituated would be vaſtly ſuperior to any other, if they had the advantage of a conſtant ſtream; but even as they are, taking the opportunity of watering them by every heavy rain or flood that happens, they will be found to be very valuable. The occupier of ſuch lands is ſtrenuouſly adviſed to let no time be loſt in appropriating them to this uſe; becauſe theſe lands are healthy for all kinds of cattle at almoſt all ſeaſons; and the expence of converting

Culture of Grafs.

verting them into this kind of water-meadow is exceeding ſmall, the annual charges afterwards quite trifling, and the produce very conſiderable."

438 Mr Wright's directions for watering through the different months of the year.

Mr Wright, having diſcuſſed the ſubject of the quality of the water, proceeds to give directions for watering through the different months of the year;—"In December and January, the chief care conſiſts in keeping the land ſheltered by the water from the ſeverity of froſty nights. It is neceſſary, however, through the whole winter, every ten days or fortnight, to give the land air, by taking the water off entirely, otherwiſe it would rot and deſtroy the roots of the graſs. It is neceſſary, likewiſe, that a proper perſon ſhould go over every meadow at leaſt twice every week, to ſee that the water is equally diſtributed, and to remove all obſtructions ariſing from the continual influx of weeds, leaves, ſticks, and the like. In February, a great deal depends upon care and caution. If you now ſuffer the water to remain on the meadow for many days without intermiſſion, a white ſcum is raiſed, very deſtructive to the graſs; and if you take off the water, and expoſe the land to a ſevere froſty night, without its being previouſly dried for a whole day, the greateſt part of the tender graſs will be cut off. The only ways to avoid both theſe injuries are, either to take the water off by day to prevent the ſcum, and to turn it over again at night to guard againſt the froſt; or, if this practice be too troubleſome, both may be prevented by taking the water entirely off for a few days and nights, provided the firſt day of taking off be a dry one; for if the graſs experience one fine drying day, the froſt at night can do little or no injury. The ſcum is generated chiefly by the warmth of the ſun, when the water is thin and uſed too plentifully. Towards the middle of this month we vary our practice in watering, by uſing only about half the quantity of water which is made uſe of earlier in the winter, all that is now required being to keep the ground in a warm moiſt ſtate, and to force vegetation.

"At the beginning of March, the crop of graſs in the meadows is generally ſufficient to afford an abundant paſture for all kinds of ſtock, and the water is taken off for near a week, that the land may become dry and firm before the heavy cattle are turned in.—It is proper, the firſt week of eating off the ſpring-feed, if the ſeaſon be cold, to give the cattle a little hay each night."

439 f eating f the ring graſs ith ewes id lambs.

"It is a cuſtom (ſays Mr Wright) with ſome farmers in Hampſhire, to eat off the ſpring graſs of their meadows with ewes and lambs, in the ſame manner that we do a field of turnips, by incloſing a certain portion each day with hurdles or ſtakes, and giving them hay at the ſame time. This is certainly making the moſt of the graſs, and an excellent method to fine and ſweeten the future herbage. In this month and April, you may eat the graſs as ſhort and cloſe as you pleaſe, but never later; for if you treſpaſs only one week on the month of May, the hay-crop will be very much impaired, the graſs will become ſoft and woolly, and have more the appearance and quality of an after-math than a crop. At the beginning of May, or when the ſpring-feeding is finiſhed, the water is again uſed for a few days by way of wetting.

"It is rather remarkable, that watering in autumn, winter, or ſpring, will not produce that kind of herbage which is the cauſe of the rot in ſheep; but has been known to remove the cauſe from meadows, which before had that baneful effect. If, however, you uſe the water only a few days in any of the ſummer months, all the lands thus watered will be rendered unſafe for the paſturage of ſheep. Of this I was lately convinced from an experiment made by a friend. At the beginning of July, when the hay was carried off, and the water rendered extremely muddy and abundant by ſeveral days rain, he thought proper to throw it over his meadows for ten days, in which time a large collection of extremely rich manure was made upon the land. In about a month the meadow was covered with uncommon luxuriancy and blackneſs of herbage. Into this graſs were turned eight ſound ewes and two lambs. In ſix weeks time the lambs were killed, and diſcovered ſtrong ſymptoms of rottenneſs; and in about a month afterwards one of the ewes was killed, and though it proved very fat, the liver was putrid and replete with the inſect called the *fluke* or *weevil*: the other ewes were ſold to a butcher, and all proved unſound. This experiment, however, convinces me, by the very extraordinary improvement made thereby in the meadow, that muddy water in the ſummer is much more enriching than it is in autumn or winter; and ought, therefore, to be uſed for a week at leaſt every wet ſummer, notwithſtanding its inconveniences to ſheep, the moſt profitable ſpecies of ſtock."

Culture of Grafs.

440 How watering may occaſion the rot in ſheep.

Mr Boſwell, beſides his general directions for watering, gives many plans of the ditches, drains, &c. for particular meadows, ſome of them done from an actual ſurvey. But theſe being confined to particular ſituations, we ſhall here only ſpeak of his method in general. In his third chapter, entitled *A general Deſcription of Water-meadows*, he obſerves, that "lands capable of being watered, lie ſometimes only on one ſide, and ſometimes on both ſides of the ſtream deſigned to ſupply them with water. In the former caſe, when they have a pretty quick deſcent, the land may be often watered by a main drawn out of the ſtream itſelf, without any ware;" though he acknowledges that it is by far the beſt way to erect a ware, and to draw mains on each ſide, to diſpoſe of the water to the beſt advantage.

441 Mr Boſwell's general directions for watering.

Boggy lands require more and longer continued watering than ſuch as are ſandy or gravelly; and the larger the body of water than can be brought upon them, the better. The weight and ſtrength of the water will greatly aſſiſt in compreſſing the ſoil, and deſtroying the roots of the weeds that grow upon it; nor can the water be kept too long upon it, particularly in the winter ſeaſon; and the cloſer it is ſed, the better.

To improve ſtrong clay ſoils, we muſt endeavour to the utmoſt to procure the greateſt poſſible deſcent from the trench to the trench drain; which is beſt done by making the trench-drains as deep as poſſible, and applying the materials drawn out of them to raiſe the trenches. Then, with a ſtrong body of water, taking the advantage of the autumnal floods, and keeping the water ſome time upon them at that ſeaſon, and as often as convenient during the winter, the greateſt improvement on this ſort of ſoils may be made. Warm ſand or gravelly ſoil, are the moſt profitable under the watering ſyſtem, provided the water can be brought over

Culture of Grass.

them at pleasure. In soils of this kind, the water must not be kept long at a time, but often shifted, thoroughly drained, and the land frequently refreshed with it: under which circumstances the profit is immense. A spring-feeding, a crop of hay, and two after-maths, may be obtained in a year; and this, probably, where in a dry summer scarce grass enough could be found to keep a sheep alive. If the stream be large, almost any quantity of land may be watered from it; and though the expence of a ware over it is great, it will soon be repaid by the additional crop. If the stream is small, the expence will be so in proportion.

442 Method of improving a springy water meadow.

The following method of improving a water meadow that was springy has been tried by Mr Boswell with success. The meadow had been many years watered by a spring rising just above it from a barren sandy heath; the soil near the surface was in some places a gravelly land, in others a spongy cork, both upon a strong clay and sand mixture, which retained the draining of the lands above it. Whenever it had been watered, and left to drain itself dry, a yellowish red water stood in many parts, and oozed out of others; the herbage being no other than a poor, miserable, hairy grass and small sedge. Chalk and ashes had been thrown over it to very little purpose. It was then drained underground athwart all the different descents, and all these drains carried into one large drain, which had been already cut for the purpose of carrying off the water when the meadow was overflowed. These drains were cut quite through the mixture of clay and sand, and as much deeper as the fall of the ground below would admit of; then, with chalk cut for the purpose, small hollow drains were formed at the bottom of these; the drains were then filled up with the materials that came out.

This was done in the beginning of summer, and the work frequently examined through the season; the soil was found firmer than before, and none of that nasty red water to be met with upon the surface, though it continually oozed into the drains. In autumn the meadow was again prepared for waterings, by repairing those trenches and drains that were properly situated; and by cutting others where wanted, for the purpose of watering the meadow. The water being then brought over it from the same spring as before, the event answered the most sanguine wishes of the proprietor; the effects were visible the first year, and the ground has been constantly improving ever since.

443 Of watering lands on the sides of hills.

Mr Boswell also informs us, that a gentleman in Scotland had applied to him for directions to water some lands lying on the sides of hills, where the descent is quick; and of which there are many in this country, as well as in the north of England. It would be difficult to water such lands by means of drains and trenches according to the directions already given; because the bends in the trenches must be very near together and large, as the water must flow out of the trench *above* the bend to flow over the pane below it; the number and size would likewise be inconvenient, and greatly offend the eye.

Lands of this sort are generally capable of being ploughed; in which case our author directs them to be once ploughed in the spring, and sown with oats or any other kind of grain that will rot the sward. When the grain is harvested, plough the land across; the last ploughing with the Kentish plough, which has a moveable mouldboard, and is called a *turn-wrist* plough. This turns the furrows down the side of the hill, the horses going forwards and backwards in the same furrows. By this means the land is laid flat without any open furrows in it: dress it down in the spring very fine, and sow it with oats, and mix with some kinds of grass seeds very thick. Thus the ground will have but few irregularities; and as soon as the corn is carried off, or the following spring at farthest, the mains and drains may be cut out.

Culture of Grass.

For watering coarse lands that are firm enough to bear the plough, and situated near a stream, our author gives the following directions.

444 Of watering coarse lands.

"Let the land thus situated be ploughed once in the spring, and sown with any grain that will rot sward. As soon as the crop is off, plough it again, and leave it rough through the winter. Work it down early in the spring, and plough it in the direction the trenches are to lie, making the ridges of a proper size for watering, ten or twelve yards wide for instance; work it fine; then gather the ridges up again in the same manner, making the last furrows of each ridge as deep as possible. If the land be not fine, dress it down again, and gather it up a second time if necessary; and with a shovel throw the earth from the edges of the furrows to the tops of the ridges, to give the greatest possible descent from the trench to the drain. Sow it with oats and grass seeds very thick; and after the corn is carried off, the trenches may be formed upon the top of each ridge, dispersing the furrows with a spade as much as the fall of the land will admit of for the drains; taking care to procure sufficient fall at all events, to drain the lands after they have been watered. By this method the crop of corn will nearly pay all the expence, and the land will be in excellent order."

445 Of the management of meadows after watering.

After the work of watering a meadow is totally finished, and the hay carried off, cattle may be let in to eat the after-math. When this is done, it will then be necessary to examine whether or not the mains have suffered any injury from their feet; whether there be quantities of mud or sand collected at the angles, &c. all of which must be thrown out and the breaches repaired; by which means the drenches, drains, &c. will last three years, but otherwise not more than two. The roots, mud, &c. may be used in repairing the breaches, but never left upon the sides of the trenches out of which they are taken. The tail-drains require to be cleansed oftener than any of the other works, for this obvious reason, that the mud, &c. is carried down from all the others into them; where, if it be allowed to accumulate, it occasions a stagnation of water upon the meadow itself. In repairing the trenches, particular care ought to be taken that the workmen do not make them any wider than before, which they are very apt to do; neither are they to be allowed to throw the materials which they dig out in a ridge behind the edge of the trench, which both widens it and promotes weeds.

446 Of the times the water should continue upon the meadows.

During the time of watering, it will be necessary to examine the meadow every two or three days in order to remove obstructions, &c. If the drains should be filled with water and run over, they ought to be made deeper; or if this cannot be done, they should be widened

ulture of Graſs.

widened. In the winter time a regular ſtrong water ſhould be kept, avoiding very ſtrong great floods. In this ſeaſon the water may be kept on the ground with ſafety for a month or even ſix weeks, if the ſoil be corky or boggy, or a ſtrong clay; but not quite ſo long if it be gravel or ſand. At the ſecond watering a fortnight or three weeks will be ſufficient; and after Candlemas a fortnight will be rather too long. At the third watering a week will be ſufficient, which will bring it to about the middle of March; by which time, if the weather be tolerably mild, the graſs will be long enough for the ewes and lambs, or fatting lambs; which may then be turned into the meadow with great advantage. Even in the end of February, if the winter has been very mild, the graſs will be long enough for them. Here they may be permitted to feed till the beginning of May, changing them into different meadows. As ſoon as they are taken out, the water muſt be turned in for a week, carefully examining every trench and drain for the reaſons already given. The water is then to be thifted into others, alternately watering and draining, leſſening the time the water remains upon it as the weather grows warmer; and in five, ſix, or ſeven weeks, the graſs will be fit to be mown for hay, and produce from one to two tons, or even more, an acre upon good ground.

Mr Boſwell directs, that about a week before the graſs is to be mown, the water ſhould be let into the meadow for 24 hours; which, he ſays, will make the ground moiſt at the bottom, the ſcythe will go through it the more eaſily, and the graſs will be mown cloſer to the ground. This practice, however, is entirely diſapproved of by Mr Wright. "Though it may prevail in Dorſetſhire (ſays he), it is very ſeldom adviſable, for the following reaſons: Water made to run through a thick crop of graſs, though it may appear ever ſo pure, will leave a certain quantity of adherent ſcum or ſediment, which can never be ſeparated from the hay, but will render it unpalatable, if not prejudicial, to the cattle that eat it. And this wetting of the land and graſs will impede the drying or making of the hay perhaps ſome days, which in difficult ſeaſons is of very great conſequence, and it will likewiſe make the turf too ſoft and tender to ſupport the wheels of a loaded waggon in carrying off the hay. Beſides, there is reaſon to believe that one day's wetting in the ſummer, will, upon moſt meadows, endanger the ſoundneſs of every ſheep that feeds upon the aftermath."

447 f ſpring. eding.

The ſpring-feeding ought never to be done by heavier cattle than ſheep or calves; for large cattle do much hurt by poaching the ground with their feet, deſtroying the trenches, and ſpoiling the graſs. Mr Boſwell likewiſe greatly recommends a proper uſe of ſpring floods, from which he ſays much benefit may be derived; but, if there is any quantity of graſs in the meadows not eaten, theſe floods muſt be kept out, otherwiſe the graſs will be ſpoiled; for they bring with them ſuch quantities of ſand and mud, which ſtick to the graſs, that the cattle will rather ſtarve than taſte it. Great quantities of graſs or after-math are frequently ſpoiled in flat countries by the floods which take place in the fall. In the winter time, however, when the ground is bare, the ſand and mud brought down by the floods is ſoon incorporated with the ſoil, and becomes an excellent manure. The certain rule with regard to this matter is, "Make uſe of the floods when the graſs cannot be uſed; avoid them when the graſs is long or ſoon to be cut."

Culture of Graſs.

448 Of watering from the end of autumn to Candlemas.

"It has often been a ſubject of diſpute (ſays Mr Boſwell), whether, from the latter end of autumn to Candlemas, the throwing a very ſtrong body of water, where it can be done, over the meadows, is of any eſſential ſervice or not? Thoſe who conſider it as advantageous, aſſert, that when the waters run rude and ſtrong over the ground, they beat down and rot the tufts of foggy or rough graſs, ſedges, &c. that are always to be found in many parts of coarſe meadow-ground; and therefore are of peculiar ſervice to them. On the other ſide it is alleged, that by coming in ſo large a body, it beats the ground (in the weak places particularly) ſo bare, that the ſward is deſtroyed; and alſo brings with it ſuch quantities of ſeeds of weeds, that at the next hay ſeaſon the land in all thoſe bare places bears a large burden of weeds, but little graſs.

"The general opinion of the watermen upon this point is, that in water meadows which are upon a warm, ſandy, or gravelly ſoil, with no great depth of loam upon them, rude ſtrong watering, even in winter, always does harm without any poſſible eſſential ſervice. On the contrary, cold ſtrong clay land will bear a great deal of water a long time without injury; and boggy, corky, or ſpongy ſoil, will alſo admit of a very large and ſtrong body of water upon it with great advantage for almoſt any length of time at that ſeaſon, provided the drains are made wide and deep enough to carry it off, without forcing back upon the end of the panes. The weight and force of the water vaſtly aſſiſts in compreſſing thoſe ſoils, which only want ſolidity and tenacity to make them produce great burdens of hay: nothing, in their opinion, corrects and improves thoſe ſoils ſo much as a very ſtrong body of water, kept a conſiderable time upon them at that ſeaſon."

Notwithſtanding the above reaſons, however, Mr Boſwell informs us, that he has doubts upon the ſubject; nor can he by any means acquieſce in this opinion, unleſs, by rude ſtrong waters he is permitted to underſtand only rather a larger quantity of water conveyed over the land at this early ſeaſon than ought to be uſed in the ſpring or ſummer: unmanageable waters he believes always hurtful.

"It may be proper juſt to add (continues he), that as ſoon as the hay is carried off the meadows, cattle of any ſort except ſheep may be put to eat the graſs out of the trenches, and what may be left by the mowers. This perhaps will laſt them a week; when the water may be put into the meadows in the manner already deſcribed, taking care to mow the long graſs which obſtructs the water in the trenches; and this mowing is beſt done when the water is in them. Let the weeds, leaves, &c. be taken out and put in heaps, to be carried away into the farm yards; examine the trenches, make up the breaches, &c. take particular care that the water only dribbles over every part of the panes as thin as poſſible, this being the warmeſt ſeaſon of the year. The firſt watering ſhould not be ſuffered to laſt longer than two or three days before it is ſhifted off (and if the ſeaſon be wet, perhaps not ſo long, as warmth

Culture of Graſs.

warmth ſeems to be the greateſt requiſite after the land is once wet to aſſiſt vegetation) to another part or meadow beat out by the cattle, by this time fit to take it. Do by this meadow exactly the ſame, and ſo by a third and fourth, if as many meadows belong to the occupier. Obſerve at all times, when the water is taken out of a meadow, to draw up the drain-ſluice hatches; as, without doing that, watering is an injury. By the time that three or four parts are thus regularly watered, the firſt will have an after-math, with ſuch rich and beautiful verdure as will be aſtoniſhing; and both quantity and quality will be beyond conception better than if the lands had not been watered.

"Hence we ſee why every perſon ſhould, if poſſible, have three or four meadows that can be watered; for here, while the cattle are eating the firſt, the ſecond is growing, the third draining, &c. and the fourth under water. In this manner the after-math will in a mild ſeaſon laſt till Chriſtmas. A reaſon was given why the ſpring-graſs ſhould be fed only by ſheep or calves; a reaſon equally cogent may be given, why the after-graſs ought not to be fed by them, becauſe it will infallibly rot them. No ſheep (ſays our author), except thoſe which are juſt fat, muſt ever be ſuffered even for an hour in water-meadows except in the ſpring of the year; and even then care muſt be taken that every part of the meadows have been well watered, and that they are not longer kept in them than the beginning of May. Although at preſent it is unknown what is the occaſion of the rot, yet certain it is, that even half an hour's feeding in unhealthy ground has often proved fatal. After a ſhort time they begin to loſe their fleſh, grow weaker and weaker; the beſt feeding in the kingdom cannot improve them after they once fall away; and when they die, animalcula like plaice are found in the livers. Scarcely any ever recover from a ſlight attack; but when farther advanced, it is always fatal. Guard by all means againſt keeping the water too long upon the meadow in warm weather; it will very ſoon produce a white ſubſtance like cream, which is prejudicial to the graſs, and ſhows that it has been too long upon the ground already. If it be permitted to remain a little longer, a thick ſcum will ſettle upon the graſs of the conſiſtence of glue, and as tough as leather, which will quite deſtroy it wherever it is ſuffered to be produced. The ſame bad effects ſeem to ariſe from rude waters; neither can the ſcum eaſily be got off.

449 Water ought not to be kept too long upon meadows.

450 Advantages of rolling meadows.

"Rolling meadows in the ſpring of the year is an excellent method. It ſhould be done after Candlemas, when the meadow has been laid dry a week. It ſhould be always rolled lengthwiſe of the panes, up one ſide of the trench and down the other. Rolling alſo contributes much to the graſs being cut cloſe to the ſurface when mown, which is no ſmall advantage; for the little hillocks, ſpewings of worms, ant-hills, &c. are by this means preſſed cloſe to the ground, which would otherwiſe obſtruct the ſcythe and take off its edge; and to avoid that inconvenience, the workmen always mow over them."

As a water-meadow has with ſo much juſtice been called a *hot-bed of graſs*, and as the practice of flooding tends ſo completely to ameliorate the pooreſt ſoils, and to extirpate heath and all coarſe and woody plants, we are ſatisfied that the knowledge of it cannot be too extenſively diffuſed, or too minutely enquired into. That it may be more clearly underſtood, therefore, we ſhall here give a ſtatement of the mode in which it is practiſed in Glouceſterſhire, as explained from Mr Wright's pamphlet, by the Rev. Mr Charles Findlater, in a letter to the conductors of the Farmer's Magazine.

Culture Graſs.

451 Watering explained by Mr Findlater.

"Fig. 6. repreſents a float-meadow under irrigation; the dark ſhading repreſenting the water.

Plate XI.

"When the hatch of the water dam-dike (marked H) is liſted up, the water runs in the natural channel of the river; when the hatch is ſhut, as repreſented in the figures, the natural channel is laid dry below it, and the water runs laterally along the main-feeder, in the direction of the arrows, and is from it diſtributed into the floating-gutters (*g*, *g*, *g*, *g*), which are formed along the crowns of the ridges, into which the meadow is arranged, overflowing on both ſides of ſaid gutters, and running down the ſides of the ridges into the furrows or drains betwixt the ridges (*d*, *d*, *d*, *d*,), which drains diſcharge it into the main-drain, whereby it is returned into its natural channel at the foot of the meadow.

"The marks (o o, or Δ Δ), and the tufts, in the main-feeder and the floating-gutters, denote—The firſt, obſtructions (made by ſmall ſtakes, or ſods, or ſtones) to raiſe the water, and make it flow over from the main-feeder into the floating-gutters, or from the latter over the ſides of the ridges; the ſecond, nicks, made in their ſides, with a ſimilar intention. If, however, the main-feeder and floating-gutters are properly conſtructed at their firſt formation, theſe ſupplementary aids will be, in a great meaſure, unneceſſary: For the main-feeder ought, at its entrance, to be of dimenſions juſt ſufficient to admit the quantity of water which is to be conveyed to the meadow; and gradually to contract its ſize as it goes along, in order that the water, for want of room, may be forced over its ſide, and into the floating-gutters: theſe laſt ought to be formed after the ſame model, that the water may, by their primary conſtruction, overflow their ſides, through their whole courſe. That as little as poſſible of the ſurface may be unproductive, a ſimilar conſtruction ſhould be adopted for the drains; they ought to be narrow neareſt to the main-feeder, where they receive little water, and to diverge as they approach the main-drain; which laſt is, for the ſame reaſon, ſimilarly conſtructed. In the plan, this mode of conſtruction is made obvious to the eye.

"The meadow, in this plate, muſt be conceived to lie in a regular and very gentle ſlope from the main-feeder to the main-drain.

"Fig. 4. and 5. preſent a view of the ridges cut acroſs, with the feeding-gutter (*g*) upon their crown, and the furrows, or diſcharging drains (*d*, *d*) along their ſides. Fig. 5. ſhows the ſhape (of gradual ſlope) into which they ought to be formed at firſt, were it not for the expence, *i. e.* when they are to be formed out of graſs fields, preſerving the graſs ſward. Fig. 4. repreſents the mode in which they may, more cheaply, though more roughly, be formed at firſt; when, the depoſitions of ſediment from the floating water, will gradually fill the ſhoulders of the floating-gutters, up to the dotted line, forming the ridge into the ſhape of fig. 5.

"In the formation of the meadow, (particularly if the declivity is very ſmall), care ſhould be taken to loſe as little as poſſible of the level in the main-feeder, and in the

Culture of Grass. the floating gutters; in order that the greater descent may be given to the water down the sides of the ridges, from the floating-gutters to their discharging drains, that the water may float over the ridges sides with the more rapidity, and in the more quick succession.

"The distance from the floating-gutter to the discharging-drain, ought not to be less than four yards, i. e. the breadth of the ridge eight yards; nor more than five yards and a half, i. e. the breadth of the ridge eleven yards.

"It is evident from the plan, that, when the hatch (H) is lifted up, the water resumes its natural channel, and the meadow becomes at once dry. Its figure frees it instantly of all surface water. If any of it is wet from springs, these must be carried off by under-draining; for it must be thoroughly drained before you can drown it to good effect.

3. 7. "This figure represents a float-meadow, where the declivity is unequal, and which, also, is too large, for the command of water, to admit of being floated all at once.

"In this meadow, it is supposed that the ground rises, from the natural channel of the river, up to (F 1.), which is a feeder, with its floating-gutters (*g, g, g, g*); and thence descends to the hollow (D 1.), which is a drain communicating with the main-drain, and receiving the water from the lesser drains or receiving furrows (*d, d, d*). It is supposed that the ground rises again from the hollow (D 1.), up to the second feeder (F 2.); and thence descends again into the hollow, along which is conducted the receiving-drain (D 2.). The remainder of the meadow is supposed to lie in a regular slope, from the main-feeder to the drain last mentioned, and the main-drain. The letter (*r*) marks a very small rut, made with a spade, or triangular hoe, for conducting water to places upon which it appears not to scatter regularly.

"The hatch upon the river's natural channel, and that upon the feeder (F 2.) are represented as shut; and, consequently the natural channel, together with that part of the meadow which is floated from the feeder (F 2.), as dry. The hatches upon the feeder (F 1.), and upon the main-feeder, are represented as drawn up; and, consequently the two parts of the meadow, floated from them, are represented as under water.

1. 8. "This represents catch-meadow, for a steep declivity, or side of a hill. It is called *catch*, because, when the whole is watered at once, the water floating over the uppermost pitches is catched in the floating-gutters, which distribute the water over the inferior pitches.

"The lateral horizontal feeding-gutters, which scatter the water over the first and second pitches, are represented as shut by sods or stones, &c. (8); and consequently these first and second pitches appear dry: The whole water is represented as passing down the main-feeder into the lowest floating-gutter, whence it floats the lowest or third pitch; and is received into the drain at the foot of the meadow, to be returned by it into the natural channel.

"When the whole is to be floated at once, the obstructions (8) are taken from the lateral floating-gutters: obstructions, mean time, are placed in the main-feeder, immediately under the floating-gutters, to force the water into said gutters.

"N. B. In obstructing the main-feeder, care must be taken not to obstruct it entirely, but to allow always a part of the water it contains to escape in it to the lower pitches; for, supposing the main-feeder to be entirely shut under the feeding-gutter (*g* 1.), so that the whole water was made to run over the first pitch, from said gutter and the horizontal part of the main-drain, the water filtrated through the grass of the first pitch, would be so very much deprived of its fertilizing qualities, as to be incapable of communicating almost any perceptible benefit to the pitches lying below. Water so filtrated, is called technically *used water;* and is esteemed next to useless; and for this reason, the grass nearest the floating-gutters is most abundant, and of best quality, in all kinds of meadow. Rotation of Crops.

"The proper breadth of the pitches of catch-meadow, from gutter to gutter, does not seem well determined; they ought, probably, not to be much broader than the distance from the floating-gutter to the receiving-drain in float-meadow, i. e. from four to five or six yards.—Catch-meadow is not so much prized as float-meadow.

"In the construction of the float-meadows, the floating-gutters die away to nothing before they meet the main-drain; the water from the end of the gutter finding its way over the intervening space, or being assisted in scattering by small ruts marked (*r*). The receiving-drains should, for like reason, not be commenced till within half a ridge breadth of the main-feeder."

It is to be observed with regard to the last of these modes of flooding, called *catch-meadow*, that although lands thus watered do not become equal to more level grounds subjected to the same process, or float-meadow, yet that the improvement of them is perhaps greater in proportion to the value of the lands in their original state; for, in this way, lands upon the declivity of hills, which once produced next to nothing, are enabled to bear a considerable crop of valuable grass. As streams of water are in high countries frequently found descending from very lofty situations, and as in these cases the expence of forming *catch-meadow* is very trifling, it may be regarded as of the most extensive utility.

Sect. V. *Rotation of Crops.*

452 Rotation of crops. No branch of husbandry requires more skill and sagacity than a proper rotation of crops, so as to keep the ground always in heart, and yet to draw out of it the greatest profit possible. Some plants rob the soil, others are gentle to it: some bind, others loosen. The nice point is, to intermix crops, so as to make the greatest profit consistently with keeping the ground in trim. In that view, the nature of the plants employed in husbandry must be accurately examined.

453 Culmiferous and leguminous plants. The difference between culmiferous and leguminous plants, is occasionally mentioned above. With respect to the present subject, a closer inspection is necessary. Culmiferous plants, having small leaves and few in number, depend mostly on the soil for nourishment and little on the air. During the ripening of the seed, they draw probably their whole nourishment from the soil; as the leaves by this time, being dry and withered, must have lost their power of drawing nourishment from the air. Now, as culmiferous plants are chiefly cultivated for their seed, and are not cut down till the seed

Rotation of Crops.

ſeed be fully ripe, they may be pronounced all of them to be robbers, ſome more, ſome leſs. But ſuch plants, while young, are all leaves; and in that ſtate draw moſt of their nouriſhment from the air. Hence it is, that where cut green for food to cattle, a culmiferous crop is far from being a robber. A hay-crop accordingly, even where it conſiſts moſtly of rye-graſs, is not a robber, provided it be cut before the ſeed is formed; which at any rate it ought to be, if one would have hay in perfection. And the foggage, excluding the froſt by covering the ground, keeps the roots warm. A leguminous plant, by its broad leaves, draws much of its nouriſhment from the air. A cabbage which has very broad leaves, and a multitude of them, owes its growth more to the air than to the ſoil. One fact is certain, that a cabbage cut and hung up in a damp place, preſerves its verdure longer than other plants. At the ſame time, a ſeed is that part of a plant which requires the moſt nouriſhment; and for that nouriſhment a culmiferous plant muſt be indebted entirely to the ſoil. A leguminous crop, on the contrary, when cut green for food, muſt be very gentle to the ground. Peaſe and beans are leguminous plants; but being cultivated for ſeed, they ſeem to occupy a middle ſtation: their ſeed makes them more ſevere than other leguminous crops cut green; their leaves, which grow till reaping, make them leſs ſevere than a culmiferous plant left to ripen.

Theſe plants are diſtinguiſhed no leſs remarkably by the following circumſtance. All the ſeeds of a culmiferous plant ripen at the ſame time. As ſoon as they begin to form, the plant becomes ſtationary, the leaves wither, the roots ceaſe to puſh, and the plant, when cut down, is blanched and ſapleſs. The ſeeds of a leguminous plant are formed ſucceſſively: flowers and fruit appear at the ſame time in different parts of the plant. This plant accordingly is continually growing, and puſhing its roots. Hence the value of bean or peaſe ſtraw above that of wheat or oats: the latter is withered and dry when the crop is cut; the former, green and ſucculent. The difference therefore, with reſpect to the ſoil, between a culmiferous and leguminous crop, is great. The latter, growing till cut down, keeps the ground in conſtant motion, and leaves it to the plough looſe and mellow. The former gives over growing long before reaping; and the ground, by want of motion, turns compact and hard. Nor is this all. Dew falling on a culmiferous crop after the ground begins to harden, reſts on the ſurface, and is ſucked up by the next ſun. Dew that falls on a leguminous crop, is ſhaded from the ſun by the broad leaves, and ſinks at leiſure into the ground. The ground accordingly, after a culmiferous crop, is not only hard, but dry: after a leguminous crop, it is not only looſe, but ſoft and unctuous.

Of all culmiferous plants, wheat is the moſt ſevere, by the long time it occupies the ground without admitting a plough. And as the grain is heavier than that of barley or oats, it probably requires more nouriſhment than either. It is obſerved above, that as peaſe and beans draw part of their nouriſhment from the air by their green leaves while allowed to ſtand, they draw the leſs from the ground; and by their conſtant growing they leave it in good condition for ſubſequent crops. In both reſpects they are preferable to any culmiferous crop. Rotation of Crops.

Culmiferous crops, as obſerved above, are not robbers when cut green: the ſoil, far from hardening, is kept in conſtant motion by the puſhing of the roots, and is left more tender than if it had been left at reſt without any bearing crop.

Bulbous-rooted plants are above all ſucceſsful in dividing and pulverizing the ſoil. Potato-roots grow ſix, eight, or ten inches under the ſurface; and, by their ſize and number, they divide and pulverize the ſoil better than can be done by the plough; conſequently, whatever be the natural colour of the ſoil, it is black when a potato-crop is taken up. The potato, however, with reſpect to its quality of dividing the ſoil, muſt yield to a carrot or parſnip; which are large roots, and pierce often to the depth of 18 inches. The turnip, by its tap-root, divides the ſoil more than can be done by a fibrous-rooted plant; but as its bulbous-root grows moſtly above ground, it divides the ſoil leſs than the potato, the carrot, or the parſnip. Red clover, in that reſpect, may be put in the ſame claſs with turnip.

Whether potatoes or turnip be the more gentle crop, appears a puzzling queſtion. The former bears ſeed, and probably draws more nouriſhment from the ſoil than the latter, when cut green. On the other hand, potatoes divide the ſoil more than turnip, and leave it more looſe and friable. It appears no leſs puzzling, to determine between cabbage and turnip: the former draws more of its nouriſhment from the air, the latter leaves the ſoil more free and open.

The reſult of the whole is what follows: Culmiferous plants are robbers; ſome more, ſome leſs: they at the ſame time bind the ſoil; ſome more, ſome leſs. Leguminous plants in both reſpects are oppoſite: if any of them rob the ſoil, it is in a very ſlight degree; and all of them without exception looſen the ſoil. A culmiferous crop, however, is generally the more profitable: but few ſoils can long bear the burden of ſuch crops, unleſs relieved by interjected leguminous crops. Theſe, on the other hand, without a mixture of culmiferous crops, would ſoon render the ſoil too looſe.

Theſe preliminaries will carry the farmer ſome length in directing a proper rotation of crops. Where dung, lime, or other manure, can be procured in plenty to recruit the ſoil after ſevere cropping, no rotation is more proper or profitable in a ſtrong ſoil, than wheat, peaſe or beans, barley, oats, fallow. The whole farm may be brought under this rotation, except ſo far as hay is wanted. But as ſuch command of manure is rare, it is of more importance to determine what ſhould be the rotation when no manure can be procured but the dung collected in the farm. Conſidering that culmiferous crops are the more profitable in rich land, it would be proper to make them more frequent than the other kind. But as there are few ſoils in Scotland that will admit ſuch frequent culmiferous crops without ſuffering, it may be laid down as a general rule, that alternate crops, culmiferous and leguminous, ought to form the rotation. Nor are there many ſoils that will ſtand good, even with this favourable rotation, unleſs relieved from time to time by paſturing a few years. If ſuch extended rotation be artfully carried on,

Rotation of Crops.

454 The nature of ſoil conſidered, with regard to the rotation of crops.

on, crops without end may be obtained in a tolerable good ſoil, without any manure but what is produced in the farm.

It is ſcarce neceſſary to be mentioned, being known to every farmer, that clay anſwers beſt for wheat, moiſt clay for beans, loam for barley and peaſe, light ſoil for turnip, ſandy ſoil for rye and buck-wheat; and that oats thrive better in coarſe ſoil than any other grain. Now, in directing a rotation, it is not ſufficient that a culmiferous crop be always ſucceeded by leguminous: attention muſt alſo be given, that no crop be introduced that is unfit for the ſoil. Wheat, being a great binder, requires more than any other crop a leguminous crop to follow. But every ſuch crop is not proper: potatoes are the greateſt openers of ſoil; but they are improper in a wheat ſoil. Neither will turnip anſwer, becauſe it requires a light ſoil. A very looſe ſoil, after a crop of rye, requires rye-graſs to bind it, or the treading of cattle in paſturing: but to bind the ſoil, wheat muſt not be ventured; for it ſucceeds ill in looſe ſoil.

Another conſideration of moment in directing the rotation is, to avoid crops that encourage weeds. Peaſe is the fitteſt of all crops for ſucceeding to wheat, becauſe it renders the grounds looſe and mellow, and the ſame ſoil agrees with both. But beware of peaſe, unleſs the ſoil be left by the wheat perfectly free of weeds; becauſe peaſe, if not an extraordinary crop, foſter weeds. Barley may be ventured after wheat, if the farmer be unwilling to loſe a crop. It is indeed a robber; better, however, any crop, than run the hazard of poiſoning the ſoil with weeds. But to prevent the neceſſity of barley after wheat, the land ought to be fallowed before the wheat: it cleans the ground thoroughly, and makes peaſe a ſecure crop after wheat. And after a good crop of peaſe, barley never fails. A horſehoed crop of turnip is equal to a fallow for rooting out weeds; but turnip does not ſuit land that is proper for wheat. Cabbage does well in wheat ſoil; and a horſehoed crop of cabbage, which eradicates weeds, is a good preparation for wheat to be ſucceeded by peaſe; and a crop of beans diligently hand-hoed, is in that view little inferior. As red clover requires the ground to be perfectly clean, a good crop of it inſures wheat, and next peaſe. In loam, a drilled crop of turnip or potatoes prepares the ground, equal to a fallow, for the ſame ſucceſſion.

Another rule is, to avoid a frequent repetition of the ſame ſpecies; for to produce good crops, change of ſpecies is no leſs neceſſary than change of ſeed. The ſame ſpecies returning every ſecond or third year, will infallibly degenerate, and be a ſcanty crop. This is remarkably the caſe of red clover. Nor will our fields bear pleaſantly perpetual crops of wheat after fallow, which is the practice of ſome Engliſh farmers.

Hitherto of rotation in the ſame field. We add one rule concerning rotation in different fields; which is, to avoid crowding crops one after another in point of time; but to chooſe ſuch as admit intervals ſufficient for leiſurely dreſſing, which gives opportunity to manage all with the ſame hands, and with the ſame cattle; for example, beans in January or February, peaſe and oats in March, barley and potatoes in April, turnip in June or July, wheat and rye in October.

For illuſtrating the foregoing rules, a few inſtances of exceptionable rotations will not be thought amiſs. The following is an uſual rotation in Norfolk. Firſt, wheat after red clover. Second, barley. Third, turnip. Fourth, barley with red clover. Fifth, clover cut for hay. Sixth, a ſecond year's crop of clover commonly paſtured. Dung is given to the wheat and turnip.—Againſt this rotation ſeveral objections lie. Barley after wheat is improper. The two crops of barley are too near together. The ſecond crop of clover muſt be very bad, if paſturing be the beſt way of conſuming it; and if bad, it is a great encourager of weeds. But the ſtrongeſt objection is, that red clover repeated ſo frequently in the ſame field cannot fail to degenerate; and of this the Norfolk farmers begin to be ſenſible. Salton in Eaſt Lothian is a clay ſoil; and the rotation there uſually has been wheat after fallow and dung. Second, barley after two ploughings; the one before winter, the other immediately before the ſeed is ſown. Third oats. Fourth, peaſe. Fifth, barley. Sixth, oats; and then fallow. This rotation conſiſts chiefly of robbing crops. Peaſe are the only leguminous crop, which, even with the fallow, is not ſufficient to looſen a ſtiff ſoil. But the ſoil is good, which in ſome meaſure hides the badneſs of the rotation. About Seaton, and all the way from Preſton to Goſford, the ground is ſtill more ſeverely handled: wheat after fallow and dung, barley, oats, peaſe, wheat, barley, oats, and then another fallow. The ſoil is excellent; and it ought indeed to be ſo, to ſupport many rounds of ſuch cropping.

Rotation of Corps. 455 Exceptionable rotations.

In the pariſhes of Tranent, Aberlady, Dirleton, North-Berwick, and Athelſtoneford, the following rotations were formerly univerſal, and to this day are much more frequent than any other mode.

1. After fallow and dung, wheat, barley, oats, peaſe and beans, barley, oats, wheat.

2. After fallow and dung, barley, oats, peaſe and beans, wheat, barley, oats, peaſe, wheat.

3. After fallow and dung, wheat, oats, peaſe, barley, oats, wheat.

4. After fallow and dung, barley, oats, beans, wheat, peaſe, barley, oats.

In the ſeveral Tours that are publiſhed by Young, are found, in the beſt counties of England, examples without end, of rotations no leſs exceptionable than many of thoſe mentioned.

456 Fields not to be kept too long in paſture.

Where a field is laid down for paſture in order to be recruited, it is commonly left in that ſtate many years; for it is the univerſal opinion, that the longer it lies, the richer it becomes for bearing corn. This may be true; but in order to determine the mode of cropping, the important point is, what upon the whole is the moſt profitable rotation; not what may produce luxuriant crops at a diſtant period. Upon that point it may be affirmed, that the farmer who keeps a field in paſture beyond a certain time, loſes every year conſiderably; and that a few luxuriant crops of corn, after 20 years of paſture, and ſtill more after 30, will not make up the loſs.

Paſture-graſs, while young, maintains many animals; and the field is greatly recruited by what they drop; it is even recruited by hay crops, provided the graſs be cut before ſeeding. But as old graſs yields little profit, the field ought to be taken up for corn when the paſture begins to fail; and after a few crops, it ought

Rotation of Crops.

to be laid down again with grafs feeds. Seduced by a chimerical notion, that a field, by frequent corn crops, is fatigued, and requires reft like a labouring man or animal, careful farmers give long reft to their fields by paſture, never adverting that it affords little profit. It ought to be their ſtudy, to improve their ſoil, by making it free, and alſo retentive of moiſture. If they accompliſh theſe ends, they need not be afraid of exhauſting the ſoil by cropping.

457 Examples of rotations.

Where a farmer has acceſs to no manure but what is his own production, the caſe under conſideration, there are various rotations of crops, all of them good, though perhaps not equally ſo. We ſhall begin with two examples, one in clay and one in free ſoil, each of the farms 90 acres. Six acres are to be incloſed for a kitchen garden, in which there muſt be annually a crop of red clover, for ſummer food to the working cattle. As there are annually 12 acres in hay, and 12 in paſture, a ſingle plough with good cattle will be ſufficient to command the remaining 60 acres.

Rotation in a clay ſoil.

Inclof.	1795.	1796.	1797.	1798.	1799.	1800.
1.	Fallow.	Wheat.	Peaſe.	Barley.	Hay.	Oats.
2.	Wheat.	Peaſe.	Barley.	Hay.	Oats.	Fallow.
3.	Peaſe.	Barley.	Hay.	Oats.	Fallow.	Wheat.
4.	Barley.	Hay.	Oats.	Fallow.	Wheat.	Peaſe.
5.	Hay.	Oats.	Fallow.	Wheat.	Peaſe.	Barley.
6.	Oats.	Fallow.	Wheat.	Peaſe.	Barley.	Hay.
7.	Paſture.	Paſture.	Paſture.	Paſture.	Paſture.	Paſture.

When the rotation is completed, the ſeventh incloſure, having been ſix years in paſture, is ready to be taken up for a rotation of crops, which begins with oats in the year 1801, and proceeds as in the ſixth incloſure. In the ſame year 1801 the fifth incloſure is made paſture, for which it is prepared by ſowing paſture-graſs ſeeds with the barley of the year 1800. And in this manner may the rotation be carried on without end. Here the labour is equally diſtributed; and there is no hurry nor confuſion. But the chief property of this rotation is, that two culmiferous or white-corn crops are never found together; by a due mixture of crops, the ſoil is preſerved in good heart without any adventitious manure. At the ſame time, the land is always producing plentiful crops: neither hay nor paſture get time to degenerate. The whole dung is laid upon the fallow.

Every farm that takes a graſs crop into the rotation muſt be incloſed, which is peculiarly neceſſary in a clay ſoil, as nothing is more hurtful to clay than poaching.

Rotation in a free ſoil.

Inclof.	1795.	1796.	1797.	1798.	1799.	1800.
1.	Turnip.	Barley.	Hay.	Oats.	Fallow.	Wheat.
2.	Barley.	Hay.	Oats.	Fallow.	Wheat.	Turnip.
3.	Hay.	Oats.	Fallow.	Wheat.	Turnip.	Barley.
4.	Oats.	Fallow.	Wheat.	Turnip.	Barley.	Hay.
5.	Fallow.	Wheat.	Turnip.	Barley.	Hay.	Oats.
6.	Wheat.	Turnip.	Barley.	Hay.	Oats.	Fallow.
7.	Paſture.	Paſture.	Paſture.	Paſture.	Paſture.	Paſture.

For the next rotation, the ſeventh incloſure is taken up for corn, beginning with an oat crop, and proceeding in the order of the fourth incloſure; in place of which, the third incloſure is laid down for paſture by ſowing paſture-graſſes with the laſt crop in that incloſure, being barley. This rotation has all the advantages of the former. Here the dung is employed on the turnip crop. Rotation of Crops.

We proceed to conſider what rotation is proper for carſe clay. The farm we propoſe conſiſts of 73 acres. Nine are to be incloſed for a kitchen garden, affording plenty of red clover to be cut green for the farm cattle. The remaining 64 acres are divided into four incloſures, 16 acres each, to be cropped as in the following table.

Inclof.	1795.	1796.	1797.	1798.
1.	Beans.	Barley.	Hay.	Oats.
2.	Barley.	Hay.	Oats.	Beans.
3.	Hay.	Oats.	Beans.	Barley.
4.	Oats.	Beans.	Barley.	Hay.

Here the dung ought to be applied to the barley.

Many other rotations may be contrived, keeping to the rules above laid down. Fallow, for example, wheat, peaſe and beans, barley, cabbage, oats, for clay. Here dung muſt be given both to the wheat and cabbage. For free ſoil, drilled turnip, barley, red clover, wheat upon a ſingle furrow, drilled potatoes, oats. Both the turnip and potatoes muſt have dung. Another for free ſoil: turnip drilled and dunged, red clover, wheat on a ſingle furrow with dung, peaſe, barley, potatoes, oats. The following rotation has proved ſucceſsful in a ſoil proper for wheat. 1. Oats with red clover, after fallow without dung. 2. Hay. The clover ſtubble dunged, and wheat ſown the end of October with a ſingle furrow. 3. Wheat. 4. Peaſe. 5. Barley. Fallow again. Oats are taken the firſt crop, to ſave the dung for the wheat. Oats always thrive on a fallow, though without dung, which is not the caſe of barley. But barley ſeldom fails after peaſe. In ſtrong clay ſoil, the following rotation anſwers. 1. Wheat after fallow and dung. 2. Beans ſown under furrow as early as poſſible. Above the beans, ſow peaſe end of March, half a boll per acre, and harrow them in. The two grains will ripen at the ſame time. 3. Oats or barley on a winter furrow with graſs-ſeeds. 4. Hay for one year or two; the ſecond growth paſtured. Lay what dung can be ſpared on the hay-ſtubble, and ſow wheat with a ſingle furrow. 5. Wheat. 6. Beans or peaſe. 7. Oats. Fallow again.

In addition to theſe, we ſhall here ſtate from the Agricultural Survey of Yorkſhire, an example of a rotation uſed in that county upon a marſh-land farm conſiſting of 432 acres of arable land, in which a very great number of hands and horſes appear to have been employed, but in which very valuable products are reared. "The ſoil, where the principal part of the potatoes are grown, is a good warp; the other part on which potatoes are alſo cultivated, a mixture of warp and ſand: the remainder of the land, clay, with a ſmall portion of warp, but too ſtrong to grow potatoes, except about 70 acres, which is tolerably good potato-

land,

Reaping and Storing up Corn and Hay

land, but at too great a diſtance from the river. Graſs land only ſufficient to keep two milch cows, and horſes neceſſary for working the farm: 69 acres of the beſt warp land divided into three equal parts; 1. fallow, with from 16 to 20 loads of manure per acre; ſet it with potatoes; after, ſow wheat; and then fallow again: three acres of the ſame kind of land that is liable to be damaged by ſparrows when ſown with corn, is ſet with potatoes every year with about 10 loads of manure per acre each year: 84 acres of the lighter land is divided in the ſame manner, one-third fallow, with 10 loads of manure per acre; ſet potatoes and then ſow wheat, and fallow again: 42 acres of land, lately an old paſture divided into three parts: one-third flax, then ſown with rape, and after they come off, plough and harrow the land three or four times, and lay upon it about 20 loads of manure per acre, which will make it in great condition; after which ſet potatoes, then ſow flax again, and rape after: 150 acres divided into three parts; 1. fallow; 2. wheat; 3. beans, drilled at 9 inches diſtance, hand-hoed twice at 6s. per acre; fallow again, &c.: 80 acres of land that was lately in old graſs divided into four parts; fallow, wheat, beans drilled, and oats; then fallow again, &c. The remaining four acres thrown to any of the crops that are likely to fail. Rent 25s. per acre; aſſeſſments 5s. acre.

"*Diſtribution of crops for* 1795.

"*Servants, Horſes, and Cows, kept upon the Farm.*

4 Houſe ſervants,
16 Labourers,
26 Horſes,
2 Milch cows.

"The above is an account of a farm belonging to one of the beſt managers of marſh-land. We muſt obſerve he fallows his land very often; yet he is well paid by his ſuperior crops. The laſt year (1795) he had 100 ſacks per acre off moſt of his potato-land; and ſold them from 8s. to 12s. per ſack of 14 pecks. All their corn is ſold by the quarter of eight Wincheſter buſhels, though I believe their meaſure rather overruns."

Sect. VI. *Of Reaping Corn and Hay Crops, and Storing them up for Uſe.*

458 ripeneſs. Culmiferous plants are ripe when the ſtem is totally white: they are not fully ripe if any green ſtreaks remain. Some farmers are of opinion, that wheat ought to be cut before it is fully ripe. Their reaſons are, firſt, that ripe wheat is apt to ſhake; and next, that the flour is not ſo good. With reſpect to the laſt, it is contrary to nature, that any ſeed can be better in an unripe ſtate than when brought to perfection; nor will it be found ſo upon trial. With reſpect to the firſt, wheat, at the point of perfection is not more apt to ſhake than for ſome days before: the huſk begins not to open till after the ſeed is fully ripe; and then the ſuffering the crop to ſtand becomes tickliſh; after the minute of ripening, it ſhould be cut down in an inſtant, if poſſible.

Reaping and Storing up Corn and Hay.

459 Of reapers. This leads to the hands that are commonly engaged to cut down corn. In Scotland, the univerſal practice was, to provide a number of hands, in proportion to the extent of the crop, without regard to the time of ripening. By this method, the reapers were often idle for want of work; and what is much worſe, they had often more work than they could overtake, and ripe fields were laid open to ſhaking winds. The Lothians have long enjoyed weekly markets for reapers, where a farmer can provide himſelf with the number he wants; and this practice is creeping into neighbouring ſhires. Where there is no opportunity of ſuch markets, neighbouring farmers ought to agree in borrowing and lending their reapers.

One ſhould imagine, that a caution againſt cutting corn when wet is unneceſſary; yet from the impatience of farmers to prevent ſhaking, no caveat is more ſo. Why do they not conſider, that corn ſtanding dries in half a day; when, in a cloſe ſheaf, the weather muſt be favourable if it dry in a month? in moiſt weather it will never dry.

460 Manner of cutting. With reſpect to the manner of cutting, we muſt premiſe, that barley is of all the moſt difficult grain to be dried for keeping. Having no huſk, rain has an eaſy acceſs; and it has a tendency to malten when wet. Where the ground is properly ſmoothed by rolling, it ſeems beſt to cut it down with the ſcythe. This manner being more expeditious than the ſickle, removes it ſooner from danger of wind; and gives a third more ſtraw, which is a capital article for dung, where a farm is at a diſtance from other manure. We except only corn that has lodged; for there the ſickle is more convenient than the ſcythe. As it ought to be dry when cut, bind it up directly: if allowed to lie any time in the ſwath, it is apt to be diſcoloured.—Barley ſown with graſs-ſeeds, red clover eſpecially, requires a different management. Where the graſs is cut along with it, the difficulty is great of getting it ſo dry as to be ventured in a ſtack. The beſt way is, to cut the barley with a ſickle above the clover, ſo as that nothing but clean barley is bound up. Cut with a ſcythe the ſtubble and graſs: they make excellent winter food. The ſame method is applicable to oats; with this only difference, that when the field is expoſed to the ſouth-weſt wind, it is leſs neceſſary to bind immediately after mowing. As wheat commonly grows higher than any other grain, it is difficult to manage it with the ſcythe; for which reaſon the ſickle is preferred in England. Peaſe and beans grow ſo irregularly, as to make the ſickle neceſſary.

461 Drying of peaſe. The beſt way for drying peaſe, is to keep ſeparate the handfuls that are cut; though in this way they wet eaſily, they dry as ſoon. In the common way of heap-

Reaping and Storing up Corn and Hay.

ing peaſe together for compoſing a ſheaf, they wet as eaſily, and dry not near ſo ſoon. With reſpect to beans, the top of the handful laſt cut ought to be laid on the bottom of the former; which gives ready acceſs to the wind. By this method peaſe and beans are ready for the ſtack in half the ordinary time.

462 Size of ſheaves.

A ſheaf commonly is made as large as can be contained in two lengths of the corn made into a rope. To ſave frequent tying, the binder preſſes it down with his knee, and binds it ſo hard as totally to exclude the air. If there be any moiſture in the crop, which ſeldom fails, a proceſs of fermentation and putrefaction commences in the ſheaf; which is perfected in the ſtack, to the deſtruction both of corn and ſtraw. How ſtupid is it, to make the ſize of a ſheaf depend on the height of the plants! By that rule, a wheat ſheaf is commonly ſo weighty, as to be unmanageable by ordinary arms: it requires an effort to move it that frequently burſts the knot, and occaſions loſs of grain, beſide the trouble of a ſecond tying. Sheaves ought never to be larger than can be contained in one length of the plant, cut cloſe to the ground; without admitting any exception, if the plants be above 18 inches high. The binder's arm can then compreſs the ſheaf ſufficiently without need of his knee. The additional hands that this way of binding may require, are not to be regarded compared with the advantage of drying ſoon. Corn thus managed may be ready for the ſtack in a week; it ſeldom in the ordinary way requires leſs than a fortnight, and frequently longer. Of a ſmall ſheaf compreſſed by the arm only, the air pervades every part; nor is it ſo apt to be unlooſed as a large ſheaf, however firmly bound. We omit the gathering of ſheaves into ſhocks, becauſe the common method is good, which is to place the ſhocks directed to the ſouth-weſt, in order to reſiſt the force of the wind. Five ſheaves on each ſide make a ſufficient ſtay; and a greater number cannot be covered with two head-ſheaves.

463 Carrying off the victual.

Every article is of importance that haſtens the operation in a country, like Scotland, ſubjected to unequal harveſt weather; for which reaſon, the moſt expeditious method ſhould be choſen for carrying corn from the field to the ſtack-yard. Our carriages are generally too ſmall or too large. A ſledge is a very awkward machine: many hands are required, and little progreſs made. Waggons and large carts are little leſs dilatory, as they muſt ſtand in the yard till unloaded ſheaf by ſheaf. The beſt way is, to uſe long carts moveable upon the axle, ſo as at once to throw the whole load on the ground; which is forked up to the ſtack by a hand appointed for that purpoſe. By this method, two carts will do the work of four or five.

464 Of ſtacking.

Building round ſtacks in the yard is undoubtedly preferable to houſing corn. There it is ſhut up from the air; and it muſt be exceeding dry, if it contract not a muſtineſs, which is the firſt ſtep to putrefaction. Add to this, that in the yard, a ſtack is preſerved from rats and mice, by being ſet on a pedeſtal: whereas no method has hitherto been invented for preſerving corn in a houſe from ſuch deſtructive vermine. The proper manner of building, is to make every ſheaf incline downward from its top to its bottom. Where the ſheaves are laid horizontally, the ſtack will take in rain both above and below. The beſt form of a ſtack is that of a cone placed on a cylinder; and the top of the cone ſhould be formed with three ſheaves drawn to a point. If the upper part of the cylinder be a little wider than the under, ſo much the better.

Reaping and Storing up Corn and Hay.

The delaying to cover a ſtack for two or three weeks, though common, is, however, exceeding abſurd; for if much rain fall in the interim, it is beyond the power of wind to dry the ſtack. Vegetation begun in the external parts, ſhuts out the air from the internal; and to prevent a total putrefaction, the ſtack muſt be thrown down and expoſed to the air every ſheaf. In order to have a ſtack covered the moment it is finiſhed, ſtraw and ropes ought to be ready; and the covering ought to be ſo thick as to be proof againſt rain.

465 Covering the ſtacks.

Scotland is ſubject not only to floods of rain, but to high winds. Good covering guards againſt the former, and ropes artfully applied guard againſt the latter. The following is a good mode. Take a hay-rope well twiſted, and ſurround the ſtack with it, two feet or ſo below the top. Surround the ſtack with another ſuch rope immediately below the eaſing. Connect theſe two with ropes in an up-and-down poſition, diſtant from each other at the eaſing about five or ſix feet. Then ſurround the ſtack with other circular ropes parallel to the two firſt mentioned, giving them a twiſt round every one of thoſe that lie up and down, by which the whole will be connected together in a ſort of net-work. What remains is, to finiſh the two feet at the top of the ſtack. Let it be covered with bunches of ſtraw laid regularly up and down; the under part to be put under the circular rope firſt mentioned, which will keep it faſt, and the upper part be bound by a ſmall rope artfully twiſted, commonly called *the crown of the ſtack*. This method is preferable to the common way of laying long ropes over the top of the ſtack, and tying them to the belting ropes; which flattens the top, and makes it take in rain. A ſtack covered in the way here deſcribed, will ſtand two years ſecured both againſt wind and rain; a notable advantage in this variable climate.

466 Hay-making.

The great aim in making hay is, to preſerve as much of the ſap as poſſible. All agree in this; and yet differ widely in the means of making that aim effectual. To deſcribe all the different means would be equally tedious and unprofitable. We ſhall confine ourſelves to two, which appear preferable to all others. A crop of rye-graſs and yellow clover ought to be ſpread as cut. A day or two after, when the dew is evaporated, rake it into a number of parallel rows along the field, termed *wind-rows*, for the convenience of putting it up into ſmall cocks. After turning the rows once and again, make ſmall cocks weighing a ſtone or two. At the diſtance of two days or ſo, put two cocks into one, obſerving always to mix the tops and bottoms together, and to take a new place for each cock, that the leaſt damage poſſible may be done to the graſs. Proceed in putting two cocks into one, till ſufficiently dry for tramp-ricks of 100 ſtone each. The eaſieſt way of erecting tramp-ricks, is to found a rick in the middle of the row of cocks that are to compoſe it. The cocks may be carried to the rick by two perſons joining arms together. When all the cocks are thus carried to the rick within the diſtance of 40 yards or ſo, the reſt of the cocks will be more expeditiouſly carried to the rick, by a rope wound about them and dragged by a horſe.

Reaping and Storing up Corn and Hay.

horſe. Two ropes are ſufficient to ſecure the ricks from wind the ſhort time they are to ſtand in the field. In the year 1775, 10,000 ſtone were put into tramp-ricks the fourth day after cutting. In a country ſo wet as many parts of Scotland are, expedition is of mighty conſequence in the drying both of hay and corn. With reſpect to hay intended for horned cattle, it is by the generality held an improvement, that it be heated a little in the ſtack. But we violently ſuſpect this doctrine to have been invented for excuſing indolent management. An ox, it is true, will eat ſuch hay; but it will always be found that he prefers ſweet hay; and it cannot well be doubted, but that ſuch hay is the moſt ſalutary and the moſt nouriſhing.

467 Hay of red clover.

The making hay conſiſting chiefly of red clover, requires more care. The ſeaſon of cutting is the laſt week of June, when it is in full bloom; earlier it may be cut, but never later. To cut it later would indeed produce a weightier crop; but a late firſt cutting makes the ſecond alſo late, perhaps too late for drying. At the ſame time, the want of weight in an early firſt cutting, is amply compenſated by the weight of the ſecond.

When the ſeaſon is too variable for making hay of the ſecond growth, mix ſtraw with that growth, which will be a ſubſtantial food for cattle during winter. This is commonly done by laying ſtrata of the ſtraw and clover alternately in the ſtack. But by this method, the ſtrata of clover, if they do not heat, turn mouldy at leaſt, and unpalatable. The better way is, to mix them carefully with the hand before they be put into the ſtack. The dry ſtraw imbibes the moiſture from the clover and prevents heating.

468 Other method.

But the beſt method of hay-making ſeems to be that recommended by Mr Anderſon*. "Inſtead (ſays he), of allowing the hay to lie, as uſual in moſt places, for ſome days in the ſwathe after it is cut, and afterwards alternately putting it up into cocks and ſpreading it out, and tedding it in the ſun, which tends greatly to bleach the hay, exhales its natural juices, and ſubjects it very much to the danger of getting rain, and thus runs a great riſk of being good for little, I make it a general rule, if poſſible, never to cut hay but when the graſs is quite dry; and then make the gatherers follow cloſe upon the cutters, putting it up immediately into ſmall cocks about three feet high each when new put up, and of as ſmall a diameter as they can be made to ſtand with; always giving each of them a ſlight kind of thatching, by drawing a few handfuls of the hay from the bottom of the cock all around, and laying it lightly upon the top with one of the ends hanging downwards. This is done with the utmoſt eaſe and expedition; and when it is once in that ſtate, I conſider my hay as in a great meaſure out of danger: for unleſs a violent wind ſhould ariſe immediately after the cocks are put up, ſo as to overturn them, nothing elſe can hurt the hay; as I have often experienced, that no rain, however violent, ever penetrates into theſe cocks but for a very little way. And, if they are dry put up, they never ſit together ſo cloſely as to heat; although they acquire, in a day or two, ſuch a degree of firmneſs, as to be in no danger of being overturned by wind after that time, unleſs it blows a hurricane.

Reaping and Storing up Corn and Hay.

"In theſe cocks I allow the hay to remain, until, upon inſpection, I judge that it will keep in pretty large tramp-cocks (which is uſually in one or two weeks, according as the weather is more or leſs favourable), when two men, each with a long pronged pitchfork, lift up one of theſe ſmall cocks between them with the greateſt eaſe, and carry them one after another to the place where the tramp-cock is to be built (1): and in this manner they proceed over the field till the whole is finiſhed.

469 Advantages of this method.

"The advantages that attend this method of making hay, are, that it greatly abridges the labour; as it does not require above the one-half of the work that is neceſſary in the old method of turning and tedding it: That it allows the hay to continue almoſt as green as when it is cut, and preſerves its natural juices in the greateſt perfection; for, unleſs it be the little that is expoſed to the ſun and air upon the ſurface of the cocks, which is no more bleached than every ſtraw of hay ſaved in the ordinary way, the whole is dried in the moſt ſlow and equal manner that could be deſired; and, laſtly, That it is thus in a great meaſure ſecured from almoſt the poſſibility of being damaged by rain. This laſt circumſtance deſerves to be much more attended to by the farmer than it uſually is at preſent; as I have ſeen few who are ſufficiently aware of the loſs that the quality of their hay ſuſtains by receiving a ſlight ſhower after it is cut, and before it is gathered; the generality of farmers ſeeming to be very well ſatisfied if they get in their hay without being abſolutely rotted, never paying the leaſt attention to its having been ſeveral times wetted while the hay was making. But, if theſe gentlemen will take the trouble at any time to compare any parcel of hay that has been made perfectly dry, with another parcel from the ſame field that has received a ſhower while in the ſwathe, or even a copious dew, they will ſoon be ſenſible of a very manifeſt difference between them; nor will their horſes or cattle ever commit a miſtake in chooſing between the two.

470 Particular caution requiſite in this method.

"Let it be particularly remarked, that in this manner of making hay, great care muſt be taken that it be dry when firſt put into the cocks; for if it is in the leaſt degree wet at that time, it will turn inſtantly mouldy, and ſit together ſo as to become totally impervious to the air, and will never afterwards become dry till it is ſpread out to the ſun. For this reaſon, if at any time during a courſe of good ſettled weather you ſhould begin to cut in the morning before the dew is off the graſs, keep back the gatherers till the dew is evaporated; allowing that which was firſt cut to lie till it is dry before it is cocked. In this caſe, you will almoſt

* *Eſſays on Agriculture*, vol. i. p. 186.

(1) If the hay is to be carried to any conſiderable diſtance, this part of the labour may be greatly abridged, by cauſing the carriers take two long ſticks of a ſufficient ſtrength, and having laid them down by the ſmall cocks parallel to one another, at the diſtance of one and a half or two feet aſunder, let them lift three or four cocks, one after another, and place them carefully above the ſticks, and then carry them altogether, as if upon a handbarrow, to the place where the large rick is to be built.

Reaping and Stacking up Corn and Hay.

moſt always find that the uncut graſs will dry ſooner than that which has been cut when wet; and therefore, the gatherers may always begin to put up that which is freſh cut before the other; which will uſually require two or three hours to dry after the new-cut hay may be cocked. And if, at any time, in caſe of neceſſity, you ſhould be obliged to cut your hay before it is dry, the ſame rule muſt be obſerved always to allow it to remain in the ſwathe till it is quite dry: but, as there is always a great riſk of being long in getting it up, and as it never in this caſe *wins* (K) ſo kindly as if it had been dry cut, the farmer ought to endeavour, if poſſible, in all caſes to cut his hay only when dry; even if it ſhould coſt him ſome additional expence to the cutters, by keeping them employed at any other works, or even allowing them to remain idle, if the weather ſhould be variable or rainy.

"But if there is a great proportion of clover, and the weather ſhould chance to be cloſe and calm at the time, it may, on ſome occaſions, be neceſſary to open up the cocks a little, to admit ſome freſh air into them; in which caſe, if they have ſtood a day or two, it may be of great uſe to turn theſe cocks and open them up a little, which ought to be done in the drieſt time of the day; the operator taking that part of each cock which was the top, and with it forming the baſe of a new one; ſo that the part which was moſt expoſed to the air becomes excluded from it, and that which was undermoſt comes to be placed upon the top, ſo as to make it all dry as equally as poſſible.

"If the hay has not been damp when it was firſt put up, the cock may be immediately finiſhed out at once; but if it is at all wet, it will be of great uſe to turn over only a little of the top of the cock at firſt, and leaving it in that ſtate to dry a little, proceed to another, and a third, and fourth, &c. treating each in the ſame way; going in that manner till you find that the inſide of the firſt opened cock is ſufficiently dried, when it will be proper to return to it, turning over a little more of it till you come to what is ſtill damp, when you leave it, and proceed to another, and ſo on round the whole; always returning afreſh till the cocks are entirely finiſhed. This is the beſt way of ſaving your hay, if you have been under the neceſſity of cutting it while damp; but it is always beſt to guard againſt this inconvenience, if poſſible."

471 Hay-ſtacks.

In the yard, a ſtack of hay ought to be an oblong ſquare, if the quantity be greater than to be eaſily ſlowed in a round ſtack; becauſe a ſmaller ſurface is expoſed to the air than in a number of round ſtacks. For the ſame reaſon, a ſtack of peaſe ought to have the ſame form, the ſtraw being more valuable than that of oats, wheat, or barley. The moment a ſtack is finiſhed it ought to be covered; becauſe the ſurface hay is much damaged by withering in dry weather, and moiſtening in wet weather. Let it have a pavilion roof; for more of it can be covered with ſtraw in that ſhape, than when built perpendicular at the ends. Let it be roped as directed above for corn-ſtacks; with this difference only, that in an oblong ſquare the ropes muſt be thrown over the top, and tied to the belt-rope below. This belt-rope ought to be fixed with pins to the ſtack: the reaſon is, that the ropes thrown over the ſtack will bag by the ſinking of the ſtack, and may be drawn tight by lowering the belt-rope, and fixing it in its new poſition with the ſame pins. Manures.

The ſtems of hops, being long and tough, make excellent ropes; and it will be a ſaving article, to propagate a few plants of that kind for that very end.

A ſtack of rye-graſs hay, a year old, and of a moderate ſize, will weigh, each cubic yard, 11 Dutch ſtone. A ſtack of clover-hay in the ſame circumſtances weighs ſomewhat leſs.

Sect. VII. *Manures.*

472 M. Parmentier's opinions concerning manure.

"The uſe of manures (ſays M. Parmentier *), has been known in all ages; but we are yet far from having any clear and preciſe ideas of the nature of the juices which are deſtined for the nouriſhment of vegetables, and of the manner in which they are tranſmitted to their organs. The writers on agriculture, who have endeavoured to explain theſe matters, perceiving ſalts in moſt plants, were perſuaded that theſe ſalts, by the help of water and heat, paſſed, in a ſaline form, through the vegetable filter. Theſe firſt philoſophers did not heſitate to conſider every thing that has been done by the induſtry of man, to improve the nature of land, and its productions, as merely forming reſervoirs of theſe ſalts, which they conſider as the principle of fertility. This opinion was ſo well eſtabliſhed among the improvers of land, that, to this day, many of them have no object in view, in their operations, but to diſengage ſalts; and, when they attempt to explain certain phenomena which take place in their fields or orchards, they talk confidently about the *nitre of the air, of rain, of ſnow, of dew, and fogs*; of the *ſalts of the earth, of dung, of marl, of lime, of chalk*, &c. and make uſe of thoſe vague terms, *oil, ſulphur, ſpirit*, &c. which ought henceforward to be baniſhed from our elementary books on agriculture.

* *Memoirs of the Royal Society of Agriculture of Paris.*

"Among the authors who have attacked, and combated with moſt ſucceſs the opinion that the fruitfulneſs of ſoils, and the aliment of vegetables, reſide in ſaline ſubſtances, muſt be reckoned Eller and Wallerius. Theſe philoſophers examined, by every means which chemiſtry at that time could furniſh, the various kinds of earth proper for cultivation, and alſo thoſe ſubſtances which have always been conſidered as the moſt powerful manures, without being able to obtain, from any of them, any thing more than mere atoms of ſalt.

"Animated with the ſame zeal, and taking advantage of the inſtructions found in their writings, I thought it neceſſary to determine, by experience, whether, as has been aſſerted, there really exiſt neutral ſalts in earths; and alſo, whether thoſe earths are more fertile in proportion to the quantity of ſuch ſalts they contain. With this view, I lixiviated, by means of diſtilled water, many ſpecies of cultivated earths, taken in various ſtates, from freſh earth to that which had

(K) By *winning* hay, is meant the operation by which it is brought from the ſucculent ſtate of graſs to that of a dry fodder.

Manures. had been impoverished by the growth of several crops: I also tried dung, reduced more or less into the state of mould; and likewise the most active manures, such as the offal of animal substances rotted by putrefaction; but in none of these, however carefully analyzed, were found any salts in a free state. They contain indeed the materials proper for forming salts, but if they contain any ready formed, it is merely by accident.

"The researches of Kraft, and those of Alston, were not attended with different results. Having sown some oats in ashes, not lixiviated, and in sand strongly impregnated with potash and with saltpetre, and having found that the oats did not grow, they concluded that neutral salts, and alkalies, not only retarded the growth of vegetables, but that they absolutely prevented it. It is well known that in Egypt there are districts where the earth is entirely covered with sea-salt, and these districts are quite barren. It is probably owing to this property of sea-salt, that the Romans were accustomed to scatter large quantities of it over fields where any great crime had been committed, and of which they wished to perpetuate the remembrance, by rendering the part barren for a certain time.

"The idea that salts had great influence in vegetation ought to have been greatly weakened by the following simple reflection. Supposing that salts existed in garden-mould, they would be very soon dissolved by the rain, and carried away, towards the lower strata of the earth, to a depth to which the longest roots would not reach. Indeed the famous experiment of Van Helmont would have been sufficient to have destroyed the above opinion, if it did not generally happen that we are no sooner set free from one error than we fall into another not less extraordinary. The surprising effects of vegetation brought about by the overflowing of water, and in the neighbourhood of salt marshes, and the infinite number of inhaling capillary tubes observed upon the surface of vegetables, led to an opinion that the air and water, absorbed by the roots and leaves of plants, were only vehicles loaded with saline matter, analogous to the vegetables nourished by them.

"To the experiment of Van Helmont, which was repeated by many accurate observers, succeeded those of modern philosophers; from which it clearly appeared, that plants could grow, and produce fruit, in the air of the atmosphere, and in distilled water, also in pure sand, in powdered glass, in wet moss or sponge, in the cavity of fleshy roots, &c. and that plants which had nothing but the above-mentioned fluids for their nourishment, gave, when submitted to chemical analysis, the same products as those which had undergone their process of vegetation in a soil perfectly well manured. It was also observed, that the most barren soils were rendered fertile when they were properly supplied with water by canals; and the efficacy of irrigation was repeatedly evinced in different ways: from these observations was formed the following system, that water rises in plants in the form of vapour, as in distillation; that air introduces itself into their pores; and that, if salts contribute to the fruitfulness of soils, it is only in consequence of their containing the two fluids above mentioned in great abundance."

Our author, after making many experiments upon various soils and salts, maintains "that saline substances have no sensible effects in promoting vegetation, except inasmuch as they are of a deliquescent nature, Manures. have an earthy basis easily decomposed, and are used only in small quantity. In those circumstances they have the power of attracting, from the immense reservoir of the atmosphere, the vapours which circulate in it; these vapours they retain, along with the moisture that is produced from rain, snow, dew, fog, &c. which moisture they prevent from running together in a mass, or from being lost, either by exhaling into the air of the atmosphere, or by filtering itself through the inferior strata of the earth, and thereby leaving the roots of vegetables dry; they distribute that moisture uniformly, and transmit it, in a state of great division, to the orifices of the tubes destined to carry it into the texture of the plant, where it is afterwards to undergo the laws of assimilation. As every kind of vegetable manure possesses a viscous kind of moisture, it thereby partakes of the property of deliquescent salts. In short, the preparation of land for vegetation has no other object in view but to divide the earthy particles, to soften them, and to give them a form capable of producing the above-mentioned effects. It is sufficient, therefore, that water, by its mixture with the earth and the manure, be divided, and spread out so as to be applied only by its surface, and that it keep the root of the plant always wet, without drowning it, in order to become the essential principle of vegetation. But as plants which grow in the shade, even in the best soil, are weakly, and as the greater part of those which are made to grow in a place that is perfectly dark neither give fruit nor flowers, it cannot be denied, that the influence of the sun is of great importance in vegetable economy."

Such was the opinion of M. Parmentier while the old theory of chemistry prevailed; but when it appeared, by more recent discoveries, that air and water are not simple but compound bodies, made up of oxygen, hydrogen, and azote, and that they are resolved into these principles by many operations of nature and of art, he so far altered his theory of vegetation as to admit, that air and water act their part in that process, not in a compound state, but by means of the principles of which they consist. He now concluded, that the value of manured earth consists of its tendency to resolve water into gasses which give out heat while they are absorbed by the plants. As he thus supposes that the gasses constitute the food of plants, it follows, that the most aerated waters will be the most favourable to vegetation; and hence arises the value of those in which putrid animal matters are dissolved. Salts and dung act as leavens in bringing on a state of fermentation in the substances with which they are mingled, and operating the decomposition of water, which along with the carbon existing in the atmosphere, he imagines contains the whole materials of the more simple vegetables. Too great a quantity of salts prevents fermentation, or the decomposition of water, and hence is prejudicial to vegetation, while a small quantity is more advantageous, as more favourable to that process of putrefaction. Different manures also give forth gasses which are absorbed by plants, and give them a peculiarity of character: hence, in a soil composed of mud and dung, cabbages acquire a bad taste, from the hepatic gas, or sulphurated hydrogen gas, which is there evolved. In addition to these chemical

proportion-

Manures. properties of manure, it alſo, by its mechanical qualities, renders the ſoil more permeable to water and to the roots of the plants, and is thus favourable to the proceſs of vegetation. At the ſame time, as the earths themſelves have a chemical action upon water, and are capable of affording a proper baſis for plants, he conſiders them as in many caſes ſufficient to promote vegetation. Upon theſe principles, M. Parmentier takes a view of different ſubſtances uſed as manures. Manures.

Marl, in his opinion, is capable of acting in the ſame manner as the moſt fertile ſoil, when the principles of which it is compoſed, namely, clay, ſand, calcareous earth, and magneſian earth, are juſtly proportioned to each other. But it is ſometimes compact and tenacious, becauſe it contains a ſuperabundant portion of clay, and at other times porous and friable, becauſe it contains too much ſand, and therefore is not in general fit for vegetation by itſelf. Theſe conſiderations ought always to be our guide when we mean to employ marl as a manure.

It has been ſuppoſed that *to marl* is a ſort of technical expreſſion, intended to denote the bringing together or dividing the earthy particles by means of clay or ſand. It appears to our author, that neither of the above operations can properly be called *marling;* becauſe, in either caſe, all we do is, to put the ſoil into a ſituation to receive and to profit by the influence of the atmoſphere, and that of the manures made uſe of. The peculiar principle of marl is, that part of it which, like lime, acts very powerfully upon the different aeriform fluids, is eaſily reduced to powder, effervеſces with acids, and ſends forth a quantity of air-bubbles when water is poured upon it. Now this matter, which in a particular manner does the office of manure, reſides neither in clay nor in ſand. Upon the proportion of it depends the duration of the fertility it produces; conſequently it is of importance, when we make uſe of marl, to know which of its conſtituent parts it contains in the greateſt proportion, otherwiſe in ſome caſes we ſhould only add one common kind of earth to another. Hence our author infers, that for a chalky ſoil clay is the proper manure, and that in ſuch a ſoil a clay bottom is of more value than a gold mine.

"Wood-aſhes, as a manure, may be, in ſome reſpects, compared to marl; at leaſt they contain the ſame earth, as thoſe which generally enter into the compoſition of marl, but they contain a greater quantity of ſaline ſubſtances, proceeding from the vegetables of which they are the reſidue, and from the proceſs made uſe of in their combuſtion; a proceſs which increaſes their activity, and ſhould render us careful in what manner and for what purpoſes we employ them. Wood-aſhes, when ſcattered over fields, at proper times and in proper quantities, deſtroy weeds, and encourage the vegetation of good plants. But do the aſhes produce this effect by a ſort of corroſive power? I cannot (ſays our author) think it; for in that caſe all kinds of plants would indiſcriminately be acted upon by them, and to a certain degree deſtroyed.

"Beſides, the aſhes of freſh wood are ſeldom employed until they have been lixiviated; in which ſtate they are deprived of their cauſtic principle; thoſe aſhes which are moſt commonly made uſe of for manure are produced either from wood that has been floated in water, or from turf, or from pit-coal, and contain little or no alkaline ſalt.

"It appears much more probable that aſhes, when laid upon ground, deſtroy the weeds by a well known effect, namely, by ſeizing with eagerneſs that moiſture which ſerved to produce thoſe weeds, and which in a ſuperabundant quantity is neceſſary to their exiſtence and ſupport. Whereas thoſe plants which have a firmer texture and a longer root, which are rendered ſtrong by age and by having withſtood the rigour of winter, and which are in fact the plants of which the fields are compoſed, do not ſuffer any damage from the application of the aſhes; but, on the contrary, by being freed from the ſuperfluous weeds which ſtifled them, and robbed them of a part of their ſuſtenance, they receive a quantity of nouriſhment proportioned to their wants. The ſtate of relaxation and languor to which they were reduced by a ſuperabundance of water, leaves them, the ſoil gets its proper conſiſtence, and the graſs, corn, &c. acquiring the ſtrength and vigour which are natural to them, ſoon overcome the moſs, ruſhes, and other weeds; thus a good crop, of whatever the field conſiſts of, is produced. It is in the above manner that wood aſhes act, whenever in the ſpring it is neceſſary to apply them to meadows, corn fields, &c. the plants of which are ſtifled and weakened by a luxuriant vegetation of weeds, the uſual conſequence of mild and wet winters.

"When wood-aſhes produce an effect different from what is above deſcribed, it is either becauſe they happen to contain too much alkaline ſalt, or that they are laid on the ground in too great quantity, or that the fields to which they are applied were not ſufficiently wet to reſtrain their action; for when they are ſcattered upon cold ſoils, and buried by the plough before the time of ſowing, they are, like lime, of great ſervice. The laſt-mentioned ſubſtance is very efficacious in other circumſtances; and there is a well known method of uſing it practiſed by the Germans, as follows: A heap of lime is formed by the ſide of a heap of poor earth, and water is poured upon the lime; the earth is then thrown over it, and becomes impregnated with the vapours which eſcape from the lime while it is ſlaked. The earth, after being thus aerated, may be ſeparated; and although no lime remains mixed with it, is, by the operation juſt deſcribed, rendered capable of giving a luxuriant vegetation to whatever plants may be put into it.

"It is poſſible, therefore, to aerate earth as well as fluids; for this purpoſe, by mixing it with certain ſubſtances during their decompoſition, we muſt attach to it the principles of which thoſe ſubſtances are compoſed; from which there reſults a matter ſo loaded with gas, as to form a more compound ſubſtance, and one which has acquired new properties. The Arabians, for example, who take great pains to improve their land, are accuſtomed to make large pits, which they fill with animals which happen to die: theſe pits they afterwards cover with calcareous or clayey earth; and after ſome time theſe earths, which of themſelves are ſterile, acquire the properties of the richeſt manures.

"The foregoing obſervations may at leaſt be conſidered as proving, that thoſe ſubſtances which, when employed freſh and in too great quantity, are moſt prejudicial to vegetation, have, on the contrary, an advantageous

Manures.

tageous effect, when they are previouſly made to undergo a fermentation; or when they are mixed with earth or water, in a proportion adapted to the end propoſed. The graſs of fields in which cattle or poultry go to feed, after the firſt or ſecond crop of hay, appears to be dried by the urine and dung of thoſe animals, as if fire had been applied to it; whereas theſe ſame excrementitious ſubſtances, when combined with earth, or diluted with water, are capable, without any other preparation, of performing the office of good manure.

"But if animal ſecretions, when applied in ſubſtance to plants, were capable of acting upon them, as is affirmed, in ſuch a way as to corrode or burn them, how could ſeed which has been ſwallowed, and eſcaped the action of the digeſtive powers, be prolific when thrown out by the animal, after having remained ſo long in its dung? yet we often ſee oats, ſo circumſtanced, grow and produce ſeed. Is it not more conſiſtent with experience and obſervation to ſuppoſe, that theſe excrementitious ſubſtances, being ſtill endowed with animal heat, and with an organic motion, diffuſe round plants in vegetation a deleterious principle or inflammable gas, which deſtroys them? for ſoon after their application, the foliage of the plant grows yellow, dries up, and the plant withers, unleſs there happens a ſhower of rain, which revives it. When theſe ſubſtances are diluted, by being mixed with water and earth, they loſe that principle which is ſo deſtructive to vegetable life, and an incipient fermentation augments their power as a manure, ſo that they may be immediately made uſe of without any apprehenſion of injury from their effects.

"It appears, therefore, that any operation upon excrementitious ſubſtances, by which they are dried and reduced to powder, cannot be practiſed without depriving thoſe ſubſtances of a great part of ſuch of their principles as are eaſily evaporated, and upon which their fluidity depends; theſe principles, when diluted with water, and confined by being mixed with earth, are capable of increaſing the produce of the ſoil. Such is the way in which the huſbandmen in Flanders make uſe of this kind of manure, in the cultivation of a kind of rape or cole ſeed, which is to them a very important branch of agricultural induſtry and commerce; and they never obſerve that the ſap carries up any of thoſe principles which give ſuch manure its offenſive ſmell; nor do they obſerve, that the fodder produced from fields ſo manured, whether eaten freſh or dry, is diſagreeable to their cattle. The excrements of all animals would be injurious to plants, if applied too freſh, or in too great quantity; and a gardener could not commit a greater fault, than to put more than a certain quantity of them into the water he means to make uſe of to water his young plants; in ſhort, this kind of manure is to be uſed in a very ſparing manner; and he that is too prodigal of it will find, to his coſt, that exceſs, even of that which is otherwiſe beneficial, becomes an evil."

"It muſt certainly be allowed, that excrementitious ſubſtances are a very advantageous manure for cold ſoils, and ſuited to moſt vegetable productions; a long experience of their effects over a large tract of country, and the acknowledged intelligence of the Flemiſh farmers, ought to be conſidered as ſufficient to overcome the prejudice that has been raiſed againſt this ſort of manure. Suppoſing that the bad effects which have been attributed to it, when uſed in the ſtate in which it is taken out of privies, &c. are not the offspring of a prejudiced imagination, they may have ariſen from its having been made uſe of at an improper time, or in too great a quantity; or from its having been applied to a ſoil and for the cultivation of plants to which it was not adapted; for we know that the exceſs of any kind of manure changes the ſmell and taſte of plants, and the ſame effect is produced by watering them too frequently. Striking examples of this change are ſeen in the ſtrawberry and in the violet, when ſuch as have grown in the woods are compared to thoſe produced from ſome of our over-manured gardens; alſo in the lettuce, and ſome other plants, when thoſe raiſed for ſale by the gardeners about Paris are compared to thoſe of ſome particular kitchen gardens. In the markets of ſome cities, the carrots, turnips, and potatoes of the fields, are preferred to the ſame kind of roots cultivated by the gardeners; for though the laſt are of a larger ſize, they have not ſo good a flavour. Some vegetables, therefore, are like certain wild ſpecies of the animal kingdom; they reſiſt every kind of culture, as thoſe animals reſiſt every effort to tame them.

Manures.

"Although experience has taught the Flemiſh farmers, that excrementitious ſubſtances are more active in their natural ſtate than when dried, yet it cannot be denied that drying them, and reducing them into powder, is ſometimes very advantageous, becauſe in that ſtate they are much leſs offenſive, are eaſily tranſported to any diſtance, and may be uſed when moſt convenient or moſt proper. In many cities the inhabitants pay to have their privies emptied: in other places, thoſe who empty them pay for their contents; and it would aſtoniſh any one to be told how great a revenue is produced in the city of Liſle in Flanders by the ſale of this kind of manure. I am, however (ſays our author), far from thinking that it is right, in all caſes, to employ it in the above-mentioned ſtate of concentration; it would be better, in my opinion, to follow the example of the Flemiſh farmers, who uſe it the firſt year for the cultivation of plants for oil, or for hemp or flax; and the ſecond year for the beſt kinds of grain: thus obtaining two crops, inſtead of one, without any farther preparation of the land. What is ſaid above may be applied alſo to the manures produced from the dung of cattle, poultry, &c. (particularly to pigeons dung, the moſt powerful manure of its kind), all which, by being dried and powdered before they are uſed, loſe a great portion of their activity. From theſe obſervations another fact may be deduced, namely, that manure ſhould not be taken from the place where it has been thrown together until the ſeaſon of the year and the ſtate of the land are ſuch that it may be put into the ground as ſoon as it is brought to it. In ſome diſtricts a very injurious cuſtom prevails of carrying the manure into the fields, and leaving it there formed into ſmall heaps, expoſed for ſome days to the elements; during which time, either the ſun and wind dry up its natural moiſture, leaving a maſs which is much leſs active; or the rain diſſolves and carries away the extractive parts impregnated with the ſalt. This kind of brine, which is the moſt powerful part of the manure, penetrates the earth to a conſiderable depth, and ſhews (by the thick tufts which ariſe in thoſe places, and which produce more ſtraw than grain) that manure

Manures. ought to be put into the ground as ſoon as it is brought to it, becauſe it then poſſeſſes its full force and effect, and conſequently would be then uſed to the greateſt advantage.

"We have always at hand the means of compoſing, from a great variety of vegetable and animal ſubſtances, ſuch manures as, when brought into a proper ſtate, and mixed with land, contribute to its fertility. Chemiſtry alſo offers to us a number of ſubſtances, which, although when uſed ſeparately they tend to diminiſh the fertilizing quality of the earth, are yet capable, by being combined, of forming excellent manures; ſuch, for inſtance, is that ſaponaceous combination which is produced from a mixture of potaſh, oil, and earth. What an advantage it would be, if, inſtead of being ſparing of manure, the inhabitants of the country would endeavour to increaſe the number of theſe reſources, and to render them more beneficial, by employing them in a more effectual manner! How many years had paſſed before it was known that the refuſe of apples and pears, after they are preſſed (and which uſed to be thrown away as uſeleſs), is capable of forming as valuable a manure, in cyder and perry countries, as the refuſe of grapes does in wine countries!"

From what has been obſerved, our author concludes, that manures act, in many circumſtances, like medicines, and conſequently that the ſame ſort of manure cannot be adapted to every ſituation, and every kind of ſoil; we muſt therefore take care to make proper diſtinctions between them. Whoever ſhall pretend that any particular kind of manure may be uſed, with equal benefit, in graſs land, corn fields, vineyards, orchards, kitchen gardens, &c. ought to be claſſed amongſt thoſe quacks who undertake to cure all perſons with the ſame remedy, without any regard to their age, conſtitution, &c. It is probably from not having paid ſufficient attention to the forementioned diſtinctions, that ſome authors have found fault with particular manures, while others have ſpoken too highly in their favour.

473 Practical rule for forming manures.

Having thus far ſtated the obſervations of this ingenious author, we think it neceſſary to remark, that the practical farmer, who wiſhes to advance ſafely and proſperouſly in his occupation, will probably find, that the beſt principle upon which he can proceed in forming his plans for the preparation of manure, will conſiſt of keeping ſtrictly in view the ideas which we formerly ſtated *, when conſidering the theory of agriculture. When we wiſh to fertilize land by art, we ought to follow nature, or to imitate the proceſs by which ſhe fertilizes it. Vegetable ſubſtances, fermented by the putrefaction of animal matters, rapidly fall down into earth, and aſſume the form of that rich black mould which is the moſt productive of all ſoils. The great object of the huſbandman, therefore, ought to be to procure large quantities of vegetable ſubſtances of every kind, ſuch as ſtraw, ſtubble, ruſhes, weeds, &c. and to lay theſe up to ferment along with the freſh dung of animals, particularly thoſe animals which chew the cud, for by digeſting their food in a very perfect manner, their dung contains a large portion of animal matter. As horſes, on the contrary, digeſt their food very weakly, their dung is often only ſufficiently animalized to bring on its own fermentation, which, however, is very ſtrong, on account of the large quantity of bits of ſtraw, hay, and other undecompoſed parts of their food which it contains. In the neighbourhood of cities, other animal ſubſtances, beſides dung, may frequently be obtained; ſuch as bullocks blood, and the refuſe of works in which train oil is prepared, none of which ought to be neglected by the huſbandman. Manures

* N° 75, 76, 77, 78.

The art of fermenting vegetable by animal matters, or the true art of making dung, has not yet been brought to perfection, nor is it in almoſt any ſituation ſufficiently attended to. In many places, we ſee large quantities of ferns, ruſhes, and the coarſe graſs of bogs, which no cattle will conſume, allowed to run to waſte; whereas, though theſe plants do not readily of themſelves run into fermentation, they might eaſily, by proper care, be made to undergo this proceſs, and conſequently be converted into a ſource of riches, that is, into fertile mould. On this ſubject, we ſhall here ſtate a mode of preparing dung upon the above principles, that has lately been diſcovered, and ſucceſsfully adopted in Mid Lothian by the Hon. Lord Meadowbank, one of the ſenators of the College of Juſtice in Scotland. It conſiſts of ſubjecting common peat-moſs to the proceſs of fermentation, now mentioned, and has been explained by his lordſhip in a ſmall printed pamphlet, of which, though not ſold to the public, a conſiderable number of copies have been diſtributed among his lordſhip's friends. It is in the following terms: "It is proper to ſtate in the outſet," ſays his lordſhip, "ſome general facts concerning the preparation of manure, which every practical farmer ſhould be acquainted with.

474 Lord Meadowbank's mode of converting moſs into manure.

"1. All recently dead animal or vegetable matter, if ſufficiently divided, moiſt, and not chilled nearly to freezing, tends ſpontaneouſly to undergo changes, that bring it at length to be a fat greaſy earth, which when mixed with ſands, clays, and a little chalk, or pounded limeſtone, forms what is called rich loam, or garden-mould.

"2. In vegetable matter, when amaſſed in quantities, theſe changes are at firſt attended with very conſiderable heat, (ſometimes proceeding the length of inflammation), which, when not exceeding blood-heat, greatly favours and quickens the changes, both in animal matter, and the further changes in vegetable matter, that are not ſenſibly attended with the production of heat. The changes attended with heat, are ſaid to happen by a fermentation, named from what is obſerved in making of ale, wine, or vinegar. The latter are aſcribed to what is called *putrefactive fermentation*.

"3. Beſides moderate moiſture and heat, and that diviſion of parts which admits the air in a certain degree, circumſtances which ſeem to be neceſſary to the production of theſe changes, ſtirring, or mechanical mixture, favours them; and a ſimilar effect ariſes from the addition of chalk, pounded limeſtone, lime, rubbiſh of old buildings, or burnt lime brought back to its natural ſtate; and alſo of aſhes of burnt coal, peat, or wood, ſoap-leys, ſoot, ſea ſhells, and ſea-ware. And, on the other hand, the changes are ſtopped or retarded by preſſure or conſolidation, excluding air; by much water, eſpecially when below the heat of a pool in ſummer; by aſtringents; and by cauſtic ſubſtances, as quicklime, acids, and pure alkalies, at leaſt till their cauſticity is mollified, at the expence of the deſtruction of part of the animal and vegetable matter to which they are added.

"4. Theſe

Manures.

" 4. Theſe changes are accompliſhed by the ſeparation or decompoſition of the parts or ingredients of which the dead vegetables and animals are compoſed; by the eſcape of ſomewhat of their ſubſtance in the form of vapours or gaſſes; by the imbibing alſo ſomewhat from water and from the atmoſphere; and by the formation of compound matters, from the reunion of parts or ingredients, which had been ſeparated by the powers of the living vegetables and animals. The earlier changes, and in general thoſe which take place previous to the deſtruction of the adheſion and texture of the dead vegetables and animals, appear to be rather pernicious than favourable to the growth of living vegetables, expoſed to the direct effect of them; whereas the changes ſubſequent to the deſtruction of the animal and vegetable texture promote powerfully the growth of plants, and, partly by their immediate efficacy on the plants expoſed to their influence, partly by the alterations they produce in the ſoil, conſtitute what is to be conſidered as enriching manure (1).

" 5. It ſhould be the object of the farmer to give his ſoil the full benefit of theſe latter changes, decompoſitions and recompoſitions, which proceed ſlowly, and continue to go on for years after the manure is lodged in the ſoil. Even loam or garden-mould is ſtill undergoing ſome remaining changes of the ſame ſort; and, by frequently ſtirring it, or removing it, and uſing it as a top-dreſſing, its ſpontaneous changes are ſo favoured, that it will yield heavy crops for a time, without freſh manure; or, in other words, it is rendered in ſo far a manure itſelf, as it decompoſes faſter than in its ordinary and more ſtationary ſtate, and, in ſo doing, nouriſhes vegetables more abundantly, or forms new combinations in the adjoining ſoil, that enable it to do ſo.

" It ſhould alſo be the object of the farmer, to employ the more early changes, not only to bring forward the ſubſtances undergoing them into a proper ſtate to be committed to the ſoil, but to accelerate or retard them, ſo as to have his manure ready for uſe at the proper ſeaſons, with as little loſs as poſſible, from part being too much and part too little decompoſed; and alſo to avail himſelf of the activity of thoſe changes, to reſtore to a ſtate of ſufficiently rapid ſpontaneous decompoſition, ſuch ſubſtances in his farm, as, though in a ſtate of decay, had become ſo ſtationary, as to be unfit for manure, without the aid of heat and mixture.

" By attention to the two firſt particulars, and the proper uſe of compreſſion, ſtirring and mixture, the farm dunghill, though formed ſlowly and of materials in very various ſtates of decay, is brought forward in nearly the ſame condition. By attention to the latter, manure may, in moſt ſituations in Scotland, be tripled or quadrupled; *et ſimum eſt aurum.* On the other hand, by inattention to them, part of the manure is put into the ſoil unprepared, that is, in a ſituation where the texture of the vegetable is ſtill entire; and, its decompoſition never having been carried far by the heat and mixture of a fermenting maſs, proceeds in the ſoil ſo ſlowly, that, like ploughed down ſtubble, it does not merit the name of manure. Part, again, is apt to be too much rotted, that is, much of it is too nearly approaching to the ſtate of garden-mould, whereby much benefit is loſt, by the eſcape of what had been ſeparated during the proceſs it has undergone, and the good effects on the ſoil of what remains are leſs durable; for, between ſolution in water and rapid decompoſition from its advanced ſtate of rottenneſs, it is ſoon reduced to that of garden-mould; and, in fine, the powers of fermenting vegetable with animal matter, which, when properly employed, are certainly moſt efficacious in converting into manure many ſubſtances that are otherwiſe very ſtationary and ſlow in their decompoſition, are loſt to the farmer, ſo that he is often reduced to adopt an imperfect and little profitable mode of cultivation, from the want of the manure requiſite for a better, though ſuch manure may be lying in abundance within his reach, but uſeleſs from his ignorance how to prepare it.

Manures

" *Peat-moſs* is to be found in conſiderable quantities within reach of moſt farms in Scotland, particularly in thoſe diſtricts where outfield land (i. e. land not brought into a regular courſe of cropping and manuring) forms the larger part of the arable land. It conſiſts of the remains of ſhrubs, trees, heath, and other vegetables, which, under the influence of a cold and moiſt climate, and in wet ſituations, have got into a condition almoſt ſtationary, but much removed from that of the recently dead vegetable, and certainly conſiderably diſtant from that of garden-mould. It is no longer ſuſceptible of going of itſelf, though placed in the moſt favourable circumſtances, into that rapid fermentation, accompanied with heat, which maſſes of freſh vegetables experience: But it is ſtill a powerful fuel when dried; and, on the other hand, it requires long expoſure to the ſeaſons, in a dry ſituation, before, without mixture, it is fit for the nouriſhing of living vegetables.

" In general, however, there is nothing in the ſituation of peat-moſs, or in the changes it has undergone, that leads to think that it has ſuffered any thing that unfits it to be prepared for manure. It is no doubt found ſometimes mixed with particular mineral ſubſtances, that may be, for a time, pernicious to vegetation; but, in general, there is no ſuch admixture, and, when it does take place, a little patience and attention will be ſufficient to cure the evil. In the ordinary caſe, the only ſubſtances found in peat that may be unfavourable to vegetation, in ſo far at leaſt as tending to keep it ſtationary and prevent its rotting, are two, and both abounding in freſh vegetables of the ſorts of which moſs is chiefly compoſed: Theſe are, gallic acid, and the aſtringent principle, or tan; and, as theſe are got the better of in freſh vegetables by the hot fermentation to which they are ſubject, ſo as to leave the general maſs of the ſubſtances to which they belonged properly prepared manure, there is no reaſon to ſuppoſe, that the ſame may not be accompliſhed with the acid and tan of peat. Again, the powers of peat as a fuel, and of aſhes of peat as a manure, ought to convince every perſon, that the material and more eſſential parts of the dead vegetable, for the formation

(1) Hot fermenting dung partakes of both ſorts of fermentation.

Manures

of manure, remain entire in peat. Here the inflammable oils and carbonaceous matter which abound in the fresh vegetable, and the latter of which also abounds in garden-mould, remain entire; the soot and ashes, too, which are the results of the inflammation of each, seem to be nearly equally fertilizing; and, in short, little seems to be lost in peat but the effects of the first fermentation in preparing the matter to undergo its future changes with the rapidity requisite to constitute manure. Besides, the soil produced from peat-earth, by exposure for a course of years, seems not to be sensibly different from that obtained from dung in the same way. Both are deficient in firmness of texture; but are very prolific when mixed with clays, sands, and calcareous earths, in due proportion.

"From considering the preceding circumstances, and from trying what substances operated on tan, and on the acid found in peat-moss, it was determined to subject it to the influence of different sorts of fermenting dung, with due attention to the proportions used, and to the effects of the different preparations; and the following is the direction, which an experience of six crops recommends to practice.

"Let the peat-moss, of which compost is to be formed, be thrown out of the pit for some weeks or months, in order to lose its redundant moisture. By this means, it is rendered the lighter to carry, and less compact and weighty, when made up with fresh dung, for fermentation; and accordingly less dung is required for the purpose, than if the preparation is made with peat taken recently from the pit.

"Take the peat-moss to a dry spot, convenient for constructing a dunghill, to serve the field to be manured. Lay it in two rows, and dung in a row betwixt them. The dung thus lies on the area of the compost-dunghill, and the rows of peat should be near enough each other, that workmen, in making up the compost, may be able to throw them together by the spade, without wheeling. In making up, let the workmen begin at one end. Lay a bottom of peat, 6 inches deep, and 15 feet wide, if the ground admit of it (M). Then lay about 10 inches of dung above the peat; then about 6 inches of peat; then four or five of dung, and then six more of peat; then another thin layer of dung; and then cover it over with peats at the end where it was begun, at the two sides, and above. It should not be raised above 4 feet, or 4½ feet high, otherwise it is apt to press too heavily on the under part, and check the fermentation. When a beginning is thus made, the workmen will proceed working backwards, and adding to the column of compost, as they are furnished with the three rows of materials, directed to be laid down for them. They must take care not to tread on the compost, or render it too compact; and of consequence, in proportion as the peat is wet, it should be made up in lumps, and not much broken.

"In mild weather, seven cart-load of common farm-dung, tolerably fresh made, is sufficient for 21 cart-loads of peat-moss: but in cold weather, a larger proportion of dung is desirable. To every 28 carts of the compost, when made up, it is of use to throw on above it a cart-load of ashes, either made from coal, peat, or wood; or if these cannot be had, half the quantity of slaked lime may be used, the more finely powdered the better. But these additions are nowise essential to the general success of the compost. Manure

"The dung to be used should either have been recently made, or kept fresh by compression; as, by the treading of cattle or swine, or by carts passing over it. And if there is little or no litter in it, a smaller quantity will serve, provided any spongy vegetable matter is added at making up the compost, as fresh weeds, the rubbish of a stack-yard, potato-shaws, sawings of timber, &c. And as some sorts of dung, even when fresh, are much more advanced in decomposition than others, it is material to attend to this; for a much less proportion of such dung, as is less advanced, will serve for the compost, provided care is taken to keep the mass sufficiently open, either by a mixture of the above-mentioned substances, or, if these are wanting, by adding the moss piece-meal, that is, first mixing it up in the usual proportion of three to one of dung, and then, after a time, adding an equal quantity, more or less, of moss. The dung of this character, of greatest quantity, is shamble-dung, with which, under the above precautions, six times the quantity of moss, or more, may be prepared. The same holds as to pigeon-dung, and other fowl-dung; and to a certain extent, also, as to that which is collected from towns, and made by animals that feed on grains, refuse of distilleries, &c.

"The compost, after it is made up, gets into a general heat, sooner or later, according to the weather, and the condition of the dung: in summer, in ten days or sooner; in winter, not perhaps for many weeks, if the cold is severe. It always, however, has been found to come on at last; and in summer, it sometimes rises so high, as to be mischievous, by consuming the materials, (fire-fanging). In that season, a stick should be kept in it in different parts, to pull out and feel now and then: for if it approaches to blood-heat, it should either be watered, or turned over; and on such an occasion, advantage may be taken to mix it with a little fresh moss. The heat subsides after a time, and with great variety, according to the weather, the dung, and the perfection of the making up of the compost; which then should be allowed to remain untouched, till within three weeks of using, when it should be turned over, upside down, and outside in, and all lumps broken: then it comes into a second heat; but soon cools, and should be taken out for use. In this state, the whole, except bits of the old decayed wood, appears a black free mass, and spreads like garden-mould. Use it, weight for weight, as farm-yard dung; and it will be found, in a course of cropping, fully to stand the comparison.

"The addition recommended of ashes or lime, is thought to favour the general perfection of the preparation, and to hasten the second heat. The lime laid on above the dunghill, as directed, is rendered mild by the vapours that escape during the first heat.

"Compost, made up before January, has hitherto been

(M) This alludes to the propriety, in clay lands, of suiting the dunghill to the breadth of a single *ridge*, free of each furrow.

Manures

been in good order for the ſpring-crops; but this may not happen in a long froſt. In ſummer, it is ready in eight or ten weeks; and if there is an anxiety to have it ſoon prepared, the addition of aſhes, or of a little lime-rubbiſh of old buildings, or of lime ſlaked with foul water, applied to the dung uſed in making up, will quicken the proceſs conſiderably.

" Lime has been mixed previouſly with the peat; but the compoſt prepared with that mixture, or with the ſimple peat, ſeemed to produce equally good crops. All the land, however, that it has been tried on, has been limed more or leſs within theſe 25 years.

" Peat prepared with lime alone, has not been found to anſwer as a good manure. In one inſtance, viz. on a bit of fallow ſown with wheat, it was manifeſtly pernicious. Neither with cow-water alone is it prepared, unleſs by lying immerſed in a pool of it for a long time, when it turns into a ſort of ſleetch, which makes an excellent top-dreſſing. Something of the ſame ſort happens with ſoap-ſuds, and water of common ſewers, &c. Lime-water was not found to unite with the tan in peat, nor was urine (x). Peat made up with ſea-weed gets into heat, and the peat ſeems to undergo the ſame change as when prepared with dung. But the effect of this preparation on crops has not yet been experienced. Peat has alſo been expoſed to the fumes of a putrefying carcaſe. In one inſtance the peat proved a manure; but much weaker than when prepared with dung. There, however, the proportion uſed was very large to the carcaſe. Other trials are making, where the proportion is leſs, and with, or without, the addition of aſhes, lime, &c. In all theſe caſes, there can be no ſenſible heat. Peat, heated and rendered friable by the action of the living principle of turnips in growing, was not found entitled, when uſed as a top-dreſſing, to the character of manure. It had been made up in the view of preſerving the turnips during froſt. But the turnips ſprung, and the maſs heated. The turnips were taken out and the peat afterwards uſed as a top-dreſſing. Peat is now under trial, as preparing with turnips and freſh weeds, in fermentation, without the admixture of any animalized matters.

" It is ſaid that dry peat-earth is uſed as a manure in ſome parts of England. But unleſs in chalky ſoils, or others where there may be a great want of carbonaceous matter, it is much doubted whether it could be uſed with any ſenſible advantage. Peat-aſhes were found to raiſe turnips, but to have no ſenſible effect on the next crop.

" The quantity of the compoſt uſed per acre, has varied conſiderably, according to the richneſs of the ſoil manured, and the condition in which it is at manuring, and the ſeaſon in which the manure is applied. From 23 to 35 cart-load, by two horſes each, is about what has been given; the leſſer to fallows and ground in good tilth, and the larger when to be ploughed in with the ſward of poor land; and the intermediate quantities, with tares, peaſe, potatoes, &c.; and it has in moſt caſes undergone comparative trials with different ſorts of common dung. Manures.

" It may be proper to add, that too much attention cannot be paid to the proper preparation of the ground for the reception of manure. It ſhould be clean, pretty dry at the application, and well mixed and friable. Much of the manure applied is otherwiſe loſt, whether lime, dung, or compoſt. The additional quantities recommended when the land is coarſe, is juſt ſo much that would have been ſaved by better cultivation. Common farmers are little aware of this. They might ſave at leaſt half their lime, did they lay it on in powder (o), and on fallows, only harrowing it, and letting it wait for a ſhower before it is ploughed in; and perhaps not much leſs of their dung. It is aſtoniſhing what a viſible effect is produced on land properly mixed by a fallow, from the addition of only a very ſmall quantity of properly prepared dung or compoſt. Both its texture and colour undergo a very ſenſible change, which cannot be accounted for, except from the extrication of ſubſtances from the decompoſing manure, (probably from its ſpontaneous tendency to decompoſe being aided by the chemical action of various matters in a ſoil ſo prepared): And from theſe ſubſtances operating in the ſoil, numberleſs compoſitions and decompoſitions, or tendencies to them, take place, from the various elective attractions of the different parts of which it is compoſed. It is obvious, that an immenſely greater proportion of manure muſt be required to produce even a little of this, where the ſoil is coarſe or lumpy, or conſolidated by wetneſs, than when put into a ſituation favourable to the reciprocal action of the various ſubſtances contained in it, a variety and an admixture formed by nature in perfection in the more favoured ſoils, (as in the bottom of drained lakes, haughs, Delta ground), and which it is the buſineſs of the ſkilful and induſtrious farmer to form or make compenſation for the want of, by judicious manuring, where nature has been leſs bountiful of her gifts.

