It may be sufficient to state that they are such as we have described in the body of this work as of the best description. Farms generally large; medium of the county about 400*l.* a year; highest 1500*l.* to 1800*l.* The first enclosures were made about 1720; farmers were introduced from Holland in 1710; the two-horse plough in 1772; and the first threshing-machine in 1786. Fallowing was introduced from England about the same time as hedges. The sixth Earl of Haddington was the first proprietor, and John Walker, of Beanston, near Dunbar, the first farmer. He took the hint from some English travellers, while they spent a night at his house, and with whom he had a good deal of conversation upon the subject, so much to his satisfaction, that he made an experiment upon six acres the following summer, which he carried through in spite of the animadversions of his neighbours, who were divided in their opinions as to the sanity of his mind, or the stability of his circumstances. The result of the experiment gave them a better opinion of both, and the return was so abundant as to induce him to extend his next year's fallow break to twenty acres; soon after which the practice began to spread, and so early as the year 1724, fallowing upon all the deep strong soils was common throughout the county, and has continued to be so ever since. There can be no doubt that the early excellence of the East Lothian agriculture was in a great measure owing to the introduction of fallowing, which, together with the use of drill crops, have continued to place it at the head of the Scotch counties. Potatoes introduced to field culture about 1760; turnips first by Cockburn, of Ormiston, about 1720; re-introduced and cultivated in the drill manner in 1760. Flax sown from time immemorial, but chiefly on a small scale, and for the home consumption of the country inhabitants. Every cottager has a small quantity, from half a peck to a peck sown, the produce of which furnishes linen for the use of his family.

Lucern tried with the greatest care; but, owing to the climate, it was found to produce less bulk of herbage than red clover.

3. *Grass.*

Natural meadows and pastures are not admitted into the East Lothian system of husbandry, as they are found only where nature, or certain local circumstances, render them, in some measure, unavoidable, and are never kept voluntarily, or from an idea of profit. Many farmers fallow land to lie for a few years in grass, especially where it has been exhausted by long and imperfect tillage; but fields of this description are not to be ranked as permanent pastures, for the object is to restore them, as soon as possible, to a state capable of bearing corn-crops to advantage.

Clovers introduced by the sixth Earl of Haddington and Cockburn, about 1720 or 1722, but made little progress till 1740; now generally sown with rye-grass. Application, grazing, soiling, and hay, but chiefly soiling.

4. *Gardens and Orchards.*

Some few market gardens and nurseries; but the climate does not admit of orchards, which are very rare. Every cottage has a garden annexed, sufficient to produce the various common kitchen vegetables for the cottager's family. This class of people are remarkably attentive to the cultivation of their little spots, and derive great advantage from them, at small cost; the labour is entirely performed after their ordinary work is finished.

5. *Woods and Plantations.*

Scarcely any of the former, and none of the latter, of any extent, excepting in gentlemen's parks. 800 acres on Tynningham demesne planted by the sixth Earl of Haddington, who wrote a treatise on planting, about 1715. Osiers cultivated by the late Mr. Sherriff, of Captain Head, for which, in 1803, he received the gold medal of the Society of Arts.

6. *Wastes and Commons.*

Are in this as in other Scotch counties generally enclosed, which is here an easy matter in comparison to what it is in England, in consequence of a general Act of Enclosure by the Scottish Parliament, in 1695.

7. *Improvements.*

Paring and burning little known, and not wanted, because very little ground is kept long in pasture that can be profitably employed in tillage, and new grass lands do not require these operations.

One attempt at irrigation on a sandy waste near Dunbar, the levels of which were taken by, and the water turned on under the direction of, the compiler of this work, in 1805.

8. *Live Stock.*

The practice of East Lothian, in this department, does not present much that can be generally interesting. Grazing, in nine cases out of ten, is carried on only as subservient to tillage, and therefore held a secondary object by cultivators. Many cattle are fed, but very few reared, in the county. Almost every person who practises the sheep husbandry, in the lower districts, buys and sells within the year. Some recent attempts have been made to keep flocks of full bred sheep, and, there is reason to believe, with considerable success; but, taking the county generally, such attempts are of little importance.

Cattle. Every farmer keeps a small number of milch cows, but few keep more than are sufficient to furnish a regular supply through the whole year, of milk, butter, and cheese, for their own families. The same attention accordingly is not paid to the kinds of cattle, as in other districts, where they form a more important object of farm management.

A very considerable number of black cattle are purchased annually at fairs and markets, to be wintered in the fold-yard, or fed on turnips in the house. Cattle kept for the dairy, or fed for the butcher-market, comprehend all that are to be found in the county; none are employed in labour. Every part of farm-labour, in which beasts are employed, is executed by horses.

Sheep. Permanent flocks, and regular sheep management, may be said to be almost confined to the higher parts of the county. In the low country they are kept chiefly to eat the turnips, and sometimes sown grass, which is permitted to lie a year or two for pasture. Flying flocks are therefore generally kept; and as soon as they are fattened for the market, which is usually within the year, they are sold off. A considerable number of lambs likewise are reared, only so far, however, as to render them fit for the butcher.

As the great object in the lower districts is feeding, little attention is paid to particular kinds; every farmer keeps those which he thinks are likely to pay best for the food which they consume. The black-faced, or Tweed-dale breed, are most generally preferred for feeding on turnips, because they are most esteemed in the market; but many of the Cheviot breed are likewise kept, and even some of the improved Leicester.

The kind of sheep bred, and most generally kept, in Lammermuir, is the black-faced, or more properly what is called the brocked-faced, a sort of dirty-looking mixture of black and white; they are for the most part horned: when they are fed the wedders weigh from ten to twelve pounds per quarter, and the ewes from eight to ten on an average.

The Bakewell breed has been tried, but not extensively till lately. Leicesters are now much more common in East Lothian than they were twenty years ago.

The Cheviot sheep were introduced several years ago, and are kept with advantage in many places. It is not the general opinion, however, that they can ever universally supplant the native breed, or even become equally numerous, with profit.

Of *horses* very few are bred in the county, not one perhaps in a dozen that are kept. In a district so well calculated for raising corn, it is more profitable to purchase horses, ready for work, than to be at the trouble and expense of rearing them. The farmers here are supplied with this part of stock chiefly from the dealers of Ayrshire and Lanarkshire, who collect many of them in these counties, and procure not a few from Ireland. The horses generally kept are of that moderate size, which may be considered as equal perhaps to any others for combining strength with activity. They may be stated, generally, to be about fifteen or sixteen hands high, and strong built. Many teams are well matched, very handsome, capable of great exertion, and kept in excellent condition.

One will hardly be at a loss to determine the character of a farmer, from the condition of his horses. Very fine high bred horses, exhibiting an appearance of being prepared for the market, may rather suggest the idea of idleness than of labour; but, on the other hand, lean spiritless creatures, worn out by toil and hunger, are the certain indicatives of a bad farmer, of one who is not thriving, and does not deserve to thrive. The man who uses bad instruments cannot have his work well done; and one important and primary step towards good farming, is to keep the labouring stock in good condition. Horses regularly fed and regularly wrought will perform a great deal of labour without falling off either in strength or appearance; it is of great importance, therefore, to distribute the labour as equally as possible, through the various seasons of the year; and if, as must sometimes be the case, an extraordinary exertion ought to be made, they are in a proper condition for making it. When horses do fall off, it requires much more to restore them, than might have kept them in a good state.

Hogs are kept in considerable numbers, in this county, at distilleries, starch work, mills, and breweries. Every farmer keeps a few, chiefly for supplying his own table, and the generality are able to sell some annually. Farm servants too, who have houses, are generally allowed to keep a pig for each family, which adds greatly to their comfort.

Poultry, pigeons, and bees, kept to a moderate extent for home use. Much land on the coast, which would be thought by many unfit for any thing but rabbit warrens, now bears turnips and rye.

9. *Rural Economy.*

There are not, perhaps, in the island more active or correct labourers than the farm servants here, and certainly none more sober and respectable; and this may, in a great measure, be ascribed to the terms on which they serve. Those servants, who lodge in the houses of their masters, are, generally speaking, on the same footing here as in other places; there is no-

thing, with respect to them, which merits particular notice. A small proportion of farm servants, however, belong to this class; married servants are uniformly preferred; those who reside in their master's house are, in many cases, not employed in regular labour, but perform that sort of extra work, and kind of household drudgery, which requires some hands on every considerable farm.

The far greater part of the regular labour is performed by married servants, called hinds; a class more numerous here than in other districts. These dwell in houses provided by their masters, and receive their wages wholly or chiefly in kind; the circumstances are so comfortable under which they are generally placed, as to secure a full supply of such servants at all times. They are more steady generally than young men: their families, and the property which they have acquired, give them a sort of interest in their situations, and afford some security for their continuing longer in their places.

The hind occupies a house provided by his master, for which his wife works in harvest; he has a cow kept all the year round, generally ten bolls of oats, three bolls of barley, two bolls of peas, all of the best quality upon the farm, seed-corn excepted. He has likewise a peck of flax-seed sown, and about the sixteenth part of an acre of ground, well prepared, and sufficiently dunged for planting potatoes; his fuel is carried; he has his victuals during harvest, which is always four weeks, sometimes six; and when he carries corn to market, he has an allowance, provincially called mags. Those who are employed in sowing and building the corn-ricks have, besides the ordinary wages, a pair of shoes and half a boll of wheat. On all well-managed farms, the labour is carried on regularly at set hours: and though it is not understood that servants, who work horses, are absolutely exempt from extra work, yet they are very seldom required to do any thing of this nature.

It is evident, that the value of hinds' wages, in money, cannot be accurately stated; that must vary according to the market price of the articles in which he is paid. On an average of some years past, it could not be less than 25*l.* sterling per annum: now from 30*l.* to 35*l.*

The circumstance which deserves particular attention with regard to this class, and which renders their condition so much more comfortable than that of the labourers in many other places, is the receiving payment of their wages in the necessaries of life. They are far more comfortable than those who receive the same rate of wages in money, any where; they are generally more faithful to their employers, and infinitely more attentive to the interests of their families. They have all the necessary articles of food continually at hand, and seldom need to purchase any thing considerable, except shoes. Their wives make linen from their own flax sufficient for their families, and often cloth, for other articles of dress. The quantity of corn which they can afford to sell, with the surplus produce of their cows and hens, brings them as much money as fully answers every demand, and enables them to give a better education to their children than is sometimes obtained by persons, considerably above their condition, in some other parts of the island. There are few of this class in East Lothian who cannot read, most of them can write; none of them fail to have their children instructed in these necessary branches of education, including the rules of arithmetic. One sees, about every farm-house, a number of children, vigorous and healthy, decently clothed, and exhibiting every appearance of being well fed. Not an instance occurs of any of these people soliciting relief from the public, unless they are by some accident disabled from future labour, or overtaken by the infirmities of age. Indeed the times which are hardest for the lower classes, in general, are usually favourable for them; because the corn and other articles which they have to sell bear a better price, while what they have to purchase is not so much affected.

The cottage system, which found many advocates some time ago, was inferior in every view of the matter to the manner in which labourers in agriculture are accommodated here. Many of those who laboured to introduce the new cottage system, deserved all praise for the purity of their motives: every friend of humanity will honour them for the generous interest which they felt in behalf of the labouring poor; but if they had understood the condition of the hinds in this county, they would have found out a much better plan for accomplishing their object, than giving to every cottager land to produce his subsistence. A hind here receives as much corn as such a cottager might be expected to raise; his labour is not interrupted to his employer, nor himself worn out by extra and excessive labour; he has no care upon his mind, no rent to pay, no bad seasons to dread; for whatever may be his master's crop, he is sure of his full share. If the labourer profit by this system, the employer and the public profit still more: the employer does not pay a man who wastes half his strength at other work, nor rely on a servant who may sometimes disappoint him, by attending to other concerns. The public must gain in the increased quantity of human food produced; for, without doubt, an acre of land occupied by a cottager will not yield as much, at as little expense, as if it made part of a farm cultivated by a person with sufficient capital.

Were all the farm servants over the kingdom paid in kind, it may be safely affirmed, from the experience of the places where this practice prevails, that the advantage would be great to themselves and to the public. The master might probably, in some case, find it more convenient to give money, but he is far more than recompensed for any trifling disadvantage attending the other mode, by the valuable moral habits which it is calculated to preserve. Every master, who properly understands his interest, will admit, that he had better pay sober, honest, and industrious servants, than have those of a different description almost for nothing. From their being accustomed to have little money pass through their hands, many of the farmers' servants in this county acquire such habits of saving, that they lay up a few pounds for old age, or to meet any contingency which may require more than their ordinary income.

10. *Political Economy.*

The first turnpike bill for Scotland was obtained for this county in 1750. The main roads are on the whole good; but the bye-roads still admit of much improvement. The commerce is chiefly in grain from North Berwick and Dunbar. There are oyster and other fisheries on the coast; and starch-works, distilleries, and breweries, but no manufactures deserving notice. The agricultural society of Edinburgh, the earliest in the United Kingdom, was founded chiefly by gentlemen of this county, and especially Cockburn of Ormiston. There are now two county societies; one, that meets at Haddington, and another at Salton. They give prizes annually for the best cattle, &c. and seem to be in a flourishing condition.

7835. BERWICKSHIRE. 285,440 acres (*Edin. Gaz. abridged*, 1829.), chiefly of gently varied surface, but partly of hilly and mountainous pasture. The soil, in the cultivatable part of the county, is chiefly clay; the mountainous part, which occupies fully one third of it, is a continuation of the Lammermuir hills. Climate of the higher parts comparatively dry, but cold and late; of the lower parts, which stretch down to the Tweed, comparatively warm and early. There are no metals or coal in the county; very little lime, but some stone quarries of the trap, and other coarse stones. Every one knows that this county is one of the best cultivated and most systematically managed in the island, and that its products are nearly equally stock and corn. It is the county of Lord Kaimes, one of the greatest patriots and best agricultural authors, and the first to propose a board of agriculture. It is also that of Small, well known as the improver of the plough. (*Kerr's Berwickshire*, 1808.)

1. *Property.*

No very large estates; largest from 8000*l.* to 10,000*l.* a year. Many of the owners reside on their estates; some farmers have of late years become respectable proprietors. Resident proprietors usually draw their own rents; and those who live at a distance employ an agent, or, if only temporarily absent, have it sent in a bank bill. Proprietors and tenants live in harmony and mutual good will, the rents of the former progressively advancing with the improvements of the country, and the fortunes of the latter augmenting continually, by industrious and judicious attention to improved agricultural practices, and to the amelioration of live stock.

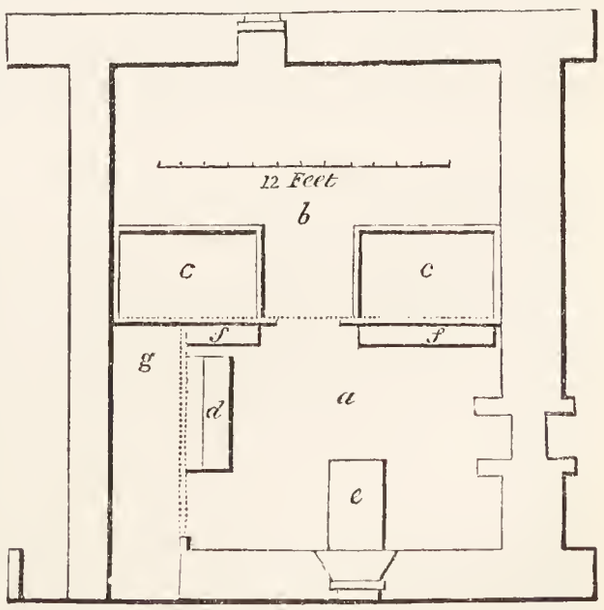
2. *Buildings.*

Farm-houses formerly of rough stone, clay, and thatch, now greatly superior to the houses that were occupied by the middling gentry, forty or fifty years ago. An excellent plan of a farmery given; but the cottages of the hinds appear uncomfortably small, and are calculated for close-panneled beds, which, wherever health and cleanliness are objects, ought to be discarded. These cottages contain only one apartment, and a sort of dark lumber place, formed by the position of the panneled beds. We much wonder that the reporter, who talks so much of the commodiousness of the houses of farmers, should not have displayed a little more feeling on the subject of the accommodations of cottagers. These remarks apply more particularly to three plans of cottages, given in Kerr's Report, Dec. 14, 1830, in the general plan of a farmery. (*Pl. facing* p. 97.) A detached plan of a cottage (*fig.* 1125.) is given, rather better arranged than these double ones, but still, in our opinion, highly objectionable. It has *two* windows, whereas the others have only one each. The larger window is in the kitchen (*a*), the smaller in the back place (*b*); these are separated by two beds (*c*); in the kitchen are shown a plate-rack and dresser (*d*), table (*e*), and two chests (*f f*). In the lobby a place for coals (*g*). No water-closets in any of the plans.

3. *Occupation.*

Farms generally large, and held on lease for different periods, from ten to thirty years, but commonly for nineteen years. Mode of culture aration and pasturage alternately. "Under this system of alternation, judiciously conducted, it may confidently be asserted that a farm of 1000 acres will raise as much grain as one of equal size entirely under perpetual tillage, and will produce in addition as much beef, and mutton, and wool, as a separate farm of 200 or 300 acres under permanent grass. If this estimation be well founded, of which the reporter has no doubt, this alternate system is obviously of superior profit to the tenancy in the first place, to the landed interest secondarily, by increased rents, and to the public ultimately and always, in the proportion of at least

1125



twenty-five per cent beyond what can be produced from the two branches separately pursued on the same extent of equal land.

In the hill district, the lands are mostly occupied as breeding sheep farms; taking advantage of all the favourable pieces of land, susceptible of cultivation, for raising a little grain to supply the farmer's family, servants, and horses; to afford litter and fodder from the straw during winter, by which dung is produced; to apply that dung to raise turnips, to carry on their sheep stock during winter, and, finally, to produce crops of artificial or sown grasses, for hay and early pastures, and to the great amelioration of permanent grass lands.

In the neighbourhood of towns and villages, various small possessions, from two or three acres or less, to twenty or more, are let on leases of various endurance, but mostly for short periods to villagers who keep one or two horses, which they chiefly occupy in leading materials for road makers, coals to the other villagers, lime, or any such employment as may occur. The great mass of the land throughout the county is let in farms of every variety of size, from 40 to 50 acres, up to 1000 or more, to tenants on leases of fixed endurance, mostly for nineteen years.

The character of farmers in a large district of country must be various; but those of Berwickshire are very generally most respectable and intelligent, and their success has been deservedly proportional. They have almost universally risen completely above the operative class in knowledge, education, and manners, assimilating in every respect to the character of country gentlemen. In every corner of the county they are to be seen carrying on extensive and costly improvements, by draining, enclosing, liming, and marling; and by careful and judicious improvements of their live stock, sheep, cattle, and even horses, with all the eagerness and intelligence of commercial speculators. They trust to the certain profits of future years to reimburse their large expenditures with reasonable profit, which they are enabled to do through the sufficiency of their capitals, and the security of their leases. The former is derived from their own successful and intelligent industry, or that of their fathers; the latter from the good sense of the landlords, in seeing their own interests most materially interwoven in the security and success of their tenants.

4. *Implements.*

No waggons or wheel ploughs, and, though drilling turnips is universal, only one or two sorts of drills in use. Few implements, and those of a simple construction, suffice for the best practicians in every art.

5. *Enclosing.*

The cultivatable lands are universally enclosed, and subdivided into regular fields, generally by hedges; but sometimes by stone walls. In the mountain district, the farms are neither enclosed nor subdivided. The boundaries of each farm are indicated by landmarks, and round each farmery there are generally two or three small fields for convenience or cultivation. Trees very generally planted in hedge-rows; hedges always cut with a bill in the wedge shape; never clipped and rounded, or broader at top than bottom; the sure means of hindering the production of side shoots, and in time producing naked places and gaps in that part of the hedge.

6. *Arable Land.*

Ample details of the turnip culture in drills is given.

7. *Orchards. Woods.*

None of the former worth notice. Some native copses and woods, and artificial plantations, but not much woodiness, excepting round gentlemen's seats.

8. *Improvements.*

In this county were begun about 1730, when Swinton of Swinton drained, marled, and completely enclosed his whole estate. Nearly about the same time, Hume of Eccles effected similar improvements. Both of these gentlemen were actuated by the example and acquaintance of Cockburn, of Ormiston. Henry Home, Lord Kaimes, was one of the early improvers of this county about 1746, at Kaimes, now Besborough. About 1750, the ardour of enclosing and improving the land spread generally among the Berwickshire proprietors.

Paring and burning, irrigation and embanking, not practised or required.

9. *Live Stock.*

The cattle of Berwickshire are so much mixed by crossing, as scarcely to admit of any particular description. Upon the whole, they are short horned, thin hided, and kindly feeders, and have been much improved by crosses with bulls of the Teeswater breed, which is the kind chiefly admired in this district. Generally speaking the oxen are not carried on to any age, and they are never worked. They are well fed from their youth up, and are generally fed off for market in their fourth year, very few reaching five years old. Cows, on the contrary, are generally old before they are fed off. Great numbers of smaller cattle are bred upon the lower hills, and are disposed of to graziers in the low country for feeding, either on grass or turnips, or by a succession of both; and many Highland cattle of various descriptions are bought in yearly for consuming straw, or for feeding on turnips during winter, and on grass in spring and summer.

The sheep bred in Berwickshire are of several kinds. In the most exposed of the Lammermuir and Lauderdale hills, the flocks are mostly of the black faced, or Tweeddale kind, and are there exclusively kept for breeding. In the cultivated tract the new Leicester breed, in a great variety of degrees of perfection, now universally prevails; and it is believed that no other known breed, in the peculiar circumstances of this county, could be so profitable to the farmer. They require, however, always to have abundance of food, and easily procured; for, being short-legged, heavy-bodied, and carrying a great weight of wool, they are unable to undergo much fatigue or hardship, and do not thrive unless plentifully supplied at all seasons. This supply the agricultural system of the district amply affords, and is indeed admirably calculated for providing. On some of the best interior hills, and upon the higher exterior lands, verging on Lammermuir and Lauderdale, called the moor-edges, the Cheviot breed, or long sheep, are kept. An intermediate breed between the Cheviot and Leicester, usually called half-bred sheep, is very prevalent upon the best of these situations. As a singular circumstance, the reporter records the case of a ewe of this county, which produced eleven lambs in three succeeding seasons.

Horses, as in East Lothian, brought from the west of Scotland.

10. *Rural Economy.*

Farm servants managed as in East Lothian, and, indeed, almost every where in the low country of Scotland.

11. *Political Economy.*

Commerce chiefly grain, wool, and salmon; scarcely any manufactures, excepting the paper-mills. The salmon fishery, including Berwick bounds and the English side of the river, employs about seventy small boats, and nearly 300 fishermen. All their fish are sold to a very respectable fraternity of traders in Berwick, named coopers, from their former business of making kits, and boiling the fish, which is now entirely discontinued. By them the salmon are packed in ice, and sent to London, to be disposed of by factors on commission. This employment of ice was first essayed by Messrs. Richardson, of Perth, on the suggestion of George Dempster, of Dunnichen, Esq. who had accidentally read that such a practice was not unusual in China.

7836. ROXBURGHSHIRE or TEVIOTDALE contains 448,000 acres, of which about three fifths are in sheep pasture, and the remaining two fifths, are occasionally under the plough, except about 8000 acres occupied in woods, pleasure-grounds, and the sites of towns and villages. The surface is exceedingly irregular, being in some places ninety, and in others 2000 feet above the level of the sea. The climate is equally various, and excessive rains, winds, frosts, and even hail and snow are by no means uncommon in spring and harvest. There is a good deal of moss and peat soil in detached portions over the county; but the general character of the district is, that the low or arable part consists chiefly of a light or turnip soil, and the hilly division of dry green pastures. There is a good deal of high, wet, barren land; but this is by no means the character of the county at large. Limestone abounds in most parts of the district, and coal has been found, but is not worked. The agriculture of the arable lands is in all respects the same as that of Berwickshire, and that of the pastures resembles the store farming of the latter county and East Lothian. Dawson, of Frogden, belongs to this county, and may be looked on as one of the greatest improvers of British agriculture. (*Douglas's Roxburghshire*, 1794. *Edin. Gaz. abridged*, 1829.)

1. *Property.*

Generally in large estates, and little change of proprietorship has taken place for many years. The largest between 25,000*l.* and 35,000*l.* a year.

2. *Implements. Arable Land.*

Fanners, the reporter states, were first made in this county by one Rogers, a farmer, of a mechanical turn, near Hawick, in 1733, or at least before 1737, who is said either to have seen a model, or a description of one, which had been brought from Holland. (*Report of North m.*) Robertson states (*Rural Recollections*, p. 147.) that he himself conversed with an old farmer, the late Mr. Thomas Shiells, at Grothill near Edinburgh, who with his own hands made the first winnowing machine in the Lothians, from a model of one imported from Holland."

Arable land enclosed, partly by hedges and partly by walls of loose stones, without mortar.

Ploughing with two horses, without a driver, was practised in this county before it was in any other. It was taught by Dawson, of Frogden, who introduced the drill culture, to James Macdougal, farmer, at Linton, in Tweeddale, alive at the time of making up Douglas's report: it spread rapidly afterwards through the county, and the neighbouring ones of Northumberland, Berwickshire, East Lothian, and Tweeddale. Potatoes first planted in large beds about 1754; in 1768, in drills in the fields. Tobacco, during the American war, was cultivated to a considerable extent in the neighbourhood of Kelso and Jedburgh, and in some other spots. Its produce was so great, that thirteen acres at Crailing fetched 104*l.* at the low rate of fourpence per pound and would have brought more than three times as much, had not an Act of Parliament obliged the cultivator to dispose of it to Government at that price. This county lost about 1500*l.* sterling by that Act, which passed while the tobacco was growing; yet it excited not so much murmuring and clamour among the sufferers as have been elsewhere repeatedly raised, with less reason, against other Acts in no respect so arbitrary and oppressive.

3. *Gardens and Orchards.*

Thrive better in the lower parts of this county than in those on the east coast. At Melrose, Jedburgh, and Kelso, are the remains of orchards planted by the priests several centuries ago, the pear-trees of which are very productive. Wonderful stories are told of their fertility. A single tree of the Thorle pear at Melrose has for these fifty years past yielded the interest of the money paid for the garden where it stands, and for a house let for seven pounds sterling yearly. Another tree there has carried fruit to the amount of three pounds annually, at an average for the same period. In the year 1795, two trees there brought to perfection about 60,000 pears, which were sold for eight guineas. These facts are well authenticated. There are also several more recent orchards near the same places, and 120 acres of nurseries. Of these one of the oldest and largest in Scotland is that of Messrs. Dicksons, of Hawick.

4. *Woods and Plantations.*

To the extent of 5290 acres; nearly two thirds artificial.

5. *Live Stock.*

Cattle, a mixed breed, as in Berwickshire. Sheep of the Cheviot kind said to be greatly improved by a cross with the

Dishley breed, introduced about 1765, by Robson, a pupil of Culley; but this is stoutly denied by most of the Cheviot breeders. Merinos and other sorts have been tried, but sufficient time has not elapsed to ascertain the result.

6. *Rural and Political Economy.*

Farm servants on the same plan as in East Lothian. Roads improving; no canals; little commerce, and almost no manufactures.

7837. SELKIRKSHIRE. 172,160 acres, almost wholly of mountainous surface, the lowest part 300 feet above the level of the sea; many houses are 600 and some more than 1000 feet above its level. The highest mountain is 2370 feet. These mountains are generally of granite or whinstone, and the surface soil is commonly gravelly and dry. In the valleys are clay, peat, morass, and lakes. The climate is cold and rather moist. There are no metals, nor coal, lime, or freestone. The most remarkable thing attending this county is, that its hills and mountains are almost every where clothed to their summits with sound sheep pasture, of which there are estimated to be 148,000 acres; 8800 acres in aration, 2000 in wood, and the rest in gardens, houses, roads, lakes, &c. (*Douglas's General View*, 1796. *Edin. Gaz. abridged*, 1829.)

Property in few hands, and in large estates. The farms are large, and the leases generally shorter than on arable farms. The sheep are a variety of the Cheviot produced by repeated crosses with the native mountain black-faced breed. In all respects the husbandry of this county may be considered the same as that of the mountainous districts of the preceding counties. There is a woollen cloth manufactory, and an excellent porter brewery, by a pupil of Meux, at Galashiels. Some agricultural societies were attempted in this and the adjoining counties about 1793, but they were of very short duration.

7838. PEEBLESHIRE or TWEEDDALE. 229,778 acres, mostly of mountain, moor, and bog, but with about one tenth part arable. The lowest part of the county is 400 feet above sea-level, and grain is cultivated to the height of 1000 feet. The climate is late, cold, and moist, and the soil moory, clayey, or sandy, according as the water is pent up; the rocks of the mountains are freestone, granite, trap, or claystone. The only minerals worth notice are lime, whinstone, and freestone. The general appearance of the country is wild, and rather dull and dreary, than romantic or sublime. The agricultural survey of this county is by the Rev. Charles Findlater, and it abounds with more valuable matter on political agriculture, on leases, prices, restrictions, markets, &c., than any survey that has been published, without a single exception. In fact, it was found to take such a masterly view of the moral incitements to agricultural industry; to expose the system of tithes, entails, lawyer's leases, &c., that it was rejected by the Board, as likely to offend the English clergy and higher classes, and the author was reduced to publish it himself. It has certainly, through the medium of the extracts from it published in the *Farmer's Magazine*, been the means of enlightening thousands, both of farmers and landlords. The fundamental principle which Findlater lays down and illustrates under the heads of leases, size of farms, usury, capital, dearth, monopoly, forestalling, government interference, tithes, poor, and other topics, is, "That the best demo of ensuring the invention and prosecution of the most advantageous measures is, an arrangement which shall communicate to those on whom their execution is devolved a sufficient personal interest in their invention and execution." To some he doubts not such views will be considered as foreign to the report of a county; whilst to others they will constitute its most essential value.

The state of property and husbandry of the country may be considered as the same as that of the other mountainous districts. The black-faced sheep are in almost universal use, except in milder situations, where the Cheviot has been introduced. There is no commerce but by retail, and only some very trifling woollen manufactures in the county.

In the Appendix an account is given of the improvement of the Whim, a flow-moss of 100 acres, twenty feet deep, and at an elevation of 700 feet above the level of the sea. It was begun to be drained in 1731, and in ten years a mansion was built, and surrounded by woods and pleasure-grounds, which show, as the Duke of Buccleugh, the proprietor, intended, the wonderful influence of art over nature. "The plantations (originally extensive) have been improved and enlarged since the property came into possession of the Lord Chief Baron; and he has also greatly enlarged the house, adding a court of offices upon a large scale, and ornamented in front, extending also the lawn. The place has, upon the whole, an air of magnificence. In the pleasure-grounds there are several artificial pieces of water. East of the house (where the soil is dry and covered with sweet grasses) the surface is agreeably diversified by gentle swells, tufted with trees. A wild wilderness walk, through a small wood, lands you upon the banks of an artificial lake, with islands, covering an extent of six or seven acres of surface. What chiefly strikes the visitor at Whim is the strongly marked contrast betwixt the improvements of human art, and nature in her wildest form, here found in immediate contact. Your ears are at once saluted with the warblings of the blackbird and thrush from the plantations, and the wild notes of the plover, the curlew, the grouse, and other moss birds from the flow-moss." (*Findlater's Report, &c.* 1804.)

7839. DUMFRIESSHIRE. 644,385 acres of maritime, vale, and mountain lands, in the proportion of one, four, and seven. The climate is variable, comparatively mild, but moist. The soil of the maritime district is light, and generally on sand, gravel, or rock; that of the vale or midland district is gravelly, sandy, or moory. The mountains are of schist, whinstone, or red freestone, and thinly covered with corresponding soils or moss. In some places they are covered with dry pasture, but more frequently with a mixture of grass and heath. The principal metallic ore found in the county is lead; but several others, as iron, copper, antimony, &c. exist, and the latter has been worked. Coal has been found, but not in strata sufficiently thick to be workable. Marble also and slate have been worked, and lime, freestone, and whinstone in abundance. There are several mineral springs in the mountain district, the principal of which is the spaw at Moffat. Fish, and especially salmon, are caught in moderate quantities in the Nith and Annan. The celebrated improver Craik was a proprietor in this county, at Ardbigland, near Dumfries, now the property of his son. (*The Rev. Dr. Singer's General View*, 1812.)

1. *Minerals.*

The lead mines occupy very barren grounds, remarkably bleak and elevated; but they are a great fund of industry and riches, and they furnish a part of the county with an excellent market for the surplus grain produced in that part. Lead hills, with the mines, are in the county of Lanark, and belong to the Earl of Hopetown, who draws about 7000*l.* a year from these mines. Wanlockhead mine is in Dumfriesshire, belonged to the Duke of Queensbury, and returns to the proprietor near 5000*l.* a year.

2. *Property.*

In large estates, owned by 453 persons. The Duke of Buccleugh's estate of very great extent. Some estates are managed by their owners, and others by commissioners having power to let. In large properties it is common to entrust the collecting rents, and arrangements relative to leases, buildings, fences, and courses of crops, to factors residing on or near the lands, who represent their constituents (if not personally present) in county and parish meetings. Millar of Dalswinton has gone over an estate of 5000 acres in twenty-five years, and improved the whole of it, with the exception of a portion which, in 1812, was under process and promised to be soon completed. His plan was not to farm his lands himself, but to prepare them, by improvement, for being let to farmers.

3. *Buildings.*

While the reporter expatiates on the ample accommodations of the modern farm-houses in this and other counties, he gives the following information as to cottages, which, we regret to find, seem by no means improved, either in this or in other parts of Scotland, in the same ratio as the habitations of inferior animals. "A common, and not inconvenient, cottage is put up as follows, viz.: stone and lime walls, seven feet high, thirty-six feet long, and fourteen to sixteen feet wide within, the roof of Scots fir, which is preserved from the worm by smoke, and covered with thatch; a chimney at one end, and an open passage for smoke in the other; affording two apartments below, one of them a kitchen, and a central apartment opposite to the door; the one end boarded over, and the other open. Such a cottage may be erected for about 30*l.* or 40*l.*; and, with half a rood for a garden, it would let at 3*l.* a year, or more, according to its finishing." Doubtless the reverend gentleman made but short prayers when he visited the sick in such smoky cottages: the surgeon need not dismount from his horse; he may speak to his patient through the window, and feel his pulse with the butt end of his whip.

4. *Occupation.*

Sheep farms from 300 to 3000 acres; arable farms from 50 to 600 acres. Leases universal, and generally for nineteen or twenty-one years. Wilkie's variation of Small's plough is in general use, as clearing the mould-board better in soft soils. The Berwickshire system of culture is practised on the turnip soils; the East Lothian on such as are loamy or clayey; and the store system on the mountain district. The cattle are of the Galloway breed, and sheep, Cheviots, or the black-faced mountain kind. More poultry is kept than in most other counties, in order to consume the light grain. Many of the fowls and eggs go to Edinburgh; but the greater part of the produce and sales in eggs go in small oval baskets, packed in

carts, to Berwick, for the London market. In one or two instances the *Hólcus lanàtus* has been cultivated on reclaimed bogs with success, but is intended to be succeeded by better grasses as soon as they will bear them. The drill culture of turnips was introduced by Craik about 1745. Draining has been extensively practised, irrigation in a few places, and some embankments made on the Solway Firth, and the Nith and Annan. There are few orchards. Some remains of coppice and forest, which, according to appearances and authentic records, seem in former times to have spread over great part of the county; and numerous young plantations. Some years ago many young Scotch firs died from the attacks of the *Tenèdo pinòrum*, as some suppose; but the cause does not seem clearly known. Some very large oaks, beeches, elms, ashes, and larch firs are described in the Report.

5. *Improvements.*

As a specimen, we shall give some notices of what has been done on the estate of Mount Annan, by General Dirom. The extent of Mount Annan estate is 2750 acres. The general began his improvements in 1793, and planted, before 1819, 168 acres. Assisted in laying out a considerable extent of public road and building bridges, the road passing through the estate. Made an improvement in the construction of lime-kilns, since perfected by Booker of Dublin. (3863.) The lime quarried and dried by means of a small stream from more elevated lands; this stream being made to turn an overshot wheel, which works two pumps. The village of Bridekirk began in 1800 (3850.) on the new road, and where the river Annan affords ample falls for machinery. Farms arranged of different sizes, and three eminent farmers settled with a view to improvement. Cottage farms, one or two; cottages; improved stock on the demesne farm; improved farm buildings; leases for fifteen years; stone quarries opened, others drained and improved; brick clay found, and bricks made; salmon fishery improved. Irrigation, fiorin, spring wheat, moss composts, mole plough, and steaming apparatus introduced. A cross moss-cutting machine, invented by the overseer, William Holliday, for cutting the furrows across in improving moor, instead of cross-ploughing; the latter operation being not only very laborious, but one which seldom succeeds in cutting the furrows into pieces small enough to be afterwards easily harrowed. This machine consists of two circular knives, if they may be so called, six inches deep in the blade, with a blunt edge fixed upon and embracing the whole of the exterior circle of two small broad wheels, and as they go round the knives cut the furrows across. The axle and frame of a roller are used for these wheels, so that the weight may be increased by loading the box of the frame, if it should be necessary to make the knives cut through the furrows. It is dragged with great ease across the ploughed moor by one horse; and when it is moist the furrows are cut through with the greatest facility, in pieces of any length, according to the number of turns taken by the machine. The furrows, when a little dry, are then turned over by the brake (break) harrow, and being all cut into small pieces, are in the best state for being reduced by repeated harrowing, or for being thrown together in heaps and burnt.

6. *Weekly Reports.*

"In carrying on the improvements which have been mentioned, at a considerable distance from my general residence, they have been greatly facilitated by requiring my overseer, or manager, to send me a weekly report of what was doing upon the farm and the estate. It shows how the servants and horses have been employed during every day; contains a journal of the weather, and of the progress of different works; and a state of his receipts and disbursements during the week. These reports, besides enabling one to judge of what is doing, and to give any directions that may be necessary, are extremely useful to refer to, and excite the overseer and servants to be diligent in my absence."

Increase of population on the estate in fifteen years, 396; viz.: from 175 to 571 inhabitants. Total expense of purchase and improvements up to 1811, 30,000*l.* Clear annual rental at that time, 2000*l.* a year, exclusive of the value of timber, and of the mansion, garden, and hot-house, &c. as a gentleman's residence.

7. *Political Economy.*

Improving roads, and some canals and railways; some commerce by sea with the port of Dumfries; manufactures inconsiderable; paper, stockings by frames, muslin weavers. A small iron-work at Kirkconnell, in which from three to four dozen spades daily are made. Cotton spinning and weaving in a few places. Carpet weaving, &c. "Salt, from the richest parts of the sea sleech, collected with horse drags in dry weather in summer, and then placed so as to be washed and filtered, and the brine that runs out of it boiled."

7840. KIRCUDBRIGHTSHIRE, 561,641 acres, and WIGTONSHIRE 288,960 acres (*Ed. Gaz. abr.* 1829), possessing great similarity of agricultural character, have been included in one report, as the district of Galloway. The climate moist but rather warm; in some parts of Wigtonshire, in genial seasons, figs ripen on the open garden walls. The soil and surface of Galloway is exceedingly various. Almost the whole of Wigtonshire is very little elevated above the surface of the sea, but great part of Kircudbrightshire is hilly and mountainous. The better soils are for the most part light, and of this and hazel loam there is a considerable portion in Wigtonshire, In some places in Kircudbrightshire it is clayey or alluvial; and there is a great deal of peat-moss, and bog, as well as improved, or grass-bearing peat. The rocks of the county are argillaceous, granite, or whinstone with some freestone. Some mineral veins have been found; and one of lead, near Gate House of Fleet, was worked at the expense of the compiler of this work for some time, but without success. In an agricultural point of view, Galloway is chiefly remarkable for its breed of cattle. Gladstone, a millwright, who has invented a reaping machine, and proposed some improvements on the threshing machine, and other implements, is of this district. (*Smith's General View*, 1810.)

1. *Property.*

More divided than in most of the counties of Scotland. Largest estate, 30,000*l.* a year, Earl of Galloway's, in Wigtonshire. Estates in general well managed: landlords in general advance money at five, six, or seven and a half per cent, for buildings, fences, drains, mineral manures, roads, &c. Dunbar Earl of Selkirk, a disciple of Craik's, one of the first who set the example of improvement, which has been persevered in by the same family to the present time.

2. *Occupation.*

In the moors, where breeding cattle and sheep is the object, farms sometimes seven or eight miles square, some ten or twelve. Arable farms 300 to 600 acres; 200 acres perhaps the average. Leases nineteen or twenty-one years, to which the late Earl of Galloway superadded the tenant's life. "From this two good effects were supposed to result; 1st. That the landlord was freed from the expenses of buildings and repairs. 2dly. That the tenant presuming (as we always do) on the continuance of life, would be disposed to go on with his improvements to the last. There is certainly, however, much liberality in the idea."

3. *Enclosing.*

Galloway dykes (3060.) very generally in use; some useful remarks on the necessity of bonding them sufficiently, and working the coping-stones to a flat under-surface.

4. *Arable Land.*

Till the middle of the eighteenth century, four and sometimes six horses yoked abreast in the old Scotch plough, and tumbrils (carts with low wheels without spokes) and cars in use; now all the improved implements; the husbandry of East Lothian on the alluvial lands and loams, too heavy for turnips; that of Berwickshire on the turnips soils; cattle bred on the mountains and moors; carrots cultivated in some places, and found to answer well; fiorin tried on bogs; some irrigation; embanking near Wigton and at Kirkcudbright, and much draining; also paring and burning, and various other means of improving bogs and flow-mosses tried, in conjunction with draining. Corn in the late districts gaited. (3176.) Barley is a good deal cultivated, and thin hot barley cakes, from dough, baked the same morning, and spread first with butter, and then with honey, and folded or rolled up (like the teff of the Abyssinians), form a part of the breakfast bread of all who can afford it in Wigtonshire.

5. *Orchards.*

Rare. "Some proprietors furnish their tenants with fruit-trees for their gardens, when they are willing to be at the trouble of cultivating them. But, from the scarcity of fruit in the country, and the idea that the plundering of an orchard is a very venial trespass, such as do cultivate them, frequently do not gather the fruits. In this we believe there is nothing peculiar to Galloway. There are a few market gardens and several nurseries."

6. *Woods and Plantations.*

Of a very limited extent, but rapidly increasing. John Earl of Stair planted extensively at Mount Kennedy, in the beginning of the eighteenth century; and Douglas Earl of Selkirk soon afterwards. The Earl of Galloway, the present Earl of Selkirk, Murray of Broughton, and various others, are great planters.

7. *Live Stock.*

The Galloway breed of cattle is well known. The breeders perhaps, in general, understand the management of cattle as well as, or better than, most others in the kingdom. They all know how to distinguish a good bull or a good cow from a bad one: and fail not to select from their own stock such as are best adapted for the improvement of the breed; and from this general attention, it no doubt arises, that the cattle in Galloway are pretty uniformly good. But among them have arisen no enthusiasts in the profession; none who have studied it scientifically, or dedicated their talents almost exclusively to this one object. No fair test has yet been given, of what might be done by a proper selection of the choicest individuals of both sexes for breeders, and uniting them in such a manner, as seemed best calculated to diminish their faults and heighten their properties, by crossing the progeny of these from time to time; and still carefully pursuing proper combinations of the most approved males with the finest females, till the improvement was carried to the greatest perfection of which the breed is susceptible. No Bakewells, no Culleys, no Collings have yet appeared in Galloway; who, with a skill, the result of long study and experience, have united sufficient capital, and by the success of their experiments have made great fortunes, and transmitted their names to the most distant parts of the kingdom. Few of the Galloway cattle (comparatively) are fed for home consumption. Dairying with Ayrshire cows has lately been introduced, and very good Dunlop cheese made.

The *sheep* for the low districts are of various breeds, those of the highlands the same as in the mountain districts of the counties already described. The South Down is found to answer well in Wigtonshire, and also the Leicester.

Horses. Galloway formerly possessed a breed of horses peculiar to itself, and in high estimation for the saddle; being, though small, exceedingly hardy and active. Accustomed to a rugged and mountainous country, and never employed in the draught, these were sure-footed, and travelled with spirit in very bad roads. They were of a larger size than the ponies of Wales, or the shelties of the north, being from twelve to fourteen hands high. It is reported that this breed originated from Spanish horses, which escaped from a vessel of the Armada, that had been wrecked on the shores of Galloway: but it appears probable from some passages in Shakspeare, that the Galloway horses were in repute at an earlier period. It is much to be regretted that this ancient breed is now almost lost. This has been occasioned chiefly by the desire of farmers to breed horses of greater weight, and better adapted for the

draught; and from the little value attached, in times of tranquillity, to horses well calculated for predatory excursions. As the soil and climate of Galloway are peculiarly adapted for rearing horses, there cannot be a doubt that under proper management, they would in general become excellent, and add much to the value of its produce. Hitherto few more have been bred than what were necessary to supply the demands of the district.

Swine increasing since the introduction of potatoes; and the prejudice against eating the flesh common to this and most districts of Scotland gradually declining. Ringing not practised; but the two strong tendons of the snout cut by a slight incision, about an inch and a half above the nose, when the animal is about two months old.

Bees of this district produce honey equal, if not superior, to any in the world; its excellence supposed to depend on the profusion of wild flowers, especially white clover and heath.

Game abundant; a few ptarmigans in the highest mountains.

8. *Political Economy.*

Roads greatly improved of late; and some cotton, woollen, paper, and other manufactures introduced.

7841. **AYRSHIRE.** 664,960 acres of irregular but not mountainous surface, and clayey or mossy soil, under a moist climate; half the county bog, hilly pasture, or waste, and the rest chiefly under alternate grass and corn. The agriculture followed is in great part the dairy system; Dunlop cheese, already described (7063.), being chiefly produced in this county. (*Aiton's General View*, 1811.)

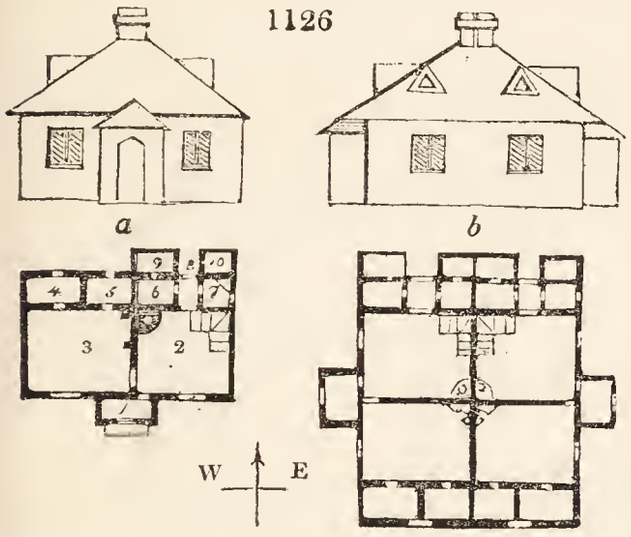
1. *Minerals.*

Coal and limestone are to be found in most parts of the county, and there are several kinds of building-stone, but no metallic ores worth working, excepting iron. Coal is the staple mineral, and is exported in large quantities to Glasgow and other towns, along the west coast, northward and southward.

2. *Buildings.*

Some good castles and mansions, as Culzean, Loudon, Eglinton, &c. Farm buildings are improving, though but slowly. Some neat elevations, and comfortable interiors on Lord Eglinton's estates; single (*fig.* 1126. *a*), and double (*b*).

1126



Each of such cottages is surrounded by a neat garden, containing a pigsty, pump, and bee-house; and the house containing a porch (1), kitchen, oven, and stair to bed-rooms (2), parlour (3), store closet (4), bed closet (5), pantry (6), coal closet (7), back entrance (8), tool house (9), and water closet (10), with two garret bed-rooms over.

3. *Occupation.*

Farms small, from 50 to 150 acres, and their culture imperfect and irregular, though rents are high from the population of the manufacturing towns.

4. *Live Stock.*

Horses are bred and sold under the general name of Lanarkshire or Clydesdale, and are in great demand; as are the Ayrshire cows for the Edinburgh and Glasgow dairymen. Indeed these cows, as we have seen (6789.), are preferred to all others in most parts of the low country of Scotland. The native horses began to be improved by crosses about 1740. In that year Robert Woodburn, in Mains of Loudoun, sold what was then considered the best stallion in the county, at the price of five guineas. The common price of draught horses did not then average more than 3*l.* each. Till about 1780, the work usually done by farm-horses was not more than one half of what they now perform. Four horses were then yoked to every plough, while as much is now turned over by two horses. (*Aiton's Dairy Husbandry*, p. 180.)

5. *Woods and Plantations.*

Most of the proprietors are extensive planters. On the Culzean estate are extensive woods, raised in the face of the west winds; most of the trees lean to the east, excepting the common maple, which is generally erect, or nearly so, and is one of the best trees for an exposed sea-coast. There are a few native coppice-woods, and some fine old birch, ash, and oak trees round Eglinton Castle.

6. *Improvements.*

Captain Smith, the proprietor of a small place abounding with peat bogs, about 1790, began to drain and dig, and lime the surface, and succeeded in reducing the peat to a black mould, and rearing tolerable crops of oats, potatoes, and clover. After five or six years, he was able to venture horses and cattle on these bogs; but at first every operation was manual.