" It was meant to have given a detailed account of many of the experiments that have been made, whether in Agriculture or Chemiſtry. But as theſe are ſtill going on, and the practical reſults have attracted ſome attention, and prompted imitation by neighbours and acquaintance, ſo that manuſcript directions have been often applied for and obtained, it has been preferred to print, in the mean time, this ſhort account of the buſineſs, diveſted of ſcientific language, and ſuited to the peruſal of any practical huſbandman. It was indeed felt as a degree of wrong, not to take ſome ſteps to make it public, as ſoon as the certainty of ſucceſs warranted. And both the power and the duration

(x) Tan combines with animal gelly, and loſes its aſtringency. The animalized matter, extricated in fermenting dung, has probably this effect on the tan in peat, as well as to render the acid innocent. As vegetable matters ſeem in general to contain the ingredients of, and often ſomewhat ſimilar to, animal gluten, it is poſſible that the fermentation of freſh vegetables alone may prove ſufficient to prepare the peat to rot in the ſoil expeditiouſly; but it is certainly deſirable to uſe alſo animalized matter for this purpoſe.

(o) This they may, though driven in winter, and drowned in the heaps by rains. They have only to turn it over with a very ſmall additional quantity of new burnt ſhells when they come to uſe it.

Manures.

tion of the manure have now ſtood the teſt of a great variety of trials, on a conſiderable extent of ground, and of much diverſity of ſoil, continued without intermiſſion during the laſt ſix years. Hitherto it has been found equal, and indeed preferable, to common farm-yard dung, for the firſt three years, and decidedly to ſurpaſs it afterwards. It has been conjectured, from the appearance and effects of the compoſt, that its parts are leſs volatile and ſoluble than thoſe of dung; but that it yields to the crop what is requiſite, by the action of the living fibres of vegetables; and in this way waſtes ſlower, and laſts longer. Whatever be in this, nothing has appeared more remarkable, than its ſuperiority in maintaining (for four and five years) freſh and nouriſhing the paſture of thin clays, that had been laid down with it, and in making them yield well when again ploughed, and that without any top-dreſſing, or new manure of any ſort. Employed in this way, the effect of common dung is ſoon over, the ſoil becoming conſolidated, and the paſture ſtunted; and hence ſuch ſoils have not uſually been cultivated with advantage, except by tillage, and by the aid of quantities of manure, got by purchaſe, and much beyond the produce of the farm-yard. It is believed that the foregoing directions will, if practiſed, prove beneficial to every farmer who has acceſs to peat-moſs within a moderate diſtance; but it is to the farmers of the ſoils now mentioned, and of hungry gravels, to whom they would be found particularly valuable.

"Let it be obſerved, that the object in making up the compoſt is to form as large a hot-bed as the quantity of dung employed admits of, and then to ſurround it on all ſides, ſo as to have the whole benefit of the heat and effluvia. Peat, as dry as garden-mould, in ſeed-time, may be mixed with the dung, ſo as to double the volume and more, and nearly triple the weight, and inſtead of hurting the heat prolong it. Workmen muſt begin with uſing layers; but, when accuſtomed to the juſt proportions, if they are furniſhed with peat moderately dry, and dung not loſt in litter, they throw it up together as a mixed maſs; and they improve in the art, ſo as to make a leſs proportion of dung ſerve for the preparation."

475 Of the more common kinds of manure.

With regard to the other kinds of manure commonly in uſe in this country, their efficacy is well known; the only difficulty is to procure them in ſufficient quantity.—In ſuch lands as lie near the ſea, ſea-weeds offer an unlimited quantity of excellent manure. In the neighbourhood of rivers, the weeds with which they abound offer likewiſe an excellent manure in plenty. Oil-cake, malt-coombs, the refuſe of ſlaughter-houſes, &c. all are excellent where they can be got: but the ſituations which afford theſe are comparatively few; ſo that in moſt caſes the farmer muſt depend much on his own ingenuity and induſtry for raiſing a ſufficient quantity of dung to anſwer his purpoſes: and the methods taken for this purpoſe vary according to the ſituation of different places, or according to the fancy of the huſbandman.

476 Manures uſed in Norfolk.

In all countries where chalk, marl, or lime are to be had, they are certainly to be employed in their proper departments; but beſides theſe, *dung*, properly ſo called, mixed with earth or putrid animal and vegetable ſubſtances, everywhere conſtitutes a principal part of the manure. In Norfolk, Mr Marſhall tells us, that the *quality* of dung is attended to with greater preciſion than in moſt other diſtricts. *Town-muck*, as it is called, is held in moſt eſtimation; and the large towns Norwich and Yarmouth ſupply the neighbouring country. As Yarmouth, however, is a maritime place, and otherwiſe in a manner ſurrounded by marſhes, ſtraw is of courſe a ſcarce and dear article; whence, inſtead of littering their horſes with it, they uſe ſand. As the bed becomes ſoiled or wet, freſh ſand is put on, until the whole is in a manner ſaturated with urine and dung, when it is cleared away, and reckoned muck of ſuch excellent quality, that it is ſent for from a very great diſtance. With regard to other kinds of dung, that from horſes fed upon hay and corn is looked upon to be the beſt; that of fatting cattle the next; while the dung of lean cattle, particularly of cows, is ſuppoſed to be greatly inferior, even though turnips make part of their food. The dung of cattle kept on ſtraw alone is looked upon to be of little or no value; while the muck from trodden ſtraw is by ſome thought to be better than that from the ſtraw which is eaten by the lean ſtock.—Compoſts of dung with marl or earth are very generally uſed.

Manures

477 In the midland diſtrict.

In the midland counties of England, Mr Marſhall informs us, the cores of horns cruſhed in a mill have been uſed as manure; though he knows not with what ſucceſs. His only objection is the difficulty of reducing them to powder. Dung is extremely dear in Norfolk; half a guinea being commonly given for a waggon-load driven by five horſes. Great quantities of lime and marle are found in this diſtrict. With regard to the method of raiſing dung in general, perhaps the obſervations of Mr Marſhall upon the management of the Yorkſhire farmers may be equally ſatisfactory with any thing that has yet been publiſhed on the ſubject.

478 Mr Marſhall's directions for raiſing dung.

"The general practice (ſays he) is to pile the dung on the higheſt part of the yard; or, which is ſtill leſs judicious, to let it lie ſcattered about on the ſide of a ſlope, as it were for the purpoſe of diſſipating its virtues. The urine which does not mix with the dung is almoſt invariably led off the neareſt way to the common ſewer, as if it were thought a nuiſance to the premiſes. That which mixes with the dung is of courſe carried to the *midden*, and aſſiſts in the general diſſipation. A yard of *dung*, nine-tenths of which are ſtraw, will diſcharge, even in dry weather, ſome of its more fluid particles; and in rainy weather, is, notwithſtanding the ſtraw, liable to be waſhed away if expoſed on a riſing ground. But how much more liable to waſte is a mixture of dung and urine, with barely a ſufficiency of ſtraw to keep them together! In dry weather the natural oozing is conſiderable; and in a wet ſeaſon every ſhower of rain waſhes it away in quantities. The Norfolk method of bottoming the dung-yard with mould is here indiſpenſably neceſſary to common good management. There is no better manure for graſs-lands than mould ſaturated with the oozing of a dunghill: it gets down quickly among the graſs, and has generally a more viſible effect than the dung itſelf. Under this management the arable land would have the ſelf-ſame dung it now has; while the graſs-land would have an annual ſupply of riches, which now run to waſte in the ſewers and rivulets. But before a dung-yard can with propriety be bottomed with mould, the bot-

Manures.

tom of the yard itſelf ought to be properly formed. A part of it ſituated conveniently for carriages to come at, and low enough to receive the entire drainings of the ſtable, cattle-ſtalls, and hog-ſties, ſhould be hollowed out in the manner of an artificial drinking-pool, with a rim ſomewhat riſing, and with covered drains laid into it from the various ſources of liquid manure. During the ſummer months, at leiſure times, and embracing opportunities of back-carriage, fill the hollow nearly full with mould, ſuch as the ſcourings of ditches, the ſhovellings of roads, the maiden earth of lanes and waſte corners, the coping of ſtone-quarries, &c. &c. leaving the ſurface ſomewhat diſhed; and within this diſh ſet the dung-pile, carefully keeping up a rim of mould round the baſe of the pile higher than the adjoining ſurface of the yard; equally to prevent extraneous matter from finding its way into the reſervoirs, and to prevent the eſcape of that which falls within its circuit."

479 Of lime as a manure. *N° 79, 80, 81.

The uſe of lime, as a manure, was formerly mentioned*, and alſo the principle upon which its value depends. It ought to be uſed not for the purpoſe of giving food to the plants, but as a ſtimulant, tending to bring the ſoil into activity, by reducing to mould all the dead roots of vegetables with which it may abound. Hence it ought never to be uſed without dung upon ſoils that have been exhauſted by repeated cropping, and that are in a clean ſtate.

480 Its operation.

However people may differ in other particulars, all agree, that the operation of lime depends on its intimate mixture with the ſoil; and therefore that the proper time of applying it, is when it is perfectly powdered, and the ſoil at the ſame time in the higheſt degree of pulverization. Lime of itſelf is abſolutely barren; and yet it enriches a barren ſoil. Neither of the two produces any good effect without the other; and conſequently, the more intimately they are mixed, the effect muſt be the greater.

Hence it follows, that lime ought always to be ſlaked with a proper quantity of water, becauſe by that means it is reduced the moſt effectually into powder. Lime left to be ſlaked by a moiſt air, or accidental rain, is ſeldom or never thoroughly reduced into powder, and therefore can never be intimately mixed with the ſoil. Sometimes an opportunity offers to bring home ſhell-lime before the ground is ready for it; and it is commonly thrown into a heap without cover, truſting to rain for ſlaking. The proper way is, to lay the ſhell-lime in different heaps on the ground where it is to be ſpread, to reduce theſe heaps into powder by ſlaking with water, and to cover the ſlaked lime with ſod, ſo as to defend it from rain. One, however, ſhould avoid as much as poſſible the bringing home lime before the ground be ready for it. Where allowed to lie long in a heap, there are two bad conſequences: firſt, lime attracts moiſture, even though well covered, and runs into clots, which prevents an intimate mixture; and, next, we know that burnt limeſtone, whether in ſhells or in powder, returns gradually into its original ſtate of limeſtone; and upon that account alſo, is leſs capable of being mixed with the ſoil. And this is verified by a fact, that, after lying long, it is ſo hard bound together as to require a pick to ſeparate the parts.

For the ſame reaſon, it is a bad practice, though common, to let ſpread lime lie on the ſurface all winter. The bad effects above mentioned take place here in part: and there is another, that rain waſhes the lime down to the furrows, and in a hanging field carries the whole away. Manures.

481 Time of liming.

As the particles of powdered lime are both ſmall and heavy, they quickly ſink to the bottom of the furrow, if care be not taken to prevent it. In that view, it is a rule, that lime be ſpread and mixed with the ſoil immediately before ſowing, or along with the ſeed. In this manner of application, there being no occaſion to move it till the ground be ſtirred for a new crop, it has time to incorporate with the ſoil, and does not readily ſeparate from it. Thus, if turnip-ſeed is to be ſown broad-caſt, the lime ought to be laid on immediately before ſowing, and harrowed in with the ſeed. If a crop of drilled turnip or cabbage be intended, the lime ought to be ſpread immediately before forming in drills. With reſpect to wheat, the lime ought to be ſpread immediately before ſeed-furrowing. If ſpread more early, before the ground be ſufficiently broken, it ſinks to the bottom. If a light ſoil be prepared for barley, the lime ought to be ſpread after ſeed-furrowing, and harrowed in with the ſeed. In a ſtrong ſoil, it ſinks not ſo readily to the bottom, and therefore, before ſowing the barley, the lime ought to be mixed with the ſoil by a brake. Where moor is ſummer-fallowed for a crop of oats next year, the lime ought to be laid on immediately before the laſt ploughing, and braked in as before. It has ſufficient time to incorporate with the ſoil before the land be ſtirred again.

482 Quantity.

The quantity to be laid on depends on the nature of the ſoil. Upon a ſtrong ſoil, 70 or 80 bolls of ſhells are not more than ſufficient, reckoning four ſmall firlots to the boll, termed *wheat meaſure;* nor will it be an overdoſe to lay on 100 bolls. Between 50 and 60 may ſuffice upon medium ſoils; and upon the thin or gravelly, between 39 and 40. It is not ſafe to lay a much greater quantity on ſuch ſoils.

483 Limurg paſture-fields.

It is common to lime a paſture-field immediately before ploughing. This is an unſafe practice; it is thrown to the bottom of the furrow, from which it is never fully gathered up. The proper time for liming a paſture-field, intended to be taken up for corn, is a year at leaſt, or two, before ploughing. It is waſhed in by rain among the roots of the plants, and has time to incorporate with the ſoil.

484 Beat limeſtone.

Limeſtone beat ſmall makes an excellent manure; and ſupplies the want of powdered lime where there is no fuel to burn the limeſtone. Limeſtone beat ſmall has not hitherto been much uſed as a manure; and the proportion between it and powdered lime has not been aſcertained. What follows may give ſome light. Three pounds of raw lime is by burning reduced to two pounds of ſhell-lime. Yet nothing is expelled by the fire but the air that was in the limeſtone: the calcareous earth remains entire. *Ergo*, two pounds of ſhell-lime contain as much calcareous earth as three pounds of raw limeſtone. Shell lime of the beſt quality, when ſlaked with water, will meaſure out to thrice the quantity. But as limeſtone loſes none of its bulk by being burnt into ſhells, it follows, that three buſhels of raw limeſtone contain as much calcareous earth as ſix buſhels of powdered lime; and conſequently, if powdered lime

Manures. lime poſſeſs not ſome virtue above raw limeſtone, three buſhels of the latter beat ſmall ſhould equal as a manure ſix buſhels of the former.

485 Of ſhell-marl. Shell-marl, as a manure, is managed in every reſpect like powdered lime; with this only difference, that a fifth or a fourth part more in meaſure ought to be given. The reaſon is, that ſhell-marl is leſs weighty than lime; and that a boll of it contains leſs calcareous earth, which is the fructifying part of both.

486 Of clay and ſtone marls. Clay and ſtone marls, with reſpect to huſbandry, are the ſame, though in appearance different.

The goodneſs of marl depends on the quantity of calcareous earth in it: which has been known to amount to a half or more. It is too expenſive if the quantity be leſs than a third or a fourth part. Good marl is the moſt ſubſtantial of all manures; becauſe it improves the weakeſt ground to equal the beſt borough-acres. The low part of Berwickſhire, termed *the Merſe*, abounds everywhere with this marl; and is the only county in Scotland where it is plenty.

Land ought to be cleared of weeds before marling; and it ought to be ſmoothed with the brake and harrow, in order that the marl may be equally ſpread. Marl is a foſſil on which no vegetable will grow; its efficacy depends, like that of lime, on its pulverization, and intimate mixture with the ſoil. Toward the former, alternate drought and moiſture contribute greatly, as alſo froſt. Therefore, after being evenly ſpread, it ought to lie on the ſurface all winter. In the month of October it may be rouſed with a brake; which will bring to the ſurface, and expoſe to the air and froſt, all the hard parts, and mix with the ſoil all that is powdered. In that reſpect it differs widely from dung and lime, which ought uſually to be ploughed into the ground without delay. Oats is a hardy grain, which will anſwer for height the firſt crop after marling better than any other; and it will ſucceed though the marl be not thoroughly mixed with the ſoil. In that caſe, the marl ought to be ploughed in with an ebb furrow immediately before ſowing, and braked thoroughly. It is tickliſh to make wheat the firſt crop: if ſown before winter, froſt ſwells the marl, and is apt to throw the ſeed out of the ground; if ſown in ſpring, it will ſuffer more than oats by want of due mixture.

Summer is the proper ſeaſon for marling; becauſe in that ſeaſon the marl, being dry, is not only lighter, but is eaſily reduced to powder. Froſt, however, is not improper for marling, eſpecially as in froſt there is little opportunity for any other work.

Marl is a heavy body, and ſinks to the bottom of the furrow, if indiſcreetly ploughed. Therefore the firſt crop ſhould always have an ebb furrow. During the growing of that crop, the marl has time to incorporate with the ſoil, and to become a part of it; after which it does not readily ſeparate.

487 Of gypſum as a manure. Of late a new manure has been introduced into ſome countries. This is gypſum, which is lime united with ſulphuric acid. In the eighth volume of the Annals of Agriculture we are informed, that it is commonly uſed as a manure in Switzerland. In the 10th volume of the ſame work, Sir Richard Sutton gives ſome account of an experiment made with it on his eſtate; but in ſuch an inaccurate manner, that nothing could be determined. "The appearance in general (ſays he), I think, was rather againſt the benefit of the plaſter, though not decidedly ſo." He tells us, that its virtues were a ſubject of debate in Germany. In America this ſubſtance ſeems to have met with more ſucceſs than in any other country. In the fifth volume of Bath Papers, Mr Kirkpatrick of the iſle of Wight, who had himſelf viſited North America, informs us, that it is much uſed in the United States, on account of its cheapneſs and efficacy; though, from what is there ſtated, we muſt undoubtedly be led to ſuppoſe, that its *efficacy* muſt be very great before it can be entitled to the praiſe of *cheapneſs*. In the firſt place, it is brought from the hills in the neighbourhood of Paris to Havre de Grace, and from thence exported to America; which of itſelf muſt occaſion a conſiderable expence, though the plaſter were originally given *gratis*. In the next place it muſt be powdered in a ſtamping mill, and the finer it is powdered ſo much the better. In the third place, it muſt be *ſown* over the ground to be manured with it. The quantity for graſs is ſix buſhels to an acre. It ought to be ſown on dry ground in a wet day; and its efficacy is ſaid to laſt from ſeven to twelve years. It operates entirely as a top-dreſſing.

In the 10th volume of the Annals of Agriculture, we have ſome extracts from a treatiſe by Mr Powel, preſident of the Philadelphia Society for encouraging Agriculture, upon the ſubject of gypſum as a manure; of the efficacy of which he gives the following inſtances. 1. In October 1786, plaſter of Paris was ſown in a rainy day upon wheat-ſtubble without any previous culture. The crop of wheat had ſcarce been worth reaping, and no kind of graſs ſeed had been ſown upon the ground; nevertheleſs, in the month of June it was covered with a thick mat of white clover, clean and even, from ſix to eight inches in height. A piece of ground adjoining to this white clover was alſo ſown with gypſum, and exhibited a fine appearance of white and red clover mixed with ſpear-graſs. Some wet ground ſown at the ſame time was not in the leaſt improved.—This anecdote reſts entirely on the veracity of an anonymous farmer. 2. Eight buſhels of plaſter of Paris ſpread upon two acres and a half of wheat-ſtubble ground, which the ſpring before had been ſowed with about two pounds of red clover-ſeed to the acre for paſture, yielded five tons of hay by the middle of June. A ſmall piece of ground of ſimilar quality, but without any plaſter, produced only one ton and a half in the ſame proportion.—Mr Powel concludes in favour of the effects of the plaſter upon arable as well as graſs land.

Other accounts to the ſame purpoſe have been publiſhed, though it muſt alſo be remarked, that various perſons who have made trial of this manure, declare themſelves diſſatisfied with it; but it does not appear that it has hitherto been at all tried in this part of the iſland.

When a ſoil abounds too much in particles of a particular kind, it has been found expedient to mix it with earth of a different character. Hence we are informed in the 12th volume of the Annals of Agriculture, that in Cornwall, large quantities of ſea-ſand are annually conveyed to the land, and laid upon the ſoil; a practice which will no doubt have a tendency to ameliorate ſtiff clays, and to render them more pervious to the roots of plants. With the ſame view, and alſo to ſave fuel, a practice is ſaid to exiſt in the Netherlands, of baking

488 Of ſea-ſ as a ma nure.

Drill or Horſe-hoeing Huſbandry.

baking up the droſs or culm of coal, and alſo peat-earth, with clay, into lumps or bricks, which when dried in the air, make excellent fuel, and alſo afford an immenſe quantity of valuable aſhes to be laid upon the land.

Sect. VIII. *Principles and Operations of the Drill or Horſe-hoeing Huſbandry.*

The general properties attributed to the new or drill huſbandry may be reduced to two, viz. the promoting the growth of plants by hoeing, and the ſaving of ſeed; both of which are equally profitable to the farmer.

489 Advantages aſcribed to horſe-hoeing.

The advantages of tillage before ſowing have already been pointed out. In this place we muſt confine ourſelves to the utility of tillage after ſowing. This kind of tillage is moſt generally known by the name of *horſe-hoeing*.

Land ſowed with wheat, however well it may be cultivated in autumn, ſinks in the winter; the particles get nearer together, and the weeds riſe; ſo that in ſpring, the land is nearly in the ſame ſituation as if it never had been ploughed. This, however, is the ſeaſon when it ſhould branch and grow with moſt vigour; and conſequently ſtands moſt in need of ploughing or hoeing, to deſtroy the weeds, to ſupply the roots with freſh earth, and, by dividing anew the particles of the ſoil, to allow the roots to extend and collect nouriſhment.

It is well known, that, in gardens, plants grow with double vigour after being hoed or tranſplanted. If plants growing in arable land could be managed with eaſe and ſafety in this manner, it is natural to expect, that their growth would be promoted accordingly. Experience ſhows, that this is not only practicable, but attended with many advantages.

In the operation of hoeing wheat, though ſome of the roots be moved or broken, the plants receive no injury; for this very circumſtance makes them ſend forth a greater number of roots than formerly, which enlarge their paſture, and conſequently augment their growth.

Sickly wheat has often recovered its vigour after a good hoeing, eſpecially when performed in weather not very hot or dry.

Wheat, and ſuch grain as is ſown before winter, requires hoeing more than oats, barley, or other grain ſown in the ſpring; for, if the land has been well ploughed before the ſowing of ſpring corn, it neither has time to harden, nor to produce many weeds, not having been expoſed to the winter's ſnow and rain.

Of Sowing.

490 Method of ſowing in the drill huſbandry.

As in the practice of the new huſbandry, plants grow with greater vigour than by the old method, the land ſhould be ſowed thinner. It is this principle of the new huſbandry that has been chiefly objected to; for, upon obſerving the land occupied by a ſmall number of plants, people are apt to look upon all the vacant ſpace as loſt. But this prejudice will ſoon be removed, when it is conſidered, that in the beſt land cultivated in the common method, and ſown very thick, each ſeed produces but one or two ears; that, in the ſame land ſown thinner, every ſeed produces two or three ears; and that a ſingle ſeed ſometimes produces 18 or 21 ears.

In the common method, as there are many more plants than can find ſufficient nouriſhment, and as it is impoſſible to aſſiſt them by hoeing, numbers die before they attain maturity; the greateſt part remain ſickly and drooping; and thus part of the ſeed is loſt. On the contrary, in the new method, all the plants have as much food as they require; and as they are, from time to time, aſſiſted by hoeing, they become ſo vigorous as to equal in their production the numerous but ſickly plants cultivated in the common method.

Drill or Horſe-hoeing Huſbandry

Of Hoeing.

The new huſbandry is abſolutely impracticable in lands that are not eaſily ploughed. Attempting to cultivate land according to this huſbandry, without attending to this circumſtance, that it is practicable in no land excepting ſuch as has already been brought into good tilth by the old method, has gone far to make it contemptible in many places.

When a field is in good tilth, it ſhould be ſown ſo thin as to leave ſufficient room for the plants to extend their roots. After being well ploughed and harrowed, it muſt be divided into rows, at the diſtance of 30 inches from one another. On the ſides of each of theſe rows, two rows of wheat muſt be ſowed ſix inches diſtant from each other. By this means there will be an interval of two feet wide betwixt the rows, and every plant will have room enough to extend its roots, and to ſupply it with food. The intervals will likewiſe be ſufficient for allowing the earth to be hoed or tilled without injuring the plants in the rows.

491 The different hoeings.

The firſt hoeing, which ſhould be given before the winter, is intended to drain away the wet, and to diſpoſe the earth to be mellowed by the froſts. Theſe two ends will be anſwered by drawing two ſmall furrows at a little diſtance from the rows, and throwing the earth taken from the furrows into the middle of the intervals. This firſt hoeing ſhould be given when the wheat is in leaf.

The ſecond hoeing, which is intended to make the plants branch, ſhould be given after the hard froſts are over. To do this with advantage, after ſtirring the earth a little near the rows, the earth which was thrown into the middle of the intervals ſhould be turned back into the furrows. This earth, having been mellowed by the winter, ſupplies the plants with excellent food, and makes the roots extend.

The third hoeing, which is intended to invigorate the ſtalk, ſhould be given when the ears of the corn begin to ſhow themſelves. This hoeing may, however, be very ſlight.

But the laſt hoeing is of the greateſt importance, as it enlarges the grain, and makes the ears fill at their extremities. This hoeing ſhould be given when the wheat is in bloom; a furrow muſt be drawn in the middle of the interval, and the earth thrown to the right and left on the foot of the plants. This ſupports the plants, prevents them from being laid, and prepares the ground for the next ſowing, as the ſeed is then to be put in the middle of the ground that formed the intervals.

The beſt ſeaſon for hoeing is two or three days after rain, or ſo ſoon after rain as the ſoil will quit the inſtrument in hoeing. Light dry ſoils may be hoed almoſt at any time, but this is far from being the caſe with ſtrong

Drill or Horſe-hoeing Huſbandry.

ſtrong clay ſoils; the ſeaſon for hoeing ſuch is frequently ſhort and precarious; every opportunity therefore ſhould be carefully watched, and eagerly embraced. The two extremes of wet and dry, are great enemies to vegetation in ſtrong clay ſoils. There is a period between the time of clay ſoils running together, ſo as to puddle by ſuperfluous wet, and the time of their caking by drought, in which they are perfectly manageable. This is the juncture for hoeing; and ſo much land as ſhall be thus ſeaſonably hoed, will not cake or cruſt upon the ſurface, as it otherwiſe would have done, till it has been ſoaked or drenched again with rain; in which caſe the hoeing is to be repeated as ſoon as the ſoil will quit the inſtrument, and as often as neceſſary; by which time the growing crop will begin to cover the ground, ſo as to act as a ſcreen to the ſurface of the land againſt the intenſe heat of the ſun, and thereby prevent, in a great meaſure, the bad effects of the ſoil's caking in dry weather.

By this ſucceſſive tillage, or hoeing, good crops will be obtained, provided the weather is not very unfavourable.

But as ſtrong vigorous plants are long before they arrive at maturity, corn raiſed in the new way is later in ripening than any other, and muſt therefore be ſown earlier.

In order to prepare the intervals for ſowing again, ſome well-rotted dung may be laid in the deep furrows made in the middle of the intervals; and this dung muſt be covered with the earth that was before thrown towards the rows of wheat. But, if the land does not require mending, the deep furrow is filled without any dung. This operation ſhould be performed immediately after harveſt, that there may be time to give the land a ſlight ſtirring before the rows are ſowed; which ſhould occupy the middle of the ſpace which formed the intervals during the laſt crop. The intervals of the ſecond year take up the ſpace occupied by the ſtubble of the firſt.

Suppoſing dung to be neceſſary, which is denied by many, a very ſmall quantity is ſufficient; a ſingle layer, put in the bottom of each furrow, will be enough.

Description of the Instruments commonly uſed in the New Husbandry.

492 Inſtruments deſcribed, Plate X.

Fig. 1. is a marking plough. The principal uſe of this plough is to ſtraight and regulate the ridges. The firſt line is traced by the eye, by means of three poles, placed in a ſtraight line. The plough draws the firſt furrow in the direction of this line; and at the ſame time, with the tooth A, fixed in the block of wood near the end of the croſs-pole or ſlider BB, marks the breadth of the ridge at the diſtance intended. The ploughman next traces the next line or rutt made by the tooth, and draws a ſmall furrow along it: and continues in this manner till the whole field is laid out in ſtraight and equidiſtant ridges.

Fig. 2. is a plough for breaking up ley, or turning up the bottom of land when greatly exhauſted. By its conſtruction, the width and depth of the furrows can be regulated to a greater certainty than by any other hitherto known in this country. Its appearance is heavy: but two horſes are ſufficient to plough with it in ordinary free land; and only four are neceſſary in the ſtiffeſt clay-ſoils. This plough is likewiſe eaſily held and tempered. A, is the ſword fixed in the ſizers B, which runs through a mortoiſe E, at the end of the beam C, and regulates the depth of the furrow by raiſing or depreſſing the beam; it is fixed by putting the pin D through the beam and ſword, and is moveable at E.

Drill or Horſe-hoeing Huſbandry.

Fig. 3. is a jointed brake-harrow with 24 teeth, ſhaped like coulters, and ſtanding at about an angle of 80 degrees. By this inſtrument the land is finely pulverized, and prepared for receiving the ſeed from the drill. It requires four horſes in ſtiff, and two in open land. This harrow is likewiſe uſed for levelling the ridges; which is done by preſſing it down by the handles where the ridge is high, and raiſing it up when low. Plate X.

Fig. 4. is an angular weeding harrow, which may follow the brake when neceſſary. The ſeven hindmoſt teeth ſhould ſtand at a more acute angle than the reſt, in order to collect the weeds, which the holder can drop at pleaſure, by raiſing the hinder part, which is fixed to the body of the harrow by two joints.

Fig. 5. is a pair of harrows with ſhafts. This harrow is uſed for covering the ſeed in the drills, the horſe going in the furrow.

Fig. 6. is a drill-plough, conſtructed in ſuch a manner as to ſow at once two rows of beans, peaſe, or wheat. This machine is eaſily wrought by two horſes. A, is the happer for containing the ſeed; B, circular boxes for receiving the ſeed from the happer; CC, two ſquare boxes which receive the ſeed from ſmall holes in the circular boxes, as they turn round; and laſt of all, the ſeed is dropped into the drills through holes in the ſquare boxes, behind the coulters D. The cylinder E follows, which, together with the wheel F, regulates the depth of the coulters, and covers the ſeed; the harrow G comes behind all, and covers the ſeed more completely. HH, two ſliders, which, when drawn out, prevent the ſeed from falling into the boxes; and, I, is a ketch which holds the rungs, and prevents the boxes from turning, and loſing ſeed at the ends of the ridges.

Fig. 7. is a ſingle hoe-plough of a very ſimple conſtruction, by which the earth in the intervals is ſtirred and laid up on both ſides to the roots of the plants, and at the ſame time the weeds are deſtroyed. AA the mouldboards, which may be raiſed or depreſſed at pleaſure, according as the farmer wants to throw the earth higher or lower upon the roots.

Fig. 2. is a drill-rake for peaſe. This inſtrument, which is chiefly calculated for ſmall incloſures of light grounds, is a ſort of ſtrong plough rake, with four large teeth at *a*, *a*, *b*, *b*, a little incurvated. The diſtance from *a* to *a*, and from *b* to *b*, is nine inches. The interval between the two inner teeth, *a* and *b*, is three feet ſix inches, which allows ſufficient room for the hole-plough to move in. To the piece of timber *c c*, forming the head of the rake, are fixed the handles *d*, and the beam *e* to which the horſe is faſtened. When this inſtrument is drawn over a piece of land made thoroughly fine, and the man who holds it bears upon the handles, four furrows, *f*, *g*, *h*, *i*, will be formed, at the diſtances determined by the conſtruction of the inſtrument. Theſe diſtances may be accurately preſerved, provided that the teeth *a a* return when the ploughman Plate IX

Drill or Horſe-hoeing Huſbandry.

man comes back, after having ploughed one turn, in two of the channels formed before, marked *b b*: thus all the furrows in the field will be traced with the ſame regularity. When the ground is thus formed into drills, the peaſe may be ſcattered by a ſingle motion of the hand at a certain diſtance from one another into the channels, and then covered with the flat part of a hand-rake, and preſſed down gently. This inſtrument is ſo ſimple, that any workman may eaſily make or repair it.

Plate XI. On Plate XI. is delineated a patent drill machine, lately invented by the Reverend James Cooke of Heaton-Norris near Manchester. A, the upper part of the ſeed-box. B, the lower part of the ſame box. C, a moveable partition, with a lever, by which the grain or ſeed is let fall at pleaſure from the upper to the lower part of the ſeed-box, from whence it is taken up by cups or ladles applied to the cylinder D, and dropped into the funnel E, and conveyed thereby into the furrow or drill made in the land by the coulter F, and covered by the rake or harrow G. H, a lever, by which the wheel I is lifted out of generation with the wheel K, to prevent the grain or ſeed being ſcattered upon the ground, while the machine is turning round at the end of the land, by which the harrow G is alſo lifted from the ground at the ſame time, and by the ſame motion, by means of the crank, and the horizontal lever *h h*. L, a ſliding lever, with a weight upon it, by means of which the depth of the furrows or drills, and conſequently the depth that the grain or ſeed will be depoſited in the land, may be eaſily aſcertained. M, a ſcrew in the coulter beam, by turning of which the ſeed-box B is elevated or depreſſed, in order to prevent the grain or ſeed being cruſhed or bruiſed by the revolution of the cups or ladles. Fig. 13. a rake with iron teeth, to be applied to the under ſide of the rails of the machine, with ſtapples and ſcrew nuts at *n n*, by which many uſeful purpoſes are anſwered, viz. in accumulating cuitch or hay into rows, and as a ſcarificator for young crops of wheat in the ſpring, or to be uſed upon a fallow; in which caſe, the ſeed-box, the ladle cylinder, the coulters, the funnels, and harrows, are all taken away.

The ſide view of the machine is repreſented, for the ſake of perſpicuity, with one ſeed-box only, one coulter, one funnel, one harrow, &c. whereas a complete machine is furniſhed with five coulters, five harrows, ſeven funnels, a ſeed-box in eight partitions, &c. with ladles of different ſizes, for different ſorts of grain and ſeeds.

Theſe machines (with five coulters ſixteen guineas, with four coulters fifteen guineas), equally excel in ſetting or planting all ſorts of grain and ſeeds, even carrot-ſeed, to exactneſs, after the rate of from eight to ten chain acres per day, with one man, a boy, and two horſes. They depoſite the grain or ſeed in any given quantity from one peck to three buſhels per acre, regularly and uniformly, and that without grinding or bruiſing the ſeed, and at any given depth, from half an inch to half a dozen inches, in rows at the diſtance of twelve, ſixteen and twenty-four inches, or any other diſtance. They are equally uſeful on all lands, are durable, eaſy to manage, and by no means ſubject to be put out of repair.

The ladle cylinder D is furniſhed with cups or ladles of four different ſizes for different ſorts of grain or ſeeds, which may be diſtinguiſhed by the numbers 1, 2, 3, 4.—N° 1. (the ſmalleſt ſize) is calculated for turnip-ſeed, clover-ſeed, cole-ſeed, rape, &c. and will ſow ſomething more than one pound per ſtatute acre. N° 2. for wheat, rye, hemp, flax, &c. and will ſow ſomething more than one buſhel per acre. N° 3. for barley; and will ſow one buſhel and a half per acre. N° 4. for beans, oats, peaſe, vetches, &c. and will ſow two buſhels per acre.

Drill or Horſe-hoeing Huſbandry.

Notwithſtanding the above ſpecified quantities of grain or ſeeds, a greater or leſs quantity of each may be ſown at pleaſure, by ſtopping up with a little clay or by adding a few ladles to each reſpective box. The grain or ſeeds intended to be ſown, muſt be put in thoſe boxes, to which the cups or ladles as above deſcribed reſpectively belong, an equal quantity into each box, and all the other boxes empty. The ladle cylinder may be reverſed, or turned end for end at pleaſure, for different ſorts of grain, &c.

For ſowing beans, oats, peaſe, &c. with a five-coulter machine, four large ladles muſt occaſionally be applied at equal diſtances round thoſe parts of the cylinder which ſubtend the two end boxes. And for ſowing barley, eight large ones muſt be applied as above; or four ladles, N° 2. to each of the wheat boxes. Theſe additional ladles are fixed on the cylinder with nails, or taken off in a few minutes; but for ſowing with a four-coulter machine, the above alterations are not neceſſary.

The funnels are applied to their reſpective places by correſponding numbers. Care ſhould be taken, that the points of the funnels ſtand directly behind the backs of the coulters, which is done by wedges being applied to one ſide or other of the coulters, at the time they are fixed in their reſpective places.

The machine being thus put together, which is readily and expeditiouſly done, as no ſeparate part will coincide with any other but that to which it reſpectively belongs, and an equal quantity of grain or ſeed in each of the reſpective boxes, the land alſo being previouſly ploughed and harrowed once or ſo in a place to level the ſurface; but if the land be very rough, a roller will beſt anſwer that purpoſe, whenever the land is dry enough to admit of it; and upon ſtrong clays, a ſpiked roller is ſometimes neceſſary to reduce the ſize of the large dry clods; which being done, the driver ſhould walk down the furrow or edge of the land, and having hold of the laſt horſe's head with his hand, he will readily keep him in ſuch a direction, as will bring the outſide coulter of the machine within three or four inches of the edges of the land or ridge, at which uniform extent, he ſhould keep his arm till he comes to the end of the land; where having turned round, he muſt come to the other ſide of his horſes, and walking upon the laſt outſide drill, having hold of the horſe's head with his hand as before, he will readily keep the machine in ſuch a direction, as will ſtrike the ſucceeding drill at ſuch a diſtance from the laſt outſide one, or that he walks upon, as the coulters are diſtant from each other.

The perſon who attends the machine ſhould put down the lever H ſoon enough at the end of the land, that the cups or ladles may have time to fill, before he begins to ſow; and at the end of the land, he muſt ap-

Drill or Horſe-hoeing Huſbandry.

ply his right hand to the middle of the rail between the handles, by which he will keep the coulters in the ground, while he is lifting up the lever H with his left hand, to prevent the grain being ſcattered upon the headland, while the machine is turning round: this he will do with great eaſe, by continuing his right hand upon the rail between the handles, and applying his left arm under the left handle, in order to lift the coulters out of the ground while the machine is turning round.

If there be any difficulty in uſing the machine, it conſiſts in driving it ſtraight. As to the perſon who attends the machine, he cannot poſſibly commit any errors, except ſuch as are wilful, particularly as he ſees at one view the whole proceſs of the buſineſs, viz. that the coulters make the drills of a proper depth; that the funnels continue open to convey the grain or ſeed into the drills; that the rakes or harrows cover the grain ſufficiently; and when ſeed is wanting in the lower boxes B, which he cannot avoid ſeeing, he readily ſupplies them from the upper boxes A, by applying his hand, as the machine goes along, to the lever C. The lower boxes B ſhould not be ſuffered to become empty before they are ſupplied with ſeed, but ſhould be kept nearly full, or within an inch or ſo of the edge of the box.

If chalk lines are made acroſs the backs of the coulters, at ſuch a diſtance from the ends as the ſeed ſhould be depoſited in the ground (viz. about two inches for wheat, and from two to three for ſpring corn), the perſon that attends the machine will be better able to aſcertain the depth the ſeed ſhould be depoſited in the drills, by obſerving, as the machine goes along, whether the chalk lines are above or below the ſurface of the land; if above, a proper weight muſt be applied to the lever L, which will force the coulters into the ground; if below, the lever L and weight muſt be reverſed, which will prevent their ſinking too deep.

In different parts of the kingdom, lands or ridges are of different ſizes; where the machine is too wide for the land, one or more funnels may occaſionally be ſtopped with a little looſe paper, and the ſeed received into ſuch funnel returned at the end of the land, or ſooner if required, into the upper ſeed-box. But for regularity and expedition, lands conſiſting of ſo many feet wide from outſide to outſide, as the machine contains coulters, when fixed at twelve inches diſtance, or twice or three times the number, &c. are beſt calculated for the machine. In wet ſoils or ſtrong clays, lands or ridges of the width of the machine, and in dry ſoils, of twice the width, are recommended. For ſowing of narrow high-ridged lands, the outſide coulters ſhould be let down, and the middle ones raiſed, ſo that the points of the coulters may form the ſame curve that the land or ridge forms. And the looſe ſoil harrowed down into the furrows ſhould be returned to the edges of the lands or ridges from whence it came, by a double mouldboard or other plough, whether the land be wet or dry.

Clover or other leys, intended to be ſown by the machine, ſhould be ploughed a deep ſtrong furrow and well harrowed, in order to level the ſurface, and to get as much looſe ſoil as poſſible for the coulters to work in; and when ſown, if any of the ſeed appears in the drills uncovered by reaſon of the ſtiff texture of the ſoil, or toughneſs of the roots, a light harrow may be taken over the land, once in a place, which will effectually cover the ſeed, without diſplacing it all in the drills. For ſowing leys, a conſiderable weight muſt be applied to the lever L, to force the coulters into the ground; and a ſet of wrought-iron coulters, well ſteeled, and made ſharp at the front edge and bottom, are recommended; they will pervade the ſoil more readily, conſequently require leſs draught, and expedite buſineſs more than adequate to the additional expence.

Drill or Horſe-hoeing Huſbandr

For every half acre of land intended to be ſown by the machine with the ſeed of that very valuable root (carrot), one buſhel of ſaw-duſt, and one pound of carrot-ſeed, ſhould be provided; the ſaw duſt ſhould be made dry, and ſifted to take out all the lumps and chips, and divided into eight equal parts or heaps; the carrot-ſeed, ſhould likewiſe be dried, and well rubbed between the hands, to take off the beards, ſo that it may ſeparate readily; aed being divided into eight equal parts or heaps, one part of the carrot-ſeed muſt be well mixed with one part of the ſaw-duſt, and ſo on, till all the parts of carrot-ſeed and ſaw-duſt are well mixed and incorporated together; in which ſtate it may be ſown very regularly in drills at twelve inches diſtance, by the cups or ladles N° 2. Carrot-ſeed reſembling ſaw-duſt very much in its ſize, roughneſs, weight, adheſion &c. will remain mixed as above during the ſowing; a ladleful of ſaw-duſt will, upon an average, contain three or four carrot-ſeeds, by which means the carrot-ſeed cannot be otherwiſe than regular in the drills. In attempting to depoſite ſmall ſeeds near the ſurface, it may ſo happen that ſome of the ſeeds may not be covered with ſoil; in which caſe, a light roller may be drawn over the land after the ſeed is ſown, which will not only cover the ſeeds, but will alſo, by levelling the ſurface, prepare the land for an earlier hoeing than could otherwiſe have taken place.

It has always been found troubleſome, ſometimes impracticable, to ſow any kind of grain or ſeeds (even broad-caſt) in a high wind. This inconvenience is entirely obviated by placing a ſcreen of any kind of cloth, or a ſack, ſupported by two uprights nailed to the ſides of the machine, behind the funnels, which will prevent the grain or ſeed being blown out of its direction in falling from the ladles into the funnels. Small pipes of tin may alſo be put on to the ends of the funnels, to convey the grain or ſeed ſo near the ſurface of the land, that the higheſt wind ſhall not be able to interrupt its deſcent into the drills.

Reſpecting the uſe of the machine, it is frequently remarked by ſome people not converſant with the properties of matter and motion, that the ſoil will cloſe after the coulters, before the ſeed is admitted into the drills. Whereas the very contrary is the caſe; for the velocity of the coulters in paſſing through the ſoil, is ſo much greater than the velocity with which the ſoil cloſes up the drills by its own ſpontaneous gravity, that the inciſions or drills will be conſtantly open for three or four inches behind the coulters; by which means, it is morally impoſſible (if the points of the funnels ſtand directly behind the coulters) that the ſeed, with the velocity it acquires in falling through the funnels, ſhall not be admitted into the drills.

Fig.

Drill or Horſe-hoeing Huſbandry.

Plate XI.

Fig. 12. is a new conſtructed ſimple hand-hoe, by which one man will effectually hoe two chain acres *per* day, earthing up the ſoil at the ſame time to the rows of corn or pulſe, ſo as to cauſe roots to iſſue from the firſt joint of the ſtem, above the ſurface of the land, which otherwiſe would never have exiſted.

This hoe is worked much in the ſame manner as a common Dutch hoe, or ſcuffle, is worked in gardens. The handle is elevated or depreſſed, to ſuit the ſize of the perſon that works it, by means of an iron wedge being reſpectively applied to the upper or under ſide of the handle that goes into the ſocket of the hoe.

The wings or moulding plates of the hoe, which are calculated to earth up the ſoil to the rows of corn, ſo as to cauſe roots to iſſue from the firſt joint of the ſtem above the ſurface, which otherwiſe would not have exiſted, ſhould never be uſed for the firſt hoeing, but ſhould always be uſed for the laſt hoeing, and uſed or not uſed, at the option of the farmer, when any intermediate hoeing is performed.

Summary of the Operations neceſſary in executing the New Husbandry with the Plough.

493 Summary of the operations.

1. It is indiſpenſably neceſſary that the farmer be provided with a drill and hoe-plough.

2. The new huſbandry may be begun either with the winter or ſpring corn.

3. The land muſt be prepared by four good ploughings, given at different times, from the beginning of April to the middle of September.

4. Theſe ploughings muſt be done in dry weather, to prevent the earth from kneading.

5. The land muſt be harrowed in the ſame manner as if it were ſowed in the common way.

6. The rows of wheat ſhould be ſowed very ſtraight.

7. When the field is not very large, a line muſt be ſtrained acroſs it, by which a rill may be traced with a hoe for the horſe that draws the drill to go in; and when the rows are ſown, 50 inches muſt be left betwixt each rill. But, when the field is large, ſtakes at five feet diſtance from each other muſt be placed at the two ends. The workman muſt then trace a ſmall furrow with a plough that has no mouldboard, for the horſe to go in that draws the drill, directing himſelf with his eye by the ſtakes.

8. The ſowing ſhould be finiſhed at the end of September, or beginning of October.

9. The furrows muſt be traced the long way of the land, that as little ground as poſſible may be loſt in headlands.

10. The rows, if it can be done, ſhould run down the ſlope of the land, that the water may get the eaſier off.

11. The ſeed-wheat muſt be plunged into a tub of lime-water, and ſtirred, that the light corn may come to the ſurface and be ſkimmed off.

12. The ſeed muſt be next ſpread on a floor, and frequently ſtirred, till it is dry enough to run through the valves of the happer of the drill.

13. To prevent ſmut, the ſeed may be put into a ley of aſhes and lime.

14. Good old ſeed-wheat ſhould be choſen in preference to new, as it is found by experience not to be ſo ſubject to ſmut.

15. After the happers of the drill are filled, the horſe muſt go ſlowly along the furrow that was traced. That a proper quantity of ſeed may be ſown, the aperture of the happer muſt be ſuited to the ſize of the grain.

Drill or Horſe-hoeing Huſbandry.

16. As the drill is ſeldom well managed at firſt, the field ſhould be examined after the corn has come up, and the deficiencies be ſupplied.

17. Upon wet ſoils or ſtrong clays, wheat ſhould not be depoſited more than two inches deep, on any account whatever; nor leſs than two inches deep on dry ſoils. From two to three inches is a medium depth for all ſpring corn. But the exact depth at which grain ſhould be depoſited in different ſoils, from the lighteſt ſand to the ſtrongeſt clay, is readily aſcertained only by obſerving at what diſtance under the ſurface of the land, the ſecondary or coronal roots are formed in the ſpring.

18. Stiff lands, that retain the wet, muſt be ſtirred or hoed in October. This ſhould be done by opening a furrow in the middle of the intervals, and afterwards filling it up by a furrow drawn on each ſide, which will raiſe the earth in the middle of the intervals, and leave two ſmall furrows next the rows, for draining off the water, which is very hurtful to wheat in winter.

19. The next ſtirring muſt be given about the end of March, with a light plough. In this ſtirring the furrows made to drain the rows muſt be filled up by earth from the middle of the interval.

20. Some time in May, the rows muſt be evened; which, though troubleſome at firſt, ſoon becomes eaſy, as the weeds are ſoon kept under by tillage.

21. In June, juſt before the wheat is in bloom, another ſtirring muſt be given with the plough. A deep furrow muſt be made in the middle of the intervals, and the earth thrown upon the ſides of the rows.

22. When the wheat is ripe, particular care muſt be taken, in reaping it, to trample as little as poſſible on the ploughed land.

23. Soon after the wheat is carried off the field, the intervals muſt be turned up with the plough, to prepare them for the ſeed. The great furrow in the middle muſt not only be filled, but the earth raiſed as much as poſſible in the middle of the intervals.

24. In September, the land muſt be again ſowed with a drill, as above directed.

25. In October, the ſtubble muſt be turned in for forming the new intervals; and the ſame management muſt be obſerved as directed in the firſt year.

We pretend not to determine whether the old or new huſbandry be preferable in every country. With regard to this point, the climate, the ſituation of particular land, ſkill and dexterity in managing the machinery, the comparative expence in raiſing crops, and many other circumſtances, muſt be accurately attended to, before a determination can be given.

To give an idea of the arguments by which the drill huſbandry was originally ſupported, we ſhall here take notice of a comparative view of the old and new methods of culture which was furniſhed for the editors of Mr Tull's Horſe-Hoeing Huſbandry, by a gentleman who for ſome years practiſed both in a country where the ſoil was light and chalky, like that from which he drew his obſervations. It is neceſſary to remark, that in the new huſbandry every article is ſtated at its full value, and the crop of each year is four buſhels ſhort of the other; though,

Drill or Horse-hoeing Husbandry

though, in several years experience, it has equalled and generally exceeded those in the neighbourhood in the old way.

"An estimate of the expence and profit of 10 acres of land in 20 years.

I. In the old way.

494 Comparative view of the expence and profits of the old and new husbandry.

	L.	s.	d.	L.	s.	d.
First year, for wheat, costs viz.	33l.	5s.				
First ploughing, at 6s. per acre	3	0	0			
Second and third ditto, at 8s. per acre	4	0	0			
Manure, 30s. per acre	15	0	0			
				22	0	0
Two harrowings, and sowing, at 2s. 6d. per acre	1	5	0			
Seed, three bushels per acre, at 4s. per bushel	6	0	0			
Weeding at 2s. per acre,	1	0	0			
Reaping, binding, and carrying, at 6s. per acre	3	0	0			
				11	5	0
Second year, for barley, costs 11l. 6s. 8d. viz.						
Once ploughing at 6s. per acre	3	0	0			
Harrowing and sowing, at 1s. 6d. per acre	0	15	0			
Weeding, at 1s. per acre	0	10	0			
Seed, four bushels per acre, at 2s. per bushel	4	0	0			
Cutting, raking, and carrying at 3s. 2d. per acre	1	11	8			
Grass-seeds, at 3s. per acre	1	10	0			
				11	6	8
				44	11	8
Third and fourth years, lying in grass, cost nothing: so that the expence of ten acres in four years comes to 44l. 11s. 8d. and in twenty years to -				222	18	4
First year's produce is half a load of wheat per acre, at 7l.	35	0	0			
Second year's produce is two quarters of barley per acre, at 1l. - -	20	0	0			
Third and fourth years grass is valued at 1l. 10s. per acre	15	0	0			
So that the produce of ten acres in four years is	70	0	0			
And in twenty years it will be				350	0	0
Deduct the expence, and there remains clear profit on ten acres in twenty years by the old way -				127	1	8

II. In the new way.

	L.	s.	d.	L.	s.	d.
First year's extraordinary expence is, for ploughing and manuring the land, the same as in the old way, L.	22	0	0			
Ploughing once more, at 4s. per acre - -	2	0	0			
Seed, nine gallons per acre, at 4s. per bushel	2	5	0			
Drilling, at 7d. per acre -	0	5	10			
Hand-hoeing and weeding, at 2s. 6d. per acre -	1	5	0			
Horse-hoeing six times, at 10s. per acre -	5	0	0			
Reaping, binding, and carrying, at 6s. per acre -	3	0	0			
The standing annual charge on ten acres, is -	13	15	10			
Therefore the expence on ten acres in twenty years is - -				275	16	8
Add the extraordinaries of the first year, and the sum is - -				297	16	8
The yearly produce is at least two quarters of wheat per acre, at 1l. 8s. per quarter; which on ten acres in twenty years, amounts to - -				560	0	0
Therefore, all things paid, there remains clear profit on ten acres in twenty years by the new way - -				262	3	4

Drill or Horse-hoeing Husbandry

395 Arguments in favour of the drill husbandry.

"So that the profit on ten acres of land in twenty years, in the new way, exceeds that in the old by 135l. 1s. 8d. and consequently is considerably more than double thereof; and ample encouragement to practise a scheme, whereby so great advantage will arise from so small a quantity of land, in the compass of a twenty-one years lease; one year being allowed, both in the old and new way, for preparing the ground.

"It ought withal to be observed, that Mr Tull's husbandry requires no manure at all, though we have here, to prevent objections, allowed the charge thereof for the first year; and moreover, that though the crop of wheat from the drill-plough is here put only at two quarters on an acre, yet Mr Tull himself, by actual experiment and measure, found the produce of his drilled wheat crop amounted to almost four quarters on an acre."

It appears also from a comparative calculation of expence and profit between the drill and common husbandry, taken from Mr Baker's report to the Dublin Society of his experiments in agriculture for the year 1765, that there is a clear profit arising upon an Irish acre of land in 15 years in the drill husbandry of 52l. 3s. 11d. and in the common husbandry of 27l. 19s. 2d.; and therefore a greater profit in the drilled acre in this time of 24l. 4s. 9d. which amounts to 1l. 12s. 3¾d. per annum. From hence he infers, that in every 15 years the fee-simple of all the tillage-lands of the kingdom is lost to the community by the common course of tillage. In stating the accounts, from which their result is obtained, no notice is taken of fences, watercutting the land, weeding and reaping, because these articles depend on a variety of circumstances, and will, in general, exceed in the common husbandry those incurred by the other.

Besides, the certainty of a crop is greater in this new

Drill or Horſe-hoeing Husbandry.

way than in the old way of ſowing; for moſt of the accidents attending wheat crops are owing to their being late ſown, which is neceſſary to the farmer in the old way; but in the horſe-hoeing method the farmer may plough two furrows whereon the next crop is to ſtand immediately after the firſt crop is off. In this manner of huſbandry, the land may be ploughed dry and drilled wet, without any inconvenience; and the ſeed is never planted under the furrow, but placed juſt at the depth which is moſt proper, that is, at about two inches; in which caſe it is eaſy to preſerve it, and there is no danger of burying it. Thus the ſeed has all the advantage of early ſowing, and none of the diſadvantages that may attend it in the other way, and the crop is much more certain than by any other means that can be uſed.

The condition in which the land is left after the crop, is no leſs in favour of the horſe-hoeing huſbandry than all the other articles. The number of plants is the great principle of the exhauſting of land. In the common huſbandry, the number is vaſtly greater than in the drilling way, and three plants in four often come to nothing, after having exhauſted the ground as much as profitable plants; and the weeds which live to the time of harveſt in the common way, exhauſt the land no leſs than ſo many plants of corn, often much more. The horſe-hoeing method deſtroys all the weeds in the far greater part of the land, and leaves that part unexhauſted and perfectly freſh for another crop. The wheat plants being alſo but a third part of the number at the utmoſt of thoſe in the ſowing way, the land is ſo much the leſs exhauſted by them; and it is very evident from the whole, that it muſt be, as experience proves that it is, left in a much better condition after this than after the common huſbandry.

496 Objections and anſwers.

The farmers who are againſt this method object, that it makes the plants too ſtrong, and that they are more liable to the blacks or blights of inſects for that reaſon; but as this allows that the hoeing can, without the uſe of dung, give too much nouriſhment, it is very plain that it can give enough; and it is the farmer's fault if he do not proportion his pains ſo as to have the advantage of the nouriſhment without the diſadvantages. It is alſo objected, that as hoeing can make poor land rich enough to bear good crops of wheat, it may make good land too rich for it. But if this ſhould happen, the ſowing of wheat on it may be let alone a while, and in the place of it the farmer may have a crop of turnips, carrots, cabbages, and the like, which are excellent food for cattle, and cannot be over-nouriſhed: or, if this is not choſen, the land, when thus made too rich, may ſoon be ſufficiently impoveriſhed by ſowing corn upon it in the common old way.

The method of horſe-hoeing huſbandry, ſo ſtrongly recommended by Mr Tull, is objected to by many on account of the largeneſs of the intervals which are to be left between the rows of corn. Theſe are required to be about five feet wide; and it is thought that ſuch wide ſpaces are ſo much loſt earth, and that the crop is to be ſo much the leſs for it. But it is to be obſerved, that the rows of corn ſeparated by theſe intervals need not be ſingle; they may be double, triple, or quadruple, at the pleaſure of the farmer; and four rows thus ſtanding as one will have the five feet interval but one-fourth of its bigneſs as to the whole quantity, and it will be but as fifteen inch intervals to plants in ſingle rows. Corn that is ſown irregularly in the common way, ſeems indeed to cover the ground better than that in rows; but this is a mere *deception viſus*; for the ſtalks of corn are never ſo thick as when they come out of one plant, or as when they ſtand in a row; and a horſe-hoed plant of corn will have 20 or 30 ſtalks in a piece of ground of the ſame quantity, where an unhoed plant will have only two or three ſtalks. If theſe ſtalks of the hoed plant were ſeparated and planted over the intervals, the whole land would be better covered than it is the common way; and the truth is, that though theſe hoed fields ſeem to contain a much leſs crop than the common ſown fields, yet they in reality do contain a much greater. It is only the different placing that makes the ſown crop ſeem the larger, and even this is only while both crops are young.

Drill or Horſe-hoeing Husbandry.

The intervals are not loſt ground, as is uſually ſuppoſed, but when well horſe-hoed they are all employed in the nouriſhment of the crop: the roots of the plants in the adjoining rows ſpreading themſelves through the whole interval, and drawing ſuch nouriſhment from it, that they increaſe accordingly. When the plants ſtand in the ſcattered way, as in common ſowing, they are too cloſe to one another; each robs its neighbour of part of their nouriſhment, and conſequently the earth is ſoon exhauſted, and all the plants half ſtarved. The cloſe ſtanding of them alſo prevents the benefit of after-tilling, as the hoe cannot be brought in, nor the ground by any means ſtirred between them to give it a new breaking, and conſequently afford them new food.

Experiments have abundantly proved, that in large grounds of wheat where the different methods have been tried, thoſe parts where the intervals were largeſt have produced the greateſt crops, and thoſe where hoeing was uſed without dung have been much richer than thoſe where dung was uſed without hoeing. If it were poſſible that plants could ſtand as thick, and thrive as well over the whole ſurface of the ground as they do in the rows ſeparated by theſe large intervals, the crops of corn ſo produced would be vaſtly greater than any that have been heard of; but the truth is, that plants receive their growth not according to the ground they ſtand on, but to the ground they can extend their roots into; and therefore a ſingle row may contain more plants than a large interval can nouriſh, and therefore the ſame number that ſtand in that row, and no more than theſe, could be nouriſhed, if ſcattered over the whole interval: and they would be much worſe nouriſhed in that way; becauſe while the interval is void, the earth may be ſtirred about them, and new roots will be formed in great numbers from every one broken by the inſtruments, and new nouriſhment laid before theſe roots by the breaking the particles of earth, by which the plants will have ſupplies that they cannot have when ſcattered over the whole ſurface, becauſe the ground is then all occupied, and cannot be moved between the plants.

497 In what ſituation the new method is not proper.

All ſoils and all ſituations are not equally proper for this method of planting in rows, with large intervals and hoeing between. The lighteſt ſoils ſeem to be beſt for it, and the tough and wet clays the worſt. Such grounds as lie on the ſides of hills are alſo leſs proper than others for this work.

This

Drill or Horſe-hoeing Huſbandry.

This method is not ſo proper in common fields, but that not in reſpect of the ſoil, but of the huſbandry of the owners, who are uſually in the old way, and change the ſpecies of corn, and make it neceſſary to fallow every ſecond, third, or fourth year. Nevertheleſs it has been found by later experiments, that the intervals betwixt the rows of plants, as recommended by Mr Tull, were too great, perhaps double of what they ſhould be in the moſt profitable method of culture; by which means much leſs crops are obtained than might be produced at nearly the ſame expence. This has rendered the profits of the drill method much leſs than they would have been in a more judicious practice, and, conſequently, has proved a great diſadvantage to it in compariſon with the broadcaſt. Mr Tull was led into this, partly from the want of more perfect inſtruments for hoeing, and of ploughs proper for drilling.

To the preceding ſtatements, the following obſervations by Sir John Anſtruther, publiſhed among the Select Papers of the Bath Society, may not be improperly ſubjoined.

498 Obſervations by Sir John Anſtruther.

The ſlow progreſs which the drill huſbandry has made in many parts of Great Britain ſince Mr Tull's time, he obſerves, has been principally owing to the want of proper drill-ploughs. Before drilling can become general, thoſe ploughs muſt be ſimple, ſuch as a common ploughman accuſtomed to uſe ſtrong inſtruments can uſe without breaking, and ſuch alſo as common workmen can eaſily make or repair. Mathematical accuracy he conſiders as not required for delivering the ſeed: for it matters very little whether there be a quarter of a peck more or leſs ſown, if it be delivered with tolerable regularity. He therefore had a plough made, according to his own directions, by a common plough-wright, of ſufficient ſtrength for any land made fit for turnips or wheat. It was tried on very rough ground unfit for ſowing, in order to aſcertain its ſtrength; and it had been uſed for eight years without its needing any repair. It is a double drill-plough, which ſows two ridges at a time, the horſe going the furrow between them, and of courſe does not tread upon the ground intended to be ſown; which with a ſingle drill muſt be the caſe, and does much harm by the horſes feet ſinking and making holes in the fine ground, which retain the water, and hurt the wheat when young.

He proceeds to obſerve, "That having read Mr Forbes upon the extenſive practice of the new huſbandry, and ſome other authors, who gave a more clear and diſtinct account of the different operations in drilling than had heretofore been given, I wiſhed to try them, and to adapt my plough to ſow the quantities therein directed. It was, however, adjuſted to ſow a ſmaller quantity, and the ſeed was not ſteeped.

"Not having ground ſo proper as I wiſhed, it was drilled on the ſide of a field, the ſoil of which was light and ſandy, and in ſuch bad order, that the preceding crop was a very indifferent one. It was therefore manured with a compoſt dunghill.

"After croſs-ploughing and manuring, it was laid into four and a half feet ridges, then harrowed and drilled with one peck and a half of wheat on an acre and a quarter, which is nearly one peck and a fifth per Engliſh acre. It was drilled the 27th of October, and rolled after drilling. The crop was late in its appearance, and very backward in the ſpring. Drill or Horſe-hoeing Huſbandry.

"March 31ſt, it was horſe-hoed one furrow *from* the rows.

"April 8th, it was hand-hoed and weeded in the rows.

"25th, horſe-hoed again, laying a furrow back *to* the rows.

"May 15th, hand-hoed the ſecond time.

"June 2d, horſe-hoed *from* the rows.

"June 12th, hand-hoed the third time.

"July 14th, horſe-hoed *to* the rows.

"At this laſt hoeing, as many of the ears were beaten down into the intervals by wind and rain, a man went before the horſe-hoe, and turned the ears back into their proper place.

"The crop, when reaped and threſhed, yielded me 36 buſhels on one acre and a quarter, which is 28 buſhels and three pecks per acre; and the produce from one peck and half 96 for one.

"As the produce appeared ſo great, from land in ſuch bad order, it was carefully meaſured again, and found to be right. But this increaſe, though great, was not ſo large as Mr Crake of Glaſgow had without dung.

"Mr Randal ſays, 'It is an experimental fact, that on a fine loam exquiſitely prepared, 144 buſhels have been produced from one acre. And, I believe, it is not known what the increaſe may be brought to in rich lands by high cultivation.'

"Some years ſince, I had beans dropt alternately with potatoes, at two feet diſtance in the rows, which were three feet apart, and ploughed in the intervals. The land adjoining was ſown with beans and peaſe, which were a good crop; but thoſe ſown among the potatoes a better one. I pulled one ſtem of the beans planted with the potatoes, which had three branches riſing from the bottom, and it produced 225 beans. In all the trials of drilled beans, moſt of the ſtems had two branches, with many pods upon each.——From theſe and other inſtances, I believe it is not yet known to what increaſe grain may be brought by drilling, good cultivation, and manure.

"Horſe-hoeing is certainly preferable to cloſe drilling or hand-hoeing; but the latter is ſuperior to broadcaſt.

"Horſe-hoeing the full depth increaſes the crop, by making it tiller or branch more than it otherwiſe would do; and the advantage is diſtinctly obſervable every hoeing, by the colour of the grain. It prepares the ground for the next crop, at the ſame time that it increaſes the crop growing, which hand-hoeing does not, although it may deſtroy the weeds. Thus drilled ground is kept in a looſe open ſtate to receive the benefit of the influence of the air and weather, which broad-caſt has not; and it is evident, from certain experience, that crops may be drilled many years to good advantage without manure.

"Suppoſe the crops only 20 buſhels per acre, what courſe of broadcaſt-crops will give 5l. an acre for the courſe? But ſuppoſe they are dunged the ſame as any ground in the moſt approved courſe, there is the greateſt reaſon to expect as much as in the above experiment,

Drill or Horse-hoeing Husbandry.

ment, which is 28¼, and at 5s. per bushel, amounts to 7l. 3s. 9d.

"Calculations may be of service to those who wish to try drilling, and have few books to direct them.

"One acre is 10 chains long, of 660 feet, or 220 yards long, and one yard broad, containing 4840 square yards. Then if the ridge is four feet six inches, this makes 24 ridges, and three feet to spare. This length of 220 yards multiplied by 24 (the number of ridges), gives a length of yards 3080, to which add 146 for the spare three feet, and it will be 3226 yards. And as two rows are drilled on a ridge, the number of rows will be in length 6452 yards; but as a deduction of 172 yards must be made for the head ridges, suppose three yards each, &c. the whole length to be sown will be 6280 yards clear. Now a gallon (Winchester) holds about 80,000 grains. The quantity, recommended to be drilled by Mr Forbes and others, being six gallons, or two-thirds of a bushel, per acre, is nearly 78 grains to a yard, or 26 to a foot. But in my experiment, by this calculation, it was only about 11 grains to a foot: which is quite sufficient, if the seed be good, and it be not destroyed by vermin.

"Now with regard to the quantity of land this drill plough may sow; if a horse walks at the rate of two miles per hour, he goes 16 miles in eight hours, or 28,460 yards. As he sows two ridges at once, this is seven lengths and two thirds per acre, or 1686 yards to sow an acre, being nearly 17 acres in a day.

"Four horse-hoeings are calculated equal to two ploughings. In plain ploughing they suppose the ridge is ploughed with four furrows, or eight for twice ploughing. The four horse-hoeings are eight furrows, equal to two ploughings.

"Mr Tull directs four hoeings, and Mr Forbes five. 1st, In November, when the plant has four blades. 2dly, In March, deep, and nearer the rows than the former; both these hoeings should be *from* the rows. 3dly, Hand-hoed when it begins to spindle, if the earth be crumbly, *to* the rows. 4thly, When it begins to blossom, *from* the rows, but as near to them as in the second hoeing. 5thly, When done blossoming, to ripen and fill the grain, *to* the rows.

"The last hoeing Mr Toll does not direct, but Mr Forbes advises it, as being of essential service in filling the grain, and saving trouble in making the next seed-furrows. They advise the patent or sowing-plough for horse-hoeing; and the expence is calculated by Mr Craick at one guinea per acre, reaping included.

"But let us suppose the following, which are the prices in the county I live in (Fife).

	L.	s.	d.
Ploughing to form the ridges,	0	4	0
Harrowing,	0	0	4
Four hoeings, equal to two ploughings,	0	8	0
Sowing	0	0	4
Hand-hoeing twice,	0	8	0
Seed, one peck and a half at 5s. a bushel	0	1	10
Whole expence per acre,	L. 1	2	6"

499 e drill l the ad-cast thods re parti- arly pared.

Drill-husbandry is, as a good writer has justly defined it, "*the practice of a garden brought into the field.*" Every man of the least reflection must be sensible, that the practice of the garden is much *better* than that of the field, only a little more expensive; but if (as is the case) this extra expence be generally much more than repaid by the superior goodness and value of drilled crops, it ought to have no weight in comparing the two modes of husbandry.

Drill or Horse-hoeing Husbandry.

In the broad-cast method the land is often sown in bad tilth, and always scattered at random, sometimes by very unskilful hands. In drilling, the land must be in fine order; the seed is set in trenches drawn regularly; all of nearly an equal depth, and that depth suited to the nature of each kind of seed. These seeds are also distributed at proper distances, and by being equally and speedily covered, are protected from vermin and other injuries; so that the practice of the garden is here exactly introduced into the field.

In the broad-cast method the seed falls in some places too thick; in others too thin; and being imperfectly covered, a part of it is devoured by vermine which follow the sower; another part is left exposed to rain or frost, or to heats, which greatly injure it. When harrowed, a great part of it (small seeds especially) is buried so deep, that if the soil be wet, it perishes before it can vegetate.

Again: When thus sown, there is no meddling with the crop afterwards, because its growth is irregular. The soil cannot be broken to give it more nourishment, nor can even the weeds be destroyed without much inconvenience and injury.

But in the drill-husbandry the intervals between the rows, whether double or single, may be horse-hoed; and thereby nourishment may repeatedly be given to the plants, and the weeds almost totally destroyed.

The very same effects which digging has upon young shrubs and trees in a garden, will result from horse-hoeing in a field, whether the crop be corn or pulse: For the reason of the thing is the same in both cases, and being founded in nature and fact, cannot ever fail. In drilling, no more plants are raised on the soil than it can well support: and by dividing and breaking the ground, they have the full advantage of all its fertility.

The plough prepares the land for a crop, but goes no further; for in the broad-cast husbandry it cannot be used: but the crop receives greater benefit from the tillage of the land by the horse-hoe, while it is growing, than it could in the preparation. No care in tilling the land previous to sowing can prevent weeds rising with the crop; and if these weeds be not destroyed while the crop is growing, they will greatly injure it. In the broad-cast husbandry this cannot be done; but in drilling, the horse-hoe will effect it easily.

And what adds to the farmer's misfortune is, that the most pernicious weeds have seeds winged with down, which are carried by the wind to great distances; such as thistles, sow-thistles, colts-foot, and some others.

If the expence of horse-hoeing be objected, there are two answers which may very properly be made: The first is, that this expence is much less than that of hand-hoeing were it practicable, or of hand-weeding. The second is, that it is more than repaid by the quantity of seed saved by drilling; to say nothing of the extra quantity and goodness of the crops, which are generally self-evident.

Upon the whole, if the particular modes of cultivating land by the new husbandry should, after all, be

Flax and Hemp.

considered as perhaps too limited to be univerſally adopted; yet it has been of great uſe in raiſing ſuſpicions concerning the old method, and in turning the views of philoſophers and farmers towards improving in general. Many real improvements in agriculture have been the conſequences of theſe ſuſpicions; and as this ſpirit of inquiry remains in full vigour, a ſolid foundation is laid for expecting ſtill further improvements in this uſeful art.

500 The drill-huſbandry is not a modern diſcovery.

It may be proper here to remark, however, that the drill-huſbandry is by no means a modern European invention. It is now uſed in the Carnatic, and in all probability has exiſted among the induſtrious nations of India from a very early period. It is uſed not only for all grains, but alſo for the culture of tobacco, cotton, and the caſtor-oil plant. Beſides the drill-plough, and the common plough, the Indians uſe a third, with a horizontal ſhare, which immediately follows the drill-plough at work. It is ſet in the earth, about the depth of 7 or 8 inches, and paſſes under three drills at once. It operates by agitating the earth, ſo as to make the ſides of the drills fall in and cover the ſeed, which it does ſo effectually as ſcarcely to leave any traces of a drill.

Flax and Hemp

PART II. CULTIVATION OF VEGETABLES MORE PROPERLY ARTICLES OF COMMERCE.

THESE in general are ſuch as cannot be uſed for food; and are principally flax, hemp, rape, hops, and timber of various kinds. Of each of theſe we ſhall treat particularly in the following ſections.

SECT. I. *Of Flax and Hemp.*

501 Flax and hemp.

FLAX is cultivated not only with a view to the common purpoſes of making linen, but for the ſake of its ſeed alſo; and thus forms a moſt extenſive article of commerce; all the oil uſed by painters, at leaſt for common purpoſes, being extracted from this ſeed. The cake which remains after the extraction of the oil is in ſome places uſed as a manure, and in others ſold for fattening of cattle. In the Vale of Glouceſter, Mr Marſhall informs us, that it is, next to hay, the main article of ſtall-fattening; though the price is now become ſo great, that it probably leaves little or no profit to the conſumer, having within a few years riſen from three guineas to ſix and ſix and a half, and the loweſt price being five guineas per ton; and even this is lower than it was lately. Hence ſome individuals have been induced to try the effect of linſeed itſelf boiled to a jelly, and mixed with flour, bran, or chaff, with good ſucceſs, as Mr Marſhall has been informed; and even the oil itſelf has been tried for the ſame purpoſe in Herefordſhire. Though this plant is in univerſal culture over the whole kingdom, yet it appears by the vaſt quantity imported, that by far too little ground is employed in that way. As Mr Marſhall takes notice of its culture only in the county of Yorkſhire, it probably does not make any great part of the huſbandry of the other counties of which he treats; and even in Yorkſhire he tells us, that its cultivation is confined to a few diſtricts. The kind cultivated there is that called *blealine*, or *the blue or lead-coloured flax*, and this requires a rich dry ſoil for its cultivation. A deep, fat, ſandy loam is perhaps the only ſoil on which it can be cultivated with advantage. If ſown upon old corn land, it ought to be well cleaned from weeds, and rendered perfectly friable by a ſummer-fallow. Manure is ſeldom or ever ſet on for a line crop: and the ſoil proceſs conſiſts generally of a ſingle ploughing. The ſeed-time is in the month of May, but much depends on the ſtate of the ſoil at the time of ſowing. "It ſhould neither be wet nor dry; and the ſurface ought to be made as fine as that of a garden bed. Not a clod of the ſize of an egg ſhould remain unbroken." Two buſhels of ſeed are uſually ſown upon an acre: the ſurface, after being harrowed, is ſometimes raked with garden or hay rakes; and the operation would be ſtill more complete if the clods and other obſtructions, which cannot be eaſily removed, were drawn into the interfurrows. A light hand-roller uſed between the final raking and harrowing would much aſſiſt this operation. The chief requiſite during the time of vegetation is weeding, which ought to be performed with the utmoſt care; and for this reaſon it is particularly requiſite that the ground ſhould be previouſly cleanſed as well as poſſible, otherwiſe the expence of weeding becomes too great to be borne, or the crop muſt be conſiderably injured. It is an irreparable injury, if, through a dry ſeaſon, the plants come up in two crops; or if by accident or miſmanagement they be too thin. The goodneſs of the crop depends on its running up with a ſingle ſtalk without branches: for wherever it ramifies, there the length of the line terminates; and this ramification is the conſequence of its having too much room at the root, or getting above the plants which ſurround it. The branches are never of any uſe, being unavoidably worked off in dreſſing; and the ſtem itſelf, unleſs it bear a due proportion to the length of the crop, is likewiſe worked off among the refuſe. This ramification of the flax will readily be occaſioned by clods on the ground when ſown. A ſecond crop is very ſeldom attended with any profit; for being overgrown with the ſpreading plants of the firſt crop, it remains weak and ſhort, and at pulling time is left to rot upon the land.

502 Linſeed-cake, linſeed itſelf, and linſeed oil, uſed for fattening cattle.

503 Culture of flax in Yorkſhire.

Flax is injured not only by drought but by froſt, and is ſometimes attacked even when got five or ſix inches high, by a ſmall white flug, which ſtrips off the leaves to the top, and the ſtalks bending with their weight are thus ſometimes drawn into the ground. Hence, if the crop does not promiſe fair at weeding time, our author adviſes not to beſtow farther labour and expence upon it. A crop of turnips or rape will generally pay much better than ſuch a crop of flax. The time of flax-harveſt in Yorkſhire is generally in the latter end of July or beginning of Auguſt.

504 Mr Marſhall's remarks on flax crop.

On the whole, our author remarks, that "the goodneſs of the crop depends in ſome meaſure upon its length; and this upon its evenneſs and cloſeneſs upon the ground. Three feet high is a good length, and the

Flax and Hemp.

the thickneſs of a crow's quill a good thickneſs. A fine ſtalk affords more line and fewer ſhivers than a thick one. A tall thick ſet crop is therefore deſirable. But unleſs the land be good, a thick crop cannot attain a ſufficient length of ſtem. Hence the folly of ſowing flax on land which is unfit for it. Nevertheleſs, with a ſuitable ſoil, a ſufficiency of ſeed evenly diſtributed, and a favourable ſeaſon, flax may turn out a very profitable crop. The flax crop, however, has its diſadvantages: it interferes with harveſt, and is generally believed to be a great exhauſter of the ſoil, eſpecially when its ſeed is ſuffered to ripen. Its cultivation ought therefore to be confined to rich graſs-land diſtricts, where harveſt is a ſecondary object, and where its exhauſtion may be rather favourable than hurtful to ſucceeding arable crops, by checking the too great rankneſs of rich freſh broken ground.

505 Mr Bartley's experiments

In the 5th volume of Bath Papers, Mr Bartley, near Briſtol, gives an account of the expences and produce of five acres of graſs cultivated on a rich loamy ſand. The total expence was 42l. 13s. 4d.; the produce was ten packs of flax at 5l. 5s. value 52l. 10s. 35 buſhels of linſeed at 5s. value 8l. 15s.; the net profit therefore was 18l. 11s. 8d. or 4l. 13s. 4d. per acre. This gentleman is of opinion that flax-growers ought to make it their ſtaple article, and conſider the other parts of their farm as in ſubſerviency to it.

506 Remarks by a Dorſetſhire gentleman.

In the ſecond volume of Bath Papers, a Dorſetſhire gentleman, who writes on the culture of hemp and flax, gives an account ſomewhat different from that of Mr Marſhall. Inſtead of *exhauſting* crops, he maintains that they are both *ameliorating* crops, if cut without ſeeding; and as the beſt crops of both are raiſed from foreign ſeed, he is of opinion that there is little occaſion for raiſing it in this country. A crop of hemp, he informs us, prepares the land for flax, and is therefore clear gain to the farmer. "That theſe plants impoveriſh the ſoil," he repeats, "is a mere vulgar notion, devoid of all truth.—The beſt hiſtorical relations, and the verbal accounts of honeſt ingenious planters, concur in declaring it to be a vain prejudice, unſupported by any authority; and that theſe crops really meliorate and improve the ſoil." He is likewiſe of opinion, that the growth of flax and hemp is not neceſſarily confined to rich ſoils, but that they may be cultivated with profit alſo upon poor ſandy ground, if a little expence be laid out in manuring it. "Spalding-moor in Lincolnſhire is a barren ſand; and yet with proper care and culture it produces the beſt hemp in England, and in large quantities. In the iſle of Aſholme, in the ſame county, equal quantities are produced; for the culture and management of it is the principal employ of the inhabitants; and, according to Leland, it was ſo in the reign of Henry VIII. In Marſhland the ſoil is a clay or ſtrong warp, thrown up by the river Ouſe, and of ſuch quality, that it cracks with the heat of the ſun, till a hand may be put into the chinks; yet if it be once covered with the hemp or flax before the heats come on, the ground will not crack that ſummer. When the land is ſandy, they firſt ſow it with barley, and the following ſpring they manure the ſtubble with horſe or cow dung, and plough it under. Then they ſow their hemp or flax, and harrow it in with a light harrow, having ſhort teeth. A good crop deſtroys all the weeds, and makes it a fine fallow for flax in the ſpring. As ſoon as the flax is pulled, they prepare the ground for wheat. Lime, marl, and the mud of ponds, is an excellent compoſt for hemp-lands."

507 Flax and hemp may be cultivated upon poor as well as rich ſoils.

Flax and Hemp.

508 Vaſt quantities of flax and hemp imported into Britain.

Our author takes notice of the vaſt quantity of flax and hemp, not leſs than 11,000 tons, imported in the year 1763 into Britain; and complains that it is not raiſed in the iſland, which he thinks might be done, though it would require 60,000 acres for the purpoſe. He obſerves, that the greater part of thoſe rich marſhy lands lying to the weſt of Mendip hills are very proper for the cultivation of hemp and flax; and if laid out in this manner could not fail of turning out highly advantageous both to the landholders and the public at large. The vaſt quantities of hemp and flax (ſays he) which have been raiſed on lands of the ſame kind in Lincolnſhire marſhes, and the fens of the iſle of Ely and Huntingdonſhire, are a full proof of the truth of my aſſertion. Many hundreds of acres in the above-mentioned places, which, for paſturage or grazing, were not worth more than twenty or twenty-five ſhillings per acre, have been readily let at 4l. the firſt year, 3l. the ſecond, and 2l. the 3d. The reaſon of this ſuppoſed declining value of land, in proportion to the number of years ſown with flax, is, that it is uſual with them to ſeed for the purpoſe of making oil, that being the principal cauſe of the land being thereby impoveriſhed.

It is certain, however, that the quantity of hemp exported from St Peterſburgh in Britiſh ſhips has continued to increaſe, ſo that in 1785 the quantity of hemp exported from Peterſburgh in Britiſh ſhips was as follows:

	Poods.
Of clean hemp, - -	1,038,791
Outſhot, - - - -	37,382
Half clean, - - -	18,374
Hemp codille, - - -	19,251
	1,113,798

There are 63 poods to a ton, conſequently the whole amounted to 17,695 tons; and it is ſaid that this quantity has ſince been tripled and quadrupled. It is therefore an object of great national importance to conſider, whether flax and hemp might not be profitably reared in our own country without producing any alarm concerning their tendency to exhauſt the ſoil. With this view we ſhall here ſtate the ſubſtance of a report made by Mr Durno, Britiſh conſul in Pruſſia in 1789, to the lords of the Committee of Council for Trade, concerning the method of cultivating flax and hemp in Pruſſia, Ruſſia, and Poland.

509 Mr Durno's report on the culture of flax and hemp in Pruſſia, &c.

A black, not moraſſy, open gravelly ſoil is preferred, as flax and hemp become exuberant and coarſe on too rich a ſoil. To aſcertain the proper middle degree of ſtrength of ſoil, previous crops of grain are taken. On a vigorous ſoil wheat is firſt ſown; then rye, barley, oats; and laſt of all flax or hemp. Two ſucceſſive crops of hemp are taken if the land is immediately dunged. For one crop of flax, it is not dunged at all. On a ſoil of leſs ſtrength, flax and hemp are ſown immediately after a winter crop of rye, the land being ploughed in autumn, if the weather allows, if not, in ſpring. It is then harrowed and manured, and again

Flax and Hemp.

ploughed immediately before ſowing. Another winter crop of rye may immediately be ſown in the ſame field after drawing the flax or hemp, but after the flax; dung is in this caſe neceſſary. A field that has been laid down in fallow, if only ploughed up, yields a better crop of flax than if manured and cultivated in the above or any other way. Flax and hemp are ſown from the 25th of May to the 10th of June, and the flax is reaped in the end of Auguſt, and hemp in the end of September.

As to their effects on the ſoil, no kind of grain can be ſown immediately after a crop of flax without dunging, but after one of hemp, any grain, and even hemp itſelf, may be ſown without manure. Hemp cleans the ground by ſuffocating, by its broad leaves, all ſorts of weeds or undergrowth; but flax muſt be weeded once or twice before it blooms. Flax is plucked when the ſtalk becomes yelloviſh, the pods brown, and the ſeed hard and full bodied. For finer flax, the ſtalk is pulled while yet green; but the ſeed is then ſacrificed, and fit only for cruſhing for oil, of which it produces a ſmall quantity. Hemp is alſo plucked or drawn when the ſtalk and pods have changed colour. If the flax is very dry when plucked, the ſeed is ſtripped off immediately; if not, it is allowed to dry on the field. Seed-pods are ſpread thinly on a floor, where they are turned twice a-day, till ſo dry that they open of themſelves; when it is thraſhed and cleaned like other grain. To gain the hemp-ſeed, the hemp itſelf, when plucked, is ſet on end againſt any convenient place. The roots and top-ends are then cut off. The roots are thrown away, and the top-ends are threſhed out and cleaned. The ſeed is apt to be ſpoiled by remaining in a moiſt ſtate for any length of time.

As ſoon as the ſeed has been gained, the flax and hemp are ſteeped in water till the flax ſeparate from the rind, and the hemp till the harl ſprings from the ſtalk. In ſoft water, in warm weather, nine or ten days are ſufficient for this purpoſe. In hard water, with cold weather, from fourteen days to three weeks are requiſite. Stagnate is preferred to running water; but fiſh ponds and the drinking places of cattle muſt be avoided, as the fiſh would be deſtroyed, and the water would be rendered unwholeſome and unpalatable to the cattle; but a muddy or ſlimy bottom is preferred. In the ſouthern provinces of Poland, as Volhinia, Podolia, &c. ſteeping is not practiſed, on the ſuppoſition that it weakens the harl and darkens the colour, though this idea ſeems to have no foundation.

After being taken out of the ſteep, the flax is dried on a graſs field; after which it is gathered up into ſmall ſtacks; but the hemp, inſtead of being ſpread out on a field, is ſet up againſt the walls of buildings till it is alſo dried, after which they are both houſed.

It is generally underſtood in theſe countries, that the cultivation of flax and hemp is more profitable than that of any kind of grain.

510 Culture of flax in Ireland.

To this we ſhall add a conciſe ſtatement of the mode of cultivating flax in Ireland. A good crop of flax is there expected from any ſtrong clays that are fit for the growth of corn; but an open black loamy ſoil, enriched by having lain long in paſture, is preferable. The ground muſt be in fine tilth, and as free from weeds as poſſible. Potatoes uſually precede flax, though turnips, beans, or any manured crop, are a good preparation: but the firſt or ſecond crop after paſture is preferred to any of theſe. Stubble lands, that have been long in tillage, may, by proper preparation, bring a crop; but it is apt to fail in ſuch ſituations, the ſtalks turning to a reddiſh colour called *firing* before it ripens; upon which it muſt immediately be pulled. Two buſhels of ſeed are uſed to the Engliſh acre, unleſs for the purpoſe of a very fine manufacture; in which caſe a large quantity of ſeed is uſed, and the flax is pulled very green. The ſeaſon of ſowing is the firſt fine weather after the middle of March. The moſt approved mode of culture is in beds about ſix feet broad, covering the ſeed about an inch and a half deep, with earth ſhoveled out of the furrows: but the moſt ordinary mode is to ſow on common ridges, and to harrow in the ſeed. Before the flax is five inches high it ſhould be carefully hand-weeded; and if any part lodges, it ſhould be turned over. The produce is uſually worth 7l. ſterling the Engliſh acre. The crop ſhould ſtand till the lower part of the ſtalk becomes yelloviſh, and the under leaves begin to wither, unleſs the ſeed is to be preſerved, which is done by rippling it through an iron comb, and the flax may be ſteeped immediately after it is pulled. Turf-bog water, if clear, anſwers well, but foul ſtagnate water ſtains the flax. Too pure a ſpring is injurious. A reſervoir dug in clay is preferred. The time of lying in the ſteep depends upon the quality of the water and the ſtate of the weather. It is dried on graſs by being ſpread thin; artificial heat has been recommended for drying flax; but no good form of it has been ſuggeſted.

Rape o Cole-See

511 Sheep employed to weed flax.

In addition to what is here ſtated, the compiler of this article accounts it proper to take notice of a mode of weeding flax that has frequently been practiſed in Scotland. It conſiſts of turning a flock of ſheep at large into the field. They will not taſte the young flax plants, but they carefully ſearch for the weeds, which they devour. It may alſo be remarked, that for drying flax in wet ſeaſons, the ſteam kiln formerly propoſed (N° 34) would be a valuable inſtrument.

Sect. II. *Rape or Cole-Seed.*

This, as well as linſeed, is cultivated for the purpoſe of making oil, and will grow almoſt anywhere. Mr Hazard informs us, that in the north of England the farmers pare and burn their paſture lands, and then ſow them with rape after one ploughing; the crop commonly ſtanding for ſeed, which will bring from 25l. to 30l. per laſt (80 buſhels). Poor clay, or ſtone-braſh land, will frequently produce from 12 to 16 or 18 buſhels per acre, and almoſt any freſh or virgin earth will yield one plentiful crop; ſo that many in the northern counties have been raiſed, by cultivating this ſeed, from poverty to the greateſt affluence. The ſeed is ripe in July or the beginning of Auguſt; and the thraſhing of it out is conducted with the greateſt mirth and jollity.

Bath Papers, vol. iv

512 Advantage of cultivating rape-ſeed.

513 Of cutting and thraſhing the rape-ſeed.

The rape being fully ripe, is firſt cut with ſickles, and then laid thin upon the ground to dry; and when in proper condition for thraſhing, the neighbours are invited, who readily contribute their aſſiſtance. The thraſhing is performed on a large cloth in the middle of

Rape or Cole-Seed.

of the field, and the ſeed put into the ſacks and carried home. It does not admit of being carried from the field in the pod in order to be thraſhed at home, and therefore the operation is always performed in the field; and by the number of aſſiſtants procured on this occaſion, a field of 20 acres is frequently thraſhed out in one day. The ſtraw is burnt for the ſake of its alkali, the aſhes being ſaid to equal the beſt kind of thoſe imported from abroad.

514 Of ſowing it.

The proper time for ſowing rape is the month of June; and the land ſhould, previous to the ſowing, be twice well ploughed. About two pounds of ſeed are ſufficient for an acre; and, according to our author, it ſhould be caſt upon the ground with only the thumb and two fore fingers; for if it be caſt with all the fingers, it will come up in patches. If the plants come up too thick, a pair of light harrows ſhould be drawn along the field length-wiſe and croſs-wiſe; by which means the plants will be equally thinned; and when the plants which the harrows have pulled up are withered, the ground ſhould be rolled. A few days after the plants may be ſet out with a hoe, allowing 16 or 18 inches diſtance betwixt every two plants.

513 Tranſplanting recommended.

Mr Hazard ſtrongly recommends the tranſplanting of rape, having experienced the good effects of it himſelf. A rood of ground, ſown in June, will produce as many plants as are ſufficient for 10 acres; which may be planted out upon ground that has previouſly borne a crop of wheat, provided the wheat be harveſted by the middle of Auguſt. One ploughing will be ſufficient for theſe plants; the beſt of which ſhould be ſelected from the ſeed-plot, and planted in rows two feet aſunder and 16 inches apart in the rows. As rape is an excellent food for ſheep, they may be allowed to feed upon it in the ſpring; or the leaves might be gathered, and given to oxen or young cattle: freſh leaves would ſprout again from the ſame ſtalks, which in like manner might be fed off by ewes and lambs in time enough to plough the land for a crop of barley and oats. Planting rape in the beginning of July, however, would be moſt advantageous for the crop itſelf, as the leaves might then be fed off in the autumn, and new ones would appear in the ſpring. Our author diſcommends the practice of ſowing rape with turnips, as the crops injure one another. "Thoſe who look for an immediate profit (ſays he), will undoubtedly cultivate rape for ſeed; but perhaps it may anſwer better in the end to feed it with ſheep; the fat ones might cull it over firſt, and afterwards the lean or ſtore-ſheep might follow them, and be folded thereon; if this is done in the autumn ſeaſon, the land will be in good heart to carry a crop of wheat; or where the rape is fed off in the ſpring, a crop of barley might follow. In either caſe rape is profitable to the cultivator; and when it is planted, and well earthed round the ſtems, it will endure the ſevereſt winter; but the ſame cannot be advanced in favour of that which is ſown broadcaſt.

516 Sheep may be fed in the ſpring with rape.

517 Culture of rape-ſeed in Brabant.

Cole ſeed is cultivated in Brabant, in the following manner, according to the Abbé Mann. "It is ſown about the middle of July, and the young plants are tranſplanted about the end of September. This is done with a narrow ſpade ſunk into the ground, and moved with the hand forwards and backwards; which ſimple motion, makes a ſufficient opening to receive the plant; a boy or girl follows the labourer with plants, and putting one of them into each hole, treads againſt it to cloſe it up. If the plantation is done with the plough, the plants are placed at regular diſtances in the furrow, and are covered with the earth turned up with the ſucceeding furrow. Sometimes, after the cole ſeed is planted, the foot of the ſtalks is covered, by means of a common ſpade or hoe, with the earth near it, which furniſhes nouriſhment for the plants during winter, by the crumbling of theſe little clods of earth over the roots. The cole-ſeed is reaped about midſummer or later, according as the ſeaſon is more or leſs advanced; it is left on the field for ten or twelve days after it is cut, and then thraſhed on a kind of ſail-cloth, ſpread on the ground for that purpoſe, and the ſeed carried in ſacks to the farm. When the crop is good, a bunder produces about forty raziers of 80lbs. weight each. It is to be obſerved, that the ground whereon cole-ſeed is to be planted, muſt be dunged and twice ploughed the ſame year it is put in uſe."

Coriander-Seed, Canary-Seed, &c.

SECT. III. *Coriander-Seed.*

THIS is uſed in large quantities by diſtillers, druggiſts, and confectioners, and might be a conſiderable object to ſuch farmers as live in the neighbourhood of great towns; but the price is very variable, viz. from 16s. to 42s. per cwt. In the 4th volume of Bath Papers, Mr Bartley gives an account of an experiment made on this ſeed, which proved very ſucceſsful. Ten perches of good ſandy loam were ſown with coriander on the 23d of March 1783. Three pounds of ſeed were ſufficient for this ſpot; and the whole expence amounted only to 5s. 10d. The produce was 87 pounds of ſeed, which, valued at 3d. yielded a profit of 5s. 11d. or 1l. 18s. 4d. per acre. He afterwards made ſeveral other experiments on a larger ſcale; but none of the crops turned out ſo well, though all of them afforded a good profit.

518 Mr Bartley's experiment.

SECT. IV. *Canary-Seed.*

THIS is cultivated in large quantity in the Iſle of Thanet, where it is ſaid they have frequently 20 buſhels to an acre. Mr Bartley, in the month of March 1783, ſowed half an acre of ground, the ſoil a mixture of loam and clay, but had only eight buſhels and a half, or 17 buſhels per acre. With this produce, however, he had a profit of 4l. 2s. 3d. per acre.

519 Culture of canary-ſeed.

SECT. V. *Woad.*

THE uſe of this in dyeing is well known, and the conſumption is ſo great, that the raiſing of the plant might undoubtedly be a object to an huſbandman, provided he could get it properly manufactured for the dyers, and could overcome their prejudices. At preſent, the growing of this plant is in a manner monopolized by ſome people in particular places, particularly at Keynſham near Briſtol in England. Mr Bartley informs us, that in a converſation he had with theſe growers, the latter aſſerted, that the growth of woad was peculiar to their ſoil and ſituation. The ſoil about this place is a blackiſh heavy mould, with a conſiderable proportion of clay, but works freely: that of Briſlington,

520 Woad eaſily cultivated.

Hops. Brillington, where Mr Bartley reſides, a hazel ſandy loam; nevertheleſs, having ſowed half an acre of this ſoil with woad ſeed, it throve ſo well, that he never ſaw a better crop at Keynſham. Having no apparatus, however, or knowledge of the manufacture, he ſuffered it to run to ſeed, learning only from the experiment, that woad is very eaſily cultivated, and that the only difficulty is the preparing it for the market.

SECT. VI. *Hops.*

521 Hops forbid by act of parliament.

THE uſes of theſe as an ingredient in malt liquors, are well known. Formerly, however, they were ſuppoſed to poſſeſs ſuch deleterious qualities, that the uſe of them was forbid by act of parliament in the reign of James VI. But though this act was never repealed, it does not appear that much regard was ever paid to it, as the uſe of hops has ſtill continued, and is found not to be attended with any bad effects on the human conſtitution. The only queſtion, therefore, is, How far the raiſing a crop of them may be profitable to a huſbandman? and indeed this ſeems to be very doubtful.

Mr Arthur Young, in a Fortnight's Tour through Kent and Eſſex, informs us*, that at Caſtle Hedingham he was told by a Mr Rogers, who had a conſiderable hop-plantation, that four acres of hop-ground coſt him upwards of 120l. and that the uſual expences of laying out an acre of ground in this way amounted to 34l. 6s. By a calculation of the expences of an acre in Kent, it appeared that the money ſunk to plant an acre there amounted to 32l. 8s. 6d.; that the annual expence was 23l. and the profit no more than 1l. 8s. 1d. In another place, he was informed by a Mr Potter, who cultivated great quantities of hops, that if it were not for ſome extraordinary crops which occurred now and then, nobody would plant them. In Eſſex, the expences of a hop-plantation are ſtill greater than thoſe we have yet mentioned; an acre many years ago requiring 75l. to lay it out on hops, and now not leſs than 100l. the annual expence being eſtimated at 31l. 1s. while the produce commonly does not exceed 32l.

Annals of Agriculture, vol. ii.

522 Expence of cultivating them at Caſtle Hedingham.

523 In Eſſex.

In the neighbourhood of Stow-market in this county, Mr Young informs us, there are about 200 acres planted with hops, but "18 or 20 are grubbed up within two years, owing to the badneſs of the times." Here they are planted on a black looſe moor, very wet and boggy; and the more wet the better for the crop, eſpecially if the gravel, which conſtitutes the bottom, be not more than three feet from the ſurface. In preparing the ground for hops, it is formed into beds, 16 feet wide, ſeparated from each other by trenches. In theſe beds they make holes ſix feet aſunder, and about 12 inches diameter, three rows upon a bed. Into each hole they put about half a peck of very rotten dung or rich compoſt; ſcatter earth upon it, and plant ſeven ſets in each; drawing earth enough to them afterwards to form ſomething of a hillock. A hop garden, Mr Young informs us, "will laſt almoſt for ever, by renewing the hills that fail, to the amount of about a ſcore annually, but it is reckoned better to grub up and new-plant it every 20 or 25 years."

In this volume of the Annals, Mr Young informs us, that "one profit of hop-land is that of breaking it up. Mr Potter grubbed up one garden, which failing, he ploughed and ſowed barley, the crop great: then mazagan beans, two acres of which produced 16 quarters and five buſhels. He then ſowed it with wheat, which produced 13 quarters and four buſhels and a half: but ſince that time the crops have not been greater than common. The ſame gentleman has had 10 quarters of oats after wheat." In the ninth volume of the ſame work, however, we have an account of an experiment by Mr Le Bland of Sittingbourn in Kent, of grubbing up 12 acres of hop-ground, which was not attended with any remarkable ſucceſs. Part of the hops were grubbed up in the year 1781, and mazagan beans ſown in their ſtead: but by reaſon of the ſeed being bad, and the dry ſummer, the crop turned out very indifferent. Next year the remainder of the hops were grubbed up, and the whole 12 acres ſown with wheat; but ſtill the crop turned out very bad, owing to the *wet* ſummer of that year. It was next planted with potatoes, which turned out well: and ever ſince that time the crops have been good. This gentleman informs us, that the perſon who had the hop-ground above mentioned did not loſe leſs by it than 1500l.

Cultivation of Fruit.

524 Profit of breaking up hop-land precarious.

525 Culture of hops in Norfolk on the decline.

The culture of hops ſeems to be confined in a great meaſure to the ſouthern counties of England; for Mr Marſhall mentions it as a matter of ſurpriſe, that in Norfolk he ſaw a "tolerably large hop garden." The proprietor informed him, that three or four years before there had been 10 acres of hops in the pariſh (Blowfield) where he reſided; which was more than could be collected in all the reſt of the county; but at that time there were not above five: and the culture was daily declining, as the crops, owing to the low price of the commodity, did not defray the expence.

From all this it appears, that hops are perhaps the moſt uncertain and precarious crop on which the huſbandman can beſtow his labour. Mr Young is of opinion, that ſome improvement in the culture is neceſſary; but he does not mention any, excepting that of planting them in eſpaliers. This method was recommended both by Mr Rogers and Mr Potter above mentioned. The former took the hint from obſerving, that a plant which had been blown down, and afterwards ſhot out horizontally, always produced a greater quantity than thoſe which grew upright. He alſo remarks, that hops which are late picked carry more next year than ſuch as are picked early; for which reaſon he recommends the late picking. The only reaſon for picking early is, that the hops appear much more beautiful than the others.

SECT. VII. *Cultivation of Fruit.*

IN Herefordſhire and Glouceſterſhire the cultivation of fruit for the purpoſe of making a liquor from the juice, forms a principal part of their huſbandry. In Devonſhire alſo conſiderable quantities of this kind of liquor are made, though much leſs than in the two counties above mentioned.

526 Fruits cultivated in Herefordſhire and Glouceſterſhire.

The fruits cultivated in Herefordſhire and Glouceſterſhire are, the apple, the pear, and the cherry. From the two firſt are made the liquors named *cyder and perry*;

Cultivation of Fruit.

ry; but though it is probable that a liquor of some value might be made from cherries also, it does not appear to have ever been attempted. Mr Marshall remarks, that nature has furnished only one species of pears and apples, *viz.* the common crab of the woods and hedges, and the wild pear, which is likewise pretty common. The varieties of these fruits are entirely artificial, being produced not by seed, but by a certain mode of culture; whence it is the business of those who wish to improve fruit therefore, to catch at superior accidental varieties; and having raised them by cultivation to the highest perfection of which they are capable, to keep them in that state by artificial propagation. Mr Marshall, however, observes, that it is impossible to make varieties of fruit altogether permanent, though their duration depends much upon management. "A time arrives (says he) when they can no longer be propagated with success. All the old fruits which raised the fame of the liquors of this country are now lost, or so far on the decline as to be deemed irrecoverable. The *red streak* is given up; the celebrated *stir-apple* is going off; and the *squash-pear*, which has probably furnished this country with more *champaign* than was ever imported into it, can no longer be got to flourish: the stocks canker, and are unproductive. In Yorkshire similar circumstances have taken place: several old fruits which were productive within my own recollection are lost; the stocks cankered, and the trees would no longer come to bear."

527 Varieties of fruits entirely artificial.

528 Varieties cannot be made permanent.

Our author controverts the common notion among orchard-men, that the decline of the old fruits is owing to a want of fresh grafts from abroad, particularly from Normandy, from whence it is supposed that apples were originally imported into this country. Mr Marshall, however, thinks, that these original kinds have been long since lost, and that the numerous varieties of which we are now possessed were raised from seed in this country. He also informs us, that at Ledbury he was shown a Normandy apple tree, which, with many others of the same kind, had been imported immediately from France. He found it, however, to be no other than the *bitter-sweet*, which he had seen growing as a neglected wilding in an English hedge.

529 Mr Marshall's directions for raising new varieties of fruit.

The process of raising new varieties of apples, according to Mr Marshall, is simple and easy. "Elect (says he) among the native species individuals of the highest flavour; sow the seeds in a highly enriched seed bed. When new varieties, or the improvement of old ones, are the objects, it may perhaps be eligible to use a frame or stove; but where the preservation of the ordinary varieties only is wanted, an ordinary loamy soil will be sufficient. At any rate, it ought to be perfectly clean at least from root weeds, and should be double dug from a foot to 18 inches deep. The surface being levelled and raked fine, the seeds ought to be scattered on about an inch asunder and covered about half an inch deep with some of the finest mould previously raked off the bed for that purpose. During summer the young plants should be kept perfectly free from weeds, and may be taken up for transplantation the ensuing winter; or if not very thick in the seed-bed, they may remain in it till the second winter.

530 The nursery ground.

The nursery ground ought also to be enriched, and double dug to the depth of 14 inches at least; though 18 or 20 are preferable. The seedling plants ought to be sorted agreeably to the strength of their roots, that they may rise evenly together. The top or downward roots should be taken off, and the longer side rootlets shortened. The young trees should then be planted in rows three feet asunder, and from 15 to 18 inches distant in the rows; taking care not to cramp the roots, but to lead them evenly and horizontally among the mould. If they be intended merely for stocks to be grafted, they may remain in this situation until they be large enough to be planted out; though, in strict management, they ought to be re-transplanted two years before their being transferred into the orchard, "in fresh but unmanured double-dug ground, a quincunx four feet apart every way." In this second transplantation, as well as in the first, the branches of the root ought not to be left too long, but to be shortened in such a manner as to induce them to form a globular root, sufficiently small to be removed with the plant; yet sufficiently large to give it firmness and vigour in the plantation.

531 Method of choosing the plants.

Having proceeded in this manner with the seed-bed, our author gives the following directions. "Select from among the seedlings the plants whose wood and leaves wear the most *apple-like* appearance. Transplant these into a rich deep soil in a genial situation, letting them remain in this nursery until they begin to bear. With the seeds of the fairest, richest, and best flavoured fruit repeat this process; and at the same time, or in due season, engraft the wood which produced this fruit on that of the richest, sweetest, best-flavoured apple: repeating this operation, and transferring the subject under improvement from one tree and sort to another, as richness, flavour, or firmness, may require; continuing this double mode of improvement until the desired fruit be obtained. There has, no doubt, been a period when the improvement of the apple and pear was attended to in this country; and should not the same spirit of improvement revive, it is probable that the country will, in a course of years, be left destitute of valuable kinds of these two species of fruit; which, though they may in some degree be deemed objects of luxury, long custom seems to have ranked among the necessaries of life."

532 Mr Grimwood's opinion of the degeneracy of apples.

In the fourth volume of Bath Papers, Mr Grimwood supposes the degeneracy of apples to be rather imaginary than real. He says, that the evil complained of "is not a real decline in the quality of the fruit, but in the tree; owing either to want of health, the season, soil, mode of planting, or the stock they are grafted on, being too often raised from the seed of apples in the same place or country. I have not a doubt in my own mind, but that the trees which are grafted on the stocks raised from the apple pips are more tender than those grafted on the real crab-stock; and the seasons in this country have, for many years past, been unfavourable for fruits, which add much to the supposed degeneracy of the apple. It is my opinion, that if planters of orchards would procure the trees grafted on real crab-stocks from a distant country, they would find their account in so doing much overbalance the extra expence of charge and carriage.

533 Mr Gillingwater's opinion.

In the same volume, Mr Edmund Gillingwater assigns as a reason for the degeneracy of apples the mixture of various farina, from the orchards being too near each other. In consequence of this notion, he

Cultivation of fruit.

he alſo thinks that the old and beſt kinds of apple trees are not loſt, but only corrupted from being planted too near bad neighbours: "Remove them (ſays he) to a ſituation where they are not expoſed to this inconvenience, and they will immediately recover their former excellency." This theory, however, is not ſupported by a ſingle experiment.

534 Mr Samuel's opinion of the method of recovering the beſt fruit.

In this volume alſo Mr Richard Samuel expreſſes his concern at the "preſent neglect of orchards, where the old trees are decaying, without proper proviſion being made for the ſucceeding age: for if a farmer plants freſh trees (which does not frequently happen), there is ſeldom any care taken to propagate the better ſorts, as his grafts are uſually taken promiſcuouſly from any ordinary kind, moſt eaſily procured in the neighbourhood." His remedy is to collect grafts from the beſt trees; by which means he ſuppoſes that the ſuperior kinds of fruit would ſoon be recovered. To a care of this kind he attributes the ſuperiority of the fruit in the neighbourhood of great towns to that in other places.

535 Cultivation, &c. of fruit trees.

With regard to the method of cultivating fruit trees, it is only neceſſary to add, that while they remain in the nurſery, the intervals between them may be occupied by ſuch kitchen-ſtuff as will not crowd or overſhadow the plants; keeping the rows in the mean time perfectly free from weeds. In pruning them, the leader ſhould be particularly attended to. If they ſhoot double, the weaker of the contending branches ſhould be taken off; but if the leader be loſt, and not eaſily recoverable, the plant ſhould be cut down to within a hand's breadth of the ſoil, and a freſh ſtem trained. The undermoſt boughs ſhould be taken off by degrees, going over the plants every winter; but taking care to preſerve heads of ſufficient magnitude not to draw the ſtems up too tall, which would make them feeble in the lower part. The ſtems in Herefordſhire are trained to ſix feet high; but our author prefers ſeven, or even half a rod in height. A tall-ſtemmed tree is much leſs injurious to what grows below it than a low-headed one, which is itſelf in danger of being hurt, at the ſame time that it hurts the crop under it. The thickneſs of the ſtem ought to be in proportion to its height; for which reaſon a tall ſtock ought to remain longer in the nurſery than a low one. The uſual ſize at which they are planted out in Herefordſhire is from four to ſix inches girt at three feet high; which ſize, with proper management, they will reach in ſeven or eight years. The price of theſe ſtocks in Herefordſhire is 1s. 6d. each. Our author met with one inſtance of crabſtocks being gathered in the woods with a good proſpect of ſucceſs.

536 Method of managing the ground of orchards in Herefordſhire and Glouceſterſhire.

In Herefordſhire it is common to have the ground of the orchards in tillage, and in Glouceſterſhire in graſs; which Mr Marſhall ſuppoſes to be owing to the difference betwixt the ſoil of the two counties; that of Herefordſhire being generally arable, and Glouceſter graſs land. Trees, however, are very deſtructive, not only to a crop of corn, but to clover and turnips; though tillage is favourable to fruit trees, in general, eſpecially when young. In graſs grounds their progreſs is comparatively ſlow, for want of the earth being ſtirred about them, and by being injured by the cattle, eſpecially when low-headed and drooping. After they begin to bear, cattle ought by all means to be kept away from them, as they not only deſtroy all the fruit within their reach, but the fruit itſelf is dangerous to the cattle, being apt to ſtick in their throats and choak them. Theſe inconveniences may be avoided, by eating the fruit grounds bare before the gathering ſeaſon, and keeping the boughs out of the way of the cattle: but Mr Marſhall is of opinion, that it is wrong to plant orchards in graſs land. "Let them (ſays he) lay their old orchards to graſs; and if they plant, break up their young orchards to arable. This will be changing the courſe of huſbandry, and be at once beneficial to the land and the trees.

Cultivation of Fruits.

537 Indolence of the farmers in theſe parts complained of.

Our author complains very much of the indolent and careleſs method in which the Herefordſhire and Glouceſterſhire farmers manage their orchards. The natural enemies of fruit trees (he ſays) are, 1. A redundancy of wood. 2. The miſſetoe. 3. Moſs. 4. Spring froſts. 5. Blights. 6. Inſects. 7. And exceſs of fruit. 8. Old age.

538 Exceſs of wood how remedied.

1. A redundancy of wood is prejudicial, by reaſon of the barren branches depriving thoſe which bear fruit of the nouriſhment which ought to belong to them. A multitude of branches alſo give the wind ſuch an additional power over the tree, that it is in perpetual danger of being overthrown by them: trees are likewiſe thus injured by the damps and want of circulation of air, ſo that only the outer branches are capable of bringing fruit to maturity. "It is no uncommon ſight (ſays he) to ſee trees in this diſtrict, with two or three tires of boughs preſſing down hard upon one another, with their twigs ſo intimately interwoven, that even when the leaves are off, a ſmall bird can ſcarcely creep in among them.

539 Miſſetoe how deſtroyed.

2. The miſſetoe in this country is a great enemy to the apple tree. It is eaſily pulled out with hooks in froſty weather, when, being brittle, it readily breaks off from the branches. It likewiſe may be applied to a profitable purpoſe, ſheep being as fond of it as of ivy.

540 Moſs of fruit trees.

3. Moſs can only be got the better of by induſtry in clearing the trees of it; and in Kent there are people who make it their profeſſion to do ſo.

541 Spring-froſts.

4. Spring-froſts, eſpecially when they ſuddenly ſucceed rain, are great enemies to fruit trees; dry froſts only keep back the bloſſoms for ſome time. Art can give no farther aſſiſtance in this caſe than to keep the tree in a healthy and vigorous ſtate, ſo as to enable them to throw out a ſtrength of bud and bloſſom; and by keeping them thin of wood, to give the man opportunity of drying quickly before the froſt ſet in.

542 Blights an uncertain term.

5. Blight is a term, as applied to fruit trees, which Mr Marſhall thinks is not underſtood. Two bearing years, he remarks, ſeldom come together; and he is of opinion, that it is the mere exhauſting of the trees by the quantity of fruit which they have carried one year, that prevents them from bearing any the next. The only thing, therefore, that can be done in this caſe is, to keep the trees in as healthy and vigorous a ſtate as poſſible.

543 Method propoſed of deſtroying waſps.

6. Inſects deſtroy not only the bloſſoms and leaves, but ſome of them alſo the fruit, eſpecially pears. In the year 1783 much fruit was deſtroyed by waſps. Mr Marſhall adviſes to ſet a price upon the female waſps in the ſpring; by which theſe miſchievous inſects would perhaps be exterminated, or at leaſt greatly leſſened.

Timber Trees.

544 Of an excess of fruit.

7. An excess of fruit stints the growth of young trees, and renders all in general barren for two or three years; while in many cases the branches are broken off by the weight of the fruit; and in one case Mr Marshall mentions, that an entire tree had sunk under its burden. To prevent as much as possible the bad effects of an excess of fruit, Mr Marshall recommends "to graft in the boughs," and when fully grown, to thin the bearing branches; thus endeavouring, like the gardener, to grow fruit every year."

545 Duration of fruit trees may be lengthened.

8. Though it is impossible to prevent the effects of old age, yet by proper management the natural life of fruit trees may be considerably protracted. The most eligible method is to graft stocks of the native crab in the boughs. The decline of the tree is preceded by a gradual decline of fruitfulness, which takes place long before the tree manifests any sign of decay. During this decline of fruitfulness, there is a certain period when the produce of a tree will no longer pay for the ground it occupies; and beyond this period it ought by no means to be allowed to stand. In the Vale of Gloucester, however, our author saw an instance of some healthy bearing apple trees, which then had the *second* tops to the same stems. The former tops having been worn out, were cut off, and the stumps sawgrafted. Our author observes, that the pear tree is much longer lived than the apple, and ought never to be planted in the same ground. He concludes with the following general observation: "Thus considering fruit trees as a crop in husbandry, the general management appears to be this: Plant upon a recently broken-up worn-out sward. Keep the soil under a state of arable management, until the trees be well grown: then lay it down to grass, and let it remain in sward until the trees be removed, and their roots be decayed; when it will again require a course of arable management."

546 Mr Marshall's observation on the culture of fruit trees.

Sect. VIII. *Of Timber Trees.*

The importance and value of these are so well known, that it is superfluous to say any thing on that subject at present: notwithstanding this acknowledged value, however, the growth of timber is so slow, and the returns for planting so distant, that it is generally supposed for a long time to be a positive loss, or at least to be attended with no profit. This matter, however, when properly considered, will appear in another light. There are four distinct species of woodlands; viz. woods, timber groves, coppices, and woody wastes. The woods are a collection of timber trees and underwood; the timber groves contain timber trees without any underwood; and the coppices are collections of underwood alone. All these turn out to advantage sooner or later, according to the quick or slow growth of the trees, and the situation of the place with respect to certain local advantages. Thus in some places underwood is of great consequence, as for rails, hoops, stakes, fuel, &c.; and by reason of the quickness of its growth it may be accounted the most profitable of all plantations. An osier-bed will yield a return of profit the second or third year, and a coppice in 15 or 20 years; while a plantation of oaks will not arrive at perfection in less than a century. This last period is so long, that it may not unreasonably be supposed likely to deter people from making plantations of this kind, as few are willing to take any trouble for what they are never to see in perfection. It must be remembered, however, that though the trees themselves do not come to perfection in a shorter time, the value of the ground will always increase in proportion to their age. Thus, says one author upon this subject, "we have some knowledge of a gentleman now living, who during his lifetime has made plantations, which in all probability will be worth to his son as much as his whole estate, handsome as it is. Supposing that those plantations have been made 50 or 60 years, and that in the course of 20 or 30 more they will be worth 50,000l.; may we not say, that at present they are worth some 20,000l. or 30,000l.? Mr Pavier, in the 4th volume of Bath Papers, computes the value of 50 acres of oak timber in 100 years to be 12,100l. which is nearly 50s. annually per acre; and if we consider that this is continually accumulating, without any of that expence or risk to which annual crops are subject, it is probable that timber planting may be accounted one of the most profitable articles in husbandry. Evelyn calculates the profit of 1000 acres of oak land, in 150 years, at no less than 670,000l.; but this is most probably an exaggeration. At any rate, however, it would be improper to occupy, especially with timber of such slow growth, the grounds which either in grass or corn can repay the trouble of cultivation with a good annual crop.

547 Different kinds of woodlands.

548 What plantation will soonest bring in a return of profit.

Timber Trees

549 Advantages of planting.

In the fourth volume of the Bath Papers, Mr Wagstaffe recommends planting as an auxiliary to cultivation. He brings an instance of the success of Sir William Jerningham, who made trial of "the most unpromising ground perhaps that any successful planter has hitherto attempted." His method was to plant beech trees at proper distances among Scotch firs, upon otherwise barren heaths. "These trees (says Mr Wagstaffe), in a soil perhaps without clay or loam, with the heathy sod trenched into its broken strata of sand or gravel, under the protection of the firs, have laid hold, though slowly, of the soil; and accelerated by the superior growth of the firs, have proportionally risen, until they wanted an enlargement of space for growth, when the firs were cut down." He next proceeds to observe, that when the firs are felled, their roots decay in the ground; and thus furnish by that decay a new support to the soil on which the beeches grow: by which means the latter receive an additional vigour, as well as an enlargement of space and freer air; the firs themselves, though cut down before they arrived at their full growth, being also applicable to many valuable purposes.

550 Planting meliorates the soil.

551 Culture of timber trees recommended by Mr Harries.

In the sixth volume of Annals of Agriculture, we find the culture of trees recommended by Mr Harries: and he informs us, that the larch is the quickest grower and the most valuable of all the resinous timber trees; but unless there be pretty good room allowed for the branches to stretch out on the lower part of the trunk, it will not arrive at any considerable size; and this observation, he says, holds good of all pyramidal trees. Scotch firs may be planted between them, and pulled out after they begin to obstruct the growth of the larch. Some of these larches he had seen planted about 30 years before, which, at 5 feet distance from the ground, measured from 4 feet to 5 feet 6 inches in circumfer-

Timber Trees.

ence. The moſt barren grounds, he ſays, would anſwer for theſe trees, but better ſoil is required for the oaks. In this paper he takes notice of the leaves of one of his plantations of oaks having been almoſt entirely deſtroyed by inſects; in conſequence of which they did not increaſe in bulk as uſual: but another which had nearly eſcaped theſe ravages, increaſed at an average 1 inch in circumference. "A tree 4 feet round (ſays he), that has timber 20 feet in length, gains by this growth a ſolid foot of timber annually, worth one ſhilling at leaſt, and pays 5 per cent. for ſtanding. It increaſes more as the tree gets from 5 to 6 feet round. I have a reaſonable hope to infer from my inquiry, that I have in my groves 3000 oaks that pay me one ſhilling each per annum, or 150l. a-year. My poplars have gained in circumference near two inches, and a Worceſter and witch elm as much. I have lately been informed, that the ſmooth cut of a holly tree, that meaſures 20 inches and upwards round, is worth to the cabinet-makers 2s. 6d. per foot.

552 Increaſe of oak trees.

553 Increaſe of trees in the marquis of Lanſdowne's plantation.

The following table ſhows the increaſe of trees in 21 years from their firſt planting. It was taken from the marquis of Lanſdowne's plantation, begun in the year 1765, and the calculation made on the 15th of July 1786. It is about ſix acres in extent; the ſoil partly a ſwampy meadow upon a gravelly bottom. The meaſures were taken at 5 feet above the ſurface of the ground; the ſmall firs having been occaſionally drawn for poſts and rails, as well as rafters for cottages; and when peeled of the bark, will ſtand well for ſeven years.

	Height in Feet.	Circumference in Feet.	Inch.
Lombardy poplar -	60 to 80	4	8
Arbeal - -	50 to 70	4	6
Plane - -	50 to 60	3	6
Acacia - -	50 to 60	2	4
Elm - -	40 to 60	3	6
Cheſnut - -	30 to 50	2	9
Weymouth pines -	30 to 50	2	5
Cluſter ditto -	30 to 50	2	5
Scotch fir -	30 to 50	2	10
Spruce ditto -	30 to 50	2	2
Larch - -	50 to 60	3	10

From this table it appears, that planting of timber-trees, where the return can be waited for during the ſpace of 20 years, will undoubtedly repay the original profits of planting, as well as the intereſt of the money laid out; which is the better worth the attention of a proprietor of land, as the ground on which they grow may be ſuppoſed good for very little elſe. From a comparative table of the growth of oak, aſh, and elm timber, given in the 11th volume of the Annals of Agriculture, it appears that the oak is by much the ſloweſt grower of the three.

554 Of underwood, &c.

With reſpect to the growth of underwood, which in ſome caſes is very valuable, it is to be remarked, that in order to have an annual fall of it, the whole quantity of ground, whatever its extent may be, ought to be divided into annual ſowings. The exact number of ſowings muſt be regulated by the uſes to which it is intended to be put. Thus if, as in Surry, ſtakes, edders, and hoops are ſaleable, there ought to be eight or ten annual ſowings; or if, as in Kent, hop-poles are demanded, 14 or 15 will be required; and if, as in Yorkſhire, rails be wanted, or, as in Glouceſterſhire, cordwood be moſt marketable, 18 or 20 ſowings will be neceſſary to produce a ſucceſſion of annual falls. Thus the buſineſs, by being divided, will be rendered leſs burdenſome: a certain proportion being every year to be done, a regular ſet of hands will, in proper ſeaſon, be employed; and by beginning upon a ſmall ſcale, the errors of the firſt year will be corrected in the practice of the ſecond, and thoſe of the ſecond in that of the third. The produce of the intervals will fall into regular courſe; and when the whole is completed, the falls will follow each other in regular ſucceſſion. The greateſt objection to this method of ſowing woodlands is the extraordinary trouble in fencing: but this objection does not hold if the ſowings lie at a diſtance from one another; on the contrary, if they lie together, or in plots, the entire plot may be incloſed at once; and if it contain a number of ſowings, ſome ſubdiviſions will be neceſſary, and the annual ſowings of theſe ſubdiviſions may be fenced off with hurdles, or ſome other temporary contrivance; but if the adjoining land be kept under the plough, little temporary fencing will be neceſſary. It muſt be obſerved, however, that in raiſing a woodland from ſeeds, it is not only neceſſary to defend the young plants againſt cattle and ſheep, but againſt hares and rabbits alſo: ſo that a cloſe fence of ſome kind is abſolutely neceſſary.

Timber Trees.

With regard to the preparation of the ground for raiſing timber, it may be obſerved, that if the ſoil be of a ſtiff clayey nature, it ſhould receive a whole year's fallow as for wheat; if light, a crop of turnips may be taken; but at all events it muſt be made perfectly clean before the tree ſeeds be ſown, particularly from perennial root weeds; as, after the ſeeds are ſown, the opportunity of performing this neceſſary buſineſs is in a great meaſure loſt. If the ſituation be moiſt, the ſoil ſhould be gathered into wide lands, ſufficiently round to let the water run off from the ſurface, but not high. The time of ſowing is either the month of October or March; and the method as follows: "The land being in fine order, and the ſeaſon favourable, the whole ſhould be ſown with corn or pulſe adapted to the ſeaſon of ſowing: if in autumn, wheat or rye may be the crop; but if in ſpring, beans or oats. Whichever of theſe three ſpecies be adopted, the quantity of ſeed ought to be leſs than uſual, in order to give a free admiſſion of air, and prevent the crop from loading. The ſowing of the grain being completed, that of the tree-ſeeds muſt be immediately ſet about. Theſe are to be put in drills acroſs the land: acorns and nuts ſhould be dibbled in, but keys and berries ſcattered in trenches or drills drawn with the corner of a hoe, in the manner that gardeners ſow their peaſe. The diſtance might be a quarter of a ſtatute rod, or four feet and one inch and a half. A land-chain ſhould be uſed in ſetting out the drills, as not being liable to be lengthened or ſhortened by the weather. It is readily divided into rods; and the quarters may be eaſily marked.

555 Method of ſowing.

The ſpecies of underwood to be ſown muſt be determined by the conſumpt of it in the neighbourhood of the plantation. Thus, if ſtakes, hoops, &c. be in requeſt, the oak, hazel, and aſh, are eſteemed

as

Timber Trees.

as underwood. Where charcoal is wanted for iron forges, beech is the prevailing underwood. The oak, box, birch, &c. are all in requeſt in different countries, and the choice muſt be determined by the prevailing demand. As the keys of the aſh ſometimes lie two or even three years in the ground, it will be proper to have the places where they are ſown diſtinguiſhed by ſome particular marks, to prevent them from being diſturbed by the plough after harveſt: as a few beans ſcattered along with them, if the crop be oats; or oats, if the crop be beans. The crop ſhould be *reaped*, not *mown*, at harveſt time, and be carried off as faſt as poſſible. Between harveſt and winter, a pair of furrows ſhould be laid back to back in the middle of each interval, for meliorating the next year's crop, and laying the ſeedling plants dry; while the ſtubble of the unploughed ground on each ſide of the drills will keep them warm during the winter. The next year's crop may be potatoes, cabbages, turnips, or if the firſt was corn, this may be beans; if the firſt was beans, this may be wheat drilled. In the ſpring of the third year the drills which roſe the firſt year muſt be looked over, and the vacancies filled up from thoſe parts which are thickeſt; but the drills of the aſh ſhould be let alone till the fourth year. The whole ſhould afterwards be looked over from time to time; and this, with cultivating the intervals, and keeping the drills free from weeds, will be all that is neceſſary until the tops of the plants begin to interfere.

The crops may be continued for ſeveral years; and if they only pay for the expences, they will ſtill be of conſiderable advantage by keeping the ground ſtirred, and preſerving the plants from hares and rabbits. Even after the crops are diſcontinued, the ground ought ſtill to be ſtirred, alternately throwing the mould to the roots of the plants, and gathering it into a ridge in the middle of the interval. The beſt method of doing this is to ſplit the ground at the approach of winter in order to throw it up to the trees on both ſides; this will preſerve the roots from froſt: gather it again in the ſpring, which will check the weeds, and give a freſh ſupply of air: ſplit again at midſummer, to preſerve the plants from drought: gather, if neceſſary, in autumn, and ſplit as before at the approach of winter. The ſpring and midſummer ploughings ſhould be continued as long as a plough can paſs between the plants.

Whenever the oaks intended for timber are in danger of being drawn up too ſlender for their height, it will be neceſſary to cut off all the reſt at the height of about an handbreadth above the ground; and thoſe deſigned to ſtand muſt now be planted at about two rods diſtant from each other, and as nearly a quincunx as poſſible. The ſecond cutting muſt be determined by the demand there is for the underwood; with only this proviſo, that the timber ſtands be not too much crowded by it; for rather than this ſhould be the caſe, the coppice ſhould be cut, though the wood may not have reached its moſt profitable ſtate. What is here ſaid of the method of rearing oak trees in woods, is in a great meaſure applicable to that of raiſing other trees in timber groves. The ſpecies moſt uſually raiſed in theſe are the aſh, elm, beech, larch, ſpruce fir, Weymouth pine, poplar, willow, alder, cheſnut, walnut, and cherry. The three laſt are uſed as ſubſtitutes for the oak and beech, and theſe two for the mahogany.

Timber Trees.

The following account of the mode of planting that was adopted by the earl of Fife, for no leſs than 550 acres of moorith lands, is worthy of attention. It is contained in a letter from his lordſhip to the publiſher of the Annals of Agriculture. "Where there are ſtones in the moor, I incloſe with a ſtone wall five feet high, coped with two turfs, which coſt about 15s. every Scots chain of 24 ells, and where there are no ſtones, which is moſtly the caſe in the moors in the county of Murray, I incloſe with a fence of turf, five feet high, four feet wide at the foundation, and 22 inches at top, at 4s. the Scots chain. I find thoſe fences anſwer as well as the ſtone, for there are many of them now above 20 years old, as good as at firſt. I plant in every acre about 1200 trees. I uſed to plant above 3000, but by experience I find it better not to plant them ſo thick, but make them up, if neceſſary, the third year (eſpecially in my plantations in the county of Murray), where ſcarcely a tree planted ever fails. The greateſt number of the trees are Scots firs raiſed by myſelf, or purchaſed at 10d. the thouſand, planted from the ſeed-bed at three years old. I only conſider them as nurſes to my other trees, for they are regularly cut out when they have done their duty as nurſes, and are profitable for fire, and uſeful in agriculture. I plant every other ſpecies of foreſt trees intermixed with the firs. I order different pieces of the moor to be trenched where the ſoil is beſt, and moſt ſheltered, and lay a little lime and dung on it, and in theſe places I ſow ſeeds of trees for nurſery. I alſo plant in beds, year-old trees of different kinds, taken from my other nurſeries. I nurſe them for three years, and then plant them all over the plantation: this I find very beneficial, as they are raiſed in the ſame ſoil. When I am filling up the plantations, the firs are, for the firſt time, cut down; or they are tranſplanted, being raiſed with balls of earth when the moor is wet with rain, which is very eaſily done, and they are carried to incloſures of ten or twelve acres, where, from a deſire of forward woods, I am planting trees more advanced. They are planted in pits about 40 feet diſtance, and ſeldom or never fail, and anſwer a ſecond time as nurſes.

Vol. ix. 556 Earl of Fife's plantations.

"My firſt care after the incloſure is properly filled up, is to guard againſt injury from cattle: a ſmall allowance given to a few labourers anſwers that purpoſe, and if the fences are properly executed they require very little repair. After the plantation is filled up, the moſt regular attention muſt be had to the weeding of it, and this is carried on over my plantations of all ages in the moſt exact manner; I make roads through all the plantations which are carried forward according to the ſituation, never in a ſtraight line ſo as to draw violent winds, and thoſe roads go to all parts of the plantation; they make agreeable rides through fine woods, formerly a bleak moor, and anſwer not only for filling up, but alſo for carrying away the neceſſary weedings. As I obſerved before, the value and proſperity of the wood depends upon the unremitted attention in weeding it.

"I begin to plant in October, and continue till April. If the weather is froſty and not fit for planting, all the people are employed in weeding the woods."

It is proper, however, upon this ſubject, to remark,

Cattle proper to be employed.

that the value of plantations of timber trees, as connected with other branches of agriculture, is not a little limited. In a mountainous country, and in bleak moorish situations, nothing tends more to increaſe the value of the ſoil, than plantations properly diſtributed. They give ſhelter both to the cattle and to the corn crops; and by preventing the warmth which is produced by proper manures, aid by the germination of vegetables, from being diſſipated, they give effect to all the efforts of induſtry. Accordingly, in ſuch ſituations, plantations are no ſooner reared, than the whole face of the country around them aſſumes an improving aſpect, and diſplays a richer verdure. When ſuddenly cut down, in conſequence of the neceſſities of an improvident proprietor, the reverſe of all this occurs. Vegetation is chilled by the piercing blaſts which now meet with no reſiſtance, and the cattle droop from want of ſhelter; ſo that in a few years the place can ſcarcely be known. But the caſe is very different with regard to a rich and level country that is meant to be cultivated for corn. There the effect of numerous plantations, of high trees and lofty hedge rows, is altogether diſtreſſing to the huſbandman. It is only in open fields that grain appears well ripened and completely filled. When ſurrounded with timber trees, on the contrary, it ripens ill, and is ill-coloured and unequal. In ſpring the high ſhelter prevents the grounds from drying, and keeps back the labour. In ſummer the crop is liable to diſeaſes from want of air, and is devoured by large flocks of ſmall birds. In autumn, from want of a free circulation of air the corn ripens late, and in a weeping climate it can never be gathered in good condition. In wet ſeaſons it is utterly ruined. In winter, when the ſnow is drifting about, the trees prepare a reſting place for large quantities of it; theſe frequently remain and ſtop the ſpring work. Add to this, that in a low country even the cattle are hurt by the ſwarms of vermin that are bred, and come forth, under the ſhelter of lofty trees and high fences.

Cattle proper to be employed.

557 Where plantations are eligible or otherwiſe.

PART III. OF THE CATTLE PROPER TO BE EMPLOYED IN FARM WORK; REARING AND MANAGEMENT OF THEM. OF HOGS, POULTRY, &c. OF THE DAIRY, MAKING OF FRUIT LIQUORS. OF FENCES.

SECT. I. *Of the Cattle proper to be employed.*

AS great part of the ſtock of a huſbandman muſt always conſiſt of cattle, and as one of his principal expences muſt conſiſt of the maintenance of them, this part of his buſineſs is certainly to be looked upon as extremely important. The cattle belonging to a farm may be divided into two claſſes, viz. ſuch as are intended for work, and ſuch as are deſigned for ſale. The former are now principally horſes, the oxen formerly employed being fallen into diſuſe, though it does not yet certainly appear that the reaſons for the exchange are ſatisfactory. In the ſecond volume of Bath Papers, we have an account of a comparative experiment of the utility of horſes and oxen in huſbandry by Mr Keddington near Bury in Suffolk, in which the preference is deciſively given to oxen. He informs us, that at the time he began the experiment (in 1779), he was almoſt certain that there was not an ox worked in the whole county; finding, however, the expence of horſes very great, he purchaſed a ſingle pair of oxen, but found much difficulty in breaking them, as the workmen were ſo much prejudiced againſt them, that they would not take the proper pains. At laſt he met with a labourer who undertook the taſk; and the oxen "ſoon became as tractable and as handy, both at ploughing and carting, as any horſes." On this he determined to part with all his cart-horſes; and by the time he wrote his letter, which was in 1781, he had not a ſingle horſe, nor any more than ſix oxen; which inconſiderable number performed with eaſe all the work of his farm (conſiſting of upwards of 100 acres of arable land and 60 of paſture and wood), beſides the ſtatute duty on the highways, timber and corn carting, harrowing, rolling, and every part of rural buſineſs. They are conſtantly ſhoed; their harneſs is the ſame as that of horſes (excepting the neceſſary alterations for difference of ſize and ſhape); they are driven with bridles and bits in their mouths, anſwering to the ſame words of the ploughman and carter as horſes will do. A ſingle man holds the plough, and drives a pair of oxen with reins: and our author informs us, that they will plough an acre of ground in leſs than eight hours time; he is of opinion that they could do it in ſeven. The intervals of a ſmall plantation, in which the trees are ſet in rows ten feet aſunder, are ploughed by a ſingle ox with a light plough, and he is driven by the man who holds it. The oxen go in a cart either ſingle, or one, two, or three, according to the load. Four oxen will draw 80 buſhels of barley or oats in a waggon with eaſe; and if good of their kind, will travel as faſt as horſes with the ſame load. One ox will draw 40 buſhels in a light cart, which our author thinks is the beſt carriage of any. On the whole, he prefers oxen to horſes for the following reaſons.

558 Mr Keddington's experiment on the comparative utility of horſes and oxen.

559 Reaſons for preferring oxen to horſes.

1. They are kept at much leſs expence, never eating meal or corn of any kind. In winter they are fed with ſtraw, turnips, carrots, or cabbages; or inſtead of the three laſt, they have each a peck of bran per day while kept conſtantly at work. In the ſpring they eat hay; and if working harder than uſual at ſeed-time, they have bran beſides. When the vetches are fit for mowing, they get them only in the ſtable. After the day's work in ſummer they have a ſmall bundle of hay, and ſtand in the ſtable till they cool; after which they are turned into the paſture. Our author is of opinion, that an ox may be maintained in condition for the ſame conſtant work as a horſe, for at leaſt 4l. leſs annually.

2. After a horſe is ſeven years old, his value declines every year; and when lame, blind, or very old, he is ſcarce worth any thing; but an ox, in any of theſe ſituations, may be fatted, and ſold for even more than the firſt purchaſe; and will always be fat ſooner after work than before.

3. Oxen are leſs liable to diſeaſes than horſes.

4. Horſes are frequently liable to be ſpoiled by ſervants

Cattle proper to be employed.

vants riding them without their master's knowledge, which is not the case with oxen.

5. A general use of oxen would make beef plentiful, and consequently all other meat; which would be a national benefit.

560 Difficulty in shoeing oxen.

Mr Kedington concludes his paper with acknowledging, that there is one inconvenience attending the use of oxen, viz. that it is difficult to shoe them; though even this, he thinks, is owing rather to the unskilfulness of the smiths who have not been accustomed to shoe these animals, than to any real difficulty. He confines them in a pound while the operation is performing.

561 Mr Marshall's calculations.

Mr Marshall, in his Rural Economy of the Midland Counties, shows the advantage of employing oxen in preference to horses from the mere article of expence, which, according to his calculation, is enormous on the part of the horses. He begins with estimating the number of square miles contained in the kingdom of England; and this he supposes to be 30,000 of cultivated ground. Supposing the work of husbandry to be done by horses only, and each square mile to employ 20 horses, which is about 3 to 100 acres, the whole number used throughout Britain would be 600,000; from which deducting one-sixth for the number of oxen employed at present, the number of horses just now employed will be 500,000. Admitting that each horse works ten years, the number of farm-horses which die annually are no fewer than 50,000; each of which requires full four years keep before he is fit for work. Horses indeed are broke in at three, some at two years old, but they are, or ought to be, indulged in keep and work till they are six; so that the cost of rearing and keeping may be laid at full four ordinary years. For all this consumption of vegetable produce he returns not the community a single article of food, clothing, or commerce; even his skin for economical purposes being barely worth the taking off. By working horses in the affairs of husbandry, therefore, "the community is losing annually the amount of 200,000 years keep of a growing horse;" which at the low estimate of five pounds a-year, amonnts to a million annually. On the contrary, supposing the business of husbandry to be done solely by cattle, and admitting that oxen may be fatted with the same expenditure of vegetable produce as that which old horses require to fit them for full work, and that instead of 50,000 horses dying, 50,000 oxen, of no more than 52 stone each, are annually slaughtered; it is evident, that a quantity of beef nearly equal to what the city of London consumes would be annually brought into the market; or, in other words, 100,000 additional inhabitants might be supplied with one pound of animal food a-day each; and this without consuming one additional blade of grass. "I am far from expecting (says Mr Marshall), that cattle will, in a short space of time, become the universal beasts of draught in husbandry; nor will I contend, that under the present circumstances of the island they ought in strict propriety to be used. But I know that cattle, under proper management, and kept to a proper age, are equal to every work of husbandry, in most, if not all situations: And I am certain, that a much greater proportion than there is at present might be worked with considerable advantage, not to the community

562 A million annually lost by keeping horses.

only, but to the owners and occupiers of lands. If only one of the 50,000 carcases now lost annually to the community could be reclaimed, the saving would be an object."

Cattle proper to be employed.

563 No oxen used in Norfolk.

In Norfolk, our author informs us, that horses are the only beasts of labour; and that there is not perhaps one ox worked throughout the whole county. It is the same in the Vale of Gloucester, though oxen are used in the adjoining counties. Formerly some oxen were worked in it double; but they were found to poach the land too much, and were therefore given up. Even when worked single, the same objection is made: but, says Mr Marshall, "in this I suspect there is a spice of obstinacy in the old way; a want of a due portion of the spirit of improvement; a kind of indolence. It might not perhaps be too severe to say of the Vale farmers, that they would rather be eaten up by their horses than step out of the beaten track to avoid them." Shoeing oxen with whole shoes, in our author's opinion, might remedy the evil complained of; "but if not, let those (says he) who are advocates for oxen, calculate the comparative difference in *wear* and keep, and those who are their enemies estimate the comparative mischiefs of treading; and thus decide upon their value as beasts of labour in the Vale."

564 Objection to them in the Vale of Gloucester.

565 Used in the Cotswold.

In the Cotswold oxen are worked as well as horses; but the latter, our author fears, are still in the proportion of two to one: he has the satisfaction to find, however, that the former are coming into more general use. They are worked in harness; the collar and harness being used as for horses, not reversed, as in most cases they are for oxen. "They appear (says our author) to be perfectly handy; and work, either at plough or cart, in a manner which shows, that although horses may be in some cases *convenient*, and in most cases *pleasurable to the driver*, they are by no means *necessary* to husbandry. A convenience used in this country is a moveable *harness-house* with a sledge bottom, which is drawn from place to place as occasion may require. Thus no labour is lost either by the oxen or their drivers.

566 Moveable harness-houses.

In Yorkshire oxen are still used, though in much fewer numbers than formerly; but our author does not imagine this to be any decisive argument against their utility. The Yorkshire plough was formerly of such an unwieldy construction, that four or six oxen, in yokes, led by two horses, were absolutely requisite to draw it; but the improvements in the construction of the plough have of late been so great, that two horses are found to be sufficient for the purpose; so that as Yorkshire has all along been famous for its breed of horses, we are not to wonder at the present disuse of oxen. Even in carriages they are now much disused; but Mr Marshall assigns as a reason for this, that the roads were formerly deep in winter, and soft to the hoof in summer; but now they are universally a causeway of hard limestones, which hurt the feet of oxen even when shod. Thus it even appears matter of surprise to our author that so many oxen are employed in this county; and the employment of them at all is to him a convincing argument of their utility as beasts of draught. The timber carriers still continue to use them, even though their employment be solely upon the road. They find them not only able to stand working every day, provided their feet do not fail them,

567 Why the use of oxen is declining in Yorkshire.

but

Cattle proper to be employed.

but to bear long hours better than horſes going in the ſame paſture. An ox in a good paſture ſoon fills his belly, and lies down to reſt; but a horſe can ſcarce ſatisfy his hunger in a ſhort ſummer's night. Oxen are alſo conſidered as much ſuperior at a difficult pull to horſes; but this he is willing to ſuppoſe ariſes from their uſing half-bred hunters in Yorkſhire, and not the true breed of cart horſes. "But what (ſays he) are thorough-bred cart horſes? Why, a ſpecies of ſtrong, heavy, ſluggiſh animals, adapted ſolely to the purpoſe of draught; and according to the preſent law of the country, cannot, without an annual expence, which nobody beſtows upon them, be uſed for any other purpoſe. This ſpecies of beaſts of draught coſt at four years old from 20l. to 30l. They will, with extravagant keep, extraordinary care and attendance, and much good luck, continue to labour eight or ten years; and may then generally be ſold for five ſhillings a-head. If we had no other ſpecies of animals adapted to the purpoſes of draught in the iſland, cart horſes would be very valuable, they being much ſuperior to the breed of ſaddle horſes for the purpoſe of draught. But it appears evident, that were only a ſmall ſhare of the attention paid to the breeding of draught oxen which is now beſtowed on the breeding of cart horſes, animals equally powerful, more active, leſs coſtly, equally adapted to the purpoſes of huſbandry if harneſſed with equal judgement, leſs expenſive in keep and attendance, much more durable, and infinitely more valuable after they have finiſhed their labours, might be produced. A ſteer, like a colt, ought to be familiarized to harneſs at two or three years old, but ſhould never be ſubjected to hard labour until he be five years old; from which age until he be 15 or perhaps 20, he may be conſidered as in his prime as a beaſt of draught. An ox which I worked ſeveral years in Surrey, might at 17 or 18 years of age have challenged for ſtrength, agility, and ſagacity, the beſt bred cart horſe in the kingdom.

568 Superiority of oxen to horſes.

569 Horſe are everywhere prevailing over oxen.

Notwithſtanding all that has been ſaid, however, and written about the ſuperiority of oxen to horſes, the latter are ſtill coming into more general uſe, eſpecially in proportion as the breed of horſes improves; and we may add, in proportion as the ſtate of cultivation in any part of the country improves. The reaſon is obvious. The horſe is a more active animal than the ox, and can be turned with greater readineſs from one kind of work to another. His hoof is leſs readily injured by the hardneſs of good roads; and for the uſe of the plough upon a well ordered farm, there is no compariſon between the two kinds of animals. Where land is once brought into a proper ſtate of tillage, it is eaſily turned over; and the value of the animal employed in doing ſo conſiſts not ſo much in the poſſeſſion of great ſtrength as in the activity which he exerts in going over a great extent of ground in a ſhort time. In this laſt reſpect, a good breed of horſes ſo far ſurpaſſes every kind of oxen yet known in this country, that we ſuſpect much the horſe will ſtill continue to be preferred by enterpriſing huſbandmen.

With regard to the loſs which the public is ſuppoſed to ſuſtain by preferring horſes to oxen, that point has of late been rendered, to ſay no more, extremely doubtful. In the Agricultural Survey of the county of Northumberland, we have the following comparative ſtatement between horſes and oxen, for the purpoſe of the draught:—"By way of preliminary, it will be neceſſary to admit as data, that a horſe which eats 70 buſhels of oats per year, will not conſume of other food ſo much as an ox that gets no corn; but in the following eſtimate we ſhall allow horſes to eat as much as oxen, as the difference is not yet ſufficiently aſcertained.

570 Calculations in favour of the uſe of horſes.

"That the oxen are yoked at three years old, and are worked till ſix, and for the firſt year require eight to do the work of two horſes; but after having been worked a year, and become tractable and ſtronger, ſix are equal to two horſes, either by being yoked three at a time, or two, and driven by the holder with cords; of courſe, the expence of a driver may be eſtimated to be ſaved for one half the year.

"That the expences of a ploughman, the plough, and other articles that are the ſame in both teams, need not be taken into the account.

"And that oxen to work regularly through the year, cannot work more than half a day at a time."

Expences of an Ox per annum.

Summering.—Graſs 2 acres at 20s. per acre				L.	2	0 0
Wintering.—On ſtraw and turnips	L.	2	0 0			
But if on hay		4	0 0			
The average is					3	0 0
				L.	5	0 0
Intereſt at 5 per cent. for price of the ox					0	10 0
Harneſs, ſhoeing, &c.					0	15 0
					6	5 0
Deduct for the increaſed value of an ox for 1 year					1	0 0
Gives the expence per annum of an ox for the team					5	5 0
And the expence of ſix oxen				L.	31	10 0
To which muſt be added the expence of a driver for half a year					3	10 0
Total expence of a team of 6 oxen				L.	35	0 0

An Eight-Ox team.

The expence of an ox per annum being	L.	5	5 0 8
That of eight will be		42	0 0
To which add the expence of a driver		8	0 0
Gives the expence per annum of an eight-ox team	L.	50	0 0
Therefore the expence of a team of oxen for the firſt year will be -	L.	50	0 0
Ditto the ſecond year - -		35	0 0
Ditto the third year - -		35	0 0
Divided by		3)120	0 0

Cattle proper to be employed.

Brought over,			
Divided by - - -	3)120	0	0
Gives the average expence per annum of an ox team from 3 to 6 years old	L.40	0	0

Expence of a Horſe per annum.

Summering.—Graſs 2 acres at 20s. per acre - - -	L 2	0	0
Wintering.—Straw 13 weeks at 9d. per week - -	0	10	0
Hay 16 ditto 1½ tons at 2l.	3	0	0
Corn (for a year) 70 buſhels of oats at 2l.	7	0	0
Shoeing and harneſs - -	1	0	0
Annuity to pay off 25l. in 16 years, the purchaſe value of the horſe at four years old - - -	2	5	0
Expence of a horſe per annum	L.15	15	0
Expence of a two-horſe team	L.31	10	0

" If a three-horſe team be uſed, the account will ſtand thus:

The expence of a horſe per annum being	L.15	15	0
			3
That of three will be - - -	47	5	0
To which add the expence of a driver	8	0	0
Gives the expence of a three-horſe team	L.55	5	0

" If the compariſon be made with the horſe team of many of the midland counties, where they uſe *five horſes yoked one before another in one plough*, the account will ſtand thus:

The expence of one horſe per annum being - - - -	L.15	15	0
			5
That of five will be - - -	78	15	0
To which add the expence of a man to drive	18	0	0
The expence of a team of five horſes will be	L.96	15	0
ditto of 3 ditto	55	5	6
ditto of 2 ditto	31	10	0
ditto of 8 oxen	50	0	0
The average expence of an ox-team from three to ſix years old, that will do the ſame quantity of work as two horſes	40	0	0

" The concluſions to be drawn from the above ſtatement, are ſo obvious as to need little elucidation. But we cannot help remarking, how ſtrong the force of prejudice muſt be, to continue the uſe of five horſes, and heavy, clumſy, unwieldy *wheel ploughs*, where a ſingle *ſwing plough* and two horſes yoked double, and driven by the holder, would do the ſame quantity of work, equally well and at one half of the expence."

" But before any proper concluſion can be drawn, whether *ox teams* or *horſe* are the moſt eligible, it will be neceſſary to conſider, whether the quantity of land employed in ſupporting thoſe animals, be uſed in the moſt profitable mode to the community, as well as to the occupier. Different Kinds of Horſes.

" With the latter, the firſt queſtion for conſideration is, whether eight oxen uſed in the team or in grazing will pay him the moſt money?

" Suppoſe eight oxen, at *three years old*, were put to the plough, and plough ſix acres per week, which, at 3s. 4d. per acre, is 20s.; and if they work forty-eight weeks in a year, their whole earnings (after deducting 6l. for expences of harneſs, ſhoeing, &c.) will be 42l.; but if they plough only *five acres per week* (which is probably nearer the truth), then their whole earnings will be only 34l.

" The ſame oxen put to graze at the ſame money ſhould improve in value 5l. 5s. each in the firſt caſe, and 4l. 5s. in the latter; but we are inclined to believe there are few ſituations, if the cattle are of a good quick-feeding kind, where they would not pay conſiderably more.

" In reſpect to the community, the account will be nearly as follows:

" From the above ſtatements, we find that an ox for ſummering and wintering requires	3½ acres
Therefore a ſix-ox team will require	21 ditto
And two horſes for graſs and hay per annum require - - -	7 ditto
For corn and ſtraw - - - -	4 ditto
Land neceſſary for keeping two horſes per annum - - -	11 ditto
The difference in the quantity of land required for a team of oxen more than horſes	10 ditto.

" Hence it appears, that a team of ſix oxen requires ten acres more land to maintain them, than a team of two horſes, which will do the ſame work; and of courſe the produce which might be derived from theſe ten acres is loſt to the community. Suppoſe it be one half in graſs, the other half in tillage, then we ſhall have

" 5 Acres of clover or graſs,
1⅔ Ditto of oats,
1⅔ Ditto of turnips or fallow,
1⅔ Ditto of wheat.

" It would then ſend to market yearly, at the loweſt computation,

7½ cwt. of beef,
8 quarters of oats,
And 5 ditto of wheat.

" From this view of the ſubject, it appears that if oxen were univerſally uſed for the draught, in the room of horſes, there would be a conſiderable defalcation, in the ſupply of the markets, both in corn and animal food. And the loſs to the farmer would be the profit derived from the produce; which, by the uſual mode of allowing one-third for the farmer's profit, would in this caſe be about 10l."

Sect. II. *Of the different kinds of Horſes, and the Method of Breeding, Rearing, and Feeding them.*

572 Account of the black cart-horſe.

The midland counties of England have for ſome time been celebrated on account of their breed of the *black cart-horſe*; though Mr Marſhall is of opinion that this kind are unprofitable as beaſts of draught in huſbandry.

Different Kinds of Horſes.

bandry. The preſent improvement in the breed took its riſe from ſix Zealand mares ſent over by the late Lord Cheſterfield during his embaſſy at the Hague. Theſe mares being lodged at his lordſhip's ſeat at Bretby in Derbyſhire, the breed of horſes thus became improved in that county, and for ſome time it took the lead for the ſpecies of theſe animals. As the improved breed paſſed into Leiceſterſhire, however, through ſome unknown circumſtances, it became ſtill more improved, and Leiceſter has for ſome time taken the lead. It is now found, however, that the very large horſes formerly bred in this diſtrict are much leſs uſeful than ſuch as are of a ſmaller ſize. Mr Marſhall deſcribes in magnificent terms one of theſe large horſes, a ſtallion belonging to Mr Bakewell named K (q), which, he ſays, was the handſomeſt horſe he ever ſaw. "He was (ſays he) the fancied *war-horſe* of the German painters; who, in the luxuriance of imagination, never perhaps excelled the natural grandeur of this horſe. A man of moderate ſize ſeemed to ſhrink behind his fore end, which roſe ſo perfectly upright, his ears ſtood (as Mr Bakewell ſays every horſe's ears ought to ſtand) perpendicularly over his fore feet. It may be ſaid, with little latitude, that in grandeur and ſymmetry of form, viewed as a picturable object, he exceeded as far the horſe which this ſuperior breeder had the honour of ſhowing to his Majeſty, and which was afterwards ſhown publicly at London, as that horſe does the meaneſt of the breed." A more *uſeful* horſe, bred alſo by Mr Bakewell, however, is deſcribed as having a "thick carcaſe, his back ſhort and ſtraight, and his legs ſhort and clean; as ſtrong as an ox, yet active as a poney; equally ſuitable for a cart or a lighter carriage."

572 Horſes belonging to Mr Bakewell deſcribed.

The ſtallions in this county are bred either by farmers or by perſons whoſe buſineſs it is to *breed* them, and who therefore have the name of *breeders*. Theſe laſt either cover with themſelves, or let them out to others for the ſeaſon, or ſell them altogether to ſtallion-men who travel about with them to different places.—The prices given for them are from 50 to 200 guineas by purchaſe; from 40 to 80 or a hundred by the ſeaſon; or from half a guinea to two guineas by the mare. The mares are moſtly kept by the farmers, and are worked until near the times of foaling, and moderately afterwards while they ſuckle: the beſt time for foaling is ſuppoſed to be the month of March or April; and the time of weaning that of November.—"The price of foals (ſays Mr Marſhall), for the laſt ten years, has been from five to ten pounds or guineas; for yearlings, 10 to 15 or 20; for two-year-olds, 15 to 25 or 30; for ſix year-olds, from 25 to 40 guineas."—Our author acknowledges that this breed of horſes, conſidered abſtractedly in the light in which they appear here, are evidently a profitable ſpecies of live ſtock, and as far as there is a market for ſix-years-old horſes of this breed, it is profitable to agriculture. "But (ſays he) viewing the buſineſs of agriculture in general, not one occupier in ten can partake of the profit; and being kept in agriculture after they have reached that profitable age, they become indiſputably one of its heavieſt burdens. For beſides a ceſſation of improvement of four or five guineas a-year, a decline in value of as much yearly takes place. Even the brood-mares, after they have paſſed that age, may, unleſs they be of a very ſuperior quality, be deemed unprofitable to the farmer."

573 Prices of ſtallions.

574 Mr Marſhall's obſervations on breeding horſes.

Different Kinds of Horſes.

Our author complains that the ancient breed of Norfolk horſes is almoſt entirely worn out. They were ſmall, brown-muzzled, and light boned; but they could endure very heavy work with little food; two of them were found quite equal to the plough in the ſoil of that county, which is not deep. The preſent breed is produced by a croſs with the large one of Lincolnſhire and Leiceſterſhire already mentioned. He approves of the Suffolk breed, which (he ſays) are a "half-horſe half-hog race of animals, but better adapted to the Norfolk huſbandry than the Leiceſterſhire breed: their principal fault, in his opinion, is a flatneſs of the rib.—In the Vale of Glouceſter moſt farmers rear their own plough-horſes, breeding of horſes not being practiſed. They are of a very uſeful kind, the colour moſtly black, inclinable to tan colour, ſhort and thick in the barrel, and low on their legs. The price of a ſix-year old horſe from 25l. to 35l. Some cart-horſes are bred in Cotſwold hills; the mares are worked till the time of foaling, but not while they ſuckle; and the foals are weaned early, while there is plenty of graſs upon the ground.

575 Norfolk breed deſcribed.

576 Suffolk and Glouceſter breeds.

Yorkſhire, which has been long celebrated for its breed of horſes, ſtill ſtands foremoſt in that reſpect among the Engliſh counties. It is principally remarkable for the breed of ſaddle-horſes, which cannot be reared in Norfolk, though many attempts have been made for that purpoſe. Yorkſhire ſtallions are frequently ſent into Norfolk; but though the foals may be handſome when young, they loſe their beauty when old. In Yorkſhire, on the other hand, though the foal be ever ſo unpromiſing, it acquires beauty, ſtrength, and activity as it grows up. Mr Marſhall ſuppoſes that from five to ten thouſand horſes are annually bred up between the eaſtern Morelands and the Humber.

577 Yorkſhire horſes.

"Thirty years ago (ſays Mr Marſhall), ſtrong ſaddle-horſes, fit for the road only, were bred in the Vale; but now the prevailing breed is the faſhionable coach-horſe, or a tall, ſtrong, and over-ſized hunter; and the ſhows of ſtallions in 1787 were flat and ſpiritleſs in compariſon with thoſe of 1783." The black cart-horſe, an object of Mr Marſhall's peculiar averſion, is alſo coming into the Vale.

In the breeding of horſes he complains greatly of the negligence of the Yorkſhire people, the mares being almoſt totally neglected; though in the brute creation almoſt every thing depends upon the female.

578 Lanarkſh breed of horſes.

Of late years a very valuable breed of horſes has been reared in the upper part of Clydeſdale or Lanarkſhire. They are of a middle ſize, well ſhaped, and extremely active. They are not fit for a very heavy draught, but the very quick ſtep which they poſſeſs gives them a decided preference for the uſe of the plough upon well cultivated lands, as they are capable of going over an immenſe quantity of ground in a ſhort time.

(q) Mr Bakewell diſtinguiſhes all his horſes, bulls, and rams, by the letters of the alphabet.

Different Kinds of Horses.

time where the draught is not severe. The same qualities render them highly useful for the ordinary purposes of farm-work. They are rapidly spreading over all parts of the country, and have found their way into the north of England where they are greatly valued. In the same part of the country, a larger breed has also of late been encouraged, which adds very considerable strength or power to the activity of the former kind. They are in great request about Glasgow and other manufacturing towns. Their usual draught is a load of about 24 cwt. in addition to the cart on which the load is placed.

With regard to the general maintenance of horses, we have already mentioned several kinds of food upon which experiments have been made with a view to determine the most profitable mode of keeping them. Perhaps, however, the most certain method of ascertaining this matter is by observing the practice of those counties where horses are most in use. Mr Marshall recommends the Norfolk management of horses as the cheapest method of feeding them practised anywhere; which, however, he seems willing to ascribe in a great measure to the excellency of their breed. In the winter months, when little work is to be done, their only rack-meat is barley-straw; a reserve of clover-hay being usually made against the hurry of seed-time. A bushel of corn in the most busy season is computed to be an ample allowance for each horse, and in more leisure times a much less quantity suffices. Oats, and sometimes barley, when the latter is cheap and unsaleable are given; but in this case the barley is generally malted, i. e. steeped and afterwards spread abroad for a few days, until it begin to vegetate, at which time it is given to the horses, when it is supposed to be less heating than in its natural state. Chaff is universally mixed with horse-corn: the great quantities of corn grown in this county afford in general a sufficiency of *natural* chaff; so that *cut chaff* is not much in use: the chaff, or rather the awns of barley, which in some places are thrown as useless to the dunghill, are here in good esteem as provender. Oat-chaff is deservedly considered as being of much inferior quality.---It may here be remarked, that this method of keeping horses which Mr Marshall approves of in the Norfolk farmers, is practised, and probably has been so from time immemorial, in many places of the north of Scotland; and is found abundantly sufficient to enable them to go through the labour required. In summer they are in Norfolk kept out all night, generally in clover leys, and in summer their keep is generally clover only, a few tares excepted.

579 Norfolk management of horses recommended.

580 This method followed in many places in Scotland.

In the fourth volume of the Annals of Agriculture, Mr Young gives an account of the expence of keeping horses; which, notwithstanding the vast numbers kept in the island, seems still to be very indeterminate, as the informations he received varied no less than from 8l. to 25l. a-year. From accounts kept on his own farm of the expence of horses kept for no other purpose than that of agriculture, he stated them as follows:

	L.	s.	d.
1763 Six horses cost per horse	10	13	0
1764 Seven do.	8	10	11
1765 Eight do.	14	6	6
1766 Six do.	12	18	9

Average on the whole 11l. 12s. 3d.

581 Calculations of the expence of keeping horses.

By accounts received from *Northumins* in Herefordshire, the expences stood as follows:

	L.	s.	d.
1768 Expence per horse	20	7	0
1769	15	8	5
1770	14	14	2
1771	15	13	3
1772	18	4	0
1773	15	11	8
1774	14	4	5
1775	19	0	5
1776	10	14	5

Average 16l. 13s. 1d.

Different Kinds of Horses.

On these discordant accounts Mr Young observes, undoubtedly with justice, that many of the extra expences depend on the extravagance of the servants; while some of the apparent savings depend either on their carelessness, or *stealing* provender to their beasts privately, which will frequently be done. He concludes, however, as follows: "The more exactly the expence of horses is examined into, the more advantageous will the use of oxen be found. Every day's experience convinces me more and more of this. If horses kept for use alone, and not for show, have proved thus expensive to me, what must be the expence to those farmers who make their fat fleck teams an object of vanity? It is easier conceived than calculated.

582 Use of roots for feeding horses.

It must be observed, however, that the above trials or accounts are of an old date; and that during the late dearth a variety of experiments were made, which shew that horses may be successfully fed, even when engaged in hard labour, with other articles than grain. With this view, different roots have been given them as substitutes; and a great saving has been experienced, attended with no loss of labour or disadvantage to the animal: so that the continuance and extension of this system is a matter of much importance to the public. The articles that have been chiefly employed are turnips, roota baga, potatoes, carrots, &c.—Turnips have been given in a raw state, withholding about one half of the usual allowance of corn, and in most instances the animals have done their work well, and appeared in good condition. When the roota baga has been used, little or no grain has been necessary, and the other roots already mentioned have been successfully used even in a raw state; but when potatoes, yams, roota baga, &c. are boiled, which has sometimes been done, it does not appear that grain is at all necessary. It is to be observed, that young horses eat these roots readily and with great relish; and that during the winter, with them and a small portion of dry food, they are kept in as good condition and spirit as when fed upon grass during the summer. This is a matter of much importance to young animals, as it must contribute greatly to their growth and future strength. Whereas, in a great majority of cases, when reared without the aid of these roots, they are fed in winter, when substantial food is most necessary to support them against the severity of the weather, in such a manner as to be barely kept alive. During the winter months their growth is thus stopt; they lose the little flesh they had acquired during the preceding summer, become stinted and hide-bound, and, when the spring arrives, they are in so miserable a state, that a considerable part even of the summer elapses before they

Breeding and Feeding of Black Cattle.

can resume their growth. In this way, four or five years are required to bring them to the size that others of the same species attain in half that time under different management.

Sect. III. *Of the Breeding and Rearing of Black Cattle.*

583 A hornless breed of black cattle desirable for work.

These are reared for two different purposes, viz. work, and fattening for slaughter. For the former purpose, Mr Marshall remarks, that it is obviously necessary to procure a breed without horns. This he thinks would be no disadvantage, as *horn*, though formerly an article of some request, is now of very little value. The horns are quite useless to cattle in their domestic state, though nature has bestowed them upon them as weapons of defence in their wild state; and our author is of opinion that it would be quite practicable to produce a hornless breed of black cattle as well as of sheep, which last has been done by attention and perseverance; and there are now many hornless breeds of these creatures in Britain. Nay, he insists, that there are already three or four breeds of hornless cattle in the island; or that there are many kinds of which numbers of individuals are hornless, and from these, by proper care and attention, a breed might be formed. The first step is to select females; and having observed their imperfections, to endeavour to correct them by a well chosen male.

584 Properties requisite in black cattle.

The other properties of a perfect breed of black cattle for the purposes of the dairy as well as others, ought, according to Mr Marshall, to be as follow: 1. The head small and clean, to lessen the quantity of offal. 2. The neck thin and clean, to lighten the fore-end, as well as to lessen the collar, and make it sit close and easy to the animal in work. 3. The carcase large, the chest deep, and the bosom broad, with the ribs standing out full from the spine; to give strength of frame and constitution, and to admit of the intestines being lodged within the ribs. 4. The shoulders should be light of bone, and rounded off at the lower point, that the collar may be easy, but broad to give strength, and well covered with flesh for the greater ease of draught, as well as to furnish a desired point in fatting cattle. 5. The back ought to be wide and level throughout; the quarters long; the thighs thin; and standing narrow at the round bone; the udder large when full, but thin and loose when empty, to hold the greater quantity of milk; with large dug-veins to fill it, and long elastic teats for drawing it off with greater ease. 6. The legs (below the knee and hock) straight, and of a middle length; their bone, in general, light and clean from fleshiness, but with the joints and sinews of a moderate size, for the purposes of strength and activity. 7. The flesh ought to be mellow in the state of fleshiness, and firm in the state of fatness. 8. The hide mellow, and of a middle thickness, though in our author's opinion this is a point not yet well determined.

585 Of rearing calves without milk.

As the milk of cows is always an article of great importance, it becomes an object to the husbandman, if possible, to prevent the waste of that useful fluid, which in the common way of rearing calves is unavoidable. A method of bringing up these young animals at less expence was at one time proposed by the Duke of Northumberland. His plan was to make skimmed milk answer the purpose of that which is newly drawn from the teat; and which, he supposed, might answer the purpose at one-third of the expence of new milk. The articles to be added to the skimmed milk are treacle and the common linseed oil-cake ground very fine, and almost to an impalpable powder, the quantities of each being so small, that to make 32 gallons would only cost 6d. besides the skimmed milk. It mixes very readily and almost intimately with the milk, making it more rich and mucilaginous, without giving it any disagreeable taste. The receipt for making it is as follows: Take one gallon of skimmed milk, and to about a pint of it add half an ounce of treacle, stirring it until it is well mixed; then take one ounce of linseed oil-cake finely pulverized, and with the hand let it fall gradually in very small quantities into the milk, stirring it in the mean time with a spoon or ladle until it be thoroughly incorporated; then let the mixture be put into the other part of the milk, and the whole be made nearly as warm as new milk when it is first taken from the cow, and in that state it is fit for use. The quantity of the oil-cake powder may be increased from time to time as occasion requires, and as the calf becomes inured to its flavour. On this subject Mr Young remarks, that in rearing calves, there are two objects of great importance. 1. To bring them up without any milk at all; and, 2. To make skimmed milk answer the purpose of such as is newly milked or sucked from the cow. In consequence of premiums offered by the London Society, many attempts have been made to accomplish these desirable purposes; and Mr Budel of Wanborough in Surrey was rewarded for an account of his method. This was no other than to give the creatures a gruel made of ground barley and oats. Mr Young, however, who tried this method with two calves, assures us that both of them died, though he afterwards put them upon milk when they were found not to thrive. When in Ireland he had an opportunity of purchasing calves at three days old from 20d. to 3s. each; by which he was induced to repeat the experiment many times over. This he did in different ways, having collected various receipts. In consequence of these he tried hay-tea, bean-meal mixed with wheat-flour, barley and oats ground nearly, but not exactly, in Mr Budd's method; but the principal one was flax-seed boiled into a jelly, and mixed with warm water; this being recommended more than all the rest. The result of all these trials was, that out of 30 calves only three or four were reared; these few were brought up with barley and oat-meal, and a very small quantity of flax-seed jelly; one only excepted, which at the desire of his coachman was brought up on a mixture of two-thirds of skimmed milk and one-third of water, with a small addition of flax-jelly well dissolved.

Breeding and Feeding of Black Cattle.

Annals of Agriculture. vol p. 296.

586 Mr Young's experiments.

The second object, viz. that of improving skimmed milk, according to the plan of the duke of Northumberland, seems to be the more practicable of the two. Mr Young informs us, that it has answered well with him for two seasons; and two farmers to whom he communicated it gave likewise a favourable report.

In the third volume of the same work, we are informed that the Cornwall farmers use the following method in rearing their calves. "They are taken from

Breeding and Feeding of Black Cattle.

from the cow from the fourth to the ſixth day; after which they have raw milk from ſix to ten or fourteen days. After this, they feed them with ſcalded ſkimmed milk and gruel made of ſhelled oats, from three quarts to four being given in the morning, and the ſame in the evening. The common family broth is thought to be as good, or better, than the gruel, the ſavour of the ſalt being ſuppoſed to ſtrengthen their bowels. The proportion of gruel or broth is about one-third of the milk given them. A little fine hay is ſet before them, which they ſoon begin to eat.

587 Method of rearing calves in Cornwall.

588 Mr Crook's method.

In the 5th volume of Bath Papers, we have an account by Mr Crook of a remarkably ſucceſsful experiment on rearing calves without any milk at all. This gentleman, in 1787, weaned 17 calves; in 1788, 23; and in 1789, '15. In 1787, he bought three ſacks of linſeed, value 2l. 5s. which laſted the whole three years. One quart of it was put to ſix quarts of water; which, by boiling 10 minutes, was reduced to a jelly: the calves were fed with this mixed with a ſmall quantity of tea, made by ſteeping the beſt hay in boiling water. By the uſe of this food three times a-day, he ſays that his calves throve better than thoſe of his neighbours, which were reared with milk. Theſe unnatural kinds of food, however, are in many caſes apt to produce a looſeneſs, which in the end proves fatal to the calves. In Cornwall, they remedy this ſometimes by giving acorns as an aſtringent; ſometimes by a cordial uſed for the human ſpecies, of which opium is the baſis.

589 Norfolk method, &c.

In Norfolk, the calves are reared with milk and turnips; ſometimes with oats and bran mixed among the latter. Winter calves are allowed more milk than ſummer ones; but they are univerſally allowed new milk, or even to ſuck. In the midland counties bull-calves are allowed to remain at the teat until they be ſix, nine, or twelve months old, letting them run either with their dams or with cows of leſs value bought on purpoſe. Each cow is generally allowed one male or two female calves. Thus they grow very faſt, and become ſurpriſingly vigorous. The method of the dairy-men is to let the calves ſuck for a week or a fortnight, according to their ſtrength; next they have new milk in pails for a few meals; after that, new and ſkimmed milk mixed; then ſkimmed milk alone, or porridge made with milk, water, ground oats, &c. ſometimes with oil-cake, &c. until cheeſe-making commences; after which they have whey-porridge, or ſweet whey in the field, being carefully houſed in the night until the warm weather come in.

590 Bradfute's mode.

A late intelligent Scottiſh clergyman, Mr John Bradfute of Dunſyre, once or twice ſucceſsfully made trial of treacle, as a food by means of which to rear calves without the aid of any kind of milk. He uſed it diluted with common water, and ſometimes with what is called *hay-tea*, that is to ſay, water in which hay had been boiled. The whole expence of the treacle neceſſary to bring a calf the length of uſing common food was at that time (15 years ago) about 4s. 6d. The animals came forward well, and enjoyed good health; but they grew much to the bone, and did not fatten for a conſiderable time.

591 Cattle are reared

For feeding cattle, two modes of practice have been propoſed, and in ſome ſituations adopted; the one mode, which is the moſt ancient, and the moſt extenſively practiſed in agricultural counties, conſiſts of turning out the cattle during the whole ſeaſon that any food for them can be found on the ground, and of taking them into the houſe during the ſeverity of winter, and of feeding them with ſuch articles as can be moſt conveniently procured in the climate and ſituation, ſuch as, ſtraw or hay of different kinds, and roots.

Breeding and Feeding of Black Cattle.

592 Or ſtall fed.

The other mode, which has been adopted to ſome extent by huſbandmen in Germany, and at times alſo in our own great towns, by perſons called *cow-feeders*, who ſupply the inhabitants with milk, is called the ſyſtem of ſtall-feeding. It conſiſts of keeping the cattle continually in the houſe at every ſeaſon of the year, and of feeding them there. By many German writers upon rural economy this ſyſtem is highly approved of, as affording the means of drawing the higheſt poſſible produce from every portion of the land, and as employing a great number of hands in the uſeful occupations of huſbandry. In a communication to the Board of Agriculture from A. Thaer, M. D. phyſician of the electoral court of Hanover, the advantages of this ſyſtem are ſaid to be founded upon the following incontrovertible principles:

593 Stall-feeding in Germany.

"1. A ſpot of ground which, when paſtured upon, will yield ſufficient food for only one head, will abundantly maintain four head of cattle in the ſtable, if the vegetables be mowed at a proper time, and given to the cattle in a proper order.

"2. The ſtall-feeding yields at leaſt double the quantity of manure from the ſame number of cattle; for the beſt and moſt efficacious ſummer manure is produced in the ſtable, and carried to the fields at the moſt proper period of its fermentation, whereas, when ſpread on the meadow, and exhauſted by the air and ſun, its power is entirely waſted.

"3. The cattle uſed to ſtall-feeding will yield a much greater quantity of milk, and increaſe faſter in weight when fattening than when they go to the field.

"4. They are leſs ſubject to accidents, do not ſuffer by the heat, by flies, and inſects, are not affected by the baneful fogs which are frequent in Germany, and bring on inflammations: on the contrary, if every thing be properly managed, they remain in a conſtant ſtate of health and vigour."

It is added that a ſufficient, or rather plentiful ſupply of food for one feed of cattle daily, if kept in a ſtable, conſiſts upon an average of 130 pounds of green, or 30 pounds of dry clover, which anſwers the ſame purpoſe. Hence one head of cattle requires in 365 days, about 10,950 pounds of dry clover, or about 100 cwts. of 110 pounds each, the portion of food being according to this mode of feeding alike both in ſummer and winter. Each head of beſt fat cattle fed in the ſtable, if plenty of food be given, yields annually 16 full double cart loads of dung. The rotation of crops that is moſt frequently uſed in Germany upon farms occupied in ſtall-feeding, appears to be the following: "One year, manured for beans, peaſe, cabbages, potatoes, turnips, linſeed, &c.; 2. Rye; 3. Barley, mixed with clover; 4. Clover, to be mowed two or three times; 5. Clover, to be mowed once, then to be broken up, ploughed three or four times, and manured; 6. Wheat; 7. Oats."—In conſequence of the large quantity of ſtable dung pro-

Breeding and Feeding of Black Cattle.

duced upon farms thus occupied, every acre of land receives every three years 10 double cart loads of that beſt of all kinds of manure.

It is undoubtedly to be wiſhed that a ſimilar mode of management could be profitably introduced into this country, from the tendency which it would have to augment the number of perſons occupied in rural affairs, from the importance which it would give to farms of a moderate extent, and from the benefit which muſt ariſe from making the moſt of every part of the ſoil. It has already been introduced into ſeveral places in England, and we have little doubt that the practice will gradually extend itſelf, in conſequence of the increaſing demand for butchers meat, and for all the productions of the dairy.

594 Two modes of ſtall-feeding.

Of ſtall-feeding, however, whether with a view to the maintenance or to the fattening of cattle, it muſt be obſerved, that there are two modes of proceeding. Of late years, it has been found advantageous to cultivate to a great extent turnips, potatoes, and other roots, and theſe now conſtitute a large portion of the winter food of cattle. Theſe roots are either given to the cattle in their natural raw ſtate, or they are given after being boiled. Of theſe two modes of feeding, that of giving them to the cattle raw has hitherto been the moſt common, but it is extremely improper, as being a thriftleſs plan of proceeding. The ſame quantity of theſe roots, if given in a raw ſtate, that will barely ſupport a horſe in idleneſs, will enable him, when boiled, to encounter the ſevereſt labour without injury to his health or ſpirit. There are many animals alſo, ſuch as hogs, which cannot be fattened by roots unleſs they undergo this proceſs. Theſe animals can be reared to the full ſize upon raw potatoes, yams, carrots, roota baga, &c. and may be kept in good health for any length of time without the aid of any other food. Under that management, however, they very ſeldom if ever fatten; but when the roots are boiled, they immediately begin to feed, and ſoon become fat upon a ſmaller allowance than what was neceſſary to keep them barely alive when given in a raw ſtate.

The ſame holds true in a great degree with regard to all cattle. With a view, therefore, to make the moſt of the various farculent roots which are now cultivated, and which will perhaps one day be accounted the moſt valuable productions of our ſoil, it is abſolutely neceſſary that they ſhould be given to cattle boiled.

595 Roots given to cattle ſhould be boiled

Many huſbandmen have long been ſenſible of this, but it has appeared a very formidable operation to boil the greateſt part of the food of perhaps 20 horſes, and 100 head of black cattle. There is nothing more true, however, than that this labour when undertaken upon ſkilful principles, may be rendered not only eaſy, but ſo trifling, that it may be performed by a ſingle old man, or by a woman. To accompliſh this object, however, it is neceſſary, that the roots be boiled not over the fire in a chaldron of metal, but at a diſtance from it in a large wooden vat or tub by the ſteam of boiling water.

596 Cheap mode of boiling roots by ſteam.

There are two ways of boiling roots by ſteam. They may either be boiled in ſuch a way as to retain their original figure, or they may be converted into ſoup; both modes are performed with equal caſe. All that is neceſſary, is to erect a boiler in any outhouſe: The boiler, which may be of caſt iron, ought to have a cloſe cover or lid, having a ſmall hole for filling it with water, which can be eaſily cloſed up, and another hole in the centre of about one-fourth of the diameter of the cover. To this laſt hole ought to be ſoldered a tube of tin-plate, commonly called *white iron*, by which the ſteam may aſcend. This tube ought to riſe perpendicularly to the height of ſix feet, narrowing gradually to about two inches diameter. It may then bend off at right angles, to the moſt convenient ſituation for the tub or vat in which the roots are to be boiled. When it comes perpendicularly over the centre of the vat, it muſt be made to deſcend to within two or three inches of the bottom of it, being properly ſupported and fixed all the way.

To boil roots with this apparatus, it is only neceſſary to tumble them into the tub or vat into which the end of the white-iron tube deſcends. The tub ought then to be covered negligently. The water in the boiler being heated to ebullition, its ſteam or vapour riſes and paſſes along the white iron tube, and at laſt deſcends to the bottom of the wooden veſſel containing the roots, and in a very trifling ſpace of time renders them completely ſoft. If it is wiſhed to convert theſe roots into ſoup, it is only neceſſary to throw among them a quantity of water, and to maſh them down with any large ladle or other inſtrument. The ſteam continuing to deſcend will ſpeedily boil the water, and agitate and mingle the whole ingredients of which the ſoup may be compoſed. In this way by various mixtures of roots, with little or no trouble, rich broths, which human beings would not diſlike, may be formed for feeding a multitude of cattle, and the ſoup may eaſily be drawn off from the bottom of the vat by means of a hole to be occaſionally opened or ſhut with a round piece of wood.

In performing the above operation, however, of forming broth or ſoup, before allowing the water in the veſſel over the fire to give over boiling, the hole ought to be opened by which it is uſually filled with water, as the liquor in the vat might otherwiſe, in conſequence of the preſſure of the atmoſphere, aſcend through the white-iron tube and come over into the boiler. To ſtrengthen the white-iron tube, it may be proper alſo to cover it all over with paper paſted to it with glue, or with a mixture of peaſe-meal and water.

597 Rules for fattening cattle.

To fatten cattle with ſucceſs, then, we apprehend that the following rules ought to be adhered to. As a man is kept thin and meagre by whatever agitates his mind, or renders him anxious, fretful, and uncomfortable, ſo we ought to conſider that cattle, though they want foreſight of the future, have nevertheleſs minds capable of being irritated and diſturbed, which muſt ſo far waſte their bodies. In attempting to fatten them, therefore, care ought to be taken to preſerve the tranquillity of their minds, and as much as poſſible to keep them in a ſtate of cleanneſs and of moderate warmth. The food they receive ought to be varied at times to increaſe their appetite; but above all things it ought to be made as far as poſſible of eaſy digeſtion, that they may receive it in larger portions, and that a greater quantity of it may incorporate with their conſtitution, and not be thrown off by dung, as happens when they receive coarſe nouriſhment. It is in vain to object to this artificial mode of proceeding, that the natural food of animals is graſs alone, and that their

natural

Rearing and Fattening Hogs.

natural dwelling is the open air. The ſame might be ſaid with regard to the human ſpecies. In his natural, that is, in his unimproved ſtate, a ſavage may be under the neceſſity of eating raw fleſh or herbs, or of climbing into a tree for ſhelter; but although it may be poſſible for him to ſubſiſt in this way, yet we know that this is by no means the beſt mode of his exiſtence, and that his life and health are better preſerved by the ſhelter of a ſettled dwelling, and by more delicate food prepared by induſtry. In the ſame manner it is no doubt true, that cattle can exiſt upon very coarſe food, and may be even fattened by means of it; but as a greater quantity of it becomes neceſſary, the huſbandman's profit in rearing them is ſo far diminiſhed, and the value of his lands to the community is leſſened.

Sect. IV. *Of the Rearing and Fattening of Hogs.*

The practice of keeping theſe animals is ſo general, eſpecially in England, that one ſhould think the profit attending it would be abſolutely indiſputable: and this the more eſpecially, when it is conſidered how little nicety they have in their choice of food. From ſuch experiments, however, as have been made, the matter appears to be at leaſt very doubtful, unleſs in particular circumſtances. In the firſt volume of Annals of Agriculture, we have an experiment by Mr Mure of feeding hogs with the cluſter potato and carrots; by which it appeared, that the profit on large hogs was much greater than on ſmall ones: the latter eating almoſt as much as the former, without yielding a proportionable increaſe of fleſh. The gain was counted by weighing the large and ſmall ones alive; and it was found, that from November 17th to January 5th, they had gained in the following proportion:

598 Mr Mure's experiments.

22 large hogs, - -	L. 1	3	6
20 ſmall, - -	0	7	8
2 ſtag hogs, - -	1	17	8

On being finiſhed with peaſe, however, it appeared, that there was not any real profit at laſt; for the accounts ſtood ultimately as follow:

Dr				Cr			
Value of hogs at putting up,	L. 44	2	0	42 hogs ſold fat at	L. 95	0	0
33 coomb peaſe, at 14s.	23	2	0				
2 ditto, 2 buſhels barley, at 14s.	1	15	0				
56 days attendance of one man, at 14d.	3	5	4				
950 buſhels of carrots, and 598 of potatoes, at 3½d. per buſhel, -	22	15	8				
	L. 95	0	0		L. 9	0	0

In ſome experiments by Mr Young, related in the ſame volume, he ſucceeded ſtill worſe, not being able to clear his expences. His firſt experiment was attended with a loſs of one guinea per hog; the ſecond with a loſs of 12s. 8d.; the third, of only 3s. In theſe three the hogs were fed with peaſe; given whole in the two firſt, but ground into meal in the laſt. The fourth experiment, in which the hog was fed with Jeruſalem artichokes, was attended with no loſs; but another, in which peaſe were again tried, was attended with a loſs of 4s. Other experiments were tried with peaſe, which turning out likewiſe unfavourable, barley was tried ground along with peaſe and beans. This was attended with a ſmall profit, counting nothing for the trouble of feeding the animals. The expences on two hogs were 14l. 13s. 10½d, the value 15l. 11s. 3½d. ſo that there was a balance in his favour of 17s. 4½d. In another experiment in which the hogs were fed with peaſe and barley ground, the beans being omitted as uſeleſs, there was a profit of 12s. 3d. upon an expence of 22l. 15s. 9d; which our author ſuppoſes would pay the attendance. In this experiment the peaſe and barley meal were mixed into a liquor like cream, and allowed to remain in that ſtate for three weeks, till it became ſour. This was attended in two other inſtances with profit, and in a third with loſs: however, Mr Young is of opinion, that the practice will ſtill be found advantageous on account of the quantity of dung raiſed; and that the farmer can thus uſe his peaſe and barley at home without carrying them to market.

It is to be obſerved, that the above experiments were not made upon the fattening of hogs in the proper manner in which that animal ought to be fed. Its food ought undoubtedly to conſiſt chiefly of roots, ſuch as yams, potatoes, &c.; but theſe roots, as already mentioned, ought always to be boiled, or made into ſoups. With this mode of proceeding, the hog, from its rapid multiplication, and quick growth, is a very profitable kind of ſtock. It ought to be remembered, however, that of this, as well as of moſt other kinds of animals, a large breed is always to be preferred; for the difference is very trifling, or rather, in general, amounts to nothing at all, between the quantity of food neceſſary to ſupport a ſmall animal, and the quantity neceſſary to ſupport a large animal of the ſame kind.

599 Deſcription of a proper hogſty.

Hogſties are of ſimple conſtruction; they require only a warm dry place for the ſwine to lie in, with a ſmall area before, and troughs to hold their food. They are generally made with ſhed roofs, and ſeldom above 6 or 7 feet wide.

Although ſwine are generally conſidered as the filthieſt of all animals, yet there is no animal delights more in a clean comfortable place to lie down in, and none that cleanlineſs has a better effect upon with reſpect to their thriving and feeding. In order to keep them dry, a ſufficient ſlope muſt be given, not only to the inſide where they lie, but to the outſide area, with proper drains to carry off all moiſture. The inſide ſhould alſo be a little elevated, and have a ſtep up from the area at leaſt 5 or 6 inches. Hogſties ſhould have ſeveral diviſions to keep the different ſorts of ſwine ſeparate, nor ſhou'd a great many ever be allowed to go together; for it is thought they feed better in ſmall numbers, and of equal ſize, than when many are put together of different ſizes. Proper diviſions muſt therefore be made, ſome for ſwine when with the boar, others for brood ſwine, and for them to farrow in, for weaning the pigs, for feeding, &c.

Swine are apt to ſpill and waſte a great deal of their meat by getting their feet among it, unleſs proper precautions

Sheep.

cautions are taken to prevent them. This may be done by making a rail or covering of thin deal ſlope from the back part of the trough towards the fore part, leaving juſt room enough to admit their heads. There ſhould alſo be diviſions acroſs the troughs, according to the number of ſwine, to prevent the ſtrongeſt driving away the weakeſt. Theſe diviſions need not extend to the bottom of the troughs, but ſhould riſe a little higher than the top, and may be made of pieces of board about 8 or 10 inches broad.

Sties ought to be conſtructed that the ſwine may be eaſily fed without going in among them. In ſome places it is ſo contrived that they may be fed through openings in the back kitchen wall, without even going out of doors. This is very convenient where only a few ſwine are kept for family uſe, and makes it eaſy to give them the refuſe of vegetables and other things from the kitchen, which perhaps, would otherwiſe be thrown away. Where pigs are to be reared on an extenſive ſcale, there ought to be what is called in England a *pigs kitchen*, that is, a proper apparatus ought to be erected adjoining to the hogſty, for boiling their food. To avoid expence, ſteam ought always to be uſed for this purpoſe, in the way already deſcribed.

Sect. V. *Sheep.*

600 Experiments on feeding ſheep with roots.

The rearing of ſheep properly belongs to the article paſturage. So far, however, as they are fed upon the products of human induſtry, they belong to the preſent ſubject. In the Memoirs of the Royal Society of Agriculture in Paris for the year 1788, the reſult is given of certain experiments upon the advantage and economy of feeding ſheep in the houſe with roots. The experiments were made by M. Cretté de Palluel. He ſtates that the cuſtom of feeding ſheep in a houſe is common in ſeveral of the French provinces, but in others is unknown: That the mode of fattening them in that ſituation conſiſted of giving them clean corn and choice hay: That in ſubſtituting roots for corn, hay was continued to be given to them, either of clover, lucern, after-math, or any other ſort. The corn commonly uſed for fattening ſheep is barley and oats. Sometimes gray peaſe, or the marſhed bean, and rye. "Although the ſheep fed upon roots (ſays M. Cretté) did not acquire quite ſo great a degree of fatneſs as thoſe fed upon corn, it is however true, that they all fattened, and that if their food had been varied, they would have made great progreſs: I can even aſſert the fact of four, which were put upon change of food towards the end of the experiment, and ate much more.

Sheep.

"The ſheep put to potatoes ate little at firſt, for ſome days, which prevented them for thriving ſo much as the others; but they recovered the ſecond month what they loſt the firſt. As for thoſe put to turnips and beets, they fed heartily from the firſt moment, and continued it. They all drank much leſs than thoſe fed upon corn.

"Corn might with advantage be added to the roots: When the ſheep are intended to be ſold, two feeds of corn given them for a fortnight, in the intervals of their meals of roots, would harden both their fleſh and their tallow.

"It was not ſufficient to prove the poſſibility of fattening ſheep with different kinds of roots; it was farther neceſſary to aſcertain the qualities which their fleſh might acquire, by the uſe of them. Four ſheep, fed upon the four regimens, were killed the ſame day; there was indeed ſome trifling difference in the texture of their fleſh, but upon the whole the flavour of all was the ſame. Let us then conclude, that the culture of roots opens to us infinite reſources, not only for fattening of ſheep, but alſo of beaſts; and we do not doubt of their being uſed to the greateſt advantage in bringing up cattle in the countries where they are bred.

"The knowledge of theſe experiments muſt induce farmers to adopt this culture, ſince it is ſo advantageous. Roots cannot be exported; corn, on the contrary, is exported; and the grower may ſell the roots inſtead of conſuming them. One acre of roots is equal to five acres of corn. By this means he multiplies his land, and may conſequently multiply his cattle and his dunghill: added to this, roots are not ſubject, like corn, to the inclemencies of the ſeaſons; the produce is always more certain; theſe plants being of different natures, it is not likely that they ſhould all fail; the earth is a more faithful depoſitory of our treaſures than the atmoſphere; the dreadful hurricane of the 15th of this month (July) deſtroyed every thing but roots; they are the only product which eſcaped its ravages; if the hail tore their leaves, others will ſoon ſhoot; and carrots, beets, turnips, and potatoes, will be ſafe."

The reſult of the experiments alluded to is given in the following terms:

Experiment

Experiment upon Fatting Sheep, and their Increaſe from Month to Month.

Sixteen ſheep, of the ſame age, of four different breeds, were picked out of my flock, viz. four the breed of the country, four of Beauce, four of Champagne, and four of Picardy: I weighed them alive, and marked each with a number; I divided them into four lots, and fed them on four different ſorts of food, as under.

"Observation. The increaſe of theſe ſheep, during the firſt month, being ſo much more conſiderable than in the following months, muſt be attributed to this cauſe, that lean cattle put up to fatten, eat greedily until they are cloyed, which only fills them, without much increaſing their fleſh; but, on the contrary, the increaſe produced in the enſuing months, although apparently leſs, turns all to profit in fleſh and tallow."

Sect. VI. *Rabbits.*

In particular ſituations theſe animals may be kept to advantage, as they multiply exceedingly, and require no trouble in bringing up. A conſiderable number of them are kept in Norfolk, where many parts, conſiſting of barren hills or heaths, are proper for their reception. They delight in the ſides of ſandy hills, which are generally unproductive when tilled; but level ground is improper for them. Mr Marſhall is of opinion, that there are few ſandy or other looſe-ſoiled hills which would not pay better in rabbit warrens than any thing elſe. "The hide of a bullock (ſays he) is not worth more than $\frac{1}{10}$th of his carcaſe; the ſkin of a ſheep may, in full wool, be worth from a ſixth to a tenth of its carcaſe; but the fur of a rabbit is worth twice the whole value of the carcaſe; therefore ſuppoſing a rabbit to conſume a quantity of food in proportion to its carcaſe, it is, on the principle offered, a ſpecies of ſtock nearly three times as valuable as either cattle or ſheep. Rabbit warrens ought to be incloſed with a ſtone or ſod wall; and at their firſt ſtocking, it will be neceſſary to form burrows to them until they have time to make them to themſelves. Boring the ground horizontally with a large auger is perhaps the beſt method that can be practiſed. Eagles, kites, and other birds of preys, as well as cats, weaſels, and pole-cats, are great enemies of rabbits. The Norfolk warreners catch the birds by traps placed on the tops of ſtumps of trees or artificial hillocks of a conical form, on which they naturally alight.—Traps alſo ſeem to be the only method of getting rid of the other enemies; though thus the rabbits themſelves are in danger of being caught.

601 Rabbits more valuable than black cattle or ſheep.

602 Method of deſtroying birds of prey.

Rabbits may be fed during the ſummer with clover and

Poultry. and other green food, and during the winter with cabbages. Where they are kept in an inclosure as part of the stock of the farm, a practice which has not yet been used in this country, they ought to be fed with great regularity, and with as much as they are willing to take. When this is done, they thrive upon a very moderate quantity of food; but if they are once allowed to suffer hunger in any great degree, they become extremely ravenous, and for a long time can scarcely be satisfied with food. In a communication to the Board of Agriculture from M. Bertrand of Mechlin, in the Netherlands, we are informed that the rabbits of the Angora breed yield in Normandy an uncommonly valuable wool, which serves as a primary material in several considerable manufactures. The Normans assert, that each rabbit yields wool of the value of a crown or six livres. M. Bertrand having discovered that these rabbits are extremely fond of the leaves of the *robinia pseudo acacia*, (the false acacia), made the following trial of its effects. He fed some females with these leaves only, while to others he gave cabbage leaves and the common food furnished to these animals. He observed that the young ones proceeding from the females fed on the leaves of the *robinia*, grew larger and in less time, and that their coats and wool were finer than on the others fed in the common way. He caused the skins of the indigenous rabbits fed with the robinia leaves to be examined by hatters, and they valued them much more than the common ones, asserting that their wool approached in quality to that of hares. The robinia, he observes, thrives on barren heaths. Its branches and leaves are remarkably numerous. Its leaves may be converted into hay, which rabbits and other animals devour eagerly. One person is able to cut a sufficient quantity of branches for a great number of rabbits; and turnips, vetches, beans, and other vegetables, can be sown under the trees.

603 Angora breed of rabbits.

Sect. VII. *Poultry.*

604 Poultry ought to be confined.

Poultry, if rightly managed, might be a source of great profit to the farmer, but where many are kept, they ought not to be allowed to go at large, in which case little profit can be expected from them, for not only will many of their eggs be lost, and many of themselves perhaps destroyed by vermin, but at certain seasons they do a great deal of mischief both in the barn-yard and in the field. No doubt they pick up some grain at the barn-doors that might otherwise be lost; but if the straw is properly threshed and shaken, there would be very little of this. In the common careless way of threshing a great deal of corn is undoubtedly thrown out among the straw; but when we consider the dung of the fowls and their feathers that get among it, and the injury these must do to the cattle, this is no object. It is much better to allow the poultry a certain quantity of food, and to let the cattle have the benefit of what corn may remain among the straw.

Poultry ought therefore always to be confined, but not in a close, dark, diminutive hovel, as is often the case; they should have a spacious airy place properly constructed for them. Some people are of opinion that each sort of poultry should be kept by itself. This, however, is not absolutely necessary; for all sorts may be kept promiscuously together, provided they have a place sufficiently large to accommodate them conveniently, and proper divisions and nests for each kind to retire to separately, which they will naturally do of themselves. Poultry.

This method is practised with great success at Mr Wakefield's, near Liverpool, who keeps a large stock of turkeys, geese, hens, and ducks, all in the same place; and although young turkeys are in general considered so difficult to bring up, he rears great numbers of them in this manner every season with little or no trouble whatever. He has about three quarters or near a whole acre inclosed with a fence only six or seven feet high, formed of slabs set on end, or any thinnings of fir or other trees split and put close together. They are fastened by a nail near the top and another near the bottom, and are pointed sharp, which I suppose prevents the poultry flying over, for they never attempt it although so low. Within this fence are places done up slightly (but well secured from wet) for each sort of poultry; also a pond or stream of water running through it. These poultry are fed almost entirely with potatoes boiled in steam, and thrive astonishingly well. The quantity of dung that is made in this poultry-place is also an object worth attention; and when it is cleared out, a thin paring of the surface is at the same time taken off, which makes a valuable compost. *Communication to the Board of Agriculture, by Robert Beatson, Esq.* 605 Example of a proper mode of keeping poultry.

It is generally understood that a full-grown hen continues in her prime for three years, and that during that period, if properly fed, she will lay at a medium 200 eggs every year. The number, however, of eggs may be greatly increased by making the place to which this kind of poultry retire at night very warm and comfortable by its being placed contiguous to a wall on the other side of which a fire is kept, or by its being heated in any other manner. In the cottages of the poor in Scotland, where the poultry and the inhabitants sleep under the same roof, the hens continue with a moderate portion of food to produce eggs during the greatest part of the winter.

606 Great number of turkeys reared in Norfolk.

In Norfolk a great number of turkeys are bred, of a size and quality superior to those in other parts. Mr Marshall accounts for their number in the following manner: "It is understood in general, that to rear turkeys with success, it is necessary that a male bird should be kept upon the spot to impregnate the eggs singly; but the good housewives of this country know, that a daily intercourse is unnecessary; and that if the hen be sent to a neighbouring cock previous to the season of exclusion, one act of impregnation is sufficient for one brood. Thus relieved from the expence and disagreeableness of keeping a male bird, most little farmers, and many cottagers, rear turkeys. This accounts for their number; and the species and the food they are fatted with (which, I believe, is wholly buck) account for their superior size and quality."

The following account of the Lincolnshire management of geese is given by Mr John Foote of Brandon, in the Annals of Agriculture. "It is generally allowed, that three geese to one gander is sufficient; more geese would be too many, so as to render the eggs abortive. The quantity of eggs to every goose for sitting about 12 or 13. They must be fed with corn Vol. xiv. 607 Lincolnshire management of geese.

Manage m nt of the Dairy.

corn in their water whilſt ſitting, near them, ſo as to feed at pleaſure. The ganders ſhould be allowed to keep near them, ſo that they can ſee them, as they will naturally watch as a guard over their own geeſe.

" Their neſts ſhould be made for them of ſtraw, and confined ſo as the eggs cannot roll out when the geeſe turn them, which they do every day.

" When near hatching, the ſhell ſhould be broke a little againſt the beak or bill of the goſling, to give air, or to enable it to receive ſtrength to throw off the ſhell at a proper time. The method of plucking them about the beginning of April is this: Pluck gently and carefully the fine feathers off their breaſt and back; but be careful not to pull or interrupt their down or pen feathers.

" You alſo pull their quills, five out of a wing; but I think four would be better. The quills will bear pulling in 13 or 14 weeks again, twice in a year; the feathers three times a year, of the old geeſe and ganders, ſeven weeks from the firſt pulling; and then again ſeven weeks after, which is the laſt pulling of the year.

" The young geeſe may be pulled once at 13 or 14 weeks old, but not quilled, being hatched in March.

" If the geeſe are late in hatching, I expect the brood geeſe ſhould not be plucked ſo ſoon as April, but the month after.

" If they are fed with barley and oats, as they ought to be, they will thrive and do the better, and their feathers will grow the faſter, and better in quality; they muſt have plenty of graſs and water.

" Although perſons not acquainted with the management of geeſe, as above deſcribed, may think it inhuman; yet I am credibly informed, they will do better than where they do not pluck them, if they are properly done, as they loſe their feathers by moulting, and would not be ſo healthy.

" It is proved, that by annually plucking geeſe, as in Lincolnſhire, there is ſaved, by the increaſe of feathers, many hundred pounds value, which other countries waſte, though a miſtaken opinion, as not an object worth their attention. Gooſe feathers are now ſold at 18s. a ſtone, that uſed about 25 years ago to be bought at 10s. or 11s. in that county.

" A gooſe will produce by this method about 1s. 6d. annually of good feathers and quills."

Sect. VIII. *Of the Management of the Dairy.*

608 mportance f the airy.

In all but the richeſt corn countries, this is a moſt important branch of the buſineſs of a huſbandman. It includes not only the proper method of preſerving milk in a wholeſome and uncorrupted ſtate, but alſo the manufacturing from it the two valuable articles of butter and cheeſe. We ſhall firſt conſider the ſubject of the dairy in a general manner; after which we ſhall take notice of the mode of preparing butter and cheeſe.

609 'rinciples n which dairy ught to be anaged.

Dr James Anderſon remarks, that when a dairy is eſtabliſhed, the undertaker may ſometimes think it his intereſt to obtain the greateſt poſſible quantity of produce: ſometimes it may be more beneficial for him to have it of the fineſt quality; and at other times it may be neceſſary to have both theſe objects in view, the one or the other in a greater or leſs proportion; it is therefore of importance that he ſhould know how he may accompliſh the one or the other of theſe purpoſes in the eaſieſt and moſt direct manner.

Manage- ment of the Dairy.

To be able to convert his milk to the higheſt poſſible profit in every caſe, he ought to be fully acquainted with every circumſtance reſpecting the manufacture both of butter and of cheeſe; as it may in ſome caſes happen, that a certain portion of that milk may be more advantageouſly converted into butter than into cheeſe, while another portion of it would return more profit if made into cheeſe.

The firſt thing to be adverted to, in an undertaking of this nature, is to chooſe cows of a proper ſort. Among this claſs of animals, it is found by experience, that ſome kinds give milk of a much thicker conſiſtence, and richer quality, than others; nor is this richneſs of quality neceſſarily connected with the ſmallneſs of the quantity yielded by cows of nearly an equal ſize; it therefore behoves the owner of a dairy to be peculiarly attentive to this circumſtance. In judging of the value of a cow, it ought rather to be the quantity and the quality of the cream produced from the milk of the cow, in a given time, than the quantity of the milk itſelf: this is a circumſtance that will be ſhewn hereafter to be of more importance than is generally imagined. The ſmall cows of the Alderney breed afford the richeſt milk hitherto known; but individual cows in every country may be found, by a careful ſelection, that afford much thicker milk than others; theſe therefore ought to be ſearched for with care, and their breed reared with attention, as being peculiarly valuable.

Few perſons, who have had any experience at all in the dairy, can be ignorant, however, that in comparing the milk of two cows, to judge of their reſpective qualities, particular attention muſt be paid to the time that has elapſed ſince their calving; for the milk of the ſame cow is always thinner ſoon after calving than it is afterwards; as it gradually becomes thicker, though generally leſs in quantity, in proportion to the time ſince the cow has calved. The colour of the milk, ſoon after calving, is richer than it is afterwards; but this, eſpecially for the firſt two weeks, is a faulty colour, that ought not to be coveted.

To make the cows give abundance of milk, and of a good quality, they muſt at all times have plenty of food. Graſs is the beſt food yet known for this purpoſe, and that kind of graſs which ſprings up ſpontaneouſly on rich dry ſoils is the beſt of all. If the temperature of the climate be ſuch as to permit the cows to graze at eaſe throughout the day, they ſhould be ſuffered to range on ſuch paſtures at freedom; but if the cows are ſo much incommoded by the heat as to be prevented from eating through the day, they ought in that caſe to be taken into cool ſheds for protection; where, after allowing them a proper time to ruminate, they ſhould be ſupplied with abundance of green food, freſh-cut for the purpoſe, and given to them by hand frequently, in ſmall quantities, freſh and freſh, ſo as to induce them to eat it with pleaſure. When the heat of the day is over, and they can remain abroad with eaſe, they may be again turned into the paſture, where they ſhould be allowed to range with freedom all night, during the mild weather of ſummer.

Cows, if abundantly fed, ſhould be milked three times a day during the whole of the ſummer ſeaſon; in the morning early, at noon, and in the evening, juſt before night-fall,

Management of the Dairy.

night-fall. In the choice of perſons for milking the cows, great caution ſhould be employed; for if that operation be not carefully and properly performed, not only the quantity of the produce of the dairy will be greatly diminiſhed, but its quality alſo will be very much debaſed; for if all the milk be not thoroughly drawn from a cow when ſhe is milked, that portion of milk which is left in the udder ſeems to be gradually abſorbed into the ſyſtem, and nature generates no more than to ſupply the waſte of what has been taken away. If this leſſened quantity be not again thoroughly drawn off, it occaſions a yet farther diminution of the quantity of milk generated; and thus it may be made to proceed, in perpetual progreſſion from little to leſs, till none at all is produced. In ſhort, this is the practice in all caſes followed, when it is meant to allow a cow's milk to dry up entirely, without doing her hurt. In this manner, therefore, the profits of a dairy might be wonderfully diminiſhed; ſo that it much behoves the owner of it to be extremely attentive to this circumſtance, if he wiſhes to avoid ruin. It ought to be a rule without an exception, never to allow this important department to be entruſted, without controul, to the management of hired ſervants. Its importance will be ſtill more manifeſt from the following aphoriſms.

Aphoriſm 1. "Of the milk that is drawn from any cow at one time, that which comes off at the firſt is always thinner, and of a much worſe quality, than that which comes afterwards; and the richneſs goes on continually increaſing to the very laſt drop that can be drawn from the udder at that time."

Few perſons are ignorant that the milk which is laſt of all taken from the cow at milking (in this country called *ſtroakings*) is richer than the reſt of the milk; but fewer ſtill are aware of the greatneſs of the diſproportion between the quality of the firſt and the laſt drawn milk, from the ſame cow, at one milking. The following facts (ſays our author) reſpecting this circumſtance were aſcertained by me many years ago, and have been confirmed by many ſubſequent experiments and obſervations.

Having taken ſeveral large tea-cups, exactly of the ſame ſize and ſhape, one of theſe tea-cups was filled at the beginning of the milking, and the others at regular intervals, till the laſt, which was filled with the dregs of the ſtroakings. Theſe cups were then weighed, the weight of each having been ſettled, ſo as to aſcertain that the quantity of milk in each was preciſely the ſame; and from a great number of experiments, frequently repeated with many different cows, the reſult was in all caſes as follows:

Firſt, The quantity of cream obtained from the firſt-drawn cup was, in every caſe, much ſmaller than from that which was laſt drawn; and thoſe between afforded leſs or more as they were nearer the beginning or the end. It is unneceſſary here to ſpecify theſe intermediate proportions; but it is proper the reader ſhould be informed, that the quantity of cream obtained from the laſt-drawn cup, from ſome cows, exceeded that from the firſt in the proportion of ſixteen to one. In other cows, however, and in particular circumſtances, the diſproportion was not quite ſo great; but in no caſe did it fall ſhort of the rate of eight to one. Probably, upon an average of a great many cows, it might be found to run as ten or twelve to one.

Secondly, The difference in the quality of the cream, however, obtained from theſe two cups, was much greater than the difference in the quantity. In the firſt cup, the cream was a thin tough film, thinner, and perhaps whiter, than writing paper; in the laſt, the cream was of a thick *butyrous* conſiſtence, and of a glowing richneſs of colour that no other kind of cream is ever found to poſſeſs.

Thirdly, The difference in the quality of the milk that remained, after the cream was ſeparated, was perhaps ſtill greater than either in reſpect to the quantity or the quality of the cream. The milk in the firſt cup was a thin bluiſh liquid, as if a very large proportion of water had been mixed with ordinary milk; that in the laſt cup was of a thick conſiſtence, and yellow colour, more reſembling cream than milk both in taſte and appearance.

From this important experiment, it appears that the perſon who, by bad milking of his cows, loſes but half a pint of his milk, loſes in fact about as much cream as would be afforded by ſix or eight pints at the beginning, and loſes, beſides, that part of the cream which alone can give richneſs and high flavour to his butter.

Aphoriſm 2. "If milk be put into a diſh, and allowed to ſtand till it throws up cream, that portion of cream which riſes firſt to the ſurface is richer in quality, and greater in quantity, than what riſes in a ſecond equal ſpace of time; and the cream that riſes in the ſecond interval of time is greater in quantity, and richer in quality, than that which riſes in a third equal ſpace of time; that of the third than the fourth, and ſo on: the cream that riſes decreaſing in quantity, and declining in quality, continually, as long as any riſes to the ſurface."

Our ingenious author confeſſes, that his experiments not having been made with ſo much accuracy in this caſe as in the former, he was not enabled to aſcertain the difference in the proportion that takes place in equal portions of time; but they have been ſo often repeated as not to leave any room to doubt the fact, and it will be allowed to be a fact of no ſmall importance in the management of the dairy. It is not certain, however, but that a greater quantity of cream may, upon the whole, be obtained from the milk by taking it away at different times: but the proceſs is ſo troubleſome as not to be counterbalanced by the increaſed quantity obtained, if indeed an increaſed quantity be thus obtained, which is not as yet quite certain.

Aphoriſm 3. "Thick milk always throws up a ſmaller proportion of the cream it actually contains, to the ſurface, than milk that is thinner; but that cream is of a richer quality. If water be added to that thick milk, it will afford a conſiderably greater quantity of cream than it would have done if allowed to remain pure, but its quality is, at the ſame time, greatly debaſed."

This is a fact that every perſon attentive to a dairy muſt have remarked; but I have never (ſays our author) heard of any experiment that could aſcertain, either the preciſe amount of the increaſed quantity of cream that might thus be obtained, or of the ratio in the decreaſe of its quality. The effects of mixing water with the milk in a dairy are at leaſt aſcertained; and the knowledge of the fact will enable attentive perſons to follow that practice which they think will beſt promote their own intereſt.

Aphoriſm 4. "Milk which is put into a bucket or other

Management of the Dairy.

other proper veſſel, and carried in it to any conſiderable diſtance, ſo as to be much agitated, and in part cooled, before it be put into the milk-pans to ſettle for cream, never throws up ſo much, nor ſo rich cream, as if the ſame milk had been put into the milk-pans directly after it was milked."

In this caſe, it is believed the loſs of cream will be nearly in proportion to the time that has elapſed, and the agitation the milk has ſuſtained, after being drawn from the cow. But Dr Anderſon ſays that he is not yet in poſſeſſion of any experiments which ſufficiently aſcertain how much is to be aſcribed to the time, and the agitation, taken ſeparately. On every branch of agriculture we find experiments wanting, at each ſtep we advance in our inquiries; and it is the duty of every inquirer to point out, as he goes along, where they are wanted, ſince the labours of no one man can poſſibly complete the whole.

From the above facts, the following corollaries ſeem to be clearly deducible:

Firſt, It is of importance that the cows ſhould be always milked as near the dairy as poſſible, to prevent the neceſſity of carrying and cooling the milk before it is put into the diſhes; and as cows are much hurt by far driving, it muſt be a great advantage in a dairy-farm to have the principal graſs fields as near the dairy or homeſtead as poſſible.

Secondly, The practice of putting the milk of all the cows of a large dairy into one veſſel, as it is milked, there to remain till the whole milking is finiſhed, before any part of it is put into the milk-pans—ſeems to be highly injudicious; not only on account of the loſs that is ſuſtained by agitation and cooling, but alſo, more eſpecially, becauſe it prevents the owner of the dairy from diſtinguiſhing the good from the bad cow's milk ſo as to ſeparate theſe from each other, where it is neceſſary. He may thus have the whole of his dairy product greatly debaſed by the milk of one bad cow, for years together, without being able to diſcover it. A better practice, therefore, would be, to have the milk drown from each cow put ſeparately into the creaming-pans as ſoon as it is milked, without being ever mixed with any other. Thus would the careful manager of the dairy be able on all occaſions to obſerve the particular quality of each individual cow's milk, as well as its quantity, and to know with preciſion which of his cows it was his intereſt to diſpoſe of, and which of them he ought to keep and breed from.

Thirdly, If it be intended to make butter of a very fine quality, it will be adviſable in all caſes to keep the milk that is firſt drawn ſeparate from that which comes laſt; as it is obvious, that if this be not done, the quality of the butter will be greatly debaſed, without much augmenting its quantity. It is alſo obvious, that if this is done, the quality of the butter will be improved in proportion to the ſmallneſs of the quantity of the laſt-drawn milk that is retained; ſo that thoſe who wiſh to be ſingularly nice in this reſpect, will do well to retain only a very ſmall portion of the laſt drawn milk.

To thoſe owners of dairies who have profit only in view, it muſt ever be a matter of trial and calculation, how far it is expedient for them to carry the improving of the quality of their butter at the expence of diminiſhing its quantity. In different ſituations prudence will point out different kinds of practices moſt eligible; and all perſons muſt be left, after making accurate trials, to determine for themſelves. It is likewiſe a conſideration of no ſmall importance, to determine in what way the inferior milk, that is thus to be ſet apart where fine butter is wanted, can be employed with the greateſt profit. In the Highlands of Scotland they have adopted, without thinking of the improvement of their butter, a very ſimple and economical practice in this reſpect. As the rearing of calves is there a principal object with the farmer, every cow is allowed to ſuckle her own calf with a part of her milk, the remainder only being employed in the dairy. To give the calf its portion regularly, it is ſeparated from the cow, and kept in an incloſure, with all the other calves belonging to the ſame farm. At regular times, the cows are driven to the door of the incloſure, where the young calves fail not to meet them. Each calf is then ſeparately let out, and runs directly to its mother, where it ſucks till the dairy-maid judges it has had enough; ſhe then orders it to be driven away, having previouſly ſhackled the hinder legs of the mother, by a very ſimple contrivance, to oblige her to ſtand ſtill. Boys drive away the calf with ſwitches, and return it to the incloſure, while the dairy-maid milks off what was left by the calf: thus they proceed till the whole of the cows are milked. They obtain only a ſmall quantity of milk, it is true, but that milk is of an exceeding rich quality; which, in the hands of ſuch of the inhabitants as know how to manage it, is manufactured into the richeſt marrowy butter that can be anywhere met with. This richneſs of the Highland butter is univerſally aſcribed to the old graſs the cows feed upon in their remote glens; but it is in fact chiefly to be attributed to the practice here deſcribed, which has long prevailed in thoſe regions. Whether a ſimilar practice could be economically adopted elſewhere, our author takes not upon him to ſay; but doubtleſs other ſecondary uſes might be found for the milk of inferior quality. On ſome occaſions, it might be converted into butter of an inferior quality; on other occaſions, it might be ſold ſweet, where the ſituation of the farm was within reach of a market-town; and on others, it might be converted into cheeſes, which, by being made of ſweet milk, would be of a very fine quality if carefully made. Still other uſes might be deviſed for its application; of which the following is worthy of notice. Take common ſkimmed milk, when it has begun to turn ſour, put it into an upright ſtand-churn, or a barrel with one of its ends out, or any other convenient veſſel. Heat ſome water, and pour it into a tub that is large enough to contain with eaſe the veſſel in which the milk was put. Set the veſſel containing the milk into the hot water, and let it remain there for the ſpace of one night. In the morning it will be found that the milk has ſeparated into two parts; a thick cream-like ſubſtance, which occupies the upper part of the veſſel, and a thin watery part that remains at the bottom. Draw off the thin part (called in Scotland *wigg*) by opening a ſtop-cock placed for that purpoſe cloſe above the bottom, and reſerve the cream for uſe. Not much leſs than half of the milk is thus converted into a ſort of cream, which, when well made, ſeems to be as rich and fat as real cream itſelf, and is only diſtinguiſhable from it by its ſourneſs. It is eaten with ſugar, and eſteemed a great delicacy, and uſually ſells at double the price

Management of the Dairy.

of freſh unſkimmed milk. It requires practice, however to be able to make this nicely; the degree of the heat of the water, and many other circumſtances, greatly affecting the operation.

Fourthly, If the quality of the butter be the chief object attended to, it will be neceſſary, not only to ſeparate the firſt from the laſt drawn milk, but alſo to take nothing but the cream that is firſt ſeparated from the beſt milk, as it is this firſt riſing cream alone that is of the prime quality. The remainder of the milk, which will be ſtill ſweet, may be either employed for the purpoſe of making ſweet-milk cheeſes, or may be allowed to ſtand, to throw up cream for making butter of an inferior quality, as circumſtances may direct.

Fifthly, From the above facts, we are enabled to perceive, that butter of the very beſt poſſible quality can only be obtained from a dairy of conſiderable extent, judiciouſly managed; for when only a ſmall portion of each cow's milk can be ſet apart for throwing up cream, and when only a ſmall proportion of that cream can be reſerved, of the prime quality, it follows (the quantity of milk being upon the whole very inconſiderable), that the quantity of prime cream produced would be ſo ſmall as to be ſcarcely worth manufacturing ſeparately.

Sixthly, From theſe premiſes we are alſo led to draw another concluſion, extremely different from the opinion that is commonly entertained on this ſubject, viz. That it ſeems probable, that the very beſt butter could be made with economy in thoſe dairies only where the manufacture of cheeſe is the principal object. The reaſons are obvious: If only a ſmall portion of milk ſhould be ſet apart for butter, all the reſt may be made into cheeſe, while it is yet warm from the cow, and perfectly ſweet; and if only that portion of cream which riſes during the firſt three or four hours after milking is to be reſerved for butter, the rich milk which is left after that cream is ſeparated, being ſtill perfectly ſweet, may be converted into cheeſe with as great advantage nearly as the newly-milked milk itſelf.

But as it is not probable that many perſons could be found who would be willing to purchaſe the very fineſt butter, made in the manner above pointed out, at a price that would be ſufficient to indemnify the farmer for his trouble in making it, theſe hints are thrown out merely to ſhew the curious in what way butter poſſeſſing this ſuperior degree of excellence may be obtained, if they chooſe to be at the expence; but for an ordinary market, Dr Anderſon is ſatisfied, from experience and attentive obſervation, that if in general about the firſt drawn half of the milk be ſeparated at each milking, and the remainder only ſet up for producing cream, and if that milk be allowed to ſtand to throw up the whole of its cream (even till it begins ſenſibly to taſte ſouriſh), and that cream be afterwards carefully managed, the butter thus obtained will be of a quality greatly ſuperior to what can uſually be procured at market, and its quality not conſiderably leſs than if the whole of the milk had been treated alike. This, therefore, is the practice that he thinks moſt likely to ſuit the frugal farmer, as his butter, though of a ſuperior quality, could be afforded at a price that would always enſure it a rapid ſale.

610 Dairy deſcribed.

Our author now proceeds to enumerate the properties of a dairy. The milk-houſe ought to be cool in ſummer and warm in winter; ſo that an equal temperature may be preſerved throughout the year. It ought alſo to be dry, ſo as to admit of being kept ſweet and clean at all times. A ſeparate building ſhould be erected for the purpoſe, near a cool ſpring or running water, where the cows may have eaſy acceſs to it, and where it is not liable to be incommoded by ſtagnant water. The apartment where the milk ſtands ſhould be well thatched, have thick walls, and a ventilator in the top for admitting a free circulation of air. There ſhould alſo be an apartment with a fire-place and caldron, for the purpoſe of ſcalding and cleaning the veſſels. The Doctor is of opinion, that the temperature of from 50 to 55 degrees is the moſt proper for ſeparating the cream from the milk, and by proper means this might eaſily be kept up, or nearly ſo, both ſummer and winter.