7. *Political Economy.*

Carpet and other woollen manufactures at Kilmarnock; thread at Beith, cotton at Catharine, iron at Muirkirk, salt and kelp on the shores, and earthenware and the usual minor manufactures, as leather, hats, &c., at various places.

The harbour and other works carried on at Ardrossan, under the auspices of the Earl of Eglinton, and the harbour of Troon, and the railway from thence to Kilmarnock, formed almost entirely at the expense of the Duke of Portland, are worthy monuments, no less of the enlightened judgment and energy, than of the wealth of these two patriotic noblemen. The harbour lately completed is one of the safest, most capacious, and most accessible on the west coast of Britain; possessing many advantages over the harbour in the Frith of Clyde, situate in a narrow channel, which can be navigated only when the wind blows from particular points, and which, for upwards of twenty miles below Glasgow, is both shallow and dangerous. A circular pier of 900 yards was finished in 1811, and every thing was then ready to begin the wet-dock, which, according to Telford's plan, was to contain from 70 to 100 vessels, in water sixteen feet deep. The other works have rather languished of late, and are not likely to be completed soon without public aid. It was part of the Earl of Eglinton's plan to raise a neat regular-built town at Ardrossan, in which some progress has been made; and he has constructed excellent baths, which draw to it a number of visitors at the proper season.

The harbour at Ardrossan was only a part of the general plan, and that from which, viewed by itself, the smallest advantages perhaps were to be expected. The leading idea was to open a direct communication between Glasgow, Paisley, and other large towns in the vicinity and the west coast, instead of the present circuitous passage by the Frith of Clyde. A canal was therefore to be cut from Glasgow to Ardrossan, about thirty-one miles and half, at the estimated expense of 125,000*l.* Of this a third part was executed, that is, from Glasgow to Johnstone, and this part, it is said, cost about 90,000*l.*

The harbour at Troon, connected, as it now is, with Kilmarnock, by means of an excellent railway, seems to possess almost all the advantages of that of Ardrossan, and promises to become, in a much shorter period, of vast utility to the populous country around it.

7842. **LANARKSHIRE or CLYDESDALE.** 556,800 acres, in great part mountain, moor, and peat-bog, with a portion of friable loam, and some retentive clays. The climate is cold, moist, and unfavourable, excepting in the low vales, where vegetable is chiefly injured by spring and autumn frosts. Average of the rain which falls at Glasgow, 30·8 inches. The minerals are lead, ironstone, coal, limestone, freestone, and whinstone, all worked to a considerable extent. The lead mines at Leadhills have been already noticed under Dumfriesshire. The husbandry of the county is chiefly distinguished for its breed of horses, and for orchards, the latter a rare production in Scotland. John Naismith, the author of a work on Industry, another on the Elements of Agriculture, and also of the Report, seems to have been a native of this county. (*Naismith's General View*, 1803.)

1. *Property.*

Three fourths of the surface the property of great landholders; the rest much divided. Farm-houses and offices were formerly very indifferent; but in this as in other adjoining counties, where the leases of farms fall in, the landlord generally enlarges or renews the buildings, as a necessary step to getting the full rental value for the land. A good deal of ground feued out to operative mechanics, weavers, &c. for building cottages.

2. *Occupation.*

Much the same as in Galloway. Breeding farms are large, and corn farms moderate. The mountainous district is occupied mostly with flocks of sheep: upon the ridges on the E. and W. sides, where the ground is marshy, and less proper for sheep, and the exposure too bleak to encourage the cultivation of corn, cattle are mostly pastured, and those generally milch cows and their young, many of which are reared; a small quantity of corn only being cultivated, principally for the sake of winter provender. The less rugged and less exposed parts are more occupied in the culture of corn; and the banks of the Clyde, between Hamilton and Lanark, with orchards.

3. *Gardens and Orchards.*

Glasgow is abundantly supplied with the common culinary vegetables from market gardens. Orchards are chiefly found in two districts in Scotland, in Clydesdale, and the Carse of Gowrie. "The Clydesdale orchards lie mostly between the bottom of the lowest fall of the river, and the mouth of the south Calder. They are chiefly of apples, with a mixture of pear trees, and some plums. Cherries are more rarely cultivated, being much subject to the depredations of birds. Few of the orchards are large, but many small ones are planted up and down the country. The whole may cover 340 acres or upwards, and are on the increase. The produce is very precarious, the fruit being frequently destroyed in the blossom, by spring frosts and caterpillars. The value of the fruit is not always in proportion to the number and size of the trees. Those who cultivate the ground around the trees, taking care not to injure the roots, and giving manure from time to time, have finer fruit, and a much greater quantity in proportion, than those who do not. Much also depends on adapting the trees to the soil and exposure. These orchards are mostly planted on very steep hanging banks, and on such they have

been found to succeed better than on plains, as subterraneous water flows most quickly away. Most of them stand on soils greatly cohesive, and on such the trees have been supposed to be surer bearers than on open sandy soils: yet there are instances of orchards, on friable and gravelly soils, uncommonly productive. Plum trees are generally planted round the verge of the orchard, and are profitable, not only for the fruit they bear, but for sheltering the other trees. The depredations committed on the orchards are become more frequent and daring, as the manufactures of the county have increased, and are a great discouragement to this species of cultivation, particularly that of small orchards, which cannot defray the expense of watching in the night."

Besides the larger fruit, great quantities of gooseberries and currants are cultivated, and, when well managed, are said to pay very well. The gooseberry and currant trees are dug around annually, kept on a single stem, and dunged every second year.

Copsewoods, or native timber trees, are not abundant; the oldest trees are on the Clyde, in and near Hamilton Park and Bothwell Castle. Many new plantations are forming in every part of the county.

4. *Live Stock.*

Cattle a mixed breed; the Ayrshire beginning to become general. Oxen formerly employed in labour, and still used by a few of the amateurs in spite of the better sense of their tenants and bailiffs. Few sheep kept, excepting on the mountains, where the black-faced sort prevails.

The daught horses of Clydesdale have long been in high estimation. Dealers from different parts of England come to the Glasgow and Rutherglen markets to purchase them, and prefer them to the Derbyshire blacks. Those of the upper ward, where the greatest number are bred, are esteemed the best. The native breed began to be improved by crosses from England and Flanders about 1760.

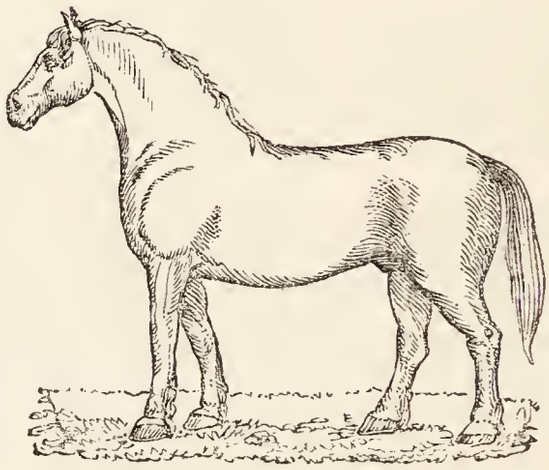
The Lanarkshire breed of horses vary in height from 12 to 18 hands; but from 14 to 16 hands is considered the proper size. "His general aspect (*fig.* 1127.) is stately, handsome, and dignified. He is round, fleshy, well proportioned, strong, and heavy, without being coarse or clumsy. His countenance is sweet and agreeable, yet lively and spirited; and his motions are steady and firm, but nimble and alert. His head is in due proportion to his body, rather small than large, no way clumsy, and not so full and prominent below the eyes as some of the English breeds. His nostrils are wide, his eyes full and animated, and his ears erect. His neck is neither long nor slender, but strong, thick, and fleshy, with a good curvature, and the mane strong and bushy. He is broad in the breast, thick in the shoulders, the blades nearly as high as the chine, and not so much stretched backwards as those of road horses. The arm tapers to the knee. The leg rather short; bone oval and strong, but solid and clean. The hoof round, of a black colour, tough and firm, with the heels wide, and no long hair on the legs, except a tuft at the heel. The body round and heavy; the belly of a proportional size, neither small nor large, and the flank full. The back straight and broad, but not too long; the loin broad and raised a little. Flucks visible, but not prominent, and but a short space between them and the ribs. The sides, from the shoulders to the hip, nearly straight; the thighs thick, and meeting each other so close under the fundament, as to leave only a small groove for the tail to rest on. The tail strong, stiff, heavy to lift, and well haired. A large sheath (vagina) is considered to be one of the marks of a good horse, and a small one the reverse." *Aiton.* They have been much improved of late, and are still improving, especially in size and weight.

Hogs. "A kind of Jewish abhorrence of swine seems to have taken place, about the rigid times of the Reformation, in the western counties of Scotland. They were unclean beasts; it was sinful to eat their flesh, and neither creditable nor profitable to keep them; and though these prejudices are now pretty much worn out, pork is not yet, in general, a favourite food, and, of course, the number of hogs kept and fed are not considerable."

5. *Political Economy.*

The roads are in many places bad, but have lately been improved; though the materials be good and abundant, the wet climate is much against them. There are several canals, the river Clyde, navigable to Glasgow, and some railways. The manufactures and commerce of Glasgow are of great extent and well known. There is a corresponding agricultural society there, and some minor societies.

1127



7843. DUNBARTONSHIRE. 147,300 acres of exceedingly irregular surface, in two parts, distant from each other six miles; possessing little agricultural interest. The arable lands are of very limited extent, and lie chiefly on the banks of the Clyde and Leven: the greatest part of the county consisting of lofty mountains incapable of cultivation. Coal, lime, freestone, and ironstone abound, and are extensively worked. There is also ochre, schistus abounding in alum pyrites, which are made into copperas, and a large quarry of blue slate. Lochlomond is well known for its scenery. (*Whyte and Macfarlane's Report*, 1811.)

1. *Property.*

Two large estates; one exceeds 3000*l.* a year. One third of the county under entail, which greatly retards its improvement.

2. *Buildings.*

More than a common share of elegant villas and gentlemen's houses. The most magnificent is Roseneath, the Duke of Argyle, built by Bonomi, in 1803 *et seq.* It is 184 feet long, and 121 in breadth, with two magnificent fronts, both ornamented with columns of the Ionic order. On his Grace's farm, which is cultivated in a very superior style, there is also a large set of farm offices, surmounted with a high tower. Common farmhouses and cottages formerly very wretched, beginning to improve, but the progress slow. Dunbarton bridge 300 feet in length, and twenty-five feet high in the centre.

3. *Occupation.*

Average extent of arable farms fifty acres; sheep, or mountain farms, average 600 acres. Farmers men of limited education, without capital, and implicitly following the practices of their forefathers. There exists among the labouring class in this district an inveterate attachment to the possession of land. When a young man is disposed to marry, he looks out for a small farm, takes it at an extravagant rent, stocks it on credit, and draws from it a scanty subsistence, while at the end of his lease his effects are often unequal to pay the debt which has accumulated during its currency. In fact the feudal state of society has not entirely disappeared in this county. There were lately, on many estates, and are still on some, farms let to three or four tenants, as conjunct lessees, to be cultivated by their united, or rather discordant exertions. Lands always let on lease, seldom for a shorter period than nineteen years.

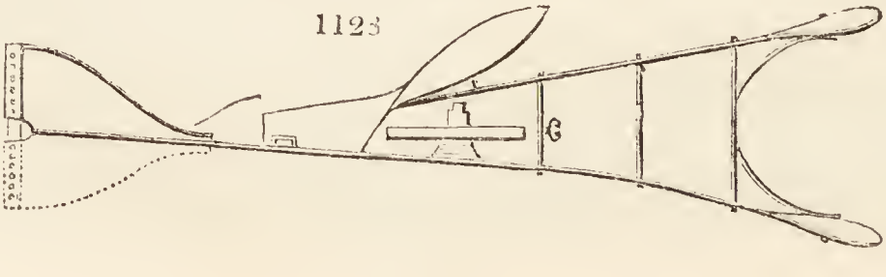
4. *Implements.*

Curved harrows of a semicircular form are used by the best farmers for dressing their potato ridges. The diameter is equal to the distance between the drills or ridges, generally near three feet; and they are used, before the young shoot of the potato springs, to dress the surface of the ridge, and destroy any weeds which may have begun to appear. The highland hand-harrow is still in use in some corners of the highland district. It is about two feet long and fifteen inches broad, consisting of three bulls, and as many cross bars, with twenty-seven teeth and two handles bent, like a hoop, with which it is wrought. It is employed on bits of land which have been dug with the highland spade, either on account of their being too steep to be tilled by the labour of a horse, or from their consisting of a number of small corners among rocks and large stones, to which a common harrow could not find access. Wilkie's wheel plough, with a shifting muzzle (*fig.* 1128.), is used to clear water-furrows on wet lands, and also for the common purposes of ploughing strong clays when wet; the muzzle being set so as both horses may walk in the furrow.

5. *Enclosing.*

Gentlemen who pay particular attention to their hedges never allow them to be cut with shears. In place of that implement a hedge-knife is used, with a short and slightly curved blade, thick in the middle, and tapering to a thin and very sharp edge on each side. By cutting always upwards, the twigs are cut clean over without being bruised or cankered, and the hedge is kept, of what is universally allowed to be the best shape, broad and bushy at the bottom, and contracting to a sharp ridge at top.

1123



6. *Arable Land.*

Potatoes cultivated better than any other crop in the county, and with the greatest success. They are planted on every variety of soil, and thrive even on the stiffest clays where there is a sufficient declivity to carry off the surface water; but a gravelly loam suits them best: about twenty tons of manure per acre is the common dressing. Drilling and dibbling are the common modes in the lowlands, and by large beds in the uplands; average produce twelve tons, but eighteen are frequently obtained.

7. *Grass Land.*

Some bog meadows, but no others; some pasture fields round gentlemen's houses, but none on lowland farms; mountains wholly in natural pasture, moss, heath, bog, and moor.

8. *Woods and Plantations.*

Copsewoods form a very important and prominent article in the produce of this county. They cover some thousands of acres of soil which would otherwise be altogether or nearly useless, and yield an income to the proprietors little inferior to what they derive from their best arable land. The steep sloping banks of Loch Lomond and Loch Long, where the bases of the mountains run into the lake, are in many places covered with them. The thin dry soil which appears in small patches among the rocks seems to be particularly adapted to the growth of oak coppice, which, from its superior value, is chiefly encouraged in such situations, while the moister and more unfavourable spots are allowed to be occupied by less valuable trees. These are chiefly ash, yew, holly, mountain-ash, birch, hazle, aspen, alder, crab, thorn, and willow. The seven last kinds are considered inferior in value to the rest, and commonly known by the name of barren timber.

Copsewoods are cut from the twenty-second to the twenty-fourth year; after the latter period the bark of oak becomes hard and corky, and of less value to the tanner.

Plantations very generally formed on the uplands. 1000 acres planted at Luss previously to 1794. The Duke of Montrose, a great planter in Stirlingshire, and partly in this county, allows 200 Scotch pine, 400 larch fir, and 1000 hardwood trees, to an acre; prefers oak plants of several years' growth; and after they have been established several years, cuts them down, when they push long and strong shoots. Plants by stellate slits, as already described (3953.), as pits in a retentive soil only serve as a receptacle for water. Firs, pines, and all trees now regularly pruned. In the Isle of Skye, Lord Macdonald planted, in 1821, 47,500 trees, and received the honorary premium of the Highland Society of Scotland. (*Trans. Highl. Soc.* vol. vi. p. 258.)

The finest tree in the county is an ash in Bonhill churchyard. Its trunk is about nine feet high, and, where smallest, upwards of eighteen feet in circumference. Of the three principal arms into which it branches, the largest is eleven, and the smallest near ten feet in circumference. The branches spread in every direction with uncommon regularity, covering an area of near 100 feet in diameter, and the general aspect is singularly venerable and majestic. There are no data from which its age can be conjectured. Nearly 100 years ago it was remarked by Marsham of Stratton, near Norwich, a celebrated planter, as one of the first ashes he had seen; and a tendency to decay in some of the boughs seems to indicate that it has stood there for several centuries.

Yew trees and hollies abound on the banks of Loch Lomond. A yew at Rosedoe is twelve feet round, and very high; one at Stockintibbert twenty-eight feet round, and the top spreading in proportion.

9. *Improvements.*

Some proprietors have drained bogs, and rendered them tolerable meadows; and drained and planted moors. Mosses sometimes burned, the ashes ploughed in, and the land cropped with oats, &c.

Irrigation, by means of the rills on the hill sides, tried in some places with success.

Embankments have been made on a small scale, and some of considerable extent might be formed with success.

10. *Live Stock.*

Highland cattle from Argyleshire in general use; but little feeding, dairying, or breeding of this species of stock. Sheep of a small black-faced kind bred in the county, to the extent admitted by the upland pastures. Horses, a small hardy breed.

Hogs increase as the prejudice against pork disappears. 200 fallow deer occupy two of the largest islands of Loch Lomond. The stag, or red deer of the mountains, has disappeared since the introduction of sheep. A few roes still inhabit the woodlands.

Bees common.

11. *Political Economy.*

Manufactures of iron, glass, cotton, paper, alkali; printing and bleaching works, &c.

Window glass manufactured extensively, and equal in quality to any in the kingdom. Pay 50,000*l.* a year of excise duties; employ 10,000 tons of shipping, and consume 1200 tons of kelp. The distillery of pyrolignous acid at Milburn employs about seven hands, and consumes daily a ton of small timber, chiefly oak, from which the liquor, a kind of coarse vinegar, is extracted. The process beautifully simple. A number of iron ovens, or retorts, are placed in a row, and filled with the timber cut into small pieces. A fire of coals or charcoal is kindled in a furnace attached to each, and by its heat forces the acid to fly off in the form of vapour. This vapour is conducted by a small tube, proceeding from each retort, into a refrigeratory, or long metal pipe, on which a jet of cold water from above is continually falling. Here the acid is condensed, and runs from the end of the pipe in a considerable stream, of a reddish brown colour. Besides the liquor thus procured, which is employed in mixing colours for the calico printers, there is a considerable quantity of tar and charcoal produced during the process, the value of which is esteemed equal to the expense of fuel.

7844. STIRLINGSHIRE. 450,560 acres, much diversified by rivers, mountains, woods, and valleys, containing some rich alluvial soil, extensive peat-bogs or mosses, and some bleak hilly districts. The culture of wheat and beans is the chief agricultural feature. Potatoes first cultivated in the fields in this county by Prentice, a farming gardener at Kilsyth. (*Belsche's General View*, 1796.)

Principal river the Forth, and mountain Benlomond; the latter a cone, upwards of 3262 feet high, of sheep-walk, belonging to the Duke of Montrose.

Lime, coal, ironstone, granite, whinstone, and freestone abundant.

The *carse lands* constitute one of the most remarkable soils in the county. They lie in a low situation on the banks of the Forth, and extend about thirty miles in length and two in breadth, at an average. They are elevated from ten to twenty-five feet above high-water mark, and a small portion of them in some places is overflowed at times by the river. The soil is universally allowed to be the alluvion deposited by the Forth and its tributary streams, and consequently to be the spoils of the higher grounds, through which the river takes its course. It chiefly consists of a hazel-coloured clay, a small quantity of sand, and a pretty large mixture of once organised matter. In some places are patches of till of various colours; but not a stone, so large as to obstruct the plough, is to be found. The soil of the best quality; when dug first from the natural bed is of a bright blue colour, and of a substance resembling the richest soap, and sometimes even serves as a substitute for fuller's earth. In many places the clay is excellently fitted for making bricks, tiles, and a coarse kind of crockery ware. The depths are from five to fifty feet. The subsoils are various, as a stiff brick clay, hard till, and sea-shells in a natural state. These beds of shells are from a few inches to four yards in thickness; they are chiefly large oysters, with a mixture of cockles, whelks, and some other shells at present found in the frith. These lands are in farms from fifteen to 100 acres each. In the higher parts of the county the extent is from twenty to 1000 acres.

Of *moors* above 90,000 acres.

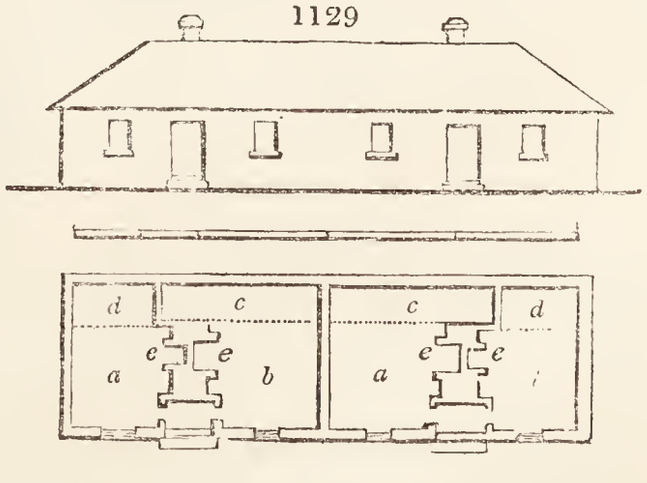
Coppice woods extensive, and plantations considerable.

Carron iron-works of great extent, and well known. Large cattle fairs held at Falkirk. Chief commerce the shipping of Carron articles for London and other places.

7845. WEST LOTHIAN or LINLITHGOWSHIRE. 71,580 acres of gently varied surface, without hills or mountains; clayey soil, and rather cold and variable climate. The minerals are coal and lime in abundance; freestone, whinstone, and some lead and iron, but the latter are not now worked. The coal at Borrowstonness has been worked upwards of five centuries. In an agricultural view, the county may be considered on a par with Mid-Lothian. (*Trotter's General View*, 1811.)

Property is in the hands of about forty proprietors. Lord Stair is supposed to have introduced the culture of clover, turnips, and cabbages at Newliston, in this county, as early as 1720; and also the Rotheram plough, for which purpose he sent a mechanic to England, to acquire the art of constructing them. A hay drag, of a very simple but convenient construction, is used in this county. Plans of a more decent form of cottages (*fig.* 1129.) are given than are to be found in some reports. Each cottage consists of two rooms (*a*, *b*); the one to be used as a kitchen has a space for two press or close beds (*c*), and in the other room there is a space for one bed (*d*); in each room is a cupboard (*e*), but no closet, which is a great defect.

1129



The contrivance for making horses draw equally in threshing-machines (2786.), was invented in this county, by G. Henderson, of Bonhard. The culture pursued is the East Lothian husbandry on the clays, and the Berwickshire on the turnip soils. The chief commerce is from the port of Borrowstonness, and there is scarcely any manufactures, unless spinning, knitting, and tambouring in private families may be named.

7846. CLACKMANNANSHIRE. 30,720 acres, principally of carse land, on the north bank of the river Forth; but partly of hilly district, belonging to the Ochills. (*Erskine's General View*, 1795.)

The carse lands are very fertile; but part of the hilly and moory district of little or no value. The agriculture is similar to that of Stirlingshire. After the invention of the threshing-machine, one of the first was erected at Kilbagie, by George Meikle, in 1787; it is driven by water. A curious source of manure is found in this county. The moss floated down from Blair Drummond (2189.) accumulates in the bays, and is mixed as deposited with the sea-weed driven on shore by the tide. This moss and weed is taken out and fermented with a small proportion of stable dung; or the farmers spread it over their cattle-yards, and it forms most excellent manure. Thus, what is a complete hinderance to improvement forty miles distant, is brought here by the river at no cost, and forms a most valuable addition to the resources of the cultivator. Till 1760, no wheat was grown in this county, though it appears by old abbey rentals that wheat was paid as rent at Cambus Kenneth so early as 1147. Now wheat enters into almost every rotation.

7847. KINROSS-SHIRE. 47,642 acres, of varied surface, but generally low. There are extensive nosses and muirs, and not much rich soil. Their agriculture is mixed, and of no great interest. (*Ure's General View*, 1795.)

Lochleven occupies 3308 acres; three small streamlets run into it, and the difference between its highest and lowest surface, at different seasons, is three feet. The trouts of this lake in high estem; those of the river Leven larger, weighing five pounds and upwards.

"Dr. Coventry, the learned Professor of Agriculture in the University of Edinburgh, possesses an estate in this county, where he sets an example of knowledge, industry, and good management to all his neighbours."

Adam, of Blair Adam, the son of the celebrated architect, the most extensive improver in the county; draining, enclosing, planting, more especially the larch and Scotch pine, and building commodious cottages, extensively and judiciously pursued.

7848. FIFESHIRE. 322,560 acres, exhibiting almost every variety of surface and soil, from the mountain to the plain, and from gravel to moss. The climate is generally mild, owing to the surrounding waters; and what adds to the value of the county, both for culture and for the formation of country-seats, it is rather drier than that of other counties equally far north. The agriculture is mixed, and may be said to excel both in the corn and cattle department. The reverend reporter displays more than the usual share of adulatory phraseology for that "highly patriotic individual, Sir John Sinclair," our "gracious Sovereign," the Board of Agriculture, and the Government, "chalking out to the people a path by which they may rise to opulence and consideration." (*Thomson's General View*, 1800.)

1. *Geographical State and Circumstances.*

Coal, lime, and the usual rocks abound; ironstone and lead and copper ore abound, but none worked. Nearer Burntisland, upon the shore, and also in some other parts of the county, there are quarries of hard stone, of a dark colour, with the peculiar property of resisting the force of fire. It will endure for many years, without being wasted or broken, though exposed to the most intense heat. On this account it is used for the soles of ovens, and for the sides of chimney grates. Common and fire bricks manufactured of an excellent quality. (*Thomson's General View*, 1800.)

2. *Property.*

Estates moderate; largest, 8000*l.* a year.

3. *Buildings.*

Few counties so richly studded with noblemen and gentlemen's houses; about a hundred enumerated as deserving of notice. Many magnificent buildings in ruins. Religious houses, castles, and Falkland Palace. Farm-houses and cottages formerly very bad, now greatly improved, and superior to those in most counties.

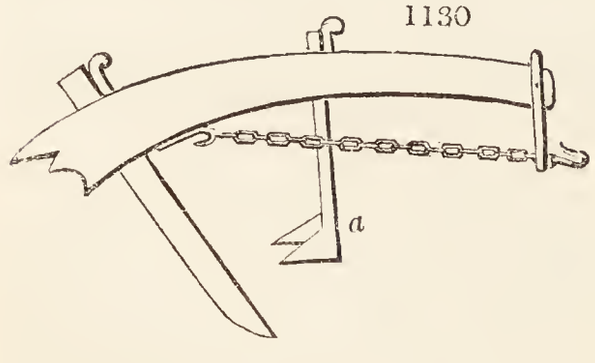
4. *Occupation.*

Farms from 50 to 500 acres of arable lands, and some of mountain pasture twice as large. Some of the largest and best farmers are men who have emigrated from other counties to this less improved district; but the greater number are sons of local farmers, and not a few farms have been in the same family for several generations. The reporter is an advocate for corn-rents, a mode first revived in this county with the improvement of not taking the corn, but paying in money, according to the average prices. Leases for nineteen years; some formerly for one or more repetitions of the period; in general the restrictions reasonable, for the managers of estates in this county are generally resident factors, and not Edinburgh lawyers.

5. *Implements.*

Ploughs with convex mould boards preferred for loose soils, especially when in a wet state; they free themselves more readily of the earth, and make a neater furrow. An addition to the plough, called a ridder (*fig.* 1130. *a.*), adopted in some places, and found to clear away the stubble from the coulter.

1130



6. *Grass.*

One fifth of the county inaccessible to the plough, and in store sheep and cattle pasture; some bog or coarse rushy meadows on peat, and a few spots of good alluvial meadow.

7. *Gardens and Orchards.*

The remains of an orchard at Lindores, but none of modern formation. Some market-gardens near the towns, but most of the inhabitants have gardens of their own. Some good nurseries. Sang, an eminent nurseryman, and manager of gentlemen's plantations,—a valuable man to the county,—has introduced an excellent system of planting, pruning, and draining. Some of the first private gardens in Scotland are in this county, as that of Keith, Wemyss Castle, &c.

8. *Woods.*

Not extensive, but young plantations very numerous and well managed. More cedars and rare sorts of trees in this county than in any other.

9. *Live Stock.*

Black cattle of Fife long distinguished. The reporter has heard an English dealer say, that a Fife bullock of forty stone will bring an equal, and often a higher, price at the London market than an English bullock ten stone heavier, and equally fat. A good Fife cow will give from five to seven gallons of milk per day, from seven to nine pounds of butter, and from ten to twelve pounds of cheese per week, tron weight, for some months after calving.

Breweries, distilleries, flour and barley mills, frequent. The linen manufacture extensive. Salt made from the sea. Tanneries, vitriol, &c.

The Fife Farming Society and the *Inverkeithing Club*, supported chiefly by farmers, are considered useful institutions. The first was formed about six years ago, and at present consists of nearly 200 members. The principal objects aimed at by this institution are, a mutual communication of discoveries and improvements in husbandry; common protection against thieves and depredators who shall unjustly invade their property; and raising a joint stock or capital for the benefit of their widows and children, and of members reduced to distress or indigence. Members pay one guinea at their entry, and half-a guinea yearly. None are admitted but men of good character; and such members as shall be found guilty of crimes and misdemeanors punishable by the laws of the land, are liable to expulsion, and a total deprivation of all benefit from the Society's fund. No member can draw any thing from the fund till it amounts to 500*l.*; neither can any one be entitled to any allowance until five years after his admission. The allowance fixed for a member fallen into distress or indigence, is thirty shillings per quarter; but this allowance is granted upon the express condition, that he has not brought the distress upon himself by drunkenness, or any other kind of disorderly conduct. And during the time he is receiving the allowance, if he shall be found guilty of dissolute or immoral behaviour, it is put in the power of the managers to deprive him of it. The widow of a member is allowed twenty-five shillings quarterly, so long only as she remains his widow, and maintains a good character. And the children, when no widow is left, are entitled to draw the half of what their father contributed. If a member shall die, and leave neither widow nor children, his next heir, or whoever shall be appointed by him, shall be entitled to the half of what he has contributed, after deducting a proportional share of the expenses incurred by the society since his entry. This society is, at present, in a very respectable and flourishing condition.

7849. PERTHSHIRE. 4,068,640 acres, almost every where mountainous, but with intervening vales of strong clayey soils, fertile in corn; some gravelly tracts, and many mosses, bogs, and moors. The mountains on the southern side of the county, where they are less high, are covered with pasture to the summits; those in the northern parts with pasture, heath, and copse. The minerals are coal, lime, freestone, slate, whinstone, granite, &c. the metallic ores, iron, lead, and copper, neither of which are at present worked. This county serves to divide that part of Scotland on the south, which is generally adapted to the raising of grain, from that of the north, which, with few exceptions, is more fitted for pasture. It also divides those parts of the kingdom on the north, where firs abounded in former times, and are still found in the mosses, from those in the south, which carried oaks and a variety of other wood, but no natural firs. It is also the general boundary, in regard to coal and granite, though both are found to a moderate extent, the former in the north, and the latter in the south. The husbandry of Perthshire is noted for its clay, or carse land culture, and for its plantations of larch trees. Its great improvers

have been, or are, Lord Kaimes, the Duke of Athol, and Lord Breadalbane. (*Dr. Robertson's Genera. View*, 1813.)

1. *Property.*

Estates are of all sizes, but the greater number large. The management of the great estates was uniformly committed in former times to the factor or chamberlain; but agriculture has become so much the amusement of the country gentlemen, since the middle of the last century, that many of the proprietors, besides the general superintendence of their estates, have a farm in their own possession, which they manage by an overseer. Many of our improvements in agriculture are suggested by the gentlemen of the army, in consequence of their remarks on the practice of other countries. The gentlemen of the law, during the recess of their courts of judicature, turn much of their attention to the cultivation of their estates; and their habits of application to the former study, quickens their ardour, and ensures their success in pursuit of the latter.

If the property be extensive, besides an overseer on the landlord's farm, there is generally a factor or steward, and sometimes two or more are appointed to manage the more distant parts of the estate. In these cases, unless the landlord have a turn for business, he is apt to lose sight of the detail of his own affairs; and if he be indolent, he has a good apology for neglecting his interest, because he pays another person for taking that charge off his hand. The prosperity of the estate, and the comfort of the tenants, depend in these cases very much on the disposition of the factor.

The boundaries of estates are marked according to the nature of the country. In the valleys of the highlands, different properties are separated either by substantial stone-walls without mortar (provincially dry stone dykes), or by a river, or a brook, or a range of rocks, or some other natural limit. The lower hills too are sometimes bisected by these walls; but more generally by hounding stones, fixed in the ground, and set up singly; in other instances, if the stones be small, they are piled in heaps. The higher mountains are frequently divided in a similar manner, especially when different proprietors occupy the same side; but when they occupy different sides of the same ridge or general line of mountain, as commonly happens between parallel glens, their properties are determined as wind and water divides, which means the line of partition on the top of the mountain between the windward and lee-side, or as it is still more nicely marked by the tendency of rain water, after it falls upon the ground.

A great proportion of this county is freehold. Many of the small proprietors hold of a subject superior. When a great baron in the feudal times had occasion to borrow money, he had recourse to wadsetts, or feued off a part of his property at a quit-rent, which was greater or less, according to the amount of the premium that was paid in hand. The wadsetts are paid up; but the feus, being irredeemable, remain.

2. *Occupation.*

Arable farms from 30 to 500 acres. Farms in the mountains large, and their extent generally defined by miles. Leases seldom shorter than nineteen years' endurance. Rent, in a few instances, partly in money and partly in the money value of corn, on an average of two or three by-gone years, according to the modern system. The culture requires scarcely any remark, since there are only two kinds of aration in Scotland, that of the clay soils of East Lothian, in which a fallow and alternate corn and green crops are introduced; and that of Berwickshire, which substitutes turnips for fallow, and allows from two to five years of pasture, according as the soil is weaker or stronger as resting crops. A full account of the clay-land culture has been given by Donaldson. In the mountainous region, cattle chiefly, and sheep to a certain extent, are bred and sold for feeding in the low arable districts, and sent to the south of Scotland and England.

3. *Gardens and Orchards.*

In the Carse of Gowrie, a number (perhaps thirty) of orchards of apples and pears, the fruit of which is sold to the neighbouring towns. A few other parts of the county adapted to open orchards, as the banks of the Tay, Earn, &c. In the valleys of the highlands, geans and cherries abound. The trees thrive well, live long, and carry fruit of the finest flavour and most savoury taste. The cream-coloured cherry of Ardvorlich, and the black gean of Castlemenzies, are highly esteemed in respect of beauty and relish.

4. *Woods and Plantations.*

The Highlands of Scotland formerly covered with wood, as the trunks of oaks and firs in the mosses, from that of Moss-Hunders, near Stirling, to the bogs of Sutherland and Caithness decidedly prove. Planting did not become general in Perthshire till after the middle of the eighteenth century. The county is now distinguished by its extensive tracts of larch, common pine, and other trees, and by the enclosure of oak, birch, and hazel; copses and woods formerly left open to the browsing of deer and cattle. Different accounts have been given of the introduction of the larch into this county. Dr. Robertson states it as "said to be brought to Athol, from Carniola, by one of the Dukes of Athol." According to others, the first plants were obtained from a nursery at Edinburgh, and planted at Dunkeld in 1741, having been previously introduced into Scotland, by Lord Kaimes, in 1734. (*Encyclopædia of Gard.* 2d edit. 7053.) Some of the first planted larches in the low grounds, near Dunkeld, have grown to the height of 120 feet in fifty years, which gives an average of two feet four inches and a quarter a year. It is stated by the Duke of Athol, in a communication to the Horticultural Society, made in June, 1820, that on mountainous tracts, at an elevation of 1500 or 1600 feet, the larch, at eighty years of age, has arrived at a size to produce six loads (300 cubic feet) of timber, appearing in durability and every other quality to be likely to answer every purpose, both by sea and land. (*Hort. Trans.* iv. 416.)

"The largest larches in Perthshire, or perhaps in several counties around it, are at Monzie, the seat of General Campbell, which measure five feet in diameter, and about fifteen in circumference. There are larches of a great size at Blair Drummond, Gleneagles, Rossie, and many other places in Perthshire. Posts of larch, which had been put into a moist soil about fifteen years ago, seemed still to be fresh and strong. It is only of late that this tree has been generally planted, and its excellence known in this country. It is the most rapid in its growth of any tree we have, and the most valuable species of the pine. It is closer in the pores, has fewer knots, and the wood is more durable than the common pine, and withal it increases double the number of cubical feet, in any given time; which is a singular property. It may vie in growth and profit with the Huntington willow, which has been said to buy the horse, before any other tree could buy the saddle."

There is a natural *fir wood* on the south side of Loch Rannoch which covers 2566 acres. One formerly existed on the Breadalbane estate, but there are now only a few gleanings.

There are more *oak woods*, and of greater value, in this county than in all the rest of Scotland. The counties of Dunbarton, Argyle, and Stirling, come next to that of Perth. The copse of oak is cut once in twenty-four or twenty-six years. A few spare trees of the most promising appearance and of the best figure are left at proper distances, from one cutting to another, and sometimes for three or four cuttings. The straightest are generally spared, without attending to this circumstance, that crooked oak is more eagerly sought after by ship-builders, and brings a higher price, than oak which is straight. Yet as coppice wood is the object, straight trees injure it least. Scotch oak has been found in general too close in the grain to bend into planks for the sides of ships, and even for the same reason it is found to snap when used as ribs to a ship: its closeness in the grain is the effect of slow growth, owing to frequent checks by early and late frosts.

Before agricultural improvements were so well understood as they are of late, or occupied so much of the attention of all ranks in this country, many moorish tracts of lands were deemed incapable of cultivation, or of making a return in any other way equal to their being planted. Proprietors, even in the Carse of Gowrie, and in the Stormont, being actuated by this principle, about thirty years ago, planted the waste lands of their estates with Scotch firs. They have now found that this soil, by being wrought, will make good arable land, and will be more profitably employed in tillage. Some thousands of acres have accordingly been cleared; the plantations rooted up; and the soil subjected to the plough, which now lets at a progressive rent, in some cases amounting already to twenty shillings the acre. Betwixt Cupar, Angus, and Perth, a tract of thirteen miles, the plantations on two thousand acres, upon both sides of the public road, have been grubbed up; and the operation is still going on, both there and in other places. So powerful is the principle of imitation, that we all go frequently one way until we have gone too far. All men can imitate example, but all men cannot reason so far as to form a principle of action to themselves. In a certain degree this operation is salutary; but if carried to excess, it will leave the face of the country naked; and, perhaps, in all cases, the cost is not counted, nor the balance fairly stated between the plantation and the produce arising from some poor soils by an arable system; yet it must be admitted, that no trees are equal in value to corn and grass, either to the landlord or the public, where the cultivation of these can be prosecuted with success.

5. *Wastes.*

The mosses and moors of this county are very extensive, and great and successful efforts have been made for their improvement. The most remarkable is that of Kincardine moss, commenced by the late Lord Kaimes, and already described. (2183.) Draining, paring and burning, irrigating, embanking, and all the different modes of improving land, have been practised; and some, as draining and burning, to a very considerable extent.

6. *Live Stock.*

Breeds of cattle very various; none peculiar to the county; Angus, Fife, and Argyle herds common among the farmers. English, Ayrshire, and most of the approved breeds of the south tried by the proprietors. Breeding is the chief object, and next the butter dairy.

Sheep. The ancient breed of sheep in this county were the white-faced. They were few in number, compared to the flocks at present; and in the highlands were housed in cots every night in winter and spring. About forty years ago, the black-faced or mountain breed was introduced from the south, and bought in, either when lambs, or at a year old. Their numbers have increased beyond all expectation, since that time, over the whole highlands of Scotland. In gentlemen's enclosures we see different kinds, according to their fancy, or the superior profit expected from one kind more than others.

Horses. The original breed were ponies, twelve to thirteen hands high, and too light for two-horse ploughs. Four of them were used abreast, as is still the case in some remote places. In the Carse of Gowrie and other lowland districts oxen were employed to draw the plough, till about 1779; and the horses were only employed to harrow in the seed, to carry out the dung, and bring home the corn to the stack-yard. When oxen were discharged from the plough, it became necessary to purchase larger horses than were then bred in the county; and the markets of Glasgow, Falkirk, Stirling, and Perth were resorted to for that purpose; which practice still continues.

At present some Northumberland stallions have been procured by proprietors, and lent to their tenants in order to raise an improved breed.

Swine. The prejudice against swine's flesh was such, that, not many years ago, no highlander would touch it; that is now fast wearing off, and the culture of swine extending.

There is a *rabbit* warren at Dunkeld, and red deer and roes in one or two places. There are also three or more kinds of fallow deer in the county.

Bees much attended to, and found profitable. Paterson of Castle Huntley sows mignonette for his bees, which gives the honey a most delicate flavour. Rosemary does the same. The honey of beans is pale; the honey of heath brown. Their flavour is also different.

7. *Political Economy.*

Roads wretched before 1745: still only bridle roads in many places of the interior. No canals; salmon fishery to a great extent on the Tay. Linen manufacture, bleaching, and various other manufactures and public works. The principal salmon fishery is rented by Richardson from different proprietors, and for the sum of 7000*l.* a year. There are five others, which produce from 100 to 200*l.* a year.

7850. ANGUS or FORFARSHIRE. 532,243 acres, one half, or more, of clayey and alluvial lowlands, and the remainder mountain pasture, moor, and bog. The climate cold, moist, and variable. It is both an agricultural and manufacturing county, and in respect to antiquities, facilities of further improvement, natural productions, &c. of great interest. The botanic family of Don are of this county. A most valuable report has been furnished by the Rev. James Headrick, and is the last of the Scotch reports which has been published. (*Headrick's General View*, 1813.)

1. *Geographical State and Circumstances.*

The Grampian mountains abound in granite, which contains topazes, or rock crystals. Quartz, mica, porcelain stone, lead, limestone, slate, jasper, porphyry, breccia, and shell marl occur in various places. The Loch of Forfar abounds with shell marl, which is taken out by scoops, and thrown into boats, by which it is conveyed to the shore. The scoop consists of a large iron scraper, somewhat similar to the Dutch hoe, which has a long wooden handle fastened into it, and a bag of strong leather fastened by whipcord around its rim. The bag is perforated by small holes, to allow the water to drain off, and has a thong at its bottom, by which it can be turned over, and its contents discharged into the boat. After the boat is firmly fastened by anchors, extended from each end, one man forcibly presses down the scoop to the bottom, by means of a long pole at the stern of the boat, while another man, by means of a windlass, or wheel and axle, fixed in the opposite end of the boat, drags the scoop along the side of the boat, by a rope attached to it, and then raises it up to the boat's side, where the contents of the bag are emptied into the boat. When the boat has received her load, the marl is thrown out upon a wooden platform at the side of the loch, to drain.

Sandstone flags are very abundant in the neighbourhood of Arbroath, and are quarried and exported in great quantities. Principal quarry, Carmylie; the flags rise from three to six inches of any portable dimensions. They are called slate-stone flags, but are in fact sandstone in plates, coated with scales of mica or tick, of a greyish blue colour; and this mica occasions their easy separation from each other. With very thin plates, called slatestones, houses are covered; they are laid in "plaster lime" or moss (Sphágnum palústre), but they seldom make a roof that is water tight, and slate is now considered cheaper. A most valuable property of the flagstone is, that when laid as pavement on wet soil, they never show this on their upper surface; so that they are excellent for paving kitchens, passages, paths in hot-houses, &c. Coal searching for, at the time the report was printing, but with no great hopes of success, the district being considerably out of the boundary of the known coal fields of Scotland. No minerals worked: various chalybeate springs. No rivers, but a number of streams that are of moderate size. Considerable sea, and some salmon, fisheries. The herring fishery has been tried in the open sea, and considerable quantities taken in June, July, and August. Those earliest taken were plump and fat, which shows that all former theories concerning this most nutritive and abundant of all fishes are erroneous, and how much it imports the interests of Britain, that the herring fishery should be conducted according to the Dutch method, in the deep sea, and, as in the Isle of Man, from May to September. Garvies or sprats, and spirlings or smelts, abound in the Frith of Tay. The sprats resemble herrings, though of smaller size, and different flavour. They are taken in great quantities at Kincardine, and other places near the junction of the Forth with its estuary, by nets or wicker traps, sunk in the ebb of the tide. The smelts are smaller than the sprats, and when fresh, emit a smell resembling that of green rushes; but when fried, make delicious food. They are caught during spring, along the Forth, often as far up as the Bridge of Stirling, by nets in the form of baskets, fastened to the end of long poles.

Haddocks, whitings, &c. cured by smoke, a practice first suggested by Headrick, the reporter, in an essay published by the Highland Society of Scotland. Dempster, of Dunnichen, in this county, first suggested the idea of conveying salmon to London packed in ice. Reporter remembers when servants in the neighbourhood of Stirling used to stipulate that they should not have salmon oftener than thrice a week; now they seldom have them once a year.

Every river is said to have its particular breed of salmon. They have recourse to fresh water, to escape the attacks of seals, otters, and porpoises, and to get rid of the sea-louse, a small black animal, whose attacks seem to inflict upon them excruciating tortures. A few gulps of river water seem either to kill the sea-louse, or to deaden the pain it inflicts. Salmon never remain longer in fresh water than is necessary to effect the purposes which brought them there; but sometimes they are surprised in the rivers by long droughts, and cannot get over mill-dams, and other obstructions which lie between them and the sea. When this happens, they soon get lean and mangy, and die, their bodies covered with white worms. But in fresh water, they take various kinds of bait, and eagerly catch at flies, and hence become a source of amusement to the angler. During autumn, the salmon always run up the rivers to deposit their spawn.

The spawning of salmon seems to be a very slow and laborious process; and they get very lean, and even become unwholesome food, while they are engaged in it. The scene of this operation is generally where a stream begins to issue from a stagnant pool, over a sandy bottom. They begin by digging a hole in the bottom, by pushing the sand and gravel before them with their snouts, in the direction of the current, until they raise it into the form of a bank, which checks the rapidity of the current, while it allows the water to percolate slowly. The male seems to exert himself most in this work; and before its commencement, his snout becomes longer and harder than usual, while, before it is finished, it is often worn entirely away. While depositing their spawn, the male and female rub their bellies upon each other; the latter throwing out her roes or eggs, while the male emits among them a milky juice, which seems to effect their impregnation. After one stratum of eggs is deposited in the artificial hollow described, they cover them with light sand, to prevent them from being washed away by the water; and thus they form alternate layers of eggs and sand, until the hollow be nearly filled up. The eggs being dropped into a hollow place, are warmed into life by the sun's rays, in early spring. The fry, being then very small, easily escape from their covering of loose sand, and soon acquire the size of small trouts, and are called salmon fry, or smolts; which seems to be a contraction of *samlets*. The first flood now washes them into the sea; and they are generally swept from our rivers before the middle of May.

Salmon trout, or grilses, which ascend the rivers towards the close of the fishing season, are by some considered a distinct species of fish; but some Caithness fishers assured the reporter, that they proved by experiment, that grilses are only salmon of one year's growth. (*Rep.* p. 103.)

The sea trout resembles the salmon, and frequents all the streams where it abounds.

Fresh water eels, contrary to the practice of salmon, breed in the sea, and thrive and fatten in the fresh-water lakes and ponds. During summer, myriads of their young fry are seen constantly ascending the fresh-water streams, where they keep near the sides, that they may avoid the current. In places where they meet with interruption, such as behind a mill-wheel, they often accumulate in large masses, and frequently make their way up the crevices of the building, or over the dry land, until they reach the stream above, in which they continue their course. The larger eels are caught in this county, while they are descending the streams during autumn, probably to deposit their spawn in the sea.

The observations of the reporter on various other species of fish, and on salmon and other fisheries, are, like every thing which flows from his pen, new and interesting.

2. *Property.*

Much divided, largest estate 12,000*l.* a year: property, at an average, changes its proprietor every forty years. During the dark night of superstition, a man could take no step respecting his property, or his domestic concerns, without having half a dozen or a score of priests to advise him: and he was obliged to compound for the safety of his soul, and the security of his property, by ample donations to the church. When a man died without granting these donations, it was presumed to be his intention to do so; and what was originally an alms, or favour, was claimed as a right. In our days, a man can hardly venture upon any step of importance without having a posse of lawyers at his elbow; and, after all, often finds himself as far from his purpose as if he had not employed them.

3. *Buildings.*

Sixty gentlemen's seats enumerated; not many with handsome buildings. Farm-houses and cottages most wretched, and slower of improvement than in most other counties.

4. *Occupation.*

Farms of all sizes, but chiefly small. On the Grampians, estimated by the number of sheep they will maintain.

5. *Implements.*

Old Scotch plough still used in a few remote places, and found an instrument well adapted for breaking up waste land that is encumbered with the roots of shrubs, or with stones. At no remote period, it was usual to yoke four or six horses, abreast in this plough. The driver walked backwards before the horses, and struck them in the face to make them come forward. At present this plough is commonly drawn by four sometimes by six horses, which are yoked in pairs, and the driver walks beside them. But, except for the purposes already specified, the plough which was first invented by the late Small, near Dalkeith, and from him named Small's plough, is universally used.

A *threshing-machine*, of a very peculiar construction, adapted to very high falls of water, erected at Howmuir, by Stirling, an ingenious man; but is not yet perfected, and if it were, could never become general.

A *pick* or lever with a tread, used in the same manner as a fork or spade, for loosening hard earth or gravel: in fact it may be called a one-pronged fork.

6. *Tillage.*

Fallowing general. Seed-wheat washed with a ley of soft soap, to remove the smut. Potatoes introduced to the gardens in 1745, but not to the fields for many years afterwards. The late Dr. Walker, Professor of Natural History in the University of Edinburgh, was in the habit, especially during years of scarcity, of using yams in place of bread in his own family. He cut them into thin slices, and either boiled them over the fire, or dressed them in the frying-pan with as much butter as prevented the pan from burning. When dressed in this way, their taste was very pleasant; and they were used in all cases where bread is commonly used.