Management of the Dairy.

611 Wooden utenſils preferable to every other kind.

The utenſils of the dairy ſhould be all made of wood, in preference either to lead, copper, or even caſt iron. Theſe metals are all very eaſily ſoluble in acids; the ſolutions of the two firſt highly poiſonous; and though the latter is innocent, the taſte of it might render the products highly diſagreeable.

612 Hiſtory of butter.

Butter, though uſed at preſent as food in moſt countries of Europe, was not known, or known very imperfectly, to the ancients. This, we think, is completely proved by Profeſſor Beckmann in the ſecond volume of his *Hiſtory of Inventions*. In our tranſlation of the Hebrew Scripture, there is indeed frequent mention made of butter at very early periods; but, as the Profeſſor well obſerves, the greateſt maſters of biblical criticiſm unanimouſly agree, that the word ſo tranſlated ſignifies milk or cream, or four thick milk, and cannot poſſibly mean what we call *butter*. The word plainly alludes to ſomething liquid, which was uſed for waſhing the feet, which was drunk, and which had ſometimes the power of intoxicating; and we know that mares milk may be ſo prepared as to produce the ſame effect. See KOUMISS.

The oldeſt mention of butter, the Profeſſor thinks, is in the account of the Scythians given by Herodotus (lib. iv. 2.), who ſays, that "theſe people pour the milk of their mares into wooden veſſels, cauſe it to be violently ſtirred or ſhaken by their blind ſlaves, and ſeparate the part which ariſes to the ſurface, as they conſider it as more valuable and delicious than what is collected below it." That this ſubſtance muſt have been a ſoft kind of butter, is well known; and Hippocrates gives a ſimilar account of Scythian butter, and calls it *πιειηδιον*, which Galen tranſlates by the word *βουτυρον*. The poet Anaxandrides, who lived ſoon after Hippocrates, deſcribing the marriage-feaſt of Iphicrates, who married the daughter of Cotys king of Thrace, ſays, that the Thracians ate butter, which the Greeks at that time conſidered as a wonderful kind of food.

Dioſcorides ſays, that good butter was prepared from the fatteſt milk, ſuch as that of ſheep or goats, by ſhaking it in a veſſel till the fat was ſeparated. To this butter he aſcribes the ſame effects, when uſed externally, as thoſe produced by our butter at preſent. He adds alſo, and he is the firſt writer who makes the obſervation, that freſh butter might be melted and poured over pulſe and vegetables inſtead of oil, and that it might be employed in paſtry in the room of other fat ſubſtances.

Management of the Dairy.

substances. A kind of soot likewise was at that time prepared from butter for external applications, which was used in curing inflammation of the eyes and other disorders. For this purpose the butter was put into a lamp, and when consumed, the lamp was again filled till the desired quantity of soot was collected in a vessel placed over it.

Galen, who distinguishes and confirms in a more accurate manner the healing virtues of butter, expressly remarks, that cows milk produces the fattest butter; that butter made from sheep's or goats milk is less rich; and that asses milk yields the poorest. He expresses his astonishment, therefore, that Dioscorides should say that butter was made only from the milk of sheep and goats. He assures us that he had seen it made from cows milk, and that he believes it had thence acquired its name. "Butter (says he) may be very properly employed for ointments; and when leather is besmeared with it, the same purpose is answered as when it is rubbed over with oil. In cold countries, which do not produce oil, butter is used in the baths; and that it is a real fat, may be readily perceived by its catching fire when poured over burning coals." What has been here said is sufficient to shew that butter must have been very little known to or used by the Greeks and Romans in the time of Galen, that is, at the end of the second century.

The professor having collected, in chronological order, every thing which he could find in the works of the ancients respecting butter, concludes, that it is not a Grecian, and much less a Roman invention, but that the Greeks were made acquainted with it by the Scythians, the Thracians, and the Phrygians, and the Romans by the people of Germany. He is likewise decidedly of opinion, that when these two polished nations had learned the art of making it, they used it not as food, but only as an ointment, or sometimes as a medicine, "We never find it (says he) mentioned by Galen and others as a food, though they have spoken of it as applicable to other purposes. No notice is taken of it by Apicius; nor is there any thing said of it in that respect by the authors who treat on agriculture, though they have given us very particular information concerning milk, cheese, and oil."

The ancient Christians of Egypt burnt butter in their lamps instead of oil; and in the Roman churches, it was anciently allowed, during Christmas time, to burn butter instead of oil, on account of the great consumption of it otherwise.

613 Qualities of butter.

Butter is the fat, oily, and inflammable part of the milk. This kind of oil is naturally distributed through all the substance of the milk in very small particles, which are interposed betwixt the caseous and serous parts, amongst which it is suspended by a slight adhesion, but without being dissolved. It is in the same state in which oil is in emulsions: hence the same whiteness of milk and emulsions; and hence, by rest, the oily parts separate from both these liquors to the surface, and form a cream. See EMULSION.

When butter is in the state of cream, its proper oily parts are not yet sufficiently united together to form a homogeneous mass. They are still half separated by the interposition of a pretty large quantity of serous and caseous particles. The butter is completely formed by pressing out these heterogenous parts by means of continued percussion. It then becomes an uniform soft mass.

Management of the Dairy.

Fresh butter, which has undergone no change, has scarcely any smell: its taste is mild and agreeable, it melts with a weak heat, and none of its principles are disengaged by the heat of boiling water. Those properties prove, that the oily part of butter is of the nature of the fat, fixed, and mild oils obtained from many vegetable substances by expression. See OILS.—The half fluid consistence of butter, as of most other concrete oily matters, is thought to be owing to a considerable quantity of acid united with the oily part; which acid is so well combined, that it is not perceptible while the butter is fresh, and has undergone no change; but when it grows old, and undergoes some kind of fermentation, then the acid is disengaged more and more; and this is the cause that butter, like oils of the same kind, becomes rancid by age.

Butter is constantly used in food, from its agreeable taste; but to be wholesome, it must be very fresh and free from rancidity, and also not fried or burnt; otherwise its acrid and even caustic acid, being disengaged, disorders digestion, renders it difficult and painful, excites acrid empyreumatic belchings, and introduces much acrimony into the blood. Some persons have stomachs so delicate, that they are even affected with these inconveniences by fresh butter and milk. This observation is also applicable to oil, fat, chocolate, and in general to all oleaginous matters.

614 Rules for making butter.

Dr James Anderson, whom we have already quoted, gives the following minute directions for making and preserving butter. The creaming dishes, when properly cleaned, sweet, and cool, ought to be filled with the milk as soon as it is drawn from the cow, having been first carefully strained through a cloth, or close strainer made of hair or wire: the doctor prefers silver wire to every other. The creaming dishes ought never to exceed three inches in depth; but they may be so broad as to contain a gallon and a half; when filled they ought to be put on the shelves of the milk-house, and remain there until the cream be fully separated. If the finest butter be intended, the milk ought not to stand above six or eight hours, but for ordinary butter it may stand 12 hours or more; yet if the dairy be very large, a sufficient quantity of cream will be separated in two, three, or four hours, for making the best butter. It is then to be taken off as nicely as possible by a skimming dish, without lifting any of the milk; and immediately after put into a vessel by itself, until a proper quantity for churning be collected. A firm, neat, wooden barrel seems well adapted for this purpose, open at one end, and having a lid fitted to close it. A cock or spigot ought to be fixed near the bottom, to draw off any thin or serous part which may drain from the cream; the inside of the opening should be covered with a bit of fine silver wire gauze, in order to keep back the cream while the serum is allowed to pass; and the barrel should be inclined a little on its stand, to allow the whole to run off.

615 Cream ought to be kept some time before it be made into butter.

The doctor contradicts the opinion that very fine butter cannot be obtained, except from cream that is not above a day old. On the contrary, he insists that it is only in very few cases that even tolerably good butter can be obtained from cream that is not above one day old. The separation of butter from cream only

Management of the Dairy.

only takes place after the cream has attained a certain degree of acidity. If it be agitated before that acidity has begun to take place, no butter can be obtained, and the agitation muſt be continued till the time that the ſoundneſs is produced; after which the butter begins to form. "In ſummer, while the climature is warm, the heating may be, without very much difficulty, continued until the acidity be produced, ſo that butter may be got: but in this caſe the proceſs is long and tedious; and the butter is for the moſt part of a ſoft conſiſtence, and tough and gluey to the touch. If this proceſs be attempted during the cold weather in winter, butter can ſcarcely be in any way obtained, unleſs by the application of ſome great degree of heat, which ſometimes aſſiſts in producing a very inferior kind of butter, white, hard, and brittle, and almoſt unfit for any culinary purpoſe whatever. The judicious farmer, therefore, will not attempt to imitate this practice, but will allow his cream to remain in the veſſel appropriated for keeping it, until it has acquired the proper degree of acidity. There is no rule for determining how long it is to be kept; but our author is of opinion, that a very great latitude is allowable in this caſe; and that if no ſerous matter be allowed to lodge among the cream, it may be kept good for making butter a great many weeks.

616 Of the churn.

The churn in which butter is made likewiſe admits of conſiderable diverſity; but our author prefers the old-faſhioned upright churn to all others, on account of its being more eaſily cleaned. The labour, when the cream is properly prepared, he thinks, very trifling. Much greater nicety, he ſays, is required in the proceſs of churning than moſt people are aware of; as a few haſty and irregular ſtrokes will render butter bad, which otherwiſe would have been of the fineſt quality. After the proceſs is over, the whole ought to be ſeparated from the milk, and put into a clean diſh, the inſide of which, if made of wood, ought to be well rubbed with common ſalt, to prevent the butter from adhering to it. The butter ſhould be preſſed and worked with a flat wooden ladle or ſkimming diſh, having a ſhort handle, ſo as to force out all the milk that was lodged in the cavities of the maſs. This operation requires a conſiderable degree of ſtrength as well as dexterity; but our author condemns the beating up of the butter with the hand as "an indelicate and barbarous practice." In like manner he condemns the employing of cold water in this operation, to *waſh* the butter as it is called. Thus, he ſays, the quality of it is debaſed in an aſtoniſhing degree. If it is too ſoft, it may be put into ſmall veſſels, and theſe allowed to ſwim in a tub of cold water; but the water ought never to touch the butter. The beating ſhould be continued till the milk be thoroughly ſeparated, but not till the butter become tough and gluey; and after this is completely done, it is next to be ſalted. The veſſel into which it is to be put muſt be well ſeaſoned with boiling water ſeveral times poured into it: the inſide is to be rubbed over with common ſalt, and a little melted butter poured into the cavity between the bottom and ſides, ſo as to make it even with the bottom; and it is then fit for receiving the butter. Inſtead of common ſalt alone, the doctor recommends the following compoſition. "Take of ſugar one part, of nitre one part, and of the beſt Spaniſh great ſalt two parts. Beat the whole into a fine powder, mix them well together, and put them by for uſe. One ounce of this is to be thoroughly mixed with a pound of butter as ſoon as it is freed from the milk, and then immediately put into the veſſel deſigned to hold it; after which it muſt be preſſed ſo cloſe as to leave no air-holes; the ſurface is to be ſmoothed and covered with a piece of linen, and over that a piece of wet parchment; or, in defect of this laſt, fine linen that has been dipped in melted butter, exactly fitted to the edges of the veſſel all round, in order to exclude the air as much as poſſible. When quite full, the caſk is to be covered in like manner, and a little melted butter put round the edges, in order to fill up effectually every cranny, and totally to exclude the air. "If all this (ſays the doctor) be carefully done, the butter may be kept perfectly ſound in this climate for many years. How many years I cannot tell; but I have ſeen it two years old, and in every reſpect as ſweet and ſound as when only a month old. It deſerves to be remarked, that butter cured in this manner does not taſte well till it has ſtood at leaſt a fortnight after being ſalted; but after that period is elapſed, it eats with a rich marrowy taſte that no other butter ever acquires; and it taſtes ſo little ſalt, that a perſon who had been accuſtomed to eat butter cured with common ſalt only, would not imagine it had got one-fourth part of the ſalt neceſſary to preſerve it." Our author is of opinion, that ſtrong brine may be uſeful to pour upon the ſurface during the time it is uſing, in order the more effectually to preſerve it from the air, and to avoid rancidity.

617 Butter ought not to be put into water.

618 Compoſition for preſerving butter.

619 To prepare butter for ſending to warm climates.

As butter contains a quantity of mucilaginous matter much more putreſcible than the pure oily part, our author recommends the purifying it from this mucilage by melting in a conical veſſel, in which the mucilage will fall to the bottom; the pure oily part ſwimming at top. This will be uſeful when butter is to be ſent a long voyage to warm climates, as the pure part will keep much better than when mixed with the other.

620 Preſerved by honey.

He propoſes another method of preſerving butter, viz. by mixing it with honey, which is very antiſeptic, and mixes intimately with the butter. Thus mixed, it eats very pleaſantly, and may perhaps be ſucceſsfully uſed with a medicinal intention.

621 Epping butter.

In England no butter is eſteemed equal to that which is made in the county of Eſſex, well known by the name of Epping butter, and which in every ſeaſon of the year yields at London a much higher price than any other. The following directions concerning the making and management of butter, including the Epping method, are extracted from the 3d volume of the Bath Society Papers.

In general it is to be obſerved, that the greater the quantity made from a few cows, the greater will be the farmer's profit: therefore he ſhould never keep any but what are eſteemed good milkers. A bad cow will be equally expenſive in her keep, and will not perhaps (by the butter and cheeſe that is made from her) bring in more than from three to ſix pounds a-year; whereas a good one will bring from ſeven to ten pounds *per annum*: therefore it is obvious that bad cows ſhould be parted with, and good ones purchaſed in their room. When ſuch are obtained, a good ſervant ſhould be employed to milk them; as through the neglect and miſmanagement of ſervants, it frequently happens that the

Management of the Dairy.

the beſt cows are ſpoiled. No farmer ſhould truſt entirely to ſervants, but ſometimes ſee themſelves that their cows are milked clean; for if any milk is ſuffered to remain in the udder, the cow will daily give leſs, till at length ſhe will become dry before the proper time, and the next ſeaſon ſhe will ſcarce give milk ſufficient to pay for her keep.

It ſometimes happens that ſome of a cow's teats may be ſcratched or wounded ſo as to produce foul or corrupted milk; when this is the caſe, we ſhould by no means mix it with the ſweet milk, but give it to the pigs; and that which is conveyed to the dairy-houſe ſhould remain in the pail till it is nearly cool, before it be ſtrained, that is, if the weather be warm; but in froſty weather it ſhould be immediately ſtrained, and a ſmall quantity of boiling water may be mixed with it, which will cauſe it to produce cream in abundance, and the more ſo if the pans or vats have a large ſurface.

During the hot ſummer months, it is right to riſe with or before the ſun, that the cream may be ſkimmed from the milk ere the dairy becomes warm; nor ſhould the milk, at that ſeaſon, ſtand longer in the vats, &c. than 24 hours, nor be ſkimmed in the evening till after ſunſet. In winter milk may remain unſkimmed for 36 or 48 hours. The cream ſhould be depoſited in a deep pan, which ſhould be kept during the ſummer in the cooleſt part of the dairy; or in a cool cellar where a free air is admitted, which is ſtill better. Where people have not an opportunity of churning every other day, they ſhould ſhift the cream daily into clean pans, which will keep it cool, but they ſhould never fail to churn at leaſt twice in the week in hot weather; and this work ſhould be done in a morning before the ſun appears, taking care to fix the churn where there is a free draught of air. If a pump-churn be to be uſed, it may be plunged a foot deep into a tub of cold water, and ſhould remain there during the whole time of churning, which will very much harden the butter. A ſtrong rancid flavour will be given to butter, if we churn ſo near the fire as to heat the wood in the winter ſeaſon.

After the butter is churned, it ſhould be immediately waſhed in many different waters till it is perfectly cleanſed from the milk; but here it muſt be remarked, that a warm hand will ſoften it, and make it appear greaſy, ſo that it will be impoſſible to obtain the beſt price for it. The cheeſemongers uſe two pieces of wood for their butter; and if thoſe who have a very hot hand were to have ſuch, they might work the butter ſo as to make it more ſaleable.

The Epping butter is made up for market in long rolls, weighing a pound each; in the county of Somerſet, they diſh it in half pounds for ſale; but if they forget to rub ſalt round the inſide of the diſh, it will be difficult to work it ſo as to make it appear handſome.

Butter will require and endure more working in winter than in ſummer; but it is remarked, that no perſon whoſe hand is warm by nature makes good butter.

Thoſe who uſe a pump-churn muſt endeavour to keep a regular ſtroke; nor ſhould they admit any perſon to aſſiſt them, except they keep nearly the ſame ſtroke: for if they churn more ſlowly, the butter will in the winter *go back*, as it is called; and if the ſtroke be more quick and violent in the ſummer, it will cauſe a fermentation, by which means the butter will imbibe a very diſagreeable flavour. Management of the Dairy.

Where people keep many cows, a barrel-churn is to be preferred; but if this be not kept very clean, the bad effects will be diſcovered in the butter; nor muſt we forget to ſhift the ſituation of the churn when we uſe it, as the ſeaſons alter, ſo as to fix it in a warm place in winter, and where there is a free air in ſummer.

In many parts of this kingdom they colour their butter in winter, but this adds nothing to its goodneſs; and it rarely happens that the farmers in or near Epping uſe any colour; but when they do, it is very innocent. They procure ſome round carrots, whoſe juice they expreſs through a ſieve, and mix with the cream when it enters the churn, which makes it appear like May butter; nor do they at any time uſe much ſalt, though a little is abſolutely neceſſary.

As they make in that county but very little cheeſe, ſo of courſe very little whey butter is made; nor indeed ſhould any perſon make it, except for preſent uſe, as it will not keep good more than two days; and the whey will turn to better account to fatten pigs with. Nothing feeds theſe faſter, nor will any thing make them ſo delicately white; at the ſame time it is to be obſerved, that no good bacon can be made from pigs thus fatted. Where much butter is made, good cheeſe for ſervants may be obtained from ſkimmed milk, and the whey will afterwards do for ſtore pigs.

622 Weſt of England mode of making butter.

The foregoing rules will ſuffice for making good butter in any country; but as ſome people are partial to the weſt country method, it ſhall be deſcribed as briefly as poſſible.

In the firſt place, they depoſite their milk in earthen pans in their dairy-houſe, and (after they have ſtood twelve hours in the ſummer, and double that ſpace in the winter) they remove them to ſtoves made for that purpoſe, which ſtoves are filled with hot embers; on theſe they remain till bubbles riſe, and the cream changes its colour; it is then deemed heated enough, and this they call ſcalded cream; it is afterwards removed ſteadily to the dairy, where it remains 12 hours more, and is then ſkimmed from the milk and put into a tub or churn: if it be put into a tub, it is beat well with the hand, and thus they obtain butter; but a cleanlier way is to make uſe of a churn. Some ſcald it over the fire, but then the ſmoke is apt to affect it; and in either caſe, if the pans touch the fire, they will crack or fly, and the milk and cream will be waſted.

623 Cambridgeſhire butter.

The Cambridgeſhire ſalt butter is held in the higheſt eſteem, and is made nearly after the ſame method as the Epping; and by waſhing and working the ſalt from it the cheeſemongers in London often ſell it at a high price for freſh butter. They depoſite it when made into wooden tubs or firkins, which they expoſe to the air for two or three weeks, and often wath them; but a readier way is to ſeaſon them with unſlaked lime, or a large quantity of ſalt and water well boiled will do; with this they muſt be ſcrubbed ſeveral times, and afterwards thrown into cold water, where they ſhould remain three or four days, or till they are wanted; then they ſhould be ſcrubbed as before, and well rinſed with cold water; but before they receive the butter,

care

Manage-ment of the Dairy.

care muſt be taken to rub every part of the firkin with ſalt: then, if the butter be properly made, and perfectly ſweet, it may be gently preſſed into the firkin; but it muſt be well ſalted when it is made up, and the ſalt ſhould be equally diſtributed through the whole maſs, and a good handful of ſalt muſt be ſpread on the top of the firkin before it is heated, after which the head ſhould be immediately put on.

624 Yorkſhire and Suffolk butter.

They purſue nearly the ſame method in Suffolk and Yorkſhire; nor is the butter that is made in theſe counties much inferior to that made in Cambridgeſhire; indeed it is often ſold in London for Cambridge butter: and no people make more butter from their cows than the Yorkſhire farmers do, which is certainly owing to the care they take of their cows in the winter; as at that ſeaſon they houſe them all, feed them with good hay, and never ſuffer them to go out (except to water) but when the weather is very ſerene; and when their cows calve, they give them comfortable malt meſhes for two or three days after; but theſe cows never anſwer if they are removed to other counties, except the ſame care and attendance be given them, and then none anſwer better.

Land whereon cows feed does very often affect the butter. If wild garlic, charlock, or May-weed, be found in a paſture ground, cows ſhould not feed therein till after they have been mown, when ſuch pernicious plants will appear no more till the following ſpring; but thoſe cows that give milk muſt not partake of the hay made therefrom, as that will alſo diffuſe its bad qualities.

Great part of the Epping butter is made from cows that feed during the ſummer months in Epping Foreſt, where the leaves and ſhrubby plants contribute greatly to the flavour of the butter. The mountains of Wales, the highlands of Scotland, and the moors, commons, and heaths in England, produce excellent butter where it is properly managed; and though not equal in quantity, yet far ſuperior in quality to that which is produced from the richeſt meadows; and the land is often blamed when the butter is bad through miſmanagement, ſluttiſhneſs, or inattention.

Turnips and rape affect milk and butter, but brewers grains are ſweet and wholeſome food, and will make cows give abundance of milk; yet the cream thereon will be thin, except good hay be given at the ſame time, after every meal of grains. Coleworts and cabbages are alſo excellent foods; and if theſe and ſavoys were cultivated for this purpoſe, the farmers in general would find their account in it.

Cows ſhould never be ſuffered to drink improper water; ſtagnated pools, water wherein frogs, &c. ſpawn, common ſewers, and ponds that receive the drainings of ſtables, are improper.

625 Frauds in the ſale of butter.

Divers abuſes are committed in the packing and ſalting of butter, to increaſe its bulk and weight, againſt which we have a ſtatute expreſs. Pots are frequently laid with good butter for a little depth at the top, and with bad at the bottom; ſometimes the butter is ſet in rolls, only touching at top, and ſtanding hollow at bottom. To prevent theſe cheats, the factors at Utoxeter keep a ſurveyor, who, in caſe of ſuſpicion, tries the pots with an iron inſtrument called a *butter-bore*, made like a cheeſe-taſter, to be ſtuck in obliquely to the bottom.

In the Annals of Agriculture, vol. xvii. the following mode of preventing butter and cream from receiving a taint from the cows feeding on cabbages and turnips is ſtated by J. Jones, Eſq. of Bolas-heath, Newport, Shropſhire. "I find by experience (ſays he), that a ſmall bit of ſaltpetre, powdered and put into the milk-pan, with the new milk, does effectually prevent the cream and butter from being tainted, although the cows be fed on the refuſe leaves of cabbages and turnips. In the beginning of this laſt winter, my men were very careful in not giving to the cows any outſide or decayed leaves of the cabbages or turnips; yet the cream and butter were ſadly tainted: but as ſoon as the maid uſed the ſaltpetre, all the taint was done away; and afterwards no care was taken in feeding the cows, for they had cabbages and turnips in all ſtates. Our milk-pans hold about nine pints of milk."

Manage-ment of t Dairy.

626 How but may be kept un-tainted b cabbages and turni

627 Extent of the butter trade.

The trade in butter is very conſiderable. Some compute 50,000 tons annually conſumed in London. It is chiefly made within 40 miles round the city. Fifty thouſand firkins are ſaid to be ſent yearly from Cambridge and Suffolk alone; each firkin containing 56 lbs. Utoxeter, in Staffordſhire, is a market famous for good butter, inſomuch, that the London merchants have eſtabliſhed a factory there for that article. It is bought by the pot, of a long cylindrical form, weighing 14 lbs.

628 Cheeſe de ſcribed.

The other grand object of the dairy is cheeſe-making. Cheeſe is the curd of milk, precipitated or ſeparated from the whey by an acid. Cheeſe differs in quality according as it is made from new or ſkimmed milk, from the curd which ſeparates ſpontaneouſly upon ſtanding, or that which is more ſpeedily produced by the addition of runnet. Cream alſo affords a kind of cheeſe, but quite fat and butyraceous, and which does not keep long. Analyzed chemically, cheeſe appears to partake much more of an animal nature than butter, or the milk from which it was made. It is inſoluble in every liquid except ſpirit of nitre, and cauſtic alkaline ley. Shaved thin, and properly treated with hot water, it forms a very ſtrong cement if mixed with quicklime *. When prepared with the hot water, it is recommended in the Swediſh Memoirs to be uſed by anglers as a bait. It may be made into any form, is not ſoftened by the cold water, and the fiſhes are fond of it. As a food, phyſicians condemn the too free uſe of cheeſe. When new, it is extremely difficult of digeſtion: when old, it becomes acrid and hot; and, from Dr Percival's experiments, is evidently of a ſeptic nature. It is a common opinion that old cheeſe digeſts every thing, yet is left undigeſted itſelf; but this is without any ſolid foundation. Cheeſe made from the milk of ſheep digeſts ſooner than that from the milk of cows, but is leſs nouriſhing; that from the milk of goats digeſts ſooner than either, but is alſo the leaſt nouriſhing. In general, it is a kind of food fit only for the laborious, or thoſe whoſe organs of digeſtion are ſtrong.

* See *Cement.*

Every country has places noted for this commodity: thus Cheſter and Glouceſter cheeſe are famous in England; and the Parmeſan cheeſe is in no leſs repute abroad, eſpecially in France. This ſort of cheeſe is entirely made of ſweet cow-milk: but at Rochefort in Languedoc, they make it of ewes milk; and in other places it is uſual to add goat or ewes milk in a certain proportion to that of the cow. There is likewiſe a kind

Management of the Dairy

kind of medicated cheese made by intimately mixing the expressed juice of certain herbs, as sage, baum, mint, &c. with the curd before it is fashioned into a cheese. The Laplanders make a sort of cheese of the milk of their rein-deer; which is not only of great service to them as food, but on many other occasions. It is a very common thing in these climates to have a limb numbed and frozen with the cold: their remedy for this is the heating an iron red hot, and thrusting it through the middle of one of these cheeses; they catch what drops out, and with this anoint the limb, which soon recovers. They are subject also to coughs and diseases of the lungs, and these they cure by the same sort of medicine: they boil a large quantity of the cheese in the fresh deer's milk, and drink the decoction in large draughts warm several times a-day. They make a less strong decoction of the same kind also, which they use as their common drink, for three or four days together, at several times of the year. They do this to prevent the mischiefs they are liable to from their water, which is otherwise their constant drink, and is not good.

619 Making of cheese.

In making cheese the same precaution is to be observed as with regard to butter, viz. the milk ought not to be agitated by carrying to any distance; nor ought the cows to be violently driven before they are milked, which reduces the milk almost to the same state as if agitated in a barrel or churn. To this cause Mr Twamley, who has written a treatise upon dairy management, attributes the great difficulty sometimes met with in making the milk coagulate; four or five hours being sometimes necessary instead of one (the usual time employed); and even after all, the curd will be of such a soft nature, that the cheese will swell, puff up, and rent in innumerable places, without ever coming to that solid consistence which it ought to have. As this frequently happens in consequence of heat, Mr Twamley advises to mix a little cold spring water with the milk. It is a bad practice to put in more runnet when the curd appears difficult to be formed, for this, after having once formed the curd by the use of a certain quantity, will dissolve it again by the addition of more.

630 General defects of cheese.

The most common defects of cheese are its appearing when cut full of small holes called *eyes;* its puffing up, cracking, and pouring out quantities of thin serous liquor; becoming afterwards rotten and full of maggots in those places from which the liquor issued. All this, according to our author, proceeds from the formation of a substance called by him *slip curd*, a kind of half coagulum, incapable of a thorough union with the true curd, and which when broken into very small bits produces *eyes;* but if in larger pieces, occasions those rents and cracks in the cheese already mentioned; for though this kind of curd retains its coagulated nature for some time, it always sooner or later dissolves into a serous liquid. This kind of curd may be produced, 1. By using the milk too hot. 2. By bad runnet. 3. By not allowing the curd a proper time to form. The first of these is remedied by the use of cold water, which our author says is so far from being detrimental to the quality of the cheese, that it really promotes the action of the runnet upon the milk. The second, viz. a knowledge of good from bad runnet, can only be acquired by long practice, and no particular directions can be given, farther than that the utmost care must be taken that it have no putrid tendency, nor any rancidity from too great heat in drying. The only rule that can be given for its preparation is to take out the maw of a calf which has fed entirely upon milk; and if it is cold, swill it a little in water; rub it well with salt; then fill it with the same, and afterwards cover it. Some cut them open and spread them in salt, putting them in layers above one another, letting them continue in the brine they produce, sometimes stirring or turning them for four, six, or nine months; after which they are opened to dry, stretched out upon sticks or splints. They may be used immediately after being dried, though it is reckoned best to keep them till they be a year old before they are used. The best method of making the runnet from the skins, according to our author, is the following: "Take pure spring water, in quantity proportioned to the runnet you intend to make; it is thought best by some two skins to a gallon of water; boil the water, which makes it softer or more pure: make it with salt into brine that will swim an egg: then let it stand till the heat is gone off to about the heat of blood-warm; then put your maw skin in, either cut in pieces or whole; the former I should imagine best or most convenient; letting it steep 24 hours, after which it will be fit for use. Such quantity as is judged necessary must then be put into the milk; about a tea-cupful being necessary for ten cows milk; though in this respect very particular directions cannot be given."

Management of the Dairy.

631 Of preparing runnet.

632 Mr Hazard's receipt for runnet.

In the Bath Papers Mr Hazard gives the following receipt for making runnet: "When the maw-skin is well prepared and fit for the purpose, three pints or two quarts of soft water, clean and sweet, should be mixed with salt, wherein should be put sweet brier, rose leaves and flowers, cinnamon, cloves, mace, and in short almost every sort of spice and aromatic that can be procured; and if these are put into two quarts of water, they must boil gently till the liquor is reduced to three pints, and care should be taken that this liquid is not smoked; it should be strained clear from the spices, &c. and when found not to be warmer than milk from the cow; it should be poured upon the vell or maw; a lemon may then be sliced into it, when it may remain a day or two; after which it should be strained again and put into a bottle, where, if well corked, it will keep good for twelve months or more; it will smell like a perfume, and a small quantity of it will turn the milk, and give the cheese a pleasing flavour." He adds, that if the vell or maw be salted and dried for a week or two near the fire, it will do for the purpose again almost as well as before.

633 Particulars to be observed in making of cheese.

In the making of cheese, supposing the runnet to be of a good quality, the following particulars must be observed: 1. The proper degree of heat. This ought to be what is called *milk-warm*, or, "a few degrees removed from coolness," according to Mr Twamley; considerably below the heat of milk taken from the cow. If too hot, it may be reduced to a proper temperature by cold water, as already mentioned. 2. The time allowed for the runnet to take effect. This, our author observes ought never to be less than an hour and a half. The process may be accelerated, particularly by putting salt to the milk before

Manage-ment of the Dairy.

for the runnet is added. Mr Twamley adviſes two handfuls to ten or twelve cows milk; but he aſſures us, that no bad conſequence can follow from the curd being formed ever ſo ſoon; as it then only becomes more ſolid and fit for making cheeſe of a proper quality. 3. To prevent any difficulty in ſeparating the curd from the whey, prepare a long cheeſe-knife from lath; one edge being ſharpened to cut the curd acroſs from top to bottom in the tub, croſſing it with lines checkerwiſe: by which means the whey riſes through the vacancies made by the knife, and the curd ſinks with much more eaſe. A ſieve has been uſed with ſucceſs, in order to ſeparate the whey perfectly from the curd. 4. Having got the curd all firm at the bottom of the tub, take the whey from it; let it ſtand a quarter of an hour to drain before you put it into the vat to break it. If any bits of ſlip-curd ſwim among the whey, pour it all off together rather than put it among the cheeſe, for the reaſons already given. Some dairy-women allow the curd to ſtand for two hours; by which time it is become of ſo firm a nature that no breaking is neceſſary: they have only to cut it in ſlices, put it into the vat, and work it well by ſqueezing thoroughly to make it ſit cloſe; then put it into the preſs. Our author, however, approves more of the method of breaking the curd, as leſs apt to make the cheeſe hard and horny. 5. When the whey is of a white colour, it is a certain ſign that the curd has not ſubſided; but if the method juſt now laid down be followed, the whey will always be of a green colour; indeed this colour of the whey is always a certain criterion of the curd having been properly managed. 6. The beſt method of preventing cheeſe from heaving, is to avoid making the runnet too ſtrong; to take care that it be clean, and not tainted; to be certain that the curd is fully come, and not to ſtir it before the air has had time to eſcape; a quantity of air being always diſcharged in this as in many other chemical proceſſes. 7. Cheeſe is very apt to ſplit in conſequence of being "ſalted within," eſpecially when the vat is about half filled. In this caſe the curd, though ſeparated only in a ſmall degree by the ſalt, never cloſes or joins as it ought to do. Mr Twamley preſers ſalting in the milk greatly to this method. 8. Dry cracks in cheeſe are generally produced by keeping curd from one meal to another, and letting the firſt become too ſtiff and hard before it is mixed with the other. 9. Curdly or wrinkle-coated cheeſe is cauſed by ſour milk. Cheeſe made of cold milk is apt to be hard, or to break and fly before the knife. 10. Such coated cheeſe is cauſed by being made too cold, as cheeſe that is made in winter or late in autumn is apt to be, unleſs laid in a warm room after it is made.

634 Different kinds of cheeſe.

Cheeſe is of very different quality, according to the milk from which it is made: Thus, in Glouceſterſhire, what is called the *ſecond* or *two-meal* cheeſe, is made from one meal of new milk and one of ſkimmed or old milk, having the cream taken away. Skimmed cheeſe or *ſlet-milk* cheeſe, is made entirely from ſkimmed milk, the cream having been taken off to make butter. It goes by the name of *Suffolk cheeſe*, and is much uſed at ſea; being leſs liable to be affected by the heat of warm climates than the other kinds. A great deal of difference, however, is to be obſerved in the quality of it, which our author ſuppoſes to ariſe chiefly from greater care being taken in ſome places than in others.

Manage-ment of the Dairy.

Slip-coat or ſoft cheeſe is made entirely of ſlip-curd, and diſſolves into a kind of creamy liquor; which is a demonſtration of the nature of this curd, as already mentioned. It is commonly computed, that as much milk is required to make one pound of butter as two of cheeſe; and even more where the land is poor, and the paſtures afford but little cream.

635 Double Glouceſte

Beſt methods of making cheeſe in England. The double Glouceſter is a cheeſe that pleaſes almoſt every palate. The beſt of this kind is made from new, or (as it is called in that and the adjoining counties) *covered milk*. An inferior ſort is made from what is called *half-covered milk*; though when any of theſe cheeſes turn out to be good, people are deceived, and often purchaſe them for the beſt *covered milk cheeſe*: but farmers who are honeſt have them ſtamped with a piece of wood made in the ſhape of a heart, ſo that any perſon may know them.

It will be every farmer's intereſt (if he has a ſufficient number of cows) to make a large cheeſe from one meal's milk. This, when brought in warm, will be eaſily changed or turned with the runnet; but if the morning or night's milk be to be mixed with that which is freſh from the cow, it will be a longer time before it turns, nor will it change ſometimes without being heated over the fire, by which it often gets duſt or ſoot, or ſmoke, which will give the cheeſe a very diſagreeable flavour.

When the milk is turned, the whey ſhould be carefully ſtrained from the curd. The curd ſhould be broken ſmall with the hands; and when it is equally broken, it muſt be put by a little at a time into the vat, carefully breaking it as it is put in. The vat ſhould be filled an inch or more above the brim, that when the whey is preſſed out, it may not ſhrink below the brim; if it does, the cheeſe will be worth very little. But firſt, before the curd is put in, a cheeſe-cloth or ſtrainer ſhould be laid at the bottom of the vat: and this ſhould be ſo large, that when the vat is filled with the curd, the ends of the cloth may turn again over the top of it. When this is done, it ſhould be taken to the preſs, and there remain for the ſpace of two hours, when it ſhould be turned and have a clean cloth put under it and turned over as before. It muſt then be preſſed again, and remain in the preſs ſix or eight hours; when it ſhould again be turned and rubbed on each ſide with ſalt. After this it muſt be preſſed again for the ſpace of 12 or 14 hours more; when, if any of the edges project, they ſhould be pared off: it may then be put on a dry board, where it ſhould be regularly turned every day. It is a good way to have three or four holes bored round the lower part of the vat, that the whey may drain ſo perfectly from the cheeſe as not the leaſt particle of it may remain.

The prevailing opinion of the people of Glouceſterſhire and the neighbouring counties is, that the cheeſes will ſpoil if they do not ſcrape and waſh them when they are found to be mouldy. But others think that ſuffering the mould to remain mellows them, provided they are turned every day. Thoſe, however, who will have the mould off, ſhould cauſe it to be removed with a clean dry flannel, as the waſhing the cheeſes

is

Manage-ment of the Dairy.

is only a means of making the mould (which is a ſpecies of fungus rooted in the coat) grow again immediately.

Some people ſcald the curd: but this is a bad and mercenary practice; it robs the cheeſe of its fatneſs, and can only be done with a view to raiſe a greater quantity of whey butter, or to bring the cheeſes forward for ſale, by making them appear older than they really are.

As moſt people like to purchaſe high coloured cheeſe, it may be right to mix a little arnotto with the milk before it is turned. No cheeſe will look yellow without it; and though it does not in the leaſt add to the goodneſs, it is perfectly innocent in its nature and effects.

636 Chedder cheeſe.

Chedder cheeſe is held in high eſteem; but its goodneſs is ſaid to be chiefly owing to the land whereon the cows feed, as the method of making it is the ſame as is purſued throughout Somerſetſhire, and the adjoining counties.

637 Cheſhire cheeſe.

Cheſhire cheeſe is much admired; yet no people take leſs pains with the runnet than the Cheſhire farmers. But their cheeſes are ſo large as often to exceed one hundred pounds weight each; to this (and the age they are kept, the richneſs of the land, and the keeping ſuch a number of cows as to make ſuch a cheeſe without adding a ſecond meal's milk) their excellence may be attributed. Indeed they ſalt the curd (which may make a difference), and keep the cheeſes in a damp place after they are made, and are very careful to turn them daily.

The following account of the mode of making this cheeſe is ſtated in the Annals of Agriculture, by Mr John Chamberlaine of Cheſter. "The proceſs of making Cheſhire cheeſe is as follows, viz. on a farm capable of keeping 25 cows, a cheeſe of about ſixty pounds weight may be daily made, in the months of May, June, and July.

"The evening's milk is kept untouched until next morning, when the cream is taken off, and put to warm in a braſs pan heated with boiling water; then one-third part of that milk is heated in the ſame manner, ſo as to bring it to the heat of new milk from the cow; (This part of the buſineſs is done by a perſon who does not aſſiſt in milking the cows during that time.) Let the cows be milked early in the morning; then the morning's new milk and the night's milk, thus prepared, are put into a large tub together with the cream; then a portion of runnet that has been put into water milk-warm the evening before is put into the tub, ſufficient to coagulate the milk; and at the ſame time, if arnotto be uſed to colour the cheeſe, a ſmall quantity, as requiſite for colouring, (or a marigold or carrot infuſion) is rubbed very fine, and mixed with the milk, by ſtirring all together; then covering it up warm, it is to ſtand about half an hour, or until coagulated; at which time it is firſt turned over with a bowl, to ſeparate the whey from the curds, and broken ſoon after with the hand and bowl into very ſmall particles; the whey being ſeparated by ſtanding ſome time, is taken from the curd, which ſinks to the bottom; the curd is then collected into a part of the tub which has a ſlip or looſe board acroſs the diameter of the bottom of it, for the ſole uſe of ſeparating them; and a board is placed thereon, with weights, from ſixty to a hundred and twenty pounds, to preſs out the whey: when it is getting into a more ſolid conſiſtence, it is cut, and turned over in ſlices ſeveral times, to extract all the whey, and then weighted as before; which operations may take up about an hour and a half. It is then taken from the tub, as near the ſide as poſſible, and broken very ſmall by hand, and ſalted, and put into a cheeſe vat, enlarged in depth by a tin hoop to hold the quantity, it being more than bulk when finally put into the preſs. Then preſs the ſide well by hand, and with a board at top well weighted; and placing wooden ſkewers round the cheeſe to the centre, and drawing them out frequently, the upper part of the cheeſe will be drained of its whey: then ſhift it out of the vat; firſt put a cloth upon the top of it, and reverſe it on the cloth into another vat, or the ſame, which vat ſhould be well ſcalded before the cheeſe is returned into it; then the top part is broken by hand down to the middle, and ſalt mixed with it, and ſkewered as before, then preſſed by hand, weighted, and all the whey extracted. This done, reverſe the cheeſe again into another vat, warmed as before, with a cloth under it; then a tin hoop or binder is put round the upper edge of the cheeſe and within the ſides of the vat, the cheeſe being firſt incloſed in a cloth, and the edges of it put within the vat.

"N. B. The cloth is of fine hemp, one yard and a half long by one yard wide. It is ſo laid, that on one ſide of the vat it ſhall be level with the ſide of it, on the other it ſhall lap over the whole of the cheeſe, and the edges put within the vat; and the tin fillet to go over the whole. All the above operations will take from ſeven in the morning till one at noon. Finally, it is put into a preſs of fifteen or twenty cwt. and ſtuck round the vat into the cheeſe with thin wire ſkewers, which are ſhifted occaſionally. In four hours more, it ſhould be ſhifted and turned, and in four hours more, the ſame, and the ſkewering continued. Next morning, let it be turned by the woman who attends the milk, and put under another or the ſame preſs, and ſo turned at night and the next morning; at noon, taken out finally to the ſalting room, there ſalt the outſide, and put a cloth binder round it. The cheeſe ſhould, after ſuch ſalting, be turned twice a-day for ſix or ſeven days, then left two or three weeks to dry, turned and cleaned every day, taken to the common cheeſe room, laid on ſtraw on a boarded floor, and daily turned until grown hard.

"The room ſhould be moderately warm; but no wind or draught of air ſhould be permitted, which generally cracks them. Some rub the outſides with butter or oil to give them a coat.

"The ſpring-made cheeſe is often ſhipped for the London market in the following autumn, and it is ſuppoſed to be much ameliorated by the heating on board the veſſel."

Manage-ment of the Dairy.

638 Stilton cheeſe.

But of all the cheeſe this kingdom produces, none is more highly eſteemed than the Stilton, which is called the *Parmeſan* of England, and (except faulty) is never ſold for leſs than 1s. or 1s. 2d. per pound.

The Stilton cheeſes are uſually made in ſquare vats, and weigh from ſix to twelve pounds each cheeſe. Immediately after they are made, it is neceſſary to put them into ſquare boxes made exactly to fit them; they being ſo extremely rich, that except this precaution

Management of the Dairy.

be taken they are apt to bulge out, and break aſunder. They ſhould be continually and daily turned in theſe boxes, and muſt be kept two years before they are properly mellowed for ſale.

Some make them in a net ſomewhat like a cabbage net; ſo that they appear, when made, not unlike an acorn. But theſe are never ſo good as the other, having a thicker coat, and wanting all that rich flavour, and mellowneſs which make them ſo pleaſing.

It is proper to mention that the making of theſe cheeſes is not confined to the Stilton farmers, as many others in Huntingdonſhire (not forgetting Rutland and Northamptonſhire) make a ſimilar ſort, ſell them for the ſame price, and give all of them the name of *Stilton cheeſes*.

Though theſe farmers are remarked for cleanlineſs, they take very little pains with the runnet, as they in general only cut pieces from the vell or maw, which they put into the milk, and move gently about with the hand, by which means it breaks or turns it ſo, that they eaſily obtain the curd. But if the method above deſcribed for making runnet were put in practice, they would make their cheeſe ſtill better; at leaſt they would not have ſo many faulty and unſound cheeſes; for notwithſtanding their cheeſes bear ſuch a name and price, they often find them ſo bad as not to be ſaleable; which is probably owing to their being ſo careleſs about the runnet.

It has been alleged, that as good cheeſe might be made in other counties, if people would adhere to the Stilton plan, which is this: They make a cheeſe every morning; and to this meal of new milk they add the cream taken from that which was milked the night before. This, and the age of their cheeſes, have been ſuppoſed the only reaſons why they are preferred to others; for, from the niceſt obſervation, it does not appear that their land is in any reſpect ſuperior to that of other counties.

Excellent cream cheeſes are made in Lincolnſhire, by adding the cream of one meal's milk to milk which comes immediately from the cow; theſe are preſſed gently two or three times, turned for a few days, and are then diſpoſed of at the rate of 1s. per pound, to be eaten while new with radiſhes, ſalad, &c.

Many people give ſkimmed milk to pigs; but the whey will do equally well after cheeſes are made from this milk: ſuch cheeſes will always ſell for at leaſt 2d. per pound, which will amount to a large ſum annually where they make much butter. The peaſants and many of the farmers in the north of England never eat any better cheeſe; and though they appear harder, experience hath proved them to be much eaſier of digeſtion than any new milk cheeſes. A good market may always be found for the ſale of them at Briſtol.

630 Parmeſan cheeſe.

Account of the making of Parmeſan cheeſe; by Mr Zappa of Milan: in anſwer to queries from Arthur Young, Eſq.

"Are the cows regularly fed in ſtables?"—From the middle of April, or ſooner, if poſſible, the cows are ſent to paſture in the meadows till the end of November uſually.

"Or only fed in ſtables in winter?"—When the ſeaſon is paſt, and ſnow comes, they are put into ſtables for the whole winter, and fed with hay.

"Do they remain in the paſture from morning till night, or only in hot weather?"—Between nine and ten in the morning the cows are ſent to water, and then to the paſtures, where they remain four or five hours at moſt, and at three or four o'clock are driven to the ſtables if the ſeaſon is freſh, or under porticoes if hot; where, for the night, a convenient quantity of hay is given them. Management of the Dairy.

"In what months are they kept at paſture the whole day?"—Moſtly anſwered already; but it might be ſaid, that no owner will leave his cattle, without great cauſe, in uncovered places at night. It happens only to the ſhepherds from the Alps, when they paſs, becauſe it is impoſſible to find ſtables for all their cattle.

"What is the opinion in the Lodeſan, on the beſt conduct for profit in the management of meadows?"—For a dairy farm of 100 cows, which yields daily a cheeſe weighing 70 or 75 lb. of 28 ounces, are wanted 1000 perticas of land. Of theſe about 800 are ſtanding meadows, the other 200 are in cultivation for corn and graſs fields in rotation.

"Do they milk the cows morning and evening?"—Thoſe that are in milk are milked morning and evening, with exception of ſuch as are near calving.

"One hundred cows being wanted to make a Lodeſan each day, it is ſuppoſed that it is made with the milk of the evening and the following morning; or of the morning and evening of the ſame day: how is it?"—The 100 cows form a dairy farm of a good large cheeſe; it is reckoned that 80 are in milk, and 20 with calves ſucking, or near calving. They reckon one with the other about 32 boccalis of 32 oz. of milk. Such is the quantity for a cheeſe of about 70 lb. of 28 ounces. They join the evening with the morning milk, becauſe it is freſher than if it was that of the morning and evening of the ſame day. The morning milk would be 24 hours old when the next morning the cheeſe ſhould be made.

"Do they ſkim or not the milk to make butter before they make the cheeſe?"—From the evening milk all the cream poſſible is taken away for butter, maſcarponi (cream cheeſe), &c. The milk of the morning ought to be ſkimmed ſlightly; but every one ſkims as much cream as he can. The butter is ſold on the ſpot immediately at 24 ſous: the cheeſe at about 28 ſous. The butter loſes nothing in weight: the cheeſe loſes one-third of it, is ſubject to heat, and requires expences of ſervice, attention, warehouſes, &c. before it is ſold; and a man in two hours makes 45 or 50 lb. of butter that is ſold directly. However, it is not poſſible to leave much cream in the milk to make Lodeſan cheeſe, called *grained cheeſe;* becauſe, if it is too rich, it does not laſt long, and it is neceſſary to conſume it while young and ſound.

"Is Parmeſan or Lodeſan cheeſe made every day in the year or not?"—With 100 cows it is. In winter, however, the milk being leſs in quantity, the cheeſe is of leſſer weight, but certainly more delicate.

"After gathering or uniting the milk, either ſkimmed or not, what is exactly the whole operation?"—The morning of the 3d of March 1786, I have ſeen the whole operation, having gone on purpoſe to the ſpot to ſee the whole work from beginning to end. "At 16 Italian hours, or ten in the morning, according to the

Management of the Dairy.

the northern way to account hours, the ſkimming of that morning's milk, gathered only two hours before, was finiſhed. I did, meanwhile, examine the boiler or pot. At the top it was eight feet (Engliſh) diameter, or thereabout; and about five feet three inches deep, made like a bell, and narrowing towards the bottom to about two and one-half feet. They joined the cream produced that morning with the other produced by the milk of the evening before. That produced by this laſt milk was double in quantity to that of the morning milk, becauſe it had the whole night to unite, and that of the morning had only two hours to do it: in which it could not ſeparate much. Of the cream, ſome was deſtined to make maſcarponics (cream cheeſe), and they put the reſt into the machine for making butter. Out of the milk of the evening before and of that morning, that was all put together after ſkimming, they took and put into the boiler 272 boccali, and they put under it two faggots of wood; which being burnt, were ſufficient to give the milk a warmth a little ſuperior to lukewarm. Then the boiler being withdrawn from the fire, the foreman put into it the runnet, which they prepare in ſmall balls of one ounce each, turning the ball in his hand always kept in the milk entirely covered; and after it was perfectly diſſolved, he covered the boiler to keep the milk defended, that it might not ſuffer from the coldneſs of the ſeaſon, particularly as it was a windy day. I went then to look on the man that was making maſcarponies, &c. and then we went twice to examine if the milk was ſufficiently coagulated. At the 18 hours, according to the Italian clocks, or noon, the true manufactory of cheeſe began. The milk was coagulated in a manner to be taken from the boiler in pieces from the ſurface. The foreman, with a ſtick that had 18 points, or rather nine ſmall pieces of wood fixed by their middle in the end of it, and forming nine points on each ſide, began to break exactly all the coagulated milk, and did continue to do ſo for more than half an hour, from time to time examining it to ſee its ſtate. He ordered to renew the fire, and four faggots of willow branches were uſed all at once: he turned the boiler that the fire might act; and then the underman began to work in the milk with a ſtick, like the above, but only with four ſmaller ſticks at the top, forming eight points, four at each ſide, a ſpan long each point. In a quarter of an hour the foreman mixed in the boiler the proper quantity of ſaffron, and the milk was all in knobs, and finer grained than before, by the effect of turning and breaking the coagulation, or curd, continually. Every moment the fire was renewed or fed; but with a faggot only at a time, to continue it regular. The milk was never heated much, nor does it hinder to keep the hand in it to know the fineneſs of the grain, which refines continually by the ſtick-work of the underman. It is of the greateſt conſequence to mind when the grain begins to take a conſiſtence. When it comes to this ſtate, the boiler is turned from the fire, and the underman immediately takes out the whey, putting it into proper receivers. In that manner the grain ſubſides to the bottom of the boiler; and leaving only in it whey enough to keep the grain covered a little, the foreman extending himſelf as much as he can over and in the boiler, unites with his hands the grained milk, making like a body of paſte of it. Then a large piece of linen is run by him under that paſte, while another man keeps the four corners of it, and the whey is directly put again into the boiler, by which is facilitated the means of raiſing that paſte that is taken out of the boiler, and put for one quarter of an hour into the receiver where the whey was put before, in the ſame linen it was taken from the boiler; which boiler is turned again directly on the fire, to extract the maſcarpa (whey cheeſe); and is a ſecond product, eaten by poor people. After the paſte remained for a quarter of an hour in that receiver, it was taken out and turned into the wooden form called *faſſera*, without any thing elſe made than the rotundity, having neither top nor bottom. Immediately after having turned it into that round wooden form, they put a piece of wood like a cheeſe on it, putting and increaſing gradually weights on it, which ſerve to force out the remnant of the whey; and in the evening the cheeſe ſo formed is carried into the warehouſe, where, after 24 hours, they begin to give the ſalt. It remains in that warehouſe for 15 or 20 days; but in ſummer only from 8 to 12 days. Meanwhile the air and ſalt form the cruſt to it; and then it is carried into another warehouſe for a different ſervice. In the ſecond warehouſe they turn every day all the cheeſes that are not older than ſix months; and afterwards it is enough if they are only turned every 48 or 60 hours, keeping them clean, in particular, of that bloom which is inevitable to them, and which, if neglected, turns muſty, and cauſes the cheeſe to acquire a bad ſmell. The Lodeſan, becauſe it is a province watered, has a great deal of meadows, and abounds with cows, its product being moſtly in cheeſe, butter, &c. However, the province of Pavia makes a great deal of that cheeſe; and we Milaneſe do likewiſe the ſame from the ſide of Porte Toſa, Romana, Ticineſe, and Vercilino, becauſe we have fine meadows and dairy farms.

Making of Fruit-Liquors.

SECT. IX. *Making of Fruit-Liquors.*

640 Fruit-liquors.

THESE, as objects of Britiſh huſbandry, are principally two, *Cyder* and *Perry*; the manufacturing of which forms a capital branch in our fruit-counties, and of which the improvement muſt be conſidered as of great importance to the public, but particularly ſo to the inhabitants of thoſe diſtricts where theſe liquors conſtitute their common beverage.

641 Excellence of cyder and perry.

Cyder and perry, when genuine and in high perfection, are excellent vinous liquors, and are certainly far more wholeſome than many others which at preſent are in much higher eſtimation. When the muſt is prepared from the choiceſt fruit, and undergoes the exact degree of vinous fermentation requiſite to its perfection, the acid and the ſweet are ſo admirably blended with the aqueous, oily, and ſpirituous principles, and the whole ſo imbued with the grateful flavour of the rinds, and the agreeable aromatic bitter of the kernels, that it aſſumes a new character; grows lively, ſparkling, and exhilarating; and when completely mellowed by time, the liquor becomes at once highly delicious to the palate, and congenial to the conſtitution; ſuperior in every reſpect to moſt other Engliſh wines, and perhaps not inferior to many of the beſt foreign wines. Such (ſays Dr Fothergill *) would

* *Bath Papers*, vol. v. p. 343.

Making of Fruit-Liquors.

would it be pronounced by all competent judges, were it not for the popular prejudice annexed to it as a cheap home-brewed liquor, and conſequently within the reach of the vulgar. To compare ſuch a liquor with the foreign fiery ſophiſticated mixtures often imported under the name of wines, would be to degrade it; for it certainly ſurpaſſes them in flavour and pleaſantneſs, as much as it excels them in wholeſomeneſs and cheapneſs. But rarely do we meet with perry or cyder of this ſuperior quality. For what is generally ſold by dealers and inn-keepers is a poor, meagre, vapid liquor, prone to the acetous fermentation, and of courſe very injurious to the conſtitution. Is it not very mortifying, after the experience of ſo many centuries, that the art of preparing thoſe ancient Britiſh liquors ſhould ſtill be ſo imperfectly underſtood as to ſeem to be in its very infancy?—That throughout the principal cyder diſtricts, the practice ſhould ſtill reſt on the moſt vague indeterminate principles, and that the excellence of the liquor ſhould depend rather on a lucky random hit, than on good management? Yet ſuch appears to be really the caſe even among the moſt experienced cyder-makers of Herefordſhire and Glouceſterſhire.

642 Art of making them not yet perfectly underſtood.

Mr Marſhall, that nice obſerver of rural affairs, in his tour† through thoſe counties (expreſsly undertaken for the purpoſe of inquiry on this ſubject), informs us, that ſcarcely two of theſe profeſſional artiſts are agreed as to the management of ſome of the moſt eſſential parts of the proceſs: That palpable errors are committed as to the time and manner of gathering the fruit—in laying it up—in neglecting to ſeparate the unſound—and to grind properly the rinds and kernels, &c.: That the method of conducting the vinous fermentation, the moſt critical part of the operation, and which ſtamps the future value of the liquor, is by no means aſcertained; while ſome promote the fermentation in a ſpacious open vat, others repreſs it by incloſing the liquor in a hogſhead, or ſtrive to prevent it altogether: That no determinate point of temperature is regarded, and that the uſe of the thermometer is unknown or neglected: That they are as little conſiſtent as to the time of racking off; and whether this ought to be done only once, or five or ſix times repeated: That for fining down the liquor, many have recourſe to that odious article, bullocks blood, when the intention might be much better anſwered by whites of eggs or iſinglaſs. And, finally that the capricious taſte of particular cuſtomers is generally conſulted, rather than the real excellence of the liquor; and conſequently that a very imperfect liquor is often vended, which tends to reduce the price, to diſgrace the vender, and to bring the uſe of cyder and perry into diſrepute.

† *Rural Econ. of Glouceſterſhire*, ii. p. 308.

643 Errors pointed out.

The art of making vinous liquors is a curious chemical proceſs; and its ſucceſs chiefly depends on a dexterous management of the vinous fermentation, beſides a cloſe attention to ſundry minute circumſtances, the theory of which is perhaps not yet fully underſtood by the ableſt chemiſts. Can we longer wonder then that ſo many errors ſhould be committed by illiterate cyder-makers, totally unverſed in the firſt principles of the chemical art? Some few, indeed, more enlightened than their brethren, and leſs bigotted to their own opinions, by dint of obſervation ſtrike out improvements, and produce every now and then a liquor of ſuperior quality, though perhaps far ſhort of excellence, yet ſtill ſufficient to ſhow what might poſſibly be accompliſhed by a ſeries of new experiments conducted on philoſophical principles. This might lead to ſucceſſive improvements, till at length our Engliſh fruit-liquors might be carried to a pitch of perfection hitherto unknown, by which the demand, both at home and abroad, would ſoon be enlarged, the prices augmented according to the quality, the value of eſtates increaſed, and the health and proſperity of theſe counties proportionably advanced. This might alſo help to point out a method of correcting the imperfections of theſe liquors; and of meliorating thoſe of a weak meagre quality, by ſafer and more effectual means than are now practiſed: and though nothing can fully compenſate the defect of ſunſhine in maturing the ſaccharine juices in unfavourable ſeaſons, yet probably ſuch liquors might, without the dangerous and expenſive method of boiling in a copper veſſel, admit of conſiderable improvement by the addition of barm or other ſuitable ferment, as yet unknown in the practice of the cyder diſtricts; or perhaps rather by a portion of rich muſt, or ſome wholeſome ſweet, as honey, ſugar-candy, or even molaſſes, added in due proportion, previous to the fermentation. In fact, it appears from a late publication *, that the Germans are known to meliorate their thin harſh wines by an addition of concentrated muſt, not by evaporation, but by freezing. By this ſimple proceſs they are made to emulate good French wines: a practice worthy of imitation, eſpecially in the northern climates.

Making of Fruit-Liquors.

644 Means of improvement.

* *Hopſon's Chemiſtry.*

Cyder, as is well known, is made from apples, and *perry* from pears only. The general method of preparing both theſe liquors is very much the ſame; and under the article CYDER a deſcription will be given of the way in which thoſe fruits are gathered, ground, and preſſed. The mill is not eſſentially different from that of a common tanner's mill for grinding bark. It conſiſts of a millſtone from two and a half to four feet and a half in diameter, running on its edge in a circular ſtone trough, from nine to twelve inches in thickneſs, and from one to two tons in weight. The bottom of the trough in which this ſtone runs is ſomewhat wider than the thickneſs of the ſtone itſelf; the inner ſide of the groove riſes perpendicularly, but the outer ſpreads in ſuch a manner as to make the top of the trough ſix or eight inches wider than the bottom; by which means there is room for the ſtone to run freely, and likewiſe for putting in the fruit, and ſtirring it up while grinding. The bed of a middle-ſized mill is about 9 feet, ſome 10, and ſome 12; the whole being compoſed of two, three, or four ſtones cramped together and finiſhed after being cramped in this manner. The beſt ſtones are found in the foreſt of Dean; generally a dark reddiſh gritſtone, not calcareous; for if it were of a calcareous quality, the acid juice of the fruits would act upon it and ſpoil the liquor: a clean grained grindſtone grit is the fitteſt for the purpoſe. The runner is moved by means of an axle paſſing through the centre, with a long arm reaching without the bed of the mill, for a horſe to draw by; on the other ſide is a ſhorter arm paſſing through the centre of the ſtone, as repreſented

645 Deſcription of a cyder mill and mill-houſe.

Making of Fruit-Liquors.

fented in the figure. An iron bolt, with a large head, paſſes through an eye, in the lower part of the ſwivel on which the ſtone turns, into the end of the inner arm of the axis; and thus the double motion of it is obtained, and the ſtone kept perfectly upright. There ought alſo to be fixed on the inner arm of the axis, about a foot from the runner, a cogged wheel working in a circle of cogs, fixed upon the bed of the mill. The uſe of theſe is to prevent the runner from ſliding, which it is apt to do when the mill is full; it likewiſe makes the work more eaſy for the horſe. Theſe wheels ought to be made with great exactneſs. Mr Marſhall obſerves, that it is an error to make the horſe draw by traces: "The acting point of draught (ſays he), the horſes ſhoulder, ought, for various reaſons, to be applied immediately at the end of the arm of the axis; not two or three yards before it; perhaps of a ſmall mill near one fourth of its circumference." The building in which the mill is incloſed ought to be of ſuch a ſize, that the horſe may have a path of three feet wide betwixt the mill and the walls; ſo that a middling-ſized mill, with its horſe-path, takes up a ſpace of 14 or 15 feet every way. The whole dimenſions of the mill-houſe, according to our author, to render it any way convenient, are 24 feet by 20: it ought to have a floor thrown over it at the height of ſeven feet; with a door in the middle of the front, and a window oppoſite, with the mill on one ſide and the preſs on the other ſide of the window. The latter muſt be as near the mill as convenience will allow, for the more eaſy conveying the ground fruit from the one to the other. The preſs, which is of a very ſimple conſtruction, has its bed or bottom about five feet ſquare. This ought to be made entirely either of wood or ſtone; the practice of covering it with lead being now univerſally known to be pernicious. It has a channel cut a few inches within its outer edge, to catch the liquor as it is expreſſed, and convey it to a lip formed by a projection on that ſide of the bed oppoſite to the mill; having under it a ſtone trough or wooden veſſel, ſunk within the ground, when the bed is fixed low, to receive it. The preſs is worked with levers of different lengths; firſt a ſhort, and then a moderately long one, both worked by hand; and laſtly, a bar eight or nine feet long worked by a capſtan or windlaſs. The expence of fitting up a mill-houſe is not very great. Mr Marſhall computes it from 20l. to 25l. and, on a ſmall ſcale, from 10l. to 15. though much depends on the diſtance and and carriage of the ſtone: when once fitted up it will laſt many years.

The making of the fruit-liquors under conſideration requires an attention to the following particulars. I. The fruit. II. The grinding. III. Preſſing. IV. Fermenting. V. Correcting. VI. Laying up. VII. Bottling; each of which heads is ſubdivided into ſeveral others.

646 Management of the fruit.

I. In the *management of the fruit* the following particulars are to conſidered.

1. The time of gathering; which varies according to the nature of the fruit. The early pears are fit for the mill in September; but few apples are ready for gathering before Michaelmas; though, by reaſon of accidental circumſtances, they are frequently manufactured before that time. For ſale cyder, and keeping drink, they are ſuffered to hang upon the trees till fully ripe: and the middle of October is generally looked upon to be a proper time for gathering the ſtire-apple. The criterion of a due degree of ripeneſs is the fruit falling from the tree: and to force it away before that time, in Mr Marſhall's opinion, is robbing it of ſome of its moſt valuable particles. "The harveſting of fruits (ſays he) is widely different in this reſpect from the harveſting of grain; which has the entire plant to feed it after its ſeparation from the ſoil; while fruit, after it is ſevered from the tree, is cut off from all poſſibility of a further ſupply of nouriſhment; and although it may have reached its wonted ſize, ſome of its more eſſential particles are undoubtedly left behind in the tree. Sometimes, however, the fruits which are late in ripening are apt to hang on the tree until ſpoiled by froſts; though weak watery fruits ſeem to be moſt injured in this manner; and Mr Marſhall relates an inſtance of very fine liquor being made from golden pippins, after the fruit had been frozen as hard as ice.

647 Method of gathering it.

2. The method of gathering. This, as generally practiſed, is directly contrary to the principle laid down by Mr Marſhall, viz. beating them down with long ſlender poles. An evident diſadvantage of this method is that the fruit is of unequal ripeneſs; for the apples on the ſame trees will differ many days, perhaps even weeks, in their time of coming to perfection; whence ſome part of the richneſs and flavour of the fruit will be effectually and irremediably cut off. Nor is this the only evil to be dreaded; for as every thing depends on the fermentation it has to undergo, if this be interrupted, or rendered complex by a mixture of ripe and unripe fruits, and the liquor be not in the firſt inſtance ſufficiently purged from its feculencies, it is difficult to clear the liquor afterwards. The former defect the cyder-makers attempt to remedy by a mixture of brown ſugar and brandy, and the latter by bullocks blood and brimſtone; but neither of theſe can be expected to anſwer the purpoſe very effectually. The beſt method of avoiding the inconveniences ariſing from an unequal ripening of the fruit is to go over the trees twice, once with a hook, when the fruit begins to fall ſpontaneouſly; the ſecond time, when the latter are ſufficiently ripened, or when the winter is likely to ſet in, when the trees are to be cleared with the poles above mentioned.

648 Maturing it, &c.

3. Maturing the gathering fruit. This is uſually done by making it into heaps, as is mentioned under the article CYDER: but Mr Marſhall entirely diſapproves of the practice; becauſe, when the whole are laid in a heap together, the ripeſt fruit will begin to rot before the other has arrived at that degree of artificial ripeneſs which it is capable of acquiring. "The due degree of maturation of fruit for liquor (he obſerves) is a ſubject about which men, even in this diſtrict, differ much in their ideas. The prevailing practice of gathering into heaps until the ripeſt begins to rot, is waſting the beſt of the fruit, and is by no means an accurate criterion. Some ſhake the fruit, and judge by the rattling of the kernels; others cut through the middle and judge by their blackneſs; but none of theſe appear to be a proper teſt. It is not the ſtate of the kernels but of the fleſh; not of a few individuals, but of the greater part of the prime fruits, which render the collective body

Making of Fruit Liquors.

dy fit or unfit to be ſent to the mill. The moſt rational teſt of the ripeneſs of the fruit, is that of the fleſh having acquired ſuch a degree of mellowneſs, and its texture ſuch a degree of tenderneſs, as to yield to moderate preſſure. Thus, when the knuckle or the end of the thumb can with moderate exertion be forced into the pulp of the fruit, it is deemed in a fit ſtate for grinding."

4. Preparation for the mill. The proper management of the fruit is to keep the ripe and unripe fruit ſeparate from each other: but this cannot be done without a conſiderable degree of labour; for as by numberleſs accidents the ripe and unripe fruits are frequently confounded together, there cannot be any effectual method of ſeparating them except by hand; and Mr Marſhall is of opinion, that this is one of the grand ſecrets of cyder-making, peculiar to thoſe who excel in the buſineſs; and he is ſurpriſed that it ſhould not before this time have come into common practice.

5. Mixing fruits for liquor. Our author ſeems to doubt the propriety of this practice; and informs us, that the finer liquors are made from ſelect fruits; and he hints that it might be more proper to mix liquors after they are made, than to put together the crude fruits.

649 Grinding.

II. *Grinding*, and management of the fruit when ground.

1. For the greater convenience of putting the fruit into the mill, every mill-houſe ſhould have a fruit-chamber over it, with a trap-door to lower the fruit down into the mill. The beſt manner in which this can be accompliſhed, is to have the valve over the bed of the mill, and furniſhed with a cloth ſpout or tunnel reaching down to the trough in which the ſtone moves. No ſtraw is uſed in the lofts; but ſometimes the fruit is turned. In Herefordſhire, it is generally believed, that grinding the rind and ſeeds of the fruit as well as the fleſhy part to a pulp, is neceſſary towards the perfection of the cyder; whence it is neceſſary, that every kind of pains ſhould be taken to perform the grinding in the moſt perfect manner. Mr Marſhall complains, that the cyder-mills are ſo imperfectly finiſhed by the workmen, that for the firſt *fifty years* they cannot perform their work in a proper manner. Inſtead of being nicely fitted to one another with the ſquare and chiſel, they are hewn over with a rough tool in ſuch a careleſs manner, that horſe-beans might lie in ſafety in their cavities. Some even imagine this to be an advantage, as if the fruit was more effectually and completely broken by rough than ſmooth ſtones. Some uſe fluted rollers of iron; but theſe will be corroded by the juice, and thus the liquor might be tinged. Smooth rollers will not lay hold of the fruit ſufficiently to force it through.

Another improvement requiſite in the cyder-mills is to prevent the matter in the trough from riſing before the ſtone in the laſt ſtage of grinding, and a method of ſtirring it up in the trough more effectually than can be done at preſent. To remedy the former of theſe defects, it might perhaps be proper to grind the fruit firſt in the mill to a certain degree; and then put it between two ſmooth rollers to finiſh the operation in the moſt perfect manner. It is an error to grind too much at once; as this clogs up the mill, and prevents it from going eaſily. The uſual quantity for a middle-ſized mill is a bag containing four corn buſhels; but our author had once an opportunity of ſeeing a mill in which only half a bag was put; and thus the work ſeemed to go on more eaſily as well as more quickly than when more was put in at once. The quantity put in at one time is to be taken out when ground. The uſual quantity of fruit ground in a day is as much as will make three hogſheads of perry or two of cyder.

Making Fruit-L quors.

2. Management of the ground fruit. Here Mr Marſhall condemns in very ſtrong terms the practice of preſſing the pulp of the fruit as ſoon as the grinding is finiſhed; becauſe thus neither the rind nor ſeeds have time to communicate their virtues to the liquor. In order to extract theſe virtues in the moſt proper manner, ſome allow the ground fruit to lie 24 hours or more after grinding, and even regrind it, in order to have in the moſt perfect manner the flavour and virtues of the ſeeds and rind.

650 Preſſing, &c.

III. *Preſſing the fruit*, and management of the *reſiduum*. This is done by folding up the ground fruit in pieces of hair-cloth, and piling them up above one another in a ſquare frame or mould, and then pulling down the preſs upon them, which ſqueezes out the juice, and forms the matter into thin and almoſt dry cakes. The firſt runnings come off foul and muddy; but the laſt, eſpecially in perry, will be as clear and fine as if filtered through paper. It is common to throw away the reſiduum as uſeleſs: ſometimes it is made uſe of when dry as fuel; ſometimes the pigs will eat it, eſpecially when not thoroughly ſqueezed; and ſometimes it is ground a ſecond time with water, and ſqueezed for an inferior kind of liquor uſed for the family. Mr Marſhall adviſes to continue the preſſure as long as a drop can be drawn. "It is found (ſays he), that even by breaking the cakes of refuſe with the hands only gives the preſs freſh power over it; for though it has been preſſed to the laſt drop, a gallon or more of additional liquor may be got by this means. Regrinding them has a ſtill greater effect: In this ſtate of the materials the mill gains a degree of power over the more rigid parts of the fruits, which in the firſt grinding it could not reach. If the face of the runner and the bottom of the trough were dreſſed with a broad chiſel, and made true to each other, and a moderate quantity of reſiduum ground at once, ſcarcely a kernel could eſcape unbroken, or a drop of liquor remain undrawn."

But though the whole virtue of the fruit cannot be extracted without grinding it very fine, ſome inconvenience attends this practice, as part of the pulp thus gets through the haircloth, and may perhaps be injurious to the ſubſequent fermentation. This, however, may be in a great meaſure remedied by ſtraining the firſt runnings through a ſieve. The whole ſhould alſo be allowed to ſettle in a caſk, and drawn off into a freſh veſſel previous to the commencement of the fermentation. The reduced fruit ought to remain ſome time between the grinding and preſſing, that the liquor may have an opportunity of forming an extract with the rind and kernels: but this muſt not be puſhed too far, as in that caſe the colour of the cyder would be hurt; and the moſt judicious managers object to the pulp remaining longer than 12 hours without preſſure. "Hence (ſays our author), upon the whole, the moſt

Making of Fruit Liquors.

eligible management in this ſtage of the art appears to be this: Grind one preſsful a day; preſs and regrind the reſiduum in the evening; infuſe the reduced matter all night among part of the firſt runnings; and in the morning repreſs while the next preſsful is grinding.

651 Fermentation.

IV. *Fermentation.* The common practice is to have the liquor turned; that is, put into caſks or hogſheads immediately from the preſs, and to fill them quite full: but it is undoubtedly more proper to leave ſome ſpace empty to be filled up afterwards. No accurate experiment has been made with regard to the temperature of the air proper to be kept up in the place where the fermentation goes on. Froſt is prejudicial: but when the proceſs uſually commences, that is, about the middle of October, the liquor is put into airy ſhades, where the warmth is ſcarce greater than in the open atmoſphere; nay, the caſks are frequently expoſed to the open air without any covering farther than a piece of tile or flat ſtone over the bunghole, propped up by a wooden pin on one ſide to cauſe the rain water to run off. In a complete manufactory of fruit liquor, the fermenting room ſhould be under the ſame roof with the mill-houſe; a continuation of the preſs-room, or at leaſt opening into it, with windows or doors on every ſide, to give a free admiſſion of air into it; ſufficient defences againſt froſt; fruit-lofts over it, and vaults underneath for laying up the liquors after fermentation; with ſmall holes in the crown of the arch to admit a leathern pipe, for the purpoſe of conveying the liquors occaſionally from the one to the other.

In making of fruit-liquors, no ferment is uſed as in making of beer; though, from Mr Marſhall's account of the matter, it ſeems far from being unneceſſary. Owing to this omiſſion, the time of the commencement of the fermentation is entirely uncertain. It takes place ſometimes in one, two, or three days; ſometimes not till a week or month after turning: but it has been obſerved, that liquor which has been agitated in a carriage, though taken immediately from the preſs, will ſometimes paſs almoſt immediately into a ſtate of fermentation. The continuance of the fermentation is no leſs uncertain than the commencement of it. Liquors when much agitated, will go through it perhaps in one day; but when allowed to remain at reſt, the fermentation commonly goes on two or three days, and ſometimes five or ſix. The fermenting liquor, however, puts on a different appearance according to circumſtances. When produced from fruits improperly managed, it generally throws up a thick ſcum reſembling that of malt liquor, and of a thickneſs proportioned to the ſpecies and ripeneſs of the fruit; the riper the fruit, the more ſcum being thrown up. Perry gives but little ſcum, and cyder will ſometimes alſo do the ſame; ſometimes it is intentionally prevented from doing it.

After having remained ſome time in the fermenting veſſel, the liquor is racked or drawn off from the lees and put into freſh caſks. In this part of the operation alſo Mr Marſhall complains greatly of the little attention that is paid to the liquor. The ordinary time for racking perry is before it has done hiſſing, or ſometimes when it begins to emit fixed air in plenty. The only intention of the operation is to free the liquor from its faeces by a cock placed at a little diſtance from the bottom; after which the remainder is to be filtered through a canvas or flannel bag. This filtered liquor differs from the reſt in having a higher colour; having no longer any tendency to ferment, but on the contrary checking the fermentation of that which is racked off; and if it loſes its brightneſs, it is no longer eaſily recovered.—A freſh fermentation uſually commences after racking; and if it become violent, a freſh racking is neceſſary in order to check it; in conſequence of which the ſame liquor will perhaps be racked five or ſix times: but if only a ſmall degree of fermentation takes place, which is called *fretting*, it is allowed to remain in the ſame caſk; though even here the degree of fermentation which requires racking is by no means determined. Mr Marſhall informs us that the beſt manufacturers, however, repeat the rackings until the liquor will lie quiet, or nearly ſo; and if it be found impracticable to accompany this by the ordinary method of fermentation, recourſe muſt be had to fumigation with ſulphur, which is called *ſtumming* the caſks. For this fumigation it is neceſſary to have matches made of thick linen cloth about ten inches long, and an inch broad, thickly coated with brimſtone for about eight inches of their length. The caſk is then properly ſeaſoned, and every vent except the bunghole tightly ſtopped; a match is kindled, lowered down into the caſk, and held by the end undipped until it be well lighted, and the bung be driven in; thus ſuſpending the lighted match within the caſk. Having burnt as long as the contained air will ſupply the fire, the match dies, the bung is raiſed, the remnant of the match drawn out, and the caſk ſuffered to remain before the liquor be put into it for two or three hours, more or leſs according to the degree of power the ſulphur ought to have. The liquor retains a ſmell of the ſulphureous acid; but this goes off in a ſhort time, and no bad effect is ever obſerved to follow.

Making of Fruit-Liquors.

In ſome places the liquor is left to ferment in open caſks, where it ſtands till the firſt fermentation be pretty well over; after which the froſt or yeaſt collected upon the ſurface is taken off, it being ſuppoſed that it is this yeaſt mixing with the clear liquor which cauſes it to fret after racking. The fermentation being totally ceaſed, and the lees ſubſided, the liquor is racked off into a freſh caſk, and the lees filtered as above directed. The author mentions a way of fermenting fruit-liquors in broad ſhallow vats, not leſs than five feet in diameter, and little more than two feet deep; each vat containing about two hogſheads. In theſe the liquor remains until it has done riſing, or till the fermentation has nearly ceaſed, when it is racked off without ſkimming, the critical juncture being caught before the yeaſt fall; the whole ſinking gradually together as the liquor is drawn off. In this practice alſo the liquor is ſeldom drawn off a ſecond time.

652 Different kinds of cyder.

Cyder is made of three different kinds, viz. *rough*, *ſweet*, and *of a middle richneſs*. The firſt kind being uſually deſtined for ſervants, is made with very little ceremony. "If it is but *cyder* (ſays Mr Marſhall), and has body enough to keep, no matter for the richneſs and flavour. The rougher it is, the further it will go, and the more acceptable cuſtom has rendered it not only to the workmen but to their maſters. A palate accuſtomed to rough cedar would judge the

Making of Fruit Liquors.

rough cyder of the farm-houſes to be a mixture of vinegar and water, with a little diſſolved alum to give it roughneſs." The method of producing this auſtere liquor is to grind the fruit in a crude under-ripe ſtate, and ſubject the liquor to a full fermentation.—For the ſweet liquor, make choice of the ſweeter fruits: mature them fully; and check the fermentation of the liquor.—To produce liquors of a middle richneſs, the nature of the fruit, as well as the ſeaſon in which it is matured, muſt be conſidered. The fruits to be made choice of are ſuch as yield juices capable of affording a ſufficiency both of richneſs and ſtrength; though much depends upon proper management. Open vats, in our author's opinion, are preferable to cloſe veſſels: but if caſks be uſed at all, they ought to be very large, and not filled; nor ought they to lie upon their ſides, but to be ſet on their ends with their heads out, and to be filled only to ſuch a height as will produce the requiſite degree of fermentation: but in whatever way the liquor be put to ferment, Mr Marſhall is of opinion that the operation ought to be allowed to go on freely for the firſt time; though after being racked off, any ſecond fermentation ought to be prevented as much as poſſible.

653 Of correcting or doctoring the liquors.

V. *Correcting*, provincially called *doctoring*. The imperfections which art attempts to ſupply in theſe liquors are, 1. Want of ſtrength; 2. Want of richneſs; 3. Want of flavour; 4. Want of colour and brightneſs.

The want of ſtrength is ſupplied by brandy or any other ſpirit in ſufficient quantity to prevent the acetous fermentation. The want of richneſs is ſupplied by what are generally termed *ſweets*, but prepared in a manner which our author ſays has never fallen under his notice. To ſupply the want of flavour, an infuſion of hops is ſometimes added, which is ſaid to communicate an agreeable bitter, and at the ſame time a fragrance; whence it becomes a ſubſtitute for the juices of the rind and kernels thrown away to the pigs and poultry, or otherwiſe waſted. The want of colour is ſometimes ſupplied by elder berries, but more generally by burnt ſugar, which gives the deſired colour, and a degree of bitter which is very much liked. The ſugar is prepared either by burning it on a ſalamander, and ſuffering it to drop, as it melts, into water; or by boiling it over the fire (in which caſe brown ſugar is to be uſed), until it acquire an agreeable bitter; then pouring in boiling water in the proportion of a gallon to two pounds of ſugar, and ſtir until the liquor become uniform. A pint of this preparation will colour a hogſhead of cyder. Brightneſs is obtained by a mixture of the blood of bullocks or ſheep; that of ſwine being rejected, though it does not appear to be more unfit for the purpoſe than either of the other two. The only thing neceſſary to be done here is to ſtir the blood well as it is drawn from the animal, to prevent the parts from ſeparating; and it ought to be ſtirred "both ways, for a quarter of an hour." The liquor, however, is not always in a proper condition for being refined with this ingredient: on which account a little of it ought frequently to be tried in a vial. A quart or leſs will be ſufficient for a hogſhead. After the blood is poured in, the liquor ſhould be violently agitated, to mix the whole intimately together. This is done by a ſtick ſlit into four, and inſerted into the bunghole; working it briſkly about in the liquor until the whole be thoroughly mixed. In about 24 hours the blood will be ſubſided, and the liquor ought inſtantly to be racked off; as by remaining upon the blood even for two or three days, it will receive a taint not eaſily to be got rid of. It is remarkable that this refinement with the blood carries down not only the fæces, but the colour alſo; rendering the liquor, though ever ſo highly coloured before, almoſt as limpid as water. Iſinglaſs and eggs are ſometimes made uſe of in fining cyder as well as wine.

Making of Fruit-Liquors.

654 Of laying up, or caſking.

VI. The *laying up* or ſhutting up the cyder in cloſe caſks, according to Mr Marſhall, is as little underſtood as any of the reſt of the parts; the bungs being commonly put in at ſome certain time, or in ſome particular month, without any regard to the ſtate the liquor itſelf is in. "The only criterion (ſays he) I have met with for judging the critical time of laying up, is when a fine white cream-like matter firſt begins to form upon the ſurface. But this may be too late; it is probably a ſymptom at leaſt of the acetous fermentation, which if it take place in any degree muſt be injurious. Yet if the caſks be bunged tight, ſome criterion is neceſſary; otherwiſe, if the vinous fermentation have not yet finally ceaſed, or ſhould recommence, the caſks will be endangered, and the liquor injured. Hence, in the practice of the moſt cautious manager whoſe practice I have had an opportunity of obſerving, the bungs are firſt driven in lightly, when the liquor is fine, and the vinous fermentation is judged to be over; and ſome time afterward, when all danger is paſt, to fill up the caſks, and drive the bungs ſecurely with a rag, and roſin them over at top. Moſt farmers are of opinion, that after the liquor is done fermenting, it ought to have ſomething to *feed upon*; that is, to prevent it from running into the acetous fermentation. For this purpoſe ſome put in parched beans, others egg-ſhells, ſome mutton ſuet, &c. Mr Marſhall does not doubt that ſomething may be uſeful; and thinks that iſinglaſs may be as proper as any thing that can be got.

655 Bottling.

VII. *Bottling*. This depends greatly on the quality of the liquors themſelves. Good cyder can ſeldom be bottled with propriety under a year old: ſometimes not till two. The proper time is when it has acquired the utmoſt degree of richneſs and flavour in the caſks; and this it will preſerve for many years in bottles. It ought to be quite fine at the time of bottling; or if not ſo naturallly, ought to be fined artificially with iſinglaſs and eggs.

656 Of cyderkin.

The liquor, called *cyderkin*, *purre*, or *perkin*, is made of the murk or groſs matter remaining after the cyder is preſſed out. To make this liquor, the murk is put into a large vat, with a proper quantity of boiled water, which has ſtood till it be cold again: if half the quantity of water be uſed that there was of cyder, it will be good; if the quantities be equal, the cyderkin will be ſmall. The whole is left to infuſe 48 hours, and then well preſſed; what is ſqueezed out by the preſs is immediately tunned up and ſtopped; it is fit to drink in a few days. It clarifies of itſelf, and ſerves in families inſtead of ſmall beer. It will keep, if boiled, after preſſure, with a convenient quantity of hops.

657 Of cyder wine, according to Dr Ruſh's recipe.

We muſt not conclude this ſection without particular

Making of Fruit-Liquors.

cular notice of the liquor called *cyder wine*, which is made from the juice of apples taken from the preſs and *boiled*, and which being kept three or four years is ſaid to reſemble Rheniſh. The method of preparing this wine, as communicated by Dr Ruſh of America, where it is much practiſed, conſiſts in evaporating in a brewing copper the freſh apple-juice till half of it be conſumed. The remainder is then immediately conveyed into a wooden cooler, and afterwards is put into a proper caſk, with an addition of yeaſt, and fermented in the ordinary way. The proceſs is evidently borrowed from what has long been practiſed on the recent juice of the grape, under the term of *vin cuit*, or boiled wine, not only in Italy, but alſo in the iſlands of the Archipelago, from time immemorial.

This proceſs has lately become an object of imitation in the cyder counties, and particularly in the weſt of England, where it is reported that many hundred hogſheads of this wine have already been made: and as it is ſaid to betray no ſign of an impregnation of copper by the uſual chemical teſts, it is conſidered as perfectly wholeſome, and is accordingly drunk without apprehenſion by the common people. Others, however, ſuſpect its innocence; whence it appeared an object of no ſmall moment to determine in ſo doubtful a matter, whether or not the liquor acquires any noxious quality from the copper in which it is boiled. With this view Dr Fothergill* made a variety of experiments; and the reſult ſeemed to afford a ſtrong preſumption that the cyder wine *does* contain a minute impregnation of copper; not very conſiderable indeed, but yet ſufficient, in the doctor's opinion, to put the public on their guard concerning a liquor that comes in ſo very "queſtionable a ſhape."

* *Bath Papers*, vol. v. p. 330.

It is a curious chemical fact, he obſerves, if it be really true, that acid liquors, while kept boiling in copper veſſels, acquire little or no impregnation from the metal, but preſently begin to act upon it when left to ſtand in the cold. Can this be owing to the agitation occaſioned by boiling, or the expulſion of the aerial acid? Atmoſpheric air powerfully corrodes copper, probably through the intervention of the aerial or rather nitrous acid, for both are now acknowledged to be preſent in the atmoſphere. But the latter is doubtleſs a much ſtronger menſtruum of copper than the former.

In the preſent proceſs the liquor is properly directed to be paſſed into a wooden cooler as ſoon as the boiling is completed. But as all acids, and even common water, acquire an impregnation and unpleaſant taſte, from ſtanding in copper veſſels in the cold, why may not the acid juice of apples act in ſome degree on the copper before the boiling commences? Add to this, that brewing coppers, without far more care and attention than is generally beſtowed on them in keeping them clean, are extremely apt to contract verdigriſe, (a rank poiſon), as appears from the blue or green ſtreaks very viſible when theſe veſſels are minutely examined. Should the unfermented juice be thought incapable of acting on the copper either in a cold or boiling ſtate, yet no one will venture to deny its power of waſhing off or diſſolving verdigriſe already formed on the internal ſurface of the veſſel. Suppoſe only one-eighth part of a grain of verdigriſe to be contained in a bottle of this wine, a quantity that may elude the ordinary teſts, and that a bottle ſhould be drunk daily by a perſon without producing any violent ſymptoms or internal uneaſineſs; yet what perſon in his ſenſes would knowingly chooſe to hazard the experiment of determining how long he could continue even this quantity of a ſlow poiſon in his daily beverage with impunity? And yet it is to be feared the experiment is but too often unthinkingly made, not only with cyder wine, but alſo with many of the foreign wines prepared by a ſimilar proceſs. For the grape juice, when evaporated in a copper veſſel, under the denomination of *vino cotto* or boiled wine, cannot but acquire an equal, if not yet ſtronger impregnation of the metal, than the juice of apples, ſeeing that verdigriſe itſelf is manufactured merely by the application of the acid huſks of grapes to plates of copper.

Making of Fruit-Liquors.

Independent of the danger of any metallic impregnation, the doctor thinks, it may be juſtly queſtioned how far the proceſs of preparing boiled wines is neceſſary or reconcileable to reaſon or economy. The evaporation of them muſt by long boiling not only occaſion an unneceſſary waſte of both liquor and fuel, but alſo diſſipates certain eſſential principles, without which the liquor can never undergo a complete fermentation; and without a complete fermentation there can be no perfect wine. Hence the boiled wines are generally crude, heavy, and flat, liable to produce indigeſtion, flatulency, and diarrhœa. If the evaporation be performed haſtily, the liquor contracts a burnt empyreumatic taſte, as in the preſent inſtance; if ſlowly, the greater is the danger of a metallic impregnation. For the proceſs may be preſumed to be generally performed in a veſſel of braſs or copper, as few families poſſeſs any other that is ſufficiently capacious. Nor can a veſſel of caſt iron, though perfectly ſafe, be properly recommended for this purpoſe, as it would probably communicate a chalybeate taſte and dark colour to the liquor. At all events, braſs and copper veſſels ought to be entirely baniſhed from this and every other culinary proceſs.

Sect. X. *Of Fences.*

653 Kinds of fences enumerated.

We ſhall conclude the preſent ſubject of agriculture by taking notice of the various kinds of fences that may be found valuable in it.—Robert Somerville, Eſq. of Haddington, in a communication to the Board of Agriculture, has endeavoured to enumerate the whole ſimple and compound fences that are at preſent uſed. *Simple fences* are thoſe that conſiſt of one kind only, as a ditch, a hedge, or a wall.—*Compound fences* are made by the union of two or more of theſe, as a hedge and ditch, or hedge and wall. The following is the liſt which he has given of them:

"*Simple Fences.*

I. Simple ditch, with a bank on one ſide.
II. Double ditch, with a bank of earth between.
II. Bank of earth, with a perpendicular facing of ſod.
IV. Ha-ha, or ſunk fence.
V. Palings, or *timber fences*, of different kinds, viz.
1. Simple nailed paling of rough timber.
2. Jointed horizontal paling.
3. Upright lath paling.

Fences.

4. Horizontal paling of young firs.
5. Upright ditto of do.
6. Chain fence.
7. Net fence.
8. Rope fence.
9. Flake or hurdle fence.
10. Ozier or willow fence.
11. Fence of growing poſts.
12. Shingle fence, horizontal.
13. Ditto, upright.
14. Warped paling.
15. Open paling, warped with dead thorns or branches of trees.

VI. Dead hedges, various kinds.

VII. Live hedges.

VIII. Walls.

1. Dry ſtone wall, coped and uncoped.
2. Stone and lime ditto, do.
3. Stone and clay, do.
4. Stone and clay, harled, or daſhed with lime.
5. Dry ſtone, ditto, lipped with lime.
6. Dry ſtone, ditto, lipped and harled.
7. Dry ſtone, pirned and harled.
8. Brick walls.
9. Frame walls.
10. Galloway dike or wall.
11. Turf wall.
12. Turf and ſtone, in alternate layers.
13. Mud walls, with ſtraw.

"*Compound Fences.*

1. Hedge and ditch, with or without paling.
2. Double ditto.
3. Hedge and bank, with or without paling.
4. Hedge in the face of a bank.
5. Hedge on the top of a bank.
6. Devonſhire fence.
7. Hedge, with ſingle or double paling.
8. Hedge and dead hedge.
9. Hedge and wall.
10. Hedge, ditch, and wall.
11. Hedge in the middle of a wall.
12. Hedge and ditch, with row of trees.
13. Hedge, or hedge and wall, with belt of planting.
14. Hedge with the corners planted.
15. Reed fence, or port and rail, covered with reeds."

659 Ditches.

Of the nature of each of theſe, and the advantages attending the uſe of them, we ſhall take ſome ſhort notice. The ditch, which is one of the ſimple fences, is moſt frequently conſidered merely as an open drain intended to relieve the ſoil of ſuperfluous moiſture. It is frequently, alſo, however, made uſe of without any ſuch intention, as a fence for the confinement of cattle; but it is more frequently uſed with the double view of ſerving as a fence, and as a drain. It is made in a variety of ways, according to the object in view. If a ditch is meant to be uſed merely as a drain, the earth thrown out of it ought by no means to be formed into a bank upon the ſide of it, becauſe ſuch a practice, as formerly ſtated, when treating of draining, has a tendency to injure its utility by cutting off its communication with one ſide of the field to be drained; but when a ditch is intended to be uſed as a fence, a different rule of proceeding muſt be followed. In that caſe, the object in view will be greatly forwarded by forming the earth taken out of the ditch into a bank upon its ſide, and when added to the depth of the ditch, will form a barrier of conſiderable value. Fences.

Ditches are ſometimes formed of an uniform breadth at top and bottom. This kind of ditch is liable to many objections. After froſts and rains, its ſides are perpetually crumbling down and falling in, and if the field in which ſuch a ditch is placed have a conſiderable declivity, the bottom of the ditch will be extremely liable to be undermined by any current of water, that either permanently or caſually takes place in it; at the ſame time, ſuch ditches have been found very uſeful in low-lying clay or carſe ſoils where the country is level. From the nature of the ſoil, the ſides of the ditches in ſuch ſituations are tolerably durable. No rapid current of water can exiſt to undermine them; and, by their figure, they withdraw from the plough the ſmalleſt poſſible portion of ſurface.

Other ditches are conſtructed wide above, with a gradual ſlope from both ſides downwards. This form of a ditch is in general the beſt, where it is at all to be uſed for the drainage of the field, as the ſides are not ſo liable as in the former caſe to be excavated by the current of water. Hence it is more durable, and by diminiſhing the quantity of digging at the bottom, it is more eaſily executed.

A third kind of ditches are ſo formed as to have one ſide ſloping, and the other perpendicular. This kind of ditch partakes of the whole perfections and imperfections of the two former. It is extremely uſeful, however, in fields of which ſheep form a part of the ſtock, and where the bottom of the ditch contains a current of water; for, in ſuch caſes, when ſheep tumble into a deep ditch, whoſe ſides are pretty ſteep, they are very apt to periſh; but by making one ſide of the ditch very much ſloped, while the other approaches to the perpendicular, they are enabled to make their eſcape; while at the ſame time by the bed of the ſtream being widened, the perpendicular ſide of the ditch is leſs liable to be undermined. When the earth taken out of a ditch is formed into a bank on one ſide, a projecting vacant ſpace of ſix or eight inches ought always to be left between the bank and the ditch, to prevent the earth from tumbling in and filling up the ditch.

A double ditch, with a bank of earth between the two, formed out of the earth obtained by digging them, has many obvious advantages over the ſingle ditch, when conſidered as a fence; for the earth taken out of the two ditches, when properly laid up in the middle, will naturally become a very formidable rampart, which cattle will not readily attempt to croſs. It is alſo excellently adapted for the purpoſe of open drainage, and it ought always to be uſed upon the ſides of highways, where the adjoining lands have a conſiderable declivity towards the road. In ſuch caſes the inner ditch receives the water from the field, and prevents it from waſhing down or overflowing the road in the time of heavy rains; an inconvenience which frequently cannot otherwiſe be avoided.

660 Bank of earth.

The bank of earth, with a perpendicular facing of ſod, and a ſlope behind, is uſeful in ſome ſituations, as in making folds for the confinement of ſheep or cattle, in which caſe the front or perpendicular ſide of the bank,

Fences. bank muſt be turned inwards. It is alſo valuable on the ſides of highways to protect the adjoining fields, and alſo for fencing belts of planting, or incloſing ſtack-yards and cottages. The front of the bank is made with the turfs taken from the ſurface of the ſloping ditch, and the mound at the back with the earth taken out of it. This fence, when well executed, is ſaid to laſt a conſiderable time.

661 The ha-ha, or ſunk fence. The ha-ha, or ſunk fence, very nearly reſembles the mound of earth with the perpendicular facing of turf, with this difference, that the facing of the ha-ha is of ſtone. The height of both depends almoſt entirely upon the depth of the ditch; both of them in truth conſiſt of the kind of ditch already mentioned, of which the one ſide ſlopes while the other is perpendicular, and differ from it chiefly in this reſpect, that the perpendicular ſide is faced with turf or ſtone. The ſtone-facing is made either of dry ſtone, or of ſtone and lime. In the Agricultural Report of Cromarty, the mode of making the ſunk fence is thus deſcribed: "Upon the line where this fence is intended, begin to ſink your ditch, taking the earth from as far as eight feet outward, and throwing it up on the inſide of the lines. This ditch and bank is not made quite perpendicular, but inclining inward towards the field as it riſes; to this is built a facing of dry ſtone, four feet and a half in height, one foot and three quarters broad at bottom, and one foot at top, over which a coping of turf is laid: the ditch or ſunk part forms an excellent drain. The whole of this is performed, when the ſtones (we ſhall ſuppoſe) can be procured at a quarter of a mile's diſtance, for 6d. per yard." The principal defect of the ſunk fence conſiſts in this, that unleſs the bank at the back of it is conſiderably ſteep, or has a railing at the top, it forms a kind of ſnare on that ſide for cattle, as they muſt always be apt to tumble over it in dark nights.

662 Palings. Paling or timber fences, are in many places much uſed, though they can never be conſidered with propriety as forming permanent incloſures. Of whatever materials they are formed, their decay commences from the inſtant they are erected. This decay begins with the part of the paling that is put into the ground, which is ſpeedily rotted by the moiſture, or conſumed by worms or other animals that attack it. To guard as much as poſſible againſt this cauſe of decay, various devices have been adopted. It is a very general practice to burn the ſurface of that part of the ſtandards of the paling which is meant to be driven into the earth. It is alſo cuſtomary to cover the ſame part of the wood with a ſtrong coat of coarſe oil paint, and Lord Dundonald's coal varniſh has been recommended with this view. The points of the ſtandards that are to be fixed in the earth, ought to be dipped in the varniſh while it is boiling hot. Common tar or melted pitch have alſo been uſed with tolerable ſucceſs to defend the extremities of the ſtandards of paling. In ſome caſes where the expence could be afforded, large ſtones have been ſunk into the earth, with holes cut into them of a ſize adapted to receive the ends of the poſts of the paling. The durability of the wood in this caſe is greater, but it bears no proportion to the additional expence incurred. When poſts for paling can be obtained conſiſting of branches of trees, with the bark ſtill upon them, this natural covering enables them to remain uncorrupted for a longer period than can be accompliſhed by any artificial coating. It is no objection to this, that a part of the uncovered wood, or the bottom of the ſtake or poſt muſt be inſerted in the earth; for it is not at the bottom that ſtakes or poſts begin to decay, but at the uppermoſt place at which the earth touches them, or between the wet and the dry as it is called. Of the kinds of paling it is unneceſſary to ſay much. Fences

The ſimple nailed paling of rough timber, conſiſts of poſts or ſtakes inſerted in the earth, and croſſed with three, four, or more horizontal bars or ſlabs as they are called in Scotland. It is the moſt common of all, and is uſed to protect young hedges, or to ſtrengthen ditches when uſed as fences.

The jointed horizontal paling, conſiſts of maſſy ſquare poles drove into the earth, and having openings cut into them for the reception of the extremities of the horizontal bars. Theſe openings, however, weaken the poles much, and cauſe them ſoon to decay; but this kind of paling has a very handſome and ſubſtantial appearance.

The upright lath paling, is formed by driving ſtrong piles of wood into the earth, and croſſing theſe at top and bottom, with horizontal pieces of ſimilar ſtrength. Upon theſe laſt are nailed, at every 6 or 12 inches diſtance, laths or pieces of ſwan wood, of the ſhape and ſize of the laths uſed for the roofs of tiled houſes. This kind of paling prevents cattle from putting their heads through to crop or injure young hedges or trees.

The horizontal paling of firs, or the weedings of other young trees, does not differ from the palings already deſcribed, unleſs in this reſpect, that the materials of which it is formed, conſiſt not of timber cut down for the purpoſe, but of the thinnings of woods or belts of planting. Such palings are uſually more formidable to cattle than any other, becauſe when the lateral twigs that grow out of large branches are loped off in a coarſe manner, the branch ſtill retains a roughneſs which keeps cattle at a diſtance.

The chain horizontal fence is made by fixing ſtrong piles of wood in the earth in the direction in which the fence is to run, and fixing three chains at regular diſtances, extending horizontally from pile to pile, inſtead of croſs bars of wood. Inſtead of poſts of wood, pillars of maſon work are ſometimes uſed, and between theſe the chains are extended. A chain fence will confine horſes or cattle, but is unfit to confine ſheep or hogs. From its expenſive nature, it can only be uſed in public walks, or for ſtretching acroſs ſtreams or pieces of water, where the incloſure can be completed in no other way.

The net fence is uſed for pleaſure grounds, and inſtead of chains, as in the former caſe, it conſiſts of a ſtrong net extended between upright piles. Such a fence may be a very pretty ornament, but could be of little uſe againſt the horns of cattle.

The rope fence is conſtructed like the chain fence, and differs from it only in the uſe of cords inſtead of metal chains, and has the ſame defect of being uſeleſs againſt ſwine and ſheep.

The moveable wooden fence or ſtake, or hurdle fence, conſiſts of a kind of moveable paling, uſed for confining ſheep or cattle to a certain ſpot when feeding upon a turnip field, and in this view it is extremely uſeful;

Fences.

useful; for if the cattle were allowed to range at large over the field, a great quantity of the turnips would be deſtroyed by having pieces eaten from them, which would immediately ſpoil and rot before the remainder could be conſumed; whereas, by the uſe of theſe moveable palings, the ſheep or cattle having only a certain quantity of food allotted to them at a time, are compelled to eat it clean up without any loſs.

The oſier or willow fence, or wattled fence, is made by driving in the direction of the fence, ſtakes of willow or poplar, of half the thickneſs of a man's wriſt, into the earth, about 18 inches aſunder. They are then bound together with ſmall twigs of the willows or poplars twiſted and interwoven with them. If the upright ſtakes have been recently cut down, and if the fence is made about the end of autumn, they will take root and grow in the ſpring. If their new lateral branches are afterwards properly interwoven and twiſted together, they will become in two or three years a permanent and almoſt impenetrable fence.

The paling of growing trees, or rails nailed to growing poſts, is formed by planting beech, larch, or other trees, at the diſtance of a yard from each other, in the direction in which the fence is wanted. When 10 or 12 feet high, they muſt be cut down to ſix feet. The cutting of the tops will make them puſh out a great number of lateral branches, which may be interwoven with the upright part of the tree, as in the caſe of the willow fence already mentioned.

The horizontal and upright ſhingle fence is formed in this manner; ſtout piles are driven into the earth, and deals, of from half an inch to an inch thick, are nailed horizontally upon them in ſuch a way, that the under edge of the uppermoſt deal projects over the upper edge of the one immediately below it, like ſlates or tiles upon houſes. In like manner, the ſhingles or boards may be placed perpendicularly and bound together, by being nailed to horizontal bars of wood.

The warped paling conſiſts of pieces of wood driven into the earth, which are twiſted and interwoven with each other, ſo as to form a very open net-work; the tops of the pieces of wood being bound together by willow or other twigs.

The light open fence with thorns, or branches of trees wove into it, is nothing more than a common paling, whoſe interſtices are filled up with thorns or branches of trees. It is a very effectual fence while it laſts.

Dead hedges are made of the prunings of trees, or the tops of live hedges that have been cut down. They are ſometimes made upon the top of the mound of earth taken out of a ditch, by inſerting the thick ends of the twigs in the earth, and making them reſt in an oblique manner. Sometimes the ſtronger pieces or ſtakes are fixed in the earth, and the ſmaller twigs are uſed to faſten them together at top, by a kind of net-work. What is called the ſtake and rue fence in Scotland, conſiſts of a dead hedge or fence, formed of upright poſts, the intervals between which are filled up with twigs woven horizontally. All theſe, however, can only be regarded as fences of a very temporary nature, which are conſtantly in want of repairs, and therefore requiring a continual expence.

663 General directions for planting hedges.

Before planting live hedges, it is proper to conſider the nature of the land, and what ſorts of plants will thrive beſt in it; and alſo, what is the ſoil from whence the plants are to be taken. As for the ſize, the ſets ought to be about the thickneſs of one's little finger, and cut within about four or five inches of the ground; they ought to be freſh taken up, ſtraight, ſmooth, and well-rooted. Thoſe plants that are raiſed in the nurſery are to be preferred. Fences

In planting outſide hedges, the turf is to be laid, with the graſs-ſide downwards, on that ſide of the ditch on which the bank is deſigned to be made; and ſome of the beſt mould ſhould be laid upon it to bed the quick, which is to be ſet upon it a foot aſunder. When the firſt row of quick is ſet, it muſt be covered with mould; and when the bank is a foot high, you may lay another row of ſets againſt the ſpaces of the former, and cover them as you did the others: the bank is then to be topped with the bottom of the ditch, and a dry or dead hedge laid, to ſhade and defend the under plantation. Stakes ſhould then be driven into the looſe earth, ſo low as to reach the firm ground: theſe are to be placed at about two feet and a half diſtance: and in order to render the hedge yet ſtronger, you may edder it, that is, bind the top of the ſtakes with ſmall long poles; and when the eddering is finiſhed, drive the ſtakes anew.

664 Of managing the hawthorn

The quick muſt be kept conſtantly weeded, and ſecured from being cropped by cattle; and in February it will be proper to cut it within an inch of the ground, which will cauſe it ſtrike root afreſh, and help it much in the growth.

665 Of the crab.

The crab is frequently planted for hedges; and if the plants are raiſed from the kernels of the ſmall wild crabs, they are much to be preferred to thoſe raiſed from the kernels of all ſorts of apples without diſtinction; becauſe the plants of the true ſmall crab never ſhoot ſo ſtrong as thoſe of the apples, and may therefore be better kept within the proper compaſs of a hedge.

666 Black thorn.

The black thorn, or ſloe, is frequently planted for hedges; and the beſt method of doing it, is to raiſe the plants from the ſtones of the fruit, which ſhould be ſown about the middle of January, if the weather will permit, in the place where the hedge is intended; but when they are kept longer out of the ground, it will be proper to mix them with ſand, and keep them in a cool place. The ſame fence will do for it when ſown, as when it is planted.

667 Holly.

The holly is ſometimes planted for hedges; but where it is expoſed, there will be great difficulty in preventing its being deſtroyed: otherwiſe, it is by far the moſt beautiful plant; and, being an evergreen, will afford much better ſhelter for cattle in winter than any other ſort of hedge. The beſt method of raiſing theſe hedges, is to ſow the ſtones in the place where the hedge is intended; and, where this can be conveniently done, the plants will make a much better progreſs than thoſe that are tranſplanted: but theſe berries ſhould be buried in the ground ſeveral months before they are ſown. The way to do this, is to gather the berries about Chriſtmas, when they are uſually ripe, and put them into large flower-pots, mixing ſome ſand with them; then dig holes in the ground, into which the pots muſt be ſunk, covering them over with earth, about ten inches thick. In this place they muſt remain till the following October, when they ſhould be taken

Fences.

taken up, and ſown in the place where the hedge is intended to be made. The ground ſhould be well trenched, and cleared from the roots of all bad weeds, buſhes, trees, &c. Then two drills ſhould be made, at about a foot diſtance from each other, and about two inches deep, into which the ſeeds ſhould be ſcattered pretty cloſe, leſt ſome ſhould fail. When the plants grow up, they muſt be carefully weeded: and if they are deſigned to be kept very neat, they ſhould be cut twice a year, that is in May and in Auguſt; but if they are only deſigned for fences, they need only be ſheered in July. The fences for theſe hedges, while young, ſhould admit as much free air as poſſible; the beſt ſort are thoſe made with poſts and rails, or with ropes drawn through holes made in the poſts; and if the ropes are painted over with a compoſition of melted pitch, brown Spaniſh colour and oil, well mixed, they will laſt ſeveral years.