7. *Gardens and Orchards.*

A great prejudice in favour of covering wall trees with nets, to preserve the blossoms from the frost; woollen nets preferred.

8. *Woods and Plantations.*

Few woods, but many plantations. In the mosses the trunks of large trees found.

9. *Rural Economy.*

Farm-servants live chiefly on oatmeal, and potatoes and milk. Their breakfast is porridge, which is made by stirring meal among boiling water, or milk, in a pot over the fire, with a little salt; and when it cools it is eaten with milk. Or they use *brose*, which is made by pouring warm water upon meal, in a wooden dish, with a little salt, taking care to stir it well. This too is eaten with milk, or with beer which is furnished in place of milk, when the latter is scarce. Sometimes, when they are in a hurry, they mix the liquid with the meal in a cold state. Their usual dinner is oat-cake, with sometimes butter or skim-milk cheese, and milk. Their supper is the same with breakfast, except that sometimes they use sowens or potatoes, in the place of porridge or brose. Butcher's meat is only used on particular occasions; and fish by those who are near the rivers and the sea-coast.

Much ridicule has been thrown on the Scotch, on account of their immoderate use of oatmeal. This has been represented as inflaming their blood, and producing their favourite disease called the *Scotch fiddle*, and other cutaneous eruptions. But oatmeal is as much used in some districts of England as in any part of Scotland; and cutaneous eruptions are much

more frequent in some of these districts than they are here, where they are seldom or never heard of. The latter ought rather to be ascribed to dirty linen or clothing, than to oatmeal, or any particular species of food. Oatmeal, when it is sufficiently diluted with any sort of liquid, is known to be a laxative aperient, wholesome, and at the same time a strengthening food for those engaged in hard labour. Engineers, who superintend the excavation of canals, have assured the reporter, that those labourers who lived entirely upon oatmeal and milk did a third more work than those who used butcher's meat, beer, and spirits. All of the former saved money, while many of the latter involved themselves in debt. As this sort of work is done by the piece, it affords a fair comparison, not only of the wholesomeness of oatmeal in promoting health, but of its power in supplying labour.

All families that have a house of their own use tea and wheaten bread; but among cottagers this is a rare and always a ceremonious entertainment, at christenings and other solemn occasions.

Several agricultural societies: the first founded by Dempster of Dunnichen, an eminent improver. An account of the native plants and animals of the county by Don, the celebrated Scotch botanist, who resided at Forfar, possesses great interest for the naturalist. Indeed the whole survey ranks, in this respect, with that of Farey of Derbyshire.

7851. KINCARDINESHIRE or MEARNS. 243,444 acres, chiefly of mountain, but containing about one third of culturable surface. The climate is severe and hilly. The soil is gravelly, mossy, or clayey, and scarcely any where naturally fertile. The only minerals are lime, found in a few parts, and granite, whin, and freestone. Improvements commenced in this county about the middle of the eighteenth century, and have since been carried on with great spirit. (*Robertson's General View*, 1795.)

1. *Property.*

In few hands: largest estate 40,715 acres, the rest in eighty or ninety estates.

2. *Buildings.*

Some old farm-houses still remain, built of stone and turf, and in all respects wretched; but as leases are renewed, new farmeries are erected on the most improved plans, with commodious dwelling-houses. So much cannot be said of the cottages, which have undergone very little alteration in structure, for a long space of time. The habitation of the farmer may have advanced in elegance and accommodation a hundred fold; but the cottager still lives in the same simple kind of fabric as his ancestor did in the most remote ages of civilisation. A cottage built of stone and turf, or more generally of stone and clay, commonly consists, like the ancient farm-house, of two apartments divided by the furniture. In each of these there is a fire-place and a window. The fire is still without a grate; but the window has two, and in some cases four, panes of glass. The house may be about thirty feet in length, and twelve feet (seldom more) in breadth, in the inside. The walls never exceed six feet in height; and the roof is covered first with thin sods, and next with thatch, carefully renewed from time to time, and tied firmly on with straw ropes. The whole has much the appearance of a low hay-sow. Every cottager has a little garden or kail-yard; and many of them bestow much care, and show no little taste, in its cultivation. Besides raising different kinds of coleworts, cabbages, onions, carrots, &c., for the pot, they frequently have rows of gooseberry and currant bushes, together with roses and other flowering shrubs. Some of them decorate the walls of their houses with honeysuckles, or with ivy; and in some instances with cherry and apple trees.

The furniture of a Mearns cottage consists, in general, of two close wooden beds, which are so arranged as to make a separation between two apartments; one or two wooden chests for holding clothes; a cask for holding meal; a set of dairy utensils; an iron pot or two for cooking the victuals; a girdle, or heating iron, for toasting the bread; and a few dishes, some of wood and some of stone ware. Two or three chairs or stools, and a press or cupboard for holding the crockery ware, and the bread, the cheese, the butter, and, at times, the whisky bottle. A tea equipage, on a small scale, has also of late become an indispensable article of cottage furniture; for tea-drinking has now found its way every where. It seems to be gentle species of ebriety, which sets the imagination and the tongue at work, without incurring the imputation of drunkenness, or breaking any one precept, human or divine. Wherever it is once introduced, it keeps its ground as certainly as snuff or tobacco, and becomes nearly as inveterate a habit; but happily it serves as an article of food, at the same time that it is a luxurious gratification. The value of the furniture of a cottage may be estimated at from ten to twenty pounds.

The cottagers are moderate and plain in their food; but they are not so in their clothing. Hardly any thing but English manufacture will serve them. At kirk and at market, it is difficult to distinguish the man from the master, and still more so, the maid-servant from her mistress. Either the one or the other have seldom less than five pounds worth of clothes, and often twice that value, on their back at once.

The *village* of Laurence-kirk was founded by the late Lord Gardenstone, about 1760, and in 1781 he procured a charter by which it was declared a burgh of barony. There is an excellent inn here, with a library and museum for the use of the traveller. There is a manufactory of sycamore snuff-boxes; and the lands in the neighbourhood have been raised in value from ten shillings to three and four pounds per acre.

3. *Occupation.*

Arable farms of various sizes: many small; some 400 or 500 acres. Hill pastures let in tracts by the thousand acres. One farm occupies 30,000 acres. Leases formerly let on periods of two, three, and four times nineteen years, with sometimes a life-rent after; of late the term seldom exceeds nineteen or twenty-one years, unless when great improvements are expected to be made by the tenants. The arable land is cultivated under judicious rotations, in which either turnips or fallow enters, according as the soil is light or clayey. The mountains are devoted to the breeding of cattle. There are few or no public gardens or orchards, but great extent of young plantations, and some patches of native birch and hazel coppice. The cattle are a small, hardy, kindly feeding breed. Horses of the Clydesdale variety are reared by many farmers, and most kinds of improved stock have been tried. Bees are generally kept. There is a good deal of sea-fishing, and some valuable salmon fisheries; but excepting ropes, nets, canvass, &c. there are no manufactures of any consequence.

7852. ABERDEENSHIRE. 1,270,744 acres, one sixteenth of Scotland, and one fiftieth of the area of Great Britain. The surface for the greater part not very irregular, but hilly and mountainous in the district adjoining Inverness-shire: the soil in general clayey and moory; the climate milder in winter than that of Middlesex, owing to the circumambient sea, but the summers short and cold; the agriculture assiduously pursued, and the products chiefly corn and cattle; — great part planted with trees. The report of the county is more than usually intelligent, and contains two preliminary sections, on the lessons which other counties may derive from Aberdeenshire, and on the improvements which this county may derive from others. Aberdeen exhibits a successful example of spade and plough culture combined, in the small holdings of tradesmen, mechanics, cow-keepers, and gardeners; and may profit from other counties southwards, by greater attention to collecting manure, employing women and children in the lighter operations of husbandry, and limiting tenants to a certain number of subtenants. The celebrated Dr. James Anderson farmed extensively in this county at Mounie, now the property of his eldest son, Alexander Anderson Seaton, a distinguished horticulturist. (*Keith's General View*, 1811. *Edin. Gaz.* 1827.)

1. *Geographical State and Circumstances.*

No metals or coal, and very little limestone, but abundance of excellent granite, which is used for every sort of building at home, and exported to London in great quantities. Besides the durability, there is one other excellence attending the use of this stone; the expense of carving it has simplified the style of architecture. The Braemar mountains abound with cairngorms and other precious stones; some topazes and beryls have been found, the latter of great value.

2. *Property.*

Much divided; only two or three large estates. Lord Aberdeen's the most valuable, consists of 50,000 arable acres, and 25,000 waste.

3. *Buildings.*

A number of ruined castles and religious buildings, and a few handsome modern houses. An ample descriptive list of gentlemen's seats, which are very numerous. Farm-houses, formerly wretched structures of clay, turf, and thatch, are now greatly improved; cottages improving. "*Decent farm-houses*" first began to be thought of about 1760. In 1794, Dr. Anderson observes in his report of the county on which the present one is founded, that they are "for the most part very poor. This is," he adds, "highly impolitic. Nothing contributes more to the content and conveniency of a farmer, than good and well disposed buildings. It elevates his mind; gives him spirit to pursue his operations with alacrity; and contributes, in many instances, to augment his profits. I never yet saw a thriving tenant who had not good houses. But on no account should he be induced to expend that stock upon building houses, which should be employed in extending his own proper business. It ought always to be done by the landlord; and, in general, a good set of houses upon a farm, will bring him much greater additional rent than the interest of the money expended upon them. Nothing will prove such an allurement as good buildings, and long leases on equitable terms." Since 1794, when Dr. Anderson wrote the above paragraph, we have got farmers from Berwickshire, Angus, Mearns, and other southern districts, who have taken farms in Aberdeenshire, and many of whom have shown excellent examples in agriculture, as well as improved their own capital; and the native farmers of the county, in consequence of their example, both in requiring good houses, and in raising good crops, are now in a much more flourishing situation.

4. *Occupation.*

The greatest diversity in the size of farms; from six acres to thousands; scarcely a mechanic, journeyman, or master, who has not a farm of one acre or two, or a garden; besides the produce, they find the labour highly conducive to health, by counteracting the effect of in-door confinement, and prolonged unfavourable bodily postures, or contaminating respiration.

5. *Implements.*

Turnips formerly sown from a small tin box, nine inches long, and one inch square, with two or three holes at one end, through which the operator shook out the seeds; thinned by a part of the blade of an old scythe fastened to a bit of iron like a common hoe; the advantages of the latter are its sharpness, but it is easily broken. A child's cradle rocked by water.

6. *Enclosures*

Stone fences, or ditches and earthen banks, the common fences; this frees the land from loose stones, which abound every where, or serves to drain it.

7. *Arable Land.*

Potatoes, as well as various other improvements, first introduced to field culture after the calamitous year 1782; not liked by farmers so well as the turnip. The reporter tried various experiments in distilling from potatoes, which are recorded in

the *Farmer's Magazine*. Yellow turnips very much sown, and generally preferred by the cow-keepers. Ruta baga in great repute; but requires to be earlier sown than the yellow, and, consequently, does not admit of so thoroughly cleaning the ground. Carrot, beet, scorzonera, and other roots, fermented and distilled by the reporter, the best spirit and greatest quantity from carrot. White beet grown, but found to yield less produce than turnip, carrot, or cabbage.

8. *Gardens and Orchards.*

The county of Aberdeen is distinguished beyond any other county in the island, for the preparatory branch of all good gardening, viz. *trenching the soil to a proper depth*. We have a numerous class of gardeners in the vicinity of Aberdeen, who cultivate the lands in the neighbourhood of that city, and whose practice deserves to be generally known, and generally imitated. They, in fact, are kitchen gardeners, seedsmen, and nurserymen. They raise all sorts of roots for the inhabitants of the cities of New and Old Aberdeen, various seeds for the use of the country at large, and nurseries so extensive, and so carefully managed, that, besides serving the landed proprietors in the county, and the owners of villas near the towns, they export considerable numbers of plants to England.

A few good private orchards; the largest that of Ferguson of Pitfour, of ten acres. The site of it, nearly 600 years ago, contained the Abbey of Deer, founded in 1218, and the garden belonging to the monastery. It is a striking proof of the luxury of the Romish clergy, and of their uncommon skill in the raising of fruit-trees, that when Ferguson was laying out his new orchard, he found in the abbey garden, first, rich soil above three feet deep; secondly, a well-paved causeway of granite; thirdly, a bed of pure sand, one foot deep; fourthly, another causeway of granite; and below the whole, a considerable depth of rich mould. No greater precaution could have been taken to hinder the roots of the fruit-trees from being injured, by piercing into a cold or wet subsoil.

9. *Woods and Plantations.*

In the higher division of Mar, occupy nearly 100 square miles, in some places very thickly planted, and in others raised by nature, at very different distances between the trees. Nearly one third has been both enclosed and planted; one third has been raised by nature, without either enclosing or planting the ground; and the remainder has been surrounded by fences for keeping out the cattle, and then been stocked with wood, raised from seed, either blown by the wind, or carried by the rooks, who, by some instinctive impulse, carry the cones of the Scotch pine in their bills, to provide habitations for their offspring, at a remote period; when the seeds contained in these cones become trees, in which they may build their nests. This supposed instinct in the rooks is more probably called forth with a view to a firm surface to break the cones on; and on such an open surface, also, the cones are sooner opened by the heat of the sun, which enables the rooks to find the seeds without labour. In these higher districts, wood grows so easily, that the proprietor need only enclose an extent of hilly ground, and thus shut out the cattle. The wind and the crows will, in time, supply him with seeds. But when these natural woods grow very irregularly, it is found prudent to assist nature, by sowing, or occasionally scratching into the soil, a number of seeds of the trees which are wished to be reared in the vacant spaces. The greater proportion of these woods consists of Scotch pine; it grows slowly at first, but is very valuable. Where the soil is most barren, and the trees grow very slowly, he wood of the Scotch pine is of the best quality. A remarkable tree, at Invercauld, was cut down about forty years ago; and the number of concentric circles near its root, viz. 229, showed it to have grown and increased in size for 229 years, besides the time that it continued stationary. Its wood was declared, by all who saw it, to be much superior in quality to any that had ever been imported from the north of Europe. There are thousands of pine trees in Braemar, some of which are nearly six feet in diameter, which are superior, in point of quality, to any wood of that denomination that was ever imported into any place in Great Britain.

10. *Improvements.*

Trenching has been already mentioned: within three miles of Aberdeen, above 3000 acres trenched; some acres paid 50*l.* per acre for granite bowlders for exportation. Practice of trenching very general throughout the county.

Irrigation adopted on poor iron-stone clay, not worth two shillings per acre, but raised in value to two pounds. The operator brought from Gloucester, by Ferguson of Pitfour.

11. *Live Stock.*

More cattle bred than in any other county. Scotch cattle first improved by crossing some English cows sent down by Henry VII. to his eldest daughter, queen of James IV. The produce was known as the Falkland breed. Williamson's three brothers sell annually about 8000 head of cattle of various breeds, in the south-country markets. They decidedly prefer the true native, unmixed, and raised by good keeping, to the mixture of the Falkland, or Fifeshire breed, with that of this county; and consider both these to be much superior to the English, or to any foreign breeds. They justly remark, that the food, or keep, should be always above the breed, and not the breed above the keep. They consider the small highland cattle, which are generally bought by inferior dealers, as too restless and impatient for feeding well. They prefer the native low country breed to the larger ones, as they are most easily maintained, more hardy in work, have flesh of the finest grain, and pay better in proportion to the goodness of their keep. Every succeeding generation, for the last thirty years, has increased in size, and that by good keeping; the native breed is double its former size (*i. e.* weighs at least double its former weight) since the introduction of the turnip husbandry. They are also decidedly of opinion, that wherever a landed proprietor breeds more than one year for family use, the stot should not be tied up, but allowed to feed loose, in order to get gentle exercise along with his food; that the second year he may be put to high feeding, and be tied up, and may be continued with this high feeding as long as he seems to thrive; but that he ought to be killed whenever he loaths his food, or appears to be sickly, or not thriving.

The sheep few, and of a mixed breed. Horses are native ponies, or purchased from Clydesdale. Poultry very common; great demand for eggs, both for the Aberdeen and London markets. Red deer in great numbers in Braemar, and roes on the hills of Cromar.

12. *Manufactures.*

County long celebrated for its woollen manufactures. About 1660, Garden of Gilcomeston, a wealthy sheep farmer and manufacturer, had a daughter, who married Lieutenant Cadogan of Cromwell's army, who afterwards was made a peer, and from whom sprang the Duke of Richmond, Earl of Leicester, Lords Cadogan, Verney, Holland, C. J. Fox, and the heads of other eminent English families.

Woollen, linen, and cotton, now extensively manufactured. Knitting of stockings and spinning lint formerly common, but little attended to since the introduction of machinery.

7853. NAIRNSHIRE and MORAYSHIRE, forming together 512,000 acres of mountainous surface, and some narrow arable vales, are included in one survey. The climate along the Moray Frith has always been noted for its mildness, which is partly owing to its localities, and partly to the general prevalence of a dry sandy soil. On the mountains the climate is more severe. Lead, iron, lime, marl, freestone, slate, &c. are found, but the first two are not worked at all, and of the others, only the freestone, to any extent. (*Leslie's General View*, 1810.)

1. *Property.*

In very large estates; as, for example, those of the Duke of Gordon, and Earls of Findlater, Moray, Fife, and Lord Cawdor.

2. *Buildings.*

Considerable as has been the alterations in the houses of proprietors, it is nothing to that which has taken place in those of farmers. Prior to the year 1760, in the dwellings of tenants there were neither floors, ceilings, nor chimneys. In a few of them, the low wall was rudely raised of stone, and clay mortar, and had a small glass window; in one only of the apartments was any plaster, and it was raked over the walls in the most artless manner; a loft, on which the roof rested without any side wall, distinguished a very few of the most respectable habitations. There was in general but one fire (which served all domestic occasions) in the apartment, where the servants and master, with his wife and maiden daughters, lived and fed together. In the higher parts of the district, matters were much worse. Now, upon every farm of any consideration, the buildings are substantial, commodious, and neat.

3. *Occupation.*

As in Kincardineshire; but the arable lands being generally light, the turnip husbandry is more prevalent. It is a singular fact, that in an island in a lake, Loughnadurb, in this county, the turnip is found more plentifully in a wild state than any where else in Britain. This island contains a fortress, and the reporter conjectures that turnips being introduced at an early period from the Continent, the small plot of ground within the walls could not be occupied by any crop more convenient for its temporary inhabitants than that of turnips and coleworts. It may be conjectured that the last crop, probably sown from 300 to 400 years ago, had never been gathered. Until of late the turnips in this island sprung up annually in a thick bed, without culture. The root, in some favoured situations, it is said, had been found of one pound weight; but they resemble in general the wild kind, having a long root like a small radish, of acid juice, and a rough pointed leaf. Some plants of red cabbage were also distinguished among them. Both were used as pot-herbs at the tables of the country people, on which account they were sometimes raised in their gardens. When they began to run to seed on this island, young cattle were ferried in to feed on them. The Rev. Francis Forbes, minister of Grange, has seen rentals of the family of Craigyvar, from which it appears that turnips were paid as an article of rent in the end of the seventeenth century. The quantity (about 200 bushels) shows that they must have been applied as food for cattle. By the famine which unfortunately took place at that period, however, every agricultural branch of industry was so deranged, that this important object, instead of being extended, was, even there, wholly abandoned.

The cultivation of turnips, as a food for cattle, was first introduced into this district, from the county of Norfolk, by the late Earl of Findlater, about the year 1760.

When the artificial grasses and herbage plants were introduced, only regular gardeners were employed to sow them; now common country operatives perform the operation. Few orchards; apples imported from England; a few natural woods, and extensive artificial plantations. In general it may be observed, that in this, as in the other counties of the north, every description of improvement has been tried, and such as are found to answer, as draining, burning, irrigation, planting, road-making, &c. carried to a great extent. All the improved implements have been tried, and the reporter even proposes an addition to them, in the form of circular harrows; the circle of cast iron, and the tines of wrought iron, screwed in or fastened with nuts and screws. (See *fig.* 7787.) There is a good deal of fishing carried on along the coast, and in the Moray Frith.

7854. The shires of ROSS, NAIRN, and CROMARTY are three adjoining mountainous districts, containing 2,204,800 acres. The soil is in general light, sandy, or peaty. Minerals of various kinds have been found, but only building-stones and lime are worked. (*Mackenzie's General View*, 1810.)

1. *Property.*

Is in few hands, and till of late underwent but few changes. There are no sources of information from which a precise knowledge of the state of agriculture in these and other northern counties, previously to the rebellion in the year 1745, can be derived; but from what it has been since that time, until about

1760, it may safely be concluded, that agricultural knowledge was neither sought for nor desired. The mode of management which has been practised in these counties, and in other parts of the highlands, and which has been handed down from father to son for many generations, is still to be found in the midst of the most improved districts. We still see the arable land divided into small crofts, and many of the hills occupied as commons. On the west coast particularly, the ground is seen covered with heaps of stones, and large quantities are collected on the divisions between the fields; so that a considerable portion of the land, capable of cultivation, is thus rendered useless, by the indulgence of the most unpardonable sloth. The management of the native farmers is most destructive. The soil of one field is dug away to be laid upon another; and crop succeeds crop, until the land refuses to yield any thing. It is then allowed to rest for a season, and the weeds get time to multiply. Such, we must suppose, was the system of farming before the rebellion; we cannot imagine it to have been worse.

2. *Buildings.*

The old highland tenantry are universally ill accommodated. They live in the midst of filth and smoke; that is their choice. But wherever farms have been laid out on a proper scale, and are occupied by substantial and well-educated men, we find the farm-houses and offices handsome and commodious. Every proprietor who wishes to see his estate rapidly improved, will erect suitable buildings, at his own expense, before he invites a good tenant to settle upon it. The interest of his money will be always cheerfully paid; and if the landlord agrees that the repairs shall be made at the mutual expense of himself and his tenant, the latter will thrive, and the former will never have to demand his rent twice. The present race of highland tenants will yet find themselves much happier, and more comfortable, in the capacity of servants to substantial tenants, than in their present situation. The dwellings of cottagers are not worse than those of the native farmers. The same roof covers men, women, children, cattle, dogs, pigs, poultry, &c. It must afford great pleasure to every lover of his country to observe the neat cottages that are erecting in every part of the country; but it will be long ere the people will learn the comforts of cleanliness and the use of chimneys. In many places where these have been constructed, the people do not use them, but prefer breaking a hole in the roof of the house, and lighting their fire on the floor. Smoke, they say, keeps them warm.

The *occupation* and management of land is the same as in other mountain districts. Some grain, chiefly oats, is raised in the low grounds, with root and herbage crops, and the pastures are devoted to the breeding of cattle and sheep. Every improvement is tried by the principal proprietors; and enlightened farmers from the south of Scotland, accustomed to breeding, induced to settle on their estates, by long leases and moderate rents. From these the smaller native farmers take an example sooner than they would from the operations of proprietors, which they are apt to consider as at least of dubious value. When a rent-paying farmer, however, adopts plans new to them, the case is very different. Of woods, in this district, there are very few; but many plantations have been lately made round gentlemen's seats, especially Lord Seaforth's. In 1821, Colin Mackenzie, Esq. of Kilcoy, planted 200 acres with 5000 trees; the sorts, oak, Scotch pine, larch, alder, birch, ash, and some ornamental trees. (*Highl. Soc. Trans.* vol. vi. p. 258.)

The *great post roads* in this district have been made, in part by government, and in part by the proprietors. There is a cotton manufactory at Cromarty, and the reporter suggests the idea of manufacturing tar from the trunks of fir trees, found bedded in all the mosses of this and other highland districts.

7855. CAITHNESS. 395,680 acres, three eighths of which is deep, mossy, and flat moors, covered with heath; three eighths mountain, moor, and some hilly pasture; and the remainder in cultivatable land, lakes, &c. There is very little wood, either natural or artificial; but excellent lime and freestone. On the whole it is one of the coldest, wettest, and most dreary counties of Scotland; and is in no way remarkable, unless for being the scene of Sir John Sinclair's practical attempts at improvement. Of these the chief seems to have been the enlargement of the town of Thurso; of which, and of various other schemes, ample information is given in the report, and in a number of appendices to it, by Sir John himself. (*Henderson's General View*, 1812.)

1. *Property.*

Is in a few hands, and the Irish practice of tacksmen tenants exists, and has existed from time immemorial in the county. These tacksmen, as they are called, generally occupy a part of the land themselves, and sub-let the remainder to the small farmers, for a certain money-rent, payments in grain, customs, and service (the latter in many cases unlimited); so as to have, upon the whole, a surplus rent for the trouble and risk of recovering their rack-rents from the sub-tenants.

A few young men from the south of Scotland have been brought to this county, to superintend the proprietors' farms or domains, for the purpose of introducing the practice of modern husbandry. These, from time to time, have taken farms in this county; but whether their agricultural skill was superficial, or that they did not understand the mode of farming best adapted to this cold and moist climate, they have neither increased the crops, nor improved the landlords' farms placed under their direction; nor has their industry or skill produced better crops on their own farms than what is raised by a similar class of the county farmers, who have never been out of it.

The principal farmers in the county under review are intelligent gentlemen, who have been for some time in the army, or followed other avocations, either in the southern counties of Scotland or in England, who work their farms upon the principles of modern agriculture, as practised in the southern counties of Scotland, as far as the state of the county, as to climate, roads, the means of improvement, markets, &c. will admit, but at a much greater expense than is done to the southward, and, of course, much less benefit to themselves. In general they have other sources of income, which enable them to live in a social and comfortable state in society; they are better educated than farmers paying a similar rent in England; agricultural knowledge, therefore, is soon circulated amongst them.

The smaller class of farmers, with but few exceptions, are industrious, sober, sagacious, and moral in their behaviour. They have, unfortunately, a turn for litigation, and expend more money than they ought to do in law, by which their circumstances are often injured.

7856. SUTHERLAND. 1,872,000 acres, chiefly of mountain and moor; and a climate about a fortnight later than that of Edinburgh. The greater part of the county is the property of the Marquess of Stafford, whose astonishing, masterly, and successful improvements have been amply detailed in Loch's work, from which we derived so much information for Staffordshire and Shropshire, and to which we again recur. (*Henderson's General View, &c. Loch's Improvements of the Marquess of Stafford, &c.* 1819.)

The *estates of Sutherland* have only lately undergone that change which began to operate in England as far back as the reign of Henry VII. This change had for its object the creation of a middle class, by the depression of the barons and the raising up of the next class of the community. This object was gradually and successfully accomplished in England by the time of Queen Elizabeth, and in the south of Scotland soon after the union of the two kingdoms: but the highlands, or most northerly counties, underwent no change till the discomfiture of the pretender, and the abolition of the heritable jurisdictions then existing in the north, in 1747. This invaluable act having brought the highland chieftains within the pale of the law, and placed them on the same footing as the other gentlemen of the land, they began rapidly to acquire the same tastes, to be occupied with the same pursuits, to feel the same desires, and to have the same wants as their brethren in the south. In order, however, to indulge these propensities, and to be able to appear in the capital with due effect, it was necessary that they should convert their estates to that mode of occupation most suited to their circumstances, and from which they could derive the greatest income. Luckily in this, as in every other instance in political economy, the interest of the individual and the prosperity of the state went hand in hand. And the demand for the raw material of wool by the English manufacturers, enabled the highland proprietor to let his lands for quadruple the amount they ever before produced to him. These arrangements continued to be carried into effect from time to time, in the southern and central highlands, up to about the commencement of the French revolution war; not always, however, without serious resistance on the part of the people.

The *northern highlands still remained to undergo that change which the rest of the island had already adopted.* In this district it naturally began to be followed in the counties situated nearest to those into which it had already been introduced. In Ross-shire, accordingly, it was undertaken on a great scale, in 1792. The dissatisfaction produced was so great, that the most serious affrays took place, and the military had to act, and blood was shed before quiet was restored. Between that time and 1815, the greater portion of the county of Sutherland, belonging to Lord and Lady Stafford, was arranged according to those plans so universally adopted. This ancient condition of society prevailed longer on the estate of Sutherland than in any other part of the island, on account of its difficult access across the Dornoch and other friths, and the total want of roads in the county till 1809. The estate of Sutherland (*fig.* 1131. *a*, *a*, *a*), including the barony of Assynt (*b*, *b*, *b*), and the late purchases made by the Marquess of Stafford, up to 1819, was computed to contain more than 800,000 acres. The estate of Lord Reay (*c*) is more than half that extent; it was purchased some time ago by the Marquess of Stafford, and annexed to his own estate. The residue of the county belongs to different smaller proprietors (*d* to *n*).

In 1809 was begun a line of road, conducted according to the best principles of the art, and made in the most perfect manner, from the town of Inverness by Beauly and Dingwall, to the boundaries of the county of Sutherland; two excellent stone bridges, consisting of five arches each, having been built across the Beauly and Conon rivers. The two principal obstructions these roads had to contend with and to surmount were those which were occasioned by the two friths of Dornoch (*fig.* 1131. 1.) and of Loch Fleet (2). The former, especially, presented obstacles of considerable moment, arising out of the width of the channel, and the want of a proper foundation on which to construct a bridge. If the same plan had been followed in this instance, which has been adopted on the two southern ferries, namely, of ascending to the point at which the frith terminates and becomes a river, it would have carried the road so much into the interior, as to counterbalance those advantages which are at all times obtained by the substitution of a bridge in the place of the most perfect ferry which can be established. To avoid either of these inconveniences, a very careful survey of the whole frith was made; and the engineer, Telford, determined to recommend the construction of an iron bridge of magnificent dimensions (See an engraved view in the *Ed. Encyc.*) at Bonar, a point where the frith narrows itself considerably, and above which it again expands, though not to its former dimensions. This structure consists of an extensive embankment, with two stone arches of fifty and sixty feet span, respectively; and one iron arch of 150 feet span. It cost 13,971*l.* From this point, the heritors of Sutherland have constructed a road (4, 4) to Tongue (*c*), the seat of Lord Reay, situated upon the Northern Ocean.

In many places, these roads are cut through the hardest rock: in others, they are obliged to be supported on bulwarks of solid masonry. Expensive drains to protect them from the mountain floods, and bridges over the innumerable streams that rush from the hills in every direction, are required. These

must be formed of the most durable materials, and the best workmanship, to resist the impetuosity of the torrents. Nothing will set this in so striking a point of view, as to state, that upon the projected road to Assynt, a distance of forty-six miles, three bridges of three arches each, two bridges consisting of one arch of forty feet span, five of twenty feet span, three of twenty-four, six of eighteen, two of twelve, besides many others of inferior dimensions, would be required. On the Stafford

1131

estate excellent inns, often combining farmeries, have been built in a number of places at an enormous expense. As an example, we may refer to one (*fig.* 1132.) containing an outer kitchen and servants' stair (*a*), with a pantry (*b*), two best parlours, with movable partition for great occasions (*c*), principal entrance (*d*), a small parlour (*e*), small room (*f*), kitchen (*g*), back kitchen and servants' stair (*h*). Over are five bedrooms, and nine garrets for beds.

Thus, in the course of twelve years, has the county of Sutherland been intersected, in some of its most important districts, with roads, in point of execution superior to most roads in England. And owing to the equally praiseworthy exertions of the counties of Ross and Inverness, on the one hand, and of Caithness on the other, the same perfect means of communication now exists, from the burgh of Inverness to the town of Thurso upon the North Sea.

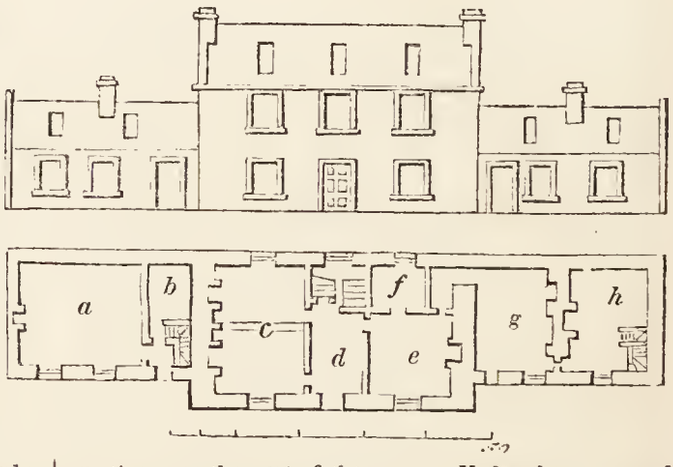
Few districts of Scotland possess so small a proportion of land fit for cultivation, compared with its extent, as Sutherland; and previously to the year 1811 but even a small portion of that was brought into cultivation. Each shore is fringed (if the expression may be used) with a narrow border of arable land, which, on the south-east coast, extends from a few hundred yards to about one mile in breadth: the interior consists entirely of mountains.

The lands were let to tacksmen, as in Ireland, till in latter times, when a certain district was let to the whole body of tenants resident in each "town or township," who bound themselves, conjointly and severally, for the payment of the whole rent. This land was held, as expressed in Scotland, "run rig," or like common field land in England.

The effect of this arrangement was to scatter thickly a hardy, but not an industrious race of people up the glens, and over the sides of the various mountains; who, taking advantage of every spot which could be cultivated, and which could with any chance of success be applied to raising a precarious crop of inferior oats, of which they baked their cakes, and of bere, from which they distilled their whiskey, added but little to the industry, and contributed nothing to the wealth, of the empire. Impatient of regular and constant work, all the heavy labour was abandoned to the women, who were employed, occasionally, even in dragging the harrow to cover in the seed.

To build their hut, or get in their peats for fuel, or to perform any other occasional labour of the kind, the men were ever ready to assist; but the great proportion of their time, when not in the pursuit of game, or of illegal distillation, was spent in indolence and sloth. Their huts were of the most miserable description. They were built of turf, dug from the most valuable portions of the mountain side. Their roof consisted of the same material, which was supported upon a rude wooden frame, constructed of crooked timber, taken from the natural woods belonging to the proprietor, and of moss-fir dug from the peat bogs. The situation they selected was uniformly on the edge of the cultivated land, and of the mountain pastures. They were placed lengthways, and sloping with the declination of the hill. This position was chosen, in order that all the filth might flow from the habitation without further

1132



exertion upon the part of the owner. Under the same roof, and entering at the same door, were kept all the domestic animals belonging to the establishment. The upper portion of the hut was appropriated to the use of the family. In the centre of this upper division was placed the fire, the smoke from which was made to circulate throughout the whole hut, for the purpose of conveying heat into its farthest extremities. The effect being to cover every thing with a black glossy soot, and to produce the most evident injury to the appearance and eyesight of those most exposed to its influence. The floor was the bare earth, except near the fire-place, where it was rudely paved with rough stones. It was never levelled with much care, and it soon wore into every sort of inequality, according to the hardness of the respective soils of which it was composed. Every hollow formed a receptacle for whatever fluid happened to fall near it, where it remained until absorbed by the earth. It was impossible that it should ever be swept; and when the accumulation of filth rendered the place uninhabitable, another hut was erected in the vicinity of the old one. The old

rafters were used in the construction of the new cottage, and that which was abandoned, formed a valuable collection of manure for the next crop.

The *introduction of the potato*, in the first instance, proved no blessing to Sutherland, but only increased this state of wretchedness, inasmuch as its cultivation required less labour.

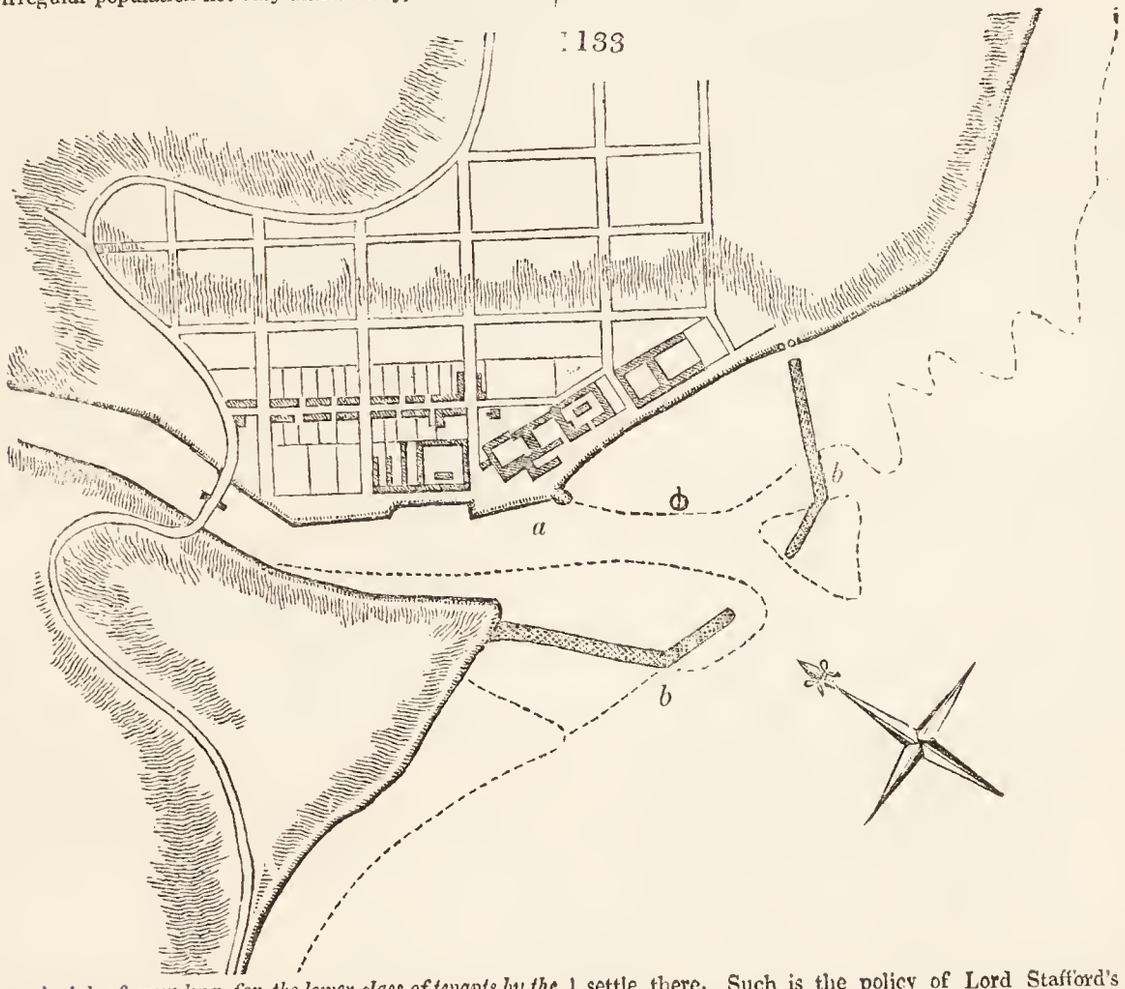
So long as this system just described remained in full force, no attempt could be made to improve or meliorate the situation of these poor people. To better their condition, however; to raise them from such a state of continual poverty and occasional want; to supply them with the means, and to create in them the habits of industry, was, and is the bounden duty of the owners of every such property. And it was not less their duty to do so, because the same arrangement which was calculated to produce this salutary effect, was at the same time the best suited to increase the value of their property, and to add to the general wealth of the community.

The *fundamental principle of agricultural improvement* in this case was derived from no speculative reasoning, but from what has actually taken place in a different but similarly circumstanced part of the kingdom.

It is well known that the borders of the two kingdoms were inhabited by a numerous population, who, in their pursuits, manners, and general structure of society, bore a considerable resemblance to that which existed in the highlands of Scotland. When the union of the crowns, and those subsequent transactions which arose out of that event, rendered the maintenance of that irregular population not only unnecessary, but a burden to the proprietor to whom the land belonged, the people were removed, and the mountains were covered with sheep. So that it had been for a length of time proved by the experience of the stock farmers of those mountain tracts which comprise the northern districts of England, and the southern parts o Scotland, that such situations were peculiarly suited for the maintenance of this species of stock. Taking this example as their guide, experience had still further proved, that the central and western highlands of Scotland were equally well calculated for the same end. Reasoning from this success, and observing that the climate of Sutherland, owing to its vicinity to the ocean, and to its being considerably intersected by arms of the sea, and much more moderate than this latter district, it was fairly concluded that this county was even better fitted for this system of management than the heights of Perthshire and Inverness-shire. The inferior elevation of its mountains contributed still further to this effect, and held out every encouragement to adopt the same course which had been pursued with such success in both parts of the kingdom.

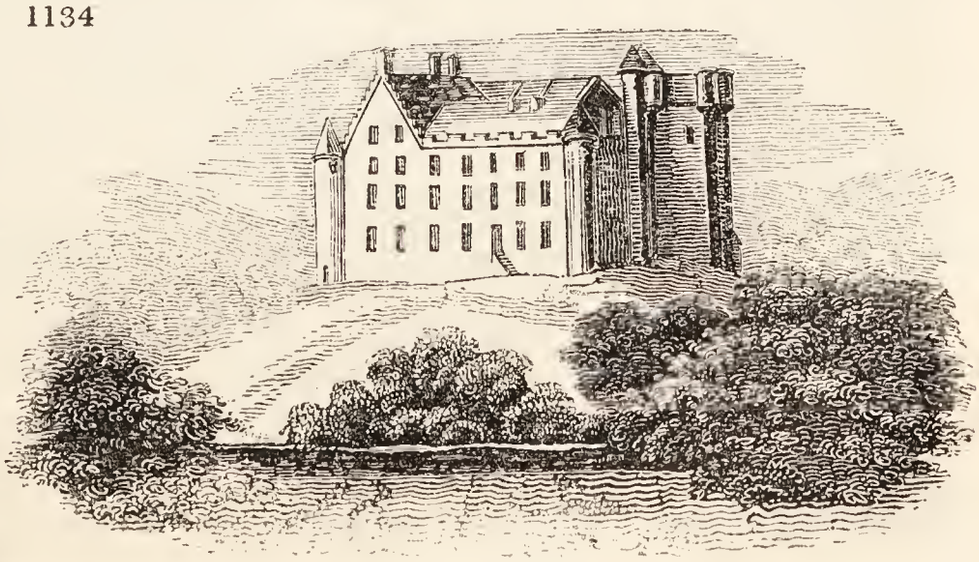
The *propriety of converting the mountainous parts of the county into sheep-walks* was in this way rendered evident, provided the people could be at the same time settled in situations, where, by the exercise of their honest industry, they could obtain a decent livelihood, and add to the general mass of national wealth, and where they should not be exposed to the recurrence of those privations, which so frequently and so terribly afflicted them, when situated among the mountains.

1133



The *principle of providing for the lower class of tenants by the establishment of fisheries* was thus derived:— It had long been known, that the coast of Sutherland abounded with many different kinds of fish, not only sufficient for the consumption of the county, but affording also a supply, to any extent, for more distant markets, or for exportation when cured and salted. Besides the regular and continual supply of white fish, with which the shores thus abound, the coast of Sutherland is annually visited by one of those vast shoals of herrings which frequent the coast of Scotland. It seemed as if it had been pointed out by nature, that the system for this remote district, in order that it might bear its suitable importance in contributing its share to the general stock of the county, was, to convert the mountainous districts into sheepwalks, and to remove the inhabitants to the coast, or to the valleys near the sea. Several seaports were improved by the construction of piers (*fig.* 1133. *a*) and breakwaters (*b*); and the plan of a town being formed, the inn, church, post-office, market-place, and other public buildings, were erected by Lord Sutherland, and the most liberal encouragement given by loans of money, grants of land at little or no feu duty, &c. to fishers, manufacturers, tradesmen, &c., both on a large and small scale, to come and settle there. Such is the policy of Lord Stafford's operations, in which he has expended, and continues to expend, independently of the cost of improvements on the mansion (*fig.* 1134.) and park of Dunrobin, immense sums. Happily the success has equalled the most sanguine expectations; but for the very interesting details of execution, our limits oblige us to refer to the work of Loch, which, as already observed (7795.), we consider of very singular agricultural interest.

1134



7857. INVERNESS-SHIRE. Upwards of 7,000,000 of by far the most mountainous region in Scotland. It reaches from sea to sea on the main land, and comprehends many islands, which are scattered far and wide. The hills and moors were formerly covered with fir woods, the remains of which are dug up in all the moors in abundance. The climate is rainy, mild on the west coast, but less so on the east. The soil of the vales is loamy or gravelly. The principal economical minerals are granite, lime stone, and slate; but lead, iron, marble, &c. have been found in different places. The county is remarkable for its native fir woods, and for that stupendous national work, the Caledonian Canal. Improvements were first commenced about Inverness by Cromwell's soldiers. (*Robertson's General View*, 1810.)

1. *Property.*
In few hands; largest, Lord Macdonald, of the Isle of Skye, the only nobleman who resides in the county. The mountain farms are large, and, as in similar cases, reckon by miles, or by the number of sheep they are supposed to carry.

2. *Gardens and Orchards.*
To be found in a few places; and some old pear trees, planted by the monks, are still in a bearing state at Beauly, and one or two other places. There is an excellent fruit and forest tree nursery at Inverness.

3. *Woods and Plantations.*
The Scotch pine, for the most part, took possession of the south side of the valley, and made choice of a northern exposure; the birch, the hazel, and the oak, occupied the warmest side of every district; while the alder and a few ashes ran along the streams. Not only the continental parts had this natural mantle, but the islands of this country appear, from the fragments of trees found in the mosses, to have been at some remote period, mostly, if not wholly, under forests. The only remains of growing wood at present in the islands are at Portree and Slate in Skye, and a little in the island of Raasa.

Trees were burned or felled to make room for men, by enlarging the pasturage of cattle, and affording fresh surface for corn. At present the Scotch pine covers more surface in this county, than all the other kinds of trees taken together; and the natural pine-woods of Inverness-shire exceed the quantity of this wood growing naturally in all the rest of Britain. In Strathspey alone, it is reported, upon authority which cannot be called into question, that fifteen thousand acres of ground are covered with natural firs. On the south-side of Locharkaig, of Glengarry, of Glenmoriston, Strathglas, Glenstrafaras, and at the head of Lochsheil, as mentioned above, the bounds of country under this wood are reckoned by miles, not by acres. The oak woods of this county are not so large, nor so well taken care of, as they are in Perthshire.

There are extensive birch woods, the timber of which is used for fencing and the coarser articles of husbandry, and the bark for tanning.

4. *Live Stock.*
Cattle are of the Skye or Kyloe breed, usually, however, known as the highland breed, and already described. (6796.) The cows yield only half the quantity of milk of the breeds of the low counties; generally from two to two gallons and a half; but it is rich, and productive of butter of excellent flavour. The diseases of highland cattle are few. The manner of disposing of cattle is as follows: When the drovers, from the south and interior of Scotland, make their appearance in the highlands, which always happens during the latter end of April, or the beginning of May, they give intimation at the churches, that upon a particular day, and in a central place of the district, they are ready to purchase cattle from any who offer them for sale. The drovers are of two descriptions: either those who buy by commission for persons of capital, who, being diffident of their own skill, or averse from fatigue, choose to remain at home; or those who purchase cattle on their own account. Much address is used on both sides, to feel the pulse of the market at these parochial meetings, before the price of the season is mutually settled; and it may happen, that many such small trysts or meetings take place in different parts of the highlands, before the price be finally determined. The anxiety on both sides is sometimes so great, that the cattle are given away upon a conditional contract, that if the price rises within a limited time, the seller will receive so much more; but if the lean cattle fall in value, the drover will get a reduction.

Sheep are extensively reared, and generally of the Linton or Lammermuir black-faced sort. The Cheviots are also very prevalent.

Horses either the native pony or improved breeds from the low countries farther south.

Roes are frequent in a wild state in all the woody and warm glens.

5. *Political Economy.*
Roads and bridges have been going forward at the expense of Government ever since 1745, and earlier; and the Caledonian Canal is well known for its magnitude and the excellence of its execution. There are various fisheries on the lakes and coasts; but few manufactures.

As one of the *obstacles to improvement*, common to this and the other highland counties, and indeed to every county, the reporter mentions the stubbornness of the common people, in adhering obstinately to old and slovenly habits. As men rise in years, the reluctance to make any uncommon exertions, and particularly to introduce change into any thing, which relates to their personal accommodation, gradually grows upon them. Having been long accustomed to a certain course of employment, of gratification, of lodging, of dress, and of food, they resist strenuously the relinquishment of any of these habits; they move on in the current of human life mechanically, like a wheel, without any apparent alteration in their motion, unless it be accomplished by some external force; and, if left to themselves, they never change their course. This propensity to remain the same men, and to retain the same customs, is more unconquerable among the illiterate and ignorant, than among the learned or enlightened part of mankind. By means of society, of conversation, and of reading, the latter acquire an enlargement of the mind, to which the former are strangers; and if they be accustomed to reflect on what they hear and see, they are always more open to conviction. When that mulishness of the disposition, which, whether in the rich or the poor, the uncultivated or the refined, is still the child of ignorance, takes fast hold of the mind, it becomes so obstinate, that it can seldom or never be removed. Its universality would lead to the opinion, that it is an original principle in the human frame; its progressive influence, which increases with age, and the apology which such men urge in their own defence, that their fathers did such things before them, would imply that it is the effect of imitation.