668 Of garden hedges.

Hedges for ornament in gardens are ſometimes planted with evergreens, in which caſe the holly is preferable to any other; next to this, moſt people prefer the yew; but the dead colour of its leaves renders thoſe hedges leſs agreeable. The laurel is one of the moſt beautiful evergreens; but the ſhoots are ſo luxuriant that it is difficult to keep it in any tolerable ſhape; and as the leaves are large, to prevent the diſagreeable appearance given them by their being cut through with the ſheers, it will be the beſt way to prune them with a knife, cutting the ſhoots juſt down to a leaf. The lauruſtinus is a very fine plant for this purpoſe; but the ſame objection may be made to this as to the laurel: this, therefore, ought only to be pruned with a knife in April when the flowers are going off; but the new ſhoots of the ſame ſpring muſt by no means be ſhortened. The ſmall-leaved and rough-leaved lauruſtinus are the beſt plants for this purpoſe. The true phillyrea is the next beſt plant for hedges, which may be led up to the height of 10 or 12 feet; and if they are kept narrow at the top, that there may be not too much width for the ſnow to lodge upon them, they will be cloſe and thick, and make a fine appearance. The ilex, or evergreen oak, is alſo planted for hedges, and is a fit plant for thoſe deſigned to grow very tall.—The deciduous plants uſually planted to form hedges in gardens are, the hornbeam, which may be kept neat with leſs trouble than moſt other plants. The beech, which has the ſame good qualities with the hornbeam; but the gradual falling of its leaves in winter cauſes a continual litter. The ſmall-leaved Engliſh elm is a proper tree for tall hedges, but theſe ſhould not be planted cloſer than eight or ten feet. The lime-tree has alſo been recommended for the ſame purpoſe; but after they have ſtood ſome years, they grow very thin at bottom, and their leaves frequently turn of a black diſagreeable colour.

669 Of flowering ſhrubs.

Many of the flowering ſhrubs have alſo been planted in hedges, ſuch as roſes, honeyſuckles, ſweet briar, &c. but theſe are difficult to train; and if they were cut to bring them within compaſs, their flowers, which are their greateſt beauty, will be entirely deſtroyed. A correſpondent of the ſociety for improving agriculture in Scotland, however, informs us, that he tried with ſucceſs the eglantine, ſweet briar, or dog-roſe, when all the methods of making hedges practiſed in Eſſex and Hampſhire had been tried in vain. His method was to gather the hips of this plant, and to lay them in a tub till March; the ſeeds were then eaſily rubbed out; after which they were ſowed in a piece of ground prepared for garden peaſe. Next year they came up; and the year after they were planted in the following manner. After marking out the ditch, the plants were laid about 18 inches aſunder upon the ſide graſs, and their roots covered with the firſt turfs that were taken off from the ſurface of the intended ditch. The earth ſide of theſe turfs was placed next to the roots, and other earth laid upon the turfs which had been taken out of the ditch. In four or five years theſe plants made a fence which neither horſes nor cattle of any kind could paſs. Even in two or three years none of the larger cattle will attempt a fence of this kind. Sheep indeed will ſometimes do ſo, but they are always entangled to ſuch a degree, that they would remain there till they died unleſs relieved. Old briars dug up and planted ſoon make an excellent fence; and, where thin, it may be eaſily thickened by laying down branches, which in one year will make ſhoots of ſix or ſeven feet. They bear clipping very well.

Fences.

670 Dr Anderſon's directions.

Dr Anderſon, who hath treated the ſubject of hedging very particularly, is of opinion, that ſome other plants beſides thoſe above mentioned might be uſefully employed in the conſtruction of hedges. Among theſe he reckons the common willow. This, he ſays, by no means requires the wetneſs of ſoil which is commonly ſuppoſed. "It is generally imagined (ſays he), that the willow can be made to thrive nowhere except in wet or boggy ground: but this is one of thoſe vulgar errors, founded upon inaccurate obſervation, too often to be met with in ſubjects relating to rural affairs; for experience has ſufficiently convinced me, that this plant will not only grow, but thrive, in any rich well cultivated ſoil (unleſs in particular circumſtances that need not here be mentioned), even although it be of a very dry nature. It could not, however, in general be made to thrive, if planted in the ſame manner as thorns; nor would it, in any reſpect, be proper to train it up for a fence in the ſame way as that plant. The willow, as a fence, could ſeldom be ſucceſsfully employed, but for dividing into ſeparate incloſures any extenſive field of rich ground: and, as it is always neceſſary to put the ſoil into as good order as poſſible before a hedge of this kind is planted in it, the eaſieſt method of putting it into the neceſſary high tilth, will be to mark off the boundaries of your ſeveral fields in the winter, or early in the ſpring, with a deſign to give a complete fallow to a narrow ridge, ſix or eight feet broad, in the middle of which the hedge is intended to be planted the enſuing winter. This ridge ought to be frequently ploughed during the ſummer ſeaſon, and in the autumn to be well manured with dung or lime, or both (for it cannot be made too rich), and be neatly formed into a ridge before winter.

* *Eſſays on Agriculture*, i. 54, &c.

671 Of the willow.

"Having prepared the ground in this manner, it will be in readineſs to receive the hedge, which ought to be planted as early in winter as can be got conveniently done; as the willow is much hurt by being planted late in the ſpring. But before you begin to make a fence of this kind, it will be neceſſary to provide a ſufficient number of plants: which will be beſt done:

Fences.

done by previouſly rearing them in a nurſery of your own, as near the field to be incloſed as you can conveniently have it; for as they are very bulky, the carriage of them would be troubleſome if they were brought from any conſiderable diſtance. The beſt kinds of willow for this uſe, are ſuch as make the longeſt and ſtrongeſt ſhoots, and are not of a brittle nature. All the large kinds of hood willows may be employed for this uſe; but there is another kind with ſtronger and more taper ſhoots, covered with a dark green bark when young, which, upon the older ſhoots, becomes of an aſh gray, of a firm texture, and a little rough to the touch. The leaves are not ſo long, and a great deal broader than thoſe of the common hoop-willow, pretty thick, and of a dark-green colour. What name this ſpecies is uſually known by, I cannot tell; but as it becomes very quickly of a large ſize at the root, and is ſtrong and firm, it ought to be made choice of for this purpoſe in preference to all other kinds that I have ſeen. The ſhoots ought to be of two or three years growth before they can be properly uſed, and ſhould never be leſs than eight or nine feet in length. Theſe ought to be cut over cloſe by the ground immediately before planting, and carried to the field at their whole length. The planter having ſtretched a line along the middle of the ridge which was prepared for their reception, begins at one end thereof, thruſting a row of theſe plants firmly into the ground, cloſe by the ſide of the line, at the diſtance of 18 or 20 inches from one another; making them all ſtant a little to one ſide in a direction parallel to the line. This being finiſhed, let him begin at the oppoſite end of the line, and plant another row in the intervals between the plants of the former row; making theſe incline as much as the others, but in a direction exactly contrary; and then, plaiting theſe baſket-ways, work them into lozenges like a net, faſtening the tops by plaiting the ſmall twigs with one another, which with very little trouble may be made to bind together very firmly. The whole, when finiſhed, aſſumes a very beautiful net-like appearance, and is even at firſt a tolerable good defence; and, as theſe plants immediately take root and quickly increaſe in ſize, it becomes, after a few years, a very ſtrong fence which nothing can penetrate. This kind of hedge I myſelf have employed; and find that a man may plant and twiſt properly about a hundred yards in a day, if the plants be laid down to his hand: and in a ſituation ſuch as I have deſcribed, I know no kind of fence which could be reared at ſuch a ſmall expence ſo quickly become a defence, and continue ſo long in good order. But it will be greatly improved by putting a plant of eglantine between each two plants of willow, which will quickly climb up and be ſupported by them; and, by its numerous prickles, would effectually preſerve the defenceleſs willow from being browſed upon by cattle.

"As it will be neceſſary to keep the narrow ridge, upon which the hedge is planted, in culture for one year at leaſt, that the plants of eglantine may not be choked by weeds, and that the roots of the willow may be allowed to ſpread with the greater eaſe in the tender mould produced by this means, it will be proper to ſtir the earth once or twice by a gentle horſe-hoe in the beginning of ſummer; and, in the month of June, it may be ſowed with turnips, or planted with cole-worts, which will abundantly repay the expence of the fallow."

Fences.

672 Of Plant hedges in expoſed ſituations, and recovering them when decayed. Vol. ii. p. 16, &c.

The ſame author alſo gives the following uſeful directions for planting hedges in ſituations very much expoſed to the weather, and recovering them when on the point of decaying. "Thoſe who live in an open uncultivated country, have many difficulties to encounter, which others who inhabit more warm and ſheltered regions never experience; and, among the difficulties, may be reckoned that of hardly getting hedges to grow with facility. For, where a young hedge is much expoſed to violent and continued guſts of wind, no art will ever make it riſe with ſo much freedom, or grow with ſuch luxuriance, as it would do in a more ſheltered ſituation and favourable expoſure.

"But although it is impoſſible to rear hedges in this ſituation to ſo much perfection as in the others, yet they may be reared even there, with a little attention and pains, ſo as to become very fine fences.

"It is adviſeable in all caſes, to plant the hedges upon the face of a bank; but it becomes abſolutely neceſſary in ſuch an expoſed ſituation as that I have now deſcribed: for the bank, by breaking the force of the wind, ſcreens the young hedge from the violence of the blaſt, and allows it to advance, for ſome time at firſt, with much greater luxuriance than it otherwiſe could have done.

"But as it may be expected ſoon to grow as high as the bank, it behoves the provident huſbandman to prepare for that event, and guard, with a wiſe forecaſt, againſt the inconvenience that may be expected to ariſe from that circumſtance.

"With this view, it will be proper for him, inſtead of making a ſingle ditch, and planting one hedge, to raiſe a pretty high bank, with a ditch on each ſide of it, and a hedge on each face of the bank; in which ſituation, the bank will equally ſhelter each of the two hedges while they are lower than it; and, when they at length become as high as the bank, the one hedge will in a manner afford ſhelter to the other, ſo as to enable them to advance with much greater luxuriance than either of them would have done ſingly.

"To effectuate this ſtill more perfectly, let a row of ſervice trees be planted along the top of the bank, at the diſtance of 18 inches from each other, with a plant of eglantine between each two ſervices. This plant will advance, in ſome degree, even in this expoſed ſituation; and by its numerous ſhoots, covered with large leaves, will effectually ſcreen the hedge on each ſide of it, which, in its turn, will receive ſome ſupport and ſhelter from them; ſo that they will be enabled to advance all together, and form, in time, a cloſe, ſtrong, and beautiful fence.

"The *ſervice* is a tree but little known in Scotland; although it is one of thoſe that ought perhaps to be often cultivated there in preference to any other tree whatever, as it is more hardy, and, in an expoſed ſituation, affords more ſhelter to other plants than almoſt any other tree I know: for it ſends out a great many ſtrong branches from the under part of the ſtem, which, in time, aſſume an upright direction, and continue to advance with vigour, and carry many leaves to the

Fences. the very bottom, almoſt as long as the tree exiſts: ſo that if it is not pruned, it riſes a large cloſe buſh, till it attains the height of a foreſt tree.

" It is of the ſame genus with the rawn-tree, and has a great reſemblance to it both in flower and fruit; its branches are more waving and pliant; its leaves undivided, broad, and round, ſomewhat reſembling the elm, but white and mealy on the under ſide. It deſerves to be better known than it is at preſent.

" But if, from the poorneſs of the ſoil in which your hedge is planted, or from any other cauſe, it ſhould ſo happen, that, after a few years, the hedge becomes ſickly, and the plants turn poor and ſtunted in appearance, the eaſieſt and only effectual remedy for that diſeaſe, is to cut the ſtems of the plants clean over, at the height of an inch or two above the ground; after which they will ſend forth much ſtronger ſhoots than they ever would have done without this operation. And if the hedge be kept free of weeds, and trained afterwards in the manner above deſcribed, it will, in almoſt every caſe, be recovered, and rendered freſh and vigorous.

" This amputation ought to be performed in autumn, or the beginning of winter; and in the ſpring, when the young buds begin to ſhow themſelves, the ſtumps ought to be examined with care, and all the buds be rubbed off, excepting one or two of the ſtrongeſt and beſt placed, which ſhould be left for a ſtem. For if the numerous buds that ſpring forth round the ſtem are allowed to ſpring up undiſturbed, they will become in a few years as weak and ſtunted as before; and the hedge will never afterwards be able to attain any conſiderable height, ſtrength, or healthfulneſs.—I have ſeen many hedges, that have been repeatedly cut over, totally ruined by this circumſtance not having been attended to in proper time.

" If the ground for ſixteen or twenty feet on each ſide of the hedge be fallowed at the time that this operation is performed, and get a thorough dreſſing with rich manures, and be kept in high order for ſome years afterwards by good culture and meliorating crops, the hedge will proſper much better than if this had been omitted, eſpecially if it had been planted on the level ground, or on the bank of a ſhallow ditch."

673 Of the black alder.

Mr Miller greatly recommends the black alder as ſuperior to any other that can be employed in moiſt ſoils. It may either be propagated by layers or truncheons about three feet long. The beſt time for planting theſe laſt is in February or the month of March. They ought to be ſharpened at their largeſt end, and the ground well looſened before they are thruſt into it, leſt the bark ſhould be torn off, which might occaſion their miſcarriage. They ſhould be ſet at leaſt two feet deep, to prevent their being blown out of the ground by violent winds after they have made ſtrong ſhoots; and they ſhould be kept clear of tall weeds until they have got good heads, after which they will require no farther care. When raiſed by laying down the branches, it ought to be done in the month of October; and by that time twelvemonth they will have roots ſufficient for tranſplantation, which muſt be done by digging a hole and looſening the earth in the place where the plant is to ſtand. The young ſets muſt be planted at leaſt a foot and a half deep; and their tops ſhould be cut off to within about nine inches of the ground; by which means they will ſhoot out many branches. This tree may be trained into very thick and cloſe hedges, to the height of 20 feet and upwards. It will thrive exceedingly on the ſides of brooks; for it grows beſt when part of its roots are in water; and may, if planted there, as is uſual for willows, be cut for poles every fifth or ſixth year. Its wood makes excellent pipes and ſtaves; for it will laſt a long time under ground or in water: and it is likewiſe in great eſtimation among plough-wrights, turners &c. as well as for making ſeveral of the utenſils neceſſary for agriculture. Its bark alſo dies a good black. Fences.

674 Of the birch.

The birch is another tree recommended by Mr Miller as proper for hedges; and in places where the young plants can be eaſily procured, he ſays that the plantation of an acre will not coſt 40 ſhillings, the after expence will not exceed 20 ſhillings: ſo that the whole will not come above three pounds. Aſh trees ought never to be permitted in hedges, both becauſe they injure the corn and graſs by their wide extended roots, and likewiſe on account of the property their leaves have of giving a rank taſte to butter made from the milk of ſuch cattle as feed upon the leaves. No aſh trees are permitted to grow in the good dairy-counties.

675 Of hedges raiſed on the top of ſtone fences.

Where there are plenty of rough flat ſtones, the fences which bound an eſtate or farm are frequently made with them. In Devonſhire and Cornwall it is common to build as it were two walls with theſe ſtones laid upon one another; firſt two and then one between: as the walls riſe they fill the intermediate ſpace with earth, beat the ſtones in flat to the ſides, which makes them lie very firm, and ſo proceed till the whole is raiſed to the intended height. Quick hedges, and even large timber trees, are planted upon theſe walls, and thrive exceeding well. Such incloſures are reckoned the beſt defence that can be had for the ground and cattle; though it can ſcarcely be ſuppoſed but they muſt be diſagreeable to the eye, and ſtand in need of frequent repairs, by the ſtones being forced out of the way by cattle. The beſt way to prevent this is to build ſuch wall in the bottom of a ditch made wide enough on purpoſe, and ſloped down on each ſide. Thus the deformity will be hid; and as the cattle cannot ſtand to face the wall ſo as to attempt to leap over it, the ſtones of which it is compoſed will be leſs liable to be beaten down. The earth taken out of the ditch may be ſpread on the adjacent ground, and its ſides planted with ſuch trees or underwood as will beſt ſuit the ſoil. By leaving a ſpace of ſeveral feet on the inſide for timber, a ſupply of that valuable commodity may be had without doing any injury to the more valuable paſture.

676 Method of conſtructing an excellent fence in graſſy places.

The following is an excellent method of making a durable and beautiful fence in graſſy places. Dig pieces of turf four or five inches thick, the breadth of the ſpade, and about a foot in length. Lay theſe turfs even by a line on one ſide, with the graſs outward, at the diſtance of ten or twelve inches within the mark at which the ditch afterwards to be dug in the ſolid ground is to begin. Then lay, in the ſame manner, but with their graſs ſides turned out the contrary way, another row of turfs, at ſuch a diſtance as to make a breadth of foundation proportioned to the intended

Fences. height of the bank. Thus, even though the ground ſhould prove defective, the bank would be prevented from giving way. A ditch may then be dug of what depth and breadth you pleaſe; or the ground may be lowered with a ſlope on each ſide; and in this caſe there will be no loſs of paſture by the fence; becauſe it may be ſowed with hay-ſeeds, and will bear graſs on both ſides. Part of the earth taken out of the ditches or ſlopes will fill the chaſm between the rows of turf, and the reſt may be ſcattered over the adjacent ground. Three, four, or more layers of turf, may be thus placed upon one another, and the interval between them filled up as before till the bank is brought to its deſired height; only obſerving to give each ſide of it a gentle ſlope for greater ſtrength. The top of this bank ſhould be about two feet and a half wide, and the whole of it filled up with earth, except a ſmall hollow in the middle to retain ſome rain. Quickſets ſhould then be planted along this top, and they will ſoon form an admirable hedge. By this means a bank four feet high, and a ſlope only two feet deep, will make, beſides the hedge, a fence ſix feet high, through which no cattle will be able to force their way: for the roots of the graſs will bind the turf ſo together, that in one year's time it will become entirely ſolid; and it will be yet much ſtronger when the roots of the quick ſhall have ſhot out among it. The only precautions neceſſary to be obſerved in making this bank are, 1. Not to make it when the ground is too dry; becauſe, if a great deal of wet ſhould ſuddenly follow, it will ſwell the earth ſo much as, perhaps, to endanger the falling of ſome of the outſide; which, however, is eaſily remedied if it ſhould happen. 2. If the ſlope be ſuch as ſheep can climb up, ſecure the young quicks, at the time of planting them, by a ſmall dead hedge, either on or near the top, on both ſides. If any of the quicks ſhould die, which they will hardly be more apt to do in this than in any other ſituation, unleſs perhaps in extremely dry ſeaſons, they may be renewed by ſome of the methods already mentioned.—Such fences will anſwer even for a park; eſpecially if we place poſts and rails, about two feet high, a little ſloping over the ſide of the bank, on or near its top: no deer can creep through this, nor even be able to jump over it. It is likewiſe one of the beſt fences for ſecuring cattle; and if the quicks on the banks be kept clipped, it will form a kind of green wall pleaſing to the eye.

677 Elms recommended. In the firſt volume of the Bath Papers we find elms recommended for fences; and the following method of raiſing them for this purpoſe is ſaid to be the beſt. When elm timber is felled in the ſpring, ſow the chips made in trimming or hewing them green, on a piece of ground newly ploughed, as you would corn, and harrow them in. Every chip which has an eye, or bud-knot, or ſome bark on it, will immediately ſhoot like the cuttings of potatoes; and the plants thus raiſed having no tap-roots, but ſhooting their fibres horizontally in the richeſt part of the ſoil, will be more vigorous, and may be more ſafely and eaſily tranſplanted, than when raiſed from ſeeds, or in any other method. The plants thus raiſed for elm fences have greatly the advantage of others; as five, ſix, and ſometimes more, ſtems will ariſe from the ſame chip; and ſuch plants, if cut down within three inches of the ground, will multiply their ſide ſhoots in proportion, and make a hedge thicker, without running to naked wood, than by any other method yet practiſed. If kept clipped for three or four years, they will be almoſt impenetrable. Fences

678 Obſervations on quick hedges. In the ſecond volume of the ſame work, we meet with ſeveral obſervations on quick hedges by a gentleman near Bridgewater. He prefers the white and black thorns to all other plants for this purpoſe; but is of opinion, that planting timber trees in them at proper intervals is a very eligible and proper method. He raiſed ſome of his plants from haws in a nurſery; others he drew up in the woods, or wherever they could be found. His banks were made flat, and three feet wide at the top, with a ſloping ſide next the ditches, which laſt were dug only two feet below the ſurface, and one foot wide at bottom. The turfs were regularly laid, with the graſs downwards, on that ſide of the ditch on which the hedge was to be raiſed, and the beſt of the mould laid at top. The ſets were ſtraight, long, ſmooth, and even growing ones planted as ſoon as poſſible after taking up. They were planted at a foot diſtance; and about every 40 feet young fruit-trees, or thoſe of other kinds, ſuch as aſh, oak, elm, beech, as the ſoil ſuited them. A ſecond row of quickſets was then laid on another bed of freſh earth at the ſame time, and covered with good mould; after which the bank was finiſhed and ſecured properly from injuries by a dead hedge well wrought together, and faſtened by ſtakes of oak-trees on the top of the bank at three feet diſtance. Wherever any of the quickſets had failed or were of a dwindling appearance, he had them replaced with freſh ones from the nurſery, as well as ſuch of the young trees as had been planted on the top of the bank; and cleared the whole from weeds. Thoſe moſt deſtructive to young hedges are the white and black bryony, bindweed, and the traveller's joy. The root of white bryony is as big as a man's leg, and runs very deep: that of black bryony often grows to 30 feet long, and with a kind of tendrils takes hold of the root of the young quick, and chokes it. This root muſt be dug very deep in order to deſtroy it. The third is ſtill more deſtructive to young quicks than the other two, overſhadowing the hedge like an arbour. Its root is ſmaller than that of the two former, but muſt be dug out very clean, as the leaſt piece left will ſend up freſh ſhoots. It is very deſtructive to hedges to allow cattle to browze upon them, which they are very apt to do; but where cattle of ſome kind muſt be allowed acceſs to them, horſes will do by far the leaſt miſchief.

679 Cyder fruit-trees recommended in hedges. With regard to the advantages ariſing from hedges, our author obſerves, that if they were of no farther uſe than as mere fences, it would be the farmer's intereſt to keep them up carefully; for the better they are, the more ſecure are his cattle and crops. But if a judicious mixture of cyder fruit-trees were planted in hedges, the profit ariſing from them only would abundantly repay the coſt of the whole without any loſs of ground. It may poſſibly be objected by ſome, that the hedges would often be hurt by the boys climbing up to get the fruit; but thoſe who make it ſhould remember, or be told, that the beſt kinds of cyder-fruit are ſo hard and auſtere at the time of their being gathered, that nobody can eat them, and even

hogs

Fences.

hogs will hardly touch them. But the greateſt benefit, where no fruit-trees are planted, ariſes from the thorns and wood which quick hedges yield for the fire and other purpoſes."

680 Method of raiſing hornbeam hedges in Germany.

The author of the Eſſays on Huſbandry recommends the hornbeam plant as one of the beſt yet known for making fences, according to the method practiſed in Germany, where ſuch fences are common. "When the German huſbandman (ſays he) erects a fence of this nature, he throws up a parapet of earth, with a ditch on each ſide, and plants his hornbeam ſets in ſuch a manner, that every two plants may be brought to interſect each other in the form of St Andrew's croſs. In that part where the two plants croſs each other, he gently ſcrapes off the bark, and binds them with ſtraw thwartwiſe. Here the two plants conſolidate in a kind of indiſſoluble knot, and puſh from thence horizontal ſtanting ſhoots, which form a ſort of living paliſado or *chevaux de friſe*; ſo that ſuch a protection may be called a rural fortification. The hedges being pruned annually, and with diſcretion, will in a few years render the fence impenetrable in every part.

681 Dr Anderſon's method of mending decayed hedges.

"It ſometimes happens (ſays Dr Anderſon) that a hedge may have been long neglected, and be in general in a healthy ſtate, but full of gaps and openings, or ſo thin and ſtraggling, as to form but a very imperfect ſort of fence. On theſe occaſions, it is in vain to hope to fill up the gaps by planting young quicks; for theſe would always be outgrown, choked, and ſtarved, by the old plants: nor could it be recovered by cutting clear over by the roots, as the gaps would ſtill continue where they formerly were. The only methods that I know of rendering this a fence are, either to mend up the gaps with dead wood, or to *plaſh* the hedge; which laſt operation is always the moſt eligible where the gaps are not too large to admit of being cured by this means.

"The operation I here call *plaſhing*, may be defined, "a wattling made of living wood." To form this, ſome ſtems are firſt ſelected, to be left as ſtakes at proper diſtances, the tops of which are all cut over at the height of four feet from the root. The ſtraggling ſide-branches of the other part of the hedge are alſo lopped away. Several of the remaining plants are then cut over, cloſe by the ground, at convenient diſtances; and the remaining plants are cut perhaps half through, ſo as to permit them to be bent to one ſide. They are then bent down almoſt to a horizontal poſition, and interwoven with the upright ſtakes, ſo as to retain them in that poſition. Care ought to be taken that theſe be laid very low at thoſe places where there were formerly gaps; which ought to be farther ſtrengthened by ſome dead ſtakes or truncheons of willows, which will frequently take root in this caſe, and continue to live. And ſometimes a plant of eglantine will be able to overcome the difficulties it there meets with, ſtrike root, and grow up ſo as to ſtrengthen the hedge in a moſt effectual manner.

"The operator begins at one end of the field, and proceeds regularly forward, bending all the ſtems in one direction, ſo that the points riſe above the roots of the others, till the whole wattling is completed to the ſame height as the uprights.

"An expert operator will perform this work with much greater expedition than one who has not ſeen it done could eaſily imagine. And as all the diagonal wattlings continue to live and ſend out ſhoots from many parts of their ſtems, and as the upright ſhoots that riſe from the ſtumps of thoſe plants that have been cut over quickly ruſh up through the whole hedge, theſe ſerve to unite the whole into one entire maſs, that forms a ſtrong, durable, and beautiful fence. Fences.

"This is the beſt method of recovering an old neglected hedge that hath as yet come to my knowledge.

"In ſome caſes it happens that the young ſhoots of a hedge are killed every winter; in which caſe it ſoon becomes dead and unſightly, and can never riſe to any conſiderable height. A remedy for this diſeaſe may therefore be wiſhed for.

"Young hedges are obſerved to be chiefly affected with this diſorder; and it is almoſt always occaſioned by an injudicious management of the hedge, by means of which it has been forced to ſend out too great a number of ſhoots in ſummer, that are thus rendered ſo ſmall and weakly as to be unable to reſiſt the ſevere weather in winter.

"It often happens that the owner of a young hedge, with a view to render it very thick and cloſe, cuts it over with the ſhears a few inches above the ground the firſt winter after planting; in conſequence of which, many ſmall ſhoots ſpring out from each of the ſtems that has been cut over:—Each of which, being afterwards cut over in the ſame manner, ſends forth a ſtill greater number of ſhoots, which are ſmaller and ſmaller in proportion to their number.

"If the ſoil in which the hedge has been planted is poor, in conſequence of this management, the branches, after a few years, become ſo numerous, that the hedge is unable to ſend out any ſhoots at all, and the utmoſt exertion of the vegetative powers enables it only to put forth leaves. Theſe leaves are renewed in a ſickly ſtate for ſome years, and at leaſt ceaſe to grow at all—the branches become covered with fog, and the hedge periſhes entirely.

"But if the ſoil be very rich, notwithſtanding this great multiplication of the ſtems, the roots will ſtill have ſufficient vigour to force out a great many ſmall ſhoots, which advance to a great length, but never attain a proportional thickneſs. And as the vigour of the hedge makes them continue to vegetate very late in autumn, the froſts come on before the tops of theſe dangling ſhoots have attained any degree of woody firmneſs, ſo that they are killed almoſt entirely by it; the whole hedge becomes covered with theſe long dead ſhoots, which are always diſagreeable to look at, and uſually indicate the approaching end of the hedge.

"The cauſes of the diſorder being thus explained, it will readily occur, that the only radical cure is amputation; which, by giving an opportunity to begin with training the hedge anew, gives alſo an opportunity of avoiding the errors that occaſioned it. In this caſe, care ought to be taken to cut the plants as cloſe to the ground as poſſible, as there the ſtems will be leſs numerous than at any greater height. And particular attention ought to be had to allow very few ſhoots to ariſe from the ſtems that have been cut over, and to guard carefully againſt ſhortening them.

"But as the roots, in the caſe here ſuppoſed, will

Fences. be very ſtrong, the ſhoots that are allowed to ſpring from the ſtems will be very vigorous, and there will be ſome danger of their continuing to grow later in the ſeaſon than they ought in ſafety to do; in which caſe, ſome part of the top of the ſhoot may perhaps be killed the firſt winter, which ought if poſſible to be prevented. This can only be effectually done by giving a check to the vegetation in autumn, ſo as to allow the young ſhoots to harden in the points before the winter approaches. If any of the leaves or branches of a tree are cut away while it is in the ſtate of vegetation, the whole plant feels the loſs, and it ſuffers a temporary check in its growth in proportion to the loſs that it thus ſuſtains. To check, therefore, the vigorous vegetation at the end of autumn, it will be prudent to chooſe the beginning of September for the time of lopping off all the ſupernumerary branches from the young hedge, and for clipping off the ſide-branches that have ſprung out from it; which will, in general, be ſufficient to give it ſuch a check in its growth at that ſeaſon, as will prevent any of the ſhoots from advancing afterwards. If the hedge is extremely vigorous, a few buds may be allowed to grow upon the large ſtumps in the ſpring, with a view to be cut off at this ſeaſon, which will tend to ſtop the vegetation of the hedge ſtill more effectually.

"By this mode of management, the hedge may be preſerved entire through the firſt winter. And as the ſhoots become leſs vigorous every ſucceſſive ſeaſon, there will be leſs difficulty in preſerving them at any future period. It will always be proper, however, to trim the ſides of a very vigorous hedge for ſome years while it is young, about the ſame ſeaſon of the year, which will tend powerfully to prevent this malady. But when the hedge has advanced to any conſiderable height, it will be equally proper to clip it during any of the winter-moths, before Candlemas."

682 Lord Kames's obſervations.

Lord Kames, in his work entitled the Gentleman Farmer, gives ſeveral directions for the raiſing and mending of hedges conſiderably different from thoſe above related. For a deer-park he recommends a wall of ſtone coped with turf, having laburnums planted cloſe to it. The heads of the plants are to be lopped off, in order to make the branches extend laterally, and interweave in the form of a hedge. The wall will prevent the deer from breaking through; and if the hedge be trained eight feet high, they will not attempt to leap over. He prefers the laburnum plant, becauſe no beaſt will feed upon it except a hare, and that only when young and the buſh tender. Therefore, no extraordinary care is neceſſary except to preſerve them from the hare for four or five years. A row of alders may be planted in front of the laburnums, which no hare nor any other beaſt will touch. The wall he recommends to be built in the following manner, as being both cheaper and more durable than one conſtructed entirely of ſtone. Raiſe it of ſtone to the height of two feet and a half from the ground, after which it is to be copped with ſod as follows. Firſt, lay on the wall, with the graſſy ſide under, ſod cut with the ſpade four or five inches deep, and of a length equal to the thickneſs of the wall. Next, cover this ſod with looſe earth rounded like a ridge. Third, prepare thin ſod, caſt with the paring ſpade, ſo long as to extend, beyond the thickneſs of the wall, two inches on each ſide. With theſe cover the looſe earth, keeping the graſſy ſide above; place them ſo much on the edge, that each ſod ſhall cover part of another, leaving only about two inches without cover: when 20 or 30 yards are thus finiſhed, let the ſod be beat with mallets by two men, one on each ſide of the wall, ſtriking both at the ſame time. By this operation, the ſod becomes a compact body that keeps in the moiſture, and encourages the graſs to grow. Laſtly, cut off the ragged ends of the ſod on each ſide of the wall, to make the covering neat and regular. The month of October is the proper ſeaſon for this operation, becauſe the ſun and wind, during ſummer, dry the ſod, and hinder the graſs from vegetating. Moiſt ſoil affords the beſt ſod. Wet ſoil is commonly too fat for binding; and, at any rate, the watery plants it produces will not thrive in a dry ſituation. Dry ſoil, on the other hand, being commonly ill bound with roots, ſhakes to pieces in handling. The ordinary way of coping with ſod, which is to lay them flat and ſingle, looks as if intended to dry the ſod and kill the graſs; not to mention that the ſoil is liable to be blown off the wall by every high wind.

683 Fence for a deer-park.

684 Advantages of a thorn hedge.

The advantages of a thorn hedge, according to our author, are, that it is a very quick grower, when planted in a proper ſoil; ſhooting up ſix or ſeven feet in a ſeaſon. Though tender, and apt to be hurt by weeds when young, it turns ſtrong, and may be cut into any ſhape. Even when old, it is more diſpoſed than other trees to lateral ſhoots; and laſtly, its prickles make it the moſt proper of all for a fence. None of theſe thorns ought to be planted in a hedge till five years of age, and it is of the utmoſt importance that they be properly trained in the nurſery. The beſt ſoil for a nurſery, his lordſhip obſerves, is between rich and poor. In the latter the plants are dwarfiſh: in the former, being luxuriant and tender, they are apt to be hurt during the ſeverity of the weather; and theſe imperfections are incapable of any remedy. An eſſential requiſite in a nurſery is free ventilation. "How common (ſays his lordſhip) is it to find nurſeries in hollow ſheltered places, ſurrounded with walls and high plantations, more fit for pine-apples than barren trees! The plants thruſt out long ſhoots, but feeble and tender: when expoſed in a cold ſituation, they decay, and ſometimes die. But there is a reaſon for every thing: the nurſeryman's view is to make profit by ſaving ground, and by impoſing on the purchaſer tall plants, for which he pretends to demand double price. It is ſo difficult to purchaſe wholeſome and well nurſed plants, that every gentleman farmer ought to raiſe plants for himſelf.

685 Of a proper nurſery for raiſing the plants.

686 Of raiſing them from the roots of old hedges.

"As thorns will grow pleaſantly from roots, I have long practiſed a frugal and expeditious method of raiſing them from the wounded roots that muſt be cut off when thorns are to be ſet in a hedge. Theſe roots, cut into ſmall parts, and put in a bed of freſh earth, will produce plants the next ſpring no leſs vigorous than what are produced from ſeed; and thus a perpetual ſucceſſion of plants may be obtained without any more ſeed. It ought to be a rule, never to admit into a hedge plants under five years old; they deſerve all the additional ſum that can be demanded for them. Young and feeble plants in a hedge are of ſlow growth; and, beſides the loſs of time, the paling neceſſary to ſecure

Fences.

Fences. secure them from cattle muſt be renewed more than once before they become a fence. A thorn hedge may be planted in every month of winter and ſpring, unleſs it be froſt. But I have always obſerved, that thorns planted in October are more healthy, puſh more vigorouſly, and fewer decay, than at any other time. In preparing the thorns for planting, the roots ought to be left as entire as poſſible, and nothing cut away but the ragged parts.

687 Proper method of planting.

"As a thorn hedge ſuffers greatly by weeds, the ground where they are planted ought to be made perfectly clean. The common method of planting, is to leave eight or nine inches along a ſide of the intended ditch, termed a *ſcarſement;* and behind the ſcarſement to lay the ſurface ſoil of the intended ditch, cut into ſquare ſods two or three inches deep, its graſſy ſurface under. Upon that ſod, whether clean or dirty, the thorns are laid, and the earth of the ditch above them. The graſs in the ſcarſement, with what weeds are in the moved earth, ſoon grow up, and require double diligence to prevent the young thorns from being choked. The following method deſerves all the additional trouble it requires. Leaving a ſcarſement as above of 10 inches, and alſo a border for the thorns, broad or narrow according to their ſize; lay behind the border all the ſurface of the intended ditch, champed ſmall with the ſpade, and upon it lay the mouldery earth that fell from the ſpade in cutting the ſaid ſurface. Cover the ſcarſement and border with the under earth, three inches thick at leaſt; laying a little more on the border to raiſe it higher than the ſcarſement, in order to give room for weeding. After the thorns are prepared by ſmoothing their ragged roots with a knife, and lopping off their heads to make them grow buſhy, they are laid fronting the ditch, with their roots on the border, the head a little higher than the root. Care muſt be taken to ſpread the roots among the ſurface-earth, taken out of the ditch, and to cover them with the mouldery earth that lay immediately below. This article is of importance, becauſe the mouldery earth is the fineſt of all. Cover the ſtems of the thorns with the next ſtratum of the ditch, leaving always an inch at the top free. It is no matter how poor this ſtratum be, as the plants draw no nouriſhment from it. Go on to finiſh the ditch, preſſing down carefully every row of earth thrown up behind the hedge, which makes a good ſolid mound impervious to rain. It is a ſafeguard to the young hedge to raiſe this mound as perpendicular as poſſible; and for that reaſon, it may be proper, in looſe ſoil, when the mound is raiſed a foot or ſo, to bind it with a row of the tough ſod, which will ſupport the earth above till it become ſolid by lying. In poor ſoil more care is neceſſary. Behind the line of the ditch the ground intended for the ſcarſement and border ſhould be ſummer fallowed, manured, and cleared of all graſs roots; and this culture will make up for the inferiority of the ſoil. In very poor ſoil, it is vain to think of planting a thorn hedge. In ſuch ground there is a neceſſity for a ſtone fence.

"The only reaſon that can be given for laying thorns as above deſcribed, is to give the roots ſpace to puſh in all directions; even upward into the mound of earth. There may be ſome advantages in this; but, in my apprehenſion, the diſadvantage is much greater of heaping ſo much earth upon the roots as to exclude not only the ſun, but the rain which runs down the ſloping bank, and has no acceſs to the roots. Inſtead of laying the thorns fronting the ditch, would it not do better to lay them parallel to it; covering the roots with three or four inches of the beſt earth, which would make a hollow between the plants and the ſloping bank? This hollow would intercept every drop of rain that falls on the bank, to ſink gradually among the roots. Why, at any rate, ſhould a thorn be put into the ground ſloping? This is not the practice with regard to any other tree; and I have heard of no experiment to perſuade me that a thorn thrives better ſloping than erect. There occurs, indeed, one objection againſt planting thorns erect, that the roots have no room to extend themſelves on that ſide where the ditch is. But does it not hold, that when, in their progreſs, roots meet with a ditch, they do not puſh onward; but, changing their direction, puſh downward at the ſide of the ditch? If ſo, theſe downward roots will ſupport the ditch, and prevent it from being mouldered down by froſt. One thing is evident without experiment, that thorns planted erect may ſooner be made a complete fence than when laid ſloping as uſual. In the latter caſe, the operator is confined to thorns that do not exceed a foot or 15 inches; but thorns five or ſix feet high may be planted erect; and a hedge of ſuch thorns, well cultivated in the nurſery, will in three years arrive to greater perfection than a hedge managed in the ordinary way will do in twice that time."

688 Of ſecuring a hedge after it is planted.

After the hedge is finiſhed, it is abſolutely neceſſary to ſecure it for ſome time from the depredations of cattle; and this is by no means an eaſy matter. "The ordinary method of a paling (ſays his lordſhip) is no ſufficient defence againſt cattle: the moſt gentle make it a rubbing poſt, and the vicious wantonly break it down with their horns. The only effectual remedy is expenſive; viz. two ditches and two hedges, with a mound of earth between them. If this remedy, however, be not palatable, the paling ought at leaſt to be of the ſtrongeſt kind. I recommend the following as the beſt I am acquainted with: Drive into the ground ſtrong ſtakes three feet and a half long, with intervals from eight to twelve inches, according to the ſize of the cattle that are to be incloſed; and all preciſely of the ſame height. Prepare plates of wood ſawed out of logs, every plate three inches broad and half an inch thick. Fix them on the head of the ſtakes with a nail driven down into each. The ſtakes will be united ſo firmly, that one cannot be moved without the whole; and will be proof accordingly againſt the rubbing of cattle. But, after all, it is no fence againſt vicious cattle. The only proper place for it is the ſide of a high road, or to fence a plantation of trees. It will indeed be a ſufficient fence againſt ſheep, and endure till the hedge itſelf becomes a fence. A fence thus completed, including thorns, ditching, wood, nails, &c. will not much exceed two ſhillings every ſix yards."

689 Of training up hedges.

His lordſhip diſcommends the ordinary method of training hedges by cutting off the top and ſhortening the lateral branches in order to make it thick and buſhy. This, as well as the method of cutting off the ſtems two or three inches above the ground, indeed produces

Fences.

produces a great number of ſhoots, and makes a very thick fence, but which becomes ſo weak when bare of leaves, that cattle break through it in every part. To determine the beſt method of proceeding in this caſe, his lordſhip made an experiment on three hedges, which were twelve years old at the time he wrote. The firſt was annually pruned at the top and ſides; the ſides of the ſecond were pruned, but not the top; and the third was allowed to grow without any pruning. The firſt, at the time of writing, was about four feet broad, and thick from top to bottom; but weak in the ſtems, and unable to reſiſt any horned beaſt: the ſecond was ſtrong in its ſtems, and cloſe from top to bottom: the third was alſo ſtrong in its ſtems, but bare of branches for two feet from the ground; the lower ones having been deprived of air and rain by the thick ſhade of thoſe above them. Hence he directs that hedges ſhould be allowed to grow till the ſtems be five or ſix inches in circumference, which will be in ten or twelve years; at which time the hedge will be fifteen feet or more in height. The lateral branches next the ground muſt be pruned within two feet of the ſtem; thoſe above muſt be made ſhorter and ſhorter in proportion to their diſtance from the ground; and at five feet high they muſt be cut cloſe to the ſtem, leaving all above full freedom of growth. By this dreſſing the hedge takes on the appearance of a very ſteep roof; and it ought to be kept in that form by pruning. This form gives free acceſs to rain, ſun, and air: every twig has its ſhare, and the whole is preſerved in vigour. When the ſtems have arrived at their proper bulk, cut them over at five feet from the ground, where the lateral branches end. This anſwers two excellent purpoſes: the firſt is to ſtrengthen the hedge, the ſap that formerly aſcended to the top being now diſtributed to the branches; the next is, that a tall hedge ſtagnates the air, and poiſons both corn and graſs near it. A hedge trained in this manner is impenetrable even by a bull.

690 Plaſhing of hedges diſcommended.

With regard to the practice of *plaſhing* an old hedge recommended by Dr Anderſon, his lordſhip obſerves that "it makes a good interim fence, but at the long run is deſtructive to the plants: and accordingly there is ſcarcely to be met with a complete good hedge where plaſhing has been long practiſed. A thorn is a tree of long life. If, inſtead of being maſſacred by plaſhing, it were raiſed and dreſſed in the way here deſcribed, it would continue a firm hedge perhaps 500 years.

691 Hedges ought to be planted on the ſide of the bank, and no trees allowed in them.

"A hedge ought never to be planted on the top of the mound of earth thrown up from the ditch. It has indeed the advantage of an awful ſituation; but being planted in bad ſoil, and deſtitute of moiſture, it cannot thrive: it is at beſt dwarfiſh, and frequently decays and dies. To plant trees in the line of the hedge, or within a few feet of it, ought to be abſolutely prohibited as a pernicious practice. It is amazing that people ſhould fall into this error, when they ought to know that there never was a good thorn hedge with trees in it. And how ſhould it be otherwiſe? An oak, a beech, an elm, grows faſter than a thorn. When ſuffered to grow in the midſt of a thorn hedge, it ſpreads its roots everywhere, and robs the thorns of their nouriſhment. Nor is this all: the tree, overſhadowing the thorns, keeps the ſun and air from them. At the ſame time, no tree takes worſe with being overſhadowed than a thorn.

Fences.

692 Of filling up gaps.

"It is ſcarcely neceſſary to mention gaps in a hedge, becauſe they will ſeldom happen where a hedge is trained as above recommended. But in the ordinary method of training, gaps are frequent, partly by the failure of plants, and partly by the treſpaſſing of cattle. The ordinary method of filling up gaps is to plant ſweet briar where the gap is ſmall, and a crab where it is large. This method I cannot approve for an obvious reaſon: a hedge ought never to be compoſed of plants which grow unequally. Thoſe that grow faſt, overtop and hurt the ſlow growers; and with reſpect, in particular, to a crab and ſweet briar, neither of them thrive under the ſhade. It is a better method to remove all the withered earth in the gap, and to ſubſtitute freſh ſappy mould mixed with ſome lime or dung. Plant upon it a vigorous thorn of equal height with the hedge, which in its growth will equal the thorns it is mixed with. In that view there ſhould be a nurſery of thorns of all ſizes, even to five feet high, ready to fill up gaps. The beſt ſeaſon for this operation is the month of October. A gap filled with ſweet briar, or a crab lower than the hedge, invites the cattle to break through and trample the young plants under foot; to prevent which, a paling raiſed on both ſides is not ſufficient, unleſs it be raiſed as high as the hedge.

693 In what caſes whins are neceſſary.

"Where a field is too poor to admit of a thorn hedge, if there be no quantity of ſtones eaſily procurable, whins are the only reſource. Theſe are commonly placed on the top of a dry earth dyke, in which ſituation they ſeldom thrive well. The following ſeems preferable. Two parallel ditches three feet wide and two deep, border a ſpace of twelve feet. Within this ſpace raiſe a bank at the ſide of each ditch with the earth that comes out of it, leaving an interval between the two banks. Sow the banks with whin ſeed, and plant a row of trees in the interval. When the whins are pretty well grown, the hedge on one of the banks may be cut down, then the other as ſoon as it becomes a fence, and ſo on alternately. While the whins are young, they will not be diſturbed by cattle, if paſſages be left to go out and in. Theſe paſſages may be cloſed up when the hedge is ſufficiently ſtrong to be a fence. A whin hedge thus managed, will laſt many years, even in ſtrong froſt, unleſs very ſevere. There are many whin hedges in the ſhire of Kincardine not ſo ſkilfully managed, and yet the poſſeſſors appear not to be afraid of froſt. Such fences ought to be extremely welcome in the ſandy grounds of the ſhire of Moray, where there is ſcarcely a ſtone to be found. The few earth fences that are there raiſed, compoſed moſtly of ſand, very ſoon crumble down."

In the fourth volume of Mr Young's Northern Tour, the author recommends the tranſplanting of old hedges, which his correſpondent Mr Beverly ſays he has tried with prodigious ſucceſs. *Annals of Agriculture*, vol. vi p. 357. ib. p 144.

694 Mr Bakewell's fences.

Mr Bakewell, we are told, is very curious in his fences, and plants his quicks in a different manner from what is common in various parts of the kingdom. He plants one row at a foot from ſet to ſet, and making his ditch, lays the earth which comes out of it to form a bank on the ſide oppoſite to the quick. In the common method, the bank is made on the quick ſide above it. Reaſons are not wanting to induce a preference of this

Fences.

this method. The plants grow only in the ſurface the earth uncovered from the atmoſphere, which muſt neceſſarily be a great advantage; whereas, in the uſual way of planting, that earth, which is always the beſt, is loaded by a thick covering obliquely of the earth out of the ditch. If the roots ſhoot in the beſt ſoil, they will be out of the reach of the influences of the air; the conſequence of which is, that they cannot have ſo large a ſpace of that earth as if ſet on the flat. The way to have a tree or a quick thrive in the beſt manner poſſible, is to ſet it on the ſurface without any ditch or trench, that cuts off half its paſture. But if a ditch is neceſſary, the next beſt way muſt of courſe be ſtill to keep it on the flat ſurface; and the worſt way to cover up that ſurface, by loading it with the dead earth out of a trench. To ſay that there are good hedges in the common method is not a concluſive argument, unleſs both were tried on the ſame ſoil and expoſure.

695 Hedges ſtony and gravelly ſoils.

In the 7th volume of the ſame work, a correſpondent, who ſigns himſelf M. M. obſerves, that notwithſtanding all the improvements that have been made in the conſtruction of hedges and fences, there are many ſoils in England, which, from their ſandy and gravelly natures, are little adapted to any of the plants in common uſe, and are therefore ſubject to all the inconveniences of dead hedges and gaps. Of this kind are all the ſandy and gravelly incloſures, which conſtitute ſo large a part of many diſtricts in the iſland. For theſe our author recommends a triple row of furze; though, notwithſtanding its advantages, he ſays it is liable to be deſtroyed by ſevere winters, contrary to the aſſertion of Lord Kames above related. "It is liable (ſays he) to be ſo completely cut off by a ſevere winter, that I have ſeen tracts of many hundred acres laid open in the ſpace of a few weeks, and reduced to as defenceleſs a ſtate as the ſurrounding waſtes. On ſuch ſoils therefore he recommends the holly; the only diſadvantage of which, he ſays, is its ſlow growth. On moſt of theſe ſoils alſo the black thorn will riſe ſpontaneouſly; and even the quick, though ſlowly, will advance to a ſufficient degree of perfection. The birch, however, he particularly recommends, as growing equally on the drieſt and on the wetteſt ſoils, propagating itſelf in ſuch numbers, that, were they not deſtroyed, all the ſandy waſtes of this kingdom would be quickly covered with them. He recommends particularly the keeping of a nurſery for ſuch plants as

696 A proper nurſery.

are commonly uſed for hedges. "I generally (ſays he) pick out a bit of barren land, and after ploughing it three or four times to bury and deſtroy the heath, I find it anſwer extremely well for a nurſery. Into this ſpot I tranſplant quick hollies, and every tree which I uſe for fences or plantations. By eſtabliſhing ſuch a nurſery, a gentleman will always be able to command a ſufficiency of ſtrong and hardy plants which will not deceive his expectations. I look upon thorns of five or ſix years old, which have been twice tranſplanted from the ſeed-bed, to be the beſt of all; but as it may be neceſſary to fill up caſual gaps in hedges that have been planted ſeveral years, a proviſion ſhould be made of plants of every age, to twelve or fourteen years old. All plants which are intended to be moved, ſhould be tranſplanted every two, or at moſt three years; without this attention, they attach themſelves ſo firmly to the ſoil as renders a ſubſequent operation dangerous. All who tranſplant quicks or hollies ought to begin their labours as early as convenient in the autumn; for I have found, by repeated experience, that neither of theſe plants ſucceed ſo well in the ſpring."

Fences.

697 Of repairing ruinous hedges.

When the fences of a tract of ground are in a very ruinous condition, it is abſolutely neceſſary to ſcour the ditches, throw up the banks, and ſecure the whole immediately by the fineſt dead fences we can procure. If there is a total want of living plants, the cultivator can do nothing but plant new hedges; but if, as is generally the caſe, the banks are furniſhed with a multitude of old ſtems, though totally unconnected as a fence, the time and labour requiſite for the intended improvement will be conſiderably abridged. All the ſtraggling branches which add no ſolidity to the fence are to be cut off; after which the reſt of the ſtems muſt be ſhortened to the height of three or four feet. The method of cutting down every thing to the ground, which is now ſo general, our author highly condemns. "Such a fence (ſays he) has within it no principle of ſtrength and connection; it is equally expoſed in every part to depredations of cattle and ſportſmen: and even ſhould it eſcape theſe, the firſt fall of ſnow will nearly demoliſh it. On the contrary, wherever theſe vegetable paliſades can be left, they are impenetrable either for man or horſe, and form ſo many points of union which ſupport the reſt."

Another method of ſtrengthening defective fences is, to bend down ſome of the lateral ſhoots in a horizontal direction, and to ſpread them along the line of the farm, like eſpalier trees in a garden. A ſingle ſtem, when it riſes perpendicularly, will not ſecure a ſpace of more than two or three feet, but when bent longitudinally, it will form a barrier at leaſt ſufficient to repel all cattle but hogs for twelve or fourteen on one ſide. By bending down, our author does not mean the common *plaſhing* method, which is very injurious to the plants; but the ſpreading two or three of the moſt convenient branches along the hedge, and faſtening them down either by pegs or tying, without injury to the ſtem, until they habitually take the propoſed direction. Thoſe who make the experiment for the firſt time will be aſtoniſhed how ſmall a number of plants may be made to fill a bank, with only trifling intervals. The birch is particularly uſeful for this purpoſe; being of ſo flexible a nature, that ſhoots of ten or twelve feet in length may be eaſily forced into a horizontal direction; and if the other ſhoots are pruned away, all the juices of the plant will be applied to nouriſh the ſelected few: by which means they will in a few years acquire all the advantages of poſts and rails, with this material difference, that inſtead of decaying, they become annually better. It is beſides the property of all inclined branches to ſend up a multitude of perpendicular ſhoots; ſo that by this horizontal inclination, if judiciouſly made, you may acquire almoſt all the advantages of the thickeſt fence; but when the ſtems are too old and brittle to bear this operation, it will be adviſable cut off all the uſeleſs ones cloſe to the ground, and next ſpring they will be ſucceeded by a number of young and vigorous ones. Select the beſt of theſe to be trained in the manner already directed, and extirpate all the reſt, to increaſe

698 Plaſhing of hedges diſcommended.

their

Fences.

their vigour. The ſhoots of ſuch old ſtems as have been juſt now deſcribed will attain a greater ſize in three or four years than any young ones that can be planted will do in twelve.

699 Of thickening hedges by laying down the young ſhoots.

Another method which our author has practiſed with the greateſt ſucceſs is the following. The tender ſhoots of moſt trees, if bended downwards and covered with earth, will put forth roots, and being divided from the parent ſtem at a proper time, become freſh plants; an operation well known to gardeners, under the name of *laying*. This may be as advantageous to the farmer, if he will take the very moderate trouble of laying down the young and flexible branches in his fences. Moſt ſpecies of trees, probably all, will be propagated by this method; but particularly the withy, the birch, the holly, the white thorn, and the crab, will alſo take root in this method, though more ſlowly; the latter being an excellent plant for fences, and not at all nice in the ſoil on which it grows. The advantage of laying down branches in this manner over the planting of young ones is, that when you endeavour to fill up a gap by the latter method, they advance very ſlowly, and are in danger of being ſtifled by the ſhade of the large trees; whereas, if you fortify a gap by ſpreading the branches along it in the manner juſt mentioned, and at the ſame time inſert ſome of the moſt thriving ſhoots in the ground, they will advance with all the vigour of the parent plant, and you may allow them to grow until they are ſo fully rooted as to be free from danger of ſuffocation.

700 In what caſe the cutting down of hedges is proper.

It frequently happens, that the fences of an eſtate have been neglected for many years, and exhibit nothing but ragged and deformed ſtems at great intervals. In this caſe it will be proper to cut them all off level with the ground: the conſequence of this is, that next year they will put forth a great number of ſhoots, which may be laid down in every direction, and trained for the improvement of the fence. When this operation is performed, however, it ought always to be done with an axe, and not with a ſaw; it being found that the latter inſtrument generally prevents the vegetation of the plant. All the ſhoots laid down in this manner ſhould be allowed to remain for ſeveral years, that they may be firmly rooted. Thus they will make prodigious advances; and it is to be obſerved, that the more the parent plant is diveſted of all ſuperfluous branches, the greater will be the nouriſhment tranſmitted to the ſcions.

Our author, however, is inclined to ſuſpect that the moſt perfect form of a hedge, at leaſt in all but thoſe compoſed of thorns and prickly plants, is to train up as many ſtems as will nearly touch each other. The force of every fence conſiſts chiefly in the upright ſtems: where theſe are ſufficiently near and ſtrong, the hedge reſiſts all oppoſition, and will equally repel the violence of the bull, and the inſidious attacks of the hogs. It is abſolutely proper that all hedges ſhould be inſpected once a-year; when not only the ditch ought to be thrown out, and the bank ſupported, but the ſtraggling ſhoots of all the live plants ought to be pruned. By theſe are meant all ſuch as project over the ditch beyond the line of the hedge, and which add nothing to its ſtrength, though they deprive the uſeful ſtems of part of their nouriſhment. Where a hedge is compoſed of plants of inferior value, it will be proper to train thoſe in the manner juſt now recommended, and to plant the bank with quick or holly. When theſe laſt have attained a ſufficient ſize, the others may be extirpated; which is beſt done by cutting down all the ſhoots repeatedly in the ſummer, and leaving the roots to rot in the hedge.

Fences.

701 Mr Erſkine's method of conſtructing hedges.

In the 13th volume of the Annals, W. Erſkine, Eſq. gives an account of a method of fencing very much reſembling that recommended by Lord Kames, and which has been already deſcribed. That gentleman is of opinion, that in ſome caſes *dead ſtone-walls*, as they are called, are more advantageous than hedges. "That hedges (ſays he) are more ornamental, cannot be denied; and they are generally allowed to afford more ſhelter: but the length of time, the conſtant attention, and continual expence of defending them until they bear even the reſemblance of a fence, induces many people in thoſe places where the materials are eaſily procured, to prefer the dry ſtone walls; for though the firſt coſt is conſiderable, yet as the farmer reaps the immediate benefit of the fence (which is undoubtedly the moſt ſecure one), they are thought on the whole to be the leaſt expenſive; beſides, the cattle in expoſed ſituations, and eſpecially in theſe northern parts, are ſo impatient of confinement at the commencement of the long, cold, wet nights, that no hedges I have ever yet ſeen, in any part of this iſland, are ſufficient to keep them in."

From conſiderations of this kind, the late Sir George Suttie of Eaſt Lothian was induced to think of a fence which might join the ſtrength of the wall to the ornament of the hedge. His thorns were planted in the uſual manner on the ſide of the ditch: but inſtead of putting behind them a poſt and rail or paling on the top of the bank, he erected a wall two feet and a half high; and being well ſituated for procuring lime, he uſed it in the conſtruction of theſe walls which Mr Erſkine greatly recommends; "as the ſatisfaction they afford, by requiring no repairs, and the duration of them, more than repay the expence: but where the price of lime is high they may be built without any cement, and anſwer the purpoſe very well if the work is properly executed."

In making a new fence of this kind, the ſurface of the ground ſhould be pared off the breadth of the ditch, and likewiſe for two feet more, in order to prevent as much as poſſible the thorns from being injured by the growth of graſs and weeds. The ditch ſhould be five feet broad, two and a half in depth, and one foot broad at the bottom. Leave one foot for an edging or ſcarſement, then dig the earth one ſpit of a ſpade for about one foot, and put about three inches of good earth below the thorn, which ſhould be laid nearly horizontal, but the point rather inclining upwards, in order to let the rain drip to the roots; then add a foot of good earth above it: leave three or four inches of a ſcarſement before another thorn is planted; it muſt not be directly over the lower one, but about nine inches or a foot to one ſide of it: then throw a foot of good earth on the thorn, and trample it well down, and level the top of the bank for about three feet and a half for the baſe of the wall to reſt on. This baſe ſhould be about nine or ten inches, but muſt not

exceed

Fences. exceed one foot from the thorn. The wall ought to be about two feet thick at the bottom and one foot at the top: the cope to be a ſingle ſtone laid flat; then covered with two ſods of turf, the graſs of the undermoſt to be next the wall, and the other ſod muſt have the graſs ſide uppermoſt. The ſods ſhould be of ſome thickneſs, in order to retain moiſture; ſo that they may adhere together, and not be eaſily diſplaced by the wind. The height of the wall to be two feet and a half, excluſive of the ſods; which together ſhould be from four to ſix inches, by which means the wall would be near to three feet altogether. The expence of the fences cannot ſo eaſily be counted, on account of the differences of the prices of labour in different parts. Mr Erſkine had them done with lime, every thing included, from 10½d. to 13d. per ell (which is equal to 37 inches 2 parts), according to the eaſe or difficulty of working the quarry, and the diſtance of it from the place where the fence is erected. The lime coſts about 6d. per boll of about 4.0872667 buſhels; and from 15 to 16 bolls of lime are uſed to the rood of 36 ſquare ells Scots meaſure; and there are upwards of 43 Scots ells, or 44 Engliſh yards. When the common round or flint ſtones are made uſe of, as they require more lime, it is neceſſary to uſe 30 or 35 bolls of lime to the rood. The thorns are ſold from five to ten ſhillings per thouſand, according to their age, reckoning ſix ſcore to the hundred. Making the ditch, laying the thorns, and preparing the top of the wall, generally coſt from 7d. to 8d. every ſix ells. About 50 carts of ſtones, each cart carrying from ſeven to nine cwt. will build a rood; the carriage at 2d. per cart for half a mile's diſtance.

Warmth is undoubtedly extremely beneficial to hedges; and the walls give an effectual ſhelter, which in expoſed ſituations is abſolutely neceſſary for rearing young hedges; and they likewiſe preſerve a proper degree of moiſture about the roots. If the hedges have been planted for ſix or ſeven years before the wall is built, cut them over to two or three inches above the ground with a ſharp tool, either in October or November, or early in the ſpring; and erect the wall as quickly in that ſeaſon as poſſible (the ſpring in this country can ſcarcely be ſaid to begin till the end of March). It is almoſt impoſſible to imagine the rapidity with which hedges grow in favourable ſituations. Mr Erſkine had one cut over in the ſpring, and by the end of the year it was almoſt as high as the wall. In three years he ſuppoſed, that not even the Highland ſheep, who eaſily overleap a wall of four feet and a half in height, would have been able to break through it.

702 Reaſons for planting oak trees in hedges.

Notwithſtanding the reaſons that have been given already againſt the planting of timber trees in hedges, we find the practice recommended by ſome authors as one of the beſt ſituations for raiſing ſhip-timber. The reaſons are, that the roots have free range in the adjoining incloſures, and the top is expoſed to the exerciſe of the winds; by which means the trees are at once enabled to throw out ſtrong arms, and have a large ſpreading head at the ſame time; ſo that we thus at once obtain quickneſs of growth with ſtrength and crookedneſs of timber. Well trained timber trees it is alleged are not prejudicial to hedges, though pollards and low ſpreading trees are deſtructive to the hedge-wood which grows under them; neither are high trees prejudicial to corn-fields like high hedges and pollards, which prevent a proper circulation of air; and in Norfolk, where the cultivation of grain is carried on in great perfection, ſuch lands are ſaid to be *wood-bound*. But when a hedge is trimmed down to four or five feet high, with oaks interſperſed, a circulation of air is rather promoted than retarded by it: and a trimmed hedge will thrive quite well under tall ſtemmed trees, particularly oaks. For arable incloſures, therefore, hedges are recommended of four or five feet high, with oak-timbers from 15 to 25 feet ſtem. Higher hedges are more eligible for graſs-lands: the graſſes affect warmth, by which their growth is promoted, and conſequently their quantity is increaſed, though perhaps their quality may ſuffer ſome injury. A tall fence likewiſe affords ſhelter to cattle, provided it be thick and cloſe at the bottom; but otherwiſe, by admitting the air in currents, it does rather harm than good. The ſhade of trees is equally friendly to cattle in ſummer: for which reaſon it is recommended in graſs incloſures to allow the hedge to make its natural ſhoots, and at the ſame time to have oak-trees planted in it at proper intervals. Upon bleak hills, and in expoſed ſituations, it will be proper to have two or even three rows of hedge-wood, about four feet diſtant from each other; the middle row being permitted to reach, and always to remain at, its natural height: whilſt the ſide rows are cut down alternately to give perpetual ſecurity to the bottom, and afford a conſtant ſupply of materials for dead hedges and other purpoſes of underwood.

703 Beſt method of planting and raiſing holly for hedges.

Much has been ſaid of the excellency of the holly as a material for hedges; and indeed the beauty of the plant, with its extreme cloſeneſs, and continuing green throughout the winter, evidently give it the preference to all others; and could it be raiſed with equal eaſe, there is no doubt that it would come into univerſal practice. Beſides the above properties, the holly will thrive almoſt upon any ſoil; but thin-ſoiled ſtony heights ſeem to be its natural ſituation; and it may properly enough be ſaid, that holly will grow wherever corn will. Its longevity is likewiſe exceſſive; and being of ſlow growth, it does not *ſuck the land*, as the farmers expreſs it, or deprive the crop of its nouriſhment, as other hedges do. The difficulty of raiſing holly may be obviated by planting it under crabs, which have a tendency to grow more upright than hawthorns, and conſequently affording more air, will not impede its progreſs though they afford ſhelter. It may even be raiſed alone without any great difficulty; only in this caſe the dead fence, to ſecure it, muſt be kept up at leaſt ten or twelve years, inſtead of ſix or ſeven, as in the other caſe; and indeed, conſidering the advantages to be derived from fences of this kind, they ſeem to merit all the additional trouble requiſite.

The holly may be raiſed either under the crab or hawthorn in two ways, viz. by ſowing the berries when the quick is planted, or by inſerting the plants themſelves the enſuing midſummer. The former is by much the more ſimple, and perhaps upon the whole the better method. The ſeeds may either be ſcattered among the roots of the deciduous plants, or be ſown in a drill in front: and if plants of holly

Fences.

be put in, they may either be planted between thoſe of the crab, or otherwiſe in front in the quincunx manner.

704 Hedges of whins or furze.

"Whins (furze) have been often employed, ſays Dr Anderſon, as a fence when ſown upon the top of a bank. They are attended with the convenience of coming very quickly to their perfection, and of growing upon a ſoil on which few other plants could be made to thrive: but in the way that they are commonly employed, they are neither a ſtrong nor a laſting fence. The firſt of theſe defects may, in ſome meaſure, be removed, by making the bank upon which they are ſowed (for they never ſhould be tranſplanted) of a conſiderable breadth; in order that the largeneſs of the aggregate body, conſidered as one maſs, may, in ſome meaſure, make up for the want of ſtrength in each individual plant. With this view, a bank may be raiſed of five or ſix feet in breadth at the top, with a large ditch on each ſide of it; raiſing the bank as high as the earth taken from the ditches will permit; the ſurface of which ſhould be ſowed pretty thick with whin ſeeds. Theſe will come up very quickly: and in two or three years will form a barrier that few animals will attempt to break through, and will continue in that ſtate of perfection for ſome years. But the greateſt objection to this plant as a fence is, that, as it advances in ſize, the old prickles always die away; there being never more of theſe alive at any time upon the plant, than thoſe that have been the produce of the year immediately preceding: and theſe thus gradually falling away, leave the ſtems naked below as they advance in height; ſo that it very ſoon becomes an exceeding poor and unſightly fence; the ſtems being entirely bare, and ſo ſlender withal as not to be able to make a ſufficient reſiſtance to almoſt any animal whatever. To remedy this great defect, either of the two following methods may be adopted. The firſt is to take care to keep the bank always ſtored with young plants; never allowing them to grow to ſuch a height as to become bare below: and it was principally to admit of this, without loſing at any time the uſe of the fence, that I have adviſed the bank to be made of ſuch an unuſual breadth. For if one ſide of the hedge be cut quite cloſe to the bank, when it is only two or three years old, the other half will remain as a fence till that ſide become ſtrong again; and then the oppoſite ſide may be cut down in its turn; and ſo on alternately as long as you may incline: by which means the bank will always have a ſtrong hedge upon it without ever becoming naked at the root. And as this plant, when bruiſed, is one of the moſt valuable kinds of winter food yet known for all kinds of domeſtic animals, the young tops may be carried home and employed for that purpoſe by the farmer; which will abundantly compenſate for the trouble of cutting, and the waſte of ground that is occaſioned by the breadth of the bank.

"The other method of preſerving a hedge of whins from turning open below, can only be practiſed where ſheep are kept: but may be there employed with great propriety. In this caſe it will be proper to ſow the ſeeds upon a conical bank of earth, ſhoved up from the ſurface of the ground on each ſide without any ditches. If this is preſerved from the ſheep for two or three years at firſt, they may then be allowed free acceſs to it; and, as they can get up cloſe to the foot of the bank upon each ſide, if they have been accuſtomed to this kind of food, they will eat up all the young ſhoots that are within their reach, which will occaſion them to ſend out a great many lateral ſhoots: and theſe being continually browſed upon, ſoon become as cloſe as could be deſired, and are then in no ſort of danger of becoming naked at the root, although the middle part ſhould advance to a conſiderable height. Fences.

Where furze or whins are to be uſed either as a fence by themſelves, or in aſſiſtance to another, it is perhaps more proper to uſe the French ſeed than that produced in Great Britain, as the former ſeldom ripens in this country, and conſequently cannot like the latter overrun the adjacent incloſure. It may be had at the ſeed-ſhops in London for about 15d. per pound, and one pound will ſow 40 ſtatute roods. When uſed as an aſſiſtant to a hedge, it is more proper to ſow it on the back of the bank than on the top of it; as in this caſe it is more apt to overhang the young plants in the face of the bank; whilſt in the other it is better ſituated for guarding the bank, and preventing it from being torn down by cattle. The method of ſowing is as follows: Chop a drill with a ſharp ſpade about two-thirds of the way up the back of the bank, making the cleft gape as wide as may be without breaking off the lip; and having the ſeed in a quart bottle, ſtopped with a cork and gooſe quill, or with a perforated wooden ſtopper, trickle it along the drill, covering it by means of a broom drawn gently above and over the mouth of the drill. Cloſing the drill with the back of the ſpade, ſhuts up the ſeeds too much from the air, and thus keeps them too long from riſing.

705 Gooſeberry hedge.

We do not know that any perſon has yet attempted to make uſe of the gooſeberry for the purpoſe of making hedges, though few plants ſeem better adapted for that purpoſe. It grows readily. Some varieties of it riſe to a conſiderable height, and by the ſtrength and number of its prickles, it would effectually prevent any animal from breaking through.—It is ſaid that ſome ſpecies of the mulberry not only grow and thrive in England, but are capable of being reared to perfection in Scotland, as has been experienced at Dalkeith. As the leaves of this plant are the food of the ſilk-worm, which produces the moſt beautiful and valuable of all the materials that can occupy the loom, it is perhaps worthy of attention how far it might be worth while to rear it as a fence in hedge-rows with a view to its becoming the baſis of a valuable manufacture.

706 Fences of ſtone walls.

Dry ſtone walls are ſometimes erected of thoſe round and apparently water-worn ſtones which the plough throws out, and which may be gathered in every field. They are uſually coped with ſod. This, however, is a very indifferent fence. In moſt inſtances it is erected by common labourers, and is therefore ill conſtructed, ſo as not even to be of an uniform thickneſs from top to bottom. The round figure of the ſtones alſo prevents the building from being well bound together. Even the cattle rubbing themſelves againſt it are apt to make conſiderable gaps, which render conſtant attention neceſſary to keep it in repair. It is cheaply executed, however, and affords the means of at once fencing the land and clearing it of ſtones. When dry ſtone walls are ſkillfully built by

Fences. by maſons, and made with quarried ſtones finiſhed with a good coping, they look well and laſt for many years; but the coping ought to be of ſtone and not of turf or mud.

To render ſtone and lime walls valuable as fences, they ſhould have a broad baſe, and have a foundation ſufficiently deep to prevent their being injured by the looſening of the ſoil which is produced by froſt. This fence is very durable, but it is alſo very expenſive. To be in perfection, it ought to be executed not with common ſtones gathered from the fields, but with ſtones from the quarry: It ought to be ſecured at the top with a coping of ſtone of the flag kind laid together in ſuch a way as to render the wall narrow at top like the roof of a houſe. If the coping is neglected, the moiſture ſoon finds its way into the heart of the wall, and it is alſo liable to various accidents from idle perſons climbing over it.

707 The Galloway dike. The Galloway dike owes its name to the county in which it was firſt uſed. It conſiſts of a broad building of dry ſtones tapering upwards. Large flat ſtones are then laid on like a coping, and project over the wall on each ſide. Above theſe ſtones large rugged round ſtones are laid, and ſmaller ſtones above theſe, ſo as to admit a free paſſage to the winds which whiſtle through them. The Galloway dike is never raiſed very high, but its tottering appearance ſo terrifies the cattle and ſheep, that they dare not touch it; ſo that it is a very effectual fence, though it neither affords ſhelter nor ornament to the country. It has the advantage, however, of being erected at a very trifling expence; it is not unſuitable to thoſe lower parts of the country in which the ſhelter of high trees and hedges would prove pernicious to the corn crop, and where the confinement of the ſtock is all that is required.

Clay is ſometimes uſed inſtead of lime for binding ſtone walls; but it is a very defective cement; for if froſt ſuddenly ſucceed to wet weather it is apt to ſwell and to tumble down at the next thaw. To guard againſt the effects of moiſture, theſe ſtone and clay walls are ſometimes rough-caſt or coated over with lime. If the coating is very thick and the wall properly coped, it may laſt in this way as long as a wall of ſtone and lime.

For the ſake of the appearance, dry-ſtone walls have ſometimes two or three inches at the top of them on each ſide lipped or waſhed with lime, which adds nothing to their ſtrength, but gives them the appearance of being built entirely with ſtone and lime. With the ſame view, and with the ſame effect, they are ſometimes alſo broad-caſt or coated with lime over their whole ſurface. Dry-ſtone walls, after they are finiſhed are ſometimes pinned and harled, or rough-caſt, that is, the maſon fills up all the interſtices of the building with ſmall ſtones, and afterwards coats it over with lime, which adds conſiderably to its durability.

Low dry-ſtone walls have ſometimes a light paling at the top, which gives them a handſome appearance.

Brick walls are ſometimes uſed where ſtones are extremely ſcarce, but they are chiefly employed for facing garden walls.

708 Frame walls. Frame walls are conſtructed in the following manner. A frame of boards of the width and heighth intended for the future wall is placed upon the line that has been dug for a foundation. The frame is filled to the top with ſtones gathered from the adjoining fields, and a quantity of liquid mortar is poured in amongſt them ſufficient to fill up every interſtice. The whole is allowed to remain for a day or two, or longer, till the building is dried ſo far as to have acquired ſome ſtability. The frame is then removed, and placed a little farther on in the ſame line, but in contact with the laſt-made piece of wall, and the operation is renewed. This is ſuppoſed to have been a very ancient mode of building. Fences

Turf walls are found very uſeful in upland diſtricts for temporary purpoſes, ſuch as for folds, or for protecting young plantations or young hedges. Their ſtrength is ſometimes increaſed, without augmenting the expence of the conſtruction, by intermingling them with ſtones, that is, by forming the wall of alternate layers of turf and ſtone.

709 Mud walls. Mud walls with a mixture of ſtraw, are very frequent in many places both of England and Scotland, and they are uſed not only for fences, but alſo for conſtructing the walls of farm houſes and offices, in the poorer parts of the country. They are formed in the following manner. Straw and clay are incorporated with each other, like hair with plaiſter lime, and formed into large pieces. A ſtratum of theſe is laid at the bottom of the intended wall. The different pieces are then firmly kneaded with the hand, and preſſed at each ſide with a flat board, which not only conſolidates, but gives ſmoothneſs and uniformity to the work. Succeſſive ſtrata are added till the wall is reared to its intended height. If walls thus conſtructed are properly coated with lime, to protect them againſt moiſture, they become very durable; and their appearance is not inferior to that of a ſtone and lime building.

710 Compound fences. Of compound fences, the moſt ordinary is the ſingle hedge and ditch, with or without paling. The mode of planting theſe hedges has been already ſtated on the authority of Lord Kames and others; and we ſhall only add, that if a hedge is wiſhed to riſe with rapidity, the ſpot in which it is planted ought to be enriched with lime, compoſt, or other manures, as hedge plants cannot, any more than other plants, ſpring rapidly without cultivation. When a hedge is planted at the top of a ditch, it may alſo be remarked, that it is doubly neceſſary to give the ditch a proper degree of ſlope, that it may not be undermined by any accident, which would have the effect to lay bare the roots of the hedge, or entirely to bring it down. Where it is wiſhed to render lands incloſed with hedge and ditch fencible at once, a kind of Galloway dike, conſiſting of ſome rows of large coarſe looſe ſtones, may be placed upon the top of the bank, which will have the effect of protecting the hedge againſt cattle.

The double ditch with a hedge in the front of each, is now practiſed, particularly on cold lands, in many parts of Great Britain, It may be remarked, that where theſe double ditches are wanted for drains, it is undoubtedly a proper practice; but in other ſituations it is exceptionable, as laying out unprofitably a large portion of the ſoil.

When a hedge and ditch is uſed, whether ſingle or double, the hedge is ſometimes placed not at the bottom of the bank, which is the uſual way, but in the middle of it, at ſome height above the ordinary ſurface of the field. In ſuch a mode of planting, the hedge is

Fences.

exposed to great injury from the bank mouldering down, and from want of proper nourishment; but the practice is sometimes necessary upon wet lands, where hedges would not thrive, if placed upon the common surface. Sometimes the face of a natural declivity is cut down, in a sloping direction, to within 18 or 20 inches of the bottom. Here a bed is made and covered with good earth, in which the plants are inserted. A hedge planted in this way looks formidable, from the side facing the bank; but it is exposed to more accidents, from a failure of its soil in consequence of frosts, than if planted at the bottom of the banks.

711 Hedge and bank fences.

Sometimes what is called a hedge and bank, or hedge on the top of a bank, is made use of. It consists of a bank of earth taken from the adjoining grounds, broad at bottom and tapering towards the top, along the summit of which the hedge is planted. Such hedges are extremely liable to decay, in consequence of the artificial mound, on which they stand, being unable to retain sufficient moisture for their support, or being washed away from about their roots.

712 Devonshire fences.

The Devonshire fence resembles the one now described. It consists of an earthen mound seven feet wide at bottom, and four at the top, and five feet in height. In the middle of the top of it a row of quicks is planted, and on each side at two feet distance a row of willow stakes, of about an inch in diameter each, and from 18 inches to two feet in length, is stuck in, sloping a little outwards. These stakes take root, and form a kind of live fence for the preservation of the quicks in the middle.

Palings are frequently employed for the protection of young hedges, whether planted on the plain soil or on the top of a ditch: dead hedges, of the kinds formerly mentioned, are also employed for the same purpose. The dead hedge is preferable to the paling, as it shelters the young plants from the inclemency of the weather. The dead hedge, however, ought always to be at some distance from the living one, to allow the latter freely to put forth its branches. As already noticed, walls of different kinds are sometimes erected, whether Galloway dikes or of stone and lime, for the protection of young hedges; but there is a mode of making a hedge in the middle or in the face of a wall which deserves attention. It is executed in the following manner: The face of the bank is first cut down not quite perpendicular, but nearly so. A facing of stone is then begun at the bottom, and carried up regularly in the manner that stone walls are generally built. When it is raised about 18 inches or two feet high, according to circumstances, the space between the wall and the bank is filled up with good earth, well broke and mixed with lime or compost. The thorns are laid upon the earth in such a manner, as that at least four inches of the root and stem shall rest upon the earth, and the extremity of the top shall project beyond the wall. When the plants are thus regularly laid, the roots are covered with earth, and the wall continued upwards, a hole having been left which each plant peeps through. As the wall advances upwards, the space between it and the bank is gradually filled up: when completed the wall is finished with a cop of sod or of stone and lime. When the plants begin to vegetate, the young shoots appear in the face of the wall, rising in a perpendicular direction.

713 Hedges in the face of a wall.

It is said, that Sir James Hall of Dunglass has adopted this mode of inclosing to a considerable extent in East Lothian; that the hedges have made great progress; and that they exhibit, upon the whole, an extremely handsome appearance.

Fences.

714 Belts of Planting.

Whatever may be thought of the propriety of planting trees in hedge-rows, there can be no doubt, that in certain situations the addition to a hedge or hedge and ditch of a belt of planting is a valuable acquisition to its owner and to the country. It is certain, however, as formerly stated, that in low rich soils where corn is chiefly cultivated, particularly when surrounded by hills, belts of planting are not only unnecessary, but even hurtful to the crop. But there are other situations in which they are of the highest value. The peninsula, which forms the county of Caithness, is said to be a proof of this. Its soil is of a good quality, but its value is greatly impaired by its being exposed to sea winds, whose severity checks all vegetation. Many tracts throughout the island are nearly in the same situation; and in all of them nothing more is wanted to improve the country than to intersect it in a judicious manner with hedges and belts of planting. Where belts of planting are meant to remain as an efficient fence, they ought to be of a considerable breadth. In poor and cold situations the breadth ought to be such as to allow space for planting a great number of trees, which, from the shelter they mutually afford, may protect each others growth against the severity of the climate. With the same view, in cold and exposed situations, the young trees should be planted very thick; perhaps four or five times the number that can grow to a full size should be planted. This practice affords a choice of the most healthy plants to be left when the plantation is thinned. In belts of planting an error is sometimes committed of mingling firs, larches, and pines, with oaks, ashes, &c. with the intention that the evergreens should protect for a certain time the other trees, and thereafter be removed. The effect of which too frequently is, that when the evergreens are taken away, their growth is not only checked for several years; but being unable, after experiencing so much shelter, to resist the severity of the climate, they die altogether. This is the more likely to happen in consequence of the rapidity with which the firs and larches grow; for the oaks and other trees are drawn up along with them, and acquire, in some measure, the nature of hot-house plants, unfit to encounter the blasts of a northern climate: hence belts of planting should either be made altogether of evergreens or altogether of deciduous plants, such as oak, ash, &c. If the evergreens are at all introduced among these last, it ought to be sparingly, and at the outside of the belt, with the view to afford only a moderate degree of shelter.

Where fields are meant to remain constantly in pasturage, the belts may be made in a serpentine, and sometimes in a circular form, both for the sake of ornament, and to afford more complete shelter; but this cannot be done where the plough is meant to be introduced. Upon a north exposure, the belts should cross each other, at proper distances, to afford more complete shelter. Upon a south exposure, they ought to run from south to north, to afford a defence against the east and west winds which are the strongest in this country.

Fences. country. Belts of planting require themſelves to be fenced. A fence, which is merely intended to protect their growth, may conſiſt of a mud wall; but if a permanent ſecurity is wanted, a hedge and ditch will be neceſſary.

In ſome ſituations, inſtead of the belt of planting, it is cuſtomary to plant only the corners of the fields; and this plan is adviſable where the country requires but a moderate degree of ſhelter, added to that which it may derive from thriving hedges.

It has been propoſed, that on all ſheep farms of any extent, there ought to be one or more circular belts of planting, incloſing a ſpace of about an acre or an acre and a half in the centre, with a ſerpentine road leading through the belt into this incloſure, the uſe of which is evident. In heavy falls of ſnow numerous flocks are ſometimes buried, and the lives of the ſhepherds are not unfrequently loſt in attempting to drive them to a place of ſafety. On ſuch occaſions, the incloſures we have now mentioned, would be of the utmoſt value. When a ſtorm threatened, the ſheep might be driven to theſe incloſures, where the ſnow could never be piled up by driving winds; and they might there be fed and remain with entire ſafety. If due care were taken to litter the place, a quantity of valuable dung might be collected, if the ſtorm ſhould remain for any length of time.

715 The reed fence.

The reed fence has hitherto been only uſed in gardens. It conſiſts of a kind of wall, formed by ſewing with wrought yarn bundles of reeds, applied perpendicularly to a railing. This fence ſeems well adapted for giving temporary ſhelter to cattle, but as the materials of it cannot be everywhere found, its uſe muſt be very limited.

Fences. The entry to every incloſure ought to be ſecured by gate-poſts; which, if circumſtances will permit, ought always to be of ſtone, and if poſſible, of hewn ſtone, as theſe, when properly conſtructed, will never fail. Trees are ſometimes planted for this purpoſe, and when they have acquired a certain ſize, they are cut over about ten feet above the ſurface of the ground. Theſe form the moſt durable of all gate-poſts. They ſometimes, however, miſgive; in which caſe it is difficult to repair the defect. When gate-poſts are made of dead timber they ſhould be ſtrong, and the wood well prepared by a coat of oil paint, as already mentioned.

716 Gate-poſts.

Of gates for incloſures there are different kinds. What is called the *ſwing-gate*, that croſſes the whole breadth of a carriage road, and is of one piece, is by no means an adviſable form. The length of its bars renders it expenſive, and its great weight with which it pulls againſt the gate-poſt, overſtrains its own hinges, and is apt to bring down the ſide of the gate, unleſs it is erected in a very coſtly and ſolid manner. For this reaſon, a gate with two folding doors is preferable: it hangs upon the gate-poſt only with half its weight, in conſequence of its being divided into two parts. Its hinges are not ſo liable to be hurt by ſtraining, nor are its joints ſo liable to be broke. What is called the *flip-bar gate*, conſiſting of three ſeparate bars which are taken out, and put into the gate poſts every time the entry to the fields is opened and ſhut, is the beſt kind of gate, ſo far as cheapneſs and durability are concerned; but it does not admit of being locked, which renders it unfit for uſe near a public road, and the opening and ſhutting of it are alſo attended with a conſiderable degree of trouble.

717 Gates.

INDEX.

Agrifolium || Agrigentum.

AGRIFOLIUM, or AQUIFOLIUM. See ILEX, BOTANY *Index*.

AGRIGAN, or iſland of St Francis Xavier, in *Geography*, one of the Ladrone or Marianne iſlands. It is 50 miles in circumference, is very mountainous, and has a volcano in it; ſituated in N. Lat. 19. 4. E. Long. 146.

AGRIGENTUM, in *Ancient Geography*, a city of Sicily, part of the ſite of which is now occupied by a town called *Girgenti* from the old name. See GIRGENTI.

According to ancient authors, Dedalus, the moſt famous mechanician of fabulous antiquity, fled to this ſpot for protection againſt Minos, and built many wonderful edifices for Cocalus king of the iſland. Long after his flight, the people of Gela ſent a colony hither 600 years before the birth of Chriſt; and from the name of a neighbouring ſtream called the new city *Acragas*, whence the Romans formed their word *Agrigentum*. Theſe Greeks converted the ancient abode of the Siculi into a citadel to guard the magnificent city which they erected on the hillocks below.

An advantageous ſituation, a free government with all its happy effects, and an active commercial ſpirit, exalted their commonwealth to a degree of riches and power unknown to the other Greek ſettlements, Syracuſe alone excepted. But the proſperity of Agrigentum appears to have been but of ſhort duration, and tyranny ſoon deſtroyed its liberties.

Phalaris was the firſt who reduced it to ſlavery. His name is familiar to moſt readers on account of his cruelty, and the brazen bull in which he tortured his enemies. (See PHALARIS.)—Phalaris met with the common fate of tyrants, and after his death the Agrigentines enjoyed their liberty for 150 years; at the expiration of which term Thero uſurped the ſovereign authority. The moderation, juſtice, and valour of this prince preſerved him from oppoſition while living, and have reſcued his memory from the obloquy of poſterity. He joined his ſon-in-law Gelo, king of Syracuſe, in a war againſt the Carthaginians; in the courſe of which victory attended all his ſteps, and Sicily ſaw herſelf for a time delivered from her African oppreſſors. Soon after his deceaſe, his ſon Thraſydeus was deprived of the diadem, and Agrigentum reſtored to her old democratical government. Ducetius next diſturbed the general tranquillity. He was a chief of the mountaineers, deſcendants of the Siculi; and was an overmatch for the Agrigentines while they were unſupported by alliances, but ſank under the weight of their union with the Syracuſans. Some trifling altercations diſſolved this union, and produced a war, in which the Agrigentines were worſted, and compelled to ſubmit to humiliating terms of peace. Reſentment led them to embrace with joy the propoſals of the Athenians, then meditating an attack upon Syracuſe. Their new friends ſoon made them feel that the ſacrifice of liberty and fortune would be the price of their protection; and this conſideration brought them ſpeedily back to their old connections. But as if it had been decreed that all friendſhip ſhould be fatal to their repoſe, the reconciliation and its effects drew upon them the anger of the Carthaginians. By this enemy their armies were routed, their city taken, their race almoſt extirpated, and ſcarce a veſtige of magnificence was left. Agrigentum lay 50 years buried under its own ruins; when Timoleon, after triumphing over the Carthaginians, and reſtoring liberty to Sicily, collected the deſcendants of the Agrigentines, and ſent them to re-eſtabliſh the dwellings of their forefathers. Their exertions were rewarded with aſtoniſhing ſucceſs; for Agrigentum roſe from its aſhes with ſuch a renewal of vigour, that in a very ſhort time we find it engaged in the bold ſcheme of ſeizing a lucky moment, when Agathocles and Carthage had reduced Syracuſe to the loweſt ebb, and arrogating to itſelf ſupremacy over all the Sicilian republics. Xenodicus was appointed the leader of this arduous enterpriſe; and had his latter operations been as fortunate as his firſt campaign, Agrigentum would have acquired ſuch a preponderance of reputation and power, that the rival ſtates would not have even dared to attack it. But a

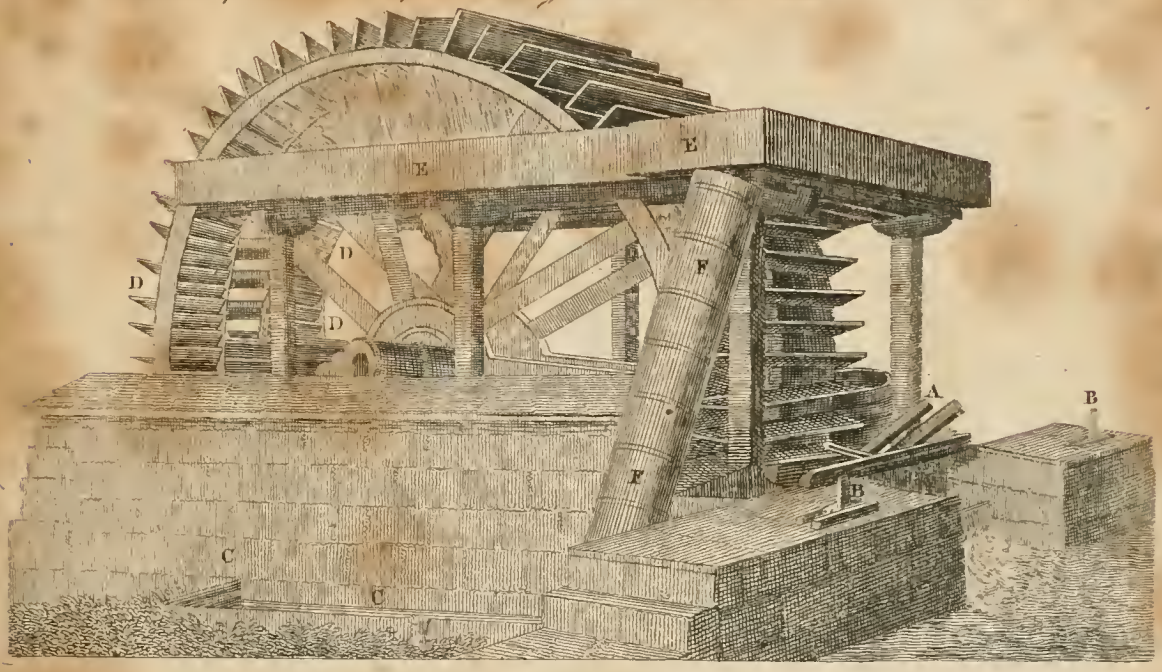
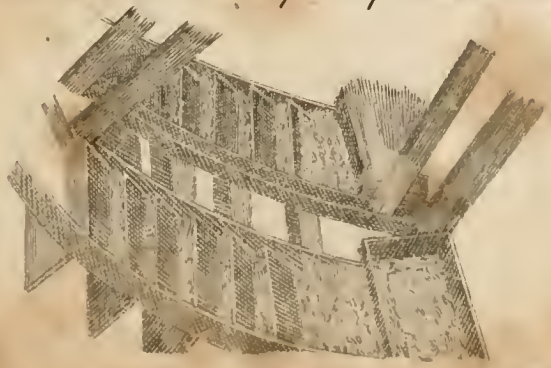
Sketch of the Wheel for raising Water at Blair Drummond



Sketch of the Cistern as seen from above

Sketch of the manner in which the Water is filled from the Troughs into the Buckets



Agrigentum. few brilliant exploits were ſucceeded by a ſevere overthrow; the Agrigentines loſt courage, diſagreed in council, and humbly ſued for peace to Agathocles. This commonwealth afterwards took a ſtrong part with Pyrrhus; and when he left Sicily to the mercy of her enemies, threw herſelf into the arms of Carthage. During the firſt Punic war Agrigentum was the head quarters of the Carthaginians, and was beſieged by the Roman conſuls, who after eight months blockade took it by ſtorm. It nevertheleſs changed maſters ſeveral times during the conteſt between theſe rival ſtates, and in every inſtance ſuffered moſt cruel outrages. After this period very little mention of it occurs in hiſtory, nor do we know the preciſe time of the deſtruction of the old city and the building of the new one. See GIRGENTI.

The principal part of the ancient city lay in the vale; the preſent town, called *Girgenti*, occupies the mountain on which the citadel of Cocalus ſtood.

It was difficult to be more judicious and fortunate in the choice of ſituation for a large city. The inhabitants were here provided with every requiſite for defence, pleaſure, and comfort of life; a natural wall, formed by abrupt rocks, preſented a ſtrong barrier againſt aſſailants; pleaſant hills ſheltered them on three ſides without impeding the circulation of air; before them a broad plain, watered by the Acragas, gave admittance to the ſea breeze, and to a noble proſpect of that awful element; the port or emporium lay in view at the mouth of the river, and probably the road acroſs the flat was lined with gay and populous ſuburbs.

The hoſpitality and parade for which the Agrigentines are celebrated in hiſtory were ſupported by an extenſive commerce; by means of which, the commonwealth was able to reſiſt many ſhocks of adverſity, and always to riſe again with freſh ſplendour. It was, however, cruſhed by the general fall of Grecian liberty; the feeble remnants of its population, which had ſurvived ſo many calamities, were at length driven out of its walls by the Saracens, and obliged to lock themſelves up for ſafety among the bleak and inacceſſible rocks of the preſent city.

At the north-eaſt angle of the ancient limits, upon ſome foundations of large regular ſtones, a church has been erected; a road appears hewn in the ſolid rock for the convenience of the votaries who viſited this temple in ancient days. It was then dedicated to Ceres and her daughter Proſerpine, the peculiar patroneſſes of Sicily.

At the ſouth-eaſt corner, where the ground, riſing gradually, ends in a bold eminence, which is crowned with majeſtic columns, are the ruins of a temple ſaid to have been conſecrated to Juno. To the weſt of this ſtands the building commonly called the temple of Concord; the ſtone of which, and the other buildings, is the ſame as that of the neighbouring mountains and cliffs, a conglutination of ſea ſand and ſhells, full of perforations, of a hard and durable texture, and a deep reddiſh brown colour. This Doric temple has all its columns, entablature, pediments, and walls entire; only part of the roof is wanting. It owes its preſervation to the piety of ſome Chriſtians, who have covered half the nave, and converted it into a church conſecrated under the invocation of St Gregory biſhop of Girgenti. Agrigentum.

Proceeding in the ſame direction, you walk between rows of ſepulchres cut in the rock wherever it admitted of being excavated by the hand of men, or was ſo already by that of nature. Some maſſes of it are hewn into the ſhape of coffins; others drilled full of ſmall ſquare holes employed in a different mode of interment, and ſerving as receptacles of urns. One ponderous piece of the rock lies in an extraordinary poſition; by the failure of its foundation, or the ſhock of an earthquake, it has been looſened from the general quarry, and rolled down the declivity, where it now remains ſupine with the cavities turned upwards. Only a ſingle column marks the confuſed heap of moſs-grown ruins belonging to the temple of Hercules. It ſtood on a projecting rock above a chaſm in the ridge, which was cut through for a paſſage to the emporium.

In the ſame tract, over ſome hills, is ſituated the building uſually called the tomb of Thero. It is ſurrounded by aged olive-trees, which caſt a wild irregular ſhade over the ruin. The edifice inclines to the pyramidical ſhape, and conſiſts at preſent of a triple plinth, and a baſe ſupporting a ſquare pedeſtal; upon this plain ſolid foundation is raiſed a ſecond order, having a window in each front, and at each angle two Ionic pilaſters crowned with an entablature of the Doric order. Its inſide is divided into a vault, a ground room, and one in the Ionic ſtory, communicating with each other by means of a ſmall internal ſtaircaſe.

In the plain are ſeen the fragments of the temple of Eſculapius; part of two columns and two pilaſters, with an intermediate wall, ſupport the end of a farmhouſe, and were probably the front of the cells. Purſuing the track of the walls towards the weſt, you arrive at a ſpot which is covered with the gigantic remains of the temple of the Olympian Jupiter, minutely deſcribed by Diodorus Siculus. It may literally be ſaid that it has not one ſtone left upon another; and it is barely poſſible, with the help of much conjecture, to diſcover the traces of its plan and dimenſions. Diodorus calls it the largeſt temple in the whole iſland: but adds, that the calamities of war cauſed the work to be abandoned before the roof could be put on; and that the Agrigentines were ever after reduced to ſuch a ſtate of poverty and dependence, that they never had it in their power to finiſh this ſuperb monument of the taſte and opulence of their anceſtors. The length of this temple was 370 Greek feet, its breadth 60, and its height 220, excluſive of the foundations or baſement ſtory: the extent and ſolidity of its vaults and underworks were wonderful; its ſpacious porticoes and exquiſite ſculpture were ſuited to the grandeur of the whole. It was not built in the uſual ſtyle of Sicilian temples with a cella of maſſive walls and a periſtyle, but was deſigned in a mixt taſte with half columns let into the walls on the outſide, the inſide exhibiting a plain ſurface.

The next ruin belongs to the temple of Caſtor and Pollux: vegetation has covered the lower parts of the building, and only a few fragments of columns appear between the vines. This was the point of the hill where the wall ſtopt on the brink of a large fiſh-pond ſpoken of by Diodorus: it was cut in the ſolid rock

Agrigentum
‖
Agrippa.

30 feet deep, and water was conveyed to it from the hills. In it was bred a great quantity of fish for the use of public entertainments; swans and various other kinds of wild fowl swam along its surface, for the amusement of the citizens, and the great depth of water prevented an enemy from surprising the town on that side. It is now dry and used as a garden. On the opposite bank, are two tapering columns without their capitals, most happily placed in a tuft of carob trees. Monte Toro, where Hanno encamped with the Carthaginian army, before the Roman consuls drew him into a engagement that ruined his defensive plan, is a noble back-ground to this picturesque group of objects. —The whole space comprehended within the walls of the ancient city abounds with traces of antiquity, foundations, brick-arches, and little channels for the conveyance of water; but in no part are any ruins that can be presumed to have belonged to places of public entertainment. This is the more extraordinary, as the Agrigentines were a sensual people, fond of shows and dramatic performances, and the Romans never dwelt in any place long without introducing their savage games. Theatres and amphitheatres seem better calculated than most buildings to resist the outrages of time; and it is surprising that not even the vestiges of their form should remain on the ground.

Hemp AGRIMONY. See EUPATORIUM, BOTANY *Index*.

Water Hemp AGRIMONY. See BIDENS, BOTANY *Index*.

AGRIONIA, in Grecian antiquity, festivals annually celebrated by the Bœotians in honour of Bacchus. At these festivals, the women pretended to search after Bacchus as a fugitive; and, after some time, gave over their inquiry, saying, that he had fled to the Muses, and was concealed among them.

AGRIOPHAGI, in antiquity, a name given to those who fed on wild beasts. The word is Greek, compounded of αγριος, "wild," "savage," and φαγω, "I eat." The name is given, by ancient writers, to certain people, real or fabulous, said to have fed altogether on lions or panthers. Pliny and Solinus speak of *Agriophagi* in Ethiopia, and Ptolemy of others in India on this side the Ganges.

AGRIPPA, CORNELIUS, born at Cologne in 1486, a man of considerable learning, and by common report a great magician; for the monks at that time suspected every thing of heresy or sorcery which they did not understand. He composed his Treatise of the Excellence of Women, to insinuate himself into the favour of Margaret of Austria, governess of the Low-Countries. He accepted of the charge of historiographer to the emperor, which that princess gave him. The treatise of the Vanity of the Sciences, which he published in 1530, enraged his enemies extremely; as did that of Occult Philosophy, which he printed soon after at Antwerp. He was imprisoned in France for something he had written against Francis I.'s mother; but was enlarged, and went to Grenoble, where he died in 1534. His works are printed in two volumes octavo.

AGRIPPA, *Herod*, the son of Aristobulus and Mariamne, and grandson to Herod the Great, was born in the year of the world 3997, three years before the birth of our Saviour, and seven years before the vulgar era. After the death of Aristobulus his father, Josephus informs us, that Herod his grandfather took care of his education, and sent him to Rome to make his court to Tiberius. The emperor conceived a great affection for Agrippa, and placed him near his son Drusus. Agrippa very soon won the graces of Drusus, and of the empress Antonia. But Drusus dying suddenly, all those who had been much about him were commanded by Tiberius to withdraw from Rome, lest the sight and presence of them should renew his affliction. Agrippa, who had indulged his inclination to liberality, was obliged to leave Rome overwhelmed with debts, and in a very poor condition. He did not think it fit to go to Jerusalem, because he was not able to make a figure there suitable to his birth. He retired therefore to the castle of Massada, where he lived rather like a private person than a prince. Herod the tetrarch, his uncle, who had married Herodias his sister, assisted him for some time with great generosity. He made him principal magistrate of Tiberias, and presented him with a large sum of money: but all this was not sufficient to answer the excessive expences and profusion of Agrippa; so that Herod growing weary of assisting him, and reproaching him with his bad economy, Agrippa took a resolution to quit Judea, and return to Rome. Upon his arrival, he was received into the good graces of Tiberius, and commanded to attend Tiberius Nero the son of Drusus. Agrippa, however, having more inclination for Caius the son of Germanicus, and grandson of Antonia, chose rather to attach himself to him; as if he had some prophetic views of the future elevation of Caius, who at that time was beloved by all the world. The great assiduity and agreeable behaviour of Agrippa so far engaged this prince, that he kept him continually about him. Agrippa

Agrippa being one day overheard by Eutyches, a slave whom he had made free, to express his wishes for Tiberius's death and the advancement of Caius, the slave betrayed him to the emperor; whereupon Agrippa was loaded with fetters, and committed to the custody of an officer. Tiberius soon after dying, and Caius Caligula succeeding him, the new emperor heaped many favours and much wealth upon Agrippa; changed his iron fetters into a chain of gold; set a royal diadem upon his head; and gave him the tetrarchy which Philip, the son of Herod the Great, had been possessed of, that is, Batanæa and Trachonitis. To this he added that of Lysanias; and Agrippa returned very soon into Judea to take possession of his new kingdom.

Caius being soon after killed, Agrippa, who was then at Rome, contributed much by his advice to maintain Claudius in possession of the imperial dignity, to which he had been advanced by the army. But in this affair Agrippa acted a part wherein he showed more cunning and address than sincerity and honesty; for while he made a show of being in the interest of the senate, he secretly advised Claudius to be resolute, and not to abandon his good fortune. The emperor, as an acknowledgment for his kind offices, gave him all Judea and the kingdom of Chalcis, which had been possessed by Herod his brother. Thus Agrippa became of a sudden one of the greatest princes of the east; and was possessed of as much, if not more territories

Agrippa, Agrippina. ritories than had been held by Herod the Great his grandfather. He returned to Judea, and governed it to the great ſatisfaction of the Jews. But the deſire of pleaſing them, and a miſtaken zeal for their religion, induced him to commit an unjuſt action, the memory of which is preſerved in Scripture, Acts xii. 1, 2, &c.; for about the feaſt of the paſſover, in the year of Jeſus Chriſt 44, St James major, the ſon of Zebedee and brother of St John the Evangeliſt, was ſeized by his order and put to death. He proceeded alſo to lay hands on St Peter, and impriſoned him, waiting till the feſtival was over, that he might then have him executed. But God having miraculouſly delivered St Peter from the place of his confinement, the deſigns of Agrippa were fruſtrated. After the paſſover, this prince went from Jeruſalem to Cæſarea, and there had games performed in honour of Claudius. Here the inhabitants of Tyre and Sidon waited on him to ſue for peace. Agrippa being come early in the morning to the theatre, with a deſign to give them audience, ſeated himſelf on his throne, dreſſed in a robe of ſilver-tiſſue, worked in the moſt admirable manner. The riſing ſun darted on it with its rays, and gave it ſuch a luſtre as the eyes of the ſpectators could not endure. When therefore the king ſpoke to the Tyrians and Sidonians, the paraſites around him began to ſay, that it was the voice of a god, and not that of a man. Inſtead of rejecting theſe impious flatteries, Agrippa received them with an air of complacency; but at the ſame time obſerved an owl above him on a cord. He had ſeen the ſame bird before when he was in bonds by order of Tiberius: and it was then told him, that he ſhould be ſoon ſet at liberty; but that whenever he ſaw the ſame thing a ſecond time, he ſhould not live above five days afterwards. He was therefore extremely terrified; and he died at the end of five days, racked with tormenting pains in his bowels, and devoured with worms. Such was the death of Herod Agrippa, after a reign of ſeven years, in the year of Chriſt 44.

Agrippa II. ſon of the preceding Herod, was made king of Chalcis; but three or four years after, he was deprived of that kingdom by Claudius, who gave him in the place of it other provinces. In the war Veſpaſian carried on againſt the Jews, Herod ſent him a ſuccour of 2000 men; by which it appears that though a Jew by religion, he was yet entirely devoted to the Romans, whoſe aſſiſtance indeed he wanted to ſecure the peace of his own kingdom. He lived to the third year of Trajan, and died at Rome A. C. 100. He was the ſeventh and laſt king of the family of Herod the Great. It was before him and Berenice his ſiſter that St Paul pleaded his cauſe at Cæſarea.

Agrippa, *Marcus Viſpanius*, ſon-in-law to Auguſtus, of mean birth, but one of the moſt conſiderable generals among the Romans. Auguſtus's victory over Pompey and Mark Antony was owing to his counſel. He adorned the city with the Pantheon, baths, aqueducts, &c.

AGRIPPINA, daughter of Germanicus, ſiſter of Caligula, and mother of Nero; a woman of wit, but exceſſively lewd. She was thrice married, the laſt time to Claudius her own uncle, whom ſhe poiſoned to make way for Nero her ſon. Nero afterwards cauſed her to be murdered in her chamber, when ſhe bid the executioner ſtab her firſt in the belly that had brought forth ſuch a monſter.

Agrippina ‖ Aguillaneuf.

AGRIPPINA COLONIA UBIORUM, in *Ancient Geography*, now *Cologne:* ſo called from Agrippina, the daughter of Germanicus, and mother of Nero, who had a colony ſent thither at her requeſt by the emperor Claudius, to honour the place of her birth. See COLOGNE.

AGRIPPINIANS, in *Church Hiſtory*, the followers of Agrippinus biſhop of Carthage, in the third century, who firſt introduced and defended the practice of re-baptization.

AGROM, a diſeaſe frequent in Bengal and other parts of the Indies, in which the tongue is parched, chaps, and is ſometimes covered with white ſpots. The Indians are very fearful of this diſeaſe, which they attribute to extreme heat of the ſtomach. Their remedy is, to drink ſome chalybeate liquor, or the juice of mint.

AGROSTEMMA, WILD LYCHNIS, or CAMPION, in *Botany*. See BOTANY *Index*.

AGROSTIS, BENT-GRASS, in *Botany*. See BOTANY *Index*.

AGROSTOGRAPHIA, ſignifies the hiſtory or deſcription of graſſes.

AGROUND, the ſituation of a ſhip whoſe bottom, or any part of it, hangs, or reſts upon the ground, ſo as to render her immoveable, till a greater quantity of water floats her off, or till ſhe is drawn out into the ſtream by the application of mechanical powers.

AGRYPNIA, among *Phyſicians*, implies an inaptitude to ſleep; a troubleſome ſymptom of feveriſh and other diſorders.

AGRYPNIA, in the *Greek Church*, implies the vigil of any of the greater feſtivals.

AGUE, a general name for all periodical fevers, which, according to the different times of the returns of the feveriſh paroxyſm, are denominated tertian, quartan, and quotidian. See MEDICINE *Index*.

AGUE-Cake, the popular name for a hard tumour on the left ſide of the belly, lower than the falſe ribs, ſaid to be the effect of intermittent fevers.

AGUE-Tree, a name given to the ſaſſafras, on account of its febrifuge qualities.

AGUEPERSE, a town of France, ſituated in the Lyonnois, in the department of Puy-de-Dome, about 15 miles north of Clermont.

AGUILLANEUF, or AUGILLANEUF, a form of rejoicing uſed among the ancient Franks on the firſt day of the year. The word is compounded of the French *A* "to," *gui* "miſleto," and *l'an neuf* "the new year." Its origin is traced from a druid ceremony: the prieſts uſed to go yearly in December, which with them was reputed a ſacred month, to gather miſleto of the oak in great ſolemnity. The prophets marched in the front, ſinging hymns in honour of their deities; after them came a herald with a caduceus in his hand; theſe were followed by three druids abreaſt, bearing the things neceſſary for ſacrifice; laſt of all came the chief or arch druid, accompanied with the train of people. The chief druid climbing the oak, cut off the miſleto with a golden ſickle, and the other druids received it in a white cloth; on the firſt day of the year it was diſtributed among the people, after having bleſſed and conſecrated it by crying *A gui l'an neuf*, to proclaim

Aguilar || Agurium.

proclaim the new year. This cry is ſtill continued in Picardy, with the addition of *Plantez, Plantez*, to wiſh a plentiful year. In Burgundy and ſome other parts, the children uſe the ſame word to beg a new-year's gift. In latter times the name *Aguillanneuf* was alſo given to a ſort of begging, practiſed in ſome dioceſes, for church tapers, on new-year's day, by a troop of young people of both ſexes, having a chief, &c. It was attended with various ridiculous ceremonies, as dancing in the church, &c. which occaſioned the ſynods to ſuppreſs it.

AGUILAR, a town of Spain, in the province of Navarre, about 24 miles weſt from Eſtella.

Aguilar del Campo, a town of Old Caſtile, with the title of marquiſate, about 15 leagues north of the city of Burgos.

AGUILLON, or AGUILLONIUS, FRANCIS, a Jeſuit, born at Bruſſels: he was rector of the Jeſuits college at Antwerp, and eminent for his ſkill in mathematics. He was the firſt who introduced that ſcience among the Jeſuits in the Low Countries: he wrote a book of Optics, and was employed in finiſhing his Catoptrics and Dioptrics, when he died in 1617.

AGUIRRA, JOSEPH SÆNZ DE, a Benedictine, and one of the moſt learned men of the 17th century, was born March 24. 1630. He was cenſor and ſecretary of the ſupreme council of the inquiſition in Spain, and interpreter of the Scriptures in the univerſity of Salamanca. He printed three volumes in folio upon Philoſophy, a commentary upon Ariſtotle's ten books of Ethics, and other pieces. He died at Rome in 1699.

AGUL, in *Botany*, a ſynonyme of the hedyſarum. See HEDYSARUM, BOTANY *Index*.

AGUR. The xxxth chapter of the Proverbs begins with this title: The words of Agur, the ſon of Jakeh;" which, according to the ſignification of the original terms, may be tranſlated, as the Vulgate has it, *Verba congregantis, filii vomentis*; which tranſlation Le Clerc condemns, ſuppoſing theſe to be proper names which ought not to be tranſlated. Theſe words are rendered by Louis de Dieu, "the words of him who has recollected himſelf, the ſon of obedience." The generality of the fathers and commentators will have it, that Solomon deſcribes himſelf under the name Agur the ſon of Jakeh; others conjecture that Agur, as well as Lemuel (in chap. xxxi. 1.) were wiſe men who lived in the time of Solomon, and were his interlocutors in the book of Proverbs; an opinion which F. Calmet thinks is without the leaſt ſhow of probability, this book being nothing like a dialogue. This laſt expoſitor thinks it probable, that Agur was an inſpired author different from Solomon, whoſe ſentences it was thought fit to join with thoſe of this prince, becauſe of the conformity of their matter.

AGURAH, in Jewiſh antiquity, the name of a ſilver coin, otherwiſe called *gerah* and *keſhita*

AGURIUM, or AGYRIUM, in *Ancient Geography*, a town of Sicily in the Val di Demona, near the river Semetus. The people were called *Populus Agyrinenſis* by Cicero; *Agyrinus* by Pliny. It was the birth-place of Diodorus Siculus, as he himſelf teſtifies; but he calls it *Argyrium*, as it is now called *S. Philippo d'Argyrone*, which modern name ſeems to confirm that *Argyrium* is the true reading.

AGUSADURA, in ancient cuſtoms, a fee due from vaſſals to their lord for the ſharpening their ploughing tackle. Anciently the tenants in ſome manors were not allowed to have their rural implements ſharpened by any but whom the lord appointed; for which an acknowledgment was to be paid, called *agu ſadura*, in ſome places *aguſage*: which ſome take to be the ſame with what was otherwiſe called *reillage*, from the ancient French *reille*, a ploughſhare. Aguſadura || Ahab.

AGUSTINA, a new earth; which, as the word ſignifies, is taſteleſs, inſoluble in water, and when pure reſembles alumina. It was diſcovered in the year 1800 by Trommſdorff in the Saxon beryl. But as his experiments have not been repeated, the exiſtence of this earth reſts ſolely on his authority.

AGUTI, in *Zoology*, the trivial name of a ſpecies of the mouſe, belonging to the mammalia glires of Linnæus.

AGYEI, in antiquity, a kind of obeliſks, ſacred to Apollo, erected in the veſtibules of houſes, by way of ſecurity.

AGYNEIA, in *Botany*. See BOTANY *Index*.

AGYNIANI, in *Church Hiſtory*, a ſect who condemned all uſe of fleſh, and marriage, as not inſtituted by God, but introduced at the inſtigation of the devil. The word is compounded of the privative α and γυνη woman. They are ſometimes alſo called *Agynenſes*, and *Agynii*: and are ſaid to have appeared about the year 694. It is no wonder they were of no long continuance. Their tenets coincide in a great meaſure with thoſe of the Abelians, Gnoſtics, Cerdonians, and other preachers of chaſtity and abſtinence.

AGYRTÆ, in antiquity, a kind of ſtrolling impoſtors running about the country, to pick up money, by telling fortunes at rich men's doors, pretending to cure diſeaſes by charms, ſacrifices, and other religious myſteries; alſo to expiate the crimes of their deceaſed anceſtors, by virtue of certain odours and fumigations; to torment their enemies, by the uſe of magical verſes, and the like. The word is Greek Αγυρται, formed of the verb αγυρω, *I congregate*; alluding to the practice of charlatans or quacks, who gather a crowd about them.

Agyrtæ, among the Greeks, amount to the ſame with *Æruſcatores* among the Latins, and differ not much from gypſies among us.

AHAB, ſon of Omri king of Iſrael, ſucceeded his father A. M. 3086, and ſurpaſſed all his predeceſſors in impiety and wickedneſs. He married Jezebel the daughter of Ethbaal king of the Zidonians, who introduced the idols of Baal and Aſtarte among the Iſraelites, and engaged Ahab in the worſhip of theſe falſe deities. God, being provoked by the ſins of Ahab, ſent the prophet Elijah to him (1 Kings xvii. 1. *ſeq.*), who declared to him, that there would be a famine of three years continuance. The dearth having laſted three years, the prophet deſired Ahab to gather all the people to Mount Carmel, and with them the prophets of Baal: when they were thus aſſembled, Elijah cauſed fire to deſcend from heaven upon his ſacrifice, after which he obtained of God that it ſhould rain; and then the earth recovered its former fertility. Six years after this, Ben-hadad king of Syria (chap. xx.) laid ſiege to Jeruſalem. But God, provoked at this proud Syrian, ſent a prophet to Ahab, not only

Ahab. to assure him of victory, but to instruct him likewise in what manner he was to obtain it. Ahab was ordered to review the princes of the provinces, which he found to be a chance company, consisting of 232 young men, who were to command the people in Samaria, amounting to about 7000 men; with this small army Ahab was directed to fall upon the great host of the Syrians, and that at noon-day, while Ben-hadad and the 32 kings that accompanied him were drinking and making merry. Ben-hadad having notice that they were marching out of the city, ordered them to be brought before him alive, whatever their designs were; but the young men, followed by this small army, advanced, and killed all that opposed them. Such a panic seized the Syrian troops, that they began to fly, and even Ben-hadad himself mounted his horse and fled with his cavalry: which Ahab perceiving, pursued them, killed great numbers of them, and took a considerable booty. After this the prophet came to Ahab, to animate him with fresh courage, and to caution him to keep upon his guard; assuring him, that Ben-hadad would return against him the year following. According to this prediction, at the end of the year he returned and encamped at Aphek, with a resolution to give the Israelites battle. Both armies being ranged in order of battle for seven days successively, at length upon the seventh day, a battle ensued, wherein the Israelites killed 100,000 of the Syrians, and the rest fled to Aphek; but as they were pressing to get into the city, the walls of Aphek fell upon them and killed 27,000 more. Ben-hadad throwing himself upon the mercy of Ahab, this prince received him into his own chariot, and made an alliance with him. The year following, Ahab desiring to make a kitchen garden near his palace (chap. xxi.), requested of one Naboth, a citizen of Jezreel, that he would sell him his vineyard, because it lay convenient for him. But being refused, he returned in great discontentment to his house, threw himself upon the bed, turned towards the wall, and would eat nothing. Jezebel his wife coming in, asked the reason of his great concern; of which being informed, she procured the death of Naboth, and Ahab took possession of his vineyard. As he returned from Jezreel to Samaria, the prophet Elijah met him, and said, "Hast thou killed and also taken possession? Now saith the Lord, In the place where dogs licked up the blood of Naboth, shall dogs lick thy blood, even thine. As for Jezebel, of her the Lord spoke, saying, The dogs shall eat Jezebel by the way of Jezreel." Ahab, hearing these and other denunciations, rent his clothes, put sackcloth upon his flesh, and gave other indications of his sorrow and repentance. But his repentance was neither sincere nor persevering. Two years after these things, Jehoshaphat king of Judah came to Samaria to visit Ahab (chap. xxii.) at a time when he was preparing to attack Ramoth-gilead, which Ben-hadad king of Syria unjustly withheld from him. The king of Israel invited Jehoshaphat to accompany him in this expedition; which that prince agreed to do, but desired that some prophet might first be consulted. Ahab therefore assembled the prophets of Baal, in number about 400; who all concurred in exhorting the king to march resolutely against Ramoth gilead But Micaiah being also consulted, at Jehoshaphat's suggestion, prophesied the ruin of Ahab. Upon this, Ahab gave orders to his people to seize Micaiah, and to carry him to Amon the governor of the city, and to Joash the king's son; telling him in his name, "Put this fellow in prison, and feed him with the bread of affliction, and with the water of affliction, until I come in peace." But Micaiah said, "If thou return at all in peace, the Lord hath not spoken by me." Ahab, therefore, and Jehoshaphat marched up to Ramoth-gilead; and the king of Israel said unto Jehoshaphat, "I will disguise myself, and enter into the battle, but put thou on my robe:" for he knew that the king of Syria had commanded two-and thirty captains that had rule over his chariots, saying, "Fight neither with small nor with great, save only with the king of Israel." These officers, therefore, having observed that Jehoshaphat was dressed in royal robes, took him for the king of Israel, and fell upon him with great impetuosity: but this prince seeing himself pressed so closely, cried out; and the mistake being discovered, the captains of the king of Syria gave over pursuing him. But one of the Syrian army shot a random arrow, which pierced the heart of Ahab. The battle lasted the whole day, and Ahab continued in his chariot with his face turned towards the Syrians. In the mean time, his blood was still issuing from his wound, and falling in his chariot; and towards the evening he died: whereupon proclamation was made by sound of trumpet, that every man should return to his own city and country. The king of Israel being dead, was carried to Samaria and buried: but his chariot and the reins of his horses were washed in the fish-pool of Samaria, and the dogs licked his blood, according to the word of the prophet. Such was the end of Ahab. His son Ahaziah succeeded him in the year of the world 3107.

Ahab ‖ Ahaz.

AHÆTULA, the trivial name of a species of the coluber. See COLUBER.

AHASUERUS, or ARTAXERXES, the husband of Esther; and according to Archbishop Usher and F. Calmet, the Scripture name for Darius, the son of Hystaspes, king of Persia; though Scaliger supposed Xerxes to have been the husband of Esther, or the Ahasuerus of Scripture: and Dr Prideaux believes him to be Artaxerxes Longimanus. See History of PERSIA.

AHAZ, king of Judah, the son of Jotham, remarkable for his vices and impieties. One of his sons he consecrated, by making him pass through and perish by the fire, in honour of the false god Moloch; and he offered sacrifices and incense upon the high places, upon hills, and in groves. Rezin king of Syria and Pekah king of Israel invaded Judah in the beginning of the reign of Ahaz; and having defeated his army and pillaged the country, they laid siege to Jerusalem. When they found that they could not make themselves masters of that city, they divided their army, plundered the country, and made the inhabitants prisoners of war. Rezin and his part of the confederate army marched with all their spoil to Damascus; but Pekah with his division of the army having attacked Ahaz, killed 120,000 men of his army in one battle, and carried away men, women, and children, without distinction, to the number of 200,000. But as they were carrying those captives to Samaria, the prophet Oded, with the principal inhabitants of the city, came out to meet

Ahaziah II Ahijah.

meet them; and by their remonſtrances prevailed with them to ſet their priſoners at liberty. At the ſame time, the Philiſtines and Edomites invaded other parts of his land, killed multitudes of the people, and carried off much booty. In this diſtreſſed condition, Ahaz finding no other remedy for his affairs, ſent ambaſſadors to Tiglath-pileſer king of the Aſſyrians; and to engage him to his intereſt, he ſtripped the temple and city of all the gold which he could meet with, and ſent it as a preſent. Accordingly Tiglath-pileſer marched to the aſſiſtance of Ahaz, attacked Rezin and killed him, took his capital Damaſcus, deſtroyed it, and removed the inhabitants thereof to Cyrene.

The misfortunes of this prince had no influence to make him better: on the contrary, in the times of his greateſt affliction, he ſacrificed to the Syrian deities, whom he looked upon as the authors of his calamities, and endeavoured to render propitious to him, by honouring them in this manner. He broke in pieces the veſſels of the houſe of God, ſhut up the gates of the temple, and erected altars in all parts of Jeruſalem. He ſet up altars likewiſe in all the cities of Judah, with a deſign to offer incenſe on them. At length he died, and was buried in Jeruſalem, but not in the ſepulchres of the kings of Judah his predeceſſors: which honour he was deprived of, on account of his iniquitous courſe of life. Hezekiah his ſon ſucceeded him in the year of the world 3287, before Jeſus Chriſt 726.

AHAZIAH, the ſon and ſucceſſor of Ahab king of Iſrael, reigned two years, part alone and part with his father Ahab, who ordained him his aſſociate in the kingdom, a year before his death. Ahaziah imitated his father's impieties (1 Kings xxii. 52, *ſeq.*), and paid his adoration to Baal and Aſtarte, the worſhip of whom had been introduced in Iſrael by Jezebel his mother. The Moabites, who had been always obedient to the kings of the ten tribes ever ſince their ſeparation from the kingdom of Judah, revolted after the death of Ahab, and refuſed to pay the ordinary tribute. Ahaziah had not leiſure or power to reduce them (2 Kings i. 1, 2, &c.); for about the ſame time, having fallen through a lattice from the top of his houſe, he hurt himſelf conſiderably, and ſent meſſengers to Ekron, in order to conſult Baalzebub, the god of that place, whether he ſhould recover of the indiſpoſition occaſioned by this accident. But the prophet Elijah went to Ahaziah, and declared that he ſhould not recover from his illneſs: and accordingly he died in the year of the world 3108, and Jehoram his brother ſucceeded to the crown.

AHAZIAH, king of Judah, the ſon of Jehoram and Athaliah, ſucceeded his father in the kingdom of Judah, in the year of the world 3119. He walked in the ways of Ahab's houſe, to which he was allied. He reigned only one year. He was ſlain by Jehu the ſon of Nimſhi.

AHEAD, a ſea term, ſignifying further onward than the ſhip, or at any diſtance before her, lying immediately on that point of the compaſs to which her ſtem is directed. It is uſed in oppoſition to *aſtern*, which expreſſes the ſituation of any object behind the ſhip.

AHIJAH, the prophet of Shilo. He is thought to be the perſon who ſpoke twice to Solomon from God, once while he was building the temple (1 Kings vi. 11.), at which time he promiſed him his protection; and at another time (*id.* xi. 6.) after his falling into all his irregularities, when God expreſſed his indignation with great threatenings and reproaches. Ahijah was one of thoſe who wrote the annals or hiſtory of this prince (2 Chr. ix. 29.). The ſame prophet declared to Jeroboam that he would uſurp the kingdom (1 Kings xi. 29, &c.), and that two heifers ſhould alienate him from the Lord, meaning the golden calves erected by Jeroboam, one at Dan, the other at Bethel. About the end of Jeroboam's reign, towards the year of the world 3046, Abijah the ſon of that prince fell ſick; upon which Jeroboam ſent his wife to this prophet to inquire what would become of the child. The queen therefore went to Ahijah's houſe in Shilo, diſguiſed: But the prophet, upon hearing the ſound of her feet, ſaid, Come in, thou wife of Jeroboam, why feigneſt thou thyſelf to be another? for I am ſent to thee with heavy tidings." Then he commanded her to go and tell Jeroboam all the evil that the Lord had declared he would bring upon his houſe for his impieties; that ſo ſoon as ſhe ſhould enter into the city her ſon Abijah ſhould die, and ſhould be the only one of Jeroboam's houſe that ſhould come to the grave or receive the honours of a burial. Ahijah in all probability did not long ſurvive the time of this laſt prophecy; but with the time and manner of his death we are not acquainted.

Ahitophel.

AHITOPHEL, a native of Gillo, was for ſome time the counſellor of King David, whom he at length deſerted, by joining in the rebellion of Abſalom. This prince, upon his being preferred to the crown by the greateſt part of the Iſraelites, ſent for Ahitophel from Gillo (2 Sam. xv. 12.) to aſſiſt him with his advice in the preſent ſtate of his affairs: for at that time Ahitophel's counſels were received as the oracles of God himſelf (chap. xvi. *ult.*) Nothing gave David more uneaſineſs than this event; and when Huſhai his friend came to wait on him and attend him in his flight, he intreated him to return rather to Jeruſalem, make a ſhow of offering his ſervices to Abſalom, and endeavour to fruſtrate the prudent meaſures which ſhould be propoſed by Ahitophel. When Abſalom was come to Jeruſalem, he deſired Ahitophel to deliberate with his other counſellors upon the meaſures which were proper for him to take. Ahitophel adviſed him in the firſt place to abuſe his father's concubines; ſo that when his party ſhould underſtand that he had diſhonoured his father in this manner, they might conclude that there were no hopes of a reconciliation, and therefore eſpouſe his intereſt more reſolutely. A tent, therefore, being prepared for this purpoſe upon the terrace of the king's palace, Abſalom, in the ſight of all Iſrael, lay with his father's concubines. The next thing Ahitophel propoſed was in the terms following: "Let me now chooſe out 12,000 men, and I will ariſe and purſue after David this night, and I will come upon him while he is weary and weak-handed, and I will make him afraid, and all the people that are with him flee, and I will ſmite the king only; and I will bring back all the people unto thee; the man whom thou ſeekeſt is as if all returned: ſo all the people ſhall be in peace." This advice was very agreeable to Abſalom and all the elders of Iſrael. However,

Abſalom

Ahmella || Ai.

Abſalom deſired Huſhai to be called to have his opinion. Huſhai being come, and hearing what advice Ahitophel had given, ſaid, "The counſel which Ahitophel has given is not good at this time; what, for the preſent, in my opinion, may do better, is this: Let all Iſrael be gathered unto thee, from Dan even to Beerſheba, as the ſand that is by the ſea for multitude, and put thyſelf in the midſt of them, and whereever David is, we may fall upon him, and overwhelm him with our numbers, as the dew falleth upon the ground." This laſt advice being more agreeable to Abſalom and all the elders of Iſrael, was preferred; upon which Ahitophel ſaddled his aſs, went to his houſe at Gillo, hanged himſelf, and was buried in the ſepulchre of his fathers. He foreſaw, without doubt, all that would happen in conſequence of Huſhai's advice, and was determined to prevent the death which he had deſerved, and which David would probably have inflicted on him, as ſoon as he ſhould be reſettled on his throne.

AHMELLA, in *Botany*. See BIDENS, BOTANY *Index*.

AHOLIBAH and AHOLAH, are two feigned names made uſe of by Ezekiel (xxiii. 4.) to denote the two kingdoms of Judah and Samaria. Aholah and Aholibah are repreſented as two ſiſters of Egyptian extraction. Aholah ſtands for Samaria, and Aholibah for Jeruſalem. The firſt ſignifies a *tent;* and the ſecond, *my tent is in her.* They both proſtituted themſelves to the Egyptians and Aſſyrians, in imitating their abominations and idolatries; for which reaſon they were abandoned to thoſe very people for whom they had ſhown ſo paſſionate and ſo impure an affection; they were carried into captivity, and reduced to the ſevereſt ſervitude.

AHULL, in the ſea-language, the ſituation of a ſhip when all her ſails are furled on account of the violence of the ſtorm, and when having laſhed her helm on the lee-ſide, ſhe lies nearly with her ſide to the wind and ſea, her head being ſomewhat inclined to the direction of the wind.

AHUN, a town of France, in the Upper Marche and generality of Moulins, in the department of Creuſe. It is ſeated on the river Creuſe, eight miles ſouth-eaſt of Gueret, 30 north-eaſt of Lomages, and 55 ſouth-eaſt of Moulins. E. Long. 1. 52. N. Lat. 49. 5.

AHUYS, a town of Gothland in Sweden. It is ſmall, but very ſtrong by its ſituation, and has a good port. It is in the principality of Gothland, in the territory of Bleckingy, near the Baltic ſea, about 18 miles from Chriſtianſtadt. E. Long. 14. 10. N. Lat. 56. 20.

AI, in *Ancient Geography*, a town in Judea, to the north of Jericho, called AIN by Joſephus, and the inhabitants *Ainatæ*. Joſhua having ſent a detachment of 3000 men againſt Ai, God permitted them to be repulſed on account of Achan's ſin, who had violated the anathema pronounced againſt the city of Jericho. But after the expiation of this offence, God commanded Joſhua (chap. viii.) to march with the whole army of the Iſraelites againſt Ai, and treat this city and the kingdom thereof as he had treated Jericho, with this difference, that he gave the plunder of the town to the people. Joſhua ſent by night 30,000 men to lie in ambuſh behind Ai; having firſt well inſtructed thoſe who had the command of them in what they were to do; and the next day, early in the morning, he marched againſt the city with the remainder of his army. The king of Ai, perceiving them, ſallied haſtily out of the town with all his people, and fell upon the forces of the Iſraelites, who, upon the firſt onſet, fled, as if they had been under ſome great terror.

Ai || Ajn.

As ſoon as Joſhua ſaw the enemy all out of the gates, he raiſed his ſhield upon the top of a pike, which was the ſignal given to the ambuſcade; whereupon they immediately entered the place, which they found without defence, and ſet fire it. The people of Ai perceiving the ſmoke aſcending, were willing to return, but diſcovered thoſe who had ſet fire to the city in their rear, while Joſhua and thoſe who were with him turning about, fell upon them, and cut them in pieces. The king was taken alive, and afterwards put to death.

The chevalier Foland obſerves, that Joſhua's enterpriſe on Ai, excepting in ſome particulars of military art, is very like that of Gibeah, which is ſcarcely any thing more than a copy of it. It would appear, ſays that writer, by the Scripture account, that Joſhua was not the author of the ſtratagem made uſe of by him: for when God directs himſelf to Joſhua, he ſays, "Go up againſt Ai; lay an ambuſcade behind the town; I have delivered the king and the people of it into thine hands:" yet notwithſtanding this, God might leave the whole glory of the invention and execution of it to him, as to a great general. "Joſhua aroſe, (ſays the ſacred author), and all the people of war, to go up againſt Ai (verſe 3.); and Joſhua choſe out 30,000 mighty men of valour, and ſent them away by night." Foland remarks, that there is a manifeſt contradiction between this verſe and the 12th, wherein it is ſaid that Joſhua choſe out 500 men, whom he ſent to lie in ambuſh, between Bethel and Ai. How is this to be reconciled? Calmet ſays, that Maſius allows but 5000 men for the ambuſcade, and 25,000 for the attack of the city, being perſuaded that an army of 60,000 men could only create confuſion on this occaſion, without any neceſſity for, or advantage in, ſuch numbers; but the generality of interpreters, continues Calmet, acknowledge two bodies to be placed in ambuſcade, both between Bethel and Ai; one of 25,000 and the other of 5000 men.

With regard to the ſignal Joſhua made to that part of his army which lay in ambuſcade, the learned Foland embraces the opinion of the Rabbins, who believe what is called the ſhield to be too ſmall to ſerve for a ſignal: hence they make it to be the ſtaff of one of their colours: from this, our author concludes, that the whole colours were uſed on this occaſion; for in the Aſiatic ſtyle, which is very near the poetic, the part is oftentimes to be taken for the whole.

AJALON, in *Ancient Geography*, a town of the tribe of Dan, one of the Levitical. Another in the tribe of Benjamin, in whoſe valley Joſhua commanded the moon to ſtand ſtill, being then in her decreaſe, and conſequently to be ſeen at the ſame time with the ſun.

AJAN, a coaſt and country of Africa, has the river Quilmanci on the ſouth; the mountains from which the river ſprings, on the weſt; Abyſſinia, or Ethiopia, and the ſtrait of Babelmandel, on the north; and the Eaſtern or Indian ocean, on the eaſt. The

Ajax || Aichſtat.

coaſt abounds with all neceſſaries of life, and has plenty of very good horſes. The kings of Ajan are often at war with the emperor of the Abyſſins; and all the priſoners they take they ſell to the merchants of Cambaya, thoſe of Aden, and other Arabs, who come to trade in their harbours, and give them in exchange, coloured cloths, glaſs-beads, raiſins, and dates; for which they alſo take back, beſides ſlaves, gold and ivory. The whole ſea coaſt, from Zanguebar to the ſtrait of Babelmandel, is called the coaſt of Ajan; and a conſiderable part of it is ſtyled the Deſert coaſt.

AJAX, the ſon of Oileus, was one of the principal generals who went to the ſiege of Troy. He raviſhed Caſſandra the daughter of Priam, even in the temple of Minerva, where ſhe thought to have found ſanctuary. It is ſaid, he made a ſerpent of 15 feet long ſo familiar with him, that it ate at his table, and followed him like a dog. The Locrians had a ſingular veneration for his memory.

AJAX, the ſon of Telamon, was, next to Achilles, the moſt valiant general among the Greeks at the ſiege of Troy. He commanded the troops of Salamis, and performed many great actions, of which we have an account in the Iliad, in *Dictys Cretenſis*, and in the 23d book of Ovid's Metamorphoſes. He was ſo enraged, that the arms of Achilles were adjudged to Ulyſſes, that he immediately became mad. The Greeks paid great honour to him after his death, and erected a magnificent monument to his memory upon the promontory of Rhetium.

AJAX, in antiquity, a ſurious kind of dance, in uſe among the Grecians; intended to repreſent the madneſs of that hero after his defeat by Ulyſſes, to whom the Greeks had given the preference in his conteſt for Achilles's arms. Lucian, in his treatiſe of Dancing, ſpeaks of dancing the *Ajax*.—There was alſo an annual feaſt called *Ajantia*, Αἰάντεια, conſecrated to that prince, and obſerved with great ſolemnity in the iſland of Salamis, at well as in Attica: where, in memory of the valour of Ajax, a bier was expoſed, ſet out with a complete ſet of armour.

AJAZZO, a ſea-port of the iſland of Corſica, in the Mediterranean, with a biſhop's ſee. It is ſituated in a fertile territory, which produces excellent wines. It has a ſmall citadel; the ſtreets are ſpacious, the houſes well built, and the walks agreeable. The number of inhabitants is computed about 4000; many of them are Greeks. The trade of Ajazzo conſiſts of timber, and black, red, and white coral; in the fiſhery of which the inhabitants are employed. E. Long. 8. 50. N. Lat. 41. 50.

AJAZZO, a ſea-port town of Natolia, in the province of Caramania, anciently Cilicia, ſeated on the coaſt of the Mediterranean, 30 miles north of Antioch and 50 weſt of Aleppo, where the city of Iſſus anciently ſtood, and near which Alexander fought his ſecond battle with Darius. E. Long. 33. 10. N. Lat. 37. 0.

AICHSTAT, a town of Germany, in Franconia, and capital of a biſhopric of the ſame name. It is remarkable for a curious piece of workmanſhip, called the Sun of the Holy Sacrament, which is in the church. It is of maſſy gold, of great weight; and is enriched with 350 diamonds, 1400 pearls, 250 rubies, and other precious ſtones. This place is moderately large, and ſeated in a valley on the river Altmul, 10 miles north of Nienburg, and 37 ſouth of Nuremberg. E. Long. 11. 10. N. Lat. 49. 0. The biſhopric is 45 miles in length and 17 in breadth; and the biſhop is chancellor of the church of Mayence or Mentz.

Aid || Aigle.

AID, in a general ſenſe, denotes any kind of aſſiſtance given by one perſon to another.

AID in *Law*, denotes a petition made in court to call in help from another perſon who has intereſt in land, or any thing conteſted.

AID-de-Camp, in military affairs, an officer employed to receive and carry the orders of a general.

AID, *Auxilium*, in ancient cuſtoms, a ſubſidy paid by vaſſals to their lords on certain occaſions. Such were the aid of relief, paid upon the death of the lord meſne to his heir; the *aid cheval*, or capital aid, due to the chief lord on ſeveral occaſions, as, to make his elder ſon a knight, to make up a portion for marrying his daughter, &c.

AIDS, in the French cuſtoms, were certain duties paid on all goods exported or imported into that kingdom.

Court of AIDS, in France, a ſovereign court formerly eſtabliſhed in ſeveral cities, which had cognizance of all cauſes relating to the taxes, gabelles, and aids, impoſed on ſeveral ſorts of commodities, eſpecially wine.

AIDS, in the manege, are the ſame with what ſome writers call *cheriſhings*, and uſed to avoid the neceſſity of corrections.—The inner heel, inner leg, inner rein, &c. are called *inner aids*; as the outer heel, outer leg, outer rein, &c. are called *outer aids*.

AIDAN, a famous Scottiſh biſhop of Lindisfarne, or Holy Iſland, in the 7th century, was employed by Oſwald king of Northumberland in the converſion of the Engliſh, in which he was very ſucceſsful. He was a monk in the monaſtery of Jona, one of the Hebrides. He died in 651.

AIGHENDALE, the name of a liquid meaſure uſed in Lancaſhire, containing ſeven quarts.

AIGE, a bailiwick in the territory of Romand in Switzerland, conſiſts of mountains and valleys, the principal of which are the Aigle and Bex. Through theſe is the great road from Valais into Italy. When you paſs by Villeneuve, which is at the head of the lake of Geneva, you enter into a deep valley three miles wide, bordered on one ſide with the Alps of Switzerland, on the other ſide with thoſe of Savoy, and croſſed by the river Rhone. Six miles from thence you meet with Aigle, a large town, ſeated in a wide part of the valley, where there are vineyards, fields and meadows. The governor's caſtle is on an eminence that overlooks the town, and has a lofty marble tower. This government has nine large pariſhes; and is divided into four parts, Aigle, Bex, Olon, and Ormont. This laſt is among the mountains, and joins to Rougemont. It is a double valley, abounding in paſture-lands. Ivorna, in the diſtrict of Aigle, was in part buried by the fall of a mountain, occaſioned by an earthquake, in 1584.

AIGLE, a ſmall town of France, in Upper Normandy, 23 miles from D'Evereux, and 38 from Roueu, in the department of Orne. It is ſurrounded with walls and ditches, and has ſix gates, three ſuburbs, and three pariſhes. It trades in corn, toys, and more particularly in needles and pins. E. Long. 1. 5. N. Lat. 48. 35.

AIGUILLON,

Aiguillon ſt Ailana.

AIGUILLON, a ſmall town of France, in the province of Guienne, and department of Garonne and Lot, which has a conſiderable trade in wines, brandy, and hemp. E. Long. 0. 22. N. Lat. 44. 45.

AIGUISCE, in *Heraldry*, denotes a croſs with its four ends ſharpened, but ſo as to terminate in obtuſe angles. It differs from the croſs fitchee, in as much as the latter tapers by degrees to a point, and the former only at the ends.

AIKMAN, WILLIAM, a painter of conſiderable eminence, was born in Scotland, October 24. 1682. He was the ſon of William Aikman Eſq. of Cairney, and was intended by his father to follow his own profeſſion, which was that of an advocate at the Scotch bar. But the genius of the ſon led him to other ſtudies. He devoted himſelf to the fine arts, eſpecially that of painting, and having for ſome time proſecuted his ſtudies in Britain, in the year 1707 he went to Italy, reſided in Rome for three years, afterwards travelled to Conſtantinople and Smyrna, and in 1712 returned to his own country. About the year 1723 he fixed his reſidence in London, where he followed the profeſſion of painting, and had the good fortune to be patroniſed by the duke of Argyle, the earl of Burlington, Sir Godfrey Kneller, and other liberal encouragers of the arts. He painted many portraits of perſons of the firſt rank in England and Scotland; and a large picture of the royal family for the earl of Burlington, now in the poſſeſſion of the duke of Devonſhire, which was unfiniſhed at his death. Some of his portraits painted in Scotland are in the poſſeſſion of the duke of Argyle, the duke of Hamilton and others. Mr Aikman died in London, June 4. 1731. Six months previous to his death he had loſt a ſon at the age of 17. The remains of both were removed to Edinburgh, and were interred in the Grayfriars churchyard on the ſame day. Mr Somerville the author of the Chace, Mr Mallet, Mr Allan Ramſay the Scottiſh poet, and Mr Thomſon, were among Mr Aikman's intimate acquaintance; and the muſe of each, in elegiac numbers, offered a warm tribute to the memory of their departed friend. The following epitaph from the pen of Mr Mallet, was engraved on his tomb:

Dear to the good and wiſe, diſprais'd by none,
Here ſleep in peace the father and the ſon;
By virtue as by nature cloſe ally'd,
The painter's genius, but without the pride:
Worth unambitious, wit afraid to ſhine,
Honour's clear light, and friendſhip's warmth divine:
The ſon fair riſing knew too ſhort a date;
But, oh! how more ſevere the father's fate!
He ſaw him torn untimely from his ſide,
Felt all a father's anguiſh—wept and died.

Mr Aikman's ſtile of painting was an imitation of the pleaſing ſimplicity of nature. It is diſtinguiſhed by ſoftneſs of light, mellowneſs of ſhade, and mildneſs and harmony of colouring. His compoſitions have more placid tranquillity of eaſe, than boldneſs of touch and brilliancy of effect. His portraits are ſuppoſed to have ſome reſemblance to thoſe of Kneller, and not only in the imitation of the dreſſes of the time, but in the ſimilarity of tint and manner of working.

AILANA, AILATH, or AHELOTH, anciently a town of Arabia Petræa, ſituated near the Sinus Elanites of the Red ſea. It was alſo called *Elath*, and *Eloth* (Stephanus, Strabo, Moſes). The ſame with *Elana*.

Ailanthus ſt Ailſa.

AILANTHUS, in *Botany*. See BOTANY *Index*.

AILE, in *Law*, a writ which lies where a perſon's grandfather, or great-grandfather, being ſeiſed of lands, &c. in fee-ſimple, the day that he died, and a ſtranger abates and enters the ſame day, and diſpoſſeſſes the heir of his inheritance.

AILESBURY, AYLESBURY, or ALESBURY, a borough town in Buckinghamſhire, conſiſting of about 400 houſes. The ſtreets lie round the market-place, in the middle of which is a convenient hall, where the ſeſſions are held, and ſometimes the aſſizes for the county. It ſends two members to parliament. It is ſixty miles ſouth-eaſt of Buckingham, and forty-four north-weſt of London. W. Long. 0. 40. N. Lat. 51. 40.

AILMER, or ÆTHELMARE, earl of Cornwall and Devonſhire, in the reign of King Edgar. It is not known of what family he was. His authority and riches were great, and ſo alſo in appearance was his piety. He founded the abbey of Cernel, in Dorſetſhire; and had ſo great a veneration for Eadwald, the brother of St Edmund the Martyr, who had lived a hermit in that country, near the Silver Well, as they called it, that with the aſſiſtance of Archbiſhop Dunſtan, he tranſlated his relics to the old church of Cernel. In 1016, when Canute, the ſon of Sueno, invaded England, and found himſelf ſtoutly oppoſed by that valiant Saxon prince Edmund Ironſide, the ſon of Æthelred, this Earl Ailmer, with that arch traitor Eadric Streone, earl of Mercia, and Earl Algar, joined the Dane againſt their natural prince, which was one great cauſe of the Saxons ruin. He did not long ſurvive this; and we find mentioned in hiſtory only one ſon of his, whoſe name was Æthelward, earl of Cornwall, who followed his father's maxims, and was properly rewarded for it. For in 1018, Canute reaping the benefit of their treaſons, and perceiving that the traitors were no longer uſeful, he cauſed the infamous Eadric Streone, and this Earl Æthelward, to be both put to death.

AILRED, or EALRED, abbot of Reveſby in Lincolnſhire, in the reigns of Stephen and Henry II. He was born in 1109, of a noble family, and educated in Scotland with Henry the ſon of King David. On his return to England, he became a monk of the Ciſtertian order, in the monaſtery of Reveſby, of which he afterwards was made abbot. He died on the 12th of January 1166, aged 57, and was buried in his monaſtery. "He was (ſays Leland) in great eſteem during his life; celebrated for the miracles wrought after his death; and admitted into the catalogue of ſaints." He was author of ſeveral works; moſt of which were publiſhed by Gilbo the Jeſuit at Douay, 1631; part of them may be alſo found in the *Bibliotheca-Ciſtertienſis*, and *Bibliotheca Patrum*. His principal work is the *Speculum charitatis*. Leland, Bale, and Pits, mention ſeveral manuſcripts which never were publiſhed.

AILSA, an inſulated rock on the weſtern coaſt of Scotland, between the ſhores of Ayrſhire and Cantire. It is two miles in circumference at the baſe, is acceſſible only at one place, and riſes to a great height in a pyramidical form. A few goats and rabbits pick up a ſubſiſtence among the ſhort graſs and furze; but the

Ainſworth || Air.

importance of the rock conſiſts in the great variety and immenſe numbers of birds which frequent it, particularly the gannets or ſolan geeſe, ſome of which are taken for the table, and others for the feathers. The rock is rented from the earl of Caſſilis at 25l. per annum. The depth of water around the baſe is from 7 to 48 fathoms. It is ſurrounded with excellent banks, well ſtocked with cod and other white fiſh. On one part of the rock are the remains of an old caſtle, which is ſaid to have been erected by Philip II. of Spain, about the time that the Spaniſh armada invaded Britain.

AINSWORTH, Dr Henry, an eminent nonconformiſt divine, who, about the year 1590, diſtinguiſhed himſelf among the Browniſts; which drew upon him ſuch troubles that he was obliged to retire to Holland, and became miniſter of a church at Amſterdam. His ſkill in the Hebrew language, and his excellent Annotations on the Holy Scriptures, which are ſtill highly eſteemed, gained him great reputation. He alſo wrote ſeveral pieces in defence of the Browniſts, and ſeveral other works.

Ainsworth, *Robert*, born at Woodyale in Lancaſhire in 1660, was maſter of a boarding ſchool at Bethnal green, from whence he removed to Hackney, and to other places in the neighbourhood of London. After acquiring a moderate fortune, he retired, and lived privately to the time of his death, which happened in 1743. We are indebted to his induſtry for a Latin and Engliſh Dictionary, which has been much uſed in ſchools: he publiſhed it in quarto 1736; and in 1752, the fourth edition, under the care of Dr Ward of Greſham College, and the Rev. William Younge, was enlarged to two vols. folio.

AIR, in *Phyſics*, a thin, fluid, elaſtic, tranſparent, ponderous, compreſſible, and dilatable body, ſurrounding the terraqueous globe to a conſiderable height. See Atmosphere, Meteorology, and Pneumatics.

Air, in *Mythology*, was adored by the Heathens under the names of Jupiter and Juno; the former repreſenting the ſuperior and finer part of the atmoſphere, and the latter the inferior and groſſer part. The augurs alſo drew preſages from the clouds, thunder, lightning, &c.

Air, in *Painting*, &c. denotes the manner and very life of action; or it is that which expreſſes the diſpoſition of the agent.—It is ſometimes alſo uſed in a ſynonymous ſenſe with geſture or attitude.

Air, in *Muſic*, is taken in different ſenſes. It is ſometimes contraſted with harmony; and in this ſenſe, it is ſynonymous with melody in general.—Its proper meaning is, A tune, which is ſet to words, or to ſhort pieces of poetry that are called *ſongs*.

In operas, we give the name of *air* to ſuch pieces of muſic as are formed with meaſures and cadences, to diſtinguiſh it from the recitative; and, in general, every piece of muſic is called an *air*, which is formed for the voice, or even for inſtruments, and adapted to ſtanzas, whether it forms a whole in itſelf, or whether it can be detached from any whole of which it forms a part, and be executed alone.

If the ſubject admits of harmony, and is ſet in parts, the *air* is, according to their number, denominated a *duett*, a *trio*, a *quartetto*, &c. We need not follow Rouſſeau, and the other philologiſts, in their endeavours to inveſtigate the etymon of the word *air*. Its derivation, though found and aſcertained, would contribute little to illuſtrate its meaning in that remote ſenſe, to which, through a long continuance of time, and the various viciſſitudes of language, it has now paſſed. The curious may conſult the ſame article in the *Dictionaire de Muſique* by M. Rouſſeau. Air.

In modern muſic, there are ſeveral different kinds of *airs*, each of which agrees to a certain kind of dancing; and from theſe dances the airs themſelves take their ſpecific names.

The *airs* of our operas are, if we may be permitted the expreſſion, the canvas or ſubſtratum upon which are painted all the pictures of imitative muſic; melody is the deſign, and harmony the colouring; every picturesque object ſelected from the moſt beautiful parts of nature, every reflected ſentiment of the human heart, are the models which the artiſt imitates; whatever gains attention, whatever intereſts the ſoul, whatever charms the ear, or cauſes emotion in the heart, theſe are the objects of his imitation. An air which delights the ear, and diſcovers the learning of the compoſer; an air invented by genius, and compoſed with taſte; is the nobleſt effort of muſic: it is this which explores the compaſs, and diſplays the delicacy, of a beautiful voice; it is in this where the charms of a well conducted ſymphony ſhine; it is by this, that the paſſions, excited and inflamed by nice gradations, reach and agitate the ſoul through the avenues of external ſenſe. After hearing a beautiful *air*, the mind is acquieſcent and ſerene: the ear is ſatisfied, not diſguſted: it remains impreſſed on the fancy, it becomes a part of our eſſence, we carry it with us, we are able to repeat it at pleaſure: without the ability acquired by habit to breathe a ſingle note of it, we execute it in our imagination in the ſame manner as we heard it upon the theatre: one ſees the ſcene, the actor, the theatre; one hears the accompaniments and the applauſes. The real enthuſiaſt in muſic never forgets the beautiful airs which he has heard; when he chooſes, he cauſes the opera to recommence.

The words to which *airs* are adapted are not always rehearſed in regular ſucceſſion, nor ſpoken in the ſame manner with thoſe of the recitative; and though, in general, they are very ſhort, yet they are interrupted, repeated, tranſpoſed, at the pleaſure of the artiſt. They do not conſtitute a narrative, which once told is over: they either delineate a picture, which it is neceſſary to contemplate in different points of view; or inſpire a ſentiment in which the heart acquieſces with pleaſure, and from which it is neither able nor willing to be diſengaged; and the different phraſes of the *air*, are nothing elſe but different manners of beholding the ſame image. This is the reaſon why the ſubject of an *air* ſhould be one. It is by theſe repetitions properly placed, it is by theſe redoubled efforts, that an impreſſion, which at firſt was not able to move you, at length ſhakes your ſoul, agitates you, tranſports you out of yourſelf: and it is likewiſe upon the ſame principle, that the runnings, as they are called, or thoſe long, mazy, and inarticulated inflections of the voice, in pathetic *airs*, frequently ſeem, though they are not always ſo, improperly placed: for whilſt the heart is affected with a ſentiment exquiſitely moving, it often expreſſes its emotions by inarticulate ſounds, more ſtrongly and ſenſibly than it could do by words themſelves.

The

Air
Air-Pipes.

The form of *airs* is of two kinds. The ſmall airs are often compoſed of two ſtrains, which ought each of them to be ſung twice; but the important airs in operas are frequently in the form of rondeaus.

AIR, in *Geography*. See AYR.

AIR-Bladder, in fiſhes. See COMPARATIVE ANATOMY and ICHTHYOLOGY *Index*.

AIR-Gun, a pneumatic machine for exploding bullets, &c. with great violence. See PNEUMATICS.

AIR-Jacket, a ſort of jacket made of leather, in which are ſeveral bags, or bladders, compoſed of the ſame materials, communicating with each other. Theſe are filled with air through a leather tube, having a braſs ſtop-cock accurately ground at the extremity, by which means the air blown in through the tube is confined in the bladders. The jacket muſt be wet before the air be blown into the bags, as otherwiſe it will immediately eſcape through the pores of the leather. By the help of theſe bladders which are placed near the breaſt, the perſon is ſupported in the water, without making the efforts uſed in ſwimming.

AIR-Pipes, an invention for drawing foul air out of ſhips, or any other cloſe places, by means of fire. Theſe pipes were firſt found out by one Mr Sutton, a brewer in London; and from him have got the name of *Sutton's Air-pipes*. The principle on which their operation depends is known to every body, being indeed no other than that air is neceſſary for the ſupport of fire; and, if it has not acceſs from the places moſt adjacent, will not fail to come from thoſe that are more remote. Thus in a common furnace, the air enters through the aſh-hole; but if this is cloſed up, and a hole made in the ſide of the furnace, the air will ruſh in with great violence through that hole. If a tube of any length whatever be inſerted in this hole, the air will ruſh through the tube into the fire, and of conſequence there will be a continued circulation of air in that place where the extremity of the tube is laid. Mr Sutton's contrivance then, as communicated to the Royal Society by Doctor Mead, amounts to no more than this: "As, in every ſhip of any bulk, there is already provided a copper or boiling place proportionable to the ſize of the veſſel; it is propoſed to clear the bad air, by means of the fire already uſed under the ſaid coppers or boiling places for the neceſſary uſes of the ſhip.

"It is well known, that under every ſuch copper or boiler, there are placed two holes, ſeparated by a grate; the firſt of which is for the fire, and the other for the aſhes falling from the ſame; and that there is alſo a flue from the fire placed upward, by which the ſmoke of the fire is diſcharged at ſome convenient place of the ſhip.

"It is alſo well known, that the fire once lighted in theſe fire-places, is only preſerved by the conſtant draught of air through the forementioned two holes and flue; and that if the ſaid two holes are cloſely ſtopped up, the fire, though burning ever ſo briſkly before, is immediately put out.

"But if, after ſhutting up the above mentioned holes, another hole be opened, communicating with any other room or airy place, and with the fire; it is clear the ſaid fire muſt again be raiſed and burn as before, there being a light draught of air through the ſame as there was before the ſtopping up of the firſt holes; this caſe differing only from the former in this, that the air feeding the fire will now be ſupplied from another place. Air-Pipes.

"It is therefore propoſed, that, in order to clear the holds of ſhips of the bad air therein contained, the two holes above mentioned, the fire-place and aſh-place, be both cloſed up with ſubſtantial and tight iron doors; and that a copper or leaden pipe, of ſufficient ſize, be laid from the hold into the aſh-place, for the draught of air to come in that way to feed the fire. And thus it ſeems plain, from what has been already ſaid, that there will be, from the hold, a conſtant diſcharge of the air therein contained; and conſequently, that that air, ſo diſcharged, muſt be as conſtantly ſupplied by freſh air down the hatches or ſuch other communications as are opened into the hold; whereby the ſame muſt be continually freſhened, and its air rendered more wholeſome and fit for reſpiration.

"And if into this principal pipe ſo laid into the hold, other pipes are let in, communicating reſpectively either with the well or lower decks; it muſt follow, that part of the air, conſumed in feeding the fire, muſt be reſpectively drawn out of all ſuch places to which the communication ſhall be ſo made."

This account is ſo plain, that no doubt can remain concerning the efficacy of the contrivance: it is evident, that, by means of pipes of this kind, a conſtant circulation of freſh air would be occaſioned through thoſe places where it would otherwiſe be moſt apt to ſtagnate and putrefy. Several other contrivances have been uſed for the ſame purpoſe; and Dr Hales's ventilators, by ſome unaccountable prejudice, have been reckoned ſuperior in efficacy and even ſimplicity to Mr Sutton's machine, which at its firſt invention met with great oppoſition, and even when introduced by Dr Mead, who uſed all his intereſt for that purpoſe, was ſhamefully neglected.

A machine capable of anſwering the ſame purpoſe was invented by Mr Deſaguliers, which he called the *ſhip's* lungs. It conſiſted of a cylindrical box ſet up on its edge, and fixed to a wooden pedeſtal. From the upper edge of the box iſſued a ſquare trunk open at the end, and communicating with the cavity of the box. Within this box was placed a cylindrical wheel turning on an axis. It was divided into 12 parts, by means of partitions placed like the radii of a circle. Theſe partitions did not extend quite to the centre, but left an open ſpace of about 18 inches diameter in the middle; towards the circumference, they extended as far as poſſible without interfering with the caſe, ſo that the wheel might always be allowed to turn freely. —Things being thus circumſtanced, it is plain, that if the wheel was turned towards that ſide of the box on which the trunk was, every diviſion would puſh the air before it, and drive it out through the trunk, at the ſame time that freſh air would come in through the open ſpace at the centre, to ſupply that which was thrown out through the trunk. By turning the wheel ſwiftly, a ſtrong blaſt of air would be continually forced out through the ſquare trunk, on the ſame principles on which a common fanner winnows corn. If the wheel is turned the oppoſite way, a draught of air may be produced from the trunk to the centre. If this machine, then, is placed in a room where a circulation of air is wanted, and the trunk made to paſs through one

of

Air-Pump || Air-Shafts.

of the walls; by turning the wheel ſwiftly round, the air will be forced with great velocity out of that room, at the ſame time that freſh air will enter through any chinks by which it can have acceſs to ſupply that which has been forced out.

It is evident, that the circulation which is promoted by this machine is entirely of the ſame kind with that produced by Mr Sutton's; the turning of the wheel in Mr Deſaguliers's machine being equivalent to the rarefaction of the air by fire in Mr Sutton's: but that the latter is vaſtly ſuperior, as acting of itſelf, and without intermiſſion, requires no arguments to prove. Mr Sutton's machine has yet another conveniency, of which no other contrivance for the ſame purpoſe can boaſt; namely, that it not only draws out putrid air, but deſtroys it by cauſing it paſs through fire; and experience has abundantly ſhown, that though putrid air is thrown into a great quantity of freſh air, it is ſo far from loſing its pernicious properties, that it often produces noxious diſeaſes. We do not ſay, indeed, that putrid air becomes ſalutary by this means; but it is undoubtedly rendered leſs noxious than before; though whether it is equally innocent with the ſmoke of a fire fed in the common way, we cannot pretend to determine.

Beſides this machine by Mr Deſaguliers, the ventilators of Dr Hales, already mentioned, and thoſe called *wind-ſails*, are likewiſe uſed for the ſame purpoſe. The former of which is an improvement of the Heſſian bellows: the other is a contrivance for throwing freſh air into thoſe places where putrid air is apt to lodge; but this has the laſt-mentioned inconvenience in a much greater degree than any of the others, as the blaſt of freſh air throws out that which was rendered putrid by ſtagnation, in ſuch a manner as to contaminate all around it.

Air Pump, a machine by which the air contained in a proper veſſel may be exhauſted or drawn out. See PNEUMATICS.

Air-Sacs, in *Birds*. See COMPARATIVE ANATOMY.

Air-Shafts, among *Miners*, denote holes or ſhafts let down from the open air to meet the adits and furniſh freſh air. The damps, deficiency, and impurity of air which occur, when adits are wrought 30 or 40 fathoms long, make it neceſſary to let down air-ſhafts, in order to give the air liberty to play through the whole work, and thus diſcharge bad vapours, and furniſh good air for reſpiration: the expence of which ſhafts, in regard of their vaſt depths, hardneſs of the rock, drawing of water, &c. ſometimes equals, nay exceeds, the ordinary charge of the whole adit.

Sir Robert Murray deſcribes a method, uſed in the coal mines at Liege, of working mines without air-ſhafts.

When the miners at Mendip have ſunk a groove, they will not be at the charge of an air-ſhaft till they come at ore; and for the ſupply of air have boxes of elm exactly cloſed, of about ſix inches in the clear, by which they carry it down about twenty fathoms. They cut a trench at a little diſtance from the top of the groove, covering it with turf and rods diſpoſed to receive the pipe, which they contrive to come in ſideways to their groove, four feet from the top, which carries down the air to a great depth. When they come at ore, and need an air-ſhaft, they ſink it four or five fathoms diſtant, according to the convenience of the breadth, and of the ſame faſhion with the groove, to draw ore as well as air.

Air Threads || Airani

Air-Threads, in *Natural Hiſtory*, a name given to the long filaments, ſo frequently ſeen in autumn floating about in the air.

Theſe threads are the work of ſpiders, eſpecially of that ſpecies called the long-legged field-ſpider; which having mounted to the ſummit of a buſh or tree, darts from its tail ſeveral of theſe threads, till one is produced capable of ſupporting the creature in the air: on this it mounts in queſt of prey, and frequently riſes to a very conſiderable height. See ARANEA.

Air Trunk, is alſo a contrivance by Dr Hales to prevent the ſtagnation of putrid effluvia in jails and other places where a great number of people are crowded together in a ſmall ſpace. It conſiſts only of a long ſquare trunk open at both ends; one of which is inſerted into the ceiling of the room, the air of which is required to be kept pure; and the other extends a good way beyond the roof. Through this trunk a continued circulation is carried on: and the reaſon is, that the putrid effluvia which do ſo much miſchief when collected, being much lighter than the pure atmoſphere, ariſe to the top of the room; and, if they there find a vent, will continually go out through it. Theſe effluvia ariſe in very conſiderable quantity, being calculated by the late Dr Keil at no leſs than 39 ounces from one man in 24 hours.

Theſe trunks were firſt made trial of by Mr Yeoman, over the Houſe of Commons, where they were nine inches wide within; and over the Court of King's Bench in Weſtminſter-hall, where they were ſix inches wide. They are ſometimes made wider, and ſometimes narrower: but the wider they are the longer they ought to be, more effectually to promote the aſcent of the vapour. The reaſon why vapours of this kind aſcend more ſwift through a long trunk than a ſhort one, is, that the preſſure of fluids is always according to their different depth, without regard to the diameter of their baſis, or of the veſſel which contains them; and, upon this principle, a gallon of water may be made to ſplit a ſtrong caſk. See HYDROSTATICS. When the column of putrid effluvia is long and narrow, the difference between the column of atmoſphere preſſing on the upper end of the trunk, and that which preſſes on the lower end, is much greater than if the column of putrid effluvia was ſhort and wide; and conſequently the aſcent is much ſwifter.—One pan of a ſingle pair of ſcales; which was two inches in diameter, being held within one of theſe trunks over the Houſe of Commons, the force of the aſcending air made it riſe ſo as to require four grains to reſtore the equilibrium, and this when there was no perſon in the houſe; but when it was full, no leſs than 12 grains were requiſite to reſtore the equilibrium; which clearly ſhows that theſe trunks muſt be of real and very great efficacy.

Air-Veſſels, are ſpiral ducts in the leaves, &c. of plants, ſuppoſed to be analogous to the lungs of animals, in ſupplying the different parts of a plant with air. See BOTANY *Index*.

AIRA, in *Botany*, HAIR-GRASS. See BOTANY *Index*.

AIRANI, in *Church Hiſtory*, an obſcure ſect of Arians, in the fourth century, who denied the conſubſtantiality of the Holy Ghoſt with the Father and the Son. They are otherwiſe called *Airaniſts*; and are ſaid to

have

Aire || Aiton.

have taken their name from one *Airos*, who diſtinguiſhed himſelf at the head of this party, in the reigns of Valentinian and Gratian.

AIRE, in *Geography*, an ancient town of France, in the department of Landes, formerly Gaſcony. It is ſeated on the river Adour, on the declivity of a mountain, 155 leagues from Paris. E. Long. 5. 26. N. Lat. 43. 47.

AIRE, a ſtrong town in the Netherlands, in the county of Artois, now the department of Pas de-Calais, with a caſtle. It was taken by the French in 1710, and was confirmed to them by the treaty of Utrecht. It is ſeated on the river Lis, 22 miles ſouth of Dunkirk, and communicates with St Omer's by a canal cut from the river Aa. E. Long. 2. 31. N. Lat. 50. 38.

AIRING, a term peculiarly uſed for the exerciſing horſes in the open air. It purifies the blood; purges the body from groſs humours; and, as the jockies expreſs it, teaches the horſe how to make his wind rake equally, and keep time with the other motions of his body. It alſo ſharpens the ſtomach, and keeps the creature hungry; which is a thing of great conſequence, as hunters and racers are very apt to have their ſtomach fall off, either from want of exerciſe, or from the too violent exerciſe which they are often expoſed to. If the horſe be over fat, it is beſt to air him before ſunriſe and after ſunſetting; and in general, it is allowed by all, that nothing is more beneficial to thoſe creatures than early and late airings. Some of our modern manegers, however, diſpute this; they ſay, that the cold of theſe times is too great for the creature; and that if, in particular, he is ſubject to catarrhs, rheums, or the like complaints, the dews and cold fogs, in theſe early and late airings, will be apt to increaſe all thoſe diſorders. Nature, we ſee, alſo points out the ſun-beams as of great uſe to theſe animals; thoſe which are kept hardy and lie out all night, always running to thoſe places where the ſunſhine comes, as ſoon as it appears in a morning. This ſhould ſeem to recommend thoſe airings that are to be made before ſunſet, and a little time after ſunriſe. As to the caution, ſo earneſtly inculcated by Markham, of uſing theſe early and late airings for fat horſes, it is found unneceſſary by many: for they ſay, that the ſame effect may be produced by airings at warmer times, provided only that they are made longer; and that, in general, it is from long airings that we are to expect to bring a horſe to a perfect wind and ſound courage.

AIRS, in the *Manege*, are the artificial motions of taught horſes; as the demivolt, curvet, capriole, &c.

AIRY, or AERY, among *Sportſmen*, a term expreſſing the neſt of a hawk or eagle.

Airy Triplicity, among *Aſtrologers*, denotes the three ſigns, Gemini, Libra, and Aquarius.

AISNE, a river of France, which riſes in Champagne, and runs weſt by Soiſſons in the Iſle of France, falling into the river Oiſe, a little above Compiegne.

It gives name to one of the five departments which comprehend the ancient Iſle of France, and contains five communal diſtricts.

AITOCZU, a conſiderable river of Leſſer Aſia, which riſes in Mount Taurus, and falls into the ſouth part of the Euxine ſea.

AITON, WILLIAM, an eminent botaniſt and gardener, was born at a village near Hamilton in Scotland, in 1731. Having been regularly trained to the profeſſion of a gardener, he came into England in the year 1754, and ſoon obtained the notice of the celebrated Philip Miller, then ſuperintendent of the phyſic-garden at Chelſea, who engaged him as an aſſiſtant. His induſtry and abilities recommended him to the princeſs dowager of Wales as a fit perſon to manage the botanical garden at Kew. In 1759, he was appointed to this office, in which he continued during life, and which was the ſource of his fame and fortune. The garden at Kew, under the auſpices of his preſent Majeſty, was deſtined to be the grand repoſitory of all the vegetable riches which could be accumulated, by regal munificence, from reſearches through every quarter of the globe. Theſe treaſures were fortunately committed to the hands of Mr Aiton, whoſe care and ſkill in their cultivation, and intelligence in their arrangement, acquired him high reputation among the lovers of the ſcience, and the particular eſteem of his royal patrons. Under his ſuperintendence, many improvements took place in the plan and edifices of Kew-gardens, which rendered them the principal ſcene of botanical culture in the kingdom. In 1783, his merit was properly rewarded with the lucrative office of managing the pleaſure and kitchen-gardens of Kew, which he was allowed to retain with the botanical department. In 1789, he publiſhed his *Hortus Kewenſis*; or a Catalogue of the Plants cultivated in the Royal Botanic Garden at Kew, in three vols. 8vo. with 13 plates; a work which had been the labour of many years. The number of ſpecies contained in this work amounted to between five and ſix thouſand, many of which had not before been deſcribed. A new and curious article in it relates to the firſt introduction of particular exotics into the Engliſh gardens. The ſyſtem of arrangement adopted is the Linnæan, with improvements, which the advanced ſtate of botanical ſcience required. Mr Aiton with candour and modeſty acknowledges the aſſiſtance he received in this work from the two eminent Swediſh naturaliſts, Dr Solander and Mr Jonas Dryander. Indeed his character was ſuch as ſecured him the friendſhip and good offices of the moſt diſtinguiſhed names in ſcience of his time. He was for many years peculiarly honoured by the notice of Sir Joſeph Banks, the preſident of the Royal Society. The *Hortus Kewenſis* was received with avidity by the botanic world, and a large impreſſion was ſoon diſpoſed of.

Aiton || Aius.

Notwithſtanding the ſingular activity and temperance of Mr Aiton, he fell into that incurable malady, a ſchirrous liver, of which he died in 1793, in his ſixty-ſecond year. His eldeſt ſon, devoted to the ſame purſuits, was, by the king's own nomination, appointed to all his father's employments. Mr Aiton's private character was highly eſtimable for mildneſs, benevolence, piety, and every domeſtic and ſocial virtue. He was interred in the churchyard of Kew, amidſt a moſt reſpectable concourſe of friends. (*Gen. Biog.*)

AITONIA, in *Botany*. See BOTANY *Index*.

AJUGA, BUGLE, in *Botany*. See BOTANY *Index*.

AIUS LOCUTIUS, the name of a deity to whom the Romans erected an altar. The words are Latin, and ſignify "a ſpeaking voice." The following accident gave occaſion to the Romans erecting an altar to

Aius,

Ajutage, Aix

Aius Locutius. One M. Sedítius, a plebeian, acquainted the tribunes, that, in walking the ſtreets by night, he had heard a voice over the temple of Veſta, giving him notice that the Gauls were coming againſt them. This intimation was, however, neglected; but after the truth was confirmed by the event, Camillus acknowledged this voice to be a new deity, and erected an altar to it under the name of *Aius Locutius*.

AJUTAGE, or ADJUTAGE, a kind of tube fitted to the mouth of the veſſel through which the water of a fountain is to be played. To the different form and ſtructure of ajutages is owing the great variety of fountains.

AIX, a ſmall but ancient town in the duchy of Savoy, with the title of a marquiſate. It is ſeated on the lake Bourget, at the foot of a mountain, between Chamberry, Annecy, and Rumilly. There is here a triumphal arch of the ancient Romans, but it is almoſt entirely ruined. The mineral waters bring a great number of ſtrangers to this place. The place was originally called *Aquæ Gratianæ*, from the hot baths built there by the emperor Gratian. E. Long. 5. 48. N. Lat. 45. 40.

AIX, in *Geography*, an ancient city, the capital of the department of the Bouches du Rhone, formerly Provence, in France. This city has an air of ſilence and gloom commonly characteriſtic of places deſtitute of commerce or induſtry. It is, however, well built; and moſt like Paris of any place in the kingdom, as well for the largeneſs of the buildings as in reſpect of the politeneſs of the inhabitants. It is embelliſhed with abundance of fine fountains, and ſeveral beautiful ſquares. The Preachers ſquare is on the ſide of a hill; it is about 160 yards in length, and is ſurrounded with trees, and houſes built with ſtone three ſtories high. The town-hall is at one end of the city, and is diſtributed into ſeveral fine apartments: the two loweſt are taken up by the board of accounts, and by the ſeneſchal; that above is deſigned for the ſeſſions of parliament. The hall of audience is adorned with the pictures of the kings of France on horſeback. The hotel of the city is a handſome building, but hid by the houſes of the narrow ſtreet in which it is placed. The cathedral church is a Gothic ſtructure, with tombs of ſeveral earls of Provence, and ſome good pictures by French maſters. The Corſe, or Orbitelle, is a magnificent walk, above 300 yards long, formed by a triple avenue of elms, and two rows of regular and ſtately houſes. The church of the fathers of the oratory is a handſome building; and not far from thence is the chapel of the blue penitents, which is full of paintings. The convent of preachers is very fine; in their church is a ſilver ſtatue of the Virgin Mary almoſt as big as the life. There are other churches and buildings which contain a great number of raritics, The baths without the city, which were diſcovered not long ſince, have good buildings, raiſed at a vaſt expence, for the accommodation of thoſe who drink the waters. Although Aix was the firſt Roman ſettlement in Gaul, it is not remarkable for ancient remains. The warm ſprings, from which it is now known and frequented, induced Sextus Calvinus to found a colony here, to which he gave the name of *Aquæ Sextiæ*. They were ſuppoſed to poſſeſs particular virtues in caſes of debility; and ſeveral altars have been dug up ſacred to Priapus, the inſcriptions on which indicate their gratitude to that deity for his ſuppoſed ſuccour and aſſiſtance. E. Long. 5. 32. N. Lat. 43. 32.

Aix, Aix-la-Chapelle

AIX, a ſmall iſland on the coaſt of France, between the iſle of Oleron and the continent. It is 12 miles north-weſt of Rochfort, and 11 ſouth-ſouth-weſt of Rochelle. W. Long. 1. 4. N. Lat. 46. 5.

AIX-LA-CHAPELLE, a fine city of Germany, in the circle of Weſtphalia and duchy of Juliers, and capital of the department of Roer.

All authors are agreed about its antiquity, it being mentioned in Cæſar's Commentaries and the Annals of Tacitus. The Romans had colonies and fortreſſes there, when they were at war with the Germans; but the mineral waters and the hot bath ſo increaſed its fame, that, in proceſs of time, it was advanced to the privileges of a city, by the name of Aquægranii, that is, the waters of Granius; that which it has now, of *Aix-la-Chapelle*, was given it by the French, to diſtinguiſh it from the other Aix. It is ſo called, on account of a chapel built in honour of the Holy Virgin by Charlemagne; who having repaired, beautified, and enlarged the city, which was deſtroyed by the Huns in the reign of Attila in 451, made it the uſual place of his reſidence. The town is ſeated in a valley ſurrounded with mountains and woods, and yet the air is very wholeſome. It may be divided into the inward and outward city. The inward is encompaſſed with a wall about three quarters of a league in circumference, having ten gates; and the outward wall, in which there are eleven gates, is about a league and a half in circumference. There are rivulets which run through the town and keep it very clean, turning ſeveral mills; beſides 20 public fountains, and many private ones. They have ſtone quarries in the neighbourhood, which furniſh the inhabitants with proper materials for their magnificent buildings, of which the ſtadt-houſe and the cathedral are the chief. There are likewiſe 30 parochial or collegiate churches. The market-place is very ſpacious, and the houſes round it are ſtately. In the middle, before the ſtadt-houſe, is a fountain of blue ſtones, which throws out water; from ſix pipes, into a marble baſon placed beneath, 30 feet in circumference. On the top of this fountain is placed the ſtatue of Charlemagne, of gilt braſs, holding a ſceptre in his right hand, and a globe in his left. The ſtadt-houſe is adorned with the ſtatues of all the emperors ſince Charlemagne. This fabrick has three ſtories, the upper of which is one entire room of 160 feet in length and 60 in breadth. In this the new-elected emperor formerly entertained all the electors of the empire.

Aix-la-Chapelle is a free imperial city, and changes its magiſtracy every year on the eve of St John Baptiſt. The mayor is in the nomination of the elector palatine, in the quality of the duke of Juliers, as protector of the city. This place is famous for ſeveral councils and treaties of peace concluded here; particularly thoſe between France and Spain in 1668, and between Great Britain and France in 1748.

The hot ſulphureous waters for which this place has ſo long been celebrated, ariſe from ſeveral ſources, which ſupply eight baths conſtructed in different parts of the town. Theſe waters near the ſources are clear

Aix-la-Chapelle

and pellucid; and have a ſtrong ſulphureous ſmell reſembling the waſhings of a foul gun; but they loſe this ſmell by expoſure to air. Their taſte is ſaline, bitter, and urinous. They do not contain iron. They are alſo neutral near the fountain, but afterwards are manifeſtly and pretty ſtrongly alkaline, inſomuch that clothes are waſhed with them without ſoap. On the vaults above the ſprings and aqueducts of theſe waters is found, every year, when they are opened, a quantity of fine white-coloured flowers of ſulphur, which has been ſublimed from the waters.

The heat of the water of the hotteſt ſpring, by Dr Lucas's account, raiſes the quickſilver of Fahrenheit's thermometer to 136°—by Monſ. Monet's account, to 146°—and the heat of the fountain, where they commonly drink, by Dr Lucas's account, to 112°.

Dr Simmons has given the following account of their ſeveral temperatures, as repeatedly obſerved by himſelf with a thermometer conſtructed by Nairne.

The ſpring which ſupplies the Emperor's Bath *(Bain de l'Empereur)*, the New Bath *(Bain Neuf)*, and the Queen of Hungary's Bath *(Bain de la Reine de Hongrie)*, - - -	127°
St Quirin's Bath *(Bain de St Quirin)*, -	112°
The Roſe Bath *(Bain de la Roſe)*, and the Poor's Bath *(Bain des Pauvres)*, both which are ſupplied by the ſame ſpring,	112°
Charles's Bath *(Bain de Charles)*, and St Corneille's Bath *(Bain de St Corneille)*, -	112°
The ſpring uſed for drinking is in the High Street, oppoſite to Charles's Bath; the heat of it at the pump is - - - - - - -	106°

Dr Lucas evaporated the water of the hotteſt ſpring (of the Emperor's Bath), and obtained 268 grains of ſolid matter from a gallon, compoſed of 15 grains of calcareous earth, 10 grains of ſelenites, and 243 grains of a ſaline matter made of natron and ſea-ſalt. They are at firſt nauſeous and harſh, but by habit become familiar and agreeable. At firſt drinking, alſo, they generally affect the head. Their general operation is by ſtool and urine, without griping or diminution of ſtrength; and they alſo promote perſpiration.

The quantity to be drank as an alterative is to be varied according to the conſtitution and other circumſtances of the patient. In general, it is beſt to begin with a quarter or half a pint in the morning, and increaſe the doſe afterwards to a pint, as may be found convenient. The water is beſt drank at the fountain. When it is required to purge, it ſhould be drank in large and often repeated draughts.

In regard to bathing, this alſo muſt be determined by the age, ſex, ſtrength, &c. of the patient, and by the ſeaſon. The degree of heat of the bath ſhould likewiſe be conſidered. The tepid ones are in general the beſt, though there are ſome caſes in which the hotter ones are moſt proper. But even in theſe, it is beſt to begin with the temperate baths, and increaſe the heat gradually.

Theſe waters are efficacious in diſeaſes proceeding from indigeſtion and from foulneſs of the ſtomach and bowels; in rheumatiſms; in the ſcurvy, ſcrophula, and diſeaſes of the ſkin; in hyſteric and hypochondriacal diſorders; in nervous complaints and melancholy; in the ſtone and gravel; in paralytic complaints; in thoſe evils which follow an injudicious uſe of mercury; and in many other caſes. They ought not, however, to be given in hectic caſes where there is heat and fever, in putrid diſorders, or where the blood is diſſolved or the conſtitution much broken down.

Aix-la-Chapelle || Akenſide.

The time of drinking, in the firſt ſeaſon, is from the beginning of May to the middle of June; and, in the latter ſeaſon, from the middle of Auguſt to the latter end of September.

There are galleries or piazzas under which the company walk during the time of drinking, in order to promote the operation of the waters.—The Poor's Bath is free for every body, and is frequented by crowds of poor people.

It is ſcarcely neceſſary to add, that there are all kinds of amuſements common to other places of public reſort; but the ſharpers appear more ſplendid here than elſewhere, aſſuming titles, with an equipage ſuitable to them. This city was taken by the French in 1792. They loſt it in the year following, but retook it in 1794. Aix-la-Chapelle is 21 miles from Spa, 36 from Liege, and 30 from Cologne. E. Long. 5. 48. N. Lat. 51. 55.

AIZOON, in *Botany*. See BOTANY *Index*.

AKENSIDE, MARK, a phyſician, who publiſhed in Latin "A Treatiſe upon the Dyſentery," in 1764, and a few pieces in the firſt volume of the "Medical Tranſactions" of the college of phyſicians, printed in 1768; but far better known, and to be diſtinguiſhed chiefly hereafter, as a poet. He was born at Newcaſtle-upon-Tyne, November 9. 1721; and after being educated at the grammar-ſchool in Newcaſtle, was ſent to the univerſities of Edinburgh and Leyden; at which laſt he took his degree of doctor in phyſic. He was afterwards admitted by mandamus to the ſame degree at Cambridge; elected a fellow of the college of phyſicians, and one of the phyſicians at St Thomas's Hoſpital; and, upon the eſtabliſhment of the queen's houſehold, appointed one of the phyſicians to her majeſty.

That Dr Akenſide was able to acquire no other kind of celebrity than that of a ſcholar and a poet, is to be accounted for by the following particulars in his life and conduct, related by Sir John Hawkins.—Mr Dyſon and he were fellow-ſtudents, the one of law and the other of phyſic, at Leyden; where, being of congenial tempers, a friendſhip commenced between them that laſted through their lives. They left the univerſity at the ſame time, and both ſettled at London: Mr Dyſon took to the bar, and being poſſeſſed of a handſome fortune, ſupported his friend while he was endeavouring to make himſelf known as a phyſician; but in a ſhort time, having purchaſed of Mr Hardinge his place of clerk of the houſe of commons, he quitted Weſtminſter-hall; and for the purpoſe of introducing Akenſide to acquaintance in an opulent neighbourhood near the town, bought a houſe at North-End, Hampſtead; where they dwelt together during the ſummer ſeaſon, frequenting the long-room, and all clubs and aſſemblies of the inhabitants.

At theſe meetings, which, as they were not ſelect, muſt be ſuppoſed to have conſiſted of ſuch perſons as uſually meet for the purpoſe of goſſiping, men of wealth, but of ordinary endowments, and able to talk of little elſe than news and the occurrences of the day, Akenſide was for diſplaying thoſe talents which had acquired him the reputation he enjoyed in other com-

Akenſide. panies: but here they were of little uſe to him; on the contrary, they tended to engage him in diſputes that betrayed him into a contempt of theſe that differed in opinion from him. It was found out that he was a man of low birth, and a dependent on Mr Dyſon; circumſtances that furniſhed thoſe whom he offended with a ground of reproach, which reduced him to the neceſſity of aſſerting in terms that he was a gentleman.

Little could be done at Hampſtead after matters had proceeded to this extremity: Mr Dyſon parted with his villa at North-End, and ſettled his friend in a ſmall houſe in Bloomſbury-ſquare; aſſigning for his ſupport ſuch a part of his income as enabled him to keep a chariot.—In this new ſituation Akenſide uſed every endeavour to become popular, but defeated them all by the high opinion he everywhere manifeſted of himſelf, and the little condeſcenſion he ſhowed to men of inferior endowments; by his love of political controverſy, his authoritative cenſure of the public councils, and his peculiar notions reſpecting government. In the winter evenings he frequented Tom's coffee-houſe in Devereux-court, then the reſort of ſome of the moſt eminent men for learning and ingenuity of the time; with ſome of whom he was involved in diſputes and altercations, chiefly on ſubjects of literature and politics, which fixed on his character the ſtamp of haughtineſs and ſelf-conceit. Hence many, who admired him for his genius and parts, were ſhy of his acquaintance.

The value of that precept which exhorts us to live peaceably with all men, or, in other words, to avoid creating enemies, can only be eſtimated by the reflection on thoſe many amiable qualities againſt which the neglect of it will preponderate. Akenſide was a man of religion and ſtrict virtue; a philoſopher, a ſcholar, and a fine poet. His converſation was of the moſt delightful kind; learned, inſtructive, and without any affectation of wit, cheerful and entertaining.

Dr Akenſide died of a putrid fever, June 23. 1770; and is buried in the pariſh church of St James's, Weſtminſter.

His poems, publiſhed ſoon after his death in 4to and 8vo, conſiſt of "The Pleaſures of Imagination," two books of "Odes," a "Hymn to the Naiads," and ſome "Inſcriptions." "The Pleaſures of Imagination," his capital work, was firſt publiſhed in 1744; and a very extraordinary production it was from a man who had not reached his 23d year. He was afterwards ſenſible, however, that it wanted reviſion and correction; and he went on reviſing and correcting it for ſeveral years: but finding this taſk to grow upon his hands, and deſpairing of ever executing it to his own ſatisfaction, he abandoned the purpoſe of correcting, and reſolved to write the poem over anew upon a ſomewhat different and enlarged plan. He finiſhed two books of his new poem, a few copies of which were printed for the uſe of the author and certain friends; of the firſt book in 1757, of the ſecond in 1765. He finiſhed alſo a good part of a third book, and an introduction to a fourth; but his moſt munificent and excellent friend, conceiving all that is executed of the new work too inconſiderable to ſupply the place, and ſuperſede the republication, of the original poem, and yet too valuable to be withheld from the public, hath cauſed them both to be inſerted in the collection of his poems.

AKIBA, a famous rabbin, flouriſhed a little after the deſtruction of Jeruſalem by Titus. He kept the flocks of a rich citizen of Jeruſalem till the 40th year of his age, and then devoted himſelf to ſtudy in the academies for 24 years; and was afterwards one of the greateſt maſters in Iſrael. According to the Jewiſh accounts, he had 24,000 ſcholars. He declared for the impoſtor Barcochebas, whom he owned for the Meſſiah; and not only anointed him king, but took upon himſelf the office of his maſter of the horſe. The troops which the emperor Hadrian ſent againſt the Jews, who under the conduct of this falſe Meſſiah had committed horrid maſſacres, exterminated this faction. Akiba was taken, and put to death with great cruelty. He lived 120 years; and was buried with his wife in a cave upon a mountain not far from Tiberias, and his 24,000 ſcholars were buried round about him upon the ſame mountain. It is imagined he invented a ſuppoſititious work under the name of the patriarch Abraham. Akiba ll Alæ.

AKISSAT, the ancient Thyatira, a city of Natolia, in Aſia, ſituated in a plain 15 miles broad, which produces plenty of cotton and grain. The inhabitants, who are reckoned to be about 5000, are ſaid to be all Mahometans. The houſes are built of nothing but earth or turf dried in the ſun, and are very low and ill contrived: but there are ſix or ſeven moſques, which are all of marble. There are remarkable inſcriptions on marble in ſeveral parts of the town, which are part of the ruins of the ancient Thyatira. It is ſeated on the river Hermus, 50 miles from Pergamos. E. Long. 28. 30. N. Lat. 38. 50.

AKOND, an officer of juſtice in Perſia, who takes cognizance of the cauſes of orphans and widows; of contracts, and other civil concerns. He is the head of the ſchool of law, and gives lectures to all the ſubaltern officers; he has his deputies in all the courts of the kingdom, who, with the ſecond *ſadra*, make all contracts.

AL, an Arabic particle prefixed to words, and ſignifying much the ſame with the Engliſh particle *the*: Thus they ſay, alkermes, alkoran, &c. *i. e.* the kermes, the koran, &c.

AL, or ALD, a Saxon term frequently prefixed to the names of places, denoting their antiquity; as Aldborough, Aldgate, &c.

ALA, a Latin term properly ſignifying a wing; from a reſemblance to which ſeveral other things are called by the ſame name: Thus,

ALA, is a term uſed by botaniſts for the hollow of a ſtalk, which either the leaf, or the pedicle of the leaf, makes with it; or it is that hollow turning, or ſinus, placed between the ſtalk or branch of a plant and the leaf, whence a new offspring uſually iſſues. Sometimes it is uſed for thoſe parts of leaves otherwiſe called *lobes*, or *wings*.

ALÆ (the plural number) is uſed to ſignify thoſe petals or leaves of papilionaceous flowers, placed between thoſe others which are called the *vexillum* and *carina*, and which make the top and bottom of the flowers. Inſtances of flowers of this ſtructure are ſeen in thoſe of peaſe and beans, in which the top leaf or petal is the vexillum, the bottom the carina, and the ſide ones the alæ.

ALÆ is alſo uſed for thoſe extremely ſlender and membranaceous

Ala
Alabaſter.

membranaceous parts of ſome ſeed, which appear as wings placed on them; it likewiſe ſignifies thoſe membranaceous expanſions running along the ſtems of ſome plants, which are therefore called *alated ſtalks*.

ALÆ, in *Anatomy*, a term applied to the lobes of the liver, the cartilages of the noſtril, &c.

ALÆ, in the *Roman Art of War*, were the two wings or extreme parts of the army drawn up in order of battle.

ALABA, one of the three ſmalleſt diſtricts of Biſcay in Spain, but pretty fertile in rye, barley, and fruits. There are in it very good mines of iron, and it had formerly the title of a kingdom.

ALABANDA, in *Ancient Geography*, a town of Caria, near the Meander, ſituated beneath eminences reſembling aſſes with pack-ſaddles, which gave riſe to the jeſt; and between Amyzo to the weſt and Stratonice to the eaſt. Under the Romans they enjoyed aſſizes, or a convention of juriſdiction, by Pliny reckoned the fourth in order; hence the proverb in Stephanus, expreſſing their happineſs. It was built by Alabandus, whom therefore they deemed a god. The people were called *Alabandi*, *Alabandenſes*, (Cicero;) and *Alabandeis*, after the Greek manner, in coins of Auguſtus and Claudius; they were alſo called *Alabandeni* (Livy).

ALABARCHA, in *Antiquity*, a kind of magiſtrate among the Jews of Alexandria, whom the emperors allowed them to elect, for the ſuperintendency of their policy, and to decide differences and diſputes which aroſe among them.

ALABASTER, William, an Engliſh divine, was born at Hadley in the county of Suffolk. He was one of the doctors of Trinity college in Cambridge; and he attended the earl of Eſſex as his chaplain in the expedition to Cadiz in the reign of Queen Elizabeth. It is ſaid, that his firſt reſolutions of changing his religion were occaſioned by his ſeeing the pomp of the churches of the Roman communion, and the reſpect with which the prieſts ſeemed to be treated amongſt them; and appearing thus to waver in his mind, he ſoon found perſons who took advantage of this diſpoſition of his, and of the complaints which he made of not being advanced according to his deſerts in England, in ſuch a manner, that he did not ſcruple to go over to the Popiſh religion, as ſoon as he found that there was no ground to hope for greater encouragement in his own country. However that matter be, he joined himſelf to the Romiſh communion, but was diſappointed in his expectations. He was ſoon diſpleaſed at this; and he could not reconcile himſelf to the diſcipline of that church, which made no conſideration of the degrees which he had taken before. It is probable too that he could not approve of the worſhip of creatures, which Proteſtants are uſed to look upon with horror. Upon this he returned to England, in order to reſume his former religion. He obtained a prebend in the cathedral of St Paul, and after that the rectory of Therfield in Hertfordſhire. He was well ſkilled in the Hebrew tongue; but he gave a wrong turn to his genius by ſtudying the Cabala, with which he was ſtrangely infatuated. He gave a proof of this in a ſermon which he preached upon taking his degree of doctor of divinity at Cambridge. He took for his text the beginning of the firſt book of Chronicles, "Adam, Seth, Enos;" and having touched upon the literal ſenſe, he turned immediately to the myſtical, aſſerting, that Adam ſignified misfortune and miſery, and ſo of the reſt. His verſes were greatly eſteemed. He wrote a Latin tragedy intitled *Roxana*; which, when it was acted in a college at Cambridge, was attended with a very remarkable accident. There was a lady who was ſo terrified at the laſt word of the tragedy, *Sequar*, *Sequar*, which was pronounced with a very ſhocking tone, that ſhe loſt her ſenſes all her lifetime after. He died in the year 1640. His *Apparatus in Revelationem Jeſu Chriſti* was printed at Antwerp in 1607. His *Spiraculum tubarum, ſeu fons Spiritualium Expoſitionum ex æquivocis Pentaglotti ſignificationibus*, and his *Ecce Sponſus venit, ſex tuba pulchritudinis, hoc eſt demonſtratio quod non ſit illicitum nec impoſſibile computare durationem mundi et tempus ſecundi adventus Chriſti*, were printed at London. From theſe titles we may judge what were the taſte and genius of the author.

Alabaſter
Aladu'ia.

ALABASTER, in *Natural Hiſtory*, a mineral ſubſtance whoſe baſe is calcareous earth. It differs from marble in being combined, not with the carbonic, but with the ſulphuric acid. See CHEMISTRY, and MINERALOGY *Index*.

ALABASTER, in *Antiquity*, a term uſed for a vaſe wherein odoriferous liquors were anciently put. The reaſon of the denomination is, that veſſels for this purpoſe were frequently made of the alabaſter ſtone, which Pliny and other ancients repreſent as peculiarly proper for this purpoſe. Several critics will have the box mentioned in the Goſpels as made of alabaſter to have been of glaſs: And though the texts ſay that the woman broke it, yet the pieces ſeem miraculouſly to have been united, ſince we are told the entire box was purchaſed by the emperor Conſtantine, and preſerved as a relic of great price. Others will have it, that the name *alabaſter* denotes the form rather than the matter of this box: In this view they define alabaſter by a box without a handle, deriving the word from the privative α and λαβὴ, *anſa*, *handle*.

ALABASTER is alſo ſaid to have been uſed for an ancient liquid meaſure, containing ten ounces of wine, or nine of oil. In this ſenſe, the alabaſter was equal to half the ſextary.

ALABASTRUM DENDROIDE, a kind of laminated alabaſter, beautifully variegated with the figures of ſhrubs, trees, &c. found in great abundance in the province of Hohenſtein.

ALADINISTS, a ſect among the Mahometans, anſwering to freethinkers among us.

ALADULIA, a conſiderable province of Turkey in Aſia, in that part called Natolia, between the mountains of Antitaurus, which ſeparate it from Amaſia on the north, and from Carimania on the weſt. It has the Mediterranean ſea on the ſouth; and the Euphrates, or Frat, on the eaſt, which divides it from Diarbeker. It comprehends the Leſſer Armenia of the ancients, and the eaſt part of Cilicia. Formerly it had kings of its own; but the head of the laſt king was cut off by Selim I. emperor of the Turks, who had conquered the country. It is now divided into two parts: the north, comprehended between Taurus, Antitaurus, and the Euphrates, is a beglerbeglic, which bears the name of Marath, the capital town; and the ſouth, ſeated between Mount Taurus and the Mediterranean, is united to the beglerbeglic of Aleppo. The country is rough,

Alain
||
Alamandus.

rugged, and mountainous; yet there are good paſtures, and plenty of horſes and camels. The people are hardy and thieviſh. The capital is Malatigah.

ALAIN, CHARTIER, ſecretary to Charles VII. king of France, born in the year 1386. He was the author of ſeveral works in proſe and verſe; but his moſt famous performance was his Chronicle of King Charles VII. Bernard de Girard, in his preface to the Hiſtory of France, ſtyles him "an excellent hiſtorian, who has given an account of all the affairs, particulars, ceremonies, ſpeeches, anſwers, and circumſtances, at which he was preſent himſelf, or had information of." Giles Coroxet tells us, that Margaret, daughter to the king of Scotland, and wife to the dauphin, paſſing once through a hall where Alain lay aſleep, ſhe ſtopped and kiſſed him before all the company who attended: ſome of them telling her, that it was ſtrange ſhe ſhould kiſs a man who had ſo few charms in his perſon, ſhe replied, "I did not kiſs the man, but the mouth from whence proceed ſo many excellent ſayings, ſo many wiſe diſcourſes, and ſo many elegant expreſſions." Mr Fontenelle, among his Dialogues of the Dead, has one upon this incident, between the princeſs Margaret and Plato. Mr Paſquier compares Alain to Seneca, on account of the great number of beautiful ſentences interſperſed throughout his writings.

ALAIS, a conſiderable town of France, in the department of Gard, and formerly the province of Languedoc, ſituated on the river Gard, at the foot of the Cevennes. The Jeſuits had a college in this place; and a fort was built here in 1689. It is 34 miles north of Montpelier, and 340 from Paris. E. Long. 4. 20. N. Lat. 44. 8.

ALAMAGAN, in *Geography*, one of the Ladrone or Marianne iſlands, in the Indian ocean, is ſituated in N. Lat. 18. 5. and E. Long. 146. 47. It is of an irregular form, and about 12 miles in circumference. The land in ſome places of this iſland is pretty high, ſo that it may be ſeen at the diſtance of 12 or 14 leagues. Near the north end of the iſland there is a volcano which emitted an immenſe body of ſmoke in the year 1799, when it was viſited by Captain Baſs. The volcano is in a mountain cloſe to the ſea, riſing above its level 1200 or 1500 feet. The high parts of the iſland are rugged and ſterile. In the lower parts there is a profuſion and luxuriance of vegetation. They abound with cocoa-nut trees, ſeveral kinds of ſtone fruit, and the mellora or bread-tree of the Nicobar iſlands. Some ſmall ſugar canes, ſome banana trees, and one bread-fruit tree, were diſcovered. Lizards, land-crabs, large partridges, quails, pigeons, owls, thruſhes, and bullfinches, are numerous. But no freſh water, which was the object of Captain Baſs's viſit, could be found.

ALAMANDUS, LEWIS, in French *Aleman*, archbiſhop of Arles, and cardinal of St Cecilia, was one of the greateſt men of the 15th century. The cardinal preſided in the council of Baſil, which depoſed Eugenius IV. and elected the antipope Felix V. He is much commended by Æneas Sylvius, as a man extremely well formed for preſiding in ſuch aſſemblies, firm and vigorous, illuſtrious by his virtue, learned, and of an admirable memory in recapitulating all that the orators and diſputants had ſaid. One day, when he harangued againſt the ſuperiority of the pope over the council, he diſtinguiſhed himſelf in ſuch an eminent manner, that ſeveral perſons went to kiſs him, while others preſſed even to kiſs his robe. They extolled to the ſkies his abilities and genius, which had raiſed him, though a Frenchman, to a ſuperiority over the Italians, notwithſtanding all their natural ſubtlety and fineſſe. There is no need of aſking, whether Pope Eugenius thundered againſt the preſident of a council which depoſed him. He deprived him of all his dignities, and treated him as a ſon of iniquity. However, notwithſtanding this, Lewis Alamandus died in the odour of ſanctity, and performed ſo many miracles after his death, that at the requeſt of the canons and Celeſtine monks of Avignon, and the ſolicitation of the cardinal of Clermont, legate *à latere* of Clement VII. he was beatified by the pope in the year 1527.

Alamanni
||
Alamos.

ALAMANNI, LEWIS, was born at Florence, of a noble family, on the 28th of October 1495. He was obliged to fly his country for a conſpiracy againſt Julius de Medici, who was ſoon after choſen pope under the name of Clement VII. During this voluntary baniſhment, he went into France; where Francis I. from a love to his genius and merit, became his patron. This prince employed him in ſeveral important affairs, and honoured him with the collar of the order of St Michael. About the year 1540, he was admitted a member of the Inflammati, an academy newly erected at Padua, chiefly by Daniel Barbaro and Ugolin Martelli. After the death of Francis, Henry duke of Orleans, who ſucceeded him in 1537, ſhowed no leſs favour to Alamanni; and in the year 1551, ſent him as his ambaſſador to Genoa: this was his laſt journey to Italy; and being returned to France, he died at Amboiſe on the 18th of April 1556, being in the 61ſt year of his age. He left many beautiful poems, and other valuable performances, in the Italian language. We have alſo ſome notes of his upon Homer's Iliad and Odyſſey; thoſe upon the Iliad were printed in the Cambridge edition of Homer in 1689, and Joſhua Barnes has alſo inſerted them in his fine edition of Homer in 1711.

ALAMODALITY, in a general ſenſe, is the accommodating a perſon's behaviour, dreſs, and actions, to the prevailing taſte of the country or times in which he lives.

ALAMODALITY of writing, is defined the accommodation of mental productions, both as to the choice of ſubject and the manner of treating it, to the genius or taſte of the times, in order to render them more acceptable to the readers.

ALAMODE, a phraſe originally French, importing a thing to be in the faſhion or mode. The phraſe has been adopted not only into ſeveral of the living languages, as the Engliſh and High-Dutch, but ſome have even taken it into the Latin. Hence we meet with *Alamodicus* and *Alamodalitas*.

ALAMODE, in *Commerce*, a thin gloſſy black ſilk, chiefly uſed for women's hoods and men's mourning ſcarfs.

ALAMOS, BALTHASAR, a Spaniſh writer, born at Medina del Campo in Caſtile. After having ſtudied the law at Salamanca, he entered into the ſervice of Anthony Perez, ſecretary of ſtate under Philip II. He was in high eſteem and confidence with his maſter, upon which account he was impriſoned after the diſgrace

of

Alan, Aland.

of this miniſter. He was kept in confinement 11 years, when Philip III. coming to the throne, ſet him at liberty, according to the orders given by his father in his will. Alamos continued in a private capacity, till the duke of Olivarez, the favourite of Philip IV. called him to public employments. He was a man of wit as well as judgement, but his pen was ſuperior to his tongue. He died in the 88th year of his age. His Spaniſh tranſlation of Tacitus, and the aphoriſms which he added in the margin, gained him great reputation. This work was publiſhed at Madrid in 1614; and was to have been followed, as mentioned in the king's privilege, with a commentary, which however has never yet appeared. The author compoſed the whole during his impriſonment.

ALAN, Cardinal William, was born at Roſſal in Lancaſhire, in the year 1532. He went to Oxford at the age of 15, and in 1550 was elected fellow of Oriel college. In 1556, being then only 24 years old, he was choſen principal of St Mary's hall, and one of the proctors of the univerſity. In 1558 he was made canon of York; but, upon Queen Elizabeth's acceſſion to the throne, he left England, and ſettled at Louvain in an Engliſh college, of which he became the chief ſupport. In 1565 he viſited his native country; but on account of his extreme activity in the propagation of the Roman Catholic religion, he was obliged to fly the kingdom in 1568. He went firſt to Mechlin, and then to Douay, where he was made doctor of divinity. Soon after, he was appointed canon of Cambray, and then canon of Rheims. He was created cardinal on the 28th of July 1587, by the title of *St Martin in Montibus;* and obtained from the king of Spain a rich abbey in the kingdom of Naples, and afterwards the biſhoprick of Mechlin. It is ſuppoſed to have been by the advice and inſtigation of this prieſt, that Philip II. attempted to invade England. He died on the 20th of October 1594, aged 63; and was buried in the Engliſh college at Rome. He was a man of conſiderable learning, and an elegant writer. He wrote many books in defence of the Romiſh religion. The moſt remarkable are, 1. *A Defence of the 12 Martyrs in one Year.* Tho. Alfield was hanged for bringing, and publiſhing, this and other of Alan's works, into England, in the year 1584. 2. *A Declaration of the Sentence of Sextus V.* &c. A work intended to explain the pope's bull for the excommunication of Queen Elizabeth, and to exhort the people of England to take up arms in favour of the Spaniards. Many thouſand copies of this book, printed at Antwerp, were put on board the Armada; but the enterpriſe failing, they were afterwards deſtroyed. 3. *Of the Worſhip due to Saints and their Relicks*, 1583. This treatiſe was anſwered by Lord Burleigh, and is eſteemed the moſt elegant of the cardinal's writings.

ALAND, in *Geography*, with its dependant iſlands, to the number of eighty, is ſituated between the gulfs of Bothnia and Finland. Theſe iſlands lie between N. Lat. 59. 47. and 60. 30. and between E. Long. 19. 17. and 22. 7. Aland conſtitues the ſmalleſt of the poſſeſſions belonging to the crown of Sweden. It contains about ſeventy-ſeven ſquare Engliſh miles and is in length about twenty Engliſh miles, and ſixteen in breadth.

Aland has been ſuppoſed anciently to have been governed by its own monarchs; it is certain, however, that ſince the fourteenth century it has made part of the biſhoprick and government of Abo, with the exception that in the year 1743 Aland and the other iſlands ſubmitted to Ruſſia, and ſwore allegiance to the czarina, but were ſoon after reſtored to Sweden by the treaty of Abo. Theſe iſlands in former times frequently ſuffered from the invaſions of the Ruſſians, and the inhabitants had been forced to fly from their houſes and fertile plains. But in 1718 a congreſs was held here for the reſtoration of peace, by which the enjoyment of tranquillity was ſecured to them. Aland

Aland and the ſeveral iſles contain eight pariſhes, each of which has a church; and beſides theſe places of worſhip, there are ſeven chapels.

The Laplanders and Fins were undoubtedly the earlieſt inhabitants of theſe iſlands, and their reſidence here is plainly to be traced in the names of places which ſtill remain.

Several lakes are met with in theſe iſlands, and but one rivulet, which however is ſufficient to work two mills, one of which is a ſaw-mill. The mountains are numerous; the higheſt of them is called Ulfdubs Klint.

The revenues which the crown of Sweden receives from Aland and the other iſlands, amount annually to nineteen thouſand nine hundred and eight-ſix rix-dollars. Two hundred and ninety-eight ſailors are regiſtered in theſe iſlands, which coſt the king of Sweden about five thouſand rix-dollars yearly.

Aland contains about three thouſand ſeven hundred and fifty acres of land in cultivation, which produce rye, wheat, oats, and barley, in the proportion of ſeven for one. The annual growth of wheat is about twenty-two thouſand five hundred barrels. There is one pariſh which has no arable land, and in this reſpect reſembles Lapland. The inhabitants of this pariſh employ themſelves in fiſhing, and purchaſe all the corn they have occaſion for of their neighbours. They catch vaſt number of pilchards, of which they make great profit, it being the chief traffic of theſe iſlands.

It has been in agitation to build a city in the iſle of Aland, but the project has not hitherto been carried into execution, owing, it is ſaid, to the difficulty of chuſing a proper ſpot for it.

The uſual route from Sweden to Finland is from the poſt-office of Griſlehamn in Upland, which is eleven and a half Swediſh miles, to Eckero in Aland; and from that place acroſs the iſland to Abo, which is five miles more. A Swediſh mile makes between ſix and ſeven Engliſh miles.

In the year 1792 the number of inhabitants upon the iſland of Aland amounted to eleven thouſand two hundred and ſixty, which is upwards of a thouſand to every ſquare Swediſh mile; a very great number when it is conſidered how mountainous the iſland is. The inhabitants of theſe iſlands live to very great ages. From the year 1692 to the preſent time, nine perſons are recorded to have died at the great age of one hundred years; and perhaps the number had been found greater, had it been thought worth while to notice this particular. In 1703 there died a woman named Anna Berg, who was one hundred and nine years old: and at Kumblinge, in the year 1766, another perſon of the ſame ſex died at an age of upwards of one hundred and twenty years. One ſixth part of the inhabitants are above fifty years old;

Aland, Alaraf.

old; a circumſtance which affords a convincing proof of the healthineſs of the place.

The ſea which ſurrounds the iſle of Aland is very ſeldom frozen, and was leſs ſo formerly than at the preſent time. In 1546 it was remarked as an extraordinary event, that in that year the ſea was ſo frozen as to be croſſed on the ice. It ſeems latterly that theſe ſevere froſts happened once in ten years. The winter of the year 1702 was remarkably mild, ſo that barley was ſown on the twenty-fifth of March, at which time there was plenty of paſture for cattle: conſidering its high latitude, Aland enjoys a very favourable climate.

In their manners and cuſtoms the inhabitants of Aland do not differ greatly from the peaſants of Upland. Their marriages and funerals are celebrated much in the ſame manner.

The Alanders commonly uſe nouriſhing food; their bread is generally made of rye, even when the crops of that kind of corn have proved unfavourable. Freſh fiſh, and fiſh dried or ſalted, together with milk, butter, cheeſe, and fleſh-meat, are their uſual fare. They make uſe of the fleſh of ſeals; and prepare a diſh called *ſkalkroppe*, compoſed of collops of the fleſh mixed up with flour and lard, and this they reckon excellent. In their voyages by ſea they lay in a good ſtock of proviſions, and at theſe times are not ſparing of meat and butter.

The dreſs of the Alanders is becoming. The men wear, in general, ſhort jackets, which on holidays are commonly of blue cloth. The young peaſants commonly wear cotton ſtockings, and many of them have even watches. The women, when full dreſſed, wear a petticoat and apron of camlet, cotton, or printed linen, and ſometimes of ſilk. Their dreſs in mourning is generally of black ſilk, with a camlet petticoat.

The dwellings of the peaſants are very neat and convenient, kept in good repair, and well lighted. They are uſually built of wood, fir, or deal, and covered with the bark of the birch tree, or ſhingles. Their outhouſes are moſtly thatched. As they have no running ſtreams and water-mills, ſcarcely any peaſant is without a wind-mill.

The Alanders are an ingenious, lively, and courteous people; and on the ſea diſplay a great degree of ſkill and reſolution. They are far from being ſuperſtitious, but are ſaid to be of a litigious diſpoſition.

No bears or ſquirrels are to be found in theſe iſlands; and the elk, which formerly was uncommonly numerous, is now no longer ſeen in them. The animals chiefly found are wolves (which are ſaid to croſs the ſea from Finland, when it has happened to be frozen over), foxes, martens, hares, ermines, bats, moles, rats, mice, &c.; otters are but rarely met with: on the coaſt are found ſeals, &c. Above a hundred ſpecies of birds are found in the iſlands. Fiſh are in great abundance. The number of inſects amounts to eight hundred ſpecies, ſome of which are extremely deſtructive to trees and newly built houſes. The mountains are chiefly formed of red granite. (*Acerbi's Travels.*)

ALARAF, in the Mahometan theology, the partition wall that ſeparates heaven from hell. The word is plural, and properly written *al araf*; in the ſingular it is written *al arf*. It is derived from the Arabic verb *arafa*, to diſtinguiſh. Alaraf gives the denomination to the ſeventh chapter of the Alcoran, wherein mention is made of this wall. Mahomet ſeems to have copied his Alaraf, either from the great gulf of ſeparation mentioned in the New Teſtament, or from the Jewiſh writers, who alſo ſpeak of a thin wall dividing heaven from hell. Mahometan writers differ extremely as to the perſons who are to be found on Alaraf. Some take it for a ſort of limbus for the patriarchs, prophets, &c. others place here ſuch whoſe good and evil works ſo exactly balance each other, that they deſerve neither reward nor puniſhment. Others imagine this intermediate ſpace to be poſſeſſed by thoſe who, going to war without their parents leave, and ſuffering martyrdom there, are excluded paradiſe for their diſobedience, yet eſcape hell becauſe they are martyrs.

Alaraf || Alaſco.

ALARBES, a name given to thoſe Arabians who live in tents, and diſtinguiſh themſelves by their dreſs from the others who live in towns.

ALARES, in *Roman Antiquity*, an epithet given to the cavalry, on account of their being placed in the two wings of the army.

ALARIC, a famous general of the Goths. He entered Thrace at the head of 200,000 men, and laid waſte all the country through which he paſſed. He marched next to Macedonia and Theſſaly: The Theſſalians met him near the mouth of the river Peneus, and killed about 3000 of his army; nevertheleſs he advanced into Greece, and after having ravaged the whole country, returned to Epirus, loaded with immenſe ſpoils. After ſtaying here five years, he reſolved to turn his arms to the weſt. He marched through Pannonia; and, finding little reſiſtance, entered Italy, in the conſulſhip of Stilicho and Aurelianus, A. D. 400. After various battles and treaties, he at laſt took Rome by treachery, and permitted his ſoldiers to plunder it; this happened A. D. 400. Alaric, having laid waſte a great part of Italy, intended to paſs into Sicily: but a ſtorm obliging him to land again, he beſieged the city of Coſenza; and having taken it, he died there in 411, eleven years after he firſt entered Italy.

ALARM, in the *Military Art*, denotes either the apprehenſion of being ſuddenly attacked; or the notice thereof, ſignified by firing a cannon, firelock, or the like. Falſe alarms are frequently made uſe of, to haraſs the enemy, by keeping them conſtantly under arms. Sometimes alſo this method is taken to try the vigilance of the piquet-guard, and what might be expected from them in caſe of real danger.

Alarm-Bell, that rung upon any ſudden emergency, as a fire, mutiny, or the like.

Alarm-Poſt, or *Alarm-place*, the ground for drawing up each regiment in caſe of an alarm. This is otherwiſe called *the rendezvous*.

Alarm, in *Fencing*, is the ſame with what is otherwiſe called an appeal, or challenge.

ALASCANI, in *Church Hiſtory*, a ſect of Anti-Lutherans, whoſe diſtinguiſhing tenet, beſides their denying baptiſm, is ſaid to have been this, that the words, *This is my body*, in the inſtitution of the euchariſt, are not to be underſtood of the bread, but of the whole action, or celebration of the ſupper. They are ſaid to have taken the name from one Joannes Alaſco, a Poliſh baron, ſuperintendant of the church of that country, in England. See the next article.

ALASCO, John, a Poliſh nobleman of the 16th century,

Alatamaha || Alay.

century, who, imbibing the reformed opinions, was expelled his country, and became preacher to a Proteſtant congregation at Embden; but foreſeeing perſecution there, came to England about the year 1551, while the reformation was carrying on under Edward the VI. The publication of the Interim driving the Proteſtants to ſuch places as afforded them toleration, 380 were naturalized here, and obtained a charter of incorporation, by which they were erected into an eccleſiaſtical eſtabliſhment, independent on the church of England. The Auguſtine friars church was granted them, with the revenues, for the maintenance of Alaſco as ſuperintendant, with four aſſiſtant miniſters, who were to be approved by the king: and this congregation lived undiſturbed until the acceſſion of Queen Mary, when they were all ſent away. They were kindly received and permitted to ſettle at Embden; and Alaſco at laſt, after an abſence of 20 years, by the favour of Sigiſmund, returned to his own country, where he died in 1560. Alaſco was much eſteemed by Erafmus, and the hiſtorians of his time ſpeak greatly in his praiſe: we have of his writing, *De Cœna Domini liber; Epiſtola continens Summam controverſiæ de Cœna Domini*, &c. He had ſome particular tenets; and his followers are called *Alaſcani* in church-hiſtory.

ALATAMAHA, a large river of North America, which, riſing in the Apalachian mountains, runs ſouth-eaſt through the province of Georgia, and falls into the Atlantic ocean, below the town of Frederica.

ALATERNUS, in *Botany*, the trivial name of a ſpecies of the rhamnus. See RHAMNUS, BOTANY *Index*.

ALAVA, a diſtrict of Spain, about 20 miles in length, and 17 in breadth, containing very good iron mines. Victoria is the capital town.

ALAUDA, or LARK. See ORNITHOLOGY *Index*.

ALAUTA, a conſiderable river of Turkey in Europe, which, after watering the north-eaſt part of Tranſylvania and part of Walachia, falls into the Danube almoſt oppoſite to Nicopolis.

ALAY, ſignifying in the Turkiſh language "The Triumph," a ceremony which accompanies the aſſembling together the forces of that vaſt empire upon the breaking out of a war. It conſiſts of the moſt inſipid buffoonery, and is attended with acts of the moſt ſhocking barbarity. That which took place upon occaſion of the late war between the Porte and Ruſſia is deſcribed by Baron Tott in his Memoirs as follows:

"It conſiſts in a kind of maſquerade, in which each trade ſucceſſively preſents to the ſpectators the mechanical exerciſe of its reſpective art. The labourer draws his plough, the weaver handles his ſhuttle, the joiner his plane; and theſe different characters, ſeated in cars richly ornamented, commence the proceſſion, and precede the ſtandard of Mahomet, when it is brought out of the ſeraglio to be carried to the army, in order to inſure the victory to the Ottoman troops.

"This banner of the Turks, which they name *Sandjak-Cheriff*, or The Standard of the Prophet, is ſo revered among them, that, notwithſtanding its reputation has been ſo often tarniſhed, it ſtill retains their implicit confidence, and is the ſacred ſignal unto which they rally. Every thing proclaims its ſanctity. None but the emirs are allowed to touch it; they are its guards, and it is carried by their chief. The Muſſulmans alone are permitted to look upon it. If touched by other hands, it would be defiled; if ſeen by other eyes, profaned. In ſhort, it is encompaſſed by the moſt barbarous fanaticiſm.

"A long peace had unfortunately cauſed the ridiculouſneſs, and eſpecially the danger, of this ceremony to be forgotten. The Chriſtians imprudently crowded to ſee it; and the Turks, who, by the ſituation of their houſes, could make money of their windows, began to profit by the advantage; when an emir, who preceded the banner, proclaimed with a loud voice, 'Let no infidel dare to profane with his preſence the holy ſtandard of the prophet; and let every Muſſulman who perceives an unbeliever make it known under pain of reprobation.'

"From that moment no aſylum was to be found; even thoſe became informers, who, by letting out their houſes, had rendered themſelves accomplices in the crime. A religious fury ſeized on every mind, and put arms in every hand; the more atrocious the cruelty, the more was it meritorious. No regard was paid to ſex or age; pregnant women, dragged by the hair, and trodden under feet by the multitude, periſhed in the moſt deplorable manner. Nothing was reſpected by theſe monſters; and under ſuch auſpices the Turks commenced the war."