The reporter, notwithstanding the above sentiments, goes on to state that he considers that the prosperity of the world would be more promoted by the steadiness and obstinacy of men living in error, than it would be by a spirit of fickleness, and a desire of change. It might easily be shown that the real meaning of such a sentiment is, that those who are already prosperous, that is, those who have already a sufficient share of the good things of life, will stand least chance of losing what they have, while things remain as they are. The prosperity of the world, it unfortunately happens, has hitherto been too frequently understood to mean the prosperity of those only who are already prosperous. This state of things is in the natural course of the progress of society from darkness to light: but it will pass away in its turn, and the time will come when the prosperity of a people will really mean what the words import. When this time arrives, what the reporter would probably call fickleness, and a desire of change, will be found to have had some share in bringing it to pass.

7858. ARGYLESHIRE. 2,433,000 acres; the eleventh part of Scotland, and the thirtieth of Great Britain, and nearly the whole of the Scottish kingdom from A. D. 503 to the subjugation of the Picts in 843. The surface of the country is rough and mountainous: in the northern parts "Alps piled on Alps hide their heads in the clouds." The climate is moderately mild, very moist in the vales and on the coast, but cold and severe on the elevations. The soil of the vales is generally light; the minerals are copper, lead, iron, coal, strontian, freestone, granite, limestone, marble of several different colours, slates, &c., but the two first are not worked at present. There are numerous bays, inlets, and lakes, in some of which excellent fish is caught. The county is in no respects remarkable in an agricultural point of view; it furnishes immense quantities of cattle and sheep to the graziers and feeders of the south; and there are some oak coppices and artificial plantations. (*Smith's General View*, 1810. *Edin. Gaz.* 1827.)

1. *Property.*
In the hands of 156 owners. Farms of the smaller size reckoned by acres, the largest by miles. One, supposed to be the largest in Britain, is eighteen or twenty in length, by three or four miles in breadth; several contain from two to six square miles: object, as in Inverness-shire, the breeding of cattle chiefly, and next sheep.

2. *Improvements.*
Have been made by most of the proprietors: some plans of farmeries are given by the reporter. One is circular, and consists chiefly of cattle sheds; but the elevation is of that mongrel Gothic, which is displayed in most of the modern highland châteaus. The fin-share or Argyleshire plough (2618.) was invented in this county by the reporter.

3. *Woods and Plantations.*
There are about 30,000 acres of coppice, chiefly oak, birch, and hazel, which, being now valuable for the bark, and the poles to be used as spokes for wheels, is beginning to be enclosed from the sheep by stone walls. The Duke of Argyle is the chief planter, and his larch plantations are of great extent, and contain an immense quantity of valuable timber. The oldest and largest of the trees at Inverary are supposed to have been planted by the Marquess of Argyle between the years 1650 and 1660. Those of the next largest size and age were raised from the seed by Archibald Duke of Argyle (called a treemonger by Walpole), in 1746 or 1747. These consist chiefly of larches, New England pines, spruce and silver firs.

4. *Live Stock.*
Cattle, the west highland breed; the best in the districts of Argyle, Lorn, Ilay, Colonsay, and Mull.

Sheep, till lately, much neglected.

Horses, a hardy native breed, larger than the pony.

5. *Political Economy.*
Roads as in Inverness-shire. A canal from the coal works in Campbelton to the sea: few manufactures. An agricultural society at Kintyre.

7859. The HEBRIDES, including BUTESHIRE, consist of nearly 300 islands, eighty-six of which are inhabited, and contain 2,037,760 acres of rocky, hilly, and, in some islands, mountainous country, with a severe, unsteady, moist climate, and a soil generally light. Almost all the minerals are found with which the continental part of Scotland is furnished. Slate, lime, granite, marble, and freestone, are in great abundance; and coal has been found in various places, though it has not been successfully worked. Steatite, or soapstone, from which porcelain is manufactured; fullers' earth, and a great variety of other

economical minerals, besides rare and curious species, are found in different islands. (*Headrick's Survey*, 1796. *Macdonald's General View*, 1811. *Edin. Gaz.* 1827.)

1. *Property.*

In the hands of forty-nine proprietors; highest rental 18,000*l.* and acres 312,500. A great many tacksmen. Those of Ilay are said to "combine with the spirit and elegant hospitality indigenous to this country, the accuracy in dealing, the punctuality in paying, and all the useful qualifications of first-rate low country farmers. It must not be forgotten, in mentioning the order of tacksmen, that they are exceedingly useful, and often necessary, for maintaining good order and government in the country. Without their aid, the efforts of the clergy and officers of justice would be painful and unavailing: and therefore they ought not to be rashly banished, were they to be viewed in no other light than merely as subsidiary to the police and moral administration of the Isles.

2. *Buildings.*

Farm-houses throughout the Hebrides are either houses of tacksmen, of tenants, or subtenants. Tacksmen's houses, though still far behind those of considerable farmers in the principal counties of England and the lowlands of Scotland, are, however, in general, beginning to be tolerably decent and comfortable; and on all the large estates they have been very much improved within the last twenty-five years. Most of them are now built of stone and lime, and roofed with blue slates, two stories high, and furnished with kitchens and other accommodations. In many instances, indeed, the office-houses are still in a deplorable state, but even these are rapidly improving; and should this order of farmers exist for half a century longer, their houses will, probably, be as commodious, and their office-houses as judiciously planned, as those of the same description of men in any part of Great Britain.

The houses of the occupying tenants are, generally speaking, wretched hovels, and those of the subtenants nasty and miserable beyond description. Pennant describes them as habitations made of loose stones, without chimney or doors, excepting the faggot opposed to the wind at one or other of the apertures permitting the smoke to escape in order to prevent the pains of suffocation. Furniture corresponds: a pot-hook hangs from the middle of the roof, with a pot hanging over a grateless fire, filled with fare that may rather be called a permission to exist than a support of vigorous life: the inmates, as may be supposed, lean, withered, dusky, and smoke-dried.

It cannot be denied, that this picture is, in some degree, realised in a few of the Hebrides, even at the present day.

The cottages in the Hebrides are almost universally so miserable, both in plan and execution, that they deserve mention only as proofs, that a sensible and sagacious race of men may, by a combination of unfavourable circumstances, not only be gradually brought to endure privations, which, to their equals in other countries, would seem intolerable, but also, in the course of time, they may lose the power, and even the will, of surmounting them. Three fourths of the 40,000 cottagers of these isles live in hovels which would disgrace any Indian tribe; and many of them are found on islands of the first rank in point of population and extent. At least 7000 of the natives of Lewis (for instance) know nothing of a chimney, table, glass window, house flooring, or even hearth stone, by their own experience at home; and what we call their furniture is, as may be imagined, wretched and scanty beyond description, corresponding with their shabby exterior.

In the woods of the park at Bute were formerly fine specimens of Swiss cottages and other fancy wooden buildings. (*fig.* 1135.)

3. *Occupation.*

In estimating the size of Hebridean farms, the common plan is to attend to three leading objects: first, the number of live stock which the farms in question can maintain; secondly, the number of bolls of grain which can be sown, or of ploughs requisite for their tillage; and, thirdly, the quantity of kelp that can be made upon them.

Grazing farms, whether for sheep or cattle, must gradually be enlarged; and kelp, or merely agricultural farms, must as naturally become limited and confined in point of extent. The hay on many of the grass-farms, and sometimes the corn on arable grounds, is obliged to be dried by hanging on poles, trees, or rods (*fig.* 1136.), as in Sweden.

1136

4. *Implements.*

Some are nearly peculiar to the Hebrides, as the caschrom or crooked spade (*fig.* 1137.), which, in two parishes in the Isle of Lewis, entirely supersedes the use of ploughs in the raising of corn and potatoes. The great advantage of this instrument is, that it enables the operator to work in mosses or bogs, where no horses can walk, and in stony ground inaccessible to the plough. Many districts of Harris and of Skye would be unsusceptible of tillage without it. Its superiority to the common trenching spade, or to any tool which penetrates the ground perpendicularly, is very great, resulting both from the ease with which the operator wields it, and the length of the horizontal clod which its powerful lever enables him to turn over.

The *ristle*, or sickle plough (a sort of paring plough), is used for cutting the strong sward of old land, or the tough roots of plants, which would otherwise greatly impede the passage of the plough.

The *clow-maik*, or wooden tongs, for drawing thistles, &c. differs little from those in use in England.

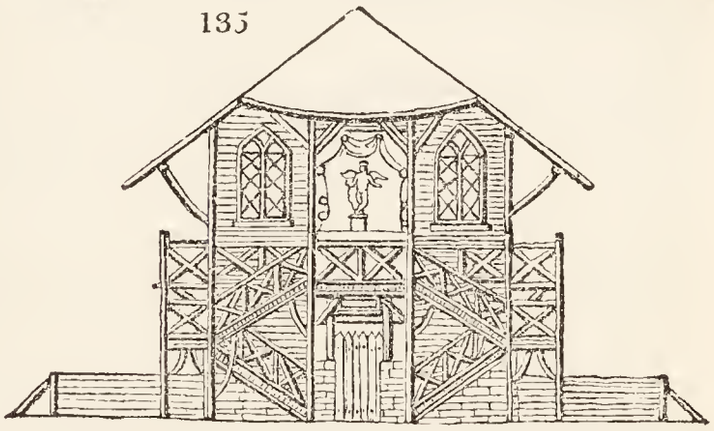
1137

5. *Arable Land.*

Tillage is in its infancy over the Hebrides, in all the isles northward of Mull; excepting half a dozen farms in Skye, a part of M'Leod, of Rasay's estate, two farms in Uist, and a little lately done in Lewis, near Stornaway, and by Campbell, of Islay, on a small island between North Uist and Harris. These improvements have been carried on within the last fifteen years.

It would be rather ludicrous than useful to describe the tillage generally practised in the Hebrides; and, accordingly, we shall not dwell upon it, or insult the common sense of the natives, by seriously requesting them to abandon the many barbarous customs which have so long disgraced their country. A man walking backwards, with his face towards four horses abreast, brandishing his cudgel in their noses and eyes, to make them advance to their enemy, followed by a ristle-plough employing a horse and two men, the three commonly altogether superfluous, still followed by four horses, dragging clumsy harrows, fixed by hair ropes to their tails, and almost bursting their spinal marrow at every tug and writhing of their tortured carcasses. All this cavalcade on ground unenclosed, undrained,

1135



and yielding at an average little returns for the seed sown, and sometimes lost altogether by the depredations of cattle, or by accident in a late harvest, is a barbarous spectacle, which must gradually vanish. It will soon give way, as it has already done in Islay, Colonsay, and part of Skye, to improved systems of tillage.

6. *Gardens and Orchards.*

It is not to be expected that much should be done in gardening, in a district of which by far the greater part of the proprietors are non-resident, nor is the climate suitable for that art. The winds are too violent, and the sun too shy of showing his face. Until trees and other sorts of shelter become, therefore, more general, the gardens and orchards of the Hebrides will probably be little more than an empty name.

7. *Woods and Plantations.*

In the sixteenth century it appears most of these isles were covered with woods, and even so late as Buchanan's time. One exhilarating remark, however, occurs to the traveller who traverses those bleak and woodless recesses, amidst the melancholy impressed upon him by comparing their present aspect with the description which he reads in Buchanan and Monro, namely, that where trees have formerly grown they will grow again; and that any regions which were once sheltered and adorned by the hand of nature, may still be in a far higher degree improved and embellished by the industry of man.

In Bute the late Lord Bute, in Islay Campbell of Shawfield, and in Skye Lord Macdonald, have planted extensively and successfully, and other proprietors are following the example. The present Marquess has almost naturalised the turkey in the plantations of Bute Park.

8. *Live Stock.*

The ancient Hebridean breed of cattle is now no longer to be found. Some persons imagine it to be the Skye, others the Mull, and others again the Lewis or Long Island variety. A person habituated to accurate observations on cattle, can easily distinguish those different breeds from one another, and all of them from the larger breed now introduced into Islay, Colon-

say, and some parts of the Long Island, especially Barray, by persons who pay attention to so important a department of agrestic economy.

Sheep. Only lately attended to. There are now three different breeds to be met with in almost all the larger islands, viz. 1. The native aboriginal breed, common to the whole Hebrides forty years ago, and still more numerous than the other two breeds taken together; 2. The Linton, or black-faced sheep of the south of Scotland; and, 3. The well known, fine-woolled, Cheviot breed. The historian Laing has a large flock of Merinos in the Orkneys.

Horses. The Hebridean breed of horses resembles that which we find in almost all countries of the same description of climate and surface. It is small, active, and remarkably durable and hardy. It possesses the prominent marks of perfection in this sort of animal, *i. e.* it is strong and nimble, of a good form and proper size for its work, healthy, patient, good-tempered, and very easily kept in good condition. It is found in the Highlands of Scotland, in Wales, Norway, Sweden, Switzerland, Tyrol, Hungary, and Transylvania, and with little variation in shape and size, in all the hilly districts of Europe. The average height of what are deemed sizeable horses is from twelve to thirteen hands; but that of the lower tenants' horses in Mull, Jura, and the northern isles, rarely exceeds eleven or twelve hands. They are handsomely shaped, have small legs, large manes, little neat heads, and manifest every symptom of activity and strength. The common colours are grey, bay, and black; the last-mentioned colour is the favourite. Excepting in Islay, and in a few gentlemen's farms, not exceeding two dozen in number in all the Hebrides, very little has hitherto been done for bringing this breed to perfection, or preventing it from degenerating.

The breeding of horses for sale is not carried on to a considerable extent in the Hebrides, nor does any of them export at an average of ten years more than it imports, excepting Islay, and perhaps Arran and Eigg.

Hogs. Considerable numbers of hogs are now reared in the Hebrides, where the ancient prejudice against pork has gradually vanished, since their more intimate connection with the lowlands of Scotland and England.

Goats still maintain their ground on several islands, and in certain circumstances constitute a valuable stock. But wherever wood is to be reared, and enclosures guarded and preserved with attention, they must be banished; for, being more a browsing than grazing animal, the goat will strain every nerve to crop twigs and plants of every description, and is a mortal enemy to every species of growing woods.

New species, or varieties of stock. Excepting the ass, and perhaps the mule, it is not clear that this extensive region would gain by introducing any new sorts of domesticated animals; indeed, the great want felt by the Hebrides is not that of animals, but of food in winter and spring for those which they possess. The native breeds of cows and horses are, perhaps, the very best possible for the country to support, and may, by due attention to feeding, and to selecting the strongest and handsomest pairs as breeders, be improved to an indefinite pitch of excellence. The breeds of sheep already recommended and described may be improved, and reared to five times their present numbers, without seriously injuring the agriculture or other interests of the country; and a vast accession of wealth and food might accrue from breeding a competent number of hogs, for which these isles, abounding in potatoes, are extremely well adapted. But all these improvements must go on progressively and slowly, and they must advance in the train of other agricultural and economical improvements.

9. *Political Economy.*

Roads much wanted, and, excepting in Bute, Islay, and Skye, in a very wretched state. No iron railways or canals. No equal portion of European population, not even excepting the Russians, and most uncivilised Poles and Croatians, possesses so few manufactures as the people of the Western Islands of Scotland. This is, among other causes, a principal source of poverty and depression of the people. It makes the little money acquired by the fisheries, and drawn in exchange for black cattle, kelps, and the other productions of the district, continually flow out of it, and prevents that gradual advancement in wealth, comfort, and agricultural and economical improvements, which are conspicuous in all other parts of Scotland, and although it does not absolutely keep these isles in a quiescent state, it greatly retards their progress.

Kelp is a well known Hebridean manufacture, and is in an advancing state. Macdonald, of Staffa, is distinguished for his attentions to this branch of Hebridean economy; and has accordingly preserved for his kelp a character, which enables him to dispose of it at a higher price than the average of the Hebrides obtains. This results principally from its being begun early in summer, its being duly attended to in the carriage and drying of the sea-weeds, and especially its being kept clean and unmixed with clay, sand, stones, and all other impurities, which greatly diminish the value of kelp on many Hebridean estates.

7860. The ORKNEY ISLANDS are thirty in number, and contain about 384,000 acres.

Many of them are uninhabited, and only afford pasture for sheep. The soil is generally peat moss or bog, but sand, clay, and gravel are found in some of the valleys. The soil is seldom more than one or two feet in depth, lying on a bed of rock. Husbandry is in a very backward state. The plough used is generally the single-stilted one; the manure is chiefly sea-weed, and on the quantity procured the farmer relies for his crop. The plan of husbandry is to till very shallow, and to harrow sparingly. Fallows are rarely used, and a proper rotation of crops never followed. Black oats are sown about April, and barley early in May; the crop is generally gathered in August; and if it remain till after the beginning of September, it is frequently lost from the violent gales and storms which follow the autumnal equinox. Except some stunted birch and hazel trees, and a few juniper bushes, scarcely a tree or shrub is to be seen; the climate is variable, and not healthy; violent storms of wind and rain, mingled with snow, visit the islands even in the month of June, and check the progress of vegetation. From the shortness of the days in winter, the sun in December and January not being more than four hours above the horizon, very little agricultural work is done in that season. The summer days are proportionably long, and it is light enough to see to read at midnight. The principal animals are small horses, black cattle, sheep, pigs, and rabbits. The sheep are very numerous, and it is calculated that there are above 50,000 in the islands; their flesh is, however, coarse and dry, and, from their proneness to feed upon sea-weed, it has a disagreeable flavour. Till within the present century, the Orkney sheep were suffered to run wild about the hills, without any care being taken of them; when in this state, the weight of the entire carcass rarely exceeds twenty-five or thirty pounds, and the wool seldom one pound and a half: when carefully treated, however, they grow much larger, and the flesh becomes very good.

One of the greatest curiosities in these islands is the circumstance of large seeds being frequently washed on shore by the Atlantic. They are called Molucca or Orkney beans, and are supposed to be of American and West Indian origin. Pods of the Mimòsa scándens are the most common. Strange fishes, marine shells, and even exotic fowls, are also sometimes cast on shore in violent weather. There are many varieties of wild fowl in the Orkneys, and eagles are not only common, but so large as to make great havoc among the lambs. The islanders have a law, by which every man who kills an eagle is entitled to a hen from every house in the parish where it was killed. The corby (*Córvus Córnix*) is also a dangerous enemy to the newly dropped lambs. The inhabitants on the coast live by fishing and making *kelp*. The staple article of trade in the other parts of the islands, is wool, which used formerly to be torn from the sheep by the fingers; the sheep are now shorn, and as they are never smeared (except when actually ill of the scab), the wool is remarkable for its softness. (*Edin. Gaz.* 1827 *Blakie on Sheep Husbandry in Orkney, in Trans. Highl. Soc.* vol. iv. p. 599.)

7861. The SHETLAND ISLES are about eighty-six in number, of which forty are inhabited; the whole contain about 48,000 acres, nearly equally divided between pasture land and arable.

The climate is very humid, and cold northern and easterly winds are extremely prevalent. Winter may be said to occupy full six months in every year, and if the harvest is not over in September, the crops are generally spoiled from tempests. There is a great diversity of soil; often deep moss on a bottom of sand, though sometimes the moss or peat is only a foot thick on a bed of clay. There are scarcely any trees or shrubs, excepting juniper, and occasionally a few mountain ash; the roots of large trees are, however, often discovered on digging deep into the ground. Turf and peat are used for fuel. The Shetland horses are well known; they are very small, rarely exceeding ten hands in height, and are celebrated for their spirit, and their power of enduring fatigue. The cattle are also very small, though they feed well, and weigh astonishingly heavy, in proportion to the size of their bones; they give generally about three English quarts of milk a day, though in rich pastures they sometimes produce double that quantity. The number of sheep kept in the Shetland Isles is calculated to be between 70,000 and 80,000. The wool is very short, and though generally fine, is sometimes nearly as coarse and hairy as that of a goat. The islands are well supplied with fish, and have multitudes of aquatic birds; the inhabitants are much annoyed by eagles and other birds of prey; there are no rivers, but abundance of lakes and rivulets, which afford an ample supply of fresh water. The chief employment of the inhabitants is in the manufacture of woollen stockings and gloves of extraordinary fineness, and in their fisheries, from the produce of which they annually export about 1000 tons of cod, tusk, and ling; they also export annually about 500 tons of kelp. Agriculture is at a very low ebb; the farming implements are of the worst possible description, and of the rudest construction; the farmhouses are wretched hovels, and the roads mere foot-paths. The small portion of land, however, which is tolerably well cultivated, is very fertile. Granite, freestone, and limestone are abundant, as is the beautiful and comparatively rare stone, called diallage rock. Bog iron ore abounds: a copper mine was formerly worked, but has been abandoned; very recently chromate of iron has been found at Unst. Various other minerals are found upon the islands; and occasionally porcelain earth; but no potteries have as yet been established. (*Edin. Gaz.* 1829.)

Sect. IV. *Agricultural Survey of Ireland.*

7862. IRELAND, the largest island in Europe next to Britain, contains above 20,000,000 of acres, much less varied in surface, soil, and climate than the latter island. There are several mountainous or hilly districts, chiefly in Ulster in the north, and Munster in the south, and very extensive flat bogs in the middle districts, and upland bogs or moors wherever there are hills or mountains. All these bogs, whether low or high, are on good soil, which, indeed, may be considered in connection with the moist warm climate as their chief cause. Nine tenths of the soil is a loam on a limestone bottom, fertile, or capable of being rendered so at little expense; the remainder is chiefly thin clay or limestone. The bogs are here considered as mere coverings to soils; their surface exceeds 1,000,000 of acres. The climate is

milder and more equable than that of England; and with the dry soil, as Wakefield remarks, is admirably adapted for pasturage and occasional aration.

7863. *Of the agricultural circumstances of Ireland* generally, we have already given a condensed account (807), and shall here submit some brief notices as to each county. These unavoidably present a degree of sameness incompatible with much interest or instruction. There are agricultural surveys of but a few of the Irish counties; so that we have drawn our resources principally from the copious and highly interesting work of Wakefield, and some more recent statistical writers and tourists. When the first edition of this Encyclopædia appeared, the statistical portion, as far as respects Ireland, was objected to in the Irish Farmer's Journal, as representing the agriculture of Ireland as being in the same state in 1823 as that in which it was in 1816, the date of Wakefield's Ireland. We have noticed this in the *Gardener's Magazine* (vol. iii. p. 229.), and have, since then, used every exertion in our power to procure later information from books or correspondents, but without much success. In fact, from all that we have been able to learn, we are compelled to conclude, that even now (1830) agriculture in Ireland is not materially different to what it was in the time when our text-book (Wakefield) was first published.

7864. DUBLIN. 228,211 acres; one eighth in mountain and waste, a tenth in buildings, roads, rivers, &c., and the remainder in arable and pasture. (*Archer's Statistical Survey, &c.* 1801. *Sup. Encyc. Brit. Edin. Gaz.* 1827.)

The *climate* of this county is drier than that of some others; east and north-east winds are less frequent than in England, but storms from the south-west and west are more frequent. Average number of dry days in Dublin for ten years, 179; or nearly half the year wet, and half dry.

The *soil* is generally shallow, and the substratum almost universally a cold clay. There is very little turf bog in the northern parts, but some considerable tracts among the mountains in the south. Freestone, granite, Irish slate, ochres, potter's clay, marl, beautiful pebbles, porphyry, crystals, limestone, and limestone gravel, abound in various parts.

Landed property in this county is a much more marketable commodity than in most other districts of Ireland. There are here no large territorial domains. Leases vary in their terms, but commonly include a life, for the purpose of creating a vote.

Farms are in general very small near the city, seldom more than twenty or thirty acres; but at a distance, from 50 to 150 acres.

The farm buildings are, for the most part, very insufficient. Near the city, the fences are of white thorn; but in the remote parts, they are nothing more than a bank and ditch. Lime, limestone gravel, and marl are used as manures. The city of Dublin might afford the means of enriching a tract of several miles around it; but its street dung is so little valued, that it is sometimes brought to Scotland by coasting vessels as ballast, and much of it is thrown into the Liffey.

On *the arable lands*, two crops of wheat in succession, and after these two of oats, without fallow or green crop, are frequently taken, according to Archer. Oats and potatoes are the standard crops. Barley is not cultivated extensively. The natural pastures are, with few exceptions, of an inferior quality. There are few or no flocks of sheep in the possession of farmers. In the city, and within four miles of it, about 1600 cows were kept in May, 1801, according to Archer, where there were formerly near 7000. The old Irish breed of cows is almost extinct, and their place is supplied by the short-horns and other breeds from England. Fuel is scarce and dear; peat and bog often cannot be procured, and the tenant is obliged to substitute straw, or any other combustible material that he can get.

There is a considerable *salmon fishery* on the Liffey, in which also abundance of eel and pike are caught. There are sea fisheries of herrings, white fish of different kinds, and oysters both in natural and artificial beds; the shells of some of the fed oysters have been found as large as a horse-shoe.

The *manufactures* of the county are chiefly of linen of different kinds, but they are of little importance. The colonial commerce with Dublin is considerable.

7865. WICKLOW. 500,000 acres, in great part mountains and bogs, and without inhabitants. (*Frazer's Survey of Wicklow*, 1801. *Sup. Encyc. Brit.*)

The *climate* so mild, that the myrtle flourishes in such profusion, as to have been sometimes used for making stable brooms. The common laurel, Portugal laurel, and Arbutus attain a great size, and can scarcely be recognised to be the same shrubs. Dublin is supplied with early potatoes and house-lamb from the sea-coast of Wicklow, the climate of which, according to Mr. Wakefield, is decidedly different from that of the rest of Ireland. This is the only part of that country where he ever saw grapes growing out of doors.

Metallic ores are supposed to abound; copper and lead have been worked, and gold has been found.

There are no navigable rivers or extensive lakes. Some of the streams precipitate themselves from considerable heights, forming beautiful cascades; the most remarkable one is at Powerscourt, where the water falls from a height of 360 feet.

Landed property in the centre of the county in large estates: Earl Fitzwilliam's nearly 100,000 acres. The sea-coast is much divided, and abounds with villas, the temporary residence of the wealthy citizens of Dublin. "It appears to me," says Wakefield, "to contain more gentlemen's seats than the same space in the vicinity of London." The common period of leases is twenty-one years and a life. Potatoes, and all the usual kinds of corn, are cultivated; but turnips, clover, and other ameliorating crops, only partially. Marl and limestone gravel are the principal manures. Irrigation is practised. A breed of fine-woolled sheep, peculiar to the mountains of this county, exhibit the only traces of a distinct race of short-woolled sheep in Ireland.

The *herring fishery* in the bay of Wicklow is the best in Ireland after Galway. Flannels are extensively manufactured, but scarcely any linen.

7866. WEXFORD. 597,760 acres, mountainous on the north and west, a light soil and tolerable cultivation on the east, and in other parts a cold stiff clay, unimproved by culture. (*Wakefield. Frazer's Survey of Wexford*, 1807. *Sup. Encyc. Brit.*)

The *climate* is mild and favourable to the growth of timber, which abounds here more than in most counties. There are some large myrtles in the open gardens.

The *landed estates* are large, from 2000*l.* to 10,000*l.* a year, and farms of various sizes; but there is little of that minute division which is common in other parts of Ireland; nor are there any rich grazing farms. Dairies, at which the principal article is butter, are numerous; but generally under bad management. The cows themselves are of a very inferior description; and the same character belongs to their sheep, which forms a very inconsiderable part of the live stock. In their modes of cultivation, however, the farmers here are more advanced than in many other parts of the island. The baronies of Forth and Bargie have been long noted for their great crops of barley; beans, too, are cultivated with success, as well as clover and turnips; the drill system is common for potatoes, and preferred to any other method; and lime, though brought from a distance at a great expense, and also marl, are very extensively employed as manure. The tenantry, including the cottars, are accordingly in a much better condition, industrious, provident, and many of them comparatively wealthy. Here, as in Cork and Waterford, whole fields are kept under furze, which, in this mild climate, is pretty much used as fuel. The bakers employ it for heating their ovens, of which a considerable number are employed, as a good deal of wheaten bread is consumed in these counties.

7867. KILKENNY. 510,000 acres, mountainous, but with some rich and beautiful vales on the banks of the Barrow, Suir, and Noire, and a climate so mild that in winter the thermometer seldom falls below the freezing point, while in summer it ranges between seventy and seventy-five degrees. There is less humidity than in Dublin and Wicklow, as well as less of the east and north winds. (*Tighe's Survey of Kilkenny*, 1802. *Sup. Encyc. Brit. Edin. Gaz.* 1827.)

This county has many romantic situations, ornamented with country seats; and its flat districts, where the tillage farms are more extensive than in most parts of Ireland, present a prospect very different from what is often met with in that country.

The *soil* is for the most part on limestone of good quality, and some of the valleys of extreme fertility. There are very few bogs; for the land declining about 500 feet from the northern to the southern boundary, the water which falls upon the surface is carried off with sufficient rapidity to prevent its making the ground marshy. The largest colliery in Ireland is at Castle Comber, near the northern boundary of the county. It is a stone coal raised in immense pieces, but of a sulphurous quality, which renders it disagreeable, and sometimes noxious; and it is, therefore, less fit for being used in families. For this reason, and also from the great expense at which it is raised, English coal is used in preference, even within a few miles of the works. There are several quarries of marble, chiefly of a black colour, of which a few tons are exported. Excellent sandstone and manganese, and iron and lead ores, have been observed in different parts.

Property in land is in several large estates, and many of a moderate extent, not exceeding a rental of 2000*l.* a year. The principal proprietors are Lords Bexborough, Clifton, and Ormond. The leases are in general for three lives, and partnership leases are common, though prohibited on one of the largest properties. On this estate the tenant is allowed to transfer his lease to one individual, but not to divide his farm.

Of the *husbandry* the most important department is the dairy, which extends over the greater part of it. The most considerable dairies are in the district called the Welsh, or Walsh Mountains; a tract of dry grassy land fit for tillage, but still in its natural state, and not enclosed. About 2000 Irish acres of the land were held in 1800 by one family, who kept 120 cows. The cattle are not for the most part housed in winter, and only those that are about the time of calving get a little hay on the fields, where the horses also are kept all the year. They fatten pigs to the weight of five hundred weight. The produce of the best dairies is one hundred weight and a half, or three firkins of butter per cow, and each cow requires from one and a half to three Irish acres. The practice of letting cows to

dairymen, which is common in Munster, is but little known in Kilkenny, the cows belonging to the dairymen themselves, who, in some situations, breed them on their own farms, and in others prefer buying them at a proper age. Too little attention is paid to cleanliness in their dairies, especially in the northern district; and for this reason, according to Wakefield, though Irish butter, when fresh, is preferable to any in Europe, yet it "is in the lowest estimation in the London market, as it is almost always heavily salted, and very frequently tastes smoky, fishy, and tallowy." The cattle of this county are a mixed race from the native breed and the English long-horned, and their sheep have been, in some parts, improved by the Leicesters. The Merinos have been introduced within these few years by Messrs. Nowlan, the proprietors of a woollen factory, who have now 600 of the pure race; and they find that both the quality and the weight of the fleece have improved since the sheep were imported. The usual corn crops are raised here, but clover and other green crops not in a suitable proportion. It is the custom to work oxen intermixed with horses, in teams of six, or three pair deep, the oxen placed foremost. Yet the fallows are better managed here than in any other part of Ireland. Irrigation has been practised for many years, but not extensively. (*Sup. Encyc. Brit. Kilkenny.*)

Salmon are caught in the rivers, and sent to Dublin packed in boxes of ice. Woollen is the chief manufacture. Messrs. Nowlan and Shaw produce excellent superfine cloths, from an establishment as celebrated in Ireland as that of Owen at Lanark is in Scotland.

7868. KILDARE. 392,397 acres, four fifths arable, meadow, and pasture, and the rest bog. (*Rawson's Survey of Kildare*, 1807. *Sup. Encyc. Brit.*)

Part of *the Bog of Allen* and other similar tracts occupy a large portion of the western side of this county. The surface is varied by a number of small hills and gentle declivities; but for the most part it is flat and nearly level; and when viewed from a commanding station, presents a rich, and, on the banks of its rivers, a beautiful landscape. The Curragh of Kildare, extending to about 5000 acres, has been long celebrated for the softness of its turf and the fineness of its pastures. But the climate of Kildare is said to be more moist than that of any other part of Ireland, which, if the statement be correct, is a very unfavourable circumstance, as a clay soil prevails very generally, and much of it is exceedingly tenacious of moisture.

There are a few large *estates* in Kildare, particularly the Duke of Leinster's, which extends over a third of the county; and several proprietors, according to Wakefield, have from 6000*l.* to 7000*l.* a year; yet many are less considerable, and property seems to be more divided here than in most of the other districts in Ireland.

The common *size of farms* is from ten Irish acres to 200; and these farms are frequently held in partnership. Large farms, however, are less rare here than in the arable tracts of the other counties. The leases were formerly for thirty-one years, but are now mostly for twenty-one years and one life. All parish and county taxes are paid by the tenant. With few exceptions, the course of cropping is the same as it has been for a century, viz., fallow, wheat, oats. Potatoes are universally cultivated. Oxen are employed in ploughing, and horses for carriages; but in many instances oxen and horses are mixed together in the plough team, which sometimes consists of six, and never less than four animals. A number of mules are also kept on the farms.

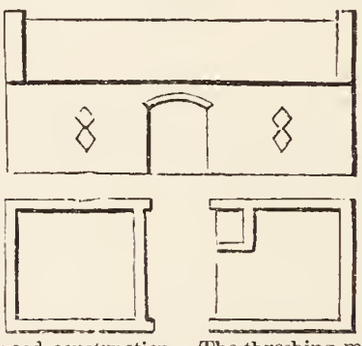
There are several streams and two canals. A woollen manufactory at Celbridge; and a catholic seminary at Maynooth for above 200 students.

7869. KING'S COUNTY. 457,000 acres, half of it bog, mountain, and waste; and the remainder arable, meadow, and pasture, of a medium quality. (*Coote's Agricultural Survey*, 1801. *Sup. Encyc. Brit.*)

The *Bog of Allen* occupies a considerable tract on the north-east coast, and the mountains are on the side of Queen's County. The soil of the arable land is either moorish or gravelly; the former productive in dry, and the latter in moist seasons, but neither of them naturally fertile. Limestone and limestone gravel, the means of their improvement, abound every where. The pastures, though in many parts fine, are not luxuriant; better adapted for sheep than cattle, and very favourable to the growth of fine wool. Much of the mountain district has an argillaceous soil, thickly interspersed with rocks of sandstone, and a deep irreclaimable bog often occurs at its base; but towards the centre of this range, where limestone prevails, there is much good pasture; and here the base of the hills, which is composed of a stiff clay, produces abundant crops of corn.

Landed property is in large estates, and many of their owners do not reside; but much of the land is held on leases in perpetuity, and the holders of these form a respectable class. The principal proprietors are Lords Digby, Rosse, and Charleville. Farms were formerly very large, not unfrequently of the extent of 2000 acres; but their size has been diminished, and such as are considered large do not now exceed, on an average, 400 English acres. Many are as small as twenty acres, though the medium size of the smaller class may be double this. Most of the arable land is tolerably enclosed; chiefly with hedges of whitethorn, which grows here to a great size. Partnership leases and sub-tenantcy are less common than in some other parts of Ireland; yet the condition of the tenantry and the peasantry does not seem to be materially more improved. The farm-buildings of every description are generally very bad; the cottages in particular; and yet those who have been long accustomed to these miserable cabins are said to prefer them to more comfortable dwellings (*fig.* 1138.), which, after having been erected by some of the proprietors, were for some time allowed to stand unoccupied.

1138



Wheat, oats, barley, and potatoes are the most common crops. The average produce of wheat is no more than sixteen bushels; of barley and oats it is about thirty-two bushels; and of potatoes only four tons per acre. Both oxen and horses are employed in labour; the plough is sometimes drawn by only two of either; in a few instances by two heifers; yet this and their other implements are not generally of a good construction. The threshing-machine has been in use in this district for about twenty years.

The *leases* were formerly for thirty-one years, or three lives; but the more common period of late is twenty-one years, to which the life of the tenant in possession at the end of it is frequently added. Some tenants hold for lives renewable for ever, paying a renewal fine equal to half a year's rent, or more, on the fall of every life. Modern leases often contain a prohibition against allenating. Nothing is so much complained of among the tenantry as the mode in which tithes are collected.

There are no considerable *manufactures*, no fisheries, and no minerals worked.

7870. QUEEN'S COUNTY. 384,000 acres, generally of a level surface, three fourths of which is of a productive soil cultivated, and the rest bog and waste. (*Coote's Agricultural Survey*, 1801. *Sup. Encyc. Brit.*)

Coal of the Kilkenny kind (7867.) is the only mineral worked; but there is iron ore, freestone, marble, &c. in different parts. The Barrow and Nore are navigable rivers.

Estates are from 5000*l.* to 15,000*l.* a year, and upwards. Some of the most valuable, having been let on perpetual leases, afford a large income to the lessees. It is these lessees who form the middle class of gentry, with clear incomes of from 100*l.* to 800*l.* per annum, obtained from tenants to whom their lands are sublet at rack-rent, and commonly in very small farms. Here, and in King's County, Wakefield observed some of the best farming in Ireland, with much more attention to a systematic course of cropping, and to keeping the land in good heart. Oxen and horses are used for the plough, the former generally preceding the latter. A good deal of cheese is made here for the Dublin market. In other respects the rural economy of this district does not differ materially from that of the Irish counties already described.

The *manufactures* are linen and coarse woollens, but to no great extent.

7871. CARLOW. 220,098 acres, of undulating surface, with some hills and mountains; the lowlands a fertile loam, and the uplands a light gravel; one tenth in mountains and bogs. (*Wakefield's Statistical Account, &c. Young's Tour, &c. Sup. Encyc. Brit.*)

The *minerals* are various, but little known.

There are no large *estates* in this county; and very little minute description of property. The hiring tenant is generally the occupier, except of small pieces. There are some excellent flocks of long-woolled sheep. Four sheep of the Irish breed and five of the English are called a "collop," and three collops are allotted to two acres of the best land. For its dairies, Carlow is not excelled by any county in Ireland. The farmers spare no trouble or expense to procure good cows. From twenty to fifty are generally kept; and during the season each cow produces, on an average, about one hundred weight and a half of butter. The dairy system pursued in Devonshire, Dorsetshire, and some of the northern counties of Ireland, of letting cows to dairymen, is followed here; but this custom was more prevalent when the Catholics could not legally purchase land, as they then employed their capital in hiring cows. The butter made in Carlow is divided into three sorts, according to its quality. The first in point of quality is sent to Dublin and England, and thence exported to the East and West Indies. It is highly esteemed in the London market, where it is often sold as Cambridge butter. That of the second quality is exported to Spain, and the worst to Portugal. It is all packed in large casks, weighing upwards of three hundred weight.

There is not much wheat grown, and it is not of a bright colour or very good quality: but the barley of Carlow is excellent; according to Young, the best in Ireland. At the time of his tour it was the only interior county which produced it; and at present more is grown here than in any other part of the kingdom. It is principally consumed by the illicit distilleries in the north of Ireland, by the breweries at Cork, or by the malting houses at Wexford. The potatoes grown in Carlow are excellent. There is little or no flax. The county is tolerably wooded. In the vicinity of Carlow a great many onions are grown, which are sold all over Ireland.

In Carlow, coarse cloth, reaping hooks, scythes, shears, &c. are made. At Leighlinbridge is one of the largest corn mills in Ireland, capable of grinding more than 15,000 barrels a year.

7872. EAST MEATH. 526,700 acres, of low, flat, rich surface; a clayey or loamy soil on limestone or gravel, with little wood, few mansions, and only one twelfth of bogs. (*Curwen's Observations*, 1818. *Thomson's Survey of Meath*, 1802. *Sup. Encyc. Brit. Edin. Gaz.* 1827.)

The *landed property* of Meath is divided into large estates, a great many of which yield an income of upwards of 2000*l.* a year. These are for the most part let out on leases of twenty-one years and a life; but on some of them there are leases in perpetuity, which have now become more valuable than the freehold property.

Grazing was, till very lately, a more important object in this county than tillage. Many persons fattened from 300 to 500 cows in a season, besides bullocks and sheep. These they purchase at the beginning of the grass season, and dispose of during the summer and autumn, as they are ready, instead of keeping a regular stock all the year. The pastures are considered too valuable to be applied to the rearing of stock. Dairying is not carried to any extent, and the butter made here is said to be held in little estimation. In some instances, where farms are let out for the dairy, the landlord supplies a succession of cows in milk, horses, and land, and the tenant furnishes labour, utensils, &c., paying at the rate of from 6*l.* to 7*l.* 10*s.* per annum for each cow. The English long-horned cattle were introduced many years ago into this district, which now contains some of the best specimens of the breed. Some marshes on the Moynalty river feed an immense number of horses in the summer season; and the Kilcrew hills, in the western angle adjoining Cavan, are remarkable for fattening sheep. The sheep are brought from other counties, and, like the cattle, the same stock is kept only for a season.

Tillage farms are larger here than in most parts of Ireland; but, according to Curwen, the system of management is little better than on the small farms of other districts. The houses and fences are, for the most part, of the worst description, especially the cabins of the farm labourers, which are miserable mud-walled hovels, sunk below the level of the ground adjoining, and occupied by cows and pigs, in common with the family. The principal food of this class is potatoes with churn-milk, and occasionally oatmeal; butcher's meat being rarely used even among the farmers; and, to add to their privations, fuel is very scarce in different parts of the county. An uninterrupted succession of oats and other corn crops for several years is common; in a few instances even for twenty years. The common rotation is wheat, oats, fallow, potatoes, clover, all without the application of manure. It is customary to work horses intermixed with oxen, of which six are generally yoked together, three pair deep, to a very ill-constructed plough; yet, notwithstanding this management, the wheat crops are in some parts excellent. Agriculture has, of late years, extended very much, and at present nearly three fourths of the county are under tillage.

Manufactures do not afford employment to any considerable part of the population, though here, as in most parts of Ireland, that of linen is carried on to some extent; and also the weaving of cotton. On the Blackwater and the Boyne there are several extensive flour mills.

7873. WESTMEATH. 378,880 acres of surface. The surface of this district is exceedingly diversified with woods, lakes, streams, bogs, and rich grazing lands; in no parts mountainous or flat, but gently undulating, or rising into hills of no great elevation. Some of these are cultivated to their summits, and others covered with wood, presenting, in several parts, some of the finest scenery in Ireland. (*Wakefield's Statistical Survey of Ireland. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

The principal river is the Shannon; and there are a number of beautiful lakes well stocked with fish; the trout in Lough Dim are said to have an emetic quality. One of the largest of the lakes is full of wooded islands.

There are few large estates, but many gentlemen of moderate fortunes, from 2000*l.* to 3000*l.* a year, most of whom are resident. The leases are commonly for twenty-one years and a life, though in some instances for thirty-one years and three lives. A great many fine long-horned cattle and long-woolled sheep occupy the grazing grounds, which extend over much of the best part of the district. Tillage is accordingly upon a limited scale, though more corn is raised than the inhabitants consume; and besides the crops common in other places, flax, hemp, and rape are cultivated, with clover and turnips; the two latter, however, not generally. The soil is mostly light, but in some parts it is rich and deep.

Few or no manufactures.

7874. LONGFORD. 234,240 acres, in great part bog, mountains, and waste; the climate on an average giving 140 dry days in the year. (*Wakefield, &c. Sup. Encyc. Brit.*)

Landed property is in estates of from 3000*l.* to 7000*l.* a year. Leases are commonly for twenty-one years and a life. Farms are, for the most part, very small, where tillage is the principal object; but only a small proportion of the district is under the plough. It is chiefly occupied in grazing, in which the resident gentry almost exclusively employ the farms which they retain in their own hands. Some linen manufacture.

7875. LOUTH. 177,926 acres, mountainous towards the north, but in other parts undulating and fertile, with little waste land, no considerable lakes, and a great number of gentlemen's seats, of which Collon is the chief. (*Wakefield. Edin. Gaz.* 1827.)

Landed property is in estates from 1500*l.* to 2000*l.* per annum. Farms are, in general, larger than in most other parts of Ireland; but there are still many very small; in some parishes, scarcely one above twenty-five acres, and in others they do seldom extend to eighty acres. As the land is chiefly occupied in tillage, little attention is paid to the improvement of cattle and sheep; of the latter, though a few are kept on most farms, the number is inconsiderable. Wheat and oats are the principal corn crops, barley being very little cultivated. The other crops are potatoes, flax, and a little hemp. Clover and turnips are almost confined to the farms of proprietors. It is only on these that the general management is good; that of the common farmers being, for the most part, slovenly; and their lands requiring heavy dressings of lime and marl to keep them productive. Yet a spirit for agricultural improvement has lately happily appeared in this county, and many of the tenants are in easy circumstances, well clothed, use meat in their families, and in every thing but their houses and farm buildings are in a condition superior to that of their brethren in most other parts of Ireland. It is common to renew the leases some time before the old ones expire, so that the tenants are not often changed; but fines are frequently paid on these renewals, which carry away much of the capital that should be applied to the soil. Tithes are very seldom taken in kind; their value is ascertained about the end of harvest, and the tenants grant their notes for the amount, which, though payable in November, is, in some cases, not exacted till almost twelve months after. The linen manufacture is carried on to a considerable extent.

7876. WATERFORD. 454,400 acres, the greater part hilly and mountainous, but rich and productive on the south-east; the climate so mild, that cattle sometimes graze all the year round. (*Wakefield, Curwen, &c. Sup. Encyc. Brit.*)

Some very large estates, of which the most extensive belongs to the Duke of Devonshire. Leases are commonly for twenty-one years and a life; and on the banks of the rivers, where the land is most valuable, farms are small. According to Wakefield's information, "In this county, when the eldest daughter of a farmer marries, the father, instead of giving her a portion, divides his farm between himself and his son-in-law; the next daughter gets one half of the remainder; and this division and subdivision continues as long as there are daughters to be disposed of. In regard to male children, they are turned out into the world, and left to shift for themselves the best way they can." The rent is chiefly paid from the produce of the dairy, which is conducted on a greater or smaller scale over all the county, and from the pigs, which are partly fed upon its offals. Some of the dairy farmers, most of whom are in easy circumstances, pay 1000*l.* a year of rent; and a great deal of butter is made, even among the mountains, where small cows, suited to the nature of the pastures, form the principal stock. In the neighbourhood of Waterford, cows were let for sixteen pounds, eighteen pounds, and even twenty pounds, for the season. There are very few sheep, and those of a bad description; and, comparatively, but a small portion is in tillage. Where lime is used as a manure, it must be brought from a distance, as there is no limestone to the east of Blackwater, and it costs upwards of five pounds for an acre. Orchards are numerous on the banks of this river, and extensive plantations of timber-trees have been formed in various parts. Furze is so much used as fuel, that whole fields are kept under this shrub for the purpose.

Hogs are an important branch of trade at Milford Haven; glass and salt the principal manufactures.

7877. CORK. 1,048,799 acres of Irish plantation measure of greatly varied surface; bold, rocky, and mountainous on the west, rich and fertile on the south and east, romantic and sublime in many places, and one fourth part waste. (*Wakefield. Townsend's Survey of Cork*, 1810. *Sup. Encyc. Brit. Edin. Gaz.* 1827.)

The *climate* is mild; but a very general opinion exists that it is changing for the worse.

The rivers of this county flow with rapidity for the most part; a circumstance unfavourable to their being rendered navigable, but presenting many eligible situations for the erection of machinery.

The most *useful fossils* are limestone, marble, and slate; coal and ironstone have been discovered, but not worked to any extent.

Estates are generally large; tillage farms are very small, seldom above thirty acres; and, when they are larger, often held in partnership, and the shares of each further diminished by the common practice of dividing the paternal possessions among the sons. The leases used to be for thirty-one years, or three lives; but of late the term has been reduced to twenty-one years, or one life; and the farms, instead of being let out to middlemen, who used to relet the land in small portions to occupiers on short leases or at will, are now held in most cases by the occupier from the proprietor himself. There is here the usual minute division of tillage lands, cultivated by the spade in preference to the plough; the usual dependence on potatoes, as the common and almost exclusive article of food; with miser-

able cabins, crowded with filth, poverty, and indolence. The crops are potatoes, in favourable situations, succeeded by wheat and oats, for one or more years; sometimes barley follows the wheat. Flax is cultivated in many small patches. Hemp very rarely. Turnips and clover are seldom to be seen on tenanted lands. Sea-sand, sea-weed, and lime, form a useful addition to the stable and farm-yard manure; which is, however, in many cases, allowed to be washed away by the rains, and greatly reduced in value by careless management. Paring and burning is practised in every part of the county, as an established mode of preparation for the first crop in the course. The implements of husbandry are generally bad: the common Irish plough and harrows, seldom furnished with iron tines, drawn by horses or mules, and, in a few instances, by oxen; wheel carriages have become common. A considerable number of dairies are kept in the vicinity of the city of Cork, where the produce, in the shape of butter and skim-milk, finds a ready market. In general the cows, which are chiefly of the half Holderness breed, are let out to a dairyman, at a certain rate for each, by the year; yet many farmers conduct the business of the dairy themselves. The average number of cows in a dairy may be from thirty to forty. A few sheep are kept on every farm, commonly in fetters, and upon the most worthless pastures. Proprietors have introduced stranger breeds, and find them to answer; but sheep can never become an object of importance in a district where farms are so small.

Tithes, of which no inconsiderable part are lay property, are generally paid by a composition with the farmers. The usual mode is to have them valued before harvest, and to appoint days of meeting with the parishioners, for the purpose of letting them.

The principal manufactures are sail-cloth, duck, canvass, and drilling; osnaburgs for negro clothing; coarse woollens; spirits at several large distilleries in Cork; and gunpowder in the neighbourhood of the same city, the only manufactory of that article in Ireland; it belongs to Government.