ALB, or ALBE, in the *Romiſh Church*, a veſtment of white linen hanging down to the feet, and anſwering to the ſurplice of the Engliſh clergy. In the ancient church, it was uſual, with thoſe newly baptized, to wear an alb, or white veſtment; and hence the Sunday after Eaſter was called *dominica in albis*, on account of the albs worn by the baptized on Eaſter-day.

ALB, is alſo a name of a Turkiſh coin, otherwiſe called *aſper*. See ASPER.

Alb || Alba.

ALBA, in *Ancient Geography*, a town of the Marſi in Italy, ſituated on the north ſide of the Lacus Fucinus, ſtill retaining its name. It ſtands upon an eminence, and is noted in Roman hiſtory for being the ſtate priſon where captive princes were ſhut up, after being barbarouſly dragged through the ſtreets of Rome at the chariot wheels of a triumphant conſul. Perſeus king of Macedon terminated his wretched career in this confinement, with his ſon, the laſt hope of an illuſtrious line of kings. Syphax the Numidian, and Bituinus king of the Averni, were alſo condemned to this gaol by the particular clemency of the ſenate, which ſometimes indulged its ſavage diſpoſition by putting its captives to death.

Alba being ſituated in the centre of Italy, amidſt difficult mountainous paſſes, and far from all means of eſcape, was eſteemed a moſt proper place for the purpoſe of guarding priſoners of importance. Artificial ſtrength was added to its natural ſecurity by fortifications, which remain to this day in a ſtate that proves their ancient ſolidity. For the entertainment of the garriſon, which was required in a place of ſuch conſequence, an amphitheatre was erected, of which the ruins are ſtill valuable, as well as the foundations of a temple, and other buildings of Roman times.

Lucius Vitellius, brother to the emperor of that name, had a villa near this place, famous for the variety and excellence of its fruit trees, which he had brought from Syria. His gardens were the nurſeries where ſeveral of the moſt delicious ſtone-fruits, that are now ſo common

Alba
||
Albanenſes.

mon in Europe, were firſt cultivated and multiplied. It muſt have been neceſſary at Alba to ſhelter trees tranſplanted from Aſia, and to treat them with great tenderneſs and care, in order to rear them to perfection: for the climate of this high region is extremely rigorous in winter; the cold ſeaſon laſts long, and is accompanied with violent ſtorms of wind and falls of ſnow. The lake has been often frozen entirely over.

Alba Firma, or *Album*, in our *Old Cuſtoms*, denoted rent paid in ſilver, and not in corn, which was called *black mail*.

Alba Terra, one of the numerous names for the philoſopher's ſtone.

Alba Regalis. See Stuhl Weissenburg.

Alba Helviorum, or *Albauguſta*, in *Ancient Geography*, afterwards called *Vivarium*, now *Viviers*, in the ſouth-eaſt of Languedoc, on the Rhone. In the lower age the inhabitants were called *Albenſes*, and their city *Civitas Albenſium*, in the Notitia Galliæ. E. Long. 4. 45. Lat. 44. 50.

Alba Julia, in *Ancient Geography*, now *Weiſſenburg*, a town of Tranſylvania, on the river Mariſius, or Meriſch, to the weſt of Hermanſtat, ſuppoſed to be called *Alba Julia*, after Julia Domna the mother of Caracalla. There are, however, ſeveral ſubſcriptions found at or near Weiſſenburg, which bear Col. Apul. that is, *Colonia Apulenſis*, without the leaſt mention of *Alba Julia*, though inſcribed after Caracalla's time. Add, that Ulpian, reciting the colonies of Dacia, calls this colony *Apulenſis*, and neither *Alba* nor *Julia*. Whence there is a ſuſpicion, that *Alba Julia* is a corruption of *Apulum*. It was alſo called *Apulum Auguſtum*. E. Long. 25. 0. Lat. 46. 46.

Alba Longa, in *Ancient Geography*, a colony from Lavinum, in Latium, eſtabliſhed by Aſcanius the ſon of Æneas, at the foot of the Mons Albanus: called *Alba*, from a white ſow found by Æneas, which farrowed 30 white pigs on that ſpot; which circumſtance was interpreted to portend the building of a city there in 30 years after (Propertius). The epithet *Longa* was added on account of its length. It was the royal reſidence till the building of Rome, as was foretold by Anchiſes (Virgil); was deſtroyed by Tullus Hoſtilius, all but the ſane or temple; and the inhabitants were tranſplanted to Rome (Strabo).

Alba Pompeia, in *Ancient Geography*, on the river Ceba, now *Ceva*, in Liguria, the birth-place of the emperor Pertinax; a colony either eſtabliſhed at firſt by Pompey, or re-eſtabliſhed by him after having been before ſettled by Scipio. The inhabitants were called *Albenſes Pompeiani*. At this day the town is ſimply called *Alba*, without any epithet.

ALBAHURIM, *figura ſexdecim laterum*, a figure of great importance according to aſtrological phyſicians, who built their prognoſtics on it.

ALBAN, St, is ſaid to have been the firſt perſon who ſuffered martyrdom for Chriſtianity in Britain; he is therefore uſually ſtyled the protomartyr of this iſland. He was born at Verulam, and flouriſhed towards the end of the third century. In his youth he took a journey to Rome, in company with Amphibalus a monk of Caerleon, and ſerved ſeven years as a ſoldier under the emperor Diocleſian. At his return home, he ſettled in Verulam; and, through the example and inſtructions of Amphibalus, renounced the errors of Paganiſm, in which he had been educated, and became a convert to the Chriſtian religion. It is generally agreed, that Alban ſuffered martyrdom during the great perſecution under the reign of Diocleſian; but authors differ as to the year when it happened: Bede and others fix it in 286; ſome refer it to the year 296; but Uſher reckons it amongſt the events of 303. The ſtory and circumſtances relating to his martyrdom, according to Bede, are as follows. Being yet a Pagan (or at leaſt it not being known that he was a Chriſtian), he entertained Amphibalus in his houſe. The Roman governor being informed thereof, ſent a party of ſoldiers to apprehend Amphibalus; but Alban, putting on the habit of his gueſt, preſented himſelf in his ſtead, and was carried before that magiſtrate. The governor having aſked him of what family he was? Alban replied, "To what purpoſe do you inquire of my family? if you would know my religion, I am a Chriſtian." Then being aſked his name, he anſwered, "My name is Alban; and I worſhip the only true and living God, who created all things." The magiſtrate replied, "If you would enjoy the happineſs of eternal life, delay not to ſacrifice to the great gods." Alban anſwered, "The ſacrifices you offer are made to devils; neither can they help the needy, or grant the petitions of their votaries." His behaviour ſo enraged the governor, that he ordered him immediately to be beheaded. In his way to execution, he was ſtopped by a river, over which was a bridge ſo thronged with ſpectators that it was impoſſible to croſs it; the ſaint, as we are told, lifted up his eyes to heaven, and the ſtream was miraculouſly divided, and afforded a paſſage for himſelf and a thouſand more perſons. Bede does not indeed give us the name of this river; but, notwithſtanding this omiſſion, the miracle, we ſuppoſe, will not be the leſs believed. This wonderful event converted the executioner upon the ſpot, who threw away his drawn ſword, and, falling at St Alban's feet, deſired he might have the honour to die with him. This ſudden converſion of the headſman occaſioning a delay in the execution till another perſon could be got to perform the office, St Alban walked up to a neighbouring hill, where he prayed for water to quench his thirſt, and a fountain of water ſprung up under his feet: here he was beheaded, on the 23d of June. The executioner is ſaid to have been a ſignal example of divine vengeance; for as ſoon as he gave the fatal ſtroke, his eyes dropt out of his head. We may ſee the opinion of Mr Milton in regard to this narrative, in his Hiſtory of England. His words are theſe, ſpeaking of St Alban: "The ſtory of whoſe martyrdom, ſoiled and worſe martyred with the fabling zeal of ſome idle fancies, more fond of miracles than apprehenſive of the truth, deſerves no longer digreſſion." Between 400 and 500 years after St Alban's death, Offa, king of the Mercians, built a very large and ſtately monaſtery to his memory; and the town of St Albans in Hertfordſhire takes its name from our protomartyr.

Alban,
Albana.

ALBANA, in *Ancient Geography*, a ſea-port town of Albania, on the Caſpian ſea, between the rivers Caſius and Albanus; now called *Bachu*, or *Bachy*, giving name to the Caſpian ſea, viz. *Mer de Bahu*. E. Long. 49. 0. N. Lat. 40. 0.

ALBANENSES, in *Church Hiſtory*, the ſame with Albigenſes. See Albigenses.

ALBANI,

Albani. ALBANI, in Roman antiquity, a college of the *Salii*, or prieſts of Mars; ſo called from Mount Albanus, the place of their reſidence. See SALII.

ALBANI, *Francis*, a celebrated painter, born in Bologna, March 17. 1578. His father was a ſilk merchant, and intended to bring up his ſon to that buſineſs; but Albani having a ſtrong inclination to painting, when his father died, devoted himſelf entirely to that art, though then but twelve years of age. He firſt ſtudied under Denys Calvert; Guido Rheni being at the ſame time under this maſter, with whom Albani contracted a very great friendſhip. Calvert drew but one profile for Albani, and afterwards left him entirely to the care of Guido; under whom he made great improvement, his fellow-diſciple inſtructing him with the utmoſt humanity and good humour. He followed Guido to the ſchool of the Caracci: but a little after their friendſhip for each other began to cool; which was owing perhaps to the pride of Albani, who could not bear to ſee Guido ſurpaſs him, or to the jealouſy of Guido at finding Albani make ſuch rapid progreſs. They certainly endeavoured to eclipſe one another; for when Guido had ſet up a beautiful altar-piece, Albani would oppoſe to it ſome fine picture of his: thus did they behave for ſome time, and yet ſpoke of each other with the higheſt eſteem. Albani, after having greatly improved himſelf under the Caracci, went to Rome, where he continued many years, and married in that city; but his wife dying in childbed, at the earneſt requeſt of his relations he returned to Bologna, where he entered again into the ſtate of matrimony. His ſecond wife (Doralice) was well deſcended, but had very little fortune; which he perfectly diſregarded, ſo ſtrongly was he captivated with her beauty and good ſenſe. Albani, beſides the ſatisfaction of poſſeſſing an accompliſhed wife, reaped likewiſe the advantage of having a moſt beautiful model; ſo that he had now no occaſion to make uſe of any other woman to paint a Venus, the Graces, Nymphs, and other deities, whom he took a particular delight in repreſenting. His wife anſwered this purpoſe admirably well; for beſides her bloom of youth, and the beauty of her perſon, he diſcovered in her ſo much modeſty, ſo many graces and perfections, ſo well adapted to painting, that it was impoſſible for him to meet with a more finiſhed woman. She afterwards brought him ſeveral boys, all extremely beautiful and finely proportioned; ſo that ſhe and her children were the originals of his moſt agreeable and graceful compoſitions. Doralice was ſo conformable to his intentions, that ſhe took a pleaſure in ſetting the children in different attitudes, holding them naked, and ſometimes ſuſpended by ſtrings, when Albani would draw them in a thouſand different ways. It was from them, too, that the famous ſculptors Flamand and Argaldi modelled their little Cupids.

Albani was of a happy temper and diſpoſition; his paintings, ſays Malvaſia, breathing nothing but content and joy. Happy in a force of mind that conquered every uneaſineſs, his poetical pencil carried him through the moſt agreeable gardens to Paphos and Cytheria: thoſe delightful ſcenes brought him over the lofty Parnaſſus to the delicious abodes of Apollo and the Muſes: whence what Du Freſnoy ſays of the famous Giulio Romano may be juſtly applied to Albani:

Albani. Albano.

> Taught from a child in the bright Muſes grots,
> He open'd all the treaſures of Parnaſſus,
> And in the lively poetry of painting
> The myſt'ries of Apollo has reveal'd.

He died the 4th of October 1660, to the great grief of all his friends and the whole city of Bologna. Malvaſia has preſerved ſome verſes of Franciſco de Lemene, intended for his monument; the ſenſe whereof is, "That the mortal remains of the illuſtrious Albani, he who gave life to ſhade, lie interred in this tomb: the earth never produced ſo wonderful an artiſt, or a hand equal to his immortal one; which gave colours to the ſoul, and a ſoul to colours. Prometheus animated clay, and gave life by means of the ſun; but Albani animated merely by the aſſiſtance of ſhade." He was very famous in his lifetime, and had been viſited by the greateſt painters. Several princes honoured him with letters; and amongſt the reſt King Charles I. who invited him to England by a letter ſigned with his own hand.

ALBANIA, a province of Turkey in Europe, on the gulf of Venice, bounded by Livadia on the ſouth, by Theſſaly and Macedonia on the eaſt, and on the north by Boſnia and Dalmatia. The people are ſtrong, large, courageous, and good horſemen; but are ſaid to be of a thieviſh diſpoſition. The grand ſeignior procures excellent ſoldiers from hence, particularly cavalry, known by the name of *Arnauts*. There are ſeveral large towns in this province; and the inhabitants are almoſt all Chriſtians of the Greek church, and deſcended from the ancient Scythians. Formerly it was part of the kingdom of Macedonia. Their chief manufacture is carpets. The principal places are Durazzo, Velona, Antivari, Scutari, Croya, Aleſſo, Dibra, Dolcigno, and Albanapoli. Long. from 18° to 21° E.; Lat. from 39° to 43° N.

ALBANIA, a country of Aſia, bounded on the weſt by Iberia; on the eaſt by the Caſpian ſea; on the north by Mount Caucaſus; on the ſouth by Armenia, and the river Cyrus, now Kur; which, ſpringing from the Moſchian mountains that ſeparate Colchis from Armenia, and watering the country of Mokan, receives the Aragus and Araxes, and falls into the Caſpian ſea within a ſmall diſtance from the ſouthern borders of this country.—The whole country formerly called *Albania*, now goes under the names of *Schirwan* and *Eaſt-Georgia*, and is extremely fruitful and pleaſant. The ancient hiſtorians take notice of the Albanian men being tall, ſtrong-bodied, and, generally ſpeaking, of a very graceful appearance; far excelling all other nations in comelineſs as well as ſtature. Modern travellers take no notice of the appearance of the men; but extol the beauty of the women, which ſeems to be unnoticed by the ancients. The Albanians were anciently an independent and pretty powerful people; but we find no mention made of their kings till the reign of Alexander the Great, to whom the king of Albania is ſaid to have preſented a dog of an extraordinary fierceneſs and ſize.—It does not appear that the Albanians were ever conquered by the Romans, even when their power was at the greateſt height; though when they ventured to engage in war with that powerful empire, they were always defeated, as might naturally be expected.

ALBANO, a town of Italy, on a lake of the ſame

Albano, Alban's.

name, in the Campagna of Rome. It was called by the ancients *Albanum Pompeii*, and built out of the ruins of the ancient Alba Longa, which was deſtroyed by Tullus Hoſtilius. It ſtands within twelve miles ſouth-eaſt of Rome, and for the pleaſantneſs of its ſituation is the ſummer retirement of a great many Roman princes. It is likewiſe the ſee of a biſhop, who is one of the ſix ſenior cardinals. The town is famous for its excellent wine, and the ruins of a mauſoleum, which, according to the tradition of the inhabitants, was made for Aſcanius. The proſpect from the garden of the Capuchins is extremely pleaſant, taking in the Campania of Rome, and terminating in a full view of the Tuſcan ſea. Cloſe by the town lies the Alban lake, of an oval figure, and about ſeven miles in circumference, which, by reaſon of the high mountains round it, looks like the area of a great amphitheatre. It abounds with excellent fiſh, and over againſt the hermitage it is ſaid to be unfathomable. The mountain of Albano is called *Monte Cavo*; on the top of which was a celebrated temple dedicated to Jupiter and Juno. Near the Capuchins there is another convent of Franciſcans; and not far from thence the palace of Cardinal Barberini, remarkable for very pleaſant gardens, with the ruins of ancient baths, and ſeveral old fragments of moſaic work. E. Long. 13. 10. N. Lat. 41. 43.

ALBANO is alſo a town in the kingdom of Naples remarkable for the fertility of the ſurrounding territory, and for the nobility of the inhabitants.

ALBAN'S, SAINT, a market town of Hertfordſhire, is a very great thoroughfare, accommodated with good inns, on the north-weſt road from London, at the diſtance of 21 miles. This town ſends two members to parliament, gives the title of *duke* to the noble family of Beauclerc, and has one of the beſt markets for wheat in England. St Alban's is ſeated near the ruins of the ancient Roman city, by Tacitus called *Verulam*; and by the Saxons *Watlingceſter*, becauſe it is ſeated on the road called *Watlingſtreet*. Nothing now remains of Verulam but the ruins of old walls; in the fields adjacent to which they continue to find Roman coins as they formerly found teſſelated pavements. In memory of St Alban, Offa, king of the Mercians, *anno* 795, erected an abbey, calling it *St Alban's*; and near it the town of the ſame name was afterwards built. The church of the abbey is remaining to this day: time and the weather have made it look like ſtone on the outſide; but if you break a bit off, the redneſs of the brick immediately appears. When the monaſteries were diſſolved, the townſmen paid 400l. to prevent its being levelled with the ground, and have ſince converted it into a pariſh-church, which, for its largeneſs, beauty, and antiquity, claims a particular regard. It had a very noble font of ſolid braſs, in which the children of the kings of Scotland were uſed to be baptized; and was brought from Edinburgh, by Sir Philip Lea, when the city was in flames; but in the times of the late civil wars, it was taken away. Not many years ſince, a tomb was diſcovered in this church, ſaid to be that of Humphry duke of Glouceſter: when the leaden coffin was opened, the body was pretty entire, being preſerved in a ſort of pickle. There was a ſtately croſs in the middle of the town, as there were in many other places, where Queen Eleanor's body reſted when it was brought out of the north for interment at Weſtminſter; but it is now demoliſhed. W. Long. 0. 12. N. Lat. 51. 44.

Albanus ‖ Albategr

ALBANUS MONS, in *Ancient Geography*, now called *Mont Albano*, 26 miles from Rome, near where Alba Longa ſtood.

ALBANUS MONS, in *Ancient Geography*, to the north of Iſtria, called *Albius* by Strabo; the extremity of the Alps, which, together with the mountains to the eaſt, joining it, called *Montes Bœbii*, ſeparate the farther Liburnia and Dalmatia from Pannonia.

ALBANY, a fortreſs belonging to the Britiſh, ſeated on the S. W. of Hudſon's bay. W. Long. 84. 20. N. Lat. 53. 20.

ALBANY, a town of North America, the capital of one of the ten counties of the province of New-York, which goes by the ſame name, is a well-built place, conſidering the country. Here the ſachems, or the kings of the Five Nations of Iroquois, met the governors of the Britiſh plantations, when they entered into any treaty with them. W. Long. 44. 29. N. Lat. 42. 30.

ALBARAZIN, a ſtrong town, and one of the moſt ancient of the kingdom of Arragon in Spain. It is ſeated upon an eminence, near the river Guadalquivir, a little below its ſource, and on the frontiers of Valencia and New Caſtile. It is the ſeat of a biſhop, and produces the beſt wool in all Arragon. It is about 100 miles eaſt of Madrid. E. Long. 2. 10. N. Lat. 40. 32.

ALBARII, in antiquity, properly denoted thoſe who gave the whitening to earthen veſſels, &c. In which ſenſe they ſtood contradiſtinguiſhed from *Dealbatores*, who whitened walls.

ALBARIUM OPUS, in the ancient building, the incruſtation or covering of the roofs of houſes with white plaſter, made of mere lime. This is otherwiſe called *opus album*. It differed from *Tectorium*, which is a common name given to all roofing or ceiling, including even that formed of lime and ſand, or lime and marble; whereas *Albarium* was reſtrained to that made of lime alone.

ALBATEGNI, an Arabic prince of Batan in Meſopotamia, and a celebrated aſtronomer, who lived about the year of Chriſt 880, as appears by his obſervations. He is alſo called *Muhammed ben Geber Albatani*, *Mahomet the ſon of Geber*, and *Muhamedes Aractenſis*. He made aſtronomical obſervations at Antioch, and at Racah or Aracta, a town of Chaldea. He is highly ſpoken of by Dr Halley, as a man of admirable genius, and an excellent obſerver.

Inſtead of the tables of Ptolemy which were imperfect, he computed new ones: theſe were adapted to the meridian of Aracta or Racah, and were long uſed as the beſt among the Arabs. Albategni compoſed in Arabic a work under the title of *The Science of the Stars*, compriſing all parts of aſtronomy, according to his own obſervations and thoſe of Ptolemy. This work was tranſlated into Latin by Plato of Tibur, and publiſhed at Nuremberg in 1537, with ſome additions and demonſtrations of Regiomontanus. It was reprinted at Bologna in 1645, with this author's notes. Dr Halley detected many faults in theſe editions: *Philoſ. Tranſ.* for 1693, N° 204. In this work, Albategni gives the motion of the ſun's apogee ſince Ptolemy's time, as well as the motion of the ſtars, which he

makes

Albati || Alberti.

makes one degree in 70 years. He made the longitude of the firſt ſtar of Aries to be 18° 2′; and the obliquity of the ecliptic 23° 35′. Upon Albategni's obſervations were founded the Alphonſine tables of the moon's motion. (*Hutton's Math. Dict.*)

ALBATI EQUI, an appellation given to ſuch horſes, in the games of the ancient circus, as wore white furniture.

ALBATROSS, in *Ornithology*, a ſpecies of the diomedea. See DIOMEDEA, ORNITHOLOGY *Index*.

ALBAZIN, a town of Greater Tartary, with a ſtrong caſtle. It is ſituated upon the river Amur, or Yamour, and belongs to the Muſcovites. E. Long. 103. 30. N. Lat. 54. 0.

ALBE, a ſmall piece of money, current in Germany, worth only a French ſol and ſeven deniers.

ALBEMARLE, or AUMARLE, a town of France, in Upper Normandy, and in the territory of Caux, from whence the noble family of Keppel takes the title of *earl*. The ſerges of this town are in high eſteem. It is ſeated on the declivity of a hill, on the confines of Picardy, 35 miles north-eaſt of Rouen, and 70 north-weſt of Paris. E. Long. 2. 21. N. Lat. 49. 50.

ALBEMARLE, the moſt northern part of the province of North Carolina in America.

ALBENGUA, a town of Italy, in the territory of Genoa. It is the ſee of a biſhop; and is a very ancient handſome town, but not well peopled on account of the inſalubrity of the air. It is ſeated in a very beautiful plain, which is well cultivated; and the outſide of the town is ſurrounded with olive-trees. It is a ſea-port, about 38 miles ſouth-weſt of Genoa. E. Long. 8. 13. N. Lat. 44. 4.

ALBERNUO, a kind of camlet, brought from the Levant by the way of Marſeilles.

ALBERONI, JULIUS, the ſon of a poor gardener in the ſuburbs of Placentia, born in 1664; who, by his great abilities and good fortune, roſe from this low origin to the employment of firſt miniſter of ſtate at the court of Spain, and to the dignity of cardinal. He rouſed that kingdom out of the lethargy it had ſunk into for a century paſt; awakened the attention, and raiſed the aſtoniſhment of all Europe, by his projects; one of which was to ſet the Pretender on the throne of Great Britain. He was at length deprived of his employment, and baniſhed to Rome. He died in 1752, at the great age of 89. His *Teſtament Politique*, collected from his memoirs and letters, was publiſhed at Lauſanne in 1753.

ALBERT, Margrave of Branbenburg, and the laſt grand maſter of the Teutonic order, laid aſide the habit of his order, embraced Lutheraniſm, and concluded a peace at Cracow in 1525, by which he was acknowledged duke of the eaſt part of Pruſſia (formerly called for that reaſon *Ducal Pruſſia*), but to be held as a fief of Poland, and to deſcend to his male heirs. See PRUSSIA.

ALBERTI, LEONE BATTISTA, was deſcended from a noble family in Florence; and was perfectly acquainted with painting, ſculpture, and architecture. He wrote of all three in Latin; but his ſtudies did not permit him to leave any thing conſiderable behind him in painting. He was employed by Pope Nicholas V. in his buildings, which he executed in a beautiful manner; and his work on architecture, which conſiſts of 10 books, is greatly eſteemed. He alſo wrote ſome treatiſes of morality, and a piece of arithmetic. He died in 1485.

Albertiſts || Albi

ALBERTISTS, a ſect of ſcholaſtics, ſo named from their leader Albertus Magnus.

ALBERTUS, MAGNUS, a Dominican friar, and afterwards biſhop of Ratiſbon, was one of the moſt learned men and moſt famous doctors of the 13th century. He is ſaid to have acted as a man-midwife; and ſome have been highly offended that one of his profeſſion ſhould follow ſuch an employment. A book entitled *De Natura Rerum*, of which he was reputed the author, gave riſe to this report. In this treatiſe there are ſeveral inſtructions for midwives, and ſo much ſkill ſhown in their art, that one would think the author could not have arrived at it without having himſelf practiſed: but the advocates for Albert ſay he was not the writer thereof, nor of that other piece *De Secretis Mulierum*; in which there are many phraſes and expreſſions unavoidable on ſuch a ſubject, which gave great offence, and raiſed a clamour againſt the ſuppoſed author. It muſt be acknowledged, however, that there are, in his Comment upon the Maſter of Sentences, ſome queſtions concerning the practice of conjugal duty, in which he has uſed ſome words rather too groſs for chaſte and delicate ears; but they allege what he himſelf uſed to ſay in his own vindication, that he came to the knowledge of ſo many monſtrous things at confeſſion, that it was impoſſible to avoid touching upon ſuch queſtions. Albert was certainly a man of a moſt curious and inquiſitive turn of mind, which gave riſe to other accuſations brought againſt him. It is ſaid, that he laboured to find out the philoſopher's ſtone; that he was a magician; and that he made a machine in the ſhape of a man, which was an oracle to him, and explained all the difficulties he propoſed. He had great knowledge in the mathematics, and by his ſkill in that ſcience might probably have formed a head with ſprings capable of articulating ſounds; like to the machines of Boetius, of which Caſſiodorus has ſaid, "Metals lowe; the birds of Diomedes trumpet in braſs; the brazen ſerpent hiſſes; counterfeited ſwallows chatter, and ſuch as have no proper note, from braſs ſend forth harmonious muſic." John Matthæus de Luna, in his treatiſe *De Rerum Inventoribus*, has attributed the invention of fire-arms to Albert; but in this he is confuted by Naude, in his *Apologie des Grandes Hommes*. Albert died at Cologne in 1280. His works were printed at Lyons, in 1651, in 21 volumes in folio.

ALBERTUS, a gold coin, worth about fourteen French livres: it was coined during the adminiſtration of Albertus archduke of Auſtria.

ALBESIA, in antiquity, a kind of ſhields otherwiſe called *Decumana*. See DECUMANA.

ALBI, a city of France, in the department of the Tarn, the capital of the Albigeois, in Upper Languedoc. The cathedral is dedicated to St Cecilia, and has one of the fineſt choirs in the kingdom. Here is a very valuable ſilver ſhrine, of exquiſite workmanſhip, of the moſaic kind: it contains the reliques of St Clair, the firſt biſhop of this city. The chapel of this pretended ſaint is magnificent, and adorned with paintings. The Lice is a fine large walk without the city: what diſtinguiſhes this from all others, is a terrace

Albigenſes. above a deep moat, which ſerves inſtead of a foſſe; it is bordered with two rows of very fine trees, which are kept in excellent order. There are four gates, through which you may view all the beauties of a delightful plain. At one end of this is the convent of the Dominicans. The archbiſhop's palace is very beautiful. The river waſhes its walls, and ſerves both for an ornament and defence. This city is ſeated on the river Tarn, 35 miles north eaſt of Toulouſe, and 250 ſouth of Paris. E. Long. 2. 9. N. Lat. 43. 56.

The Albigeois is a ſmall territory about twenty-ſeven miles in length, and twenty in breadth, abounding in corn, woad, grapes, ſaffron, plums, and ſheep; and the inhabitants have a great trade in dried prunes, grapes, a coarſe ſort of cloth, and wine of Gaillac. Theſe wines are the only ſort hereabouts that are fit for exportation: they are carried down to Bourdeaux, and generally ſold to the Britiſh. They have likewiſe ſeveral coal mines.

ALBIGENSES, in church hiſtory, a ſect or party of reformers, about Toulouſe and Albigeois in Languedoc, who ſprung up in the 12th century, and diſtinguiſhed themſelves by their oppoſition to the diſcipline and ceremonies of the Romiſh church.

This ſect had their name, it is ſuppoſed, either by reaſon there were great numbers of them in the dioceſe of Albi, or becauſe they were condemned by a council held in that city. In effect, it does not appear that they were known by this name before the holding of that council. The *Albigenſes* were alſo called *Albiani*, *Albigeſei*, *Albii*, and *Albanenſes*, though ſome diſtinguiſh theſe laſt from them. Other names given to them are *Henricians*, *Abelardiſts*, *Bulgarians*, &c.; ſome on account of the qualities they aſſumed; others on that of the country from whence it is pretended they were derived; and others on account of perſons of note who adopted their cauſe, as Peter de Brius, Arnold de Breſſe, Abelard, Henry, &c. Berengarius, if not Wickliff himſelf, is by ſome ranked in the number. The *Albigenſes* are frequently confounded with the *Waldenſes*; from whom, however, they differ in many reſpects, both as being prior to them in point of time, as having their origin in a different country, and as being charged with divers hereſies, particularly Manicheiſm, from whence the *Waldenſes* are exempt. But ſeveral Proteſtant writers have vindicated them from that imputation. Dr Allix ſhows that a great number of *Manichees* did ſpread over the weſtern countries from Bulgaria; and ſettled in Italy, Languedoc, and other places, where they were alſo *Albigenſes*; by which means, being both under the imputation of *hereſy*, they came, either by ignorance or malice, to be confounded, and called by the ſame common name, though in reality entirely different.

Other errors imputed to them by their opponents, the monks of thoſe days, were, That they admitted two Chriſts; one evil, who appeared on earth; the other good, who has not yet appeared: That they denied the reſurrection of the body; and maintained human ſouls to be demons impriſoned in our bodies, by way of puniſhment for their ſins: That they condemned all the ſacraments of the church; rejected baptiſm as uſeleſs; held the euchariſt in abhorrence; excluded the uſe of confeſſions and penance; maintained marriage unlawful; laughed at purgatory, prayers for the dead, images, crucifixes, &c. There were likewiſe ſaid to be two claſſes of them; the Perfect and the Believers. The perfect boaſted of their living in continence, of eating neither fleſh, eggs, nor cheeſe. The believers lived like other men, and were even looſe in their morals; but they were perſuaded they ſhould be ſaved by the faith of the perfect, and that none were damned who received impoſition of hands from them. But from theſe charges alſo they are generally acquitted by Proteſtants, who conſider them as the pious inventions of the Romiſh church, whoſe members deem it meritorious by any means to blacken heretics. Albigenſes.

However this be, the Albigenſes grew ſo formidable, that the Catholics agreed upon a holy league or cruſade againſt them. They were at firſt ſupported by Raimond, count of Toulouſe. Pope Innocent III. deſirous to put a ſtop to their progreſs, ſent a legate into their country; which failing, he, ſtirred up Philip Auguſtus, king of France, and the other princes and great men of the kingdom, to make war upon them. Upon this the count of Toulouſe, who had ſided with them, made his ſubmiſſion to the pope, and went over to the Catholics: but ſoon after, finding himſelf plundered by the cruſades, he declared war againſt them, and was joined by the king of Arragon. His army was defeated at the ſiege of Muret, where he himſelf was killed, and the defeat followed by the ſurrender of the city of Toulouſe, and the conqueſt of the greateſt part of Languedoc and Provence. His ſon Raymond ſucceeded him; who agreed with the king and the pope to ſet up the inquiſition in his eſtates, and to extirpate the Albigenſes. In an aſſembly held at Milan, the archbiſhop of Toulouſe drew up articles; agreeable to which the count made a moſt ample declaration againſt them, which he publiſhed at Toulouſe in 1253. From this time the Albigenſes dwindled by little and little, till the time of the Reformation; when ſuch of them as were left fell in with the Vaudois, and became conformable to the doctrine of Zuinglius and the diſcipline of Geneva.

ALBIGENSES is alſo a name ſometimes given to the followers of Peter Vaud, or Waldo; and hence ſynonymous with what we more properly call *Waldenſes*, or Poor Men of Lyons. In this ſenſe the word is applied by Camerarius, Thuanus, and ſeveral other writers. The reaſon ſeems to be, that the two parties agreed in their oppoſition to the papal innovations and encroachments, though in divers other reſpects ſaid to be different enough. The biſhop of Meaux labours hard to ſupport a diſtinction between the two ſects, alleging that the *Albigenſes* were heretics and Manichees; whereas the *Waldenſes* were only ſchimatics, not heretics; being ſound as to articles of faith, and only ſeparating from the church of Rome on account of forms and diſcipline. Dr Allix endeavours to ſet aſide the diſtinction: and ſhows, that both of them hold the ſame opinions, and were equally condemned and held for heretics; and this not for points of faith, but for declaiming againſt the papal tyranny and idolatry, and holding the pope to be the Antichriſt; which laſt, according to M. de Meaux, conſtitutes nothing leſs than Manicheiſm. In this ſenſe the Lollards and Wickliffites in England were not only Albigenſes but Manichees.

ALBINTEMELIUM,

Albintemelium Albinos

ALBINTEMELIUM, ALBINTIMILIUM (Tacitus); or at full length, ALBIUM INTEMELIUM (Pliny, Strabo); now *Vintimiglia*, situated in the south-weſt of the territory of Genoa, near the borders of the county of Nice, with a port on the Mediterranean, at the mouth of the rivulet Retta, about halfway between Monaco and St Remo. E. Long. 7. 40. N. Lat. 43. 17.

ALBIOECE, or ALBIECE (Pliny, Strabo); otherwiſe called *Reii apollinares*, from their ſuperſtitious worſhip of Apollo; alſo *Civitas Reienſium*; now *Riez*, in Provence, about 18 leagues to the north-eaſt of Toulon, on the north ſide of the rivulet Verdon; was originally a Roman colony (Inſcription). It is ſometimes written *Regium*. The people were called *Albici*, (Cæſar.) E. Long. 1. 0 N. Lat. 43. 20.

ALBINI, in *Antiquity*, the workmen employed in what was called *Opus Albarium*. They make a different profeſſion from the *dealbatores* or *whiteners*.

ALBINOS, the name by which the Portugueſe call the white Moors, who are looked upon by the negroes as menders. They at a diſtance might be taken for Europeans; but, when you come near them, their white colour appears like that of perſons affected with a leproſy.

In Sauſſure's *Voyages dans les Alpes*, is the following account of the two boys, at Chamouni, who have been called *Albinos*. "The elder, who was at the end of the year 1785 about twenty or one-and-twenty years of age, had a dull look, with lips ſomewhat thick, but nothing elſe in his features to diſtinguiſh him from other people. The other, who is two years younger, is rather a more agreeable figure; he is gay and ſprightly, and ſeems not to want wit. But their eyes are not blue; the iris is of a very diſtinct roſe colour; the pupil too, when viewed in the light, ſeems decidedly red; which ſeems to demonſtrate, that the interior membranes are deprived of the uvea, and of that black mucous matter that ſhould line them. Their hair, their eye-brows, and eye-laſhes, the down upon their ſkin, were all in their infancy, of the moſt perfect milk-white colour, and very fine; but their hair is now of a reddiſh caſt, and has grown pretty ſtrong. Their ſight, too, is ſomewhat ſtrengthened; though they exaggerate to ſtrangers their averſion for the light, and half ſhut the eyelids, to give themſelves a more extraordinary appearance. But thoſe who, like me, have ſeen them in their infancy, before they were tutored to this deceit, and when too few people came to Chamouni to make this affectation profitable to them, can atteſt that then they were not very much offended with the light of day. At that time they were ſo little deſirous of exciting the curioſity of ſtrangers, that they hid themſelves to avoid ſuch; and it was neceſſary to do a ſort of violence to them before they could be prevailed on to allow themſelves to be inſpected. It is alſo well known at Chamouni, that when they were of a proper age they were unable to tend the cattle like the other children at the ſame age; and that one of their uncles maintained them out of charity, at a time of life when others were capable of gaining a ſubſiſtence by their labour.

"I am therefore of opinion, that we may conſider theſe two lads as two albinos; for if they have not the thick lips and flat noſes of the white negroes, it is becauſe they are albinos of Europe, not of Africa. This infirmity affects the eyes, the complexion, and the colour of the hair; it even diminiſhes the ſtrength, but does not alter the conformation of the features. Beſides, there are certainly in this malady various degrees; ſome may have leſs ſtrength, and be leſs able to endure the light: but theſe circumſtances in thoſe of Chamouni are marked with characters ſufficiently ſtrong to entitle them to the unhappy advantage of being claſſed with that variety of the human ſpecies denominated albinos. Albinos.

"When nature preſents the ſame appearance often, and with circumſtances varied, we may at laſt diſcover ſome general law, or ſome relation which that appearance has with known cauſes: but when a fact is ſo ſingular and ſo rare, as that of thoſe albinos, it gives but little ſcope to a conjecture: and it is very difficult to verify thoſe by which we attempt to explain it.

"I at firſt imagined that this diſeaſe might be referred to a particular ſort of organic debility; that a relaxation of the lymphatic veſſels within the eye might ſuffer the globules of the blood to enter too abundantly into the iris, the uvea, and even into the retina, which might occaſion the redneſs of the iris and of the pupil. The ſame debility ſeemed alſo to account for the intolerance of the light, and for the whiteneſs of the hair.

"But a learned phyſiologiſt, Mr Blumenbach, profeſſor in the univerſity at Gottingen, who has made many profound obſervations on the organs of ſight, and has conſidered with great attention the albinos of Chamouni, attributes their infirmity to a different cauſe.

"The ſtudy of comparative anatomy has furniſhed him with frequent opportunities of obſerving this phenomenon; he has found it in brutes, in white dogs, and in owls; he ſays, it is generally to be ſeen in the warm-blooded animals; but that he has never met with it in thoſe with cold blood.

"From his obſervations, he is of opinion, that the redneſs of the iris, and of the other internal parts of the eye, as well as the extreme ſenſibility that accompanies this redneſs, is owing to the total privation of that brown or blackiſh mucus, which, about the fifth week after conception, covers all the interior parts of the eye in its ſound ſtate. He obſerves, that Simon Pontius, in his treatiſe *de Coloribus Oculorum*, long ago remarked, that in blue eyes the interior membranes were leſs abundantly provided with this black mucus, and were therefore more ſenſible to the action of light. This ſenſibility of blue eyes agrees very well, ſays M. Blumenbach, with northern people, during their long twilight; while, on the contrary, the deep black in the eyes of negroes enables them to ſupport the ſplendour of the ſunbeams in the torrid zone.

"As to the connection between this red colour of the eyes, and the whiteneſs of the ſkin and hair, the ſame learned phyſiologiſt ſays, that it is owing to a ſimilarity of ſtructure, *conſenſus ex ſimilitudine fabricæ*. He aſſerts, that this black mucus is formed only in the delicate cellular ſubſtance, which has numerous blood-veſſels contiguous to it, but contains no fat; like the inſide of the eye, the ſkin of negroes, the ſpotted palate of ſeveral domeſtic animals, &c. And, laſtly, he ſays,

Albinos. says, that the colour of the hair generally corresponds with that of the iris. *Gazette Litt. de Gotingue*, Oct. 1784.

" At the very time that M. Blumenbach was reading this memoir to the Royal Society of Gottingen, M. Buzzi, surgeon to the hospital at Milan, an eleve of the celebrated anatomist Moscati, published in the *Opuscoli Scelti de Milan*, 1784, tom. ii. p. 11. a very interesting memoir, in which he demonstrates by dissection what Blumenbach had only supposed.

" A peasant of about 30 years of age died in the hospital of Milan of a pulmonary disorder. His body, being exposed to view, was exceedingly remarkable by the uncommon whiteness of the skin, of the hair, of the beard, and of all the other covered parts of the body. M. Buzzi, who had long desired an opportunity of dissecting such a subject, immediately seized upon this. He found the iris of the eyes perfectly white, and the pupil of a rose colour. The eyes were dissected with the greatest possible care, and were found entirely destitute of that black membrane which anatomists call the *uvea:* it was not to be seen either behind the iris or under the retina. Within the eye there was only found the choroid coat extremely thin, and tinged of a pale red colour, by vessels covered with discoloured blood. What was more extraordinary, the skin, when detached from different parts of the body, seemed almost entirely divested of the *rete mucosum:* maceration did not discover the least vestige of this, not even in the wrinkles of the abdomen, where it is most abundant and most visible.

" M. Buzzi likewise accounts for the whiteness of the skin and of the hair, from the absence of the *rete mucosum*, which, according to him, gives the colour to the cuticle, and to the hairs that are scattered over it. Among other proofs of this opinion, he alleges a well-known fact, that if the skin of the blackest horse be accidentally destroyed in any part of the body, the hairs that afterwards grow on that part are always white, because the *rete mucosum* which tinges those hairs is never regenerated with the skin.

" The proximate cause of the whiteness of albinos, and the colour of their eyes, seems therefore pretty evidently to depend on the absence of the *rete mucosum:* But what is the remote cause?

" In the first place, it seems probable that men affected with this infirmity form no distinct species, for they are produced from parents that have dark skins and black eyes. What is it then that destroys the *rete mucosum* in such persons? M Buzzi relates a singular fact, which seems to throw some light on this subject.

" A woman of Milan, called Calcagni, had seven sons. The two eldest had brown hair, and black eyes; the three next had white skins, white hair, and red eyes; the two last resembled the two eldest. It was said that this woman, during the three pregnancies that produced the albinos, had a continual and immoderate appetite for milk, which she took in great quantities: but that when she was with child of the other four children, she had no such desire. It is not however ascertained, that this preternatural appetite was not itself the effect of a certain heat, or internal disease, which destroyed the *rete mucosum* in the children before they were born.

" The albinos of Chamouni are also the offspring of parents with dark skins and black eyes. They have three sisters by the same father and mother, who are also brunettes. One of them that I saw had the eyes of a dark brown, and the hair almost black. They are said, however, to be all afflicted with a weakness of sight. When the lads are married, it will be curious to observe how the eyes of their children will be formed. The experiment would be particularly decisive if they were married to women like themselves. But this faulty conformation seems to be more rare among women than among men; for the four of Milan, the two of Chamouni, the one described by Maupertuis, the one by Helvetius, and almost all the instances of these singular productions, have been of our sex. It is known, however, that there are races of men and women affected with this disease, and that these races perpetuate themselves in Guinea, in Java, at Panama, &c. Albinovanus Albinus.

" Upon the whole, this degeneration does not seem to be owing to the air of the mountains; for though I have traversed the greatest part of the Alps, and the other mountains of Europe, these are the only individuals of the kind that I ever met with."

ALBINOVANUS, a Latin poet, whom Ovid surnamed the *Divine*. There is now nothing of his extant, except an elegy on Drusus, and another on the death of Mecænas.

ALBINUS, Bernhard Siegfred, a celebrated physician and anatomist, was born of an illustrious family at Francfort on the Oder in 1697. His father was then professor of the practice of medicine in the university of Francfort; but in the year 1702 he repaired to Leyden, being nominated professor of anatomy and surgery in that university. Here his son had an opportunity of studying under the most eminent masters in Europe, who, from the singular abilities which he then displayed, had no difficulty in prognosticating his future eminence. But while he was distinguished in every branch of literature, his attention was particularly turned to anatomy and surgery. His peculiar attachment to these branches of knowledge gained him the intimate friendship of Ruysch and Rau, who at that time flourished in Leyden; and the latter, so justly celebrated as a lithotomist, is said to have seldom performed a capital operation without inviting him to be present. Having finished his studies at Leyden, he went to Paris, where he attended the lectures of Du Verney, Vaillant, and other celebrated professors. But he had scarce spent a year there when he was invited by the curators of the university of Leyden to be a lecturer in anatomy and surgery at that place. Though contrary to his own inclination, he complied with their request, and upon that occasion was created doctor of physic without any examination. Soon after, upon the death of his father, he was appointed to succeed him as a professor of anatomy; and upon being admitted into that office on the 9th of November 1721, he delivered an oration, *De vera via ad fabricæ humani corporis cognitionem ducente;* which was heard with universal approbation. In the capacity of a professor, he not only bestowed the greatest attention upon the instruction of the youth intrusted to his care, but in the improvement of the medical art. With this view he published many important discoveries of his own; and

Albion || Alborak.

by elegant editions, turned the attention of phyſicians to works of merit, which might otherwiſe have been neglected. By theſe means his fame was ſoon extended over Europe; and the ſocieties of London, Peterſburgh, and Haerlem, cheerfully received him as an aſſociate. In 1745, he was appointed profeſſor of the practice of medicine at Leyden, and was ſucceeded in the anatomical chair by his brother Frid. Bern. Albinus. He was twice rector of the univerſity, and as often he refuſed that high honour when it was voluntarily offered him. At length, worn out by long ſervice and intenſe ſtudy, he died on the 9th of September 1770, in the 74th year of his age.

ALBION, the ancient name of Britain.

New Albion, a name given by Sir Francis Drake to California, on the north-weſt coaſt of America, which he diſcovered and took poſſeſſion of in the year 1578. Captain Cook viſited this coaſt in 1778, and landed in a place ſituated in N. Lat. 44. 33. E. Long. 235. 20. In the year 1792, it was again viſited by Captain Vancouver, who was employed in ſurveying the weſtern coaſt of North America. The extent of New Albion, according to the latter circumnavigator, is between the 30th and 45th degrees of N. Latitude.

ALBIREO, in *Aſtronomy*, a ſtar of the third or fourth magnitude, in the conſtellation Cygnus.

ALBIS, in *Ancient Geography*, now the Elbe, which divided ancient Germany in the middle, and was the boundary of this country, ſo far as it was known to the Romans: all beyond they owned to be uncertain, no Roman except Druſus and Tiberius having penetrated ſo far as the Elbe. In the year of the building of the city 744, or about ſix years before Chriſt, Domitius Ahenobarbus, croſſing the river with a few, merited the ornaments of a triumph; ſo glorious was it reckoned at Rome to have opened this paſſage. In the following age, however, the river that before occupied the middle of ancient Germany, became its boundary to the north, from the irruptions of the Sarmatæ, who poſſeſſed themſelves of the Tranſalbin Germany. The Elbe riſes in the borders of Sileſia out of the Riſenberg, runs through Bohemia, Miſnia, Upper Saxony, Anhalt, Magdeburg, Brandenburg, Danneberg, Lauenburg, Holſtein, and after being ſwelled by many other rivers, and paſſing by Hamburg and Gluckſtadt, to both which places the river is navigable by large veſſels, falls into the German or North ſea.

ALBISOLA, a ſmall town belonging to the republic of Genoa. Here is a porcelain manufacture, and ſeveral country-houſes of the Genoeſe nobility. It was bombarded in 1745 by the Engliſh. E. Long. 8. 20. N. Lat. 44. 15

ALBOGALERUS, in Roman antiquity, a white cap worn by the *flamen Dialis*, on the top of which was an ornament of olive branches.

ALBORAK amongſt the Mahometan writers, the beaſt on which Mahomet rode in his journeys to heaven. The Arab commentators give many fables concerning this extraordinary mode of conveyance. It is repreſented as of an intermediate ſhape and ſize between an aſs and a mule. A place, it ſeems, was ſecured for it in paradiſe at the interceſſion of Mahomet; which, however, was in ſome meaſure extorted from the prophet, by Alborak's refuſing to let him mount when the angel Gabriel was come to conduct him to heaven.

Alboro || Albumen.

ALBORO, in *Zoology*, a name by which the erythrinus, a ſmall red fiſh caught in the Mediterranean, is commonly known in the markets of Rome and Venice.

ALBOURG, a town of Denmark, in North Jutland, capital of the dioceſe of the ſame name, and a biſhop's ſee. It has this name, which ſignifies *eel-town*, on account of the great number of eels taken here. It is ſeated on a canal, 10 miles from the ſea, 30 north of Wiburg, and 50 north of Arhuys. It has an exchange for merchants, and a ſafe and deep harbour. They have a conſiderable trade in herrings and corn; and a manufactory of guns, piſtols, ſaddles, and gloves. E. Long. 29. 16. N. Lat. 56. 35.

ALBRICIUS, born at London, was a great philoſopher, a learned and able phyſician, and well verſed in all the branches of polite literature. He lived in the 11th century, and wrote ſeveral works in Latin; particularly, 1. Of the Origin of the Gods. 2. The Virtues of the Ancients. 3. The Nature of Poiſon, &c.

ALBUCA, Baſtard Star-of-Bethlehem. See Botany *Index*.

ALBUGINEA tunica, in *Anatomy*, the third or innermoſt coat or covering of the teſtes; it is likewiſe the name given to one of the coats of the eye.

ALBUGINEUS, in *Anatomy*, a term ſometimes applied to the aqueous humour of the eye.

ALBUGO, or Leucoma, in *Medicine*, a diſtemper occaſioned by a white opaque ſpot growing on the *cornea* of the eye, and obſtructing viſion. See Medicine *Index*.

ALBUM, in *Antiquity*, a kind of white table or regiſter, wherein the names of certain magiſtrates, public tranſactions, &c. were entered. Of theſe there were various ſorts; as the *album decurionum*, *album ſenatorum*, *album judicum*, *album prætoris*, &c.

Album Decurionum, was the regiſter wherein the names of the decuriones were entered. This is otherwiſe called *matriculatio decurionum*.

Album Senatorum, the liſt of ſenators names, which was firſt introduced by Auguſtus, and renewed yearly.

Album Judicum, that wherein the names of the perſons of thoſe *decuriæ* who judged at certain times were entered.

Album Prætoris, that wherein the *formulæ* of all actions, and the names of ſuch judges as the prætor had choſen to decide cauſes, were written.

The high prieſt entered the chief tranſactions of each year into an *album*, or table, which was hung up in his houſe for the public uſe.

Album is alſo uſed, in later times, to denote a kind of table, or pocket-book, wherein the men of letters with whom a perſon has converſed, inſcribed their names with ſome ſentence or motto.

Album Græcum, the white dung of dogs, formerly preſcribed for inflammations of the throat, &c. but now diſuſed, and chiefly employed by leather-dreſſers to ſoften leather after the application of lime.

ALBUMAZAR, a learned Arabian aſtronomer in the tenth century, who wrote a treatiſe Of the Revolution of the Years.

ALBUMEN, a ſubſtance found both in animal and vegetable

Albuquerque ‖ Alcæus.

vegetable matters, and in great abundance in the white of eggs. See CHEMISTRY *Index*.

ALBUQUERQUE, a town of Spain, in the province of Eſtremadura, is ſeated on an eminence, nine miles from the frontiers of Portugal. It is commanded by an almoſt impregnable fortreſs, built on a high mountain, and ſerving to defend the town. It carries on a great trade in wool and woollen manufactures. It was taken by the allies of Charles king of Spain in 1705. W. Long. 7. 0. N. Lat. 38. 52.

ALBURN, the Engliſh name of a compound colour, being a mixture of white and red, or reddiſh brown. Skinner derives the word, in this ſenſe, from the Latin *albus*, and the Italian *burno*, from *bruno*, "brown."

ALBURNUM, the ſoft white ſubſtance which in trees is found between the liber or inner bark and the wood, and in proceſs of time acquiring ſolidity, becomes itſelf the wood. From its colour and comparative ſoftneſs, it has been ſtyled by ſome writers the fat of trees, *adeps arborum*.

The alburnum is found in largeſt quantities in trees that are vigorous; though in ſuch as languiſh, or are ſickly, there is a great number of beds. In an oak ſix inches in diameter, this ſubſtance is nearly equal in bulk to the wood. In a trunk of one foot diameter, it is as one to three and a half; of two and a half feet diameter, as one to four and a half, &c. but theſe proportions vary according to the health and conſtitution of the trees.—The alburnum is frequently gnawed in pieces by inſects, which lodge in the ſubſtance, and are nouriſhed from it.

ALBURNUS, in *Zoology*, a ſpecies of the *cyprinus* of Linnæus. See CYPRINUS, ICHTHYOLOGY *Index*.

ALCA, or AUK. See ORNITHOLOGY *Index*.

ALCÆUS, a famous ancient lyric poet, born at Mitylene, in the iſland of Leſbos. Horace ſeems to think him the inventor of this kind of poeſy;

> Now the Roman muſe inſpire,
> And warm the ſong with Grecian fire. FRANCIS.

He flouriſhed in the 44th Olympiad, at the ſame time with Sappho, who was likewiſe of Mitylene. Alcæus was a great enemy to tyrants, but not a very brave ſoldier. He was preſent at an engagement, wherein the Athenians gained a victory over the Leſbians; and here, as he himſelf is ſaid to have confeſſed in one of his pieces, he threw down his arms, and ſaved himſelf by flight. Horace, who, of all the Latin poets, moſt reſembled Alcæus, has made the like confeſſion:

> With thee I ſaw Philippi's plain,
> Its fatal rout, a fearful ſcene!
> And dropp'd, alas! th' inglorious ſhield,
> Where valour's ſelf was forc'd to yield;
> Where foil'd in duſt the vanquiſh'd lay,
> And breath'd th' indignant ſoul away. FRANCIS.

The poetical abilities of Alcæus are indiſputable; and though his writings were chiefly in the lyric ſtrain, yet his muſe was capable of treating the ſublimeſt ſubjects with a ſuitable dignity. Hence Horace ſays,

> Alcæus ſtrikes the golden ſtrings,
> And ſeas, and war, and exile, ſings.
> Thus while they ſtrike the various lyre,
> The ghoſts the ſacred ſounds admire:
> But when Alcæus lifts the ſtrain
> To deeds of war and tyrants ſlain,
> In thicker crowds the ſhadowy throng
> Drink deeper down the martial ſong. FRANCIS.

Alcæus ‖ Alcaic.

ALCÆUS, an Athenian tragic poet, and, as ſome think, the firſt compoſer of tragedies. He renounced his native country Mitylene, and paſſed for an Athenian. He left 10 pieces, one of which was Paſiphaë, that which he produced when he diſputed with Ariſtophanes, in the 4th year of the 97th Olympiad.

There is another ALCÆUS mentioned in Plutarch, perhaps the ſame whom Porphyrius mentions as a compoſer of ſatirical iambics and epigrams, and who wrote a poem concerning the plagiariſm of Euphorus the hiſtorian. He lived in the 145th Olympiad.

We are told likewiſe of one ALCÆUS, a Meſſenian, who lived in the reign of Veſpaſian and Titus. We know not which of theſe it was who ſuffered for his lewdneſs a very ſingular kind of death, which gave occaſion to the following epitaph:

Αλκαιω ταφος υτος, &c.

This is Alcæus's tomb; who died by a radiſh,
The daughter of the earth, and puniſher of adulterers.

This puniſhment inflicted on adulterers, was thruſting one of the largeſt radiſhes up the anus of the adulterer: or, for want of radiſhes, they made uſe of a fiſh with a very large head, which Juvenal alludes to:

> *Quoſdam mœchos et mugilis intrat.* Sat. x.
> The mullet enters ſome behind.

Hence we may underſtand the menace of Catullus,

> *Ah! tum te miſerum, malique fati,*
> *Quem attractus pedibus, patente porta,*
> *Percurrent raphanique, mugileſque.* Epig. xv.
>
> Ah! wretched thou, and born to luckleſs fate,
> Who art diſcover'd by the unſhut gate!
> If once, alas! the jealous huſband come,
> The radiſh or the ſea-fiſh is thy doom.

ALCAICS, in *Ancient Poetry*, a denomination given to ſeveral kinds of verſe, from Alcæus, their inventor.

The firſt kind conſiſts of five feet, viz. a ſpondee, or iambic; an iambic; a long ſyllable; a dactyle; another dactyle: ſuch is the following verſe of Horace:

> *Omnes | eo|dem cogimur, | omnium*
> *Verſa|tur ur|na | ſerius | ocyus |*
> *Sors exitura.*

The ſecond kind conſiſts of two dactyles and two trochees: as,

> *Exil|ium impoſi|tura | cymbæ.*

Beſides theſe two, which are called *dactylic Alcaïcs*, there is another ſimply ſtyled *Alcaïc*; conſiſting of an epitrite; a choriambus; another choriambus; and a bacchius: the following is of this ſpecies,

> *Cur timet fla|vum Tiberim tan|gere, cur | olivum?*

ALCAIC Ode, a kind of manly ode, compoſed of ſeveral ſtrophes, each conſiſting of four verſes; the two firſt of which are always alcaïcs of the firſt kind; the third verſe is a dimeter hypercatalectic, or conſiſting of four feet and a long ſyllable; and the fourth verſe is an alcaïc of the ſecond kind. The following ſtrophe

Alcaid ‖ Alcanna.

is of this ſpecies, which Horace calls *minaces Alcæi camenæ*.

Non poſſidentem multa vocaveris
Recte beatum: rectius occupat
Nomen beati, qui deorum
Muneribus ſapienter uti, &c.

ALCAID, ALCAYDE, or ALCALDE, in the polity of the Moors, Spaniards, and Portugueſe, a magiſtrate, or officer of juſtice, anſwering nearly to the French provoſt and the Britiſh juſtice of peace.—The alcaid among the Moors is veſted with ſupreme juriſdiction, both in civil and criminal caſes.

ALCALA DE GUADEIRA, a ſmall town of Spain, in Andaluſia, upon the river Guadeira. Here are abundance of ſprings, from whence they convey water to Seville by an aqueduct. W. Long. 6. 16. N. Lat. 37. 15.

ALCALA de Henares, a beautiful and large city of Spain, in New Caſtile, ſeated upon the river Henares, which waſhes its walls. It is built in a very agreeable plain, and is of an oval figure. The ſtreets are handſome and pretty ſtraight; one of them is very long, running from one end of the city to the other. The houſes are well built; and there are ſeveral ſquares, the largeſt of which is an ornament to the city; it is ſurrounded on all ſides with piazzas, where tradeſmen have their ſhops, to expoſe ſeveral ſorts of commodities to ſale, of which there is as great plenty and variety as in moſt towns of Spain. The univerſity was founded by Cardinal Ximenes, archbiſhop of Toledo, about the beginning of the 16th century. The land about Alcala is watered by the Henares, well cultivated, and very fruitful, while that at a diſtance is dry and ſterile: it yields grain in plenty, very good muſcat wine, and melons of a delicious kind. Without the walls is a ſpring, the water of which is ſo pure and ſo well taſted, that it is incloſed and ſhut up for the king of Spain's own uſe, from whence it is carried to Madrid.—This city is 10 miles ſouth-weſt of Guadalaxara, and 13 miles eaſt of Madrid. W. Long. 4. 20. N. Lat. 40. 30.

ALCALA-Real, a ſmall city of Spain, in Andaluſia, with a fine abbey. It is built on the top of a high mountain, in a mountainous country; and the road to it is incommodious, rough, and unequal; but to make amends for this, here are ſeveral kinds of exquiſite fruit and wine. W. Long. 4. 15. N. Lat. 37. 18.

ALCALY, or ALCALI, or ALKALI. See CHEMISTRY *Index*.

ALCANIS, a town of Arragon in Spain, ſeated on the river Guadalopne, 12 miles from Caſpe. It was formerly the capital of the kingdom of the Moors; but being taken from them, it was made a commandery of the order of Calatrava. Here is a very remarkable fountain, which throws up water through 42 pipes. It is ſurrounded with gardens and fruit trees, and defended by a good fortreſs. W. Long. 0. 5. N. Lat. 41. 0.

ALCANNA, or ALKANNA, in *Commerce*, a powder prepared from the leaves of the Egyptian privet, in which the people of Cairo drive a conſiderable trade. It is much uſed by the Turkiſh women to give a golden colour to their nails and hair. In dyeing, it gives a yellow colour when ſteeped with common water, and a red one when infuſed in vinegar. There is alſo an oil extracted from the berries of alcanna, which is ſometimes uſed in medicine.

Alcantara ‖ Alcaſſar.

ALCANTARA, a ſmall, but very ſtrong city of Eſtremadura, in Spain. It gives name to one of the three orders of knighthood. It is ſeated on the banks of the Tajo or Tagus, 21 miles from Coria, in a very fruitful ſoil, and is celebrated for its bridge over that river. This was built in the time of the emperor Trajan, as appears by an inſcription over one of the arches, by the people of Luſitania, who were aſſeſſed to ſupply the expence. It is raiſed 200 feet above the level of the water; and though it conſiſts but of ſix arches, is 670 feet in length, and 28 in breadth. At the entrance of the bridge, there is a ſmall antique chapel hewn in a rock by the ancient Pagans, who dedicated it to Trajan, as the Chriſtians did to St Julian. This city was built by the Moors, on account of the convenience of this bridge; which is at a place where the Tajo is very deep, running between two high ſteep rocks: for this reaſon they called it *Al-Cantara*, which in their language ſignifies *the Bridge*. It was taken from them in 1214, and given to the knights of *Calatrava*, who afterwards aſſumed the name of *Alcantara*. It was taken by the earl of Galway, in April 1706, and retaken by the French in November following. It is 45 miles from Madrid, and 125 from Seville. W. Long. 7. 12. N. Lat. 39. 30.

Knights of ALCANTARA, a military order of Spain, which took its name from the above-mentioned city. They make a very conſiderable figure in the hiſtory of the expeditions againſt the Moors. The knights of Alcantara make the ſame vows as thoſe of Calatrava, and are only diſtinguiſhed from them by this, that the croſs fleur de lys, which they bear over a large white cloak, is of a green colour. They poſſeſs 37 commanderies. By the terms of the ſurrender of Alcantara to this order, it was ſtipulated, that there ſhould be a confraternity between the two orders, with the ſame practices and obſervances in both; and that the order of Alcantara ſhould be ſubject to be viſited by the grand-maſter of Calatrava. But the former ſoon releaſed themſelves from this engagement, on pretence that their grand-maſter had not been called to the election of that of Calatrava, as had been likewiſe ſtipulated in the articles. After the expulſion of the Moors, and the taking of Granada, the ſovereignty of the order of Alcantara and that of Calatrava was ſettled in the crown of Caſtile by Ferdinand and Iſabella.—In 1540, the knights of Alcantara ſued for leave to marry, which was granted them.

ALCAREZ, a ſmall city of La Mancha in Spain, defended by a pretty ſtrong caſtle, and remarkable for an ancient aqueduct. It ſtands near the river Guadamena, and the ſoil about it is very fruitful. They have a breed of little running horſes, which are very fleet and ſtrong. It is 25 miles north of the confines of Andaluſia, 108 ſouth of Cuenza, and 138 ſouth by eaſt of Madrid. W. Long. 1. 50. N. Lat. 38. 28.

ALCASSAR DO-SAL, a town of Portugal, in Eſtremadura, which has a caſtle ſaid to be impregnable. It is indeed very ſtrong, both by art and nature, being built on the top of a rock which is exceedingly ſteep on all ſides. Here is a ſalt-work, which produces very white ſalt, from whence the town takes its name. The

Alcaſſar ‖ Alcazar.

fields produce large quantities of a ſort of ruſhes, of which they make mats, which are tranſported out of the kingdom. W. Long. 9. 10. N. Lat. 38. 18.

ALCASSAR, a city of Barbary, ſeated about two leagues from Larache, in Aſga, a province of the kingdom of Fez. It was of great note, and the ſeat of the governor of this part of the kingdom. It was built by Jacob Almanzor, king of Fez. about the year 1180, and deſigned for a magazine and place of rendezvous for the great preparations he was making to enter Granada in Spain, and to make good the footing Joſeph Almanzor had got ſome time before. It is ſaid his father firſt invaded Spain with 300,000 men, moſt of whom he was obliged to bring back to Africa to quell a rebellion that had broke out in Morocco. This done, he returned to Spain again with an army, as is ſaid, of 200,000 horſe and 300,000 foot. The city is now fallen greatly to decay, ſo that of fifteen moſques there are only two that they make uſe of. The reaſon, probably, is the bad ſituation of the town; for it ſtands ſo low, that it is exceſſively hot in ſummer, and almoſt overflowed with water in the winter. This they affirm to be owing to the curſe of one of their ſaints. Here are a great number of ſtorks, who live very familiarly with the people, walking about the town, poſſeſſing the tops of the houſes and moſques without moleſtation; for they eſteem them ſacred birds, and account it ſinful to diſturb them. At preſent, the baſhaw of Tetuan appoints a governor to this town, which is the laſt of his dominions towards Mequinez. Near this city there is a high ridge of mountans, running towards Tetuan, whoſe inhabitants were never brought entirely under ſubjection; and whenever it was attempted, they revenged themſelves by infeſting the roads, and robbing and deſtroying the travellers. When they were purſued, they retired into their woody mountains, where none could ſafely follow them. Not far from hence is the river Elmahaſſen, famous for the battle fought between Don Sebaſtian king of Portugal and the Moors; in which the Portugueſe were defeated, and their king ſlain. W. Long. 12. 35. N. Lat. 35. 15.

ALCAVALA, in the Spaniſh finances, was at firſt a tax of ten per cent. afterwards of 14 per cent. and is at preſent of only 6 per cent. upon the ſale of every ſort of property, whether moveable or immoveable; and it is repeated every time the property is ſold. The levying of this tax requires a multitude of revenue officers ſufficient to guard the tranſportation of goods, not only from one province to another, but from one ſhop to another. It ſubjects not only the dealers in ſome ſort of goods, but thoſe in all ſorts, every farmer, every manufacturer, every merchant and ſhopkeeper, to the continual viſits and examination of the taxgatherers. Through the greater part of a country in which a tax of this kind is eſtabliſhed, nothing can be produced for diſtant ſale. The produce of every part of the country muſt be proportioned to the conſumption of the neighbourhood. It is to the Alcavala, accordingly, that Uſtariz imputes the ruin of the manufactures of Spain. He might have imputed to it likewiſe the declenſion of agriculture, it being impoſed not only upon manufactures, but upon the rude produce of the land.

ALCAZAR LEGUER, a town of Africa, in the kingdom of Fez, and in the province of Habat. It was taken by Alphonſo, king of Portugal, in 1468; but ſoon after that it was abandoned to the Moors. It is ſeated on the coaſt of the ſtraits of Gibraltar. W. Long. 3. 50. N. Lat. 38. 0.

Alcazer ‖ Alciat.

ALCAZER, a town of Spain, in New Caſtile, ſeated on the river Guardamena, which has a fortreſs on a high hill for its defence, and lies in a very fruitful country. It is 100 miles north-weſt of Carthagena. W. Long. 2. 10. N. Lat. 38. 15.

ALCE, ALCES, or ELK, in *Zoology*, the trivial name of a ſpecies of the cervus, belonging to the order of mammalia pecora. See CERVUS.

ALCEA, the HOLLY-HOCK. See BOTANY *Index*.

ALCEDO, or KINGSFISHER. See ORNITHOLOGY *Index*.

ALCHEMILLA, or LADIES-MANTLE. See BOTANY *Index*.

ALCHEMIST, a practitioner in alchemy.

ALCHEMY, that branch of chemiſtry which had for its principal objects the tranſmutation of metals into gold; the panacea, or univerſal remedy; an alkaheſt, or univerſal menſtruum; an univerſal ferment; and many other things equally ridiculous.

Kircher, inſtructed in all the ſecrets of chemiſtry, has fully expoſed the artifices and impoſtures of alchemiſts. An alchemiſt puts into a crucible the matter which is to be converted into gold: this he ſets on the fire, blows it, ſtirs it with rods; and, after divers operations, gold is found at the bottom of the crucible, inſtead of the matter firſt put in. This there are a thouſand ways of effecting, without any tranſmutation. Sometimes it is done by dexterouſly dropping in a piece of gold concealed between the fingers, ſometimes by caſting in a little of the duſt of gold or ſilver diſguiſed under the appearance of ſome elixir, or other indifferent matter; ſometimes a crucible is uſed which has a double bottom, and gold put between the two; ſometimes the rod uſed to ſtir the matter is hollow, and filled with the duſt of the metal deſired; at other times there is metal mixed with the charcoal, the aſhes of the furnace, or the like. Mr Harris very properly diſtinguiſhes alchemy from chemiſtry; and defines the former to be *ars ſine arte, cujus principium eſt mentiri, medium laborare, et finis mendicare;* and the Italians have a proverb, *non ti fidiare al alchemiſta povero o medico amalato.* The ruin which has attended this deluſion has occaſioned ſeveral ſtates to make ſevere laws againſt pretences to alchemy. The Romans formerly baniſhed all ſuch as profeſſed it; and the ſacred canons likewiſe directed the thunder of their cenſure againſt them. Diocleſian and Cæſar directed all books which treated of this ſubject to be burnt. Rymer furniſhes us with a licenſe for practiſing alchemy, with all kinds of metals and minerals, granted to one Richard Carter in 1476; *Rym. Fœd.* tom. xii. Nevertheleſs, we have had ſevere laws againſt alchemy, and multiplying of metals, as much ſo as againſt coining itſelf.

ALCHORNEA. See BOTANY *Index*.

ALCIAT or ALCIATE, ANDREW, a great lawyer, who flouriſhed in the tenth century, was born at Milan. He mixed much of polite learning in the explication of the laws, and happily drove out the barbarity of language which till then had reigned in the lectures and writings of lawyers; for which Thuanus highly

praiſes

Alcibiades || Alcmaer.

praiſes him. He publiſhed a great many law-books, and ſome notes upon Tacitus. His emblems have been much admired, and tranſlated into French, Italian, and Spaniſh; and ſeveral learned men have written commentaries on them.

ALCIBIADES, an Athenian general. It was the fate of this great man to live at a time when his country was a ſcene of confuſion. The Greeks, grown inſolent from their conqueſts in Perſia, turned their armies againſt each other, and bandied together under the conduct of the two moſt opulent ſtates, Athens and Lacedæmon. Alcibiades, in the midſt of an expedition he had planned againſt the enemies of his country, was recalled home to anſwer ſome charge of a private nature; but fearing the violence of his enemy, inſtead of going to Athens, he offered his ſervices at Sparta, where they were readily accepted. By his advice the Lácedæmonians made a league with Perſia, which gave a very favourable turn to their affairs. But his credit in the republic raiſing jealouſies againſt him, he privately reconciled himſelf to his country, and took again the command of the Athenian army. Here victory, waiting as it were at his command, attended all his motions. The loſs of ſeven battles obliged the Spartans to ſue for peace. He enjoyed his triumphs, however, only a ſhort time at Athens. One unſucceſsful event made him again obnoxious to the malice of his citizens; and he found it expedient to retire from Athens. In his abſence the Spartans again took the lead, and at the fatal battle of Ægos entirely ſubdued the Athenian power. Alcibiades, though an exile, endeavoured to reſtore the power of his country; of which the Spartans having intelligence, procured him to be aſſaſſinated. He was a man of admirable accompliſhments, but indifferently principled; of great parts; and of an amazing verſatility of genius.

ALCINOUS, king of the Phæacians, in the iſland now called Corfu, was ſon of Nauſithous, and grandſon of Neptune and Peribea. It is by his gardens this king has chiefly immortalized his memory. He received Ulyſſes with much civility, when a ſtorm had caſt him on his coaſt. The people here loved pleaſure and good cheer, yet were ſkilful ſeamen; and Alcinous was a good prince.

ALCMAER, a city of the United Provinces, ſeated in North Holland, about four miles from the ſea, 15 from Haerlem, and 18 from Amſterdam. It is a handſome city, and one of the cleaneſt in Holland. The ſtreets and houſes are extremely neat and regular, and the public buildings very beautiful. It had formerly two pariſh churches, dedicated to St Matthew and St Lawrence. The latter had ſo high a tower, that it ſerved for a ſea-mark to the veſſels that were in the open ſea; but, in 1464, it tumbled down, and damaged the other church ſo much, that they were both demoliſhed in 1670, and one church was built in their ſtead, dedicated to the ſame ſaints. The Spaniards, under the command of Frederic of Toledo, ſon of the duke of Alva, came to beſiege it, after they had taken Haerlem in 1573; but were forced to raiſe the ſiege after lying three months before it, as well on account of the infection of the air as the ſtout reſiſtance of the inhabitants and ſoldiers; even the women ſignalizing themſelves bravely in its defence. It is recorded in the regiſter of this city, that, in the year 1637, 120 tulips, with the offſets, ſold for 90,000 florins. The town has a very great trade in butter and cheeſe, of which a vaſt quantity is ſold every year, and is eſteemed the beſt in Holland. E. Long. 4. 26. N. Lat. 52. 28.

Alcman || Alcohol

ALCMAN, a lyric poet, who flouriſhed in the 27th Olympiad, about 670 years before Chriſt. He was born at Sparta; and compoſed ſeveral poems, of which only ſome fragments are remaining, quoted by Athenæus and ſome other ancient writers. He was very amorous; accounted the father of gallant poeſy; and is ſaid to have been the firſt that introduced the cuſtom of ſinging love ſongs in company. He is reported to have been one of the greateſt orators of his age; upon which Mr Bayle remarks, that ſuch a quality would have been extremely inconvenient, if poetry had been at that time upon ſuch a footing as it has been often ſince, not able to procure the poet bread. He died of a ſtrange diſeaſe; for he was eaten up with lice.

ALCMANIAN, in ancient lyric poetry, a kind of verſe, conſiſting of two dactyles and two trochees: as,—

Virgini|bus pue|riſque|canto.

The word is formed from *Alcman*, the name of an ancient Greek poet, in great eſteem for his erotics or amorous compoſitions.

ALCMENA, the daughter of Electryo king of Mycenæ, and wife of Amphitryon. Jupiter putting on the ſhape of her huſband while he was abroad in the wars, begot Hercules upon her: he made that night as long as three ordinary ones.

ALCOCK, JOHN, doctor of laws, and biſhop of Ely, in the reign of King Henry VII. was born at Beverly in Yorkſhire, and educated at Cambridge. He was firſt made dean of Weſtminſter, and afterwards appointed maſter of the rolls. In 1471, he was conſecrated biſhop of Rocheſter: in 1476, he was tranſlated to the ſee of Worceſter; and in 1486, to that of Ely, in the room of Dr John Morton, preferred to the ſee of Canterbury. He was a prelate of great learning and piety, and ſo highly eſteemed by King Henry, that he appointed him lord preſident of Wales, and afterwards lord chancellor of England. Alcock founded a ſchool at Kingſton upon Hull, and built the ſpacious hall belonging to the epiſcopal palace at Ely. He was alſo the founder of Jeſus-college in Cambridge, for a maſter, ſix fellows, and as many ſcholars. This houſe was formerly a nunnery, dedicated to St Radigund: and, as Godwin tells us, the building being greatly decayed, and the revenues reduced almoſt to nothing, the nuns had all forſaken it, except two; whereupon Biſhop Alcock procured a grant from the crown, and converted it into a college. But Camden and others tell us, that the nuns of that houſe were ſo notorious for their incontinence, that King Henry VII. and Pope Julius II. conſented to its diſſolution: Bale accordingly calls this nunnery *ſpiritualium meretricum cœnobium*, "a community of ſpiritual harlots." Biſhop Alcock wrote ſeveral pieces; amongſt which are the following: 1. *Mons Perfectionis*. 2. *In Pſalmos Penitentiales*. 3. *Homiliæ Vulgares*. 4. *Meditationes Piæ*. He died October 1. 1500; and was buried in the chapel he had built at Kingſton upon Hull.

ALCOHOL, or ALKOOL, in *Chemiſtry*, ſpirit of wine highly rectified. It is alſo uſed for any highly

Alcohol || Alcoran.

rectified ſpirit.—Alcohol is extremely light and inflammable: it is a ſtrong antiſeptic, and therefore employed to preſerve animal ſubſtances. See CHEMISTRY *Index*.

ALCOHOL, is alſo uſed for any fine impalpable powder.

ALCOHOLIZATION, the proceſs of rectifying any ſpirit. It is alſo uſed for pulverization.

ALCOR, in *Aſtronomy*, a ſmall ſtar adjoining to the large bright one in the middle of the tail of *urſa major*.—The word is Arabic. It is a proverb among the Arabians, applied to one who pretends to ſee ſmall things, but overlooks much greater: *Thou canſt ſee Alcor, and yet not ſee the full moon.*

ALCORAN, or AL-KORAN, the ſcripture or bible of the Mahometans. The word is compounded of the Arabic particle *al* and *coran* or *koran*, derived from the verb *caraa* or *karaa*, to read. The word therefore properly ſignifies, *the reading*; or rather, *that which ought to be read.* By this name the Mahometans denote not only the entire book or volume of the Koran, but alſo any particular chapter or ſection of it; juſt as the Jews call either the whole Scripture, or any part of it, by the name of *Karah*, or *Mikra*, words of the ſame origin and import.

Beſides this peculiar name, the Koran is alſo honoured with ſeveral appellations common to other books of Scripture: as, *al Farkan*, from the verb *foraka*, *to divide* or *diſtinguiſh*; not, as the Mahometan doctors ſay, becauſe thoſe books are divided into chapters or ſections, or diſtinguiſh between good and evil; but in the ſame notion that the Jews uſe the word *Perek*, or *Piska*, from the ſame root, to denote a ſection or portion of Scripture. It is alſo called *al Moſhaf*, *the volume*, and *al Kitab*, *the book*, by way of eminence, which anſwers to the *Biblia* of the Greeks; and *al Dhikr*, *the admonition*, which name is alſo given to the Pentateuch and Goſpel.

The Koran is divided into 114 larger portions of very unequal length, which we call *chapters*; but the Arabians *ſowar*, in the ſingular *ſura*, a word rarely uſed on any other occaſion, and properly ſignifying a row, order, or a regular ſeries; as a courſe of bricks in building, or a rank of ſoldiers in an army; and is the ſame in uſe and import with the Sura, or Tora, of the Jews, who alſo call the fifty-three ſections of the Pentateuch *Sedarim*, a word of the ſame ſignification.

Theſe chapters are not, in the manuſcript copies, diſtinguiſhed by their numerical order, but by particular titles, which are taken ſometimes from a particular matter treated of, or perſon mentioned therein; but uſually from the firſt word of note, exactly in the ſame manner as the Jews have named their Sedarim; though the word from which ſome chapters are denominated be very far diſtant, towards the middle, or perhaps the end of the chapter; which ſeems ridiculous. But the occaſion of this appears to have been, that the verſe or paſſage wherein ſuch word occurs, was, in the point of time, revealed and committed to writing before the other verſes of the ſame chapter, which precede it in order; and the title being given to the chapter before it was completed, or the paſſages reduced to their preſent order, the verſe from whence ſuch title was taken did not always happen to begin the chapter. Some chapters have two or more titles, occaſioned by the difference of the copies. Alcoran.

Some of the chapters having been revealed at Mecca, and others at Medina, the noting this difference makes a part of the title: but the reader will obſerve, that ſeveral of the chapters are ſaid to have been revealed partly at Mecca and partly at Medina; and, as to others, it is yet a diſpute among the commentators to which of the two places they belong.

Every chapter is ſubdivided into ſmaller portions, of very unequal length alſo, which we cuſtomarily call *verſes*; but the Arabic word is *ayat*, the ſame with the Hebrew *ototh*, and ſignifies *ſigns* or *wonders*: ſuch as are the ſecrets of God, his attributes, works, judgements, and ordinances, delivered in thoſe verſes; many of which have their particular titles alſo, impoſed in the ſame manner as thoſe of the chapters.

Beſides theſe unequal diviſions of chapter and verſe, the Mahometans have alſo divided their Koran into ſixteen equal portions, which they call *Ahzab*, in the ſingular *Hizb*, each divided into four equal parts; which is alſo an imitation of the Jews, who have an ancient diviſion of their Mithna into ſixty portions called *Maſſicoth*. But the Koran is more uſually divided into thirty ſections only named *Ajza*, from the ſingular *Joz*, each of twice the length of the former, and in the like manner ſubdivided into four parts. Theſe diviſions are for the uſe of the readers of the Koran in the royal temples, or in the adjoining chapels where the emperors and great men are interred. There are thirty of theſe readers belonging to every chapel, and each reads his ſection every day; ſo that the whole Koran is read over once a day.

Next after the title, at the head of every chapter, except only the ninth, is prefixed the following ſolemn form, by the Mahometans called the *Biſmallah*, IN THE NAME OF THE MOST MERCIFUL GOD; which form they conſtantly place at the beginning of all their books and writings in general, as a peculiar mark or diſtinguiſhing characteriſtic of their religion, it being counted a ſort of impiety to omit it. The Jews, for the ſame purpoſe, make uſe of the form, *In the name of the* LORD, or, *In the name of the great* GOD; and the eaſtern Chriſtians that of, *In the name of the Father, and of the Son, and of the Holy Ghoſt.* But Mahomet probably took this form, as he did many other things, from the Perſian Magi, who uſed to begin their books in theſe words, *Benam Yezdan bakſhaiſhgher dadar*; that is, *In the name of the moſt merciful juſt* GOD.

There are twenty-nine chapters of the Koran, which have this peculiarity, that they begin with certain letters of the alphabet, ſome with a ſingle one, others with more. Theſe letters the Mahometans believe to be the peculiar marks of the Koran, and to conceal ſeveral profound myſteries; the certain underſtanding of which, the more intelligent confeſs, has not been communicated to any mortal, their prophet only excepted. Notwithſtanding which, ſome will take the liberty of gueſſing at their meaning by that ſpecies of Cabala called by the Jews *Notarikon*, and ſuppoſe the letters to ſtand for as many words, expreſſing the names and attributes of God, his works, ordinances, and decrees; and therefore theſe myſterious letters, as well as the

verſes

Alcoran. verſes themſelves, ſeem in the Koran to be called *ſigns*. Others explain the intent of theſe letters from their nature or organ, or elſe from their value in numbers, according to another ſpecies of the Jewiſh Cabala called *Gematria*; the uncertainty of which conjectures ſufficiently appears from their diſagreement. Thus, for example, five chapters, one of which is the ſecond, begin with theſe letters. A. L. M. which ſome imagine to ſtand for *Allah latiff magid*, "God *is gracious and to be glorified*; or, *Ana li minni*, i. e. *to me and from me*, viz. belongs all perfection, and proceeds all good; or elſe for *Ana Allah alam*, "*I am the moſt wiſe* God," taking the firſt letter to mark the beginning of the firſt word, the ſecond the middle of the ſecond word, and the third the laſt of the third word; or for *Allah, Gabriel, Mohammed*, the author, revealer, and preacher of the Koran. Others ſay, that as the letter A belongs to the lower part of the throat, the firſt of the organs of ſpeech; L to the palate, the middle organ; and M to the lips, which are the laſt organ; ſo theſe letters ſignify that God is the beginning, middle, and end, or ought to be praiſed in the beginning, middle, and end, of all our words and actions: or, as the total value of thoſe three letters, in numbers, is ſeventy-one, they ſignify, that, in the ſpace of ſo many years, the religion preached in the Koran ſhould be fully eſtabliſhed. The conjecture of a learned Chriſtian is at leaſt as certain as any of the former, who ſuppoſes thoſe letters were ſet there by the amanuenſis, for *Amar li Mohammed*, i. e. *at the command of Mohammed*, as the five letters prefixed to the nineteenth chapter ſeem to be there written by a Jewiſh ſcribe, for *Coh yaas, Thus he commanded*.

The Koran is univerſally allowed to be written with the utmoſt elegance and purity of language, in the dialect of the tribe of Koreiſh, the moſt noble and polite of all the Arabians, but with ſome mixture, though very rarely, of other dialects. It is confeſſedly the ſtandard of the Arabic tongue, and, as the more orthodox believe, and are taught by the book itſelf, inimitable by any human pen (though ſome ſectaries have been of another opinion), and therefore inſiſted on as a permanent miracle, greater than that of raiſing the dead, and alone ſufficient to convince the world of its divine original.

And to this miracle did Mahomet himſelf chiefly appeal for the confirmation of his miſſion, publicly challenging the moſt eloquent men in Arabia, which was at that time ſtocked with thouſands whoſe ſole ſtudy and ambition it was to excel in elegance of ſtyle and compoſition, to produce even a ſingle chapter that might be compared with it (A).

To the pomp and harmony of expreſſion ſome aſcribe all the force and effect of the Alcoran; which they conſider as a ſort of muſic, equally fitted with other ſpecies of that art to raviſh and amaze. In this Mahomet ſucceeded ſo well, and ſo ſtrangely captivated the minds of his audience, that ſeveral of his opponents thought it the effect of witchcraft and enchantment, as he himſelf complains.—Others have attributed the effect of the Alcoran to the frequent mention of rewards and puniſhments; heaven and hell occurring almoſt in every page. Some ſuppoſe, that the ſenſual pleaſures of paradiſe, ſo frequently ſet before the imaginations of the readers of the Alcoran, were what chiefly bewitched them. Though, with regard to theſe, there is a great diſpute whether they are to be underſtood literally or ſpiritually. Several have even allegorized the whole book. Alcoran.

The general deſign of the Koran was to unite the profeſſors of the three different religions, then followed in the populous country of Arabia (who for the moſt part lived promiſcuouſly, and wandered without guides, the far greater number being idolaters, and the reſt Jews and Chriſtians moſtly of erroneous and heterodox belief), in the knowledge and worſhip of one God, under the ſanction of certain laws, and the outward ſigns of ceremonies partly of ancient and partly of novel inſtitution, enforced by the conſideration of rewards and puniſhments both temporal and eternal; and to bring them all to the obedience of Mahomet, as the prophet and ambaſſador of God, who, after the repeated admonitions, promiſes, and threats, of former ages, was at laſt to eſtabliſh and propagate God's religion on earth, and to be acknowledged chief pontiff in ſpiritual matters, as well as ſupreme prince in temporal.

The great doctrine then of the Koran, is the unity of God; to reſtore which point Mahomet pretended was the chief end of his miſſion; it being laid down by him as a fundamental truth, That there never was, nor ever can be, more than one true orthodox religion. For, though the particular laws or ceremonies are only temporary, and ſubject to alteration, according to the divine directions; yet the ſubſtance of it being eternal truth, is not liable to change, but continues immutably the ſame. And he taught, that, whenever this religion became neglected, or corrupted in eſſentials, God had the goodneſs to re-inform and re-admoniſh mankind thereof, by ſeveral prophets, of whom Moſes and Jeſus were the moſt diſtinguiſhed, till the appearance of Mahomet, who is their ſeal, and no other to be expected after him. The more effectually to engage people to hearken to him, great part of the Koran is employed in relating examples of dreadful puniſhments formerly inflicted by God on thoſe who rejected and abuſed his meſſengers; ſeveral of which ſtories, or ſome circumſtances of them, are taken from the Old and New Teſtaments, but many more from the apocryphal books and traditions of the Jews and Chriſtians of thoſe ages, ſet up in the Koran as truths in oppoſition to the Scriptures, which the Jews and Chriſtians are charged with having altered; and indeed, few or none of the relations or circumſtances in the Koran were invented by Mahomet, as is generally ſuppoſed, it being eaſy to trace the greateſt part of them

(A) As the compoſition and arrangement of words, however, admit of infinite varieties, it can never be abſolutely ſaid that any one is the beſt poſſible. In fact, Hamzah Benahmed wrote a book againſt the Alcoran with at leaſt equal elegance; and Moſelema another, which even ſurpaſſed it, and occaſioned a defection of a great part of the Muſſulmans. *Journ. de Sçav.* tom. viii. p. 280. *Oeuvr. de Sçav.* Nov. 1708. p. 404.

Alcoran. them much higher, as the reſt might be, were more of thoſe books extant, and was it worth while to make the inquiry.

The reſt of the Alcoran is taken up in preſcribing neceſſary laws and directions, frequent admonitions to moral and divine virtues, the worſhip and reverence of the Supreme Being, and reſignation to his will. One of their moſt learned commentators diſtinguiſhes the contents of the Alcoran into *allegorical* and *literal;* under the former are comprehended all the obſcure, parabolical, and enigmatical paſſages, with ſuch as are repealed, or abrogated; the latter, ſuch as are clear, and in full force.

The moſt excellent moral in the whole Alcoran, interpreters ſay, is that in the chapter *Al Alraf*, viz. "Shew mercy, do good to all, and diſpute not with the ignorant;" or, as Mr Sale renders it, "Uſe indulgence, command that which is juſt, and withdraw far from the ignorant." Mahomet, according to the authors of the *Keſchaf*, having begged of the angel Gabriel a more ample explication of this paſſage, received it in the following terms: "Seek him who turns thee out, give to him who takes from thee, pardon him who injures thee; for God will have you plant in your ſouls the roots of his chief perfections." It is eaſy to ſee that this commentary is copied from the goſpel. In reality, the neceſſity of forgiving enemies, though frequently inculcated in the Alcoran, is of a later date among the Mahometans than among the Chriſtians; among thoſe latter, than among the heathens; and to be traced originally among the Jews. (See EXODUS xxxiii. 4. 5.) But it matters not ſo much who had it firſt, as who obſerves it beſt. The caliph Haſſan, ſon of Hali, being at table, a ſlave unfortunately let fall a diſh of meat reeking hot, which ſcalded him ſeverely. The ſlave fell on his knees, rehearſing theſe words of the Alcoran, "Paradiſe is for thoſe who reſtrain their anger." I am not angry with thee, anſwered the caliph—"And for thoſe who forgive offences againſt them," continues the ſlave. I forgive thee thine, replies the caliph—"But above all, for thoſe who return good for evil," adds the ſlave. I ſet thee at liberty, rejoined the caliph; and I give thee ten dinars.

There are alſo a great number of occaſional paſſages in the Alcoran, relating only to particular emergencies. For this advantage Mahomet had in the piecemeal method of receiving his revelation, that whenever he happened to be perplexed and gravelled with any thing, he had a certain reſource in ſome new morſel of revelation. It was an admirable contrivance of his, to bring down the whole Alcoran at once, only to the loweſt heaven, not to earth; ſince, had the whole been publiſhed at once, innumerable objections would have been made, which it would have been impoſſible for him to ſolve; but as he received it by parcels, as God ſaw fit they ſhould be publiſhed for the converſion and inſtruction of the people, he had a ſure way to anſwer all emergencies, and to extricate himſelf with honour from any difficulty which might occur.

It is the general and orthodox belief among the Mahometans, that the Koran is of divine original; nay, that it is eternal and uncreated, remaining, as ſome expreſs it, in the very eſſence of God: that the firſt tranſcript has been from everlaſting by God's throne, written on a table of vaſt bigneſs, called the *preſerved table*, in which are alſo recorded the divine decrees paſt and future: that a copy from this table, in one volume on paper, was by the miniſtry of the angel Gabriel ſent down to the loweſt heaven, in the month of Ramadan, on the night of *power:* from whence Gabriel revealed it to Mahomet by parcels, ſome at Mecca, and ſome at Medina, at different times, during the ſpace of 23 years, as the exigency of affairs required; giving him, however, the conſolation to ſhow him the whole (which they tell us was bound in ſilk, and adorned with gold and precious ſtones of paradiſe) once a-year; but in the laſt year of his life he had the favour to ſee it twice. They ſay, that few chapters were delivered entire, the moſt part being revealed piecemeal, and written down from time to time by the prophet's amanuenſis in ſuch a part of ſuch and ſuch a chapter, till they were completed, according to the directions of the angel. The firſt parcel that was revealed is generally agreed to have been the firſt five verſes of the 46th chapter. Alcoran.

After the new-revealed paſſages had been from the prophet's mouth taken down in writing by his ſcribe, they were publiſhed to his followers; ſeveral of whom took copies for their private uſe, but the far greater number got them by heart. The originals, when returned, were put promiſcuouſly into a cheſt, obſerving no order of time; for which reaſon it is uncertain when many paſſages were revealed.

When Mahomet died, he left his revelations in the ſame diſorder, and not digeſted into the method, ſuch as it is, in which we now find them. This was the work of his ſucceſſor Abu Becr; who, conſidering that a great number of paſſages were committed to the memory of Mahomet's followers, many of whom were ſlain in their wars, ordered the whole to be collected, not only from the palm leaves and ſkins on which they had been written, and which were kept between two boards or covers, but alſo from the mouths of ſuch as had gotten them by heart. And this tranſcript, when completed, he committed to the cuſtody of Haſſa the daughter of Omar, one of the prophet's widows.

From this relation is is generally imagined that Abu Becr was really the compiler of the Koran; though, for aught appears to the contrary, Mahomet left the chapters complete as we now have them, excepting ſuch paſſages as his ſucceſſor might add or correct from thoſe who had gotten them by heart; what Abu Becr did elſe, being perhaps no more than to range the chapters in their preſent order, which he ſeems to have done without any regard to time, having generally placed the longeſt firſt.

However, in the 30th year of the Hegira Othman being then caliph, and obſerving the great diſagreement in the copies of the Koran in the ſeveral provinces of the empire: thoſe of Irak, for example, following the reading of Abu Muſa al Aſhari, and the Syrians that of Macdad Ebn Aſwad; he, by the advice of the *companions*, ordered a great number of copies to be tranſcribed from that of Abu Becr, in Haſſa's care, under the inſpection of Zeid Ebn Thabet, Abd'allah Ebn Zobair, Said Ebn al As, and Abd'alrahman Ebn al Hareth the Makhzumite; whom he directed, that, wherever they diſagreed about any word, they ſhould write it in the dialect of the Koreiſh,

Alcoran. reiſh, in which it was at firſt delivered. Theſe copies, when made, were diſperſed in the ſeveral provinces of the empire, and the old ones burnt and ſuppreſſed. Though many things in Haffa's copy were corrected by the above-mentioned reviſers, yet ſome few various readings ſtill occur.

In fine, the book of the Alcoran is held in the higheſt eſteem and reverence among the Muſſulmans. They dare not ſo much as touch the Alcoran without being firſt waſhed, or legally purified; to prevent which, an inſcription is put on the cover or label, *Let none touch but they who are clean.* It is read with great care and reſpect; being never held below the girdle. They ſwear by it; take omens from it on all weighty occaſions; carry it with them to war; write ſentences of it in their banners; adorn it with gold and precious ſtones; and knowingly ſuffer it not to be in the poſſeſſion of any of a different religion. Some ſay that it is puniſhable even with death, in a Chriſtian, to touch it; others, that the veneration of the Muſſulmans leads them to condemn the tranſlating it into any other language as a profanation: but theſe ſeem to be aggravations. The Mahometans have taken care to have their Scripture tranſlated into the Perſian, the Javaneſe, the Malayan, and other languages; though, out of reſpect to the original, theſe verſions are generally, if not always, interlineated.

View of Chriſtianity and Mahometaniſm, p. 257.

By the advocates of Mahometaniſm, the Koran, as already obſerved, has always been held forth as the greateſt of miracles, and equally ſtupenduous with the act of raiſing the dead. The miracles of Moſes and Jeſus, they ſay, were tranſient and temporary; but that of the Koran is permanent and perpetual; and therefore far ſurpaſſes all the miraculous events of preceding ages. We will not detract from the real merit of the Koran: we allow it to be generally elegant, and often ſublime: but at the ſame time we reject with diſdain its arrogant pretence to any thing ſupernatural; all the real excellence of the work being eaſily referable to natural and viſible cauſes.

"In the language of Arabia, a language extremely loved and diligently cultivated by the people to whom it was vernacular, Mahomet found advantages which were never enjoyed by any former or ſucceeding impoſtor. It requires not the eye of a philoſopher to diſcover in every ſoil and country a principle of national pride: and if we look back for many ages on the hiſtory of the Arabians, we ſhall eaſily perceive that pride among them invariably to have conſiſted in the knowledge and improvement of their native language. The Arabic, which has been juſtly eſteemed the moſt copious of the Eaſtern tongues; which had exiſted from the remoteſt antiquity; which had been embelliſhed by numberleſs poets, and refined by the conſtant exerciſe of the natives; was the moſt ſucceſsful inſtrument which Mahomet employed in planting his new religion among them. Admirably adapted by its unrivalled harmony, and by its endleſs variety, to add painting to expreſſion, and to purſue the imagination in its unbounded flight; it became in the hands of Mahomet an irreſiſtible charm to blind the judgment, and to captivate the fancy of his followers.

"Of that deſcription of men, who firſt compoſed the adherents of Mahomet, and to whom the Koran was addreſſed, few, probably, were able to paſs a very accurate judgement on the propriety of the ſentiments, or on the beauties of the diction: but all could judge of the military abilities of their leader; and in the midſt of their admiration it is not difficult to conceive, that they would aſcribe to his compoſitions every imaginary beauty of inſpired language. Alcoran.

"The ſhepherd and the ſoldier, though awake to the charms of thoſe wild but beautiful compoſitions, in which were celebrated their favourite occupations of love or war, were yet little able to criticiſe any other works than thoſe which were addreſſed to the imagination or the heart. To abſtract reaſonings on the attributes and the diſpenſations of the Deity, to the comparative excellencies of rival religions, to the conſiſtency of any one religious ſyſtem in all its parts, and to the force of its various proofs, they were quite inattentive. In ſuch a ſituation, the appearance of a work which poſſeſſed ſomething like wiſdom and conſiſtence; which preſcribed the rules, and illuſtrated the duties of life; and which contained the principles of a new and comparatively ſublime theology, independently of its real and permanent merit, was likely to excite their aſtoniſhment, and to become the ſtandard of future compoſition.

"In the firſt periods of the literature of every country, ſomething of this kind has happened. The father of Grecian poetry very obviouſly influenced the taſte and imitation of his countrymen. The modern nations of Europe all poſſeſs ſome original author, who, riſing from the darkneſs of former ages, has begun the career of compoſition, and tinctured with the character of his own imagination the ſtream which has flowed through his poſterity.

"But the prophet of Arabia had in this reſpect advantages peculiar to himſelf. His compoſitions were not to his followers the works of man, but the genuine language of Heaven, which had ſent him. They were not confined therefore to that admiration which is ſo liberally beſtowed on the earlieſt productions of genius, or to that fond attachment with which men everywhere regard the original compoſitions of their country: but with their admiration they blended their piety. To know and to feel the beauties of the Koran, was in ſome reſpect to ſhare in the temper of heaven; and he who was moſt affected with admiration in the peruſal of its beauties, ſeemed moſt fitly the object of that mercy which had given it to ignorant man. The Koran, therefore, became naturally and neceſſarily the ſtandard of taſte. With a language thus hallowed in their imaginations, they were too well ſatisfied, either to diſpute its elegance or improve its ſtructure. In ſucceeding ages, the additional ſanction of antiquity, or preſcription, was given to theſe compoſitions which their fathers had admired: and while the belief of its divine original continues, that admiration, which has thus become the teſt and the duty of the faithful, can neither be altered nor diminiſhed.

"When therefore we conſider theſe peculiar advantages of the Koran, we have no reaſon to be ſurpriſed at the admiration in which it is held. But if, deſcending to a more minute inveſtigation of it, we conſider its perpetual inconſiſtence and abſurdity, we ſhall indeed have cauſe for aſtoniſhment at that weakneſs of humanity which could ever have received ſuch compoſitions as the work of the Deity.

"The

Alcoran. "The firſt praiſe of all the productions of genius, is invention; that quality of the mind, which, by the extent and quickneſs of its views, is capable of the largeſt conceptions, and of forming new combinations of objects the moſt diſtant and unuſual. But the Koran bears little impreſſion of this tranſcendent character. Its materials are wholly borrowed from the Jewiſh and Chriſtian Scriptures, from the Talmudical legends and apocryphal goſpels then current in the Eaſt, and from the traditions and fables which abounded in Arabia. The materials collected from theſe ſeveral ſources are here heaped together, with perpetual and needleſs repetitions, without any ſettled principle or viſible connection.

"When a great part of the life of Mahomet had been ſpent in preparatory meditation on the ſyſtem he was about to eſtabliſh, its chapters were dealt out ſlowly and ſeparately during the long period of 23 years. Yet thus defective in its ſtructure, and not leſs exceptionable in its doctrines, was the work which Mahomet delivered to his followers as the oracles of God.

"The moſt prominent feature of the Koran, that point of excellence in which the partiality of its admirers has ever delighted to view it, is the ſublime notion it generally impreſſes of the nature and attributes of God. If its author had really derived theſe juſt conceptions from the inſpiration of that Being whom they attempt to deſcribe, they would not have been ſurrounded, as they now are on every ſide, with error and abſurdity. But it might eaſily be proved, that whatever it juſtly defines of the divine attributes, was borrowed from our Holy Scripture; which even from its firſt promulgation, but eſpecially from the completion of the New Teſtament, has extended the views and enlightened the underſtandings of mankind; and thus furniſhed them with arms, which have too often, though ineffectually, been turned againſt itſelf by its ungenerous enemies.

"In this inſtance particularly, the copy is far below the great original, both in the propriety of its images, and the force of its deſcriptions. Our Holy Scriptures are the only compoſitions that can enable the dim ſight of mortality to penetrate into the inviſible world, and to behold a glimpſe of the Divine perfections. Accordingly, when they would repreſent to us the happineſs of Heaven, they deſcribe it, not by any thing minute and particular, but by ſomething general and great; ſomething that, without deſcending to any determinate object, may at once by its beauty and immenſity excite our wiſhes and elevate our affections. Though in the prophetical and evangelical writings the joys that ſhall attend us in a future ſtate are often mentioned with ardent admiration, they are expreſſed rather by alluſion than ſimilitude, rather by indefinite and figurative terms, than by any thing fixed and determinate. 'Eye hath not ſeen, nor ear heard, neither have entered into the heart of man, the things which God hath prepared for them that love him.' 1. *Cor.* ii. 9. What a reverence and aſtoniſhment does this paſſage excite in every hearer of taſte and piety! What energy, and at the ſame time what ſimplicity, in the expreſſion! How ſublime, and at the ſame time how obſcure, is the imagery!

"Different was the conduct of Mahomet in his deſcriptions of heaven and of paradiſe. Unaſſiſted by the neceſſary influence of virtuous intentions and Divine inſpiration, he was neither deſirous, nor indeed able, to exalt the minds of men to ſublime conceptions, or to rational expectations. By attempting to explain what is inconceivable, to deſcribe what is ineffable, and to materialize what in itſelf is ſpiritual; he abſurdly and impiouſly aimed to ſenſualize the purity of the Divine eſſence. Thus he fabricated a ſyſtem of incoherence, a religion of depravity, totally repugnant indeed to the nature of that Being, who, as he pretended, was its object; but therefore more likely to accord with the appetites and conceptions of a corrupt and ſenſual age. Alcoran.

"That we may not appear to exalt our Scriptures thus far above the Koran by an unreaſonable preference, we ſhall produce a part of the ſecond chapter of the latter, which is deſervedly admired by the Mahometans, who wear it engraved on their ornaments, and recite it in their prayers. 'God! there is no God but he; the living, the ſelf-ſubſiſting: neither ſlumber nor ſleep ſeizeth him: to him belongeth whatſoever is in heaven, and on earth. Who is he that can intercede with him but through his good pleaſure? He knoweth that which is paſt, and that which is to come. His throne is extended over heaven and earth, and the preſervation of both is to him no burden. He is the high, the mighty.' *Sale's Kor.* ii. p. 30. 4to edit.

"To this deſcription who can refuſe the praiſe of magnificence? Part of that magnificence, however, is to be referred to that verſe of the Pſalmiſt, whence it was borrowed, 'He that keepeth Iſrael, ſhall neither ſlumber nor ſleep.' *Pſal.* cxxi. 4.

"But if we compare it with that other paſſage of the ſame inſpired Pſalmiſt, all its boaſted grandeur is at once obſcured, and loſt in the blaze of a greater light.

"O my God, take me not away in the midſt of my days; thy years are throughout all generations. Of old haſt thou laid the foundations of the earth; and the heavens are the work of thy hands. They ſhall periſh, but thou ſhalt endure: yea all of them ſhall wax old, as doth a garment; as a veſture ſhalt thou change them, and they ſhall be changed; but thou art the ſame, and thy years ſhall not fail.'

"The Koran, therefore, upon a retroſpective view of theſe ſeveral circumſtances, far from ſupporting its arrogant claim to a ſupernatural work, ſinks below the level of many compoſitions confeſſedly of human original; and ſtill lower does it fall in our eſtimation, when compared with that pure and perfect pattern which we juſtly admire in the Scriptures of truth.

"It is therefore abundantly apparent, that no miracle either was externally performed for the ſupport, or is internally involved in the compoſition, of the Mahometan revelation."

ALCORAN, is alſo figuratively applied to certain other books full of impieties and impoſtures. In this ſenſe we meet with the Alcoran of the Cordeliers, which has made a great noiſe; wherein St Francis is extravagantly magnified, and put on a level with Jeſus Chriſt. The Alcoran of the Cordeliers is properly an extract of a very ſcarce book, entitled, The Conformity of the Life of the ſeraphic father St Francis with the Life of Chriſt, publiſhed in 1510, 4to; ſince, at Bologna, in folio. Eraſmus Albertus, being by the elector of Brandenburg appointed to viſit a monaſtery of Franciſcans,

Alcoranists || Alcuinus

Franciscans, found this book; and being struck with the extreme folly and absurdity of it, collected a number of curiosities out of it, and published them under the title of the *Alcoran* of the Franciscans, with a preface by Martin Luther.

ALCORANISTS, among Mahometans, those who adhere strictly to the letter or text of the Alcoran, from an opinion of its ultimate sufficiency and perfection. The Persians are generally *Alcoranists*, as admitting the Alcoran alone for their rule of faith. The Turks, Tartars, Arabs, &c. besides the Alcoran, admit a multitude of traditions. The Alcoranists, among Mahometans, amount to much the same with the Textuaries among the Jews. The Alcoranists can find nothing excellent out of the Alcoran; are enemies of philosophers, metaphysicians, and scholastic writers. With them the Alcoran is every thing.

ALCOVE, in *Architecture*, a recess, or part of a chamber separated by an estrade, or partition of columns, and other corresponding ornaments, in which is placed a bed of state, and sometimes seats to entertain company. These alcoves are frequent in Spain; and the bed is raised two or three ascents, with a rail at the foot.

ALCUINUS, Flaccus, an ecclesiastic of the eighth century. He was born, it is supposed, in Yorkshire. He was educated, however, at York, under the direction of Archbishop Egbert, as we learn from his own letters, in which he frequently calls that great prelate his beloved master, and the clergy of York the companions of his youthful studies. As he survived Venerable Bede about 70 years, it is hardly possible that he could have received any part of his education under him, as some writers of literary history have affirmed; and it is worthy of observation, that he never calls that great man his master, though he speaks of him with the highest veneration. It is not well known to what preferments he had attained in the church before he left England, though some say he was abbot of Canterbury. The occasion of his leaving his native country, was his being sent on an embassy by Offa king of Mercia to the emperor Charlemagne; who contracted so great an esteem and friendship for him, that he earnestly solicited, and at length prevailed upon him, to settle in his court, and become his preceptor in the sciences. Alcuinus accordingly instructed that great prince in rhetoric, logic, mathematics, and divinity; which rendered him one of his greatest favourites. "He was treated with so much kindness and familiarity (says a cotemporary writer) by the emperor, that the other courtiers called him, by way of eminence, *the emperor's delight*." Charlemagne employed his learned favourite to write several books against the heretical opinions of Felix bishop of Urgel, in Catalonia, and to defend the orthodox faith against that heresiarch, in the council of Francfort, A. D. 894; which he performed to the entire satisfaction of the emperor and council, and even to the conviction of Felix and his followers, who abandoned their errors. The emperor consulted chiefly with Alcuinus on all things relating to religion and learning; and, by his advice, did many great things for the advancement of both. An academy was established in the imperial palace, over which Alcuinus presided, and in which the princes and prime nobility were educated; and other academies were established in the chief towns of Italy and France at his instigation, and under his inspection. "France (says one of our best writers of literary history) is indebted to Alcuinus for all the polite learning it boasted of in that and the following ages. The universities of Paris, Tours, Fulden, Soissons, and many others, owe to him their origin and increase; those of whom he was not the superior and founder, being at least enlightened by his doctrine and example, and enriched by the benefits he procured for them from Charlemagne." After Alcuinus had spent many years in the most intimate familiarity with the greatest prince of his age, he at length, with great difficulty, obtained leave to retire from court to his abbey of St Martin's at Tours. Here he kept up a constant correspondence by letters with Charlemagne; from which it appears, that both the emperor and his learned friend were animated with the most ardent love to learning and religion, and constantly employed in contriving and executing the noblest designs for their advancement. He composed many treatises on a great variety of subjects, in a style much superior in purity and elegance to that of the generality of writers in the age in which he flourished. Charlemagne often solicited him, with all the warmth of a most affectionate friend, to return to court, and favour him with his company and advice; but he still excused himself; and nothing could draw him from his retirement in his abbey of St Martin in Tours, where he died A. D. 804. His works were collected and published by Andrew du Chesne in one volume folio, Paris, 1617. They consist of 1. Tracts upon Scripture. 2. Tracts upon doctrine, discipline, and morality. 3. Historical treatises, letters, and poems. Since that edition, there has been published an incredible number of tracts, poems, &c. ascribed to this author, most of which, in all probability, were not his.