7878. TIPPERARY. 882,398 acres, diversified with heaths, mountains, and fertile vales; of which the Golden Vale is among the richest land in the kingdom. The climate so mild, that cattle graze out all the year. There are 36,000 acres of bog in this county, including part of the Great Bog of Allen. From the survey made by Mr. Ather, under the direction of the commissioners for enquiring into the nature and extent of Irish bogs, it appears that this waste land might be easily drained. (*Wakefield, &c. Sup. Encyc. Brit. Edin. Gaz.*)

Minerals. Slate, lead, and coal are worked.

Estates are of various sizes, some of them very large, but a greater number of a medium extent, worth from 4000*l.* to 6000*l.* a year. Of the proprietors, the influence of Lord Llandaff is by far the most considerable, though several others have estates worth from 10,000*l.* to 15,000*l.* a year and upwards. The graziers here, as in Roscommon, have leasehold properties, frequently of much greater value than the freeholds, of which, also, they often become the purchasers. Properties of this description, worth from 2000*l.* to 4000*l.* a year, are very common.

Tillage farms, however, are generally of small extent, one of ninety Irish acres being thought large; yet the management is, in many instances, more respectable than in most other parts of Ireland. But the principal business is grazing, every variety of this kind of land being found here. The exemption of grazing land from every kind of tithe operates as an encouragement to persevere in this system. Leases are commonly for twenty-one years and a life. The cattle, which are long-horned, may be ranked with the best in Ireland, and many of the fine flocks of long-woolled sheep are not inferior, in Wakefield's opinion, to those of Leicestershire. The rich lands produce a kind of flax, very different from that which is raised in the north: it grows to a great height, and appears to be exceedingly well adapted for sail-cloth.

The manufacture of broad-cloth is carried on to some extent at Carrick; and that of linen, worsted, and coarse woollens, as branches of domestic industry. But the wealth of this extensive district chiefly consists in its cattle and sheep, corn, and other land produce.

7879. LIMERICK. 622,975 acres, of low-lying fertile lands, surrounded by higher grounds. (*Wakefield, &c. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

Landed property is in large masses, generally let to tacksmen, on long leases, and sub-let almost *ad infinitum*. The land seems to be of greater yearly value than in most parts of Britain at a distance from large towns; for, according to Wakefield's information, the green acres would have let, in 1808, for three guineas the Irish acre, or almost forty shillings the English. Considerable farms brought five guineas the Irish acre, and in some instances more. The rent of the mountain land had increased in a still greater proportion than the grazing and corn farms. One grazier held land of the value of 10,000*l.* a year; and in one season slaughtered, in Cork, 800 head of cattle. Many of the best long-horned cattle of the United Kingdom are fattened here, and also a considerable number of sheep. Two-year-old wethers sold then, without their fleece, at from 2*l.* 10*s.* to 3*l.*

Only a small proportion of the land is in *tillage*; the produce of this, and some of the adjacent counties, in proportion to the seed, is stated by the same author to be at a medium: of wheat ten, bere seventeen, barley twelve, oats nine, and potatoes ten. Hemp was formerly cultivated extensively on the rich low grounds, called the Carcasses, on the banks of the Shannon; but this tract is now occupied in grazing. Flax of an excellent quality for sail-cloth is still grown in several parts. The common term of leases is thirty-one years and three lives. Great part of the provision and corn trade is possessed by the city of Limerick.

The soil is remarkably fertile, and consists chiefly of fine mould covering a light limestone gravelly soil: it produces all kinds of grain in abundance.

7880. CLARE. 962,560 acres, nearly half productive land, and the remainder moors, mountains, and bogs, with more than 100 lakes interspersed. The climate, though moist, is not unfavourable to health and longevity; fevers, which sometimes prevail to a great extent here, being occasioned chiefly by the dampness of the houses, and inattention to domestic and personal cleanliness. (*Dutton's Survey of Clare*, 1808. *Sup. Encyc. Brit. Edin. Gaz.* 1827.)

Limestone abounds, and coal, ironstone, black marble, lead, &c., have been found, but not worked.

Landed property is in a few large estates, of which the most noted was that belonging to the Marquess of Thomond's heirs, lately sold and divided.

The *size of farms* varies greatly. Those under tillage are from one or two acres to fifty, but of the latter size there are few. Grazing farms extend from 100 to 800 acres, several of which, and sometimes in distant situations, are held by one individual. Frequently several persons join in the occupation of an arable farm, and have about ten acres each. The general term of leases from proprietors is for three lives or thirty-one years; sometimes, but not often, for three lives and thirty-one years; twenty-one years or one life, and twenty-one years and a life. The tenure of under tenants is variable, and often arbitrary.

All the different species of grain are cultivated with considerable success. Rape and flax, the former chiefly for its seed, and the latter for home manufacture, are sown to a moderate extent. Potatoes occupy a part of every farm, and their culture is conducted with more care and judgment than that of any other crop, though at a greater expense of time and labour than would be thought necessary in most other places. In regard to the kinds of crops cultivated, the greatest defect is in what are called green crops, corn being, with potatoes, the chief and almost the only objects of attention to the arable farmer; and turnips and cultivated herbage being either grown on a very small scale, or, as is the case throughout the greater part of the county, altogether disregarded or unknown. The corn crops thus necessarily follow each other, until the soil is exhausted; and where extra manure, such as sea-weed and sea-sand, both of which are used as manure with good effect, cannot be procured, it must be left in an unproductive state for several years afterwards. Potatoes are in most cases planted upon land that has been prepared by burning; and the same crop is sometimes taken for two years more without manure; in the fourth year wheat follows, and then repeated crops of oats, as long as they will replace the cost of seed and labour.

The *implements* in common use are generally rudely constructed, and imperfect as well as expensive in their operation; in many parts, even where the soil is light and dry, the plough is drawn by four horses abreast, with traces of rope, and collar of straw. But from the roughness of the surface, the poverty of the tenantry, and the minute division of farm lands, the spade is much more extensively employed than the plough, over all the arable land of this county.

The *pastures* of the Carcasses or low grounds, on the rivers Shannon and Fergus, are equal to the fattening of the largest oxen. This rich tract extends from Paradise to Limerick, about twenty miles, and is computed to contain about 20,000 acres, of a deep dark-coloured soil, over a bluish or black clay, or moory substratum; producing, owing to the indolence of its occupiers, along with the most valuable herbage, a great quantity of rushes and other useless weeds. The rent of this land for grazing was, several years ago, as high as 5*l.* per acre, equal to about 3*l.* 2*s.* per English acre, and for meadow, in many instances, much more. These meadows are said to produce at the rate of more than four tons of hay the English acre. The cattle of this county are almost all long-horned, good milkers, and very hardy. The sheep have been greatly improved in shape, by crosses with Leicester rams; but there is a general complaint that the quality of the native wool has been deteriorated. A vast number of mules are bred here; asses are very generally employed by the poorer classes; but little attention is paid to the breed of horses, which has degenerated.

Clare was formerly noted for its orchards, and for cider of a very fine quality, made from the celebrated cockagee apple, which is still found near the small town called Six Mile Bridge. "An acre of trees," says Young, "yields from four to ten hogsheads per annum, average six; and, what is very uncommon in the cider counties of England, yields a crop every year." It does not appear from the latest accounts, that any considerable quantity of this cider is now produced here, though what there is seems to maintain its former character, and is held in great estimation.

Manufactures are yet in their infancy. All the linen made in the county is used for home consumption.

7881. KERRY. 1,128,320 acres, more than three fifths mountainous and waste; the sea-coast and islands being the most westerly land in Europe. Some of the mountains 3000 feet high. (*Smith's History of Kerry. Wakefield. Sup. Encyc. Brit. Bicheno's Ireland*, 1830, *&c.*)

The mountains are chiefly occupied with young cattle and goats; sheep, apparently the most profitable animal in such situations, are neither numerous nor of a valuable kind; and the little cultivation to be found here is so generally performed with the spade, that, in some entire parishes, as Young assures us, there was not a single plough.

The prevailing soil in the low grounds is clay, of different qualities; some of it seems to be a species of pipe-clay, and other sorts might be converted into bricks and earthenware.

Estates are very large, both in extent and value; some of them, according to Wakefield, worth 30,000*l.* a year. Leases are in general for thirty-one years and three lives, and a considerable portion of the whole county is let to partnership tenants. Few of the tenants in the north quarter about Kerry head occupy so much land as to require them to employ labourers; they pay their rents by the sale of butter and pigs, and by turf which they carry to Limerick. It is the practice for farmers to hire large tracts, which they stock with cows, and these cows are then let out to dairymen upon such terms as leave them but a very small return for their labour. The best corn land is about Tralee, and towards Dingle, where more flax is raised than in any other part of the county.

The principal articles which Kerry affords for export are its raw produce, beef, butter, hides, and tallow. It does not raise more corn than is necessary for its home consumption, and carries on no manufacture for sale but that of coarse linen, which is only on a small scale.

Agriculture is at a low ebb; and the general face of the country gives the impression of wildness and discomfort. Instead of hedges, mounds of earth and stone, called ditches, are every where to be seen; and as these afford but a slight protection against the trespassing of cattle, it is customary to tie the legs of each quadruped together with wisps of straw, and sometimes to yoke two together; even fowls and turkeys are thus bound. (*Bicheno.*)

7882. ROSCOMMON. 556,847 acres of flat surface, in some places sprinkled with rocks, and in many interrupted by extensive bogs; the richest land on limestone, and adapted either for aration or pasture. (*Wakefield. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

Coal and iron works were formerly carried on, but are now neglected.

Estates were once very large; but they have been broken down in some instances, by the granting of leases in perpetuity; a practice which has given rise to a class of landholders, interposed between a few great proprietors on the one hand, and a numerous body of cultivators on the other.

Some of the best long-horned cattle and long-woolled sheep in Ireland fed, but there are few dairies. During the late war, its fine green pastures, under this management, afforded a very ample rent, and tillage was therefore conducted on a small scale; but the plough has been more in request since the peace, both here and in other parts of Ireland; and the soil of such rich grazing lands, requiring nothing more than the common operations of tillage to yield large crops, the growth of corn throughout Ireland has been greatly increased; yet, within these few years, agriculture was here in a very backward state. "In Roscommon," says Wakefield, "I heard of horses being yoked to the plough by the tail, but I had not an opportunity of seeing this curious practice. I was, however, assured by Dean French, that it is still common with two-year-old colts in the spring." Potatoes, oats, and flax are the principal crops. There are several fine lakes, and the Shannon runs along nearly the whole of the eastern boundary.

7883. GALWAY. 1,659,520 acres of varied surface; above a third part bogs, mountains, and lakes, and very unproductive, and thinly inhabited. (*Dutton's Survey of Galway*, 1824. *Wakefield. Sup. Encyc. Brit., &c.*)

The east part of the county is flat, warm, and fertile, with many seats, though none of note. Rivers and lakes abound. Lough Reagh and Lough Coutra are fine pieces of water; the latter is said to possess all the beauties that hills, woods, and islands can impart to that feature of landscape.

Several large estates, affording an income of from 5000*l.* to 10,000*l.* a year, and upwards. One of these, the most extensive in the British Isles, stretches along the sea-coast for seventy miles. Only a small portion is held by absentees. A full third of the land is let on partnership leases, to an indefinite number of persons, very often twenty, who by law are joint tenants, and entitled to the benefit of survivorship. The leases are commonly for three lives or thirty-one years. "These people," says Wakefield, "divide the land and give portions to their children, which consist of a fourth or fifth of what they call 'a man's share;' that is, of the land which originally belonged to one name in the lease. A certain portion of the whole farm, or take, as it is styled, is appropriated for tillage, and this portion is then divided into lots, perhaps twenty or thirty. These lots are again subdivided into fields, which are partitioned into small lots, each partner obtaining one or two ridges; but these ridges do not continue in the hands of the same occupier longer than the time they are in tillage. The pasture is held in common; and the elders of the village are the legislators, who establish such regulations as may be judged proper for their community, and settle all disputes that arise among them. Their houses stand close to each other, and form what is here called a village."

The *cattle of Galway* are long-horned and of an excellent description, fully equal, in the opinion of Wakefield, to any in England. But sheep form the most valuable part of their live stock; "some of the first flocks in the world," says the same writer, "are to be found in this county." The crops are the same as in other parts of Ireland, but potatoes are not cultivated to so great an extent. They plant potatoes on an oat stubble, or on ley that has been burned or manured, and follow with wheat, bere or barley, or oats; the latter kind of grain is not unfrequently taken after wheat and barley. Paring and burning the soil is very common. The greater part of the rent of some of the estates on the shore is paid from kelp, which is prepared in large quantities.

In common with the greater part of Ireland, Galway employs some of its people in the linen manufacture, and it seems to be the only manufacture in it worth notice.

7884. MAYO. 1,270,144 acres, in great part mountains, bogs, and lakes; half-heathy mountains, with valleys very fertile, but neither woods nor plantations, excepting on one or two estates. (*M'Parlan's Survey of Mayo*, 1802. *Wakefield. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

Many valuable fossils; iron formerly made, but discontinued for want of fuel. Excellent slate; and petro-silex semilucidus, similar to what is used in the English potteries. The low grounds of the county are composed of limestone, or limestone gravel, and are equally well adapted to tillage or pasture.

The *estates* worth from 7000*l.* to 20,000*l.* a year; but their extent, owing to their containing a great proportion of waste land, is still greater than the ratio of their value.

The size of farms varies with the nature of the soil and surface; but, though several hundred acres are sometimes let out in one farm, yet, as the farms are commonly held in partnership, the space allotted to each tenant is generally only a few acres. As each of them keeps a horse, it is computed that there is one for every ten or twelve Irish acres. The leases are for different periods, fifteen years, twenty-one years, and one, two, and sometimes three lives, or thirty-one years.

Agriculture is in a very backward state. The plough, commonly drawn by four horses abreast, is of the worst description, and the harrows are often furnished with tines of wood, instead of iron. It is still the practice, in the mountain district, to yoke the horses by the tail. But in some of the baronies, the plough is seldom or never employed at all, the tillage being performed by the spade; and in others they use the spade in cultivating potatoes, and the plough only for corn. Yet potatoes, oats, and on the sea-coast barley, are sown to a considerable extent, and also flax. Wheat is cultivated only in particular spots, and chiefly by proprietors, a few of whom have also introduced turnips, peas, beans, rape, and cabbage. There is some excellent grazing land for cattle in the barony of Tyrawley, and good sheep pastures in Kilmain. Some graziers hold 3000 Irish acres. The English long-horned cattle, which were imported by the principal proprietors, have greatly improved the native breed.

The habitations of the labourers, or cottars, are in general very wretched, and shared by them with their cow and pig.

7885. LEITRIM. 407,260 acres, one half bog, waste, and water, and the remainder dark fertile soil, incumbent on limestone. (*M'Parlan's Survey of Leitrim*, 1802. *Wakefield. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

Coal, ironstone, lead, copper, &c. are found, but not worked.

Estates large, and nearly all the great proprietors are absentees. The leases are commonly for three lives or thirty-one years. Agriculture is here in a very low state. The tillage farms are small, seldom exceeding fifty or sixty acres, and these are almost always occupied in common by a number of tenants. The plough is very little used. The most common implement is the loy, a kind of spade eighteen inches long, about four inches broad at the bottom, and five or six inches at the top, where it is furnished with a wooden handle about five feet long. The first two crops are potatoes, which are followed by flax, and then oats for one or more years. Clovers and other green crops are unknown to the practice of the tenantry. The county raises grain and potatoes sufficient for its own consumption, but exports very little of either. Its cattle have been much improved by the introduction of English breeds, to which some of those now bred and reared in it are said to be not inferior. There are no considerable dairies, yet a good deal of butter is made throughout the district. The sheep are of the native race, small, and but few in number.

About the beginning of the eighteenth century, Leitrim is said to have been almost a continued forest. There is now little wood in it, and no considerable plantations. The proprietors, however, have of late paid some attention to this method of improvement, and several large nurseries have been established for the sale of forest and other trees.

There are several bleach-fields, and some coarse potteries; and a number of people are employed in weaving. But the linen made here, as well as the coarse woollen goods, is chiefly for the use of the inhabitants themselves. The houses of the lower classes are of the worst description; even the more recently erected farm buildings, including a little barn and cow-house, do not cost more than ten or twelve pounds. Turf is their only fuel, and potatoes and oaten bread the chief articles of food, meat being used on extraordinary occasions only.

7886. SLIGO. 397,060 acres, a third part bogs, mountains, and waters, and the remainder fit for tillage or grazing. (*M'Parlan's Survey of Sligo*, 1802. *Wakefield. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

The soil is generally of a light, sandy, gravelly loam, or moory; in some parts the lands are rich and fertile, but the subsoil of a considerable tract is a grey flag, provincially leaclea, unfavourable to vegetation. Numerous streams and lakes; the wooded islands and scenery around Lough Gill very striking. On the Sligo and Moy, considerable salmon fisheries; trouts abound, and white fish on the shores.

Estates of almost every size. A few are worth from 500*l.* to 9000*l.* a year; yet a considerable proportion of the county is divided into small properties. The principal proprietors are absentees. Farms vary in size, from three Irish acres to 500; the larger farms, however, are not held by individual tenants, but in partnership. The leases are for thirty-one years and three lives, and, in some instances, for sixty-one years and three lives; being, in general, longer here than in other parts of Ireland. Tillage-farming is still in a very backward state. The plough is worked by three or four horses yoked abreast, directed by a man who walks backward before them. Oats, barley, and potatoes are the principal crops. Of the two former, a great proportion is consumed in illicit distillation, which, within these few years, was carried on in almost every part of the county. It was to the sale of these spirits that many of the small tenants looked as the means of paying their rents. In some parts, both cattle and sheep are kept in considerable numbers, and a great deal of butter is exported from the town of Sligo; but the land occupied in this way bears but a small proportion to the whole; to grow corn, being the principal object. Limestone and limestone-gravel, which are in abundance in most places, are in general use as manures; also marl, and, on the coast, sea-weeds. Among the hills are several large lakes, and abundance of rivers.

The *manufactures* for export are linen, salt, and kelp.

The cabins, food, fuel, and clothing of the lower classes, seem to be as uncomfortable as in any of the Irish counties.

7887. CAVAN. 499,957 acres, almost entirely covered with hills; the surface, soil, and climate, being alike bleak and uncomfortable. There are no fewer than 91 bogs, occupying 17,000 acres. (*Coote's Statistical Account. Wakefield. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

Near Farnham, the appearance of the country is favourable; the lakes there are picturesque, and communicate with each other by a river. The fossils are various, but neglected.

Two *estates* are of 30,000 and 26,000 acres; besides these there are none of very great extent. Nearly the whole of the land is under tillage, but the agriculture in every respect is very bad. The size of the farms is from 50 to 100 acres; but these are generally subdivided into farms of from two to twenty acres, which are re-let to the manufacturers or "cottars," who pay a high rent for them, by means of their other employments. Their principal object is to raise a sufficient quantity of oats and potatoes to feed their families, and of flax to give employment to the women and children. Most of the land is dug with the spade, and trenched: where the plough is used, they put three or four horses to it; and when Young visited the county, he found that all over it the horses were yoked to the ploughs and harrows by the tail; that practice, however, is now disused. Almost the only grain sown is oats, which are reckoned to be in the proportion of seventy to one, to all other grain; there is scarcely any wheat. In 1809, there were 4300 acres of flax, from which 6500 bushels of seed were saved. Though the very tops of the hills are tilled, yet it does not appear that this county produces more grain than is necessary for its home consumption; nor has the bounty on the inland carriage of corn to Dublin, increased the very trifling quantity brought to that market. From the coldness and moisture of the climate, all the corn of Cavan is obliged to be kiln-dried.

The *stock-farms* generally consist of about 100 or 150 acres, the farmers buy young cattle, and sell them again without fattening; a few, however, fatten bullocks or sheep, but the latter are very poor. There are very few dairy farms, though from these, as they are in the richest parts of the county, a good deal of butter is sent. Many pigs are kept by the cottars; and near all the cabins are to be seen goats tethered to the tops of the banks, or "ditches," as they are here called, which divide the fields.

Cavan was formerly celebrated for its extensive woods, and trees of an immense size; but at present it is, in general, bare of timber, except near Kilmore, Farnham, and a few other places. Wakefield remarks, that the ash is confined to parts of the county, and to Tyrone and Fermanagh.

The *linen manufacture* is the staple.

7888. FERMANAGH. 450,000 acres, in great part covered by water, and much of the rest of the surface rugged and mountainous, but better wooded than other parts of Ireland. (*Wakefield. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

The *ash* grows in the hedge-rows; beeches come to a large size, and also the yew, near Lough Erne; and fir, oak, and yew are found in the bogs. The grand feature in the natural scenery of this county is Lough Erne, which occupies about one eighth of the surface, and contains more than three hundred islands. It contains most of the fish that are found in other fresh water lakes, and is noted for its salmon and eels, particularly the latter. Four of the eel weirs near the falls of Belleek afford a rent of 100*l.* each.

Estates are large; three proprietors mentioned by Wakefield have 13,000*l.* a year each, and other three from 6000*l.* to 7000*l.* The leases are most commonly for twenty-one years and a life. In the northern part of the county, the farms are larger and more productive than in most other parts of Ulster. Oats, barley, potatoes, and flax are the principal crops: very little wheat, clover, or turnips being cultivated, except in small patches near the towns. The high grounds are chiefly occupied in rearing cattle, and much of the better pastures with dairy stock. There are no large flocks of sheep, and their breed of this animal is of a very inferior description. Agriculture is in a very backward state, and as lately as the year 1808 the peasantry were accustomed to fasten their ploughs to the horses' tails.

Linen, seven eighths wide, manufactured to some extent; and there are several bleach-fields, which finish for sale the linens sent to England. Illicit distillation is said to be very general.

7889. MONAGHAN. 288,500 acres of low grounds, with detached hills, and a considerable space occupied by bogs and small lakes. (*Coote's Survey of Monaghan*, 1801. *Wakefield. Sup. Encyc. Brit. Edin. Gaz.* 1827.

There are a *few large estates*, but the greater part small ones, many of which do not even yield a free income equal to the ordinary wages of labour. A few years ago, there were only 172 freeholders of 50*l.* and upwards, out of nearly 6000; most of the considerable proprietors are absentees; and very little of the landed property is in the hands of Catholics.

Farms were so small a few years ago, as not to average ten Irish acres over the whole county; and the management, as might be expected, was exceedingly unskilful and unproductive. The spade was used much more than the plough: the latter being an implement which, with the team required to work it, and the party to attend and direct it, could be brought into action only by the united efforts of several tenants. The general term of leases is twenty-one years and a life, or sometimes three lives. The principal crops are oats, potatoes, and flax, with wheat and barley in a small proportion; these last, however, extend over a much greater tract now than they did a few years ago. They make a good deal of butter, but there are no large dairies. Goats are in greater numbers than sheep, which is of itself a sufficient proof of the low state of its agriculture.

The *linen manufacture* is said to have averaged, twenty years ago, about 200,000*l.* a year. It is carried on by the greater portion of the inhabitants of both sexes, all the small farmers being also weavers.

7890. TYRONE. 813,440 acres in great part mountainous, and containing, among other mountains, Bessy Bell and Mary Gray, celebrated in song. The territorial value of this inland and northern district is much inferior to that of most others. (*M'Evoy's Survey of Tyrone*, 1802. *Sup. Encyc. Brit.*)

Various valuable *fossils* found, but not worked: the best pottery in Ireland, near Dungannon. Lough Neagh, the largest lake in Ireland, covers 110,000 acres, but is not celebrated for its scenery.

Estates are of very great extent, many of them worth from 5000*l.* to 7000*l.* a year, and the productive or arable land divided into very small farms, not often exceeding twenty Irish acres. The chief proprietors are the Marquess of Abercorn, Lords Belmore, Northland, and Mountjoy. The leases are for various periods, thirty-one years and three lives, three lives, and twenty-one years and a life. On some estates the land passes through the hands of middlemen, in portions of various sizes, till it reaches the actual cultivator, for the most part, in very minute subdivisions. It is customary for several persons to be concerned in one townland, which is held in what is called rundale; the cultivated land being divided into shares, which are changed every year, and the cattle pasturing in common — a system utterly inconsistent with profitable occupation, or the amelioration of the soil and live stock. The cattle and sheep are accordingly of a very inferior description; and the latter, which are not numerous, may frequently be seen tethered upon the small patches of herbage which are interspersed among the shares of these partnership concerns. The tillage land, too, is more frequently stirred with the spade than the plough; and where a plough is used, the team, consisting of horses, bullocks, and even milch cows, must be supplied by the contributions of three or four neighbours, who unite their means for the purpose, each attending the operation, lest his poor animal should have more than his proper share of the labour. Potatoes, oats, and flax are the principal crops.

The *linen manufacture* is carried on to a great extent, and the potteries and collieries employ a considerable number of hands; to which we may add illicit distillation, which prevails throughout the north-western counties of Ireland. The food of the lower classes is oatmeal and potatoes; wheaten bread and butcher-meat never being used but on extraordinary occasions.

7891. DONEGAL. 1,100,000 acres of ragged, boggy, and mountainous surface, with a cold, wet climate, and neither woods nor plantations to shelter from the blast. (*M'Parlan's Survey of Donegal*, 1802. *Wakefield. Sup. Encyc. Brit.*)

Landed property is in few hands.

Agriculture is in a very backward state in Donegal. The use of the plough is confined to a small proportion of the cultivated land, and is generally of a bad construction; spade labour is preferred in most places. Barley is the chief grain crop, and it is almost all used in distillation; oats are only grown for home consumption, and wheat is confined to a few favourite spots. There are only two flour mills in the county. The culture of flax is considerable in the barony of Raphoe, and is extending even in the mountain districts. Potatoes are cultivated every where; turnips, clovers, and other green crops, are almost unknown among the tenantry. Village or partnership farms still abound, but farms now begin to be let to individuals as separate holdings. In the low country they are from ten to fifty acres in extent, and from 40 to 500 in the mountains. The fences are commonly nothing better than ditches, with banks of turf or clay, so that the cattle require to be herded while the crops are growing; and in many parts they are allowed to graze promiscuously as soon as the crops are removed. Sea-weed and shell-sand are used as manures, but very little limestone, or limestone gravel. The practice of paring and burning, so common in many parts of Ireland, is seldom resorted to in this county. Leases are granted for twenty-one years and a life.

The *staple manufacture* of Donegal is linen. Women are much employed in knitting stockings. Kelp is prepared along the north-west coast; and, during the fishing season, three or four salt-pans used to be kept in full work. But whisky, says Dr. M'Parlan, particularly in the mountain region, and all around the coast, is the chief manufacture. "It is by running their barley into this beverage that they provide for one half-year's rent. This is, therefore, a tax raised by the rich on the morals and industry of the poor."

7892. LONDONDERRY. 510,720 acres, generally mountainous, fertile and beautiful in the valleys, and containing every variety of soil. (*Sampson's Survey of Londonderry*, 1802. *Wakefield. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

Landed property. With the exception of lands belonging to the church, and the towns of Londonderry and Coleraine, and certain portions reserved by the crown to be afterwards erected into freeholds, the whole of Londonderry was granted by James I. to the twelve companies or guilds of London. The estates are, therefore, held from these companies, either in perpetuity, or on determinable leases. The principal proprietors or leaseholders are Lords Waterford and Londonderry, Conolly, Ogilby, and the families of Beresford and Ponsonby.

The average *size of farms* is from five to twenty Irish acres, or at a medium little more than fifteen acres English. Whole districts are subdivided into patches of seven or eight acres, but in a few situations there are farms of upwards of 300 acres. The leases, though most commonly for twenty-one years and one life, are frequently for such very short periods, as to be a great drawback upon agriculture. The practice of letting land upon short leases is, however, only recently introduced.

The *principal crops* are potatoes, barley, oats, and flax. Wheat is not in general cultivation. Turnips are very rare, and sown grasses and clovers far from being common. No uniform rotation of crops is recognised in practice, but it is usual to take two crops of oats successively, and sometimes flax the year following. Fiorin is the predominating plant in the meadows, where it grows spontaneously with great luxuriance. The live stock presents nothing worthy of particular notice. Grazing grounds are not extensive, and there are few dairies. On the east side of the Bawn there are two extensive rabbit-warrens.

The principal *manufacture* is linen; the value exceeds half a million sterling, besides brown or unbleached linens.

Granite, freestone, sandstone, and those beautiful rock crystals, which, when cut, are termed Irish diamonds, are found in various parts. Iron, copper, lead, and coal have also been found.

7893. ARMAGH. 293,871 acres of varied and rather interesting surface of mountain, plain, and bog; with rivers, streams, and lakes, and a climate mild for the latitude; 244,000 acres are esteemed fit for cultivation. The celebrated George Ensor is a native of this county, and resides on his own estate at Loughgall, near Armagh. (*Coote's Survey of Armagh*, 1804. *Wakefield. Sup. Encyc. Brit. Edin. Gaz.* 1827.)

Marble of an excellent quality, and of great beauty, is wrought in Armagh. The chain of mountains called the Fews, of which Sleive Gullian is the highest, present many highly sublime and picturesque scenes.

Estates in this county are not large, there being only seven or eight proprietors who possess them of the annual value of from 6000*l.* to 10,000*l.* The farms also are small, being commonly from five to twenty acres, and seldom exceeding forty or fifty.

Neither the arable nor the pasture *husbandry* of this county present much that is worthy of notice. Potatoes, flax, and oats are the chief produce of the arable districts; and those are cultivated in a very rude and inferior manner, in consequence of the ignorance of the farmers, and their want of capital.

There are no extensive dairy farms, nor are there any farmers exclusively in this branch of husbandry; nevertheless a considerable quantity of butter is made here. One hundred weight per cow is considered as the average produce. The proportion of the milch cows to the size of the farms is, on small farms under five acres, one cow; on farms exceeding five, and under ten acres, perhaps two cows, seldom more. A considerable number of cattle are reared. From the low country they are sent to the mountain farms, and frequently afterwards sold in the Scotch market. They are in general of a small stunted breed. The native sheep are an awkward breed; the wool coarse, and in small quantity; very little of it is exposed to sale, there being hardly sufficient for domestic use. Goats, swine, and poultry abound. Wild geese, swans, wild ducks, and several other species of aquatic birds, are indigenous to the lakes and rivers. Formerly bees were much attended to, but at present they are neglected.

The *roads* in general are bad; and, what is extraordinary, the turnpikes are the worst, and the cross roads the best.

The principal *manufacture* is that of linen.

7894. DOWN. 559,995 acres, of which one eighth are mountainous and waste, the remainder hilly and productive, cultivated by small manufacturers, and embellished by plantations, bleaching grounds, and neat white-washed habitations. The climate is variable, but not subject to extremes. (*Dubourdieu's Survey of Down*, 1802. *Sup. Encyc. Brit. Edin. Gaz.* 1827.)

Landed property. There are some large estates, though in general it is much divided, and has all the different gradations, from the most opulent nobleman to the tenant in perpetuity who farms his own land. Most of it is freehold. The rental was above the average rental of the best counties in Scotland, as returned to the commissioners of the property-tax in 1811.

The *farms* may be divided into two kinds: the first, such as are possessed by farmers who have recourse to no other branch of industry; the second, such as are held by weavers and other tradesmen. The former run from twenty to fifty, and, in some instances, so far as 100 acres; the latter are of every size, from one to twenty acres. It has been remarked that the divisions of the farms are so minute, as to be extremely prejudicial to agriculture. The rent is always paid in money; personal services are never extracted. Some leases are for lives and years, others for lives alone. Fences consist chiefly of a ditch and bank, without quicks of any kind, or sometimes with a few plants of furze stuck into the face of the bank; but dry stone walls are frequent in the stony mountainous parts. Great improvement has been made in its agriculture within these twenty years. Threshing-mills and two-horse ploughs have been introduced; but it cannot be said that a good system prevails generally, which the small size of the farms, indeed, renders impracticable. A regular rotation is rarely followed in the crops; fallows, clovers, and turnips, are upon a very small scale; and from the greater part of the arable land, it is still the practice to take crops of grain in succession, only partially interrupted by potatoes, flax, and peas. Oats, the principal grain, are grown on all soils; barley is usually sown after potatoes, and also wheat to some extent on the coast. Of flax they sow four bushels an Irish acre, and the medium produce is fifty stones. Rye and peas occupy but a small space. Lime, marl, shelly-sand, and sea-weed, are used as manures. Paring and burning are confined to the mountains.

There are *extensive meadows* on the banks of the Bann and the Laggan; but the soil, except on the mountains, is thought to be better adapted to tillage than pasture. A good many beasts are fatted, but cows are the prevailing stock, kept in small numbers on every farm. They are long-horned, thin in the sides, and deep in the belly, but yield much milk when well fed, and each of them from 60 to as much as 120 pounds of butter in the year, or about two thirds of the medium produce of the butter dairies of England. Numerous horses are reared in the mountainous districts; and goats, furnishing the inhabitants with milk are seen around all the cottages. Sheep, in flocks of any size, are confined to the mountain districts. They are very small, many of them, when fat, not weighing more than seven or eight pounds a quarter. On the low ground there are a few, seldom exceeding half a score, on almost every farm. A great number of hogs are fattened; many of them bred in the county, but not a few brought from the west of Ireland. The dry hills of this county, covered with heath and odoriferous herbs, are well adapted to bees, but the number of hives has greatly decreased within these twenty years.

The principal *manufacture* is linen, which is carried on in all its branches. Kelp is also an article of commerce.

Copper and lead are found within the precincts of Down, and marine exuviæ among the hills at a great distance from the sea. There is also black marble susceptible of a high degree of polish, slate, coal, freestone, and crystals. Natural woods are seen in some parts, but plantations are scarce; there are a good many orchards, a small one being attached to almost every cottage in the bleaching districts on the low grounds. Bleaching is conducted on a considerable scale upon the banks of the rivers; and vitriolic acid is made in several of the towns. Fish abound on the coast; but the inhabitants of Down derive little benefit from the bounty of nature in this particular.

7895. ANTRIM. 622,059 acres; on the east and north mountainous, destitute of plantations, and abounding in bogs; the other parts more level and fruitful, and the climate drier than in some other counties. (*Newenham's Statistical Survey. Wakefield. Dubourdieu's Survey of Antrim*, 1812. *Sup. Encyc. Brit.*)

Minerale. Besides basalt, limestone, gypsum, coals, fossil-wood, or wood-coal, sandstone, &c. are found. The fossil-wood, or wood-coal, in most places, is covered with columns of basalt, and is curious as explanatory of the origin of coal. Notwithstanding the compressed state in which it is found, the bark and knots are quite distinct, and the rings denoting the annual growth of the wood may be counted. In some instances the roots of the trees may be traced. Of the only two coal mines which are wrought in the province of Ulster, there is one in Antrim, at Bally Castle. The coals are bituminous, and of a bad quality; a great part of them are exported.

Landed Property. Estates are in general freehold, being either immediate grants from the Crown, or held under those grants. The exceptions are the properties under the see of Connor. Some of the estates are very large. The Marquess of Hertford and the Antrim family possess the fee of the major part of the county. The former has 64,000 *green acres*; that is, land capable of tillage, and independently of bog and mountain. Most of the Antrim estate is let on perpetuity, in farms worth 2000*l.* or 3000*l.* per annum. The other great proprietors are the Marquess of Donegal, Lord Templeton, and Lord O'Neil. The estate of Lord Templeton, however, is only leasehold under the Marquess of Donegal, who lets his land for sixty-one years and a life, but renews at the end of a few years for a price.

The *farms* are in general very small. The principal feature in the tillage system is the potato fallow. The small size of the farms, and, in some places, the rockiness of the soil, precludes the use of the ordinary means of culture, and therefore a part of the land is dug with the spade. The quantity of potato-land is regulated by the quantity of manure that can be collected. After potatoes, flax is sown, and the quantity of flax ground is regulated by the ability to purchase the seed. A crop of oats finishes the regular rotation. When the ground is exhausted, it is turned to rest, that is, it is suffered to lie till it is covered with natural grass. Such is the most general plan of husbandry pursued in Antrim. In those parts where the farms are too large for the spade culture, the land is ploughed by three or four neighbours uniting their strength; one supplying the plough, and the others bringing a horse, bullock, or even a milch cow. Wheat is a plant of very modern introduction in Antrim, and very little of it is sown.

The most important crop is flax.

The cattle consist chiefly of milch cows, belonging to small occupiers, of a small stunted breed. Sheep are very little attended to; and the few that are kept are of a very inferior kind. Goats are numerous in the mountainous parts of the county. Pigs also are kept in great numbers.

This county by no means abounds with wood; nor are fruit-trees cultivated in great abundance, or with very much success. Of the apple, however, several new and valuable varieties have lately been introduced, and advantageously cultivated.

Antrim has long been distinguished for its *linen manufacture*; but latterly the manufacture of cotton has, in some measure, supplanted it, especially in the vicinity of Belfast.

There is a considerable salmon-fishing on the coast.

The stupendous assemblage of basaltic columns, called "the Giant's Causeway," lies on the maritime confines of Antrim.

Chap. IV.

Literature and Bibliography of Agriculture.

7896. *The first books on agriculture* were written by the Greeks before the Christian æra, and by the Romans about the commencement of that period. Hesiod is the only writer of the former people exclusively devoted to husbandry: the earliest Roman author is Cato; and the latest, Palladius, in the fourth century A.D. The works of these and the other agricultural writers of antiquity have been already enumerated (25. and 44.), and the most interesting have lately been re-translated (7110. anno 1800).

7897. *In the dark ages* few books were written except on religion. The first author that appeared on the revival of the arts was Crescentius in Italy, in the fifteenth century; and soon after, in the sixteenth, Fitzherbert in England, Olivier des Serres in France, Heresbach in Germany, and Herrera in Spain. Since these works appeared, many others have been published in every country in Europe, especially in England, France, and Germany. Though our business is chiefly with the works which have appeared in Britain: yet we shall, after enumerating the chief of them, notice also what has been done in other countries; many foreign works, especially of France, Germany, and Italy, being familiar, either in the original or by translations, to the reading agriculturists of this country. All the works of importance, whether foreign or domestic, published or to be published since 1825, will be found noticed or reviewed in the *Gardener's Magazine*, commenced in that year, and in continuation,

Sect. I. *Bibliography of British Agriculture.*

7898. *A general view* of the literature of British agriculture having been already given (801.), we have here only to supply the bibliographical enumeration confirmatory of that view. Of agricultural books very few at the present day are worth reading for their scientific information; they are chiefly to be considered as historical documents of the progress of opinions and practices; and this is the reason we have arranged them in the order of their appearance, instead of classing them according to the subjects treated of. Those who wish to see them so classed will be amply gratified by Watts's *Bibliogràphia Británnica.* In our list we have omitted many works on subjects belonging to political agriculture, as the corn laws, tithes, poor-rates, &c.; and also most of those on veterinary surgery, horsemanship, bees, hunting, planting, &c., as not strictly belonging to the subject, and as being for the greater part, those on the veterinary art in particular, worse than useless. In short, the improvements in chemistry, animal and vegetable physiology, and the comparatively clear views of political economy which have taken place chiefly since the commencement of the present century, have rendered most books on agriculture, whether political or professional, not published within the last ten years, of very little value, and a number of them more injurious than useful. This second edition of British authors on agriculture is considerably reduced, in order to render it more select; and, through the obliging disposition of Mr. Forsyth, perhaps the only man in existence thoroughly acquainted with the bibliography of British agriculture and gardening, it is rendered much more accurate.

1500. *Groshede*, Bishop of Lincoln.

Here begyneth a Treatyse of Husbandry, which Mayster Groshede, sotyme Bysshop of Lyncolne, made and translated out of Frensshe into Englyshe. Lond. 4to.

1523. *Fitzherbert*, or *Fitzherbarde*, Sir *Anthony*, a very learned lawyer, and also known as the father of English husbandry, was born at Norbury, in Derbyshire, and died there in 1538. He was made judge of the Common Pleas in the 15th of Henry VIII., and wrote several books on law.

1. The Book of Husbandry, very profitable and necessary for all persons. Lond. 1523, 4to; 1532, 16mo.
2. Surveying. Lond. 1523, 4to; 1539, 16mo.
3. De Extenta Manerii. Lond. 1539.

1538. *Benese*, Sir *Richard*, Canon of Marton Abbey, near London.

The Manner of Measuryng all Maner of Land. 16mo.

1557. *Tusser*, *Thomas*, styled the British Varro, was born near Witham, in Essex, 1515; received a liberal education at Eton School, and at Trinity Hall, Cambridge; lived many years as a farmer in Suffolk, and afterwards removed to London, and published his experience in agriculture and gardening. He died in 1580.

1. A hundreth good Pointes of Husbandrie. Lond. 4to.
2. Five Hundreth Points of Good Husbandry, suited to as many of Good Huswifere; with divers approved lessons concerning Hops and Gardening. Lond. 4to. 1573.

1581. *Mascall*, *Leonard*, author of a work on sowing, planting, and grafting trees, &c. 1572.

1. The Husbandlye Ordering and Government of Poultrie, &c. Lond. 8vo.
2. The First Book of Cattel, &c. Lond. 1587. 4to.
3. A Booke of Fishing with Hooke and Line, and all other Instruments thereunto belonging: another of Sundrie Engines

and Trappes to take Polecats, Buzards, Rats, Mice, and all other kindes of Vermin and Beasts whatsoever; moste profitable for all Warriners, and suche as delight in this kinde of sporte and pastime. Lond. 1590. 4to.

1601. *Anon.*

God speede the Plough. Lond. 4to.

1601. *Plat, Hugh.*

The new and admirable Arte of setting of Corne, with all the necessarie Tooles; and other Circumstances belonging to the same. Lond. 4to.

1610. *Vaughan, Rowland.*

Most approved and long experienced Water Works: containing the Manner of Summer and Winter drowning of Meadow and Pasture by the Advantage of the least River, Brooke, Fount, or Water Trill adjacent. Lond. 4to.

1613. *Markham, Gervase, Jarvise,* or *Gervas.* An author who wrote on a great variety of subjects during the reigns of James I. and Charles I., and died about 1685. He appears, says Harte (*Essays,* ii. 32.) to be the first Englishman who deserves to be called a hackney writer.

1. The English Husbandman; 2 Parts. Lond. 1613. 4to.
2. Farewell to Husbandry. Lond. 1620. 4to.
3. Cheap and Good Husbandry, for the well ordering of all Beasts and Fowls, &c. Lond. 1616, 1631. 4to.
4. Enrichment of the Weald of Kent, &c. Lond. 1620, 1631. 4to.

1616. *Stevens* and *Liebault.*

Maison Rustique, or the Country Farm; translated into English by Richard Surflet, Practitioner in Physicke, newly reviewed, &c.; and the Husbandrie of France, Italy, and Spaine reconciled and made to agree with any here in England. By Gervase Markham. Lond. fol.

1635. *Calthorpe, Charles.*

The Relation between a Lord of a Manor and the Copyholder, his Tenant. Lond. 4to.

1639. *Plattes, Gabriel,* author of some tracts on Gardening; a poor man but a useful writer. Harte says, he had a bold adventurous cast of mind, and preferred the faulty sublime to faulty mediocrity. As great a genius as he was, he was allowed to drop down dead in London streets with hunger; nor had he a shirt upon his back when he died. He bequeathed his papers to Hartlib, who seems to have published but few of them.

1. Discovery of infinite Treasure, hidden since the World's beginning, in the Way of Husbandry. 4to.
2. Discoverie of Subterraneal Treasure, viz. all manner of Mines and Minerals, from the Gold to the Coal, &c., with directions for the finding them. Lond. 1653. 4to.
3. Observations and Improvements in Husbandry, with Twenty Experiments. Lond. 1653. 4to.

1642. *Vermuyden,* Sir *C.,* a native of Holland, and a colonel in Cromwell's army.

Discourse touching the Dreyning the great Fenns lying within the several Counties of Lincolne, Northampton, Huntingdon, Norfolke, Suffolke, Cambridge, and the Isle of Ely. 4to.

1645. *Weston,* Sir *Richard.*

Discourse of Husbandry used in Brabant and Flanders, shewing the wonderful Improvements of Land there. Lond. 4to.

1649. *Blith, Walter,* an officer in Cromwell's army, who, with other English gentlemen holding commissions at that time, was eminently useful in introducing improvements into Ireland and Scotland.

1. The English Improver, or a new Survey of Husbandry, discovering to the kingdom that some Land, both Arable and Pasture, may be advanced Double and Treble, and other, Five and Ten fold. Lond. 4to.
2. The English Improver improved; or the Survey of Husbandry surveyed. Lond. 1652. 4to. 3d Edit.

1651. *Hartlib, Samuel,* an ingenious writer on agriculture, and author of several theological tracts. He was the son of a Polish merchant, and came to England, according to Weston, about 1640; but the time when he died is unknown. He was a great promoter of husbandry during the times of the commonwealth, and was much esteemed by all ingenious men in those days. Milton addressed to him his treatise on education, and Sir William Petty inscribed two letters to him on the same subject. Cromwell allowed him a pension of 100*l.* a year.

1. Legacy; or, an Enlargement on the Discourse of Husbandry used in Brabant and Flanders. This work is said in the *Census Literaria* to be written by Robert Child. With an Appendix. 1651. 4to. Lond.
2. Appendix to the Legacy, relating more particularly to the Husbandry and Natural History of Ireland. Lond. 1652. 4to.
3. Essay on the Advancement of Husbandry and Learning, with propositions for erecting a College of Husbandry. Lond. 1651. 4to.
4. The Reformed Husbandman; or, a brief Treatise of the Errors, Defects, and Inconvenience of our English Husbandry, in ploughing and sowing for Corn; with the Reasons and general Remedies, and a large yet faithful Offer or Undertaking for the Benefit of them that will joyn in this good and public Work. Lond. 1651. 4to.
5. Design for Plenty, by a Universal Planting of Trees; tendered by some well-wishers to the Public. Lond. 1652. 4to.
6. Discovery for Division or Setting out of Land in England and Ireland. Lond. 1653. 4to.
7. The Complete Husbandman; or, a Discourse of Husbandry, both Foreign and Domestic. And a particular Discourse of the Natural History of Husbandry in Ireland. Lond 1659. 4to.

1659. *Speed, Adam.*

1. Adam out of Eden; or, an Abstract of divers excellent Experiments, touching the Advancement of Agriculture. Lond. 12mo.
2. Husbandman, Farmer, and Grazier's Complete Instructor. Lond. 1697. 12mo.

1662. *Dugdale, William.*

History of the embanking and drayning of divers Fens and Marshes, both in forrain parts and in this kingdom. Lond. fol. 2d edit. pt. 1772. Revised by C. N. Cole, Esq.

1664. *Forster, John.*

England's Happiness increased; or a sure and easie Method against all succeeding dear Years, by a Plantation of the Roots called Potatoes, &c. Lond. 4to.

1665. *Dodson,* Colonel *William.*

The Design for the perfect Draining of the great Level of the Fen, called Bedford Level, with Maps, &c. Lond. 4to.

1669. *Worlidge, John,* gentleman, author of some works on gardening.

Systema Agricultura, &c. Lond. fol.

1670. *Smith, John,* Gent.

England's Improvement revived; plainly discovering the several Ways of improving the several Sorts of waste and barren Grounds, and of enriching all Earths; with the natural Quality of all Lands, and the several Seeds and Plants which naturally thrive therein, observed; together with the manner of planting all Sorts of Timber Trees and Underwoods; experienced in 30 Years' Practice; in 6 Books. Lond. 4to. 1673.

1681. *Houghton, John,* F.R.S.

A Collection of Letters for the Improvement of Husbandry and Trade. Lond. 4to. Again in 1728, 4 vols. 8vo, revised by R. Bradley.

1683. *Lister, Martin,* M.D., an eminent physician and natural philosopher; was born in Buckinghamshire about 1638; practised in London; died 1711-12. He wrote various works.

Of Plants which may be usefully cultivated for Grass or Hay. 1696. (*Phil. Trans. N. Abr.* iv. 136.)

1685. *Moore,* Sir *Jonas,* Knight, F.R.S., a very respectable mathematician, and surveyor-general of his majesty's ordnance, was born in Lancashire, 1617; died 1679.

1. History or Narrative of the great Level of the Fens called Bedford Level; with a large Map of the said Level, as drained, surveyed, and described. 8vo.
2. England's Interest; or the Gentleman and Farmer's Friend. Lond. 1695. 8vo.

1694. *Floyd, Edward.*

1. Account of Locusts in Wales. (*Phil. Trans. Abr.* iii. p. 617.)
2. On the spontaneous Combustion of several Hay-stacks, &c. (*Ib.* p. 618.)

1697. *Donaldson, James,* a native of Scotland, and one of the earliest and most useful writers on the agriculture of his country.

Husbandry Anatomised; or an Enquiry into the present manner of Tilling and Manuring the Ground in Scotland. Edin. 12mo.

1697. *Meager, Leonard,* author of *The English Gardener* and other works.

The Mystery of Husbandry. Lond. 12mo.

1700. *Nourse, Timothy,* F.R.S.

Campania Felix; or a Discourse of the Benefits and Improvements of Husbandry. Lond. 8vo.

1707. *Mortimer, John,* author of some tracts on religious education. His works on husbandry were translated into Swedish, and published in Stockholm, in 1727.

The whole Art of Husbandry, in the way of Managing and Improving Land. Lond. 8vo.

1717. *Laurence, Edward,* brother to John Laurence, a clergyman, author of a work on gardening. (See A. D. 1726.)

The Duty of a Steward to his Lord; with an Appendix on Farming. Lond. 1727. 4to.

1721. *Bradley, Richard,* F.R.S., and Professor of Botany in the University of Cambridge; a most voluminous writer on gardening, botany, &c.; died 1732. (*Encyc. of Gard.* p. 1102.)

1. Philosophical Treatise of Husbandry and Gardening. Lond. 4to.
2. The Country Gentleman, and Farmer's Monthly Director. Lond. 1721. 8vo.
3. Experimental Husbandman and Gardener. Translated from the German of G. A. Agricola. Lond. 4to. 1726.
4. A Complete Body of Husbandry. Lond. 1727. 8vo.
5. The Weekly Miscellany for the Improvement of Husbandry, Arts, and Sciences. 21 Nos. 1727. 8vo.
6. The Science of Good Husbandry, or the Economy of Xenophon; translated from the Greek. Lond. 1727. 8vo.
7. The Riches of a Hop Garden explained, with the Observations of the most celebrated Hop Planters in Britain. Lond. 1729. 8vo.

1724. *Anon.*

A Treatise concerning the Manner of fallowing Ground, raising of Grass Seeds, and training of Line and Hemp. Edin. 8vo. Plates.

1726. *Lawrence, John,* M.A., author of *The Clergyman's Recreation,* a gardening work of use in its time; he died in Durham, 1732. (*Encyc. of Gard.* p. 1102.)

The New System of Agriculture; being a complete Body of Husbandry and Gardening in all the parts of them. Lond. fol.

1729. *Mackintosh, Borland.*

Essay on Ways and Means for Inclosing, Fallowing, Planting, &c. Scotland, and that in sixteen Years at farthest. Edin. 8vo.

1730. *Richards, John.*

The Gentleman's Steward and Tenants of Manors instructed Lond. 8vo.

1730. *Rye, George.*
Observations on Agriculture. Dub. 8vo.

1731. *Tull, Jethro,* was born in Oxfordshire; he was a barrister, and made the tour of Europe; after which he settled on his paternal estate, which he cultivated with so much attention as brought on a disorder in his breast. He then went abroad, and, on his return, fixed his residence on a farm in Berkshire, where he renewed his experiments in horse-hoeing husbandry: he died in 1740. His son, John Tull, was an officer in the army, but ruined himself by projects, and died in the Fleet in 1764. (*Gent. Mag.*) Mr. Tull's farm was "situated at a place called Prosperous (probably so called from his great success), in a tract of very indifferent land, lying on the north side of the Hampshire hills, near the borders of Wiltshire, but being itself in the county of Berks. It is, I believe, in the parish of Ink-pen. I visited it in the company of Mr. Budd of Newbury, who had visited it long before with Arthur Young, who, like me, visited it in the character of a pilgrim, and in honour of the memory of the real founder of every recent improvement that has been made in the agriculture of England." (*Cobbett's Treatise on Cobbett's Corn*, chap. vi.)

1. Specimen of a Work on Horse-hoeing Husbandry. Lond. 4to.
2. New Horse-hoeing Husbandry; or an Essay on the Principles of Tillage and Vegetation; wherein is shown a Method of introducing a sort of Vineyard Culture into the Corn Fields, in order to increase their Product, and diminish the common Expense by the use of Instruments, described in Cuts. 1733. fol.
3. Supplement to the New Horse-hoeing, &c. Lond. 1739.

1732. *Ellis, William,* a farmer at Little Gaddesdon, near Hemel Hempstead, in Hertfordshire.

1. The Modern Husbandman; or, Practice of Farming. Lond. 1744. 8 vols. 8vo.
2. The Country Housewife's Family Companion. Lond. 1750. 8vo.
3. The Complete Planter and Cyderist. Lond. 1757. 8vo.
4. Ellis's Husbandry abridged and methodised. Lond. 1772. 2 vols. 8vo.

1737. *Phillips, Robert.*
Dissertation concerning the present State of the High Roads of England, especially those near London; wherein is proposed a New Method of repairing and maintaining them. Lond. 8vo.

1741. *Blackwell, Alexander,* M.D., a native of Aberdeenshire. Blackwell studied physic under Boerhaave at Leyden, took the degree of M.D., practised as a physician at Aberdeen, and afterwards at London, but meeting with no success, turned printer, and became bankrupt in 1734. About 1740 he went to Sweden, turned projector, and laid a scheme before his Swedish Majesty for draining the fens and marshes. He was suspected of being concerned in a plot with Count Tessin, and was beheaded August 9. 1748. His wife Elizabeth was the author of a curious herbal.
A new Method of Improving cold, wet, and barren Land, particularly clayey Grounds, &c. Lond. 8vo.

1743. *Maxwell, Robert,* an eminent Scotch improver.

1. Select Transactions of the Honourable Society of Improvers in the Knowledge of Agriculture in Scotland. Edinb. 1743. 8vo. Plates.
2. The Practical Husbandman. Edin. 8vo. 1757.

1744. *Claridge, John.*
The Shepherd of Banbury's Rules to know of the Change of the Weather. Lond. 8vo.

1757. *Home, Francis,* M.D., Professor of Materia Medica in the University of Edinburgh.
The Principles of Agriculture and Vegetation. Lond. 8vo.

1757. *Lisle, Edward,* Esq., late of Crux-Easton, in Hampshire.
Observations on Husbandry. Lond. 4to, and 2 vols. 8vo.

1759. *Stillingfleet, Benjamin,* grandson to the bishop of that name, and an ingenious naturalist and miscellaneous writer, interesting in agriculture as a promoter of the introduction of artificial grasses; was born about 1702; died 1771.

1. Miscellaneous Tracts relating to Natural History, Husbandry, and Physic. Translated from the Latin; with Notes. Lond. 8vo.
2. Calendar of Flora, Swedish and English, made in the year 1755. Lond. 8vo. 1761.

1759. *Mills, John,* F.R.S., author and translator of several works, and among others of Gyllenborg's *Natural and Chemical Elements of Agriculture*, an ingenious work for its time and country.

1. A Practical Treatise of Husbandry, collected by Duhamel, and also the most approved practice of the best English farmers. Lond. 4to.
2. A New and Complete System of Practical Husbandry. Lond. 1762-5. 5 vols. 8vo.
3. An Essay on the Weather; with Remarks on the Shepherd of Banbury's Rules for Judging of its Changes, and Directions for preserving Hives and Buildings from the fatal effects of Lightning. Lond. 1770. 8vo.
4. A Treatise on Cattle, &c. Lond. 1776. 8vo.

1760. *Hill, Thomas,* gardener to Lord Manners, at Bloxholme in Lincolnshire, and author of a meritorious work on fruit trees.
A Treatise of Husbandry; or the Improvement of dry and barren Lands. Lond. 8vo.

1761. *Mordant, John.*
The Complete Steward; or the Duty of a Steward to his Lord. Lond. 2 vols. 8vo.

1762. *Dickson, Adam,* A.M., minister of Dunse in Scotland. Considered a good classical scholar, and an excellent practical farmer. He died before *The Husbandry of the Ancients* was prepared for the press, which is the occasion of some defects in that work.

1. Treatise on Agriculture. Edin. 8vo. This is one of the best works on tillage that ever has appeared.
2. The Husbandry of the Ancients. Edin. 1778. 2 vols. 8vo.

1763. *Anon.*
Museum Rusticum et Commerciale; or Select Papers on Agriculture, Commerce, &c. Lond. 6 vols. 8vo.

1764. *Ladnar,* of Kroy, in Yorkshire.
The Farmer's New Guide. Lond. 8vo.

1764. *Randall, J.,* some time master of the academy at Heath, near Wakefield, Yorkshire.

1. The Semi-Virgilian Husbandry, deduced from various Experiments. Lond. 8vo.
2. Construction and extensive Use of a new-invented Seed Furrow Plough, suited to all Soils; of a Draining Plough; and of a Potato Drill Machine; with the Theory of a Common Plough; illustrated with 7 plates. Lond. 1764. 4to.

1765. *Fordyce, George,* M.D., F.R.S., a distinguished physician, and teacher of medicine in London; was born at Aberdeen, 1736; died 1802.
Elements of Agriculture and Vegetation. Edin. 8vo.

1766. *Homer, Henry,* an excellent classical scholar, was born in Warwickshire, 1752; died 1791.

1. An Essay on the Nature and Method of ascertaining the specific Shares of Proprietors upon the Inclosure of Common Fields. Lond. 8vo.
2. An Inquiry into the Means of Preserving and Improving the Public Roads of this kingdom. Oxf. 1767. 8vo.

1766. *Anon.*
The Complete Farmer: or a General Dictionary of Husbandry in all its branches, &c., by a Society of Gentlemen, Members of the Society of Arts, Manufactures, &c. London. Fol. Plates.
London, 1807, 2 vols. 4to, 5th edit. entitled The Complete Farmer, or General Dictionary of Agriculture and Husbandry, &c., wholly re-written and enlarged. Plates.

1767. *Young, Arthur,* F.R.S., an eminent agriculturist, secretary to the Board of Agriculture, was the son of Arthur Young, a prebendary of Canterbury, and author of *An Historical Dissertation of Corruptions in Religion.* He was born in 1741. He served his apprenticeship to a wine merchant; but on entering into the possession of his paternal estate, near Bury St. Edmunds, he became a farmer, and impoverished himself by experiments. After this he set up as a teacher of others, and in 1771 published a volume called *The Farmer's Calendar*, which was followed in 1784 by *The Annals of Agriculture*, in which he had Ralph Robinson, George III.'s farming bailiff, for a correspondent. Young also made excursions through the British islands and on the Continent, to collect information on subjects of rural economy. At length a Board of Agriculture was established, of which he was appointed secretary, with a salary of six hundred a year. He became blind some years before his death, which happened February 20. 1820. His works are numerous, and his travels amusing. (*Annual Biography.*)

1. The Farmer's Letters to the People of England, &c. Lond. 8vo.
2. The Farmer's Letters to the Landlords of Great Britain. Lond. 1771. 8vo.
3. A Six Weeks' Tour through the Southern Counties of England and Wales. Lond. 1768. 8vo.
4. Treatise on the Management of Hogs. Lond. 1769. 8vo.
5. A Six Months' Tour through the North of England. Lond. 1770. 4 vols. 8vo.
6. The Farmer's Guide in Hiring and Stocking Farms, &c. Lond. 1770. 2 vols. 8vo.
7. Rural Economy; or Essays on the Practical Part of Husbandry. Lond. 1770. 8vo.
8. A Course of Experimental Agriculture. Lond. 1770. 2 vols. 4to.
9. The Farmer's Tour through the East of England. Lond. 1770. 4 vols. 8vo.
10. Observations on the Present State of the Waste Lands in Great Britain. Lond. 1772. 8vo.
11. Tour in Ireland; with General Observations on the Present State of that Kingdom, made in 1776-7-8, and 9. Dub. 1780. 2 vols. 8vo.
12. An Essay on the Culture of Cole-seed for feeding Sheep and Cattle. 8vo.
13. Annals of Agriculture, and other useful Arts. Published in Nos. Bury St. Edmunds, 1790, 40 vols. 8vo.
14. Travels during the years 1787-8, and 9, undertaken more particularly with a View of ascertaining the Cultivation, Wealth, Resources, and National Prosperity of the Kingdom of France. Bury St. Edmunds, 1792. 4to. 2 vols.
15. General View of the Agriculture of the County of Suffolk; drawn up for the Board of Agriculture. Lond. 1797. 8vo.
16. General View of the Agriculture of the County of Lincoln; drawn up for the Board of Agriculture. Lond. 1799. 8vo.

A New System of Husbandry. Lond. 3 vols. 8vo.

1774. *Barron, William,* F.R.S.E., Professor of Logic and Belles Lettres in the University of St. Andrew's.

Essays on the Mechanical Principles of the Plough. Edin. 8vo.

1775. *Kent, Nathanicl,* of Fulham, Middlesex. He studied agriculture in Flanders, and became an eminent land valuer and agent. He was also for some time farm bailiff to George III. He died in 1818.

1. Hints to Gentlemen of Landed Property. Lond. 8vo.
2. General View of the Agriculture of the County of Norfolk; drawn up for the Board of Agriculture and Internal Improvement. Norwich, 1796. 8vo.
3. Account of the Improvements made on the Farm in the Great Park of His Majesty the King, at Windsor. (*Nicholson's Journal,* iii. 428.) 1799.

1775. *Harrison, Gustavus,* Esq.

Agriculture Delineated; or, the Farmer's Complete Guide, being a Treatise on Lands in general. 8vo.

1775. *Anderson, James,* LL.D., an eminent agricultural writer, was born at Hermiston, a village near Edinburgh, in 1730, on a farm which his parents had possessed for some generations, and which he was intended to inherit and to cultivate. He lost his parents at an early age, but his education was not neglected; he studied chemistry under Dr. Cullen, and soon leaving his farm near Edinburgh, took one in Aberdeenshire of 1300 acres, which, after improving and cultivating for twenty years, he let, and enjoyed an annuity from it during his life. He settled, after leaving Aberdeenshire, in the neighbourhood of Edinburgh, where he published the *Bee,* in weekly sixpenny numbers, till it extended to 18 volumes. In 1797 he removed to Isleworth, near London, where he published *Recreations in Agriculture,* in six volumes, and his *Description of a Patent Hothouse.* Here he enjoyed his garden, and died of a decline in 1808, aged 69. Besides the works which bear his name, he wrote the reviews of books on rural matters for the *Monthly Review* for many years.

1. Essays relating to Agriculture and Rural Affairs. Edin. 8vo. Lond. 3 vols. 8vo.
2. Miscellaneous Thoughts on Planting and Training Timber Trees, by Agricola. Edin. 1777. 8vo.
3. An Account of the Present State of the Hebrides and Western Coasts of Scotland, with Hints for encouraging the Fisheries, and promoting other Improvements in these countries; being the Substance of a Report to the Lords of the Treasury. Edin. 1785. 8vo.
4. A Practical Treatise on Peat Moss, considered as in its Natural State fitted for affording Fuel, or as susceptible of being converted into Mould, capable of yielding abundant Crops of useful Produce, with full Directions for converting and cultivating it as a Soil. Edin. 1794. 8vo.
5. A General View of the Agriculture and Rural Economy of the County of Aberdeen, with Observations on the Means of its Improvement. Chiefly drawn up for the Board of Agriculture, in two parts. Edin. 1794. 8vo.
6. A Practical Treatise on Draining Bogs and Swampy Grounds; with cursory Remarks on the Originality of Elkington's Mode of Draining. Lond. 1794. 8vo.
7. Recreations in Agriculture, Natural History, &c. Lond. 1799. 6 vols. 8vo.

1776. *Home, Henry,* usually called Lord Kames, an eminent Scotch lawyer, philosopher, and critic, was born at Kames, in Berwickshire, 1796; died 1782. He farmed his own estate in Berwickshire many years; he afterwards removed to Blair Drummond, near Stirling, where he made various and extensive improvements, the most important of which was the clearing, cultivating, and peopling great part of Flanders Moss.

The Gentleman Farmer; being an attempt to improve Agriculture, by subjecting it to the test of Rational Principles. Edin. 8vo.

1777—1816. *Anon.*

Letters and Papers on Agriculture, Planting, &c., selected from the Correspondence of the Bath and West of England Society. Bath. 14 vols. 8vo.

1777. *Clarke, Cuthbert.*

The true Theory and Practice of Husbandry, deduced from Philosophical Researches and Experience, &c. Lond. 4to.

1778. *Forbes, Francis,* gentleman.

1. The extensive Practice of the New Husbandry. Lond. 8vo.
2. The Improvement of Waste Lands. Lond. 1778. 8vo.

1778. *Wight, Andrew,* a farmer in East Lothian, and one of the earliest writers among that class in Scotland.

The Present State of the Husbandry in Scotland. Edin. 6 vols. 8vo.

1777. *Black, James,* of Morden, Surrey, a surveyor, in his day in great practice.

Observations on the Tillage of the Earth, and on the Theory of Instruments adapted to this end. Lond. 4to.

1778. *Marshall, William,* Esq., a native of Yorkshire, brought up to trade; he was some years in the West Indies, as a planter; returned about 1775, and took a farm in Surrey; went down into Norfolk as agent to Sir Harbord Harbord's estate in 1780; he left this situation in 1784, and went and resided at Stafford, near the junction of the four counties of Leicester, Warwick, Stafford, and Derby, where he remained till 1786, occupied in collecting materials for his *Economical Surveys,* and in printing some of his works. From this time till about 1808, he resided chiefly in Clement's Inn, London, in winter, and visited different parts of the country during summer. He spent one summer in Perthshire, chiefly on the Earl of Breadalbane's estates at Taymouth; and partly also on the Earl of Mansfield's at Scone. He proposed arrangements for the tenantable land, and also the park and woody scenery on various estates; and finally retired to a considerable property he purchased in his native country, in the vale of Cleveland, in 1808, where he died at an advanced age in 1819. He was a man of little education, but of a strong and steady mind; and pursued in the most consistent manner, from the year 1780 to his death, the plan he originally laid down; that of collecting and condensing the agricultural practices of the different counties in England, with a view to a general work on *Landed Property,* which he published; another on *Agriculture,* which he did not live to complete; and a *Rural Institute,* in which he was supplanted by the Board of Agriculture.

1. Minutes of Agriculture, made on a Farm of 300 acres, of various Soils, near Croydon, Surrey. Lond. 4to.
2. Experiments and Observations concerning Agriculture and the Weather. Lond. 1779. 4to.

2. General View of the Agriculture of Inverness-shire. 8vo.
3. General View of the Agriculture of Kincardineshire. 1811. 8vo.

1800—1825. *Anon.* (R. Brown of Markle, near Haddington, farmer, and afterwards J. Cleghorn of Edinburgh, accountant.)
Farmer's Magazine. Edin. 26 vols. 8vo. Plates.

1800. *Washington*, Gen. *George*, first president of the United States of America, and commander in chief of the armies, was born in the county of Virginia, 1732; died 1799. The most illustrious character of the age in which he lived; his mantle seems to have fallen on General Lafayette.
1. Letters from him to Sir John Sinclair, on Agricultural and other interesting Topics; engraved from the original Letters, so as to be an exact Fac-simile of the Handwriting of that celebrated Character. Lond. 4to.
2. Letters to Arthur Young, Esq., containing an Account of his Husbandry, with a Map of his Farm; his Opinions on various Questions in Agriculture, and many Particulars of the Rural Economy of the United States. Lond. 1801.

1800. *Thomson*, Rev. *John*, D.D.
General View of the Agriculture of the County of Fife. Edin. 8vo.

1800. *Stacey*, Rev. *Henry Peter*, LL.B., F.L.S.
Observations on the Failure of Turnip Crops. Lond. 8vo.

1800. *Parry, Caleb Hillier*, M.D., F.R.S., physician, Bath. He cultivated his own estate, and greatly improved the Merino-ryland breed of sheep.
Facts and Observations, tending to show the Practicability, and Advantage to the Individual and the Nation, of producing in the British Isles Clothing-wool equal to that of Spain; together with some Hints towards the Management of fine-woolled Sheep. Lond. 8vo.

1800. *Dalrymple, William*, Esq.
Treatise on the Culture of Wheat. Lond. 8vo.

1800. *Darwin, Erasmus*, M.D., F.R.S., an eminent physician, philosopher, and poet, was born near Newark, in Nottinghamshire, 1731; died 1802.
Phytologia; or the Philosophy of Agriculture and Gardening. Lond. 4to.

1802. *Alderson, John*, M.D., physician at Hull.
On the Improvement of Poor Soils, in Answer to the following Question:—"What is the best Method of cultivating and improving Poor Soils, where Lime and Manure cannot be had?" Lond. 8vo.

1802. *Bartley, Nehemiah*, Esq., secretary to the Bath Agricultural Society.
Some cursory Observations on the Conversion of Pasture Lands into Tillage, and, after a certain Course of Crops, relaying the same into Pasture, &c. Lond. 8vo.

1802. *Tighe, William*, Esq.
Statistical Observations relative to the County of Kilkenny. Dub. 8vo.

1802. *Bell, Benjamin*, F.R.S.E., surgeon, Edinburgh.

Essays on Agriculture. Edin. 8vo.

1802. *Findlater*, Rev. *Charles*, minister of the parish of Newlands, in the county of Peebles; a man of sound views of political economy, whose work, and whose communications to the *Farmer's Magazine*, have greatly enlightened the farmers in Scotland, on the subjects of rent, demand and supply, market prices, value, &c.

General Survey of the Agriculture of the County of Peebles. Edin. 8vo.

1804. *Knapp, J. L.*, Esq., F.L. and A.SS., author of *The Journal of a Naturalist.*

Gramina Britannica, or Representations of the British Grasses; with Remarks and occasional Descriptions. Lond. 4to.

1804. *Dickson, R. W.*, M.D., of Hendon, Middlesex, author of various works. He died in London, in penurious circumstances, in 1824.

1. Practical Agriculture. Plates. Lond. 2 vols. 4to.
2. Agricultural Magazine; or Farmer's Monthly Journal of Husbandry and Rural Affairs, &c. From July 1807, to December 1808. 8 vols. 8vo. (See 1799.)
3. The Farmer's Companion; being a complete System of Modern Husbandry. (Being Practical Agriculture, with a new title-page!) Lond. 1811. 4to.
4. An improved System of Cattle Management. Lond. 1822. 2 vols. 4to.

1804. *Forsyth, Robert*, Esq. advocate, Edinburgh, author of *Elements of Moral Science*, and other esteemed philosophical works.

Principles and Practice of Agriculture systematically explained; being a Treatise compiled for the Fourth Edition of the Encyclopædia Britannica, revised and enlarged. 2 vols. 8vo.

1805. *Luccock, John*, woolstapler at Leeds.

1. The Nature and Properties of Wool illustrated; with a Description of the English Fleece. Leeds. 12mo.
2. An Essay on Wool; containing an Examination of the present Growth of Wool in every District throughout the Kingdom, and the Means pointed out for its Improvement. 1807.

1805. *Pearson, George*, M.D., F.R.S., senior physician to St. George's Hospital, lecturer in chemistry, and on the theory and practice of medicine in London.

A Communication to the Board of Agriculture, on the Use of Green Vitriol, or Sulphate of Iron, as a Manure; and on the Efficacy of Paring and Burning depending partly on Oxide of Iron. Lond. 4to.

1805. *Somerville, Robert*, a surgeon in Haddington, and for some time joint editor with Brown of Markle of *The Farmer's Magazine.* (See 1799.) He died in 1803.

General View of the Agriculture of East Lothian, from the papers of the *late* Robert Somerville. Lond. 8vo.

1805. *Aiton, William*, sheriff-substitute for the middle ward of Lanarkshire, author of various papers in *The Farmer's Magazine.*

1. Essay on the Origin, Qualities, and Cultivation of Moss Earth. Glasg. 8vo.
2. General View of the Agriculture of the County of Ayr, with Observations on the Means of its Improvement. Glasg. 1811. 8vo.
3. General View of the County of Bute, &c. Glasg. 1816. 8vo.
4. A Treatise on Dairy Husbandry. Edin. 8vo. 1825.

1805. *Barber, William*, a London architect.

1. Farm Buildings; containing Designs for Cottages, Farmhouses, Lodges, Farm-yards, &c. Six Plates. Lond. 4to.
2. A Description of the Mode of Building in Pisé. 1806. 4to.

1805. *Hood, Thomas Sutton*, Esq.; sometimes called *Sutton Thomas Wood.*

A Treatise on Gypsum; on its various Uses, and on its Application as a Manure. 8vo.

1805. *Malcolm, James*, land surveyor to the Prince of Wales, &c.

A Compendium of Modern Husbandry, &c. Lond. 3 vols. 8vo.

1806. *Smith, William*, engineer and mineralogist; a man of extraordinary exertion and merit, more especially as having been the first to compose a geological map of England, and also most valuable county geological maps.

1. The Improvement of Boggy Land by Irrigation, as carried into effect by him. Lond. 8vo.
2. Observations on the Utility, Form, and Management of Water Meadows, and the Draining and Irrigating Peat-bogs; with an Account of Prisley Bog, and other extraordinary Improvements conducted for the Duke of Bedford. Lond. 1809. 8vo.
3. Geological Map of England and Wales and part of Scotland. 1815.
4. Geological Table of British organised Fossils. 1819.
5. County Geological Maps. 1819.

1806. *Ainslie, John*, a land surveyor at Edinburgh.

1. Tables for computing the Weight of Hay, Cattle, &c. by Measurement. Lond. 12mo.
2. Farmer's Pocket Companion. Edin. 1812. 8vo.

1807. *Vancouver, Charles*, land valuer.

1. A General View of the Agriculture of the County of Devon. Lond. 8vo.
2. General View of the Agriculture of Hampshire, including the Isle of Wight. 1811. 8vo.

1807. *Holland, Henry*, Esq., M.D., honorary member of the Geological Society, author of *Travels in Greece*, and other works; an eminent London physician.

General View of the Agriculture of Cheshire. Lond. 8vo.

1807. *Headrick, James*, a clergyman in Angusshire, an excellent chemist, a good naturalist, and an agricultural philosopher.

1. View of the Mineralogy, Agriculture, Manufactures, and Fisheries of the Island of Arran, &c. Edin. 8vo.
2. General View of the Agriculture of the County of Angus. 1813. 8vo.

1808. *Tibbs, Thomas*, farmer.

The Experimental Farmer. 8vo.

1808. *Coventry, Andrew*, M.D., professor of agriculture in the university of Edinburgh; a learned, ingenious, and most benevolent man. He cultivated his own estate in Kinross-shire, and was extensively employed as a land valuer and rural counsellor. He died in December 1830.

1. Discourse explanatory of the Nature and Plan of a Course of Lectures on Agriculture and Rural Economy. Edin. 8vo.
2. Observations on Live Stock, in a Letter to Henry Cline, Esq. Edin. 8vo.
3. Notes on the Culture and Cropping of Arable Land. Edin. 1812. 8vo.

1808. *Gray, Andrew*, a retired machinist at Edinburgh.

Plough-wright's Assistant; or, a Practical Treatise on various Implements employed in Agriculture; illustrated with 16 Engravings. Edin. 8vo.

1808. *Beddoes, Thomas*, M.D., born in Shropshire, 1760, was lecturer in Boton, at Oxford, and afterwards physician at Bristol, where he died, 1808.

1. Good Advice for the Husbandman in Harvest, and for all those in Labour in Hot Births; as also for others who will take it in Warm Weather. 8vo.
2. On the Means of foretelling the Character of the Summer Season, and the Benefits to be expected from the Cultivation of Grasses which vegetate at low Temperatures. (*Nic. Jour.* v. 131.) 1802.

1808. *Bakewell, Robert*, Esq., an eminent geologist and mineralogist, author of *Travels in the Tarentaise, &c.*; an instructive and entertaining work, published in 1823.

Observations on the Influence of Soil and Climate upon Wool, with an easy Method of improving the Quality of English Clothing Wool, and Hints for the Management of Sheep, &c.; with occasional Notes and Remarks by the Right Hon. Lord Somerville. Lond. 8vo.

1808. *Dutton, Hely*, Esq., landscape gardener.

1. Statistical Survey of the County of Clare. Dublin, 8vo.
2. Statistical Survey of the County of Galway. Dublin, 1824. 8vo.

1808. *Curwen, John Christian*, M.P., of Workington Hall, Cumberland.

1. Hints on the Economy of Feeding Stock, and bettering the Condition of the Poor. Lond. 8vo.
2. A Tour in Ireland. 2 vols. 8vo. 1819.

1809. *Stevenson, W.*, Esq., M.A., librarian to the Treasury, author of various works, and a writer in the principal encyclopædias. He died in 1829.

General View of the Agriculture of the County of Surrey. Lond. 8vo.

1809. *Kerr, Robert*, surgeon, F.R. and A.SS. Edinburgh, an excellent naturalist and general scholar; died, 1814.

Statistical, Agricultural, and Political Survey of Berwickshire. 8vo.

1809. *Williamson*, Capt. *Thomas*, upwards of 20 years in Bengal.

Agricultural Mechanism; or, a Display of the several Properties and Powers of the Vehicles, Implements, and Machinery connected with Husbandry. Lond. 8vo.

1810. *Davies, Walter*, A.M.

A General View of the Agriculture and Domestic Economy of North Wales. Lond. 8vo.

1810. *Hunt, Charles Henry*, Esq.

Treatise on the Merino and Anglo-Merino Breeds of Sheep. Lond. 8vo.

1810. *Adams, George.*

A New System of Agriculture and Feeding Stock. Lond. 8vo.

1810. *Farish, John*, Dumfries.

A Treatise on Fiorin Grass. 8vo.

1810. *Edgeworth, Richard Lovell*, Esq., F.R.S. and M.R.I.A., civil engineer, resident at Edgeworth Town, Ireland, author of various works.

An Essay on the Construction of Roads and Carriages. Lond. 8vo.

1811. *Keith, George Skeene*, D.D.

A General View of the Agriculture of Aberdeenshire. 8vo.

1811. *Henderson, Robert*, farmer at Broomhill, near Annan, Dumfriesshire.

Treatise on the Breeding of Swine and Curing of Bacon; with Hints on Agricultural Subjects. Edin. 8vo.

1811. *Farey, John*, sen., mineral surveyor. A man of sound views on all subjects; a philosopher and an agriculturist, and territorial improver of great experience.

General View of the Agriculture and Minerals of Derbyshire. Lond. 3 vols.

1811. *Loudon, John Claudius*, F.L.G. Z. and H.S., landscape gardener, author of the *Encyclopædia of Gardening*, and other works, and founder and con-

ductor of the *Gardener's Magazine*, and of the *Magazine of Natural History*; born in Lanarkshire in 1782, began to practise in 1803; to farm extensively in Oxfordshire in 1809, and in Middlesex in 1810; travelling on the Continent in 1813-14-15, in 1819, and again in 1828-29; now residing at Bayswater.

1. Designs for laying out Farms and Farm Buildings in the Scotch Style, adapted to England; comprising an Account of the Introduction of the Berwickshire Husbandry into Middlesex and Oxfordshire. Lond. 4to.
2. An Encyclopædia of Agriculture. Lond. 8vo. 1825.

1813. *Walker, W.*

An Essay on Draining Land by the Steam Engine. Lond. 8vo.

1813. *Davy*, Sir *Humphry*, president of the Royal Society, LL.D., V.P.R.I., F.R.S., Edin. M.R.I.A., &c.

Elements of Agricultural Chemistry; in a Course of Lectures for the Board of Agriculture. 4to and 8vo.

1814. *Shirreff, John*, farmer at Captain Head, near Haddington, Scotland, and one of the authors of the *Survey of the West Riding of Yorkshire*, along with Mr. Brown and Mr. Rennie (see 1799); afterwards a land agent, and finally steward to a nobleman near Stirling.

General View of the Agriculture of the Orkney Islands. Edin. 8vo.

1815. *Moubray, Bonnington*, Esq.

A practical Treatise on the Method of Breeding, Rearing, and Fattening Domestic Poultry, Pigeons, and Rabbits. 8vo.

1815. *Little, John.*

Practical Observations on the Improvement and Management of Mountain Sheep and Sheep Farms. 8vo.

1814—1815. *Simpson, Pinder.*

1. Treatise on the Cultivation of Mangold Wurzel, as Winter Food for Cattle. Lond. 8vo.
2. On the improved Beet-root as Winter Food for Cattle.

1815. *Birkbeck, Morris*, Esq., formerly a farmer in Suffolk, afterwards an extensive proprietor and resident cultivator in the Illinois. Drowned there in 1825.

1. Notes in a Journey through France from Dieppe, through Paris and Lyons to the Pyrenees, and back through Toulouse in 1814; describing the Habits of the People, and the Agriculture of the Country. 8vo.
2. Notes in a Journey in America, from the Coast of Virginia to the Territory of Illinois. Lond. 1818. 8vo.

1815. *Hornby, Thomas*, Esq., surgeon, York.

Dissertation on Lime, and its use and abuse in Agriculture, embracing a View of its Chemical Effects. 8vo.

1816. *Anderson, William*, farmer, Angusshire.

Observations on a new Mode of Stacking Corn, peculiarly adapted to Wet Seasons; recommending a Plan, successfully practised, by which corn may be stacked with advantage soon after being cut down. 8vo.

1818. *Macwilliam, Robert*, Esq. architect and surveyor, London.

An Essay on the Origin and Operation of the Dry Rot; to which are annexed, Suggestions for the Cultivation of Forest Trees, and an Abstract of the Forest Laws. 4to.

1819. *Radcliffe*, Rev. *T.*

A Survey of the Husbandry of Eastern and Western Flanders, made under the Authority of the Dublin Farming Society. 8vo.

1819. *Williams, T. W.*

The Farmer's Lawyer; containing the Whole of the Law and local Customs in regard to Agricultural Possessions, Properties, and Pursuits. 8vo.

1819. *Swinbourne, R.*

The Farmer's New and Complete Account Book.

1819. *Blaikie, Francis*, first gardener, and afterwards steward to T. W. Coke, Esq. M.P. of Holkham.

1. On the Conversion of arable Land into Pasture, and on other rural Subjects. Lond. 1819. 12mo.
2. On the Management of Farm-yard Manure, and on other rural Subjects. Lond. 1819. 12mo.
3. A Treatise on the Management of Hedge and Hedgerow Timber. 12mo.
4. On the Economy of Farm Yard Manure, &c. 12mo. 1820.
5. On Mildew, and the Culture of Wheat. 12mo. 1821.
6. On Smut in Wheat. 12mo. 1822.

1820. *Rigby, Edward*, M.D. F.L.S.

1. Framlingham, its Agriculture, &c., including the Economy of a small Farm. 8vo.
2. Holkham, its Agriculture, &c. 8vo. 1821.

1820. *Grisenthwaite, William*, apothecary, of Wells, in Norfolk.

A new Theory of Agriculture, in which the Nature of Soils, Crops, and Manures is explained, many prevailing Prejudices are exploded, and the Application of Bones, Gypsum, Lime, Chalk, &c. determined on scientific Principles. 12mo.

1820. *Monteath, Robert*, a forester in considerable practice as agent and valuator.

The Forester's Guide. Stirling. 12mo. 2d edition with Additions, &c. Edin. 8vo. 1824, plates.

1820. *Mather, John*, Castle Hill, Carse of Gowrie.

The Farmer and Land Steward's Assistant; or, a Specimen of Farm Book-keeping, exhibiting, in a concise and simple Form, the Transactions in the arable, grazing, and woodland Departments; a general Cash Account; and an Account of the Charge and Discharge upon each Department; the Whole selected from Books of real Business. 4to.

1820. *Johnson, Cuthbert William*, F.L. and H.S.

An Essay on the Uses of Salt for Agricultural Purposes, with Instructions for its Employment as a Manure, and in the Feeding of Cattle, &c. New Edition in 1827.

1820. *Burroughs, Edward*, Esq.

Essays on Practical Husbandry and Rural Economy, 8vo.

1820. *Beatson*, Major General *Alexander*, late Governor of St. Helena, &c.

A new System of Cultivation without Lime or Dung on Summer Fallows, as practised at Knowle Farm, in the County of Sussex. Lond. 1820, 8vo, Plates, and Supplement. 1821, 8vo, Plates.

1822. *Finlayson, John*, of Kaines, near Muirkirk, Inventor and Patentee of the self-cleaning Ploughs and Harrows, a practical farmer and an ingenious man.

A Treatise on Agricultural Subjects. 8vo, plates. Subsequently changed to The British Farmer, &c. London. 1830. 8vo.

1822. *Salisbury, W.*, formerly a botanical nurseryman, now a private teacher of botany, &c.

The Cottager's Agricultural Companion. 12mo.

1822. *Munro*, Colonel *Innes.*

A Guide to Farm Book-keeping, founded upon actual Practice, and upon new and concise Principles. Royal 8vo.

1822. *Napier*, Hon. *William John*, F.R.S. Edin. post captain in the Royal Navy; a vice-president of the Pastoral Society of Selkirkshire, &c.

A Treatise on Practical Store Farming, as applicable to the Mountainous Region of Ettrick Forest, and the Pastoral District of Scotland in general. With Engravings. 8vo.

1822. *Cleghorn, James*, Esq., formerly a practical farmer, afterwards editor of *The Farmer's Magazine*, author of the article "Agriculture" in the Supplement to the *Encyc. Brit.*, and of various articles in that work. One of the best modern writers on agriculture. Mr. C. is now an accountant in Edinburgh.

On the depressed State of Agriculture. Edin. 8vo.

1823. *Fairbarn, John.*

A Treatise upon Breeding, Rearing, and Feeding Cheviot and Black-faced Sheep in high Districts; with Observations on laying out and conducting a Store Farm, &c. Berwick. 8vo.

1823. *Low, David*, Esq. said to be editor of the *Quarterly Journal of Agriculture.*

Observations on the present State of Landed Property, and on the Prospects of the Landholder, and the Farmer. Edin. 8vo.

1824. *Morice, Francis.*

An Essay on Agriculture, and the Management of Landed Estates. Aberdeen. 8vo.

1824. *Sinclair, George*, F.L.S F.H.S., formerly gardener to the Duke of Bedford, at Woburn, now of the firm of Cormack, Son, and Sinclair, nurserymen, New Cross, Deptford.

Hortus Gramineus Woburnensis; or, an Account of the Results of various Experiments on the Produce and Fattening Properties of different Grasses, and other Plants used as the Food of the more valuable domestic Animals; instituted by John Duke of Bedford. To which is added, an Appendix, pointing out the different Grasses best adapted for the Manufacture of Leghorn Bonnets, &c. Lond. Royal 8vo.

1824 *Western, C. C.*, Esq. M.P.

A few Practical Remarks on the Improvement of Grass Land, by means of Irrigation, Winter-flooding, and Drainage; in a Letter to the Owners and Occupiers of Land in the County of Essex. Lond. 8vo.

1824. *Slaney, Robert A.*, Esq. barrister.

Essay on the beneficial Direction of Rural Expenditure. Lond. 12mo.

1825. *Holditch, Benjamin*, a farmer on the Duke of Bedford's estate, near Peterborough, and for some time editor of the *Farm. Journ.* newspaper.

Essay on the Weeds of Agriculture. Lond. 8vo. Edited by G. Sinclair, for the benefit of his widow.

1825. *Hayward, Joseph*, author of the Science of Horticulture.

The Science of Agriculture, comprising a Commentary on, and comparative Investigation of, the Agricultural Chemistry of Mr. Kirwan, and Sir Humphry Davy; and the Code of Agriculture of Sir John Sinclair, Sir Joseph Banks, and other Authors on the subject: with Remarks on the Rust, or black Blight in Wheat; of which the true Cause and its Prevention are explained. Lond. 8vo.

1825. *Anon.*

A Treatise on Milk. Lond. 8vo.

1825. *Bayldon, J. S.*, land-agent and appraiser.

The Art of valuing Rents and Tillages, and the Tenants Right on entering and quitting Farms. 2d edit. Lond. 8vo.

1825. *Buchanan, George*, civil engineer.

A Treatise on Road-making, Railways, Wheel Carriages, and the Strength of Animals.

1825. *Cleghorn, James*, accountant in Edinburgh, conductor of the *Farmer's Magazine.*

Thoughts on the Expediency of a General Provident Institution for the Benefit of the Working Classes, &c. &c. Edin. 8vo.

1826. *Steele, Andrew*, a proprietor in the neighbourhood of Edinburgh.

The National and Agricultural History of Peat Moss, &c. Edinburgh, 8vo.

1826. *Withers, William*, junior, Esq. of Holt, Norfolk.

A Memoir addressed to the Society for the Encouragement of Arts, Manufactures, and Commerce, on the Planting and Rearing of Forest Trees, &c. &c. Holt and London, 8vo. pamph.

1826. *Waistell, Charles*, Esq., chairman of the

Committee of Agriculture, of the Society of Arts. Edited by Joseph Jopling, architect, member of the Institution of Civil Engineers, inventor of the Septenary System of generating Lines by simple continuous Motion, Instruments for drawing Curves, &c. &c.

Designs or Agricultural Buildings, &c. &c.: to which are added, Plans and Remarks on Caterham Farm-yard, as it formerly was; and also as it has been improved. Lond. 8vo.

1826. *Collyns, W.*, Esq., surgeon, Kenton, near Exeter.

Ten Minutes' Advice to my Neighbours, on the Use and Abuse of Salt as a Manure, &c. Exeter, pamph. 8vo.

1826—1831. *Fleming*, —, and *J. Main.*

Fleming's British Farmer's Magazine. Lond. 2 vols. 8vo. Continued under the name of the British Farmer's Magazine, 2 vols. 8vo.

1827. *Anon.*

The Farmer's Register and Monthly Magazine of Foreign and Domestic Events. Glasgow. In 8vo numbers, monthly. Completed in one volume.

1828. *Meadows, Arthur*, Esq.

Hints to the Farmers of the Baronies of Forth and Bargy on the Cultivation of Mangold Wurzel, Beans, Carrots, and Parsneps. Wexford, 8vo.

1828—1831. *Anon*, believed to be *David Low*, Esq.

The Quarterly Journal of Agriculture. Edinburgh, 2 vols. 8vo.

The Prize Essays and Transactions of the Highland Society of Scotland are publishing along with this work. See 1799.

1828. *Kennedy, Lewis*, Esq., son of Mr. Kennedy the late eminent nurseryman of Hammersmith, steward to Lord Willoughby De Eresby, author of the *Tenancy of Land in Great Britain*, &c.

1. On the Cultivation of the Waste Lands in the United Kingdom, for the purpose of finding Employment for the able Poor now receiving Parochial Aid, and thereby diminishing the heavy Burdens of the Poor Rates; and on the Expediency of making some Provision for the aged and disabled Paupers of Ireland. Lond. 8vo.

2. The present State of the Tenancy of Land in Great Britain; showing the principal Customs and Practices between incoming and outgoing Tenants, &c. Lond. 8vo.

1829. *Lambert, Joseph*, Esq.

Observations on the Rural Affairs of Ireland, or a Practical Treatise on Farming, Planting, and Gardening, adapted to the Circumstances, Resources, Soil, and Climate of the Country. Dublin, 8vo, pp. 327.

1829. *Stephens, George*, drainer, member of the Nerecian and Wermlandska Agricultural Societies in Sweden.

The Practical Irrigator; being an Account of the Utility, Formation, and Management of Irrigated Meadows, with a particular Account of the Success of irrigation in Scotland. To which is added, a Practical Treatise on straightening Water-courses, protecting River Banks, and embanking Low Lands. Edin. 8vo.

1829. *Doyle, Martin.*

Hints originally intended for the small Farmers of the County of Wexford; but suited to the Circumstances of many Parts of Ireland. Dublin, 18mo.

1829. *Fall, Thomas*, Surveyor of Roads.

The Surveyor's Guide; or, every Man his own Road-maker: comprising the whole Art of making and repairing Roads, Prices for Work. East Retford. 12mo.

1829. *Harley, William*, originally a manufacturer in Glasgow; afterwards a great cow-keeper and builder there. He died in London in 1830.

The Harleian Dairy System, and an Account of the various Methods of Dairy Husbandry pursued by the Dutch. Also, a new and improved Mode of ventilating stables; with an Appendix, containing useful Hints (founded on the Author's experience) for the Management of Hedgerow Fences, Fruit Trees, &c., and the Means of rendering Barren Land fruitful. Lond. 8vo.

1829. *Strickland, G.*, Esq.

A Discourse on the Poor Laws of England and Scotland, on the Poor of Ireland, and on Emigration. Lond. 8vo.

1829. *Trimmer, Joshua Kirby.*

Practical Observations on the Improvement of British Fine Wool, and the National Advantages of the arable System of Sheep Husbandry; with Remarks on the Saxon and French Systems.

1830. *Anon.*

The Library of Useful Knowledge; Farmer's Series. 8vo, 13 numbers to January 1, 1831.

1830. *Jennings, James*, Esq., author of the *Family Cyclopædia*, &c.

A Practical Treatise on the History, Medical Properties, and Cultivation of Tobacco. London.

1830. *Berry*, the Rev. *Henry*, an extensive farmer in Worcestershire, and understood to be the principal proprietor of the *British Farmer's Magazine.*

Improved Short-horns, and their Pretensions stated; being an Account of this celebrated Breed of Cattle, derived from authentic Sources: to which is added, an Enquiry as to their Value for General Purposes, placed in Competition with the improved Herefords. Lond. pamph. 8vo. 2d edit.

1830. *Brodigan, Thomas*, Esq.

A Botanical, Historical, and Practical Treatise on the Tobacco Plant, in which the Art of growing and curing Tobacco in the British Isles is made familiar to every Capacity, as deduced from the Observations of the Author in the United States of America, and his Practice in Field Cultivation in Ireland. Lond. 8vo.

1830. *Davey, John*, Esq.

Observations on the Disease which has lately been so destructive to Sheep, called Bane or Coath; particularising the Causes, and minutely describing the Modes of effecting its Cure; and pointing out those Means which ought to be adopted to prevent its Recurrence. Bath, pamph. 8vo.

Sect. II. *Bibliography of Agriculture in Foreign Countries.*

7899. *Numerous works on agriculture* are published in the French and German languages, and a considerable number in the Italian; but a great proportion of these are translations from British authors. Very few agricultural books have been printed in the Dutch, Flemish, Danish, Swedish, Polish, Spanish, or Portuguese languages, and scarcely any in those of Russia or Hungary. We shall notice the principal French, German, and Italian works, exclusive of translations, and add a few American books.

Subsect. 1. *Bibliography of French Agriculture.*

7900. *Of French books on agriculture* we have given a selection only: those who wish to see a complete list are referred to the *Bibliographie Agronomique*, Paris, 8vo; in which are given the titles of upwards of 2000 works, including translations and books on gardening. A general idea of French culture in all its branches may be obtained from the *Nouveau Cours Complet d'Agriculture*, 16 vols. 8vo (edition of 1821.), compiled by the members of the Section of Agriculture of the French Institute, each of whose names are given to the articles he contributed.

1529. *Etienne, Charles*, et *J. Liébault*, physicians. Etienne, *i.e.* Stephanus or Stephens, in the beginning of the sixteenth century published various small tracts on Gardening and other rural topics; and in 1529 he collected them together and published them, under the title of *Prædium Rusticum*, treating of gardens, trees, vines, fields, meadows, lakes, forests, orchards, &c. Having married his daughter to Liébault, they afterwards studied agriculture conjointly, and published the *Maison Rustique*, the modern editions of which are still the most popular agricultural works in France.

1. Prædium Rusticum; in fol.

2. L'Agriculture et Maison Rustique. Paris, in 4to, 1570.

1569. *Hesson, Jacques*, of Dauphiny.

De l'Art et Science de trouver surement les Eaux, Sources, et Fontaines cachées sous Terre, autrement que par les Moyens Vulgaires des Agriculteurs et Architectes, in 4to.

1583. *Hegemon, Philibert*, a lawyer born at Chalons-sur-soane. Died in 1595.

La Colombière et Maison Rustique, contenant une Description des Douze Mois et des Quatre Saisons de l'Année, avec Enseignement de ce que le Labourcur doit faire par chaque Mois. Paris, in 8vo.

1600. *Serres, Olivier de*, the Lord of Predel in Languedoc. He was born in 1539, and died in 1619, at the age of 80 years. He was employed by Henry IV. to form a plantation of the white mulberry in the garden of the Tuilleries; and he is generally considered as the father of the culture of that tree in France. He published a great many useful works, the principal of which is his *Théâtre d'Agriculture*, the first edition of which was published in 1600, and the 20th in 1675.

Le Théâtre d'Agriculture et Mesnage des Champs. Paris, small 8vo. An enlarged edition in 2 vols. 4to, with voluminous Notes, and a Historical Introduction, in 1804.

1602. *Letellier.*

Brief Discours contenant la Manière de nourrir les Vers à Soie, &c. Avec de belles Figures. Paris, in 4to.

1604. *Laffenas, Barthelemy de*, valet de chambre to Louis XIII.

La Façon de faire et semer la Graine de Mûriers, les élever et replanter, gouverner les Vers à Soie au Climat de France. Paris, in 12mo.

1607. *Vinet, Elie*, a learned professor at Bourdeaux, author of a work on land surveying.

La Maison Champestre et Agriculture. Paris, in 4to

1663. *Patin, Charles*, son of a physician of that name.

Traité des Tourbes Combustibles. Paris, in 4to.

1703. *Liger, Louis*, born 1658, died in 1717. In the latter part of his life he seems to have been a bookseller, or an author by profession.

1. Dictionnaire Général des Termes propres à l'Agriculture, avec leurs Définitions et Etymologies. Paris, in 12mo.
2. La Nouvelle Maison rustique, ou Economie Générale des Biens de la Campagne. Paris, 2 vols. in 4to. 1755.
3. L'Economie Générale de la Campagne, ou Nouvelle Maison rustique. 1762.
4. Nouveau Système d'Agriculture. 3 vols. in 8vo. 1775.

1749. *Boucher d'Argis, Antonine Gaspard*, advocate and author of some works on jurisprudence.

Code Rural, ou Maximes et Réglemens concernant les Biens de la Campagne, 2 vols.

1749. *Réaumur, Réné, Antoine Ferchault, sieur de*, a learned naturalist, born at Rochelle in 1683, died in 1757.

Art et Pratique de l'Art de faire éclorer, en toutes Saisons, des Oiseaux Domestiques de toutes Espèces. Paris, Imprim. Royale, 3 vols. in 12mo, avec fig.

1750. *Hamel, Du Monceau, Henry Lewis du*, a famous French writer on Rural Economy and Vegetable Physiology, was born at Paris, 1700; died there 1782.