Alcuinus || Alcyonius.

ALCYON, the trivial name of a species of alcedo. See Alcedo, Ornithology *Index*.

ALCYONIUM, an obsolete name of a submarine plant. It is also used for a kind of coral, or astroites, frequently found fossil in England.

Alcyonium Stagnum, in *Ancient Geography*, a lake in the territory of Corinth, whose depth was unfathomable, and in vain attempted to be discovered by Nero. Through this lake Bacchus is said to have descended to hell, to bring back Semele; (Pausanias.)

ALCYONIUS, Peter, a learned Italian, who flourished in the 16th century. He was well versed in the Greek and Latin tongues, and wrote some pieces of eloquence which met with great approbation. He was corrector of the press a considerable time for Aldus Manutius, and is entitled to a share in the praises given to the editions of that learned printer. He published a treatise concerning banishment, which contained so many fine passages intermixed with others quite the reverse, that it was thought he had tacked to somewhat of his own, several fragments of a treatise of *Cicero de Gloria*; and that afterwards, in order to save himself from being detected in this theft, he burnt the manuscript of Cicero, the only one extant. Paulus Manutius, in his commentary upon these words of Cicero, *Librum tibi celeriter mittam de gloria*, "I will speedily send you my treatise on Glory;" has the following passage relating to this affair: "He means (says

Alcyonius || Alderman.

(says he) his two books on Glory, which were handed down to the age of our fathers; for Bernard Justinian, in the index of his books, mentions *Cicero de Gloria*. This treatise, however, when Bernard had left his whole library to a nunnery, could not be found, though sought after with great care: nobody doubted but Peter Alcyonius, who, being physician to the nunnery, was entrusted with the library, had basely stolen it. And truly, in his treatise of Banishment, some things are found interspersed here and there, which seem not to favour of Alcyonius, but of some higher author." The two orations he made after the taking of Rome, wherein he represented very strongly the injustice of Charles V. and the barbarity of his soldiers, were excellent pieces. There is also an oration ascribed to him, on the knights who died at the siege of Rhodes.

ALDBOROUGH, a sea-port town of England in Suffolk. It is pleasantly situated in a dale, between a high hill to the westward, on which its large old-built church stands; the sea to the east, and its river running south-west. It is a large, long, ordinary town, made up of two or three streets of low houses, running parallel to each other. A quarter of a mile to the south lies Slaughden, where they have a commodious key, with warehouses for fish: more southerly still, they have conveniences for drying their north-sea fish. Their employment in the fishery is their chief business, which is considerable in the seasons for catching herrings and sprats; and it is the only place in England for curing red sprats. It is a town corporate, and sends two members to parliament. Towards the sea, it has some pieces of cannon planted for its defence. It is 88 miles north-east form London. E. Long. 1. 32. N. Lat. 52. 50.

ALDBOROUGH, a market-town in the west riding of Yorkshire, seated on the river Ouse, 15 miles north-west of York, and 200 miles north of London. It sends two members to parliament. W. Long. 0. 20. N. Lat. 54. 15. It was anciently a Roman city, called *Isurium Brigantum;* and several coins and monuments of the Saxons and Romans have been discovered there.

ALDEBARAN, in *Astronomy*, a star of the first magnitude, called in English the *bull's eye*, as making the eye of the constellation Taurus. Its longitude is 6 deg. 32 min. 9 sec. of Gemini, and its latitude 5 deg. 29 min. 40 sec. south.

ALDER TREE. See BETULA, BOTANY *Index*.

ALDERHOLM, an island of Sweden, formed by the three arms of a river running through Gentle, a a town of Nordland, in Sweden, 80 miles north from Stockholm. Here is a wharf, a repository for planks and deals, two packing houses, a large custom-house for taking toll of the ships, an arsenal for cannon, and a granary.

ALDERMAN, in the British policy, a magistrate subordinate to the lord-mayor of a city or town-corporate. The number of these magistrates is not limited, but is more or less according to the magnitude of the place. In London there are 26; each having one of the wards of the city committed to his care. This office is for life; so that when one of them dies, or resigns, a wardmote is called, who return two persons, one of whom the lord-mayor and aldermen choose to supply the vacancy. All the aldermen are justices of the peace, by a charter of 15 Geo. II. The aldermen of London, &c. are exempted from serving inferior offices; nor shall they be put upon assizes, or serve on juries, so long as they continue to be aldermen. Alderman || Aldhelm.

ALDERMAN, among our Saxon ancestors, was a degree of nobility answering to earl or count at present.

ALDERMAN was also used, in the time of King Edgar, for a judge or justice. Thus we meet with the titles of *aldermannus totius Angliæ*, *aldermannus regis*, *comitatis*, *civitatis*, *burgi*, *castelli*, *hundredi sive wapentachii*, *et novemdecimorum*. According to Spelman, the *aldermannus totius Angliæ* seems to have been the same officer who was afterwards styled *capitalis justiciarius Angliæ*, or chief-justice of England; the *aldermannus regis* seems to have been an occasional magistrate, answering to our justice of assize; and the *aldermannus comitatus*, a magistrate who held a middle rank between what was afterward called the *earl* and the *sheriff;* he sat at the trial of causes with the bishop: the latter proceeding according to ecclesiastical law, and the former declaring and expounding the common law of the land.

ALDERNEY, an island in the British channel, subject to the crown of Great Britain. It is about eight miles in compass, and is separated from Cape la Hogue, in Normandy, by a narrow strait, called the *Race of Alderney*, which is a very dangerous passage in stormy weather when the two currents meet; otherwise it is safe, and has depth of water for the largest ships. Through this strait the French fleet made their escape after their defeat at La Hogue, in 1692. It is a healthy island, has but one church, is fruitful both in corn and pasture, and is remarkable for a fine breed of cows. The inhabitants, for their greater safety, live together in a town of the same name. The number of houses is said to be 200, and the inhabitants 1000. It has but one harbour, called *Crabby*, which is at a good distance from the town; and is only fit for small vessels. To the west lie the range of rocks called the *Caskets*, so dangerous to mariners. W. Long. 2. 17. N. Lat. 49. 50.

ALDHELM, or ADELM, ST, bishop of Shireburn in the time of the Saxon Heptarchy. He is said to have been the son of Kenred, brother to Ina, king of the West-Saxons; but, in the opinion of William of Malmsbury, his father was no more than a distant relation to the king. Having received the first part of his education in the school which one Macdulf, a learned Scot, had set up in the place where Malmsbury now stands, he travelled into France and Italy for his improvement. At his return home, he studied some time under Adrian abbot of St Augustine's in Canterbury, the most learned professor of the sciences who had ever been in England. In these different seminaries he acquired a very uncommon stock of knowledge; and became famous for his learning, not only in England, but in foreign countries; whence several learned men sent him their writings for his perusal and correction; particularly Prince Arcivil, a son of the king of Scotland, who wrote many pieces, which he sent to Aldhelm, "entreating him to give them the last polish, by rubbing off their Scots rust." He was the first Englishman who wrote in the Latin language both in prose and verse, and composed a book for the instruction of his countrymen in the prosody of that language. Besides

Aldhelm || Aldred.

fides this, he wrote ſeveral other treatiſes on various ſubjects; ſome of which are loſt, and others publiſhed by Martin Delrio and Caniſius. Venerable Bede, who flouriſhed in the end of this and the beginning of the next century, gives the following character of Aldhelm: "He was a man of univerſal erudition, having an elegant ſtyle, and being wonderfully well acquainted with books, both on philoſophical and religious ſubjects." In fact, conſidering the cloud of ignorance by which he was ſurrounded, and the great difficulty of acquiring knowledge without proper inſtruction, Aldhelm was a very extraordinary man. From one of his letters to Hedda biſhop of Wincheſter, concerning the nature of his ſtudies whilſt at Canterbury, he appears to have been indefatigably determined to acquire every ſpecies of learning in his power. For a copy of this curious epiſtle, ſee Henry's Hiſtory, vol. ii. p. 320. King Alfred the Great declared, that Aldhelm was the beſt of all the Saxon poets; and that a favourite ſong, which was univerſally ſung in his time, near 200 years after its author's death, was of his compoſition. When he was abbot of Malmſbury, having a fine voice, and great ſkill in muſic as well as poetry, and obſerving the backwardneſs of his barbarous countrymen to liſten to grave inſtructions, he compoſed a number of little poems, which he ſung to them after maſs in the ſweeteſt manner; by which they were gradually inſtructed and civilized. After this excellent perſon had governed the monaſtery of Malmſbury, of which he was the founder, about 30 years, he was made biſhop of Shireburn, where he died A. D. 709.—He wrote, 1. *De octo vitiis principalibus.* This treatiſe is extant in *Bibliotheca Patrum* of Caniſius. 2. *Ænigmatum verſus mille.* This, with ſeveral other of his poems, was publiſhed by Martin Delrio at Mentz, 8vo, 1601. 3. A book addreſſed to a certain king of Northumberland, named Alfrid, on various ſubjects. 4. *De vita monachorum.* 5. *De laude ſanctorum.* 5. *De arithmetica.* 7. *De aſtrologia.* 8. A book againſt the miſtake of the Britons concerning the celebration of Eaſter; printed by Sonius, 1576. 9. *De laude virginitatis;* manuſcript, in Bennet-college, Cambridge; publiſhed among Bede's *Opuſcula.* Beſides many ſonnets, epiſtles, and homilies in the Saxon language.

ALDPORT, an ancient name for Mancheſter. See MANCHESTER.

ALDRED, abbot of Taviſtock, was promoted to the biſhopric of Worceſter in the year 1046. He was ſo much in favour with King Edward the Confeſſor, and had ſo much power over his mind, that he obliged him to be reconciled with the worſt of his enemies, particularly with Sweyn ſon of the earl Goodwin, who had revolted againſt him, and came with an army to invade the kingdom. Aldred alſo reſtored the union and friendſhip between King Edward and Griffith king of Wales. He took afterwards a journey to Rome, and being returned into England, in the year 1054, he was ſent ambaſſador to the emperor Henry II. He ſtaid a whole year in Germany, and was very honourably entertained by Herman archbiſhop of Cologne, from whom he learned many things relating to eccleſiaſtical diſcipline, which on his return he eſtabliſhed in his own dioceſe. In the year 1058 he went to Jeruſalem, which no archbiſhop or biſhop of England had ever done before him. Two years after he returned to England; and Kinſius archbiſhop of York dying the 22d of December 1060, Aldred was elected in his ſtead on Chriſtmas day following, and was permitted to retain the ſee of Worceſter with the archbiſhopric of York, as ſome of his predeceſſors had done. Aldred went ſoon after to Rome, in order to receive the pall from the pope: He was attended by Toſton earl of Northumberland, Giſo biſhop of Wells, and Walter biſhop of Hereford. The pope received Toſton very honourably, and made him ſit by him in the ſynod which he held againſt the ſimoniſts. He granted to Giſo and Walter their requeſt, becauſe they were tolerably well learned, and not accuſed of ſimony. But Aldred being by his anſwers found ignorant, and guilty of ſimony, the pope deprived him very ſeverely of all his honours and dignities; ſo that he was obliged to return without the pall. On the way home he and his three fellow-travellers were attacked by ſome robbers, who took from them all that they had, though they did not offer to kill them. This obliged them to return to Rome; and the pope, either out of compaſſion, or by the threatenings of the earl of Northumberland, gave Aldred the pallium; but he was obliged to reſign his biſhopric of Worceſter. However, as the archbiſhopric of York had been almoſt entirely ruined by the many invaſions of foreigners, King Edward gave the new archbiſhop leave to keep 12 villages or manors which belonged to the biſhopric of Worceſter. Edward the confeſſor dying in 1066, Aldred crowned Harold his ſucceſſor. He alſo crowned William the Conqueror, after he had made him take the following oath, viz. that he would protect the holy churches of God and their leaders; that he would eſtabliſh and obſerve righteous laws; that he would entirely prohibit and ſuppreſs all rapines and unjuſt judgements. He was ſo much in favour with the Conqueror, that this prince looked upon him as a father; and, though imperious in regard to every body elſe, he yet ſubmitted to obey this archbiſhop: John Brompton gives us an inſtance of the king's ſubmiſſion, which at the ſame time ſhows the prelate's haughtineſs.—It happened one day, as the archbiſhop was at York that the deputy-governor or lord-lieutenant going out of the city with a great number of people, met the archbiſhop's ſervants, who came to town with ſeveral carts and horſes loaded with proviſions. The governor aſked them to whom they belonged; and they having anſwered they were Aldred's ſervants, the governor ordered that all theſe proviſions ſhould be carried to the king's ſtorehouſe. The archbiſhop ſent immediately ſome of his clergy to the governor, commanding him to deliver the proviſions, and to make ſatisfaction to St Peter, and to him the ſaint's vicar, for the injury he had done them; adding, that if he refuſed to comply, the archbiſhop would make uſe of his apoſtolic authority againſt him, (intimating thereby that he would excommunicate him). The governor, offended at this proud meſſage, uſed the perſons whom the archbiſhop had ſent him very ill, and returned an anſwer as haughty as the meſſage was. Aldred thereupon went to London to make his complaint to the king; but in this very complaint he acted with his wonted inſolence; for meeting the king in the church of St Peter at Weſtminſter, he ſpoke to him in theſe words: "Hearken, O William: when thou waſt but a foreigner, and

Aldred.

Aldred, Aldrich.

God, to punish the sins of this nation, permitted thee to become master of it, after having shed a great deal of blood, I consecrated thee, and put the crown upon thy head with blessings; but now, because thou hast deserved it, I pronounce a curse over thee, instead of a blessing, since thou art become the persecutor of God's church, and of his ministers, and hast broken the promises and the oaths which thou madest to me before St Peter's altar." The king, terrified at this discourse, fell upon his knees, and humbly begged the prelate to tell him, by what crime he had deserved so severe a sentence. The noblemen, who were present, were enraged against the archbishop, and loudly cried out he deserved death, or at least banishment, for having offered such an injury to his sovereign; and they pressed him with threatenings to raise the king from the ground. But the prelate, unmoved at all this, answered calmly, "Good men, let him lie there, for he is not at Aldred's but at St Peter's feet; he must feel St Peter's power, since he dared to injure his vicegerent." Having thus reproved the nobles by his episcopal authority, he vouchsafed to take the king by the hand, and to tell him the ground of his complaint. The king humbly excused himself, by saying he had been ignorant of the whole matter; and begged of the noblemen to intreat the prelate, that he might take off the curse he had pronounced, and to change it into a blessing. Aldred was at last prevailed upon to favour the king thus far: but not without the promise of several presents and favours, and only after the king had granted him to take such a revenge on the governor as he thought fit. Since that time (adds the historian) none of the noblemen ever dared to offer the least injury. It may be questioned, which was more surprising here, whether the archbishop's haughtiness, who dared to treat his sovereign after so unbecoming a manner; or the king's stupidity, who suffered such insolence and audaciousness from a priest.—The Danes having made an invasion in the north of England in the year 1068, under the conduct of Harold and Canute the sons of King Sweyn, Aldred was so much afflicted at it, that he died of grief the 11th of September in that same year, having besought God that he might not see the desolation of his church and country.

ALDRICH, Robert, bishop of Carlisle, was born at Burnham in Buckinghamshire about the year 1493, and educated at Eaton school; from whence, in 1507, he was elected scholar of King's college, Cambridge, where he took his degree in arts, and was afterwards proctor of the university. In 1525, he was appointed master of Eaton school, then became fellow of that college, and finally provost. In 1529, he went to Oxford, where, being first incorporated bachelor of divinity, in the following year he proceeded doctor in that faculty: in 1531, he was made archdeacon of Colchester; in 1534, canon of Windsor; and the same year, registrary of the order of the garter. He was consecrated bishop of Carlisle in the year 1537, and died at Horncastle in Lincolnshire in 1556. He wrote, 1. *Epistola ad Gul. Hormanum*, in Latin verse; printed in Horman's *Antibossican*, Lond. 1521, of which book Pitts erroneously makes Aldrich the author. 2. *Epigrammata varia*. 3. *Latin verses, and another epistle to Horman*, prefixed to the *Vulgaria puerorum* of that author, Lond. 1519, 4to. 4. *Answers to certain queries concerning the abuses of the mass*; also *about receiving the sacrament*.

Aldrich.

Aldrich, *Dr Henry*, an eminent English divine and philosopher, born at London in 1647, was educated at Westminster school under the famous Dr Busby, and admitted of Christ-church college, Oxford. He had a great share in the controversy with the Papists in the reign of James II. and Bishop Burnet ranks him among those who examined all the points of Popery with a solidity of judgment, clearness of argument, depth of learning, and vivacity of writing, far beyond any who had before that time written in our language. He rendered himself so conspicuous, that at the Revolution, when Massey the Popish dean of Christ church fled, his deanery was conferred on him. In this station he behaved in an exemplary manner, and that fabric owes much of its beauty to his ingenuity: it was Aldrich who designed the beautiful square called *Peckwater Quadrangle*, which is esteemed an excellent piece of architecture. In imitation of his predecessor Dr Fell, he published, yearly, a piece of some ancient Greek author, as a present to the students of his house. He published *A System of Logic*, with some other pieces: and the revising Clarendon's History of the Rebellion was intrusted to him and Bishop Spratt; but it doth not appear that they made any additions, or considerable alterations in it, as has been asserted by Mr Oldmixon. Besides his preferments above mentioned, Dr Aldrich was also rector of Wem in Shropshire. He was chosen prolocutor of the convocation in 1702. This worthy person died at Christ-church on the 14th of December 1710. As to his character, he was a most universal scholar, and had a taste for all sorts of learning, especially architecture. Sir John Hawkins has favoured the public with several particulars relative to Dr Aldrich's skill in music; and on account of the Doctor's eminence in this respect, Sir John hath given his life, with his head prefixed. His abilities as a musician rank him, we are told, among the greatest masters of the science. He composed many services for the church, which are well known; as are also his anthems, nearly to the number of 20. He adapted, with great skill and judgment, English words to many of the notes of Palestrina, Carissimi, Victoria, and other Italian composers for the church, some of which are frequently sung in our cathedrals as anthems. By the happy talent which Dr Aldrich possessed, of naturalizing the compositions of the old Italian masters, and accommodating them to an English ear, he increased the stores of our own church. Though the Doctor chiefly applied himself to the cultivation of sacred music, yet, being a man of humour, he could divert himself by producing pieces of a lighter kind. There are two catches of his; the one, "Hark the bonny Christ-church Bells;" the other entitled, "A Smoking Catch," to be sung by four men smoking their pipes, which is not more difficult to sing than diverting to hear. His love of smoking was, it seems, so excessive as to be an entertaining topic of discourse in the university. Such was Dr Aldrich's regard for the advancement of music, and the honour of its professors, that he had formed a design of writing a history of the science; and the materials from which he proposed to compile it are yet extant in the library of his own college. It appears from these materials, that he had marked

Aldrich || Aldrovandus.

marked down every thing which he had met with concerning muſic and muſicians; but that he had brought no part of them into any kind of form.

Dr Aldrich is of ſome note as a Latin poet. In the *Muſæ Anglicanæ*, we find two elegant copies of verſes by him; one on the acceſſion of King William III. and the other on the death of the duke of Glouceſter. Sir John Hawkins has preſerved a humorous tranſlation by him of the well-known Engliſh ballad,

"A ſoldier and a ſailor,
"A tinker and a tailor," &c.

The following epigram, entitled "Cauſæ Bibendi," is likewiſe aſcribed to Dr Aldrich:

"*Si bene quid memini, Cauſæ ſunt quinque bibendi,*
"*Hoſpitis Adventus; præſens Sitis, atque futura;*
"*Aut Vini Bonitas; aut quæ libet altera Cauſa.*"

The epigram has been thus tranſlated:

"If on my theme I rightly think,
"There are five reaſons why men drink:
"Good wine, a friend, becauſe I'm dry,
"Or leaſt I ſhould be and bye,
"Or any other reaſon why."

The tranſlation is not equal to the original. It is evident, from the verſes cited and referred to, that Dr Aldrich was of a very cheerful and pleaſant turn of mind. Indeed, he is always ſpoken of as having been a man of wit; and as one who, to his great talents and virtues joined thoſe amiable qualities which rendered him the object of general affection, as well as of general eſteem and reſpect. Having never been married, he appropriated his income to works of hoſpitality and beneficence, and encouraging learning to the utmoſt of his power, of which he was a moſt munificent patron, as well as one of the greateſt men in England, if conſidered as a Chriſtian or a gentleman. He had always the intereſt of his college at heart, whereof he was an excellent governor. His modeſty and humility prevented him from prefixing his name to the learned tracts which he publiſhed during his life. At his death he wiſhed to be buried in the cathedral without any memorial; which his thrifty nephew complied with, depoſiting him on the ſouth ſide of Biſhop Fell's grave, December 22. eight days after his deceaſe; which happened in the 63d or 64th year of his age.

ALDROVANDA. See BOTANY *Index*.

ALDROVANDUS, ULYSSES, profeſſor of philoſophy and phyſic at Bologna, the place of his nativity. He was a moſt curious inquirer into natural hiſtory, and travelled into the moſt diſtant countries on purpoſe to inform himſelf of their natural productions. Minerals, metals, plants, and animals, were the objects of his curious reſearches; but he applied himſelf chiefly to birds, and was at a great expence to have figures of them drawn from the life. Aubert le Mire ſays, that he gave a certain painter, famous in that art, a yearly ſalary of 200 crowns, for 30 years and upwards; and that he employed at his own expence Lorenzo Bernini and Cornelius Swintus, as well as the famous engraver Chriſtopher Coriolanus. Theſe expences ruined his fortune, and at length reduced him to the utmoſt neceſſity; and it is ſaid that he died blind in an hoſpital at Bologna, at a great age, in 1605. Mr Bayle obſerves, that antiquity does not furniſh us with an inſtance of a deſign ſo extenſive and ſo laborious as that of Aldrovandus, with regard to natural hiſtory; that Pliny has treated of more kinds of ſubjects, but only touches lightly on them, ſaying but a little upon any thing, whereas Aldrovandus has collected all he could meet with. His compilation, or that compiled upon his plan, conſiſts of 13 volumes in folio, ſeveral of which were printed after his death. He himſelf publiſhed his Ornithology, or Hiſtory of Birds, in three folio volumes, in 1599; and his ſeven books of inſects, which make another volume of the ſame ſize. The volume Of Serpents, three Of Quadrupeds, one Of Fiſhes, that Of exanguious Animals, the Hiſtory of Monſters, with the Supplement to that of Animals, the treatiſe Of Metals, and the Dendrology or Hiſtory of Trees, were publiſhed at ſeveral times after the death of Aldrovandus, by the care of different perſons; and Aldrovandus is the ſole author only of the firſt ſix volumes of this work, the reſt having been finiſhed and compiled by others, upon the plan of Aldrovandus: a moſt extenſive plan, wherein he not only relates what he has read in naturaliſts, but remarks alſo what hiſtorians have written, legiſlators ordained, and poets feigned: he explains alſo the different uſes which may be made of the things he treats of, in common life, in medicine, architecture, and other arts; in ſhort, he ſpeaks of morality, proverbs, devices, riddles, hieroglyphics, and many other things which relate to his ſubject.

Alduabis, Ale.

ALDUABIS, in *Ancient Geography*, a river of Celtic Gaul, which riſing from Mount Jura, ſeparating the Sequani from the Helvetii, and running through the county of Burgundy, or the Franche Comté, environs almoſt on every ſide the city of Beſançon; and running by Dole, falls into the Saone near Chalons. By Cæſar it is called *Alduaſdubis*; in Ptolemy, *Dubis*: now *le Doux*.

ALE a fermented liquor obtained from an infuſion of malt, and differing from beer chiefly in having a leſs proportion of hops. (See BREWING). This liquor, the natural ſubſtitute of wine in ſuch countries as could not produce the grape, was originally made in Egypt, the firſt planted kindom, on the diſperſion from the eaſt, that was ſuppoſed unable to produce grapes. And, as the Noachian colonies pierced further into the weſt, they found, or thought they found, the ſame defect, and ſupplied it in the ſame manner. Thus the natives of Spain, the inhabitants of France, and the aborigines of Britain, all uſed an infuſion of barley for their ordinary liquor: and it was called by the various names of *Cælia* and *Ceria* in the firſt country, *Cerevifia* in the ſecond, and *Curmi* in the laſt; all literally importing only *the ſtrong water*.

"All the ſeveral nations (ſays Pliny) who inhabit the weſt of Europe, have a liquor with which they intoxicate themſelves made of corn and water. The manner of making this liquor is ſometimes different in Gaul, Spain, and other countries, and is called by many various names; but its nature and properties are everywhere the ſame. The people of Spain, in particular, brew the liquor ſo well, that it will keep good a long time. So exquiſite is the cunning of mankind, in gratifying their vicious appetites, that they have thus invented a method to make water itſelf intoxicate."

Ale. cate." The method in which the ancient Britons, and other Celtic nations, made their ale, is thus described by Isidorus and Orosius. "The grain is steeped in water and made to germinate, by which its spirits are excited and set at liberty; it is then dried and grinded; after which it is infused in a certain quantity of water; which, being fermented, becomes a pleasant, warming, strengthening, and intoxicating liquor." This ale was most commonly made of barley, but sometimes of wheat, oats, and millet. Ale.

Anciently the Welch and Scots had also two kinds of ale, called *common ale* and *spiced ale;* and their value was thus ascertained by law: "If a farmer hath no mead, he shall pay two casks of spiced ale, or four casks of common ale, for one cask of mead." By this law, a cask of spiced ale, nine palms in height, and 18 palms in diameter, was valued at a sum of money equal in efficacy to 7l. 10s. of our present money; and a cask of common ale, of the same dimensions, at a sum equal to 3l. 15s. This is a sufficient proof, that even common ale in this period was an article of luxury among the Welch, which could only be obtained by the great and opulent. Wine seems to have been quite unknown, even to the kings of Wales, in this period, as it is not so much as once mentioned in their laws; though Giraldus Cambrensis, who flourished about a century after the Conquest, acquaints us, that there was a vineyard in his time at Maenarper, near Pembroke, in South Wales.

Ale was the favourite liquor of the Anglo-Saxons and Danes, as it had been of their ancestors the ancient Germans. Before their conversion to Christianity, they believed that drinking large and frequent draughts of ale was one of the chief felicities which those heroes enjoyed who were admitted into the hall of Odin.

There are various sorts of ale known in Britain, particularly *pale* and *brown:* the former is brewed from malt slightly dried; and is esteemed more viscid than the latter, which is made from malt more highly dried or roasted.

Pale ale brewed with hard waters, as those of springs and wells, is judged the most wholesome, in regard the mineral particles tend to prevent the cohesion of those drawn from the grain, and enable them to pass the proper secretions the better; softer waters, as those of rivers, and rain, seem better suited to draw out the substance of high dried malts, which retain many igneous particles best absorbed in a smooth vehicle.

In Staffordshire, they have a secret of fining ale in a very short time. Plot conjectures it to be done by adding alum, or vinegar, in the working.

Ale is prepared various ways, and of various ingredients, as of wheat, rye, millet, oats, barley, the berries of the quickbean, &c.

Some have found that the juice which bleeds from the birch or sycamore is of great use on this occasion, applied instead of water. It makes one bushel of malt go as far as four in the common way.

Some have a method of preparing ale, so that it will keep, carried to the East or West Indies. The secret is, by mashing twice with fresh malt; boiling twice; and, after shipping it, putting to every five gallons two new-laid eggs whole, to remain therein. It is said, that in a fortnight's time the shell shall be dissolved; and the eggs become like wind-eggs; and that afterwards the white would disappear and the yolk remain untouched. Ale.

The consumption of ale in these kingdoms is incredible. It was computed twenty years ago at the value of four millions yearly, including Great Britain and Ireland.

The duties on ale and beer make a principal branch of the revenue in Britain. They were first imposed by the 12th of Car. II. and have been continued by several subsequent acts of parliament to first Geo. III. which lays an additional duty of 3d. per barrel. In the whole, the brewer of ale and beer for sale shall pay 8s. for every barrel of either above 6s. a barrel; and for every barrel of 6s. or under, the sum of 1s. 4d.

Medicated Ales, those wherein medicinal herbs have been infused, or added during the fermentation.

Gill Ale, is that in which the dried leaves of gill or ground-ivy have been infused. It is esteemed abstersive and vulnerary, and consequently good in disorders of the breast and obstructions of the viscera.

Ale Conner, an officer in London, who inspects the measures used in public houses. There are four ale conners, who are all chosen by the liverymen in common hall in Midsummer day.

Alehouses must be licensed by justices of the peace, who take recognizances of the persons licensed, and of their sureties, viz. 10l. each, that they will not suffer unlawful gaming, nor other disorderly practices in their houses. Every person, excepting those who sell ale in fairs, neglecting to procure a license, is liable to a penalty of 40s. for the first offence, 4l. for the second, and 6l. for the third, with all costs. The license granted on the first of September, or within twenty days after, at a general meeting of the justices for the division to which he belongs, upon his producing a certificate to his character, unless, by living in a city or town corporate, this last circumstance is dispensed with, and continues in force for one year only. Alehouse keepers, selling ale in short measure, are liable to a penalty not exceeding 40s. and not less than 10s. and likewise to a fine of 10s. for permitting tippling, &c.

By 29th Geo. II. c. 12. persons keeping alehouses in Scotland shall be licensed as in England, and the justices there shall meet annually to license alehouses; on each of which licenses a fee of 1s. is payable to the clerk of the peace. Magistrates of royal boroughs shall meet yearly for the like purpose; but where there shall not be a sufficient number of magistrates to act in any royal borough, justices may grant licenses, to be in force for one year only. *Ibid.*

Persons in Scotland convicted of keeping unlicensed alehouses shall forfeit for the first offence 5s. for the second 10s. for the third 20s. and to be disqualified; and for every subsequent offence 40s. to be levied by distress and sale, one moiety to the informer, the other to the poor of the parish. Conviction to be intimated to the offender, and certified to the clerk of the peace, and recorded: but persons aggrieved may appeal to the quarter-sessions. *Ibid.*

Licenses for houses on the military roads in Scotland shall be issued on payment of 1s. only to the clerk of the peace: making out licenses before the same be stamped, is a penalty of 10l. and making them contrary

Ale ‖ Alectoromantia.

trary to the intention of this act, 5l. and the same shall be vacated, unless the duty and fine be paid, and the receipt produced, and license stamped. *Ibid.*

Ale-Silver, a tax paid annually to the lord-mayor of London by all who sell ale within the city.

ALEA, in Roman antiquity, denotes in general all manner of games of chance; but, in a more restricted sense, was used for a particular game played with dice and tables, not unlike our backgammon.

ALEANDER, Jerome, cardinal and archbishop of Brindisi, was born in 1480; and distinguished himself at the beginning of the reformation, by the opposition he made to Luther: for being sent into Germany as the pope's nuncio in 1519, he acted, as occasion served, in the character of both ambassador and doctor; and declaimed three hours together against Luther's doctrine before the diet at Worms, but could not prevent that celebrated reformer from being heard in that diet. He published several works, and died at Rome in 1542.

Aleander, *Jerome*, nephew of the former, a learned man of the seventeenth century, born in the principality of Friuli, of the same family with the preceding. When he went to Rome, he was employed as secretary under Cardinal Octavius Bandini, and discharged this office with great honour for almost twenty years. He afterwards, by the persuasion of Urban VIII. who had a great esteem for him, became secretary to Cardinal Barberini, whom he accompanied to Rome when he went there in the character of legate *à latere*, and in whose service he died in 1631. He was one of the first members of the academy of Humorists, wrote a learned treatise in Italian on the device of the society, and displayed his genius on many different subjects. Barberini gave him a magnificent funeral at the academy of Humorists; the academists carried his corpse to the grave; and Gaspar Simeonibus, one of the members, made his funeral oration.

ALECTO, one of the Furies, daughter of Acheron and Night, or, as others would have it, of Pluto and Proserpine.

ALECTORIA, a stone said to be formed in the gall-bladder of old cocks, to which the ancients ascribed many fabulous virtues. This is otherwise called *Alectorius lapis*, sometimes *Alectorolithos*, in English the *cock-stone*. The more modern naturalists hold the *alectorius lapis* to be originally swallowed down, not generated in, the stomach and gizzard of cocks and capons. It is known that many of the fowl kind make a practice of swallowing pebbles, as it is supposed to be of service in the business of trituration and digestion.

ALECTOROMANTIA, in *Antiquity*, a species of divination performed by means of a cock. This is otherwise called *Alectryomancy*; of which there appear to have been different species. But that most spoken of by authors was in the following manner: A circle was described on the ground, and divided into twenty-four equal portions; in each of these spaces was written one of the letters of the alphabet, and on each of the letters was laid a grain of wheat; after which, a cock being turned loose in the circle, particular notice was taken of the grains picked up by the cock, because the letters under them, being formed into a word, made the answer desired. It was thus, according to Zonoras, that Libanius and Jamblicus sought who should succeed the emperor Valens; and the cock eating the grains answering to the spaces ΘΕΟΔ, several whose names began with those letters, as Theodotus, Theodistes, Theodulus, &c. were put to death; which did not hinder, but promote, Theodosius to the succession. But the story, however current, is but ill supported: It has been called in question by some, and refuted by others, from the silence of Marcellinus, Socrates, and other historians of that time.

Alee ‖ Alembert.

ALEE, in the sea-language, a term only used when the wind, crossing or flanking the line of a ship's course, presses upon the masts and sails so as to make her incline to one side, which is called the lee-side: hence, when the helm is moved over to this side, it is said to be *alee*, or *hard a-lee*.

ALEGAMBE, Philip, a celebrated Jesuit, born at Brussels in 1592, distinguished himself by publishing a Bibliotheque of the writers of his order, and died at Rome in 1652.

ALEGRETTE, a small town of Portugal, in Alentejo, on the confines of Port Alegre, on the river Caja, which falls into the Guadiana, a little below Badajoz, near the frontiers of Spanish Estremadura. It is a very pretty town, and finely situated; seven miles south-east of Port Alegre, and thirty north of Elvas. W. Long. 5. 20. N. Lat. 39. 6.

ALEIUS campus, in *Ancient Geography*, a plain in Cilicia, on this side the river Pyramus, near the mountain Chimera, famous for Bellerophon's wandering and perishing there, after being thrown off Pegasus; which is the reason of the appellation.

ALEMANIA, or Allemania, in *Ancient Geography*, a name of Germany, but not known before the time of the Antonines, and then used only for a part. After the Marcomanni and their allies had removed from the Rhine, a rabble, or collection of people from all parts of Gaul, as the term *Alemanni* denotes, prompted either by levity or poverty, occupied the lands, called *Decumates* by Tacitus, because they held them on a tithe; now supposed to be the duchy of *Wirtemburg*. Such appear to have been the small beginnings of Alemania, which was in after-times greatly enlarged: but still it was considered as a distinct part; for Caracalla, who conquered the Alemanni, assumed the surname both of *Alemannicus* and *Germanicus*.

ALEMBDAR, an officer in the court of the Grand Signior, who bears the green standard of Mahomet when the sultan appears in public on any solemn occasion.

ALEMBERT, John le Rond d', an eminent French philosopher, was born at Paris in 1717. He derived the name of John le Rond from that of the church near which, after his birth, he was exposed as a foundling. His father, informed of this circumstance, listened to the voice of nature and duty, took measures for the proper education of his child, and for his future subsistence in a state of ease and independence.

He received his first education in the College of the Four Nations, among the Jansenists, where he gave early marks of capacity and genius. In the first year of his philosophical studies, he composed a Commentary on the Epistle of St Paul to the Romans. The Jansenists considered this production as an omen that portended to the party of Port-Royal a restoration to some

Alembert. some part of their ancient splendour, and hoped to find one day in M. d'Alembert a second Pascal. To render this resemblance more complete, they engaged their rising pupil in the study of the mathematics: but they soon perceived that his growing attachment to this science was likely to disappoint the hopes they had formed with respect to his future destination: they therefore endeavoured to divert him from this line; but their endeavours were fruitless.

At his leaving college, he found himself alone and unconnected with the world: and sought an asylum in the house of his *nurse*. He comforted himself with the hope, that his fortune, though not ample, would better the condition and subsistence of that family, which was the only one that he could consider as his own: Here, therefore, he took up his residence, resolving to apply himself entirely to the study of geometry: And here he lived, during the space of forty years, with the greatest simplicity, discovering the augmentation of his means only by increasing displays of his beneficence, concealing his growing reputation and celebrity from these honest people, and making their plain and uncouth manners the subject of good-natured pleasantry and philosophical observation. His good nurse perceived his ardent activity: heard him mentioned as the writer of many books; but never took it into her head that he was a great man, and rather beheld him with a kind of compassion. "*You will never*," said she to him one day, "*be any thing but a philosopher—and what is a philosopher?—a fool, who toils and plagues himself during his life, that people may talk of him when* HE IS NO MORE."

As M. d'Alembert's fortune did not far exceed the demands of necessity, his friends advised him to think of a profession that might enable him to augment it. He accordingly turned his views to the law, and took his degrees in that line: but soon abandoned this plan, and applied to the study of medicine. Geometry, however, was always drawing him back to his former pursuits; and after many ineffectual efforts to resist its attractions, he renounced all views of a lucrative profession, and gave himself over entirely to mathematics and poverty.

In the year 1741 he was admitted member of the Academy of Sciences: for which distinguished literary promotion, at such an early age, he had prepared the way by correcting the errors of a celebrated work *, which was deemed *classical* in France in the line of geometry. He afterwards set himself to examine, with deep attention and assiduity, what must be the motion of a body which passes from one fluid into another more dense, in a direction not perpendicular to the surface separating the two fluids. Every one knows the phenomenon which happens in this case, and which amuses children under the denomination of *Ducks and Drakes*; but M. d'Alembert was the first who explained it in a satisfactory and philosophical manner.

* The *Analyse demontrée* of F. Reman.

Two years after his election to a place in the academy, he published his Treatise on Dynamics. The new principle developed in this treatise consisted in establishing equality, at each instant, between the changes that the motion of a body has undergone, and the forces or powers which have been employed to produce them; or, to express the thing otherwise, in separating into *two parts* the action of the moving powers, and considering the *one* as producing alone the motion of the body in the second instant, and the *other* as employed to destroy that which it had in the first. Alembert.

So early as the year 1744, M. d'Alembert had applied this principle to the theory of the equilibrium, and the motion of fluids; and all the problems before solved by geometricians became, in some measure, its corollaries. The discovery of this new principle was followed by that of a new calculus, the first trials of which were published in a *Discourse on the general Theory of the Winds*, to which the prize-medal was adjudged by the academy of Berlin in the year 1746, and which was a new and brilliant addition to the fame of M. d'Alembert.

He availed himself of the favourable circumstance of the king of Prussia having just terminated a glorious campaign by an honourable peace, and in allusion to this dedicated his work to that prince in the three following Latin verses:

Hæc ego de ventis, dum ventorum ocyor alis,
Palantes agit Austriacos Fredericus, et orbi,
Insignis lauro, ramum prætendit olivæ.

Swifter than wind, while of the winds I write,
The foes of conquering Frederick speed their flight,
While laurel o'er the hero's temple bends
To the tir'd world the olive branch he sends.

This flattering dedication procured the philosopher a polite letter from Frederick, and a place among his literary friends.

In the year 1747 d'Alembert applied his new calculus of "Partial Differences" to the problem of vibrating chords, whose solution, as well as the theory of the oscillation of the air and the propagation of sound, had been given but incompletely by the geometricians who preceded him, and these were his masters or his rivals.

In the year 1749 he furnished a method of applying his principles to the motion of any body of a given figure; and he solved the problem of the precession of the equinoxes, determined its *quantity*, and explained the phenomenon of the nutation of the terrestrial axis discovered by Dr Bradley.

In 1752, M. d'Alembert published a treatise on the *Resistance of Fluids*, to which he gave the modest title of an *Essay*; but which contains a multitude of original ideas and new observations. About the same time he published, in the Memoirs of the Academy of Berlin, *Researches concerning the Integral Calculus*, which is greatly indebted to him for the rapid progress it has made in the present century.

While the studies of M. d'Alembert were confined to geometry, he was little known or celebrated in his native country. His connexions were limited to a small society of select friends: he had never seen any man in high office except Messrs d'Argenson. Satisfied with an income which furnished him with the necessaries of life, he did not aspire after opulence or honours, nor had they been hitherto bestowed upon him, as it is easier to confer them on those who solicit them than to look out for men who deserve them. His cheerful conversation, his smart and lively sallies, a happy knack at telling a story, a singular mixture of malice of speech with goodness of heart, and of delicacy

of wit with ſimplicity of manners, rendered him a pleaſing and intereſting companion, and his company conſequently was much ſought after in the faſhionable circles. His reputation, at length, made its way to the throne, and rendered him the object of royal attention and beneficence. He received alſo a penſion from government, which he owed to the friendſhip of Count d'Argenſon.

The tranquillity of M. d'Alembert was abated when his fame grew more extenſive, and when it was known beyond the circle of his friends, that a fine and enlightened taſte for literature and philoſophy accompanied his mathematical genius. Our author's eulogiſt aſcribes to envy, detraction, and to other motives equally ungenerous, all the diſapprobation, oppoſition, and cenſure that M. d'Alembert met with on account of the publication of the famous Encyclopedical Dictionary of Arts and Sciences, in conjunction with Diderot. None ſurely will refuſe the well-deſerved tribute of applauſe to the eminent diſplays of genius, judgement, and true literary taſte, with which M. d'Alembert has enriched the great work now mentioned. Among others, the Preliminary Diſcourſe he has affixed to it, concerning the riſe, progreſs, connections, and affinities of all the branches of human knowledge, is perhaps one of the firſt productions of which the philoſophy of the preſent age can boaſt, and will be regarded as a ſtriking ſpecimen of juſt arrangement and ſound criticiſm, and alſo as a model of accurate thinking and elegant writing.

Some time after this, D'Alembert publiſhed his Philoſophical, Hiſtorical, and Philological Miſcellanies. Theſe were followed by the Memoirs of Chriſtina queen of Sweden; in which M. d'Alembert ſhowed that he was acquainted with the natural rights of mankind, and was bold enough to aſſert them. His *Eſſay on the Intercourſe of Men of Letters with Perſons high in Rank and Office*, wounded the former to the quick, as it expoſed to the eyes of the public the ignominy of thoſe ſervile chains, which they feared to ſhake off, or were proud to wear. A lady of the court hearing one day the author accuſed of having exaggerated the deſpotiſm of the great, and the ſubmiſſion they require, anſwered ſlyly, *If he had conſulted me, I would have told him ſtill more of the matter.*

M. d'Alembert gave very elegant ſpecimens of his literary abilities in his tranſlations of ſome ſelect pieces of Tacitus. But theſe occupations did not divert him from his mathematical ſtudies: for about the ſame time he enriched the Encyclopédie with a multitude of excellent articles in that line, and compoſed his *Reſearches on ſeveral important Points of the Syſtem of the World*, in which he carried to a higher degree of perfection the ſolution of the problem of the perturbations of the planets, that had ſeveral years before been preſented to the Academy.

In 1759 he publiſhed his *Elements of Philoſophy*: a work extolled as remarkable for its preciſion and perſpicuity; in which, however, are ſome tenets relative both to metaphyſics and moral ſcience, that are far from being admiſſible.

The reſentment that was kindled (and the diſputes that followed it) by the article *Geneva*, inſerted in the Encyclopédie, are well known. M. d'Alembert did not leave this field of controverſy with flying colours. Voltaire was an auxiliary in the conteſt: but, as, in point of candour and decency, he had no reputation to loſe; and as he weakened the blows of his enemies, by throwing both them and the ſpectators into fits of laughter, the iſſue of the war gave him little uneaſineſs. It fell more heavily on D'Alembert; and expoſed him, even at home, to much contradiction and oppoſition.

It was on this occaſion that the late king of Pruſſia offered him an honourable aſylum at his court, and the place of preſident of his academy; and was not offended at his refuſal of theſe diſtinctions, but cultivated an intimate friendſhip with him during the reſt of his life. He had refuſed, ſome time before this, a propoſal made by the empreſs of Ruſſia to intruſt him with the education of the grand duke;—a propoſal accompanied with all the flattering offers that could tempt a man ambitious of titles, or deſirous of making an ample fortune: but the objects of his ambition were tranquillity and ſtudy.

In the year 1765, he publiſhed his *Diſſertation on the Deſtruction of the Jeſuits*. This piece drew upon him a ſwarm of adverſaries, who confirmed the merit and credit of his work by their manner of attacking it.

Beſide the works already mentioned, he publiſhed nine volumes of memoirs and treatiſes under the title of *Opuſcules*; in which he has ſolved a multitude of problems relative to aſtronomy, mathematics, and natural philoſophy; of which our panegyriſt gives a particular account, more eſpecially of thoſe which exhibit new ſubjects, or new methods of inveſtigation.

He publiſhed alſo *Elements of Muſic*; and rendered, at length, the ſyſtem of Rameau intelligible; but he did not think the mathematical theory of the ſonorous body ſufficient to account for the rules of that art. He was always fond of muſic; which, on the one hand, is connected with the moſt ſubtile and learned reſearches of rational mechanics; while, on the other, its power over the ſenſes and the ſoul exhibits to philoſophers phenomena no leſs ſingular, and ſtill more inexplicable.

In the year 1772, he was choſen ſecretary to the French academy. He formed, ſoon after this preferment, the deſign of writing the lives of all the deceaſed academicians from 1700 to 1772; and in the ſpace of three years he executed this deſign, by compoſing 70 eulogies.

M. d'Alembert died on the 29th of October 1783. There were many amiable lines of candour, modeſty, diſintereſtedneſs, and beneficence, in his moral character: which are deſcribed, with a diffuſive detail, in his *eloge*, by M. Condorcet, *Hiſt. de l'Acad. Royale des Sciences*, 1783.

ALEMBIC, a chemical veſſel uſually made of glaſs or copper, formerly uſed for diſtillation. The bottom part, which contained the ſubject for diſtillation, is called, from its ſhape, the *cucurbit*; the upper part, which receives and condenſes the ſteam, is called the *head*, the beak of which is fitted into the neck of a receiver. Retorts, and the common *worm ſtill*, are now more generally employed.

ALEMBROTH, in the writings of the alchemiſts, a word uſed for a ſort of fixed alkaline ſalt, which had the power of the famous alkaheſt, in diſſolving bodies, opening the pores of moſt or all known ſubſtances, and

Alenio of Aleppo.

thence, as well as by deſtroying ſulphurs, promoting the ſeparation of metals from their ores.—It is alſo uſed for a compound of corroſive mercury and ſal ammoniac.

ALENIO, JULIUS, a Jeſuit, born at Breſcia in the republic of Venice. He travelled into the eaſtern countries; and arrived at Macao in 1610, where he taught mathematics. From thence he went to the empire of China, where he continued to propagate the Chriſtian religion for thirty-ſix years. He was the firſt who planted the faith in the province of Xanſi, and he built ſeveral churches in the province of Fokien. He died in Auguſt 1649, leaving behind him ſeveral works in the Chineſe language.

ALENTEJO, a province of Portugal, between the rivers Tajo and Guadiana: the ſoil is very fertile, and the inhabitants laborious and induſtrious. The principal town is Evora.

ALENZON, a town of France, the capital of the department of Orne, in Lower Normandy. It is ſurrounded with good walls, and flanked with towers. The caſtle was formerly a place of great conſequence, and has held out long ſieges. It has but one pariſh-church, which has a bold and noble front. Among the nunneries, that of St Clair is moſt remarkable. It is ſeated on the river Sarte, in a vaſt open plain, which produces all ſorts of corn and fruit. Near it there are quarries of ſtone fit for building, wherein are found a ſort like Briſtol ſtones. The trade of Alenzon is in linen, lace, ſtuffs, and leather. It is 20 miles north of Mons, 63 ſouth-by-weſt of Rouen, and 88 ſouth-weſt of Paris. Long. 0. 10. N. Lat. 48. 25.

ALEPPO, or HALAB, the capital of a pachalic, and of all Syria, and the ordinary reſidence of the pacha, is ſituated in the vaſt plain which extends from the Orontes to the Euphrates, and which towards the ſouth terminates in the deſert. It is built on eight hills or eminences, on the higheſt of which the caſtle is erected, and is ſuppoſed to be the ancient Beræa. This mount is of a conic form, and ſeems in a great meaſure to be raiſed with the earth thrown up out of a deep broad ditch which ſurrounds it. The ſuburbs to the north-north-eaſt are next in height to this, and thoſe to the weſt-ſouth-weſt are much lower than the parts adjacent, and than any other part of the city. The houſes are large and commodious, having terraces on their tops, and generally ſky-lights in form of a dome to let the light into the rooms, which from their loftineſs, the gilding on the window ſhutters, cupboard doors, &c. have at firſt entrance a very grand and agreeable effect. They are all ſo equal in height, that there are ſeldom any ſteps to aſcend or deſcend in going from one houſe to another; while ſeveral large vaulted ſtreets increaſe the facility of communication, by affording a paſſage to every part of the city free from the embarraſſment of the open ſtreets. They are carefully paved; have gutters and a foot-pavement on each ſide; and the middle of the ſtreet is laid with brick, the ſmall end upwards, for the convenience of the horſes. There is alſo a cleanlineſs obſerved here unknown to the other cities of Turkey, and which is not attended with the trouble of our ſcavengers, there being aſs-drivers who go about the city and take up the rubbiſh and duſt, which each inhabitant is obliged to ſweep together; and though the heat of the climate renders this labour more eaſy, the ſame heat obliges them to greater cleanlineſs in order to preſerve the ſalubrity of the air. Aleppo

The moſques in Aleppo are numerous, and ſome few of them magnificent. Before each of them is an area, with a fountain in the middle, deſigned for ablutions before prayers; and behind ſome of the larger there are little gardens. There are many large khans, or caravanſeras, conſiſting of a capacious ſquare, on all ſides of which are a number of rooms, built on a ground-floor, uſed occaſionally for chambers, warehouſes, or ſtables. Above ſtairs there is a colonnade or gallery on every ſide, in which are the doors of a number of ſmall rooms, wherein the merchants, as well ſtrangers as natives, tranſact moſt of their buſineſs.

The bazars or market-places are long covered narrow ſtreets, on each ſide of which are a great number of ſmall ſhops, juſt ſufficient to hold the tradeſman and his goods, the buyer being obliged to ſtand without. Each ſeparate branch of buſineſs has a particular bazar, which is locked up, as well as the ſtreets, an hour and a half after ſunſet: but the locks are of wood, though the doors are caſed with iron. The ſlaughter houſes are in the ſuburbs, open to the fields. The tanners have a khan to work in near the river. To the ſouthward in the ſuburbs they burn lime; and a little beyond that there is a village where they make ropes and catgut. On the oppoſite ſide of the river, to the weſtward, there is a glaſs-houſe, where they make a coarſe white glaſs, in the winter only; for the greateſt part of this manufacture is brought from a village 35 miles weſtward.

The ſituation of Aleppo, beſide the advantage of a rich and fruitful ſoil, poſſeſſes alſo that of a ſtream of freſh water, which never becomes dry. This rivulet, which is about as large as that of the Gobelins at Paris, or the New River near London, riſes in the mountains of Aentab, and terminates ſix leagues below Aleppo, in a moraſs full of wild boars and pelicans. Near Aleppo, its banks, inſtead of the naked rocks, which line them in the upper part of its courſe, are covered with a fertile earth, and laid out in gardens, or rather orchards, which, in a hot country, and eſpecially in Turkey, cannot but be delightful. The city is in itſelf one of the moſt agreeable in Syria, and is perhaps the cleaneſt and beſt built of any in Turkey. Or whatever ſide it is approached, its numerous minarets and domes preſent an agreeable proſpect to the eye, fatigued with the continued ſameneſs of the brown and parched plains. In the centre is an artificial mountain ſurrounded by a dry ditch, on which is a ruinous fortreſs. From hence we have a fine proſpect of the whole city, and to the north diſcover the ſnowy tops of the mountains of Bailan; and on the weſt, thoſe which ſeparate the Orontes from the ſea; while to the ſouth and eaſt, the eye can diſcern as far as the Euphrates. In the time of Omar, this caſtle ſtopped the progreſs of the Arabs for ſeveral months, and was at laſt taken by treachery, but at preſent would not be able to reſiſt the feebleſt aſſault. Its ſlight wall, low, and without a buttreſs, is in ruins; its little old towers are in no better condition; and it has not four cannon fit for ſervice, not excepting a culverine nine feet long, taken from the Perſians at the ſiege of Baſſora. Three hundred and fifty Janizaries, who

ſhould

Aleppo. should form the garriſon, are buſy in their ſhops, and the aga ſcarcely finds room in it to lodge his retinue. It is remarkable that this aga is named immediately by the Porte, which, ever ſuſpicious, divides as much as poſſible the different offices. Within the walls of the caſtle is a well, which, by means of a ſubterraneous communication, derives its water from a ſpring a league and a quarter diſtant. In the environs of the city, we find a number of large ſquare ſtones, on the top of which is a turban of ſtone, which are ſo many tombs. There are many riſing grounds round it, which, in caſe of a ſiege, would greatly facilitate the approaches of the aſſailants. Such, among others, is that on which the houſe of the Derviches ſtands, and which commands the canal and the rivulet: Aleppo, therefore, cannot be eſteemed a place of importance in war, though it be the key of Syria to the north; but, conſidered as a commercial city, it has a different appearance. It is the emporium of Armenia and Diarbekar; ſends caravans to Bagdad and into Perſia, and communicates between the Perſian gulf and India by Baſſora, with Egypt and Mecca by Damaſcus, and with Europe by Scanderoon (Alexandretta) and Latakia. Commerce is there principally carried on by barter. The chief commodities are raw or ſpun cottons, clumſy linens fabricated in the villages, ſilk ſtuffs manufactured in the city, copper, *bourres* (coarſe cloths) like thoſe of Rouen, goats hair brought from Natolia, the gall nuts of the Kourdeſtan, the merchandiſe of India, ſuch as ſhawls and muſlins, and piſtachio nuts of the growth of the neighbourhood. The articles ſupplied by Europe are the Languedoc cloths, cochineal, indigo, ſugar, and ſome other groceries. The coffee of America, though prohibited, is introduced, and ſerves to mix with that of Moka. The French have at Aleppo a conſul and ſeven counting-houſes; the Engliſh and the Venetians two, and the merchants of Leghorn and Holland one. The emperor appointed a conſul there in 1784, in the perſon of a rice Jew merchant, who ſhaved his beard to aſſume the uniform and the ſword. Ruſſia has alſo ſent one very lately. Aleppo is not exceeded in extent by any city in Turkey, except Conſtantinople and Cairo, and perhaps Smyrna. The number of inhabitants has been computed at 200,000; but in theſe calculations certainty is impoſſible. However, if we obſerve that this city is not larger than Nantes or Marſeilles, and that the houſes conſiſt only of one ſtory, we ſhall perhaps not think it probable they exceed 100,000. The people of this city, both Turks and Chriſtians, are with reaſon eſteemed the moſt civilized in all Turkey; and the European merchants nowhere enjoy ſo much liberty, or are treated with ſo much reſpect.

The air of Aleppo is very dry and piercing, but at the ſame time very ſalubrious for all who are not troubled with aſthmatic complaints. The city, however, and the environs, are ſubject to a ſingular endemial diſorder, which is called the ringworm or pimple of Aleppo: it is in fact a pimple which is at firſt inflammatory, and at length becomes an ulcer of the ſize of the nail. The uſual duration of this ulcer is one year; it commonly fixes on the face, and leaves a ſcar which diſfigures almoſt all the inhabitants. It is alleged that every ſtranger who reſides there three months is attacked with it; experience has taught that the beſt mode of treatment is to make uſe of no remedy. No reaſon is aſſigned for this malady: but M. Volney ſuſpects it proceeds from the quality of the water, as it is likewiſe frequent in the neighbouring villages, in ſome parts of Diarbekar, and even in certain diſtricts near Damaſcus, where the ſoil and the water have the ſame appearances. Of the Chriſtian inhabitants the greater number are Greeks, next to them the Armenians, then the Syrians, and laſtly the Maronites; each of whom have a church in the city called *Judida*; in which quarter, and the parts adjacent, moſt of them reſide. The common language is the vulgar Arabic, but the Turks of condition uſe the Turkiſh. Moſt of the Armenians can ſpeak the Armenian, ſome few Syrians underſtand Syriac, and many of the Jews Hebrew; but ſcarce one of the Greeks underſtands a word of Greek. The people in general are of a middle ſtature, and tolerably well proportioned; but they ſeem neither vigorous nor active. Both ſexes are handſome when young: but the beard ſoon diſfigures the men: and the women, as they come early to maturity, alſo fade very ſoon; females are generally married from 14 to 18 years of age, and many under 14. The people of rank here are polite and affable, making allowances for that ſuperiority which the Mahometan religion inſtructs its votaries to aſſume over all who hold a different faith. Their bread is generally of wheat flour made into thin cakes, but very ill prepared, and is generally eaten as ſoon as it comes out of the oven. The principal people have ſmall loaves of a finer flour, which are well fermented and baked. Beſides theſe, there is a variety of biſcuits, moſt of which are ſtrewed on the top with ſome kind of ſeeds. The Europeans have very good bread, baked and prepared in the French manner. All the inhabitants of both ſexes ſmoke tobacco to great exceſs; even the very ſervants have almoſt conſtantly a pipe in their mouths. Coaches or carriages are not uſed here; therefore perſons of quality ride on horſeback in the city, with a number of ſervants walking before them, according to their rank: ladies of the firſt diſtinction are even compelled to walk on foot in the city, or to any place at a moderate diſtance; in longer journeys they are carried by mules, in a kind of couch cloſe covered up. There are a number of public bagnios in this city, which are uſed by people of all ranks, except thoſe of the higheſt diſtinction, who commonly have baths and every other convenience in their own houſes. Aleppo is 70 miles eaſt of Scanderoon, on the ſea-coaſt, and 175 north-by-eaſt of Damaſcus. E. Long. 37. 40. N. Lat. 36. 12.

Aleppo

Aleppo, The Pachalic of, one of the five governments into which Syria is divided. It comprehends the country extending from the Euphrates to the Mediterranean, between two lines, one drawn from Scanderoon to Beer, along the mountains: the other from Beles to the ſea, by Mara and the bridge of Shoger. This ſpace principally conſiſts of two plains; that of Antioch to the weſt, and that of Aleppo to the eaſt: the north and the ſea-coaſt are occupied by conſiderably high mountains, known to the ancients by the names of Amanus and of Rhoſus. In general, the ſoil of this government is fat and loamy. The loſty and vigorous plants which ſhoot up everywhere after the winter rains prove its fertility, but its actual fruitfulneſs is but little. The greateſt part of the lands lie waſte;

Aleppo. waſte; ſcarcely can we trace any marks of cultivation in the environs of the towns and villages. Its principal produce conſiſts in wheat, barley, and cotton, which are found eſpecially in the flat country. In the mountains, they rather chooſe to cultivate the vine, mulberry, olive, and fig trees. The ſides of the hills towards the ſea-coaſt are appropriated to tobacco, and the territory of Aleppo to piſtachios. The paſturage is not to be reckoned, becauſe that is abandoned to the wandering hordes of the Turcomans and Curds.

In the greater part of the pachalics the pacha is, as his title imports, at once the viceroy and farmer-general of the country; but in that of Aleppo he does not poſſeſs the later office. This the Porte has beſtowed on a *mehaſſel* or collector, who is immediately accountable for what he receives. His leaſe is only for a year. The preſent rent of his farm is 800 purſes (above 40,000l.); but to this muſt be added the price of the *tabouches* (Turkiſh ſlippers), or a preſent of three or four thouſand pounds, to purchaſe the favour of the vizier, and men in office. For theſe two ſums the farmer receives all the duties of the government; which are, firſt, The produce of import and export duties on merchandiſe coming from Europe, India, and Conſtantinople, and on that exported in exchange. Secondly. The taxes paid by the herds of cattle brought every year by the Turcomans and Curds from Armenia and Diarbekar, to be ſold in Syria. Thirdly, The fifth of the ſalt-works of Djeboul. And laſtly, The miri, or land-tax. Theſe united may produce about 60,000l.

The pacha, deprived of this lucrative branch of the adminiſtration, receives a fixed allowance of about 8300l. This revenue has always been inadequate to the expences; for beſides the troops he is obliged to maintain, and the reparation of the highways and fortreſſes, the expences of which he is obliged to defray, he is under the neceſſity of making large preſents to the miniſters, in order to keep his place; but the Porte adds to the account the contributions he may levy on the Curds and Turcomans, and his extortions from the villages and individuals; nor do the pachas come ſhort of this calculation. Abdi Pacha, who governed 13 or 14 years ago, carried off, at the end of 15 months, upwards of 160,000l. by laying under contribution every trade, even the very cleaners of tobacco-pipes; and very lately another of the ſame name has been obliged to fly for ſimilar oppreſſions. The former was rewarded by the divan with the command of an army againſt the Ruſſians; but if the latter has not enriched himſelf, he will be ſtrangled as an extortioner. Such is the ordinary progreſs of affairs in Turkey!

In conſequence of ſuch wretched government, the greater part of the pachalics in the empire are impoveriſhed and laid waſte. This is the caſe in particular with that of Aleppo. In the ancient *defiars*, or regiſters of impoſts, upwards of 3200 villages were reckoned; but at preſent the collector can ſcarcely find 400. Such of our merchants as have reſided there 20 years, have themſelves ſeen the greater part of the environs of Aleppo become depopulated. The traveller meets with nothing but houſes in ruins, ciſterns rendered uſeleſs, and fields abandoned. Thoſe who cultivated them have fled into the towns, where the population is abſorbed, but where at leaſt the individual conceals himſelf among the crowd from the rapacious hand of deſpotiſm.

Aleria Alet.

ALERIA, ALALIA, or ALARIA, in *Ancient Geography*, a town of Corſica, ſituated near the middle of the eaſt ſide of the iſland, on an eminence, near the mouth of the river Rotanus mentioned by Ptolemy; built by the Phocæans (Diodorus Siculus). Afterwards Sylla led a colony thither. It is now in ruins, and called *Aleria Diſtructa*.

ALES, ALEXANDER, a celebrated divine of the confeſſion of Augſburg, was born at Edinburgh the 23d of April 1500. He ſoon made a conſiderable progreſs in ſchool divinity, and entered the liſts very early againſt Luther, this being then the great controverſy in faſhion, and the grand field wherein all authors, young and old, uſed to diſplay their abilities. Soon after, he had a ſhare in the diſpute which Patrick Hamilton maintained againſt the eccleſiaſtics, in favour of the new faith he had imbibed at Marpurg. He endeavoured to bring him back to the Catholic religion; but this he could not effect, and even began himſelf to doubt about his own religion, being much affected by the diſcourſe of this gentleman, and ſtill more by the conſtancy he ſhowed at the ſtake, where David Beaton, archbiſhop of St Andrew's, cauſed him to be burnt. Beginning thus to waver, he was himſelf perſecuted with ſo much violence, that he was obliged to retire into Germany, where he became at length a perfect convert to the Proteſtant religion. The change of religion which happened in England after the marriage of Henry VIII. with Anna Bullen, induced Ales to go to London in 1535. He was highly eſteemed by Cranmer archbiſhop of Canterbury, Latimer, and Thomas Cromwell, who were at that time in high favour with the king. Upon the fall of theſe favourites, he was obliged to return to Germany; where the elector of Brandenburg appointed him profeſſor of divinity at Frankfort upon the Oder, in 1540. But leaving this place upon ſome diſguſt, he returned to Leipſic, where he was choſen profeſſor of divinity, and died in March 1565. He wrote a Commentary on St John, on the Epiſtles to Timothy, and on the Pſalms. &c.

ALESA, ALÆSA, or HALESA, in *Ancient Geography*, a town of Sicily, on the Tuſcan ſea, built, according to Diodorus Siculus, by Archonides of Herbita, in the ſecond year of the 94th Olympiad, or 403 years before Chriſt; ſituated on an eminence about a mile from the ſea: now in ruins. It enjoyed immunity from taxes under the Romans (Diodorus, Cicero). The inhabitants were called *Haleſini* (Cicero, Pliny); alſo *Aleſini*, and *Alæſini*.

ALESHAM, a ſmall neat town in Norfolk. It is 15 miles north of Norwich, and 121 north-eaſt by north of London. E. Long. 0. 30. N. Lat. 52. 53. The town conſiſts of about 400 houſes.

ALESIA, in *Ancient Geography*, called *Alexia* by Livy and others; a town of the Mandubii, a people of Celtic Gaul; ſituated, according to Cæſar, on a very high hill, whoſe foot was waſhed on two ſides by two rivers. The town was of ſuch antiquity, that Diodorus Siculus relates it was built by Hercules. It is ſuppoſed to be the city of *Aliſe*, in the duchy of Burgundy, not far from Dijon.

ALET, a town of France, in the department of the Aude,

Aletris || Alexander.

Aude, and district of Limoux, at the foot of the Pyrenees. It is remarkable for its baths, and for the grains of gold and silver found in the stream which runs from the Pyrenean mountains, at the foot of which it stands. It is seated on the river Aude, 15 miles south of Carcassone, and 37 north-west of Narbonne. E. Long. 2. 5. N. Lat. 42. 59.

ALETRIS. See BOTANY *Index*.

ALETUM, or ALETA, in *Ancient Geography*, a town of Celtic Gaul, now extinct. From its ruins arose St Malo in Brittany, at the distance of a mile. Its ruins are called *Guich Aleth* in the British.

ALEURITES. See BOTANY *Index*.

ALEUROMANCY, the same with what was otherwise called *aphtomantia*, and *crithomantia*, and means an ancient kind of divination performed by means of meal or flower.

ALEUTIAN, or ALEUTSKY ISLANDS, a group or chain of islands on the north-east side of Kamtschatka, and near the continent of America, which are subject to Russia. Part of these islands were discovered by Behring in the year 1741, and the rest at different periods since that time. Captain Cook visited these islands in 1778, and directed his researches and observations to a survey of them and of the adjacent coasts of Asia and America. On the Aleutian islands and the neighbouring coast, the Russians have formed numerous establishments for the support of the fur-trade, which is one of the most advantageous commercial concerns to the Russian empire. Captain Billings, who was sent out by the late empress Catharine to make discoveries in the north-east sea, explored, in the summer 1790, the whole chain of these islands. They seem to be of volcanic origin; have no wood, but what floats from sea; and lie between the 51st and the 56th degrees N. Lat. and the 164th and the 197th degrees of E. Long.

ALEXANDER THE GREAT, king of Macedonia. His father Philip laid the plan of that extensive empire, which his son afterwards completed. Philip, having made himself master of Greece, began to cast his eyes upon Persia, with a view to retaliate upon that haughty empire the injuries of former times. It was the popular topic of the day. But this prince was cut off in the midst of his enterprise. Such, however, was the influence of Alexander in the assembly of the Grecian states, that he was created general of their combined forces in the room of his father. Having made every needful preparation, at the head of a veteran army he invaded Asia. The lieutenants of Darius, who was then king of Persia, opposed him at the river Granicus, where Alexander obtained a complete victory, after which he pursued his march through Asia. At Issus, near Scanderoon, he was met by Darius in person, at the head of a prodigious army. Here he obtained a second victory; and took the camp of Darius, together with his family, whom he treated with the utmost humanity. Contrary to all the maxims of war, instead of pursuing Darius, he made an excursion into Egypt; and, as far as appears, through no better motives than those of vanity. Here he was acknowledged to be the son of Jupiter Ammon. In the mean time Darius recruited his strength, and got together an army superior to what he brought into the plain of Issus.

Alexander having finished his Egyptian expedition, traversed Asia, and passed the Euphrates. At Arbela, a town in Assyria, he met Darius. Here a decisive battle was fought, which put all Persia into the hands of Alexander. His ambition not being satisfied with the conquest of that vast country, he projected an expedition into India. Here he met with great opposition from Porus, a gallant prince, whom in the end he reduced. Beyond the Ganges lay a country still unsubdued. He notified it to his army, that he proposed to pass the river. But these veterans, harassed with their fatigues, and seeing no end of their labour, mutinied, and refused to march further. The disappointed chief was therefore obliged to return. At Babylon he proposed to receive ambassadors, appoint governors, and settle his vast monarchy; but his excesses put an end to his life in the midst of his designs, and in the flower of his age. Alexander

The character of this hero is so familiar to every body, that it is almost needless labour to draw it. All the world knows, says Mr Bayle, that it was equally composed of very great virtues and very great vices. He had no mediocrity in any thing but his stature: in his other properties, whether good or bad, he was all extremes. His ambition rose even to madness. His father was not at all mistaken in supposing the bounds of Macedon too small for his son: for how could Macedon bound the ambition of a man, who reckoned the whole world too small a dominion? He wept at hearing the philosopher Anaxarchus say, that there was an infinite number of worlds: his tears were owing to his despair of conquering them all, since he had not yet been able to conquer one. Livy, in a short digression, has attempted to inquire into the events which might have happened, if Alexander, after the conquest of Asia, had brought his arms into Italy? Doubtless things might have taken a very different turn with him; and all the grand projects, which succeeded so well against an effeminate Persian monarch, might easily have miscarried if he had had to do with rough hardy Roman armies. And yet the vast aims of this mighty conqueror, if seen under another point of view, may appear to have been confined in a very narrow compass; since, as we are told, the utmost wish of that great heart, for which the whole earth was not big enough, was, after all, to be praised by the Athenians: for it is related, that the difficulties which he encountered in order to pass the Hydaspes, forced him to cry out, "O Athenians, could you believe to what dangers I expose myself for the sake of being celebrated by you?" But Bayle affirms, that this was quite consistent with the vast unbounded extent of his ambition, as he wanted to make all future time his own, and be an object of admiration to the latest posterity; yet did not expect this from the conquest of worlds, but from books. He was perfectly in the right, says Bayle; "for if Greece had not furnished him with good writers, he would long ago have been as much forgotten as the kings who reigned in Macedon before Amphitryon."

Alexander has been praised upon the score of continency, yet his life could not surely be quite regular in that respect. Indeed, the fire of his early youth appeared so cold towards women, that his mother suspected.

Alexander. pected him to be impotent; and, to satisfy herself in this point, did, with the consent of Philip, procure a very handsome courtezan to lie with him, whose caresses, however, were all to no purpose. His behaviour afterwards to the Persian captives shows him to have had a great command over himself in this particular. The wife of Darius was a finished beauty; her daughters likewise were all beauties; yet this young prince, who had them in his power, not only bestowed on them all the honours due to their high rank, but managed their reputation with the utmost delicacy. They were kept as in a cloister concealed from the world, and secured from the reach of every dishonourable (not only attack, but) imputation. He did not give the least handle to scandal, either by his visits, his looks, or his words: and for other Persian dames his prisoners, equally beautiful in face and shape, he contented himself with saying gayly, that they gave indeed much pain to his eyes. The amazon Thalestris could not obtain from him a compliance with her gallant request till after a delay of thirteen days. In the mean time, what are we to conclude from his causing his favourite mistress Pancaste to be drawn naked by Apelles, though it is true he gave her to the painter, who fell in love with her? What of that immoderate love of boys, which Athenæus relates of him? What of that prodigious number of wives and concubines which he kept?

His excesses with regard to wine were notorious, and beyond all imagination; and he committed, when drunk, a thousand extravagances. It was owing to wine, that he killed Clitus who saved his life, and burnt Persepolis, one of the most beautiful cities of the East: he did this last indeed at the instigation of the courtezan Thaïs; but this circumstance made it only the more heinous. It is generally believed, that he died by drinking immoderately: and even Plutarch, who affects to contradict it, owns that he did nothing but drink the whole day he was taken ill.

In short, to sum up the character of this prince, we cannot be of opinion, that his good qualities did in anywise compensate for his bad ones. Heroes make a noise: their actions glare, and strike the senses forcibly; while the infinite destruction and misery they occasion lie more in the shade, and out of sight. One good legislator is worth all the heroes that ever did or will exist. See MACEDON.

ALEXANDER AB ALEXANDRO, a Neapolitan lawyer, of great learning, who flourished toward the end of the 15th and beginning of the 16th century. He followed the profession of the law first at Naples, afterwards at Rome: but he devoted all the time he could spare to the study of polite literature; and at length he entirely left the bar, that he might lead a more easy and agreeable life with the Muses. The particulars of his life are to be gathered from his work entitled "Dies Geniales:" We are there informed, that he lodged at Rome, in a house that was haunted; and he relates many surprising particulars about the ghost. He says also, that when he was very young, he went to the lectures of Philelphus, who explained at Rome the Tusculan questions of Cicero; he was there also when Nicholas Perot and Domitius Calderinus read their lectures upon Martial. The particular time when he died is not known; but he was buried in the monastery of the Olivets. Tiraquea wrote a learned commentary upon his work, which was printed at Lyons in Alexander 1587, and reprinted at Leyden, in 1673, with the notes of Dennis Godfrey, Christopher Colerus, and Nicholas Mercerus.

ALEXANDER, *Neckham*, an eminent English writer in the 12th and 13th centuries, born at St Alban's in Hertfordshire. In 1215 he was made abbot of Exeter, and died in 1227. He wrote several works, which were never published; but they are to be found in manuscript in the libraries of England and other countries.

ALEXANDER, *Noel*, an indefatigable writer of the 17th century, born at Rouen in Normandy, 1639. After finishing his studies at Rouen, he entered into the order of Dominican friars, and was professed there in 1655. Soon after he went to Paris, to go through a course of philosophy and divinity in the great convent, where he distinguished himself so, that he was appointed to teach philosophy there, which he did for 12 years. M. Colbert showed him many marks of his esteem; and being determined to omit nothing to perfect the education of his son, afterwards archbishop of Rouen, he formed an assembly of the most learned persons, whose conferences upon ecclesiastical history might be of advantage to him. Father Alexander was invited to this assembly, where he exerted himself with so much genius and ability, that he gained the particular friendship of young Colbert, who showed him the utmost regard as long as he lived. These conferences gave rise to Alexander's design of writing an ecclesiastical history; for, being desired to reduce what was material in these conferences to writing, he did it with so much accuracy, that the learned men who composed this assembly, advised him to undertake a complete body of church history. This he executed with great assiduity, collecting and digesting the materials himself, and writing even the tables with his own hand. He at last completed his work in 1686. Towards the latter part of his life, he was afflicted with the loss of his sight; a most inexpressible misfortune to one whose whole pleasure was in study, yet he bore it with great patience and resignation. He died merely of a decay of nature, 1724, in the 86th year of his age.

ALEXANDER SEVERUS, emperor of Rome, succeeded Heliogabalus about A. D. 222, when but 16 years of age. His mother's name was Mammæa, and by her advice he in a great measure regulated his conduct. He applied himself to the reformation of abuses, the state having been greatly disordered by the vicious conduct of his predecessor; he was a most strict lover of justice, an encourager of learning and learned men, and favourable to the Christians. He made a successful expedition against the Persians; but endeavouring to reform his troops, who had grown very licentious under the late bad government, they murdered him at the instigation of Maximinus, in the 29th year of his age, together with his mother, A. D. 235.

ALEXANDER VI. *Pope*, had four bastards when he was cardinal, for one of which he had so great affection, that he stuck at nothing to raise him. Designing to poison some cardinals, he was poisoned himself, A. D. 1503. See BORGIA.

ALEXANDER VII. *Pope*. See CHIGI.

ALEXANDER bishop of Lincoln, in the reigns of Henry I. and Stephen, was a Norman by birth, and nephew

Alexander. phew of the famous Roger, biſhop of Saliſbury, who firſt made him archdeacon of Saliſbury, and afterwards, by his intereſt with the king, raiſed him to the mitre. Alexander was conſecrated at Canterbury, July 22. 1123. Having received his education under his uncle the biſhop of Saliſbury, and been accuſtomed to a ſplendid way of living, he affected ſhow and ſtate more than was ſuitable to his character, or conſiſtent with his fortunes. This failing excepted, he was a man worthy of honour, and every way qualified for his ſtation. The year after his conſecration, his cathedral church at Lincoln having been accidentally burnt down, he rebuilt it, and ſecured it againſt the like accident for the future by a ſtone roof. This prelate increaſed the number of prebends in his church, and augmented its revenues with ſeveral manors and eſtates. In imitation of the barons and ſome of the biſhops, particularly his uncle the biſhop of Saliſbury, he built three caſtles; one at Banbury, another at Sleaford, and a third at Newark. He likewiſe founded two monaſteries; one at Haverholm, for regular canons and nuns together, the other at Tame for white friars. He went twice to Rome in the years 1142 and 1144. The firſt time, he came back in quality of the pope's legate, for the calling a ſynod, in which he publiſhed ſeveral wholeſome and neceſſary canons. In Auguſt 1147, he took a third journey to the pope, who was then in France; where he fell ſick through the exceſſive heat of the weather, and returning with great difficulty to England, where he died in the 24th year of his prelacy.

ALEXANDER, *William*, earl of Stirling, an eminent Scots ſtateſman and poet in the reigns of James VI. and Charles I. who, after travelling with the duke of Argyle as his tutor or companion, wrote a poetical complaint of his unſucceſsful love of ſome beauty, under the title of *Aurora*. He then removed to the court of James VI. where he applied to the more ſolid parts of poetry, forming himſelf upon the plan of the Greek and Roman tragedians. In 1607, he publiſhed ſome dramatic performances, entitled *The Monarchic Tragedies*, dedicated to King James; who was ſo well pleaſed with them, as to call him his philoſophical poet. After this, he is ſaid to have written *A Supplement* to complete the third part of Sir Philip Sidney's Arcadia; and in 1613, he produced a poem called *Doomſday*, or *the Great Day of Judgment*. He was made gentleman uſher to Prince Charles, and maſter of the requeſts; was knighted; and obtained a grant of Nova Scotia, where he projected the ſettlement of a colony, but afterwards ſold it to the French. In 1626, he was made ſecretary of ſtate for Scotland; was created firſt viſcount, and then earl, of Stirling; and died in 1640.

ALEXANDER I. *St*, whom St Irenæus reckons the fifth biſhop of Rome, ſucceeded St Evariſtus in the year 109, and died in the year 119. There is no account of his life; and the epiſtles which are attributed to him are ſuppoſititious.

ALEXANDER II. king of Scotland, ſucceeded his father William in 1213, at 16 years of age. He made an expedition into England, to oppoſe the tyranny of King John; who returned the viſit, and was offered battle by Alexander, but refuſed it. He took the city of Carliſle from Henry III. which was afterwards exchanged for Berwick. Alexander died in 1249, in the 51ſt year of his age, and 35th of his reign; and left for his ſucceſſor, his ſon—— Alexander II. Alexandretta.

ALEXANDER III. who was crowned king of Scotland in 1249. The Cummings, a powerful family, took arms againſt him; and taking him priſoner, confined him at Stirling: but he was afterwards releaſed by his ſubjects. He married the daughter of Henry III. king of England; and was at length killed by a fall from his horſe, on the 10th of April 1290, after having reigned 42, or according to others 37, years.

ALEXANDERS, in *Botany*. See SMYRNIUM.

ALEXANDRETTA, by the Turks called *Scanderoon*; a town in Syria, at the extremity of the Mediterranean ſea. It is the port of Aleppo, from which it is diſtant 28 or 30 leagues. It is now, properly ſpeaking, nothing elſe but a village, without walls, in which the tombs are more numerous than the houſes, and which entirely owes its exiſtence to the road which it commands. This is the only road, in all Syria, where veſſels anchor on a ſolid bottom, without their cables being liable to chafe: but in other reſpects it has many inconveniences. It is infeſted, during winter, by a peculiar wind, called by the French ſailors *le Raguier*, which, ruſhing from the ſnowy ſummits of the mountains, frequently forces ſhips to drag their anchors ſeveral leagues: And when the ſnow begins to cover the mountains which ſurround the gulf, tempeſtuous winds ariſe which prevent veſſels from entering for three or four months together. The road alſo to Aleppo by the plain is inveſted by Curd robbers, who conceal themſelves in the neighbouring rocks, and frequently attack and plunder the ſtrongeſt caravans. But the worſt circumſtance is the extreme unwholeſomeneſs of the air, occaſioned here by ſtagnant waters and mephitic exhalations. It may be affirmed that this every year carries off one-third of the crews of the veſſels which remain here during the ſummer; nay, ſhips frequently loſe all their men in two months. The ſeaſon for this epidemic diſorder is principally from May to the end of September: it is an intermitting fever of the moſt malignant kind; and is accompanied with obſtructions of the liver, which terminate in dropſy. To this baneful epidemic, Alexandretta, from its ſituation, ſeems to be irremediably condemned: for the plain on which the town is built is ſo low and flat, that the rivulets, finding no declivity, can never reach the ſea. When they are ſwelled by the winter rains, the ſea, ſwelled likewiſe by tempeſts, hinders their diſcharging themſelves into it: hence their waters, forced to ſpread themſelves, form lakes in the plain. On the approach of the ſummer, the waters become corrupted by the heat, exhale vapours equally corrupt, and which cannot diſperſe, being confined by the mountains that encircle the gulf. The entrance of the bay beſides lies to the weſt, which in thoſe countries is the moſt unhealthy expoſure when it correſponds with the ſea. The labour neceſſary to remedy this would be immenſe, and after all inſufficient: and, indeed, ſuch an undertaking would be abſolutely impoſſible under a government like that of the Turks. A few years ago, Mr Volney informs us, the merchants of Aleppo, diſguſted with the numerous inconveniences of Alexandretta, wiſhed to abandon that port and carry the trade

to

Alexandretta, Alexandria.

to Latakia. They propoſed to the pacha of Tripoli to repair the harbour at their own expence, provided he would grant them an exemption from all duties for ten years. To induce him to comply with their requeſt, the agent they employed talked much of the advantage which would, *in time*, reſult to the whole country: "But what ſignifies it to me what may happen *in time*, replied the pacha? I was yeſterday at Marach; to-morrow, perhaps, I ſhall be at Djedda: Why ſhould I deprive myſelf of preſent advantages, which are certain, for future benefits I cannot hope to partake?" The European factors were obliged therefore to remain at Scanderoon. There are three of theſe factors, two for the French, and one for the Engliſh and Venetians. The only curioſity which they have to amuſe ſtrangers with conſiſts in ſix or ſeven marble monuments, ſent from England, on which you read: *Here lies ſuch a one, carried off in the flower of his age, by the fatal effects of a contagious air.* The ſight of theſe is the more diſtreſſing, as the languid air, yellow complexion, livid eyes, and dropſical bellies of thoſe who ſhow them, make it but too probable they cannot long eſcape the ſame fate. It is true, they have ſome reſource in the village of Bailan, the pure air and excellent water of which ſurpriſingly reſtore the ſick. The aga, for ſome years paſt, has applied the duties of the cuſtomhouſe of Alexandretta to this own uſe, and rendered himſelf almoſt independent of the pacha of Aleppo. The Turkiſh empire is full of rich rebels, who frequently die in peaceable poſſeſſion of their uſurpations.

ALEXANDRIA, in *Ancient Geography*, a mountain of Myſia, on the ſea coaſt, forming a part of Mount Ida, where Paris gave judgement on the three goddeſſes.

ALEXANDRIA, now *Scanderia*, by Athenæus called Χρυσή; a city of Lower Egypt, and for a long time its capital. This city was built by Alexander the Great, ſoon after the overthrow of Tyre, about 333 years before Chriſt. It is ſituated on the Mediterranean, twelve miles weſt of that mouth of the Nile anciently called *Canopicum*; and lies in E. Long. 30. 9. N. Lat. 31. 10.

Alexander is ſaid to have been induced to build this city, on account of its being conveniently ſituated for a fine port; and ſo ſudden was his reſolution, that after he had directed where every public ſtructure was to be placed, fixed the number of temples, and the deities to whom they ſhould be dedicated, &c. there were no inſtruments at hand proper for marking out the walls, according to the cuſtom of thoſe times. Upon this, a workman adviſed the king to collect what meal was among the ſoldiers, and to ſift it in lines upon the ground, whereby the circuit of the walls would be ſufficiently marked out. This advice was followed; and the new method of marking out the walls was, by Ariſtander, the king's ſouthſayer, interpreted as a preſage of the city's abounding with all the neceſſaries of life. Nor was he deceived in his predictions; for Alexandria ſoon became the ſtaple, not only for merchandiſe, but alſo for all the arts and ſciences of the Greeks.

Alexandria was a league and a half long, by one-third in breadth, which made the circumference of its walls about four leagues. Lake Mareotis bathed its walls on the ſouth, and the Mediterranean on the north. It was interſected lengthwiſe by ſtraight parallel ſtreets. This direction left a free paſſage to the northern wind, which alone conveys coolneſs and ſalubrity into Egypt. A ſtreet of 2000 feet wide began at the gate of the ſea, and terminated at the gate of Canopus. It was decorated with magnificent houſes, temples, and public buildings. In this extenſive range, the eye was never tired with admiring the marble, the porphyry and obeliſks, which were deſtined at ſome future day to embelliſh Rome and Conſtantinople. This ſtreet, the handſomeſt in the univerſe, was interſected by another of the ſame breadth, which formed a ſquare at their junction of half a league in circumference. From the middle of this great place, the two gates were to be ſeen at once, and veſſels arriving under full ſail from the north and from the ſouth. Alexandri

A mole of a mile in length ſtretched from the continent to the iſle of Pharos, and divided the great harbour into two. That which is to the northward preſerved its name. A dike drawn from the iſland to the rock whereon was built the Pharos, ſecured it from the weſterly winds. The other was called *Eunoſtos*, or the Safe Return. The former is called at preſent the new, the latter the old harbour: a bridge that joins the mole to the city, ſerved for a communication between them. It was raiſed on lofty pillars ſunk into the ſea, and left a free paſſage for ſhips. The palace, which advanced beyond the promontory of *Lochias*, extended as far as the dike, and occupied more than a quarter of the city. Each of the Ptolemies added to its magnificence. It contained within its encloſure, the muſeum, an aſylum for learned men, groves, and buildings worthy of royal majeſty, and a temple where the body of Alexander was depoſited in a golden coffin. The infamous Seleucus Cibyoſactes violated this monument, carried off the golden coffin, and put a glaſs one in its place. In the great harbour was the little iſland of Anti-Rhodes, where ſtood a theatre, and a royal place of reſidence. Within the harbour of Eunoſtos was a ſmaller one, called *Kibotos*, dug by the hand of man, which communicated with Lake Mareotis by a canal. Between this canal and the palace was the admirable temple of Serapis, and that of Neptune near the great place where the market was held. Alexandria extended likewiſe along the ſouthern banks of the lake. Its eaſtern part preſented to view the gymnaſium, with its porticoes of more than 600 feet long, ſupported by ſeveral rows of marble pillars. Without the gate of Canopus was a ſpacious circus for the chariot races. Beyond that, the ſuburb of Nicopolis ran along the ſea-ſhore, and ſeemed a ſecond Alexandria. A ſuperb amphitheatre was built there with a race-ground, for the celebration of the quinquennalia.

Such is the deſcription left us of Alexandria by the ancients, and above all by Strabo.

The architect employed by Alexander in this undertaking was the celebrated Dinocrates, who had acquired ſo much reputation by rebuilding the temple of Diana at Epheſus. The city was firſt rendered populous by Ptolemy Soter, one of Alexander's captains, who, after the death of the Macedonian monarch, being appointed governor of Egypt, ſoon aſſumed the title of king, and took up his reſidence at Alexandria, about 304 years before Chriſt.

Alexandria. In the 30th year of Ptolemy's Soter's reign, he took his ſon Ptolemy Philadelphus partner with him in the empire; and by this prince the city of Alexandria was much embelliſhed. In the firſt year of his reign the famous watch-tower of Pharos was finiſhed. It had been begun ſeveral years before by Ptolemy Soter; and, when finiſhed, was looked upon as one of the wonders of the world. The ſame year, the iſland of Pharos itſelf, originally ſeven furlongs diſtant from the continent, was joined to it by a cauſeway. This was the work of Dexiphanes, who completed it at the ſame time that his ſon put the laſt hand to the tower. The tower was a large ſquare ſtructure of white marble; on the top of which fires were kept conſtantly burning, for the direction of ſailors. The building coſt 800 talents; which, if Attic, amounted to 165,000l.; if Alexandrian, to twice that ſum.

The architect employed in this famous ſtructure fell upon the following contrivance to uſurp the whole glory to himſelf.—Being ordered to engrave upon it the following inſcription:—"King PTOLEMY to the Gods the Saviours for the benefit of Sailors;" inſtead of the king's name he ſubſtituted his own, and then filling up the hollow of the marble with mortar, wrote upon it the above-mentioned inſcription. In proceſs of time, the mortar being worn off, the following inſcription appeared: "SOSTRATUS the CNIDIAN, the ſon of DEXIPHANES, to the Gods the Saviours, for the benefit of Sailors."

This year alſo was remarkable for the bringing of the image of Serapis from Pontus to Alexandria. It was ſet up in one of the ſuburbs of the city called *Rhacotis*, where a temple was afterwards erected to his honour, ſuitable to the greatneſs of that ſtately metropolis, and called, from the god worſhipped there, *Serapeum*. This ſtructure, according to Ammianus Marcellinus, ſurpaſſed in beauty and magnificence all others in the world, except the capitol at Rome.—Within the verge of this temple was the famous Alexandrian library. It was founded by Ptolemy Soter, for the uſe of an academy he inſtituted in this city; and, by continual additions by his ſucceſſors, became at laſt the fineſt library in the world, containing no fewer than 700,000 volumes. The method followed in collecting books for this library, was, to ſeize all thoſe which were brought into Egypt by Greeks or other foreigners. The books were tranſcribed in the muſeum by perſons appointed for that purpoſe; the copies were then delivered to the proprietors, and the originals laid up in the library. Ptolemy Euergetes, having borrowed from the Athenians the works of Sophocles, Euripides, and Æſchylus, returned them only the copies, which he cauſed to be tranſcribed in as beautiful a manner as poſſible; preſenting the Athenians at the ſame time with fifteen talents (upwards of 3000l. ſterling) for the exchange.

As the muſeum was at firſt in that quarter of the city called *Bruchion*, near the royal palace, the library was placed there likewiſe; but when it came to contain 400,000 volumes, another library, within the Serapeum, was erected by way of ſupplement to it, and on that account called the *daughter* of the former. In this ſecond library 300,000 volumes, in proceſs of time, were depoſited; and the two together contained the 700,000 volumes already mentioned. In the war Alexandria. carried on by Julius Cæſar againſt the inhabitants of this city, the library in the Bruchion, with the 400,000 volumes it contained, was reduced to aſhes. The library in the Serapeum, however, ſtill remained; and here Cleopatra depoſited 200,000 volumes of the Pergamean library, which Marc Antony preſented her with. Theſe, and others added from time to time, rendered the new library at Alexandria more numerous and conſiderable than the former; and though it was often plundered during the revolutions and troubles of the Roman empire, yet it was again and again repaired, and filled with the ſame number of books.

For 293 years Alexandria was held in ſubjection by the Ptolemies. Here is a liſt of theſe princes, with the dates of their reſpective reigns.

Ptolemy the ſon of Lagus, ſurnamed *Soter*, reigned 39 years, and died in the year of the world 3720. Ptolemy Philadelphus reigned 39 years, and died in 3758. Ptolemy Euergetes reigned 25 years, and died in 3783. Ptolemy Philopater reigned 17 years, and died in 3800. Ptolemy Epiphanes reigned 24 years, and died in 3824. Ptolemy Philometor reigned 37 years, and died in 3861. Ptolemy Euergetes, or Phyſcon, reigned 53 years, part with his brother Philometor and part alone. He died in 3888. Ptolemy Lathyrus reigned 36 years ſix months. He died in 3923. Cleopatra, the daughter of Lathyrus and wife of Alexander I. reigned ſix months. Alexander I. the nephew of Lathyrus, was eſtabliſhed in 3924, and died in 3943. Alexander II. the ſon of Alexander I. was diſpoſſeſſed by the Alexandrians in 3939. Ptolemy Nothus, or Auletes, the ſon of Lathyrus, reigned 13 years, and died in 3953. Ptolemy, ſurnamed *Dionyſius* or *Bacchus*, reigned three years eight months, and died in 3957. Cleopatra reigned from 3957, and killed herſelf in 3974.

This city, as we have already obſerved, ſoon became extremely populous, and was embelliſhed both by its own princes and the Romans; but, like moſt other noted cities of antiquity, hath been the ſeat of terrible maſſacres. About 141 years before Chriſt, it was almoſt totally depopulated by Ptolemy Phyſcon. That barbarous monſter, without the leaſt provocation, gave free liberty to his guards to plunder his metropolis and murder the inhabitants at their pleaſure. The cruelties practiſed on this occaſion cannot be expreſſed; and the few who eſcaped were ſo terrified that they fled into other countries. Upon this, Phyſcon, that he might not reign over empty houſes, invited thither ſtrangers from the neighbouring countries; by whom the city was repeopled, and ſoon recovered its former ſplendour. On this occaſion many learned men having been obliged to fly, proved the means of reviving learning in Greece, Aſia Minor, the iſlands of the Archipelago, and other places, where it was almoſt totally loſt.

The new inhabitants were not treated with much more kindneſs by Phyſcon than the old ones had been; for, on their complaining of his tyrannical behaviour, he reſolved on a general maſſacre of the young men. Accordingly, when they were one day aſſembled in the gymnaſium, or place of their public exerciſes, he ordered it to be ſet on fire; ſo that they all periſh-

Alexandria ed, either in the flames, or by the ſwords of his mercenaries, whom the tyrant had placed at all the avenues.

Though Julius Cæſar was obliged to carry on a war for ſome time againſt this city, it ſeems not to have ſuffered much damage, except the burning of the library already mentioned. Before Cæſar left Alexandria, in acknowledgment of the aſſiſtance he had received from the Jews, he confirmed all their privileges there, and even engraved his decree on a pillar of braſs. This, however, did not prevent the maſſacre of 50,000 of them in this city about the year of Chriſt 67.

The city of Alexandria ſeems to have fallen into decay ſoon after this, and to have forfeited many of its ancient privileges, though for what offence is not known; but when Adrian viſited Egypt, about the year 141, it was almoſt totally ruined. He repaired both the public and private buildings, not only reſtoring the inhabitants to their ancient privileges, but heaping new favours upon them; for which they returned him their ſolemn thanks, and conferred upon him what honours they could while he was preſent; but as ſoon as he was gone, they publiſhed the moſt bitter and virulent lampoons againſt him.

The fickle and ſatirical humour of the Alexandrians was highly diſliked by Adrian, though he inflicted no puniſhment upon them for it; but when they lampooned Caracalla, he did not let them eſcape ſo eaſily. That tyrant, in the year 215, when he viſited their city, having become the ſubject of their fooliſh ſatires, ordered a general maſſacre by his numerous troops, who were diſperſed all over the city. The inhuman orders being given, all were murdered, without diſtinction of age or ſex; ſo that in one night's time the whole city floated in blood, and every houſe was filled with carcaſes. The monſter who occaſioned this had retired during the night to the temple of Serapis, to implore the protection of that deity; and, not yet ſatiated with ſlaughter, commanded the maſſacre to be continued all the next day; ſo that very few of the inhabitants remained. As if even this had not been ſufficient, he ſtripped the city of all its ancient privileges; ſuppreſſed the academy; ordered all ſtrangers who lived there to depart; and that the few who remained might not have the ſatisfaction of ſeeing one another, he cut off all communication of one ſtreet with another, by walls built for that purpoſe, and guarded by troops left there.

Notwithſtanding this terrible diſaſter, Alexandria ſoon recovered its former ſplendour, as Caracalla was murdered a ſhort time after. It was long eſteemed the firſt city in the world, next to Rome; and we may judge of its magnificence, and the multitude of people contained in it, from the account of Diodorus Siculus, who relates, that in his time (44 years before Chriſt) Alexandria had on its rolls 300,000 freemen. Towards the middle of the ſixth century, Amrou *Ebn al Aas*, Omar's general, took it by ſtorm, after a ſiege of 14 months, and with the loſs of 23,000 men. Heraclius, then emperor of Conſtantinople, did not ſend a ſingle ſhip to its aſſiſtance. This prince affords an example very rare in hiſtory; he had diſplayed ſome vigour in the firſt year of his reign, and then ſuffered himſelf to be lulled into idleneſs and effeminacy. Awakened ſuddenly from his lethargy by the noiſe of the conqueſts of Coſroes, that ſcourge of the eaſt, he Alexandr put himſelf at the head of his armies, diſtinguiſhed himſelf as a great captain from his very firſt campaign, laid waſte Perſia for ſeven years, and returned to his capital covered with laurels: he then became a theologian on the throne, loſt all his energy, and amuſed himſelf the reſt of his life with diſputing upon Monotheiſm, whilſt the Arabs were robbing him of the fineſt provinces of his empire. Deaf to the cries of the unfortunate inhabitants of Alexandria, as he had been to thoſe of the people of Jeruſalem, who defended themſelves for two years, he left them a ſacrifice to the fortunate aſcendant of the indefatigable Amrou. All their intrepid youth periſhed with their arms in their hands.

The victor, aſtoniſhed at his conqueſt, wrote to the caliph, "I have taken the city of the weſt. It is of an immenſe extent. I cannot deſcribe to you how many wonders it contains. There are 4000 palaces, 4000 baths, 12,000 dealers in freſh oil, 12,000 gardeners, 40,000 Jews who pay tribute, 400 theatres or places of amuſement."

At this time, according to the Arabian hiſtorians, Alexandria conſiſted of three cities, *viz. Menna*, or the port, which included Pharos, and the neighbouring parts; *Alexandria*, properly ſo called, where the modern Scanderia now ſtands; and *Nekita*, probably the Necropolis of Joſephus and Strabo.

At that time John, ſurnamed *the Grammarian*, a famous Peripatetic philoſopher, being in the city, and in high favour with Amrou Ebn al Aas the Saracen general, begged of him the royal library. Amrou replied, that it was not in his power to grant ſuch a requeſt; but that he would write to the caliph on that head; ſince, without knowing his pleaſure, he dared not to diſpoſe of a ſingle book. He accordingly wrote to Omar, who was then caliph, acquainting him with the requeſt of his friend: to which the ignorant tyrant replied, That if thoſe books contained the ſame doctrine with the Koran, they could be of no uſe, ſince the Koran contained all neceſſary truths; but if they contained any thing contrary to that book, they ought not to be ſuffered; and therefore, whatever their contents were, he ordered them to be deſtroyed. Purſuant to this order, they were diſtributed among the public baths; where, for the ſpace of ſix months, they ſerved to ſupply the fires of thoſe places, of which there was an incredible number in Alexandria.

After the city was taken, Amrou thought proper to purſue the Greeks who had fled farther up the country; and therefore marched out of Alexandria, leaving but a very ſlender garriſon in the place. The Greeks, who had before fled on board their ſhips, being appriſed of this, returned on a ſudden, ſurpriſed the town, and put all the Arabs they found therein to the ſword: but Amrou, receiving advice of what had happened, ſuddenly returned, and drove them out of it with great ſlaughter; after which the Greeks were ſo intimidated, that he had nothing farther to fear from them.—A few years after, however, Amrou being deprived of his government by the caliph Othman, the Egyptians were ſo much diſpleaſed with his diſmiſſion that they inclined to a revolt; and Conſtantine the Greek emperor, having received intelligence of their diſaffection, began to meditate the reduction of Alexandria. For this purpoſe, he

Alexandria. he ſent one Manuel, an eunuch, and his general, with a powerful army, to retake that place; which, by the aſſiſtance of the Grecks in the city, who kept a ſecret correſpondence with the imperial forces while at ſea, and joined them as ſoon as they had made a deſcent, he effected, without any conſiderable effuſion of Chriſtian blood. The caliph, now perceiving his miſtake, immediately reſtored Amrou to his former dignity. This ſtep was very agreeable to the natives; who having had experience of the military ſkill and bravery of this renowned general, and apprehending that they ſhould be called to an account by the Greeks for their former perfidious conduct, had petitioned Othman to ſend him again into Egypt.—Upon Amrou's arrival, therefore, at Alexandria, the Copts or natives, with the traitor Al-Mokawkas (who had formerly betrayed to Amrou the fortreſs of Meſr) at their head, not only joined him, but ſupplied him with all kinds of proviſions, exciting him to attack the Greeks without delay. This he did; and, after a moſt obſtinate diſpute which laſted ſeveral days, drove them into the town, where, for ſome time, they defended themſelves with great bravery, and repelled the utmoſt efforts of the beſiegers. This ſo exaſperated Amrou, that he ſwore, "If God enabled him to conquer the Greeks, he would throw down the walls of the city, and make it as eaſy of acceſs as the houſe of a proſtitute. Nor did he fail to execute his threat; for having taken the town by ſtorm, he quite diſmantled it, entirely demoliſhing the walls and fortifications. The lives of the citizens, however, were ſpared, at leaſt as far as lay in the general's power; but many of them were put to the ſword by the ſoldiers on their firſt entrance. In one quarter particularly, Amrou found them butchering the Alexandrians with unrelenting barbarity; to which, however, by his ſeaſonable interpoſition, he put a ſtop, and on that ſpot erected a moſque, which he called the *moſque of mercy*.

From this time Alexandria never recovered its former ſplendour. It continued under the dominion of the caliphs till the year 924, when it was taken by the Magrebians, two years after its great church had been deſtroyed by fire. This church was called by the Arabs *Al Kaiſaria*, or *Cæſarea*; and had formerly been a pagan temple, erected in honour of Saturn by the famous Queen Cleopatra.

The city was ſoon after abandoned by the Magrebians; but in 928 they again made themſelves maſters of it; their fleet being afterwards defeated by that belonging to the caliph, *Abul Kaſem* the Magrebian general retired from Alexandria, leaving there only a garriſon of 300 men; of which *Thmaâl*, the caliph's admiral, being appriſed, he in a few days appeared before the town, and carried off the remainder of the inhabitants to an iſland in the Nile called *Abukair*. This was done to prevent Abul Kâſem from meeting with any entertainment at Alexandria, in caſe he ſhould think proper to return. According to Eutychius, above 200,000 of the miſerable inhabitants periſhed this year.

What contributed to raiſe Alexandria to ſuch a prodigious height of ſplendour as it enjoyed for a long time, was its being the centre of commerce between the eaſtern and weſtern parts of the world. It was with the view of becoming maſter of this lucrative trade, that Alexander built this city, after having extirpated the Tyrians who formerly engroſſed all the Eaſt India traffic. Of the immenſe riches which that trade afforded, we may form an idea, from conſidering that the Romans accounted it a point of policy to oppreſs the Egyptians, eſpecially the Alexandrians; and after the defeat of Zenobia, there was a ſingle merchant of Alexandria who undertook to raiſe and pay an army out of the profits of his trade. The Greek emperors drew prodigious tributes from Egypt, and yet the caliphs found their ſubjects in ſo good circumſtances as to ſcrew up their revenues to three hundred millions of crowns. Alexandria.

Though the revolutions which happened in the government of Egypt, after it fell into the hands of the Mahometans, frequently affected this city to a very great degree; yet ſtill the excellence of its port, and the innumerable conveniencies reſulting from the Eaſt India trade, to whomſoever were maſters of Egypt, preſerved Alexandria from total deſtruction, even when in the hands of the moſt barbarous nations. Thus, in the 13th century, when the barbariſm introduced by the Goths, &c. began to wear off from the European nations, and they acquired a taſte for the elegancies of life, the old mart of Alexandria began to revive; and the port, though far from recovering its former magnificence, grew once more famous by becoming the centre of commerce: but having fallen under the dominion of the Turks, and the paſſage round the Cape of Good Hope being diſcovered by the Portugueſe in 1499, a fatal blow was given to the Alexandrian commerce, and the city has ſince fallen into decay.

At preſent, the city of Alexandria is reckoned to have about 14,000 or 15,000 inhabitants; a ſtrange colluvies of different nations, as well as from various parts of the Turkiſh empire. They are in general given to thieving and cheating; and (like their predeceſſors) ſeditious above all others, were they not kept in awe by the ſeverity of their government. The Britiſh and French carry on a conſiderable commerce with them, and have each a conſul reſiding here. Some Venetian ſhips alſo ſail thither yearly, but with French colours, and under the protection of France. The ſubjects of thoſe kingdoms which keep no conſul here, are ſubjected to a tax by the Grand Signior: but the Jews have found out a method of indemnifying themſelves for this diſadvantage; namely, by ſelling their commodities cheaper than other foreigners can afford. They are alſo favoured by the farmers of the revenue; who know, that if they do not pay ſome private regard to them, the Jews have it in their power to cauſe fewer merchandiſes come into their port during the two years that their farm laſts.

The preſent city is a kind of peninſula ſituated between the two ports. That to the weſtward was called by the ancients the *Portus Eunoſtus*, now the *Old Port*, and is by far the beſt: Turkiſh veſſels only are allowed to anchor there: the other called the *New Port*, is for the Chriſtians; at the extremity of one of the arms of which ſtood the famous Pharos. The New Port, the only harbour for Europeans, is clogged up with ſand, inſomuch that in ſtormy weather ſhips are liable to bilge; and the bottom being alſo rocky, the cables ſoon chafe and part; ſo that one veſſel driving againſt a ſecond, and that againſt a third, they are perhaps all loſt. Of this there was a fatal inſtance ſome years ago, when 42 veſſels were daſhed to pieces on the mole

Alexandria. in a gale of wind from the north-weſt, and numbers have been ſince loſt there at different times. If it be aſked in Europe, Why do they not repair the New Port? the anſwer is, That in Turkey they deſtroy every thing, and repair nothing. The old harbour will be deſtroyed likewiſe, as the ballaſt of veſſels has been continually thrown into it for the laſt 200 years. The ſpirit of the Turkiſh government is to ruin the labours of paſt ages, and deſtroy the hopes of future times, becauſe the barbarity of ignorant deſpotiſm never conſiders to-morrow.

In time of war, Alexandria is of no importance; no fortification is to be ſeen; even the Farillon, with its lofty towers, cannot be defended. It has not four cannon fit for ſervice, nor a gunner who knows how to point them. The 500 janizaries, who ſhould form the garriſon, reduced to half that number, know nothing but how to ſmoke a pipe. But Alexandria is a place of which the conqueſt would be of no value. A foreign power could not maintain itſelf there, as the country is without water. This muſt be brought from the Nile by the kalidj, or canal of 12 leagues, which conveys it thither every year at the time of the inundation. It fills the vaults or reſervoirs dug under the ancient city, and this proviſion muſt ſerve till the next year. It is evident, therefore, that were a foreign power to take poſſeſſion, the canal would be ſhut, and all ſupplies of water cut off. It is this canal alone which connects Alexandria with Egypt; for from its ſituation without the Delta, and the nature of the ſoil, it really belongs to the deſerts of Africa. Its environs are ſandy, flat, and ſterile, without trees and without houſes; where we meet with nothing but the plant which yields the kali, and a row of palm trees which follows the courſe of the kalidj or canal.

The city is governed like others in the ſame kingdom. (See EGYPT.) It hath a ſmall garriſon of ſoldiers, part of which are Janizaries and Aſſaffs; who are very haughty and inſolent, not only to ſtrangers, but to the mercantile and induſtrious part of the people, though ever ſo conſiderable and uſeful. The government is ſo remiſs in favour of theſe wretches, that Mr Norden informs us, one of them did not heſitate to kill a farmer of the cuſtoms, for refuſing to take leſs of him than the duty impoſed, and went off unpuniſhed; it being a common ſalvo among them, that what is done cannot be undone.

The preſent condition of Alexandria is very deſpicable, being now ſo far ruined, that the rubbiſh in many places overtops the houſes. The famous tower of Pharos has long ſince been demoliſhed, and a caſtle, called *Farillon*, built in its place. The cauſeway which joined the iſland to the continent is broken down, and its place ſupplied by a ſtone bridge of ſeveral arches.