1. Traité de la Culture des Terres. Par. 6 vols. 12mo.
2. Elémens d'Agriculture. Par. 1764, 2 vols. 12mo.
3. Traité de la Conservation des Graines, et en particulier du Froment. Par. 1754. 12mo.
4. Traité des Arbres et Arbustes, qui se cultivent en France, en pleine Terre. Par. 1755, 2 vols. 4to.
5. Traité complet des Bois et des Forêts. Par. 1758, 6 tom. 4to.
6. Des Semis et Plantations des Arbres, et de leur Culture. Par. 1760. 4to.
7. Histoire d'un Insecte qui devore les Grains de l'Augoumois. Par. 1762. 12mo.
8. De l'Exploitation des Bois, ou Moyen de tirer Parti des Taillis demi Futayes et hautes Futayes. Par. 1764. 2 vols. 4to.
9. Mémoire sur la Garence et sa Culture, in 4to. 1765.
10. Du Transport, de la Conservation, et de la Force du Bois. 1767. 4to.

1751. *Desbois, Francis Alexander Aubert de la Chesnaie*, a laborious Dictionary-maker; was born at Ernée in the Maine, 1699; died 1784.

Dictionnaire d'Agriculture. 2 vols. 8vo.

1755. *Blavet*, librarian to the Prince of Conti.

Essai sur l'Agriculture Moderne. Paris, in 12mo.

1755. *Tillet, du*, of Bourdeaux, a zealous agriculturist, author of several works. He died in 1791.

Dissertation sur la Cause qui corrompt et noircit les Graines de Blé dans les E'pis, in 4to.

1756. *Hastfer, F. W.*

Instruction sur la Manière d'élever et de perfectionner les Bêtes à Laine. Paris, 2 vols. in 12mo.

1760. *Alletz, Pons Augustin*, an advocate, and indefatigable compiler.

L'Agronome, ou Dictionnaire portatif du Cultivateur, 2 vols. in 8vo.

1760. *Buch'oz, Pierre Joseph*, a physician, and member of several societies; born at Metz in 1731, died in great distress at Paris in 1807. He wrote above three hundred volumes relative to medicine, agriculture, the veterinary art, and natural history. A plant (Buchoz*iàna*) was named after him by L'Héritier.

1. Lettre sur la Méthode de s'enrichir promptement et de conserver sa Santé par la Culture des Végétaux, in 8vo.
2. Lettre sur le Blé de Smyrne, in 8vo. 1768.
3. Histoire des Insectes nuisibles à l'Homme, aux Bestiaux, &c. in 12mo. 1781.
4. Manuel usuel et économique des Plantes, contenant leur Propriétés pour les Usages économiques. Paris, in 12mo. 1782.
5. Histoire des Insectes utiles à Homme, aux Animaux, et aux Arts. Paris, in 12mo. 1785.
6. Traité de la Pêche, ou l'Art de soumettre les Poissons à l'Empire des Hommes, précédé de l'Histoire Naturelle de ces Animaux, in 12mo. 1786.
7. Dissertation sur la Betterave et la Poirée, leur Culture, Méthode pour en tirer du Sucre, &c. fol. 1787.
8. Dissertation sur le Cochon, in fol. 1789.
9. Dissertation sur le Lin de Sibérie, in fol. 1789.
10. Dissertation sur la Taupe; les Moyens de la prendre, in fol. 1790.
11. Dissertation sur le Tirage de la Soie, in fol. 1792.
12. Manuel Tabacal et Sternutatoire des Plantes, ou Traité des Plantes qui sont propres à faire éternuer, avec la Manière de cultiver le Tabac, de le préparer, et de juger de ses bons Effets dans la Société, in 8vo. 1799.
13. Manuel Territorial des Plantes, in 8vo. 1799.
14. Manuel Vétérinaire des Plantes, in 8vo. 1799.
15. Mémoire sur le Blé de Smyrne, sur le Blé de Turquie, le Millet d'Afrique, et la Poherbe d'Abyssinie, Plantes Alimentaires pour l'Homme; in 8vo. 1824.
16. Mémoire sur la Manière de former des Prairies Naturelles, in 8vo. 1805.

1760. *Turbilly, Louis François Henri de Menon*, Marquis de, a proprietor in Anjou, who had been in the army, but who retired to his estates and broke up and improved a number of acres, of which he published an account, well known at that time in England. Arthur Young, when in France in 1787, was anxious to visit the Marquis; but after, with difficulty, finding out the estate of Turbilly, he found the Marquis had died in 1776, having ruined himself by establishing a pottery. There is a very interesting account of this visit in *Young's Tour*, part I. p. 294. *et seq.*

1. Mémoire sur les Défrichemens, in 12mo.
2. Pratique des Défrichemens. Paris, in 12mo. 1701.

1761. *Guillot, Julien Jean Jacques.*

Discours sur les Branches d'Agriculture les plus avantageuses à la Province de Normandie.

1761. *Neuve-Eglise, Louis Joseph Bellepière de*, an officer in the army.

1. L'Agronomie, ou Corps complet des Principes de l'Agriculture, &c. 8 vols. in 8vo.
2. Boussole Agronomique, ou le Guide des Laboureurs, in 8vo. 1762.

1762. *Desplaces, Laurent Benoist.*

1. Préservatif contre l'Agronomie, ou l'Agriculture réduite à ses vrais Principes. Paris, in 12mo.
2. Histoire de l'Agriculture ancienne, extraite de l'Histoire Naturelle de Pline, avec des Eclaircissemens et des Remarques. 12mo. 1765.

1762. *Despommiers.*

L'Art de s'enrichir promptement par l'Agriculture. Paris, 12mo.

1762. *Lafaille, Clement*, advocate, and member of several societies.

1. Mémoire sur les Moyens de multiplier aisément les Fumiers dans le Pays d'Aunis.
2. Essai sur l'Histoire naturelle de la Taupe; sur les différens Moyens qu'on peut employer pour la détruire. La Rochelle, in 12mo, fig. 1768.

1762. *L'Etang de la-Salle, Simon Philibert de*, of Rheims, a lawyer.

Des Prairies artificielles, ou Moyens de perfectionner l'Agriculture dans toutes les Provinces de France, surtout en Champagne, par l'Entretien et le Renouvellement de l'Engrais; avec un Traité sur la Culture de la Luzerne, du Trèfle, et du Sainfoin, et une Dissertation sur l'Exportation du Blé. Paris. 8vo.

1763. *Barthez de Marmorières*, an officer, secretary of embassy, and member of various societies.

Mémoires d'Agriculture, &c. 8vo.

1763. *Duvergé*, a physician of Tours.

Analyse chémique des Terres de la Province de Touraine, des différens Engrais propres à les améliorer, et des Semences convenables à chaque Espèce de Terre. Tours. 8vo.

1763. *François, Nicholas*, de Neufchâteau, member of the Institute, the Senate, &c., a distinguished member of the Paris Agricultural Society, and author of numerous papers in their memoirs.

1. Avis aux Cultivateurs et Propriétaires de Troupeaux, sur l'Amélioration des Laines. Paris. 8vo. an. vii.
2. Essai sur les Moyens de tirer le Parti le plus avantageux de l'Exploitation d'un Domaine borné, ou Système d'Agriculture pour les petits Propriétaires. Neufchâteau. 8vo. 1790.
3. Essai sur la Nécessité et les Moyens de faire entrer dans l'Instruction publique l'Enseignement de l'Agriculture; lu à la Société d'Agriculture de la Seine, &c. 8vo. 1802.

Essai sur le Haras; ou Examen des Moyens propres pour établir, diriger et faire prospérer les Haras: suivi d'une Méthode facile de bien examiner les Chevaux que l'ont veut acheter. 8vo, fig.

1769. *Rigaud de l'Isle*, of Crest, in Dauphiny.

Mémoire sur la Culture de l'Esparcette, ou Sainfoin. Paris. 8vo.

1769. *Sieuve.*

1. Mémoire et Journal d'Observations sur les Moyens de garantir les Olives de la piqûre des Insectes et nouvelle Méthode pour en extraire l'Huile plus abondante par l'Invention d'un Moulin domestique, avec la Manière de la garantir de toute Rancissure. Paris, 12mo.

2. Mémoires sur diverses Constructions en Terre ou Argile, propres à faire jouir les petits Ménages de l'Economie des combustibles. Poitiers, 8vo. 1804.

1770. *Amiot, Le P.*, missionary at Pekin.

Reflexions sur l'Agriculture, et sur ceux qui s'y consacrent: tirées de l'éloge de la Ville de Moukden et de ses Environs. Poëme composé par Kien-Long, Empereur de la Chine et de la Tartarie, actuellemen regnant, traduit en Français par le P. Amiot, et publié par M. Deguignes, Membre de l'Académie Royale des Inscriptions et Belles Lettres, et Professeur des Langues Orientales au College Royale. Paris, 8vo. Cet ouvrage est curieux sous plus d'un rapport.

1770. *Beaunié, Antoine*, an eminent French chemist, was born at Senlis, 1728; died 1805.

Mémoire sur les Argiles; ou, Recherches sur la Nature de Terres les plus propres à l'Agriculture, et sur les Moyens de fertiliser celles qui sont Stériles. Paris, 8vo.

1770. *Ricm.*

Encyclopédie Economique, ou Système général d'Economie rustique, contenant les meilleures Pratiques pour fertiliser les Terres, la Conservation des Grains, &c.; par quelques Membres de la Société d'Agriculture de Berne. Yverdon, 16 vols. 8vo.

1770. *Rozier, François*, born in Lyons, 1734, and killed there on the 29th September 1793, during the siege of that city, by a bombshell, which buried his shattered remains in the ruins of the apartment which he occupied; he began his career as an author, by writing in the *Journal de Physique et d'Histoire Naturelle*, of which Gauthier Dagoty was editor. He next occupied himself with his *Agricultural* or *Rural Dictionary*, the work by which he is chiefly known. He cultivated a farm near Bezières, which Arthur Young went to see when on his tour in France in 1787; but the Abbé had left it on account of the Bishop of Bezières, who kept a mistress somewhere near, and for his more commodiously visiting her, got a road made across the farm at the expense of the province. This occasioned a quarrel between the Abbé and the Bishop, which ended in the former being obliged to quit his farm. The Abbé, like all other men who depart from common practices, was looked on as a fanciful and wild cultivator; and, because he paved his stables and cow-houses, it was reported by his neighbours that he paved his vineyard. He wrote a great many works, chiefly on agriculture.

1. L'Art du Maçon piseur, extrait du Journal d'Observations sur la Physique, in 12mo.

2. Traité de la meilleure Manière de cultiver la Navette et le Colsa, et d'en extraire une Huile Dépouillée de son manuvaise Goût et de son Odeur désagréable. Paris, in 8vo. 1774.

3. Cours Complet d'Agriculture, Théorique, Pratique, Economique, etc.; ou Dictionnaire universel d'Agriculture. 12 vols. in 4to. 1796.

1773. *Bexon, Gabriel Leopold Charles Ame*, a French miscellaneous writer, was born at Remiremont, 1748; died at Paris 1784: he had a great turn for Natural History, and assisted Buffon in the latter volumes of his great work.

Recueil Industriel, Agricole, et Commercial. Paris, 8vo monthly Numbers.

Subsect. 2. *Bibliography of German Agriculture*

7901. The *German agricultural works* are as numerous as those of the French, but chiefly translations, and these, for the most part, from the English. We have given a very limited selection, the German language being less generally understood than either the French or Italian. In forest management (*Forstwissenschaft*) the German bibliography is very rich; and it is chiefly these books, and descriptions of local practices, which can be of any interest to the British cultivator. The older German works in rural affairs are enumerated in Haller's *Bibliography;* and the modern ones, and new editions in Ersch's *Handbuch der Deutschen Litteratur*, and the Leipsic *Catalogues*, published annually. Thäer of Moeglin is decidedly the highest in repute as an author, and Sickler's *Deutsche Landwirthschaft*, a voluminous work, will give a general idea of every part of German husbandry

1578. *Heresbachius*, *Conradus*, counsellor to the Duke of Cleve; was born in 1508, died in 1576. He wrote various theological works, besides his *Rei Rusticæ*, libri iv., which was published in 1570, and his *Legum rusticarum et Operarum per singulos Menses digestæ*, in 1595. The former was translated by Barnaby Googe, of Lincolnshire, with the following title:—
Foure Bookes of Husbandrie, containing the whole Art and Trade of Husbandrie, Gardening, Graffing, and Planting, with the Antiquitie and Commendation thereof. Newly Englished and increased by Barnebe Googe, Esquire. At London, 4to. 1578. Leaves 194, besides the Dedication, Epistle and Table at the beginning; and Olde English Rules in Verse for purchasing Lande, at the end.

His authorities extend from the Bible and doctors of the church, through the Greek and Roman writers, Homer, Cato, &c., to the moderns as low as Ruellius, Fuchsius, Matthiolus, Cardanus, and Tragus. He subjoins a list of his friends and others who assisted him. S. Nich. Malbec, M. Cap. Byngham, M. John Somer, M. Nicas. Yetzwert, M. Fitzherbert, M. Willi. Lambert, M. Tusser, M. Tho. Whetenhall, M. Ri. Deering, M. Hen. Brookhu l M. Franklin, H. King, Richard Andrews, Henry Denys, William Pratte, John Hatche, Philip Partridge, Kenworth Daforth.

The work is in dialogue. The persons are Cono, a gentleman retired into the country; Rego, a courtier; Metella, wife of Cono; and Hermes, a servant.

1591. *Colerus*, *J.*
1. Calendarium œconomicum et perpetuum. Wittebergæ.
2. Economiæ Pars prima; qua tractatur quemadmodum bonus Œconomus famulos suos regere debet et Bona sua augere potest per veras honestas Artes, et utilia Compendia circa Res domesticas, Agriculturum, Piscatum, Aucupia, Venationes et Vinearum Culturum. Wittebergæ, 4to. 1593.

1829. *Elsner, J. G.*
Uebrsicht der Europ veredelten Schafzucht. Prague 2 theile, 8vo.

Subsect. 3. *Bibliography of Italian Agriculture.*

7902. *A number of Italian agricultural works* have been published; such as they are, perhaps more of them are original than of the books of the French or Germans, because the culture of other parts of Europe is but ill adapted for Italy. The vine, olive, mulberry, orange, and the irrigation of lands, have a good deal occupied the Italian writers. Ré may be reckoned their general and popular author, and his *Nuovi Elementi*, 4 vols. 8vo, 1815, and *Annali del Agricultura*, &c. 22 vols. 8vo to 1814, will give a good idea of Italian husbandry and gardening, the two arts in that country being for the most part combined.

1471. *Crescentius, Crescenzio*, or *De Crescentiis*, was born at Bologna about 1233; died 1320.

1. Opus Ruralium Commodorum, sive de Agricultura, libri xii. Augsburg, fol.

Osservazioni ed Esperienze agrarie. Turin. 8vo.

Subsect. 4. *Bibliography of the Agriculture of the other Countries of Europe.*

7903. *Germany and Britain* are the only countries in Europe in which it answers to print agricultural books for the sake of the indigenous readers. In Britain, education is so general among the middling and lower orders, that reading among them is a necessary convenience of life; in Germany, education and reading are equally general and essential: and consequently, in either of these two countries a book will pay by its sale within the country. But this is not the case in any other European country. In France the mass of the people do not read, but books printed there pay, because they are in a language more universal than any other, and perfectly understood by all men of education in Europe. Italian books pay, because they are enquired for by the agriculturists of the south of France, all Spain, and in part of Spanish America.

7904. *Spanish and Portuguese books on agriculture* are in much too limited a demand for production. The earliest Spanish author is Herrera, in 1596; and there are scarcely half a dozen since. After the most particular researches of a book agent at Madrid, he was only able to send a list of translations, and the transactions of the Economical Society of Madrid; who have also published Herrera's work with notes within the present century. In 1815, a professor at Madrid published *Lecciones de Agricultura explicadas en el Jarden Botanico*, 2 tomes 4to. An anonymous author, *Disertaciones sobre varios Piantos Agronomicos*, 1 tom. 4to. Of Portuguese books we could hear of none.

7905. *Of Flemish and Dutch books on agriculture* there are scarcely any. These languages are very limited, and every reader in Holland or Flanders understands French or German. Many works have been published in the Low Countries in Latin and French, but these cannot be considered indigenous. The few Dutch works on culture belong almost all to gardening (*Encyc. of Gar.* 7695.). The result of our correspondence with Amsterdam is a *Nieuwe Naamlijst van Boeken, &c.*, from which we see little worth taking. There are several translations from British works on culture, and French veterinary books, and the following seem the latest on husbandry.

Magazijn van Vaderlandschen Landbouw, door J. Kops, Commissaris tot den Landbouw. 6 deelen kompleet met register.

Aanwijzing ter verbetering van de Akkerbouw en Landhuishoukunde, in de Nederlanden, door Professor A. Bruchausen. 2 deelen.

De Boeren Goudmijn, of kunst, om van verschillende soorten van Landerijen, het meeste nut te trekken, meer Vee te kunnen houden, en andere Wetenswaardigheden tot den Landbouw, door J. F. Serrurier en J. Kops, met platen.

Lichtervelde, J. F. de, Member of the Royal Society of Agriculture and Botany of the city of Ghent: La Bèche, ou la Mine d'Or de la Flandre Orientale. Brussels. 8vo.

Cale's, M. V. M., M.D. at Liege: Instructions sur le Parcage des Moutons; ou, Moyen d'engraisser les Campagnes en faisant coucher les Moutons dans les Champs. Liège. Pamph. 8vo.

7906. *Of Swedish and Danish books on agriculture*, there are necessarily very few; these languages being of very limited use, and the mass of the people too poor to be able to afford to read about ordinary matters, or what they consider as already well known to them. The time such a people give to reading will be devoted to religious subjects, heroic and romantic poetry, or history. The universities of Stockholm and Upsal, every one knows, have produced some useful naturalists: some of these have

written tracts on agricultural improvements, especially on planting fruit-trees (*Frukt-Träd.*) and cultivating culinary vegetables (*Köchs-och Krydd*). A few of such works we have enumerated in our Bibliography of Gardening (7696.), but we can scarcely find any fit to be inserted here as agricultural. *The Natural and Chemical Elements of Agriculture*, by Count Gustavus Adolphus Gyllenborg, a learned Swedish statesman, were translated by John Mills in 1770, and may be considered as the prototype of Davy's *Agricultural Chemistry*. There are several treatises on the culture of the potatoe in the *Swedish Transactions;* also on tobacco, on the management of sandy soils, on the cultivation of the Cerealia; and on the hop and plants for fodder.

1825. *Anon.*: Kongl. Svenska Landtbrüks Academiens Annala. Year 9. Part I. 8vo.

1826. *Winstrup*, M., machinist to the king at Fredericksberg, near Copenhagen: Afbildwinger af de bedste og nyeste Agerdyrkningsredskaber, &c. Copenhagen. 4to.

7907. *Of Polish and Russian books on agriculture*, it may be easily conceived, there are very few. Some translations from French works were made into the Polish language under Fred. Augustus II.; but few or none since that time, the German or French being universally understood by the reading class. Books of agriculture in the Russian language could be of little use. The only things printed in that way there are in the transactions of the Economical Society of St. Petersburgh, by foreigners resident there, and in Latin or German. The best informed Russian nobles read French or German like the Poles. There is an agricultural society at Warsaw, which occasionally prints its transactions; and another has lately been established at Moscow, which publishes an agricultural newspaper. (*See Gard. Mag.* vols. i. and ii.)

1825. *Parlof*, M.: Zemliédelteheskaïa Chimia. Moscow. 8vo.

1825. *Apraxin*, M., a nobleman possessing one of the largest houses in Moscow: Zemliédièltchesky Journal, &c. Moscow. 8vo.

1825. *Anon:* Avantages résultant de l'Introduction de la Culture variée des Terres. Warsaw. 8vo.

Subsect. 5. *Agricultural Bibliography of North America.*

7908. *There are a few American books of agriculture*, and republications there of most of our best works on the subject. Dean's *New England Farmer's Dictionary* and Dwight's *Travels* may be considered as giving an idea of the husbandry of that part of the country, and Roughley's *Jamaica Planter* of the agriculture of the West India Islands. A number of interesting papers on the subject will be found in the transactions of the American, New York, Philadelphia, and other societies.

1744. *Bartram, John*, M.D., Philadelphia.
On the Salt Marsh Musell: On Oyster Banks and the Fresh Water Musell of Pennsylvania. (*Phil. Trans. Abr.* ix. p. 70.)

1754. *Flemyng*, or *Fleming, Malcolm*, M.D., of Brigg.
A Proposal in order to demonstrate the Progress of the Distemper among Horned Cattle: supported by Facts. York. 8vo.

1755. *Belgrove, William.*
A Treatise upon Husbandry and Planting. Boston, New England. 4to.

1764. *Elliot.*
Essays upon the Husbandry in New England. Lond. 4to.

1779. *Carver, Jonathan*, Esq., born in America in 1732; died at London, 1780, in great poverty.
A Treatise on the Culture of the Tobacco Plant, with the Manner in which it is usually cured, adapted to Northern Climates, and designed for the Use of Landholders of Great Britain, with two Plates of the Plant and its Flowers. Lond. 8vo.

1785—1826. *Anon.*
Memoirs of the Philadelphia Society for promoting Agriculture; containing Communications on various Subjects in Husbandry and Rural Affairs. Philadelphia. 8vo.

1789. *Antill*, Hon. *Edward*, Esq., of New Jersey.
1. An Essay on the Cultivation of the Vine, and the making and preserving of Wine, suited to the different Climates of North America. (*Americ. Trans.* i. 181.)
2. The Method of curing Figs; and Observations on the raising and dressing of Hemp. (*Ib.* i. 266.)

1789. *Bartram, Moses.*
Observations on the Native Silk Worms of North America. (*Americ. Trans.* i. 294.)

1789. *Carter, Landon*, of Sabine Hall, Virginia.
Observations concerning the Fly-weevil that destroys the Wheat; with some useful Discoveries and Conclusions. (*Trans. Americ. Soc.* i. 274.)

1790. *Dean*, Dr.
New England Farmer's Dictionary.

1796. *Higgins, Jesse*, of Delaware.
A Method of draining Ponds in Level Grounds. (*Trans. Amer. Soc.* vol. iii. p. 325.)

179 . *Greenway*, Dr. *James*, of Dinwiddie county, in Virginia.
Of the Beneficial Effects of the Cássia Chamæcrísta in recruiting worn-out Lands, and enriching such as are naturally Poor. (*Trans. Amer. Soc.* iii. p. 226.)

1800. *Destère.*
La Science du Cultivateur American: Ouvrage destiné aux Colons et aux Commerçans. 8vo.

1801. *Bordley, J. B.*
Essays and Notes on Husbandry and Rural Affairs. Philadelphia. 8vo.

1812. *Barton, Benjamin Smith*, M.D., professor of natural history and botany in the university of Philadelphia.
On the Native Country of the Solànum tuberòsum, or Potato. (*Nic. Jour.* xxxi. 290.)

1821—1826. *Anon.*
Memoirs of the Board of Agriculture of the State of New York. Albany. 8vo. 5 vols. to 1826.

1822. *Fessenden, Thomas G.*
The New England Farmer; containing Essays, original and selected, relating to Agriculture and Domestic Economy, with Engravings and the Prices of Country Produces. Boston. 5 vols. 4to to 1827.

1823. *Roughley, Thomas*, nearly twenty years a sugar planter in Jamaica.
The Jamaica Planter's Guide; or, a System for planting and managing a Sugar Estate or other Plantations in that Island, and throughout the British West Indies in general. Illustrated with interesting Anecdotes. 8vo.

1825. *Anon.*
The Ploughboy. Vol. ii. 4to.

1825. *Anon.*
Massachussetts Agricultural Repository and Journal. 7 vols. 4to.

1828. *Anon.*
New York Farmer and Horticultural Repository. New York. 4to.

1829. *Lathrop, E. L.*, Esq.
The Farmer's Library; a Series of Essays and Papers for the Promotion of the Study of Agriculture. (Windsor, U. S. 12mo.

Chap. V.

Professional Police and Public Laws relative to Agriculturists and Agriculture.

7909. *By professional police* we mean those associations which agriculturists have formed, at different times and in different manners, for mutual benefit or instruction; and also those institutions for the same purpose established by the legislature, or of such a nature as to be considered public or national. By laws we allude to those special legislative enactments which affect more particularly agriculture. These are so numerous that we must refer the reader to his lawyer or law dictionary.

7910. *There are few or no agricultural lodges* of the nature of those of masonry or gardening. In Scotland it would appear something of this kind had existed among ploughmen at one time, as the passwords and initiatory ceremonies are talked of in some of the counties by old men. In Forfar, Kincardine, Banff,

&c. it is not uncommon for ploughmen, as well as various descriptions of operatives, to belong to gardeners' lodges. In the southern districts where sheep farming is followed there are some shepherds' societies, for mutual interchange of experience, and aid in case of losses of such sheep as are the shepherd's perquisite. There are some ploughmen's clubs in different places, and various associations among them of the nature of benefit societies; but these do not come under the description of professional.

7911. *Agricultural societies* for interchange of knowledge are of modern date, but they have increased rapidly since 1794: the number at present or lately existing in the British isles is at least equal to the number of the counties. Societies of this description are either general, as the Board of Agriculture and Society of Arts; national, as the Highland Society and Dublin Institution; particular, as the Bath and West of England Society; provincial, as county societies; or parochial, as being limited to a few individuals within one parish. Of this kind are farmers' clubs, ploughing societies, &c. In regard to the end in view, these societies either embrace the arts in general; the rural arts in general; some branch of the rural art, as agriculture; or some department in that branch, as live stock, sheep, wool, &c.

7912. *All these societies hold meetings* at stated periods. Most of them offer premiums for particular objects, — specimens of vegetable or animal culture or produce, agricultural operations, moral and professional merits as servants, &c.; some of them form a library and museum of models or full-sized implements; a few publish transactions; and one or two, as the Dublin Society, send out itinerant ploughmen and agricultural mechanics to instruct practical farmers. These societies are almost wholly supported, and the funds for premiums raised, by the subscriptions of members, and by voluntary donations, legacies, &c.; but some, as the Board of Agriculture and the Dublin Society, have received assistance from government.

7913. *Of English agricultural societies* the oldest is the Society of Arts, founded in 1754 oy Lord Folkstone, Lord Romney, Dr. Hales, and Shepley. They have published many volumes of transactions, awarded immense sums in premiums, and on the whole done much good. (See *Rees's Cyc.* art. *Society*.)

7914. *The Bath and West of England Society* was founded in 1777, for purposes similar to those of the London Society of Arts. They have published some valuable volumes of transactions, and distributed various rewards, &c. (*Rees's Cyc. &c.*)

7915. *The Board of Agriculture* was founded, under the authority of government, in 1793. Much was expected from this Board; but, except the publication of the county reports, and the general attention which it called to agriculture, it may well be asked what advantages arose from it. Their *Communications*, in several quarto volumes, contain fewer valuable papers, in proportion to their total number, than the publications of either the London Society of Arts or the Bath Society. In short it has been ably shown, in *The Farmer's Magazine* and the article *Agriculture* in the supplement to the *Encyc. Brit.*, that the Board never directed its efforts in a manner suitable to its powers and consequence; and that, instead of discussing modes of culture, its attention ought to have been directed to the removal of the political obstacles to agriculture, and to the eliciting of agricultural talent by honorary rewards, &c. No idea is more erroneous than that of such a Board, or any other, doing much good by a national "experimental farm." The government withdrew its support from this Board about 1816; and there being no longer funds for a handsome salary for a secretary, it soon after fell to pieces, and is now only remembered, at least by us, for its lofty pretensions and its worse than inutility.

7916. *Of Welsh societies* there are only two or three, of inferior note, which have been already noticed in the topography of the country.

7917. *Of Scotch societies* the principal now existing are the Highland Society and the Dalkeith Farming Society.

7918. *The Highland Society* of Scotland was established in 1715, to enquire into the state of the highlands, to consider the means of their improvement and the preservation of their language; it is chiefly supported by the subscriptions of its members, at a guinea each a year, and soon after its establishment it had a grant of 3000*l.* from government. It has published 7 vols. of prize essays and papers, and now extends its prizes to all the low counties of Scotland. (*Farm. Mag.* vol. 16. p. 316.)

7919. *Of Irish societies* the principal are the Dublin Society and the Cork Institution.

7920. *The Dublin Society* was established in 1731, and incorporated in 1749. Arthur Young observes, that it was the parent of all the similar societies now existing in Europe; but the Edinburgh Agricultural Society, as we have seen (775. and 801.), was established nearly ten years before. The Dublin Society, in its present advanced state, is one of the most complete establishments of the kind. (*Rees's Cyc.* art. *Dublin*.)

7921. *The Farming Society of Ireland* was established under the patronage of the Dublin Society, in 1800. The object is to improve the agriculture and live stock of the kingdom. (*Archer's Dublin*, 160.)

7922. *The Cork Institution*, for applying science to the common purposes of life, originated in private subscriptions, about the beginning of the present century. It has since been incorporated, and has received the assistance of government. It possesses a house and a large botanic garden, and under its auspices are delivered lectures on chemistry, botany, agriculture, &c.; it is not, however, in a flourishing state, and has never been of much use.

7923. *The principal county societies* in the three kingdoms have been noticed in the topography of agriculture: many of them were established several years before the Board of Agriculture.

7924. *The only other institutions for the improvement of agriculturists and agriculture* are public professorships. Of these there is one in the university of Edinburgh, established in 1795; one in Dublin, supported by the Dublin Society; one in Cork; and one is destined to be established at some future period in Oxford, agreeably to the will and donation of Dr. Sibthorpe (806. and 7789.), professor of botany there.

BOOK II.

THE FUTURE PROGRESS OF AGRICULTURE IN BRITAIN.

7925. *The improvement of agriculture*, like that of every art, manufacture, or commodity, necessarily depends on demand and production: a powerful or effectual demand will ensure produce, and excellent produce will, to a certain extent, create demand. A general nicety of taste in coach or saddle horses will call forth a superior description of these animals, and superior animals will tempt purchasers; if the inhabitants of any district who live chiefly on barley or oats indicate a preference for wheat, and a willingness to pay for that grain, wheat will be produced, and so on. Again, as the object of every individual who engages in art or trade is to acquire gain, the advancement of an art will depend mainly on the profits it affords; an art or occupation which affords less than the average profits on capital will only be followed by such as, from habit or other reasons, cannot apply themselves to any thing better, but extra-profits

will command both capital and skill. From these considerations it is obvious, that the improvement of agriculture depends on the profits on capital employed in it, on the taste of those who purchase its products, and on the knowledge of those who are engaged in agriculture as a profession. The first subject would lead us further into political economy than would be of much use in a work of this kind, and therefore we shall limit ourselves to a few remarks on the other topics.

Chap. I.

Improvement of Agriculture, by refining the Taste of the Purchasers of its Products, and increasing the Knowledge of Agricultural Patrons.

7926. *The desire of being comfortable* is the first step towards improvement; but before any thing can be desired, we must know what it is. Men, when they know of nothing better, rest satisfied with what they have; and therefore one of the main sources of improving the taste both of those who purchase agricultural produce from necessity, and of those patrons of agriculture who purchase from the conjoined impulses of necessity and choice, is the increase of knowledge. However paradoxical it may seem, discontent is the parent of all improvement, as certainly as the acorn is the germ of the future oak, or the time present that of all future times. The grand achievement of the present age, an eminent writer observes (*Examiner*, Jan. 9. 1831.), "is the diffusion of superficial knowledge;" and on this diffusion, superficial though it may be, the progress of agriculture and of every other art depends far more than on any thing else.

7927. *In Scotland and Ireland* could a taste for wheaten bread and butcher's meat be introduced generally among the operative classes, the advantages to agriculture would be immense. Could the same persons be taught to desire a greater degree of cleanliness, light, and warmth in their cottages; a greater variety of potherbs, salads, fruits, and flowers in their gardens; and handsome dresses for their wives and daughters, how great the general benefit! Much may be done to bring about this change, by the opulent who are willing to reside on their estates and to take a little trouble. Building good and comfortable cottages; attaching proper gardens stocked with trees and plants from the demesne garden; and offering little premiums, or marks of distinction for keeping them in the nicest order, and for decently clothed well-bred children, would soon have a sensible effect. Attending to that kind of education which consists in teaching infants civility and politeness, with mutual respect and restraint as occasion requires; and instructing grown children how to work at almost every thing likely to come in their way, as done in the improved German and Swiss schools, would, independently of reading and writing, do a great deal to soften and humanise the peasant mind. Encouragement should be given to save money for unforeseen wants, or against old age; and the certain effects pointed out of early marriages, followed by a numerous offspring. These and a variety of similar means would be productive of some change of taste in the operative part of rural society.

7928. *The introduction of manufacturing establishments*, wherever it could be properly done, would contribute to the same effect: those who work at manufactures, and even common mechanics, generally live better, and are better clothed and lodged, than the common country labourer; therefore their example would be of use in introducing a salutary degree of luxury. "The endeavouring to impress on the minds of the lower classes the propriety of being contented with the simplest and cheapest fare, is extremely pernicious to the best interests of mankind. Encomiums ought not to be bestowed on those who are contented with mere necessaries: on the contrary, such indifference ought to be held disgraceful. A taste for the comforts, the enjoyments, and even the luxuries of life, should be as widely diffused as possible, and, if practicable, interwoven with the national character and prejudices. This, as it appears to us, is the best mode of attempting the amelioration of the condition of the lower classes. Luxuries, and if you will have it so, even wasteful habits, are incomparably better than that cold, sluggish apathy, which would content itself with what can barely continue mere animal existence." Mr. Peel observed in the House of Commons that "he thought it one of the first duties of the legislature, to do all in its power to excite a taste in the humbler classes of society for those comforts and those enjoyments — those luxuries, he might add — of civilised society, the desire for which, and the habitual possession of which, would form the best guarantee for their good conduct, and the best guarantee that the higher classes could have for the possession of their property and their power, as at present enjoyed." (*Manual of Cottage Gardening, Husbandry, and Architecture, &c.*) "In those countries," Ricardo judiciously observes, "where the labouring classes have the fewest wants, and are contented with the cheapest food, the people are exposed to the greatest vicissitudes and miseries: they have no place of refuge from calamity; they cannot seek safety in a lower station; they are already so low that they can fall no lower. On any deficiency of the chief article of their subsistence, there are few substitutes of which they can avail themselves, and dearth to them is attended with almost all the evils of famine." (*Sup. Encyc. Brit.* art. *Corn Laws.*) Such is the case in Ireland, where, amidst the germs of the greatest riches and luxury, the inhabitants are contented to live on less than any other people in the world.

7929. *The taste of the superior patrons* of agriculture is to be improved by visiting the best cultivated districts, reading agricultural works, attending agricultural societies, and, above all, by cultivating a farm, and establishing on it a systematic order and regularity in every detail. Let such observe the hedges, gates, verges of fields, and the beautiful rows of turnips, of Berwickshire or Northumberland; the correctly drilled beans of East Lothian; and the live stock of Leicestershire. But few are the proprietors of lands who either employ a proper bailiff or demesne steward; and of those who do, how few who do not limit and fetter them in their operations, or else neglect them and leave them to sink into that supine state in which the uppermost wish is to enjoy the comforts of the situation with the least possible degree of exertion! Some proprietors desire to have their home farm managed with a view to profit, as the cheapest way of getting hay, straw, mutton, &c.; these are sordid patrons. A home farm ought to combine an elegant orderly style of management, high-kept horses, harness, implements, &c., well clothed servants, and every thing in a superior style to what is seen on common farms. Particular attention ought to be paid to the buildings, which should combine architectural design, fitness, strength, and elegance; the roads ought to be like approaches to a mansion; the hedges like those of gardens; the green verges round the fields kept mown like lawns or grass walks, and the ditches, bridges, and gates in corresponding neatness; the finest trees ought to be encouraged in proper situations, and correctly pruned; substantial watering places formed and kept supplied; every operation on plants, or the ground, performed in a garden-like manner; and no individual of any species of stock kept, of which a drawing might not be taken and preserved as a beauty. Even the dress and deportment of the servants on such a farm ought to harmonise with the rich culture, orderly display, and high keeping of the whole.

Chap. II.

Improvement of Agriculture, by the better Education of those who are engaged in it as a Profession.

7930. *By education* is generally understood that portion of knowledge which is obtained at schools; but in a more extended sense (as Mills observes), it may be defined the means which are employed to render man competent for pursuing the part which he undertakes to perform in life, with increased satisfaction to himself and others. Education may thus be considered as extending to every thing which operates on the body or mind, from the earliest periods of our existence to the final extinction of life. It is unnecessary here to embrace the subject in its full extent; but we shall offer some remarks on the education of practical men in general, on the professional education of an agriculturist, and on the general conduct and economy of his life.

Sect. I. *Degree of Knowledge which may be attained by Practical Men, and general Powers of the human Mind as to Attainments.*

7931. *The kind and degree of education* that we think ought to be given to every human being in this and in every country, and in every state of civilisation, may be thus defined: — All the knowledge and accomplishments that a child's body or mind, and the state of knowledge and the art of teaching at the time, will admit, previously to the age of puberty; giving preference to those branches of knowledge considered the most useful, and those accomplishments and manners considered the most humanising, by the wise and good of the age. It seems unreasonable to employ any child in aiding to procure the means of its subsistence, or that of its parents, before the age of puberty. Previously to that age, by means of infant schools, and of the adoption of the various improvements that have been recently made in modes of teaching, all that is worth knowing may be taught more effectually than common reading, writing, and arithmetic are, during the same time, by the common methods. Man, so trained and instructed, and living under an enlightened government, will become as different an animal from what he is at present, even in Britain, as the most enlightened modern moralist and philosopher of Europe is from an African savage. " It is not necessary," says Lequinio, writing in 1792, " to render an agricultural labourer a learned man;" but I am well assured, from my own experience, that the knowledge of every thing useful, and of much that is agreeable, both in knowledge and manners, is perfectly consistent with a life of labour in the fields. But hitherto the education of the labouring classes in the country has proved rather an obstacle to the developement of reason than otherwise. Eight or ten years are employed in filling the head of a child with chimeras and prejudices, which twenty years of study will scarcely succeed in entirely rooting out. It remains for national philosophical institutions to destroy this national evil; and we shall one day have under the thatched cottage of the country hamlet thinking men endowed with reason, and capable at once of taking a part in the political and moral affairs of their country, and holding the plough or guiding the cart on their own farm. " Il faut," says this admirable writer, " que les premières leçons soient l'apprentissage des droits de l'homme, et qu'ils soient enseignés sans aucun mélange des perfides principes du fanatisme et des fruits barbares des gothiques préjugés, de quelqu' espèce que ce puisse être. Les notions de la raison et du bon sens tombent sous tous les intellects. Les droits de l'homme intéressent tous les individus, et l'esprit et le cœur seront bientôt d'accord pour s'en faire une science impérissable; gravés une fois, je le répète, ils ne s'effaceront jamais; ils se conçoivent avec aisance, et ils se fixeront bien plus solidement que ces antiques assertions données sur la foi d'autrui, et transmises à travers les ténèbres des siècles les plus obscurs; assertions ridicules, et qui, pour la plupart, n'ont seulement pas en leur la simple vraisemblance; ils se fixeront, sur-tout, parcequ'ils seront aisément et avantageusement comparés à toutes ces faussetés miraculeuses et folles dont le néant alors éclatera pour tous, et parcequ'ils seront encore plus avantageusement mis en parallèle avec ces mystères absurdes que l'homme ne pouvait admettre qu'en rejetant l'évidence, et en se dépouillant totalement de son intelligence et de sa raison. C'est par ce simple enseignement que s'élèvera tout d'un coup dans nos campagnes une espèce raisonnante et libre. Sortie, par cette création morale, du cahos ténébreux, et de l'existence léthargique où, depuis le commencement des siècles, elle croupissait sous le joug de tous les impudens habiles qui se permettaient de la dominer, nous la verrons une race nouvelle, intelligente et hardie, laisser un espace incommensurable entr'elle et les générations qui l'ont précédée." (*Les Préjugés détruits, par J. M. Lequinio.* Paris, 1792. *Parochial Institutions; or, an Outline of a Plan for a National Education Establishment, &c.:* and *Des Etablissemens pour l'Education Publique en Bavière, dans le Wurtemberg, et dans le Pays de Bade.*)

7932. *A high and equal degree of education* has some powerful advocates in North America, and, it is thought by many, will, at no distant period, be adopted in several of the states. The *New York Daily Sentinel* and the *Working Man's Advocate* are two of several newspapers which support what are called ' working men's measures." Among these the first and most important is a " republican education, free for all, equal for all, and at the expense of all; conducted under the guardianship of the state, at the expense of the state; embracing every branch of useful instruction, moral, intellectual, and operative, and extending to the entire protection, maintenance, and guidance of children and youth, male and female, without distinction of class, sect, or party, or reference to any of the arbitrary distinctions of the existing state of society." (*Six Essays on Public Education*, New York, 1830; *Cooper's Lectures on Political Economy*, as quoted in the *Spectator*, Dec. 4. 1830: and *Gard. Mag.* vol. vii.)

7933. *This high and equal degree of education* we consider to be as much the birthright of a child in a community where there is a high degree of civilisation, as food and clothes are its birthright in the rudest state of society; because, without it, a man or woman is ushered into society without a fair chance of being able to procure those means of subsistence and of happiness which belong to human nature under the given degree of civilisation; in short, without a fair chance of making the most of life. To introduce an ignorant youth into a highly civilised country, under the supposition that he could obtain the requisite degree of prosperity and happiness, would be more absurd than to turn an educated child into a country of savages. This is one view of the subject, and it is a view on which all who can afford the expense act with respect to their own children. If we regard the subject in the light of humanity, and the sympathy of one part of society with another, this principle will equally dictate the duty of bestowing, as far as practicable, that good on others which we feel to be a good in ourselves, and which we are convinced would add to the general happiness. Viewed as a matter of public policy, and considering that the grand object of every government ought to be, with reference to its subjects, their happiness and prosperity; and, with reference to other governments, its own stability; reason dictates the use of the most important means for gaining these ends; and that it would be prudent, no less than just, in government so to legislate, as that every individual subject should have the degree of education above defined. Let none,

therefore, exist in society who have not their minds matured by the care and culture of public teachers, as their bodies are by the nourishment and clothing of their parents. The religious and humane owe this to the poor as a part of human nature; the benevolent, as sympathising with the miseries they suffer; the enlightened, in order to raise them to their rank in the scale of creation; the rich, to give them a greater chance of possessing property, in order that they may respect the property of others; the prudent, that they also may become prudent; and government, that they may not be made the tools of faction, foreign or domestic. (*Parochial Institutions, &c.*)

7934. *Knowledge gives power;* and if one part of society has the degree of cultivation desired, and the other has it not, it is evident that there can be very little sympathy between them. The experience of ages shows the continual tendency of the powerful in wealth or in skill to oppress the weak; and the continual tendency of the weak to re-act by personal force, by cunning, or by numbers, on the strong. Materials so discordant can never form the basis of a sound, healthy, and permanent state of society: the poor and ignorant becoming, under such circumstances, little better than slaves to the rich and enlightened, regard them as their enemies, and often finding them to be such, must and will rebel; and the result is, sooner or later, a subversion of society. It would evidently contribute to the stability and harmony of society to moderate this action and re-action, by a more equal distribution of power; and, as knowledge gives power, the most obvious and effectual way of attaining the end proposed is, by diffusing such a high and equal degree of school education as we have defined. It must be evident, we think, that the state of society which this degree of education will sooner or later produce, will include in it every amelioration and happiness of which human nature, under any given circumstances, is susceptible. (*Ibid.*)

7935. *The knowledge of languages, history, geography, arts, sciences, and literature*, which an agriculturist, whether a ploughman, shepherd, bailiff, steward, or rent-paying farmer, daily occupied with his profession, may acquire by his own exertions, provided he begins at the earliest moment, say at fifteen years of age, and continues to employ his leisure hours in reading till he is twenty or twenty-five, is by no means inconsiderable; not that he can or need become learned; but, if desirous, he may become generally intelligent, render himself fit, as far as conversation is concerned, for good society, prove instructive and entertaining to others by his conversation, and provide a reserve fund of enjoyment, by laying up a store of ideas for reflection in misfortune, disease, or old age.

7936. *The utility of knowledge* to that part of mankind who are doomed to a life of mechanical labour, or rather who suffer themselves to be doomed to it, has been questioned; it is said to render them dissatisfied with their condition, to produce various other evils, and at all events in no way to add to their happiness or the good of society. To a man whose business in life is the mere mechanical performance of operations which any other animal might perform if furnished with hands, education is doubtless less necessary than to a man whose business is to direct the operations of others; but it does not follow, that though less necessary, it may not be highly useful: if, for example, it renders him dissatisfied with his condition, it will, at the same time, be more likely than any thing else to lead him to some proper mode of improving it; or if almost unimprovable, education certainly will be more likely than a state of ignorance to teach patience and submission, by enabling him to reflect on the folly of grieving at what is inevitable, and the consequences of committing what is unjust or criminal to relieve himself. "The low Irish," Marshal remarks, "are sufficiently dissatisfied with their condition; those who know how to alleviate it by emigration, go to Britain or America; those who know nothing, stay at home, commit acts of violence, and are hanged."

7937. *To decide as to the utility of knowledge to the operative parts of society* would perhaps require a previous decision of the question, "What constitutes happiness?" The general answer is, the exercise of all our faculties of body and mind: every one who has lived thirty or forty years in the world, knows that there is no such thing as absolute happiness: the Prince de Ligne, a man of great natural parts, with every advantage of person, birth, and wealth, and in favour at all the courts of Europe; fond alike of war, literature, gallantry, and agriculture, and who lived to be upwards of 90 years of age, has left on record that he was only perfectly happy two or three times in his life, and only for a few minutes each time. Forsyth (*Principles of Moral Science*, vol. i. chap. 1.) says perfect happiness is a thing not to be thought of; and that all that men and women can do in order to make the most of their existence, is to occupy themselves and make progress in whatever they engage in: progress in enjoyment, or approximation to happiness, is therefore the object to have in view.

7938. *The utility of knowledge to every human being* is consequently, in our opinion, unquestionable, on the mere principle of adding to enjoyment; nor do we believe that there is more danger from excess of knowledge in any particular class of society, high or low, than there is from excess in their eating or drinking. A number of men possessed of property or power by inheritance, favour, or chance, who are very conscious that they never could have acquired those advantages by the common competition of talent and industry, and who are in fact wrapt up in selfishness, are naturally jealous of the progress of knowledge; their secret maxim is to keep down the lower orders, and to impress on their minds only the duties of loyalty, religion, and, as Vancouver adds, hard work. This monopoly of power and knowledge, however, cannot be maintained for ever, and in every country it is found rapidly yielding to the general progress of society. It is only those who have to dread this progress that fear the diffusion of education and liberal principles.

7939. *Education in all countries*, in as far as it has been carried, has had the effect of rendering the poor content. Compare the poor of Sweden and Germany with those of England. The uneducated are prone to consider wealth and happiness as synonymous, a delusion which knowledge quickly dispels; philosophy teaches its fallacy, and history exemplifies it. For our own part, we can see nothing in education but increased security to the rich, and increased happiness to the poor. One of the great evils which at present afflict society in this country is over-production; not only of manufactured goods, but also of human beings. We are apt to believe that even this calamity might be remedied, if every labourer in the country considered a high and equal degree of education as a necessary of life, and no more to be dispensed with in a child than food or clothing; as in that case he would not think of marrying till he could bestow this degree of education on his children. If any labourer acted otherwise, he would bring himself into disgrace among his own class; he would suffer a loss of reputation for good sense and good taste; and his wife and himself would no longer be able to associate with their neighbours, either from the extraordinary exertions which they must make, in order to educate their children up to the general level, or in consequence of not being able to do so, and having it done for them by the parish as paupers. The dread of the reflections and neglect of the children when they arrived at maturity, and found that they were indebted to the parish more than to their parents for their education, and that they had, in fact, to pay the parish for this education themselves, would also act as a powerful inducement to prudential conduct. Besides, when parents themselves have once enjoyed the degree of education defined, they will consider it cruel and unjust not to bestow the same degree of education on their children. This is, in fact, the feeling of all educated parents; and one great object that we have in view is to communicate the same feeling to the very lowest member of society. We are justified in concluding that universal education would do so, by what actually takes place at present among the educated classes. (*Parochial Institutions, &c.*; and *The Objects to be obtained by Reform in Parliament, &c.*)

7940. *The terms knowledge and ignorance are entirely relative:* the knowledge of a modern chemist's porter would have subjected him to be hanged and burned in the days of the first popes; and any bricklayer's labourer of the present day, who reads the London newspapers, has more correct ideas of the principles of political economy than nine tenths of the nobility in Russia and Spain. It is impossible to set limits to the knowledge which may be obtained by those who are destined even to the most severe and constant labour; the intelligence of the miners in Scotland and Sweden may be referred to as proofs

The miners at Leadhills have a regular library and reading society; and the works they make choice of are not only histories, voyages, travels, &c. but even works of taste, such as the British classics, and best novels and romances. The degree to which knowledge will prevail among any class of labouring men will depend jointly on their own ambition, on the demand for knowledge, or the reputation in which it is held, and on the opportunities of acquiring it. A dull, stupid person, with little native activity, will never desire to know more than what enables him to supply the ordinary wants of life; but where the workmen of any art are required to have technical knowledge of any particular kind, they will be found invariably to possess it. Thus carpenters and masons require some knowledge of the mechanical principles of architecture, and working engineers of the strength of materials; and these kinds of knowledge are acquired by them without an hour's interruption of their daily labour: on the contrary, the habit of evening study renders them more steady, sober, and industrious than other workmen: than bricklayers and paperhangers, for example, whose employments require much less intellectual skill. If every cook-maid, before she could obtain a first-rate place, were required to be able to read *Apicius* in the original tongue, there would be no want of learned cooks; and if no bailiff could obtain a first-rate situation who had not written a thesis in Greek, or who had not made the tour of Europe, there would soon be found abundance of bailiffs so qualified. A Caledonian, when he comes to the low country, soon acquires the English tongue, and, if he has been taught Latin, thus knows three languages. The servants at the inns on some parts of the Continent, frequented by different nations, often acquire a moderate knowledge of three or four languages: a late custom-house officer on the island of Cronstadt spoke and wrote ten languages; and the bar-maid at the hotel de Londres, at which we lodged in Moscow, in 1814, could make herself intelligible in Swedish, Russian, Polish, German, French, Italian, and English.

7941. *The certain way of obtaining any thing* is to be impressed with the necessity of possessing it, either to avoid the evil of being without it; or to satisfy the desires of others as to ourselves; or our own desires. There is scarcely any thing a rational man can desire that he may not obtain, by maintaining on his mind a powerful impression of the necessity of obtaining it; pursuing the means of attainment with unceasing perseverance, and keeping alive that enthusiasm and ardour which always accompany powerful desires. All may not acquire, by the same degree of labour, the same degree of eminence; but any man, by labour, may attain a knowledge of all that is already known on any subject, and that degree of knowledge is respectable; what many never attain to, and what few go beyond.

7942. *The grand drawback to every kind of improvement* is, the vulgar and degrading idea that certain things are beyond our reach; whereas the truth is, every thing is attainable by the employment of means; and nothing, not even the knowledge of a common labourer, without it: there are many things, which it is not desirable to wish for, and which are only desired by men of extraordinary minds; but let no man fancy any thing is impossible to him, for this is the bane of all improvement. Let no young ploughman, therefore, who reads this, even if he can but barely read, imagine that he may not become eminent in any of the pursuits of life or departments of knowledge, much less in those of his profession: let him never lose sight of this principle—that to desire and apply is to attain, and that the attainment will be in proportion to the application.

Sect. II. *Professional Education of Agriculturists.*

7943. *In order that a professional man should excel as such*, every other acquirement must be kept subservient to that of his profession. No branch of knowledge should be pursued to any extent that, either of itself, or by the habits of thinking to which it gives rise, tends to divert the mind from the main object of pursuit; something, it is true, is due to relaxation in every species of acquirement; but judicious relaxation only serves to whet the appetite for the vigorous pursuit of the main object. By the professional education of agriculturists, we mean that direction of their faculties by which they will best acquire the science and manual operations of agriculture, and we shall suppose agricultural pupils generally to have no other scholastic education than some knowledge of reading, writing, and arithmetic.

7944. *All young men who intend embracing agriculture as a profession*, whether as ploughmen, bailiffs, stewards, land-valuers, or rent-paying farmers, ought to undergo a course of manual labour for one year or more, in order to acquire the mechanism of all agricultural operations. When the pupil is not destined for any particular county, then he should be sent to a farmer in a district of mixed agriculture; as, for example, East Lothian, where he would, if placed in a wheat and bean culture farm, see at no great distance the turnip system and feeding, and a few miles off, the mountain sheep-farming or breeding: when the pupil is intended to be settled in any particular county, he ought to be sent to a county as near as possible of similar soil and climate, where the best practices are in use; as from all the turnip counties, pupils should go to Northumberland or Berwickshire; from the clay counties to East Lothian, or the Carse of Gowrie; from a mountainous district to the Cheviot hills, and Tweeddale, &c.

7945. *The term of apprenticeship* completed, the future time of the pupil ought to be regulated according to the ultimate object in view: if he is intended for a ploughman, shepherd, or hedger, perhaps to introduce new practices in other counties, he may remain for a year or two longer with other masters in the same district, in order not merely to acquire but to habituate himself to all the improved operations and practices. If he is intended for a bailiff, then, after having been two years on one character of farm, let him engage himself for a second two years in a district of an opposite or at least of a different character; and for a third two years, on a third character. There are, as already shown, only three descriptions of farming in Britain: the bean and clover, or clay-land farming, which includes feeding by soiling; the turnip farming, which includes feeding both by soiling and pasturage; and the hill, or mountain, or pasture farming, which includes all the varieties of breeding. A young man therefore of ordinary intellect, who has worked two years in East Lothian on a clay farm, two years in the lower Berwickshire, or in the low part of Northumberland, and two years on the Northumbrian hills, must have a very competent knowledge of that part of agriculture known as farming or husbandry.

7946. *The higher branches of agriculture*, or what may be called the engineering, valuing, and estate-agency departments, can only be completely acquired by first going through the course above described, as suitable for bailiffs and common stewards, and next placing themselves under an eminent steward, land valuator, drainer, road engineer, irrigator, &c. as the case may be; making choice of a steward who has extensive woods and plantations, and also, if possible, some quarries, fisheries, or even mines under his care, and of a land valuer or drainer in full employment. When a solid foundation is laid by a thorough practical knowledge of all the operations of common agriculture, the higher part is attained with ease, and may be practised with confidence; but, on the contrary, when young men who know nothing of common country work are sent direct from school, or from an attorney's office, to a land steward or agent, in order to acquire the art of managing landed estates, the worst consequences may be dreaded, both to the proprietors and the occupiers of the territory which may be subjected to them. The condition of many estates and tenants, managed by attorneys, may be referred to in proof of our assertion.

7947. *Young men intended as rent-paying farmers*, after two years' labour as common servants, should be kept as assistant bailiffs on other farms, till they are at least 25 years of age: no young man, in our opinion, ought to be put in a farm on his own account, or employed as a master bailiff, at an earlier period.

7948. *In all cases when young men are destined for particular purposes*, they should be sent chiefly to particular districts; as, for example, young men intended for road-surveyors, to where roads are best managed, drainers to a draining country, embankers to Lincolnshire, warpers to the Humber, irrigators to South Cerney, hedgers to Berwickshire, woodmen and foresters to Dunkeld, or Blair in Athol, &c. It

would contribute much to the improvement of agriculture in the backward counties, if landed gentlemen would prevail on their tenants to send their sons as apprentices, or even as ploughmen or farm labourers, to the improved counties; or if lads brought up by the parish were sent there with a view to their acquiring the use of the improved implements.

7949. *Whatever is the kind of professional knowledge to be acquired*, the means of attainment is the pupil's paying such attention to what he sees and hears as to fix it in his memory. One of the first things, therefore, that a young man should do is to cultivate the faculty of attention, which he may do every hour of the day, by first looking at an object and then shutting his eyes, and trying whether he recollects its magnitude, form, colour, &c.; whether he would know it when he saw it again, and by what special mark or marks he would know it or describe it. When he goes from one part of the farm to another, or is on a walk or journey, let him pay that degree of attention to every thing he sees and hears, which will enable him to give some account of them when returned from his walk or journey; and let him try next day, or some days afterwards, if he can recollect what he had seen then, or at any particular time and place.

7950. *The attention to be exercised in such a way as to impress the memory*, and enable the observer or hearer, not only to recollect objects, but to describe them, must be exercised systematically. A thing or a discourse must be attended to, not only as a whole, but as a composition of parts; and these parts must be considered not only as to their qualities of dimension, colour, consistency, &c., but as to their relative situation and position. To be able to give an account of a town or village, for example, the first thing is to get a general idea of the outline of its ground-plan, which may be done by looking from a church tower or adjoining hill; next, its relative situation to surrounding objects, as what hills, or woods, or waters join it, and in what quarters; next, the direction of the leading street or streets must be noticed; then the intersecting or secondary streets, the principal public buildings, the principal private ones, where the lowest houses and narrowest streets are situated, and what is the character of the greatest number of houses composing the whole assemblage.

7951. *To treasure up in the mind* the characteristic marks of particular varieties and subvarieties of stock is a most important part of an agriculturist's professional education. To do this effectually, some knowledge of sketching is of great use, and, if possible, ought to be acquired by every person intending to fill the situation of bailiff or steward. The knowledge of soils, plants, and their culture is a very simple business compared with the knowledge of stock, which is not only of difficult and tedious acquirement, but easily forgotten or lost: for one gentleman's bailiff that knows any thing of stock there are at least a score that know nothing.

7952. *In connection with professional studies*, the pupil may find it necessary, if his education has been neglected, to go on at his leisure hours with all the usual branches of education, either assisted by books alone, or by books and the best assistance he can procure. If his school education has extended to arithmetic, mensuration, mathematics, and drawing, he should occupy himself in acquiring a knowledge of botany, zoology, geology, and mineralogy, without a tolerable knowledge of each of which he will ever be in the dark among modern agriculturists, and in reading books on the subject. Next, let him study the various arts and manufactures that have any relation to agriculture, and store his mind with all he can acquire from one of the best general *Encyclopædias*, as that of Rees, or the *Encyclopædia Britannica*, with its excellent supplementary volumes. If he will go farther, and if he wishes to know the extent to which he may go, he may consult what we have advanced on the subject of education in the *Encyclopædia of Gardening*.

Sect. III. *Conduct and Economy of an Agriculturist's Life.*

7953. *A plan for the general conduct of life* should be fixed on by every one when he arrives at manhood, and steadily pursued for the time to come: most commonly such a plan is formed by the parents soon after the child's birth, and, at the latest, when the boy is taken from school. The boy arrived at manhood, however, is entitled to examine this plan, and amend it, or devise another more congenial to his own notions; but the risk of any change of this sort by persons so young and inexperienced is so great, that no youth ought to venture on it without the utmost consideration, and the firmest persuasion in his own mind: where the parent has done his duty, such changes of plan will not often be attempted; for, by the early infusion into the mind of a child of ideas relative to the pursuit that is intended for him, a taste for that pursuit or employment will grow up with him, and become as it were his own natural inclination. This will happen in most cases, but in some children the bias or force of nature for some particular purpose is so strong, that by no parental intreaties or reasoning can it be overcome; even where a sense of duty induced compliance with a parent's wishes for a time, the dormant inclination has at last broke out and taken the lead. In such cases, the parent may generally conclude, that where the pursuit or purpose is not bad, the force of natural inclination will be more likely to command success than the influence of parental authority; and that a pursuit or business, commonly of little profit or repute, will be more profitable and respectable when followed by a genius powerfully impelled to it, than a profitable and reputable business followed by any one against his inclination.

7954. *The plan and conduct of life are in most cases determined by accidental circumstances.* The son of the labouring man grows up without any regular training or education for a particular end, and finds himself at the age of manhood engaged in rural labour, and apparently incapable of any other; his notions and his ambition are so limited that he dare not venture to desire a change for the better; for no man ever desires that which he thinks it impossible to attain, and the mere idea of this impossibility, however erroneous, effectually restrains the attempt at improvement. The life of the ploughman or labourer, much as it differs from that of a man of eminent natural powers and superior education, is capable of much amelioration by being directed to a suitable end or object as the ultimatum, or in other words, by proceeding on a plan; plan indeed, as we have elsewhere observed (*Encyc. of Gard.* 2d edit. 7778.), is predestination, as conduct is fate.

7955. *The greater part of mankind enter on life without any fixed plan* or object in view, or, if they have some general notion of acquiring wealth or distinction, they form no plan by which it is to be accomplished; the consequence is, that such persons, after blundering on through their best years, arrive at the end without having gained any thing but experience, now of no use to them. No man is born in possession of the art of living, any more than of the art of agriculture; the one requires to be studied as well as the other, and a man can no more expect permanent satisfaction from actions performed at random, than he can expect a good crop from seeds sown without due regard to soil and season. When we look round and observe the quantity of misery in the world, the greater proportion is, or seems to be, the result of a want of plan, or of a bad plan of life. How many parents are unsuccessful in their struggles to maintain a large family, the result of too early marriages: how many find themselves arrive at old age with no other resource for support but charity, the consequence of want of foresight in expenditure: how many are suffering under poverty, brought on by their own want of frugality, or positive extravagance; or under disease from excesses and irregularities committed in the heyday of life: and how many among those not born to inherit property, who, at no period of their life, have any other alternative between hard labour and deficient food, than disease and want!

7956. *Want of plan* may not in every case be the cause of all this misery, because accident enters into life for something, both on the unfavourable as well as the favourable side of the question; but we have no hesitation in asserting, that want of plan, as a cause of misery, is as ninety-nine to a hundred: any plan at all, even a bad plan, is better than none; because those who set out on any plan will, in all probability, sooner discover its errors if a bad one, and correct them, than those who set out on no plan will

discover the want of one and form a good plan. The young man who is just setting out in life may well tremble at the consequences of proceeding on the journey without the guide of a judicious plan; this plan he must form himself, because he alone feels what he wants, and what he can do to gratify them; all that we can do is to offer a few hints.

7957. *In order to be able to form a plan* it is previously necessary to determine the object to be attained by it. Happiness is the object of every action of human life, and consists in the gratification of certain wants and desires: some of these desiderata are peculiar to youth, and others to old age; but many, as clothing, food, rest, relaxation, entertainment, &c., begin with the earliest, and continue to the latest period of life. All these gratifications are procured by labour; in savage life, by hunting, fishing, and gathering fruits, till the man, no longer possessing strength enough for these labours, is obliged to lie down and die of want: in civilised society, they are also obtained by labour; but here what is called property exists, and man, in the vigour of his days, when the supplies of his labour are greater than the demands of his wants and desires, or when he chooses not to gratify the latter to the full extent admitted by the former, can, as it were, embody a part of his labour, to be made use of when he is no longer able to perform it with ease: a man in this case is said to arrive at independence, instead of want, as in the case of the savage, or of beggary, as in the case of the improvident.

7958. *Independence is the grand object* which every man destined to live by the exercise of his labour or talents ought to have in view. At certain periods of life, when the imagination is vivid, and health and animal spirits in their utmost vigour, some may prefer present enjoyment, mere animal gratifications, or imaginary distinctions, amatory conquests, titles, rank, military glory, and high literary or professional reputation: it is a noble attribute of our nature to prefer some of these to the mere accumulation of money; but a great warrior, poet, or painter, arrived at old age and want, if the latter be brought on by common improvidence, will not find himself surrounded by many marks of distinction; and though it may possibly be some consolation to him that the three or four letters composing his name will be sometimes pronounced together after he is dead, yet it will not be much.

7959. *The exercise of his profession* is the most rational mode in which an agriculturist, of whatever grade, can pursue independence. Only extraordinary circumstances can justify a change of profession; in common cases it indicates a want of steadiness of character, or a want of success, and the latter is commonly attributed to want of skill; it is better, therefore, to pursue unremittingly the profession to which we have been educated, even though we should not be very successful in it, than to risk an infringement on character by adopting another. The practice of agriculture, as we have already seen, (7710.) is carried on by three different classes, serving, commercial, and artist agriculturists: on each of these classes we submit a few hints to aid them in forming a plan of life, and regulating their expectations.

7960. *The greater number of agriculturists must ever belong to the lower grades of the serving class;* and act as ploughmen, herdsmen, shepherds, hedgers, woodmen, and labourers of all-work. These form the greater proportion of mankind in every civilised country, and must ever remain the bulkiest material in the social fabric. Comparing one age and country with another, however, there may be the greatest difference in their intellectual and physical condition. The ploughman of Russia is but a remove from his horse. The ploughmen in different parts of Britain are as intelligent as their employers: in Scotland they have the Bible by heart, are familiar with the history of their country, and not ignorant of its literature; they lead a laborious life, but they enjoy the inestimable blessings of health, sound sleep, and peace of mind, till the latest period; they are almost always independent, either from their labour, their savings, or, in old age or sickness, from the assistance they receive of their children in return for what was laid out on their education. These men are as happy, relatively to their capacity for happiness, as any other class whatever: if their measure is smaller, it is as full as the largest; for the essential materials of comfort and happiness are the same in all classes, and in all classes a man's wants and wishes accommodate themselves to the means of gratifying them. The rich have no wants, and their desires for the most part are no sooner expressed than gratified; the pains and pleasures of life are neutralised into a kind of insipidity, till ennui brings on disease, which to this class becomes a blessing, by procuring for them the occupation of taking medicine, the duty of attending to the doctor's regulations, and the pleasures of convalescence.

7961. *Constant labour*, even that of the humblest description in the country, when it is not oppressive, and where it is accompanied with abundance of food, sufficient clothing, and good health, is by no means inconsistent with happiness. It is a common but most erroneous idea, that happiness is confined either to the rich or the independent. Health and activity are the woods, and a rich man who has nothing to do is unquestionably more miserable than any ploughman in the empire. "Happiness," says one who has thought much on the subject, "is the full and vivid satisfaction of the mind; and it consists in content and uninjurious enjoyment, that is, enjoyment not injurious either to oneself or to any other. Among the very first requisites to this satisfaction, it will readily be perceived, is employment, either bodily or mental; and the more energetic, without exhaustion, is the employment, the more full and vivid will be the satisfaction. The human mind is naturally active; and, except in sleep, if even then, cannot with impunity be motionless or torpid. Occupation is as necessary to its health as circulation of the blood is to the body's. Employed it must be, to know content or feel enjoyment; for, by any want productive of pain, either bodily or mental, especially the latter, content and enjoyment are, according to the degree of the pain, destroyed or diminished; and the want, which the unemployed mind invariably feels, is as invariably productive of uneasiness, of listlessness, and lassitude, and their inseparable attendant, mental pain. Indeed this pain is, not unfrequently, altogether unendurable. 'All the importunities and perplexities of business,' says Dr. Johnson, 'are softness and luxury compared with the incessant cravings of vacancy and the unsatisfactory expedients of idleness.' 'It is this *intolerable* vacuity of mind,' says Paley, 'which carries the rich and great to the race-course and the gaming-table.' It is this vacuity, says experience, which often arms them against themselves, and hurries them to self-destruction. If, also, employment is necessary to the health of the mind, exercise is to that of the body. Employment to the mind and exercise to the body are in some degree substitutes for each other; but, for the full content and enjoyment which constitute happiness, they both, in due proportion, are necessary." (*Co-operative Magazine*, vol. i. p. 6.)

7962. *The plan of life suitable for the operative agriculturist* may very well be founded on the condition of this class of men in the northern counties of Northumberland, Berwickshire, East Lothian, and others. We have already (7809. and 7834.) described in general terms the manner in which farm servants are hired, lodged, and paid in these counties; and details by an eminent Northumberland farmer will be found in the sixth volume of the *Gardener's Magazine* (p. 589.). The essence of the mode consists in the employer providing the employed with comfortable cottages and gardens, and paying them chiefly in the necessaries of life, in so much meal or flour, so much ground to grow potatoes and flax or hemp, a cow's keep, the run of a pig, if a shepherd so much wool or so many sheep, the loan of a team to bring home coal or other fuel, and a certain proportion of money. By this mode of payment the operative countryman is always sure of a comfortable home and food, sure of milk, butter, meal, bread, and potatoes, the produce of a pig, poultry, and bees, and of the produce of his garden; and this, however high may be the prices of these articles in the public market. These good things can only be rendered nugatory by the evil of a bad wife. All country servants hired by the year might be accommodated and paid more or less in this manner; and to this mode of life and payment they ought to look forward as the ultimatum of their grade in the scale of operative agriculturists. By prudent conduct, in regard to the increase of their family, and by frugality, they may live in decency and comfort, educate one or two children, and save something for old age, or unforeseen occurrences.

7963. *The Northumberland ploughman* is the happiest of labourers, and never feels a bad season. His wages are certain; and with frugality and care, his wife may bring up a large family upon this income. The reverse is sometimes the case; but this is attributed to a bad wife, who wastes the produce of the cow. The small stock of the hind being always his own, and the cow generally so, makes him prudent and careful during single service to save as much of his wages as will set him up for himself. To this, and the fact that the wages of labour are never paid out of the poor's rate, the enviable state of the Northumbrian labourer is to be attributed. It appears to operate as a preventive check upon population, and beautifully illustrates Mr. Malthus's theory; or, in the words of Burns, it teaches them to "know that prudent cautious *self-control* is wisdom's root." They are all anxious to give their children such education as they can command. When they are within the reach of a charity-school they thankfully avail themselves of it, and we find in every hamlet some person who teaches the younger children the rudiments; and several of these, when they get older, work and save the wages of summer to pay for putting themselves to schools in winter. (J. C. in *Gard. Mag.* vol. vi. p. 591. See also *Denson's Peasant's Voice.*)

7964. *The day labourer who has no particular employer*, and probably no fixed residence, is much less comfortable than the yearly servant; in England more especially, under the present system of poor laws and parish management, which is calculated to degrade him, and effectually to prevent any attempt at improving his condition. If, as Slaney observes, "by unremitted industry, he has been enabled to do without parochial relief, and bring up his children decently, it is as much as could be expected; for an attack of illness, or the temporary loss of employment, he is in general totally unprepared; he thinks not much of the morrow, and, as it stands, it is perhaps well for him that he does not anticipate evils which he cannot prevent. Every one knows how beneficial to the community, how advantageous to the individual, the hope of bettering his condition in life is: it cheers him in adversity, encourages his industry, promotes his content, yet from this hope the major part of the agricultural labourers of England are excluded; they toil indeed, but it is to continue, not to better their existence." (*Essay on the beneficial Direction of Rural Expenditure*, p. 170.; see also the succeeding chapters of these judicious and intelligent essays.)

7965. *The condition of the labouring classes* has lately been considered by the editor of the *Scotsman*, in an article in his xivth volume (Nos. 1131, and 1132.), which is also published separately in a tract entitled *The Scotsman's Advice to the Labouring Classes.* The condition of the labouring classes, it is observed in this tract, may be deteriorated in two ways; "by increasing their numbers too rapidly, and by diminishing the capital which provides them with employment. Now capital is either diminished, or its natural growth is impeded, by the enormous sums paid to the government, by the tax on corn imposed for the benefit of the aristocracy, and by the many absurd restrictions on industry, which have arisen from the ignorance or misconceptions of our legislators. To repeal or reduce taxes, and relieve industry from the restrictions which fetter it, benefits the working classes by enlarging the fund which creates a demand for their labour. The sufferings of these classes are therefore, in no small extent, imputable to the exactions and misconduct of the government. Culpable and injurious, however, as the extravagance of the government has been, I am convinced that were all the public burdens annihilated, and all the obstacles to freedom of industry removed, the relief given would be but temporary. The misery of the working classes might be mitigated by such means, but it cannot be eradicated by legislation, nor by any human means except such as shall put some check on the increase of their numbers. Scientific thinkers regard this conclusion as established on the clearest evidence; how then is the principle of increase to be checked? Only in one way: by enlightening the minds of the working classes; by inspiring them with feelings of self-respect; by teaching them the immense importance of habits of prudence, forethought, and self-control to their own happiness; by giving them true notions of their situation as moral agents, responsible for the consequences of their acts, and endowed with powers which, if rightly used, would make them to a great extent masters of their own destiny."

7966. *A radical evil in human conduct*, is that "in the article of marriage men consider life as a *lottery*, and they rush into the most important of all ties, without making any provision for discharging the obligations it lays upon them. This applies to the middle ranks as well as to the lower." Thousands and tens of thousands marry every year whose earnings hardly suffice for their own subsistence; and multitudes throw their offspring on the world "with as little rational consideration about its future well-being, as the crocodile shows when she drops her egg in the sand, and leaves it to the sun and the winds to hatch her young into life." Such persons shelter their thoughtless conduct under the plea of trusting to Providence: but what is trusting to Providence but trusting to chance? Nature has endowed us with reason to regulate our conduct, and in most of the common concerns of life has enabled us to foresee the consequences of our acts. After making all the use of our reason that we can, enough will still be left for chances, which may turn out, as every day shows, as much against us as for us. "To neglect the admonitions of reason, and then trust to Providence to free us from the evils induced by our own thoughtlessness, is to call upon the Deity to work a miracle in our favour; and this, instead of promoting our improvement, is only to harden us in our folly."

7967. *There are two truths of vast importance* to the well-being of the labouring classes; the first is, that as no efforts of legislation can lift them out of their misery, their happiness must always depend on their own habits of prudence, forethought, and self-control. The second is, that no man has a right to bring human beings into the world, who is not able to provide for their support and education. The law punishes severely the act of exposing a child; but the man who marries and becomes the father of children, without having any reasonable prospect of being able to keep them from beggary with all its attendant miseries, is guilty of the same crime in a lower degree.

7968. *To convert the burthens which marriage brings with it into money*, the *Scotsman* suggests the following scheme: he takes the case of an industrious mechanic beginning to earn 16*s.* per week at the age of eighteen, and he shows what he could accomplish by living economically, and deferring marriage till he was twenty-eight: he supposes him able to live upon 12*s.* 6*d.* per week, and to place 3*s.* 6*d.* per week in a savings' bank, by which his stock, including interest, will amount in ten years to about 100*l.* At his marriage he is supposed to spend 30*l.* of this 100*l.* in furnishing a house, &c. and to dispose of the remaining 70*l.* to provide against the following casualties.

7969. *The first casualty after marriage* which he has to provide against is sickness, which may be done by a weekly contribution of 4*d.* for himself and his wife.

7970. *The second casualty* is the infirmity of old age. This is to be provided against by an annuity from government, or a benefit society; and 17*l.* 1*s.* 9*d.* paid at once, or an annual payment of 9*s.* 6*d.* by a man at the age of twenty-eight, will obtain an annuity for him of 20*l.* per annum for whatever number of years he may live beyond the age of sixty-eight.

7971. *The third casualty* to be provided for is the possible widowhood of his wife: this he may do by paying down 32*l.* 12*s.*, for which a man of twenty-eight may secure for his wife, supposing her age to be the same, an annuity of 10*l.* for life, in the event of her being left a widow, at whatever period it may happen. On this subject the benevolent and philosophic author of the scheme observes, "When society is more enlightened, it appears to me that a provision against the chance of widowhood will be considered as indispensable at marriage as a suit of wedding clothes.

7972. *The fourth casualty* is the chance of the death of the father before his child is able to shift for itself; that is, before it is fifteen or sixteen years of age. To ensure each child against this casualty, it is proposed to secure a small annuity to it in the event of his death, of say 3*s.* per week, up to its fifteenth year. This, the father being aged thirty, he calculates may be purchased for 5*l.* paid down the first year of the child's life. "A similar deposit of 5*l.* would be requisite at each addition made to the family; and as a marriage is assumed to produce on an average four children, the whole sum expended under this head would be 20*l.*" Those who have more than four children must make extraordinary exertions.

7973. *A reasonable degree of security against the casualties of life* may be afforded to a working man about to enter into the married state and his family for the sum of 100*l.*, which it is shown he might save by the age of twenty-eight. That sum would be disposed of thus:

Furniture, exclusive of what was provided by the wife	£30
Annuity for himself in old age of 20*l.* per annum	17
Annuity of 10*l.* per annum for his widow	33
Provision for four children	20
	£100

Therefore, let no man whatever, not even the most humble country labourer, think of marrying before he has saved 100*l.*; and let him beware of spending any part of this sum, even that part which is allotted for his furniture, before he has provided for the four casualties of the married state.

7974. *To carry this scheme into effect*, mutual assurance societies by the working classes themselves, or benefit societies, would probably be the best mode, and government and the more wealthy members of society ought to lose no time in assisting in their formation. It is justly observed, however, that it cannot be too often inculcated upon the working classes, that the improvement of their condition must be their own work. Were this scheme carried into practice, "it would diminish their numbers relatively to capital, and as a consequence, *their wages would rise.* Secondly, it would rescue them and their families from extreme poverty, give them independence of character, secure to all of them the advantages of education, and thus break down the barrier which confines them to the sphere they are born in, and precludes them from obtaining any of the higher prizes in the lottery of life. To society the system would be equally beneficial: poor's rates, with all the abuses they engender, would be done away; crimes would be rare when pauperism was eradicated; and by the universal diffusion of education, all the talent in society would be made available. And last, not least, when every grown-up man had either a small stock of savings in hand, or investments in a common fund, we should have the very best guarantee for the public tranquillity. Did the working classes fully understand this scheme," its excellent author continues, "nine tenths of all the poverty, misery, and crime which we see around us would disappear; we should in fact find ourselves in a new world, full of intelligence, peace, and good order, in which life and property would be ten times more secure, happiness more equally distributed, and an admirable foundation laid for the further amelioration of the lot of mankind." (*Scotsman*, Nov. 13. 1830.)

7975. *The plan of life for the directive class of agriculturists* need hardly be pointed out; the rise from a farm bailiff to a steward's bailiff, or to a demesne bailiff or steward, and thence to the general steward or factor of an estate, is an obvious object of ambition. In another direction he may rise through the different gradations of the commercial agriculturist, or, adopting the rank of counsellor or artist, he may become a salesman, appraiser, timber or land-surveyor, land-valuer, agent, or agricultural engineer: rarely, however, can he attempt the veterinary profession, or that of draftsman, author, or professor.

7976. *The remuneration to which a directive agriculturist is naturally entitled*, should be regulated by his professional abilities and experience; that which he will commonly receive will be regulated by the quantity of agricultural talent and experience in the market; it ought always to be such as will render it worth his while to be honest, assiduously attentive to the interest of his employer, and of polite and obliging manners. A handsome salary to such a servant is wise economy.

7977. *The object of the artist or counsellor agriculturist* may be either to ascend to the rank of author or professor, conditions of more honour than profit; or to realise property and become a proprietor cultivator. For a rent-paying farmer, no artist or author is at all adapted.

7978. *The legitimate object of a commercial agriculturist* is to rise in the different grades of his class, and become either a large farmer, a gentleman farmer, or, best of all, a proprietor cultivator.

7979. *The profits to which a commercial agriculturist is entitled*, comparatively with those of other commercial men, are theoretically determinable by the risk attending the employment of his capital, and the skill requisite to prosecute his art; but, practically, this remuneration will depend on the quantity of skill and capital in the market. The risk attending capital employed in the culture of the useful products of the soil, is evidently less than the risk of capital employed in many or perhaps most manufactures; and the skill requisite to enable any one to become a farmer, according to the customary practices of the country surrounding him, is less than that required for almost any branch of manufacture. In consequence of these things, there are men every where ready to become farmers; hence the profits of farming are naturally less than those of most other pursuits; but, to counterbalance this, the farmer has several advantages peculiar to his profession. First, the nature of his residence in the country, which assumes a certain degree of consequence from its connection with a considerable group of out-offices, surrounded by a garden, orchard, fields, woods, and other rural scenery, all in his occupation, and inhabited by servants in cottages, horses, cattle, sheep, and other domestic animals, in subjection to him, gives him a degree of consequence both real and apparent; and assimilates him more nearly to a lord of the soil, and to the possessor of that sort of rural retirement and independence which is the object of almost every commercial man's ambition, than any other mode of life could do. Secondly, many trades and professions preclude (according to general prejudices) their followers from being gentlemen: whereas, though every farmer is not a gentleman, yet any gentleman may become a farmer, without in any degree lowering his rank and character; a farmer may, therefore, if he chooses to adopt the habits and manners of a gentleman, be reckoned as such. Thirdly, the farmer's products are in universal demand, and he is sure of a market at some reasonable rate, a fact otherwise with many manufactures. Fourthly, he is sure of a home, of the necessaries of life, and, in general, of most vigorous health. Fifthly, he is generally a man of more parochial influence than the tradesman or manufacturer.

7980. *Scarcely any farmer makes a fortune by his profession:* the utmost exertions of the most skilful and industrious men, in the most improved districts, seldom do more than enable them to keep pace with the times; and the great majority, in all countries, lead a life of great labour and anxiety, and end as they began. No farmer, in a general way, can raise more than one corn crop in a year, and in this respect the farmer of Russia and Poland has the advantage of the British farmer; for the lands of the former being from five to eight months under snow, all root-weeds are destroyed, and the ground so loosened by the frosts and thaws, as to require very little stirring for the seed: the rapid summer which succeeds ripens all annual plants that will grow there, nearly as well as in England, and better than in many parts of Scotland and Ireland. The British farmers, however, have the great advantage of perpetual pastures, owing to the mildness of our winters; but still no art of man will shorten the period of animal gestation, and originate a lamb or a calf in shorter periods than five months and forty weeks. How often does the tradesman or manufacturer turn his capital in that time! There are three varieties of professional farmers, however, who occasionally realise some property: the grazier who feeds with oil-cake, grains, and other artificial foods; the dealer in corn or cattle, who has the art to buy at a falling and sell at a rising market; and the dealer or jobber in farms, who sublets or sells his lease, or in purchases of land, who subdivides and sells estates. The profits of the first are not great, and those of the last two are attended with great risk: the only farmer whose lot is to be envied, lives under a landlord who does not take the full marketable price for his lands: such as Burdett, Coke, Bedford, Northumberland, and many others in the south; but few in the north, or in the west.

CALENDARIAL INDEX.

THOUGH agricultural operations, in general, require less nicety as to the exact time of performing them than many of those of gardening, yet there are exceptions in respect to some field crops; for example, beans and turnips. It is proper to observe, therefore, that the *almanac time* in this Calendar is calculated for the meridian of London; but as a *Calendar of nature* is given for the metropolitan district, the almanac time may, in every part of the empire, be varied to suit the local climate and vegetation.

In general, other circumstances being alike, four days may be allowed for every degree, or every 70 miles north or south of London; in spring, operations may be commenced earlier in that proportion southwards, and later northwards; but in autumn the reverse, and operations deferred as we advance southwards, and accelerated as we proceed to the north. In every case allowing a due weight to local circumstances.

Our notices under each month extend only to a few of the leading features of country-work; — to attempt to insert every thing, or even most of the things that require attending to, we conceive impossible; and, if it could be done, quite useless. A man will always act better when guided by his own judgment, than when following implicitly that of another. Calendars should only be considered as remembrancers, never as directories.

JANUARY.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	35 9	6	29 56	1·957 inch.	A cold January is reckoned seasonable; the air being drier during a low state of the thermometer than when it is a little above or below the freezing point; winter-cold is generally less felt by animals than that of March. Winds often prevail during this month. The calendar of animated nature is much more to be depended on than the vegetable calendar; for except the catkins on trees, the state of the other plants during this month depends much on the character of the preceding autumn.
Edinburgh	34 5	- -	29 194	2·094	
Dublin -	39 92	- -	29 721	2·697	

1. *Calendar of Animated Nature round London.*

In the first week: shelless snails (Hèlix) and earth-worms (*Lumbrìcus terréstris*) appear.

Second week: redbreast (*Motacílla Rubícola*) whistles, nuthatch (*Sítta europæ'a*) chatters, missel thrush (*Túrdus viscívorus*) sings, and wagtails (*Motacílla álba* et *flàva*) appear.

Third week: the common lark (*Alaúda arvénsis*) congregates.

Fourth week: snails (*Hèlix horténsis*) and slugs (*Limax àter* et *hyálinus*) abound in the sheltered parts of gardens; the hedge sparrow (*Motacílla modulàris*) whistles, the large titmouse (*Pàrus màjor*) sings, and flies appear on windows.

2. *Calendar of Vegetable Nature round London.*

In the first week: some plants accidentally in flower; and others, as the Laurustinus, continued from December.

Second week: winter aconite (*Eránthis hyemàlis*), Christmas rose (*Helléborus fœ'tidus*) in flower, and hazel (*Córylus Avellàna*) catkins beginning to appear: common honeysuckle (*Lonicèra Periclýmenum*) buds begin to appear.

Third week: primrose (*Prímula vulgàris*) flowers in sheltered places; daisy (*Béllis perénnis*) and chickweed (*Alsìne mèdia*) begin to flower.

Fourth week: mezereon (*Dáphne Mezèreum*) begins to flower; and sometimes spurry (*Spérgula arvénsis*), pansey (*Víola tricolor*), white scented violet (*Víola odoràta*), archangel (*Làmium rùbrum*), and coltsfoot (*Tussilàgo purpùrea* et *odoràta*) show blossoms.

3. *Farm-yard.* (2902)

Attend to cattle, whether in the open yard on straw and a few turnips (5411.), in hammels for feeding (6855.), or in stalls (6852.). See that the weak are not driven from their proper share of green food by the strong; notice any in bad condition, and put them in a place by themselves for a few weeks. When the hay or straw is of inferior quality or flavour, sprinkle with salt water, which will make it more palatable.

Threshing (3199.) goes on pretty regularly at this season for the sake of a supply of straw. In some districts it is common to thresh an hour every morning by candle-light during the three winter months, the candles being hung up in lanterns. See that the gudgeons and other places are kept oiled, and the teeth of wheels greased or soaped, or coated with anti-attrition.

Implements not now in use may be repaired, also harness greased, ropes spliced, and various evening jobs executed, where it is customary to work a part of the winter evenings.

Men's lodge. (4160.) In some districts the unmarried farm-servants have a common living-room in the farmery, with a sleeping-room over, or sleeping-rooms over the horses. It is the duty of the farmer or bailiff to see that these young men are properly occupied during the long winter evenings. A portion of every man's time will be taken up in mending his clothes or shoes, and sometimes in oiling and cleansing horse harness; the rest they ought to be encouraged to pass in reading, or otherwise instructing themselves. One may read aloud to the rest; one may instruct the others on any subject; a master may be got in for an hour or two every evening, who would teach them all. A master suitable for this purpose will often be found among the married servants, or among the village mechanics. To serious studies may be joined recreative ones, such as the flute, violin, story telling, singing, speech-making, dramatic attempts, &c. The bailiff or farmer should occasionally come and examine each lad, and bestow some mark of approbation on the most deserving.

4. *Live Stock.* (6216.)

Store farms (7191.), whether of sheep or cattle, require considerable attention during the winter and spring months to supply straw and hay, with such green food as can be spared, to stock on scanty pastures; and to shelter during storms, especially of snow.

Lambs are dropped during this month by the Dorset sheep, and near London are generally kept in the house and fed. (7224.) These require regular attention.

Calves fatting at this season (6843.) should be kept very clean, and their supplies of milk liberal. Calves to be reared as stock should never be dropped sooner than April.

Pigs (7283.), *poultry* (7438.), and stock in general, should be kept in good heart at this season, otherwise in the spring months they will be fit for nothing, and half the summer will elapse before they recover the bad effects of winter starvation.

Fish, when the ponds are covered with ice, require attention, to break holes to admit air. (7572.)

Bees if dormant do not require to be fed; but if the weather is so mild, or they are placed in so warm a situation as to occasion their flying about, they should be examined, to ascertain if feeding be requisite. (7602.)

5. *Grass Lands.* (5643.)

Dry soils and uplands should alone be stocked with cattle or young horses at this season. (5839.) Sheep should not be allowed to graze either on wet marshy meadows or on young clovers. (5543.) Grass lands, under a system of irrigation, may now be kept covered. (4387.) Clayey soils and others not properly drained should now have that operation effectually performed on the surface (4294.) or under it (4282.), according to circumstances.

Worms (7704.) on some soils do considerable injury to grass. Where the labour is not considered too much, and there is a water barrel at any rate, they may be killed by mixing powder of lime with the water, at the rate of one pint to ten gallons. On lawns, and in small paddocks, or in the case of *fermes ornées*, getting rid of worm casts is an object worth attending to; and this month, February, and October, are the best seasons for the operation.

6. *Arable Lands.* (4925.)

Plough when the soil is not too wet. Lead out dung and form field dunghills, also compost heaps, with peat or other matters. See that drains, ditches, and water-furrows run freely, and answer their respective ends.

Beans (5222.) are in some dry situations planted in the last week of the month; and also peas, and sometimes oats, are sown. On the whole, however, it is better to defer the beans and peas till the first and second weeks of February, and the oats till the two last weeks of that month.

Spring wheat of the common kind (5025.) may be sown where the soil is suitable.

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)

Hawthorns may be planted in fence-lines, in any of the different modes. (2972.) Ditches, walls, palings, and all other fences of the common kind may be formed; but none where hollies or other evergreens are to be used. Repair by the different modes. (2987.) Roads and drains may be formed at all times and seasons.

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)

Prune trees and free them of moss. Where digging round each tree is practised, this is a good season. Stake and tie newly planted trees. Plant orchards. Trench ground for hop plantations. (6007.)

9. *Wood-lands and Plantations.* (3906.)

Prepare the soil for planting. Plant deciduous hard-wooded trees in mild weather. Plant and sow the larger tree seeds, whether in places where they are finally to remain, or in nursery-grounds.

Fell timber and coppice not valuable on account of its bark. Stock up roots, stack them, and char them.

Prune deciduous trees; fill up vacancies. Cut hawthorn hedges. (2983.) Gather any tree seeds not before gathered.

Drain wood-lands and cut paths or other openings required through them, the leaves being now off the deciduous sorts.

FEBRUARY.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.
London -	42 3	5	29 94	0·873 inch.
Edinburgh	36 6	- -	29 556	1·269
Dublin -	43 78	- -	30 091	2·24

REMARKS.

This month (the *spring* or *sprout kale month* of the Saxons) is usually subject to much rain or snow; either is accounted seasonable: the old proverb being, "February fill dike with either black or white." Round London, the sap in vegetables shows evident symptoms of motion about the middle of the month, and sometimes a week earlier. The animal calendar, and inflorescence of native trees for this month, will generally be found very correct.

1. *Calendar of Animated Nature round London.*

In the first week: bees (*A*pis mellífica) come out of their hives, gnats (*C*ùlex) play about, insects (Insécta) swarm under sunny hedges, and the earth-worm (*L*umbrìcus terréstris) lies out; hen-chaffinches (*F*ringílla) flock, and the song-thrush, or throstle (*T*úrdus mùsicus), and common lark (*A*laùda arvénsis) sing.

Second week: the buntings (Emberìza álba), and linnets (*F*ringílla Linòta), appear in flocks; sheep (*O*vis *A*ries) drop their lambs; geese (*A*nas *A*nser) begin to lay.

Third week: rooks (*C*órvus frugílegus) begin to pair, and resort to their nest-trees; house-sparrows (*F*ringílla doméstica) chirp, and begin to build; the chaffinch (*F*ringílla cœlebs) sings.

Fourth week: the partridge (*T*étrao *P*érdix) begins to pair, the blackbird (*T*úrdus *M*érula) whistles, and the wood-lark (*A*laùda arvénsis et arbórea) sings; the hen (*P*hasiànus *G*állus) sits.

2. *Calendar of Vegetable Nature round London.*

In the first week: the snowdrop (Galánthus nivàlis), whin (*U*lex europæa), white deadnettle (*L*àmium álbum), polyanthus (Primula vèris) flowers; and the elder (*S*ambùcus nigra), and some roses and honeysuckles, begin to expand their leaves.

Second week: common crowfoot (*R*anúnculus rèpens), dandelion (Léontodon *T*aráxacum), and the female flowers of hazel (*C*órylus *A*vellàna) appear.

Third week: Verónica agréstis in flower; many of the poplar and willow tribe show their catkins; and also the yew (*T*áxus baccàta), alder (*A*lnus commùnis), the tulip (*Tùlipa*), crown imperial (Fritillària imperiàlis), and various other bulbs, boldly emerging from the ground.

Fourth week: the *E*rica cárnea, wood strawberry (*F*ragària vésca), some speedwells (*Verónica*), the groundsel, and sometimes the stocks and wall-flower (Cheiránthus) in flower. Some sorts of gooseberries, apricots, and peaches, beginning to open their buds.

3. *Farm-yard.* (2902.)

See last month. In taking in stacks to thresh, destroy vermin as much as possible. (6632.) Clear away the bottoming of straw, faggots, or other temporary matter, and leave the site perfectly neat and clean: the poultry will pick up what grains may have dropped. Be vigilant in keeping stock of every description in order; wintering cattle by frequent supplies of fresh straw and turnips, or other roots; horses by sound corn, and good peas-straw, or clover-hay, dispensing as much as possible with wheat and oat straw. The evening food should, occasionally at least, be of carrots or potatoes.

Poultry now lay freely; and if some indicate a desire to incubate, so much the better where an early brood is an object.

Men's lodge. There are still a good many hours for mental improvement.

4. *Live Stock.* (6216.)

Sheep generally begin to lamb during this month, and require unremitting attention from the shepherd. (7112.) Attend to feeding lambs as before (7224.), and to milch cows (6863.) and fattening calves. (6843.)

5. *Grass Lands.* (5643.)

See last month. Manures, where applied to grass lands, may be laid on at this season; and such old mossy lands as are to be broken up may now be pared with a view to burning next month.

The watering of meadows in warm situations may be partially left off towards the middle of the month, to encourage the growth of the grass. (4585.)

6. *Arable Lands.* (4925.)

Beans should be put in during this month. (5222.) Peas for podding, and for a ripened crop, may be sown at different periods (5121.), and tares for soiling or seed. (5257.) Oats sown from the middle of this month to the middle of March (5120.) unless on very old turf, where they may be sown later. It is a common but erroneous opinion, that old grass lands intended to be broken up and sown with oats or beans, should be ploughed as early as possible, so as the frost may have some effect on the furrow before seed-time. But this, though most plausible, is a most dangerous doctrine, it being found from experience, that lands so ploughed and sown are always more subject to have the plant of corn destroyed by the grub, wire-worm, or other larvæ. The only safe mode with such lands, is not to plough them till about the middle of March, and then to plough, sow, and roll immediately afterwards. It would appear that by this practice the larvæ of insects are buried so deep, that they have not time to reach the surface before the grain has germinated and grown out of the reach of their attacks, or probably they may be so deeply buried as to be obliged to remain another season under ground; it being known to naturalists, that the eggs, larvæ, and chrysalidæ of many insects, like the seeds of many plants, will, when buried too deep, or otherwise placed in circumstances not favourable for their immediate hatching or germination, remain there, retaining their principle of life, till they can make their way, or are by accident placed in circumstances favourable for their development. The safest plan, however, to break up old grass land is to pare and burn. (5865.)

Spring wheat of the common kind may now be advantageously sown (5004.), and barley is also sown in some warm spots in the last week of the month.

7. *Fences* (4213.), *Roads* (3523.), *Drains, Ditches* (2960.), *Ponds.* (4467.)

Hedges may be planted (2978.), grown ones pruned (2981.), old ones plashed or cut down (2987.), and imperfect ones repaired. Walls built (3056.), water fences and ponds formed. (4467.)

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)

See last month.

9. *Wood-lands and Plantations.* (3906.)

As in last month. Where there is a nursery store, nut and kernel tree seeds may now be sown.

MARCH.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.
London -	46 4	4	30 20	0·716 inch.
Edinburgh	41 7	- -	28 886	1·455
Dublin -	44 09	- -	29 707	2·364

REMARKS.

The beginning of March usually concludes the winter; and the end of the month is generally indicative of the succeeding spring; according to the proverb, "March comes in like a lion, and goes out like a lamb." The Saxons called this month *the lengthening month*, in allusion to the increasing of the days. This is a laborious and trying month, both for men and cattle engaged in field operations.

1. *Calendar of Animated Nature round London.*

In the first week: the ring-dove (*C*olúmba *P*alúmbus) coos; the white wagtail (*M*otacílla álba) sings, and the yellow wagtail (*M*otacílla flàva) appears. The earthworm (*L*umbrìcus terréstris), and the snail (Hèlix) and slug (*L*imax) engender.

Second week: the jackdaw (*C*órvus *M*onédula) begins to come to churches; the tomtit (Pàrus cærùleus) makes its spring note; brown wood-owls (*Strix U*lula) hoot; and the small tortoise-shell butterfly (*P*apílio urticæ *L.*) appears.

Third week: the marsh titmouse (Pàrus palùstris) begins his notes. Various flies (*M*uscæ) appear. The fox (*C*ànis *V*úlpes) smells rank. The turkey-cock (*M*elèagris *G*allo-*P*ávo) struts and gobbles.

Fourth week: the yellowhammer (Emberìza Citrinélla) and green wood-pecker (*Pìcus vìridis*) sing; rooks, ravens (*Córvi*), and house pigeons (*Colúmbæ*) build; the goldfinch (*Fringílla Carduèlis*) sings. Field-crickets (*Scarabæ'i*) open their holes; and the common flea (*Pùlex ìrritans*) appears.

2. *Calendar of Vegetable Nature round London.*

In the first week: various species of the pine, larch, and fir tribe in full flower; the rosemary (*Rosmarìnus officinàlis*), the willow (*Sàlix*) and bay (*Laúrus nóbilis*) in blossom; various trees and shrubs beginning to open their buds.

Second week: the common honeysuckle (*Lonicèra Periclýmenum*), and some roses in leaf; *Cròcus vérnus*, and other subspecies, and some *Scìllæ* in flower. Pilewort (*Ficària*), and creeping crowfoot (*Ranúnculus rèpens*), Hepática, and elder (*Sambùcus nìgra*), sometimes in leaf.

Third week; *Saxífraga oppositifòlia*, *Dràba vérna*, *Dáphne póntica*, and *collìna*; and *Lonicèra nìgra*, in flower.

Fourth week: the peach, nectarine, apricot, *Córchorus japónicus*, *Pyrus japónica*, crown imperial, *Saxífraga crassifòlia*, *Búxus sempervìrens*, and other plants, in warm situations, in flower, or just advancing to that state.

3. *Farm-yard.* (2902.)

Wintering cattle should be liberally supplied with food from this time, till they can be wholly turned to grass: as straw and hay gets drier at this season, more should be given, and the supply of turnips, or other roots, rather increased than diminished. Where oil cake, brewers' grains, and similar articles can be obtained, they are valuable auxiliaries. Fatting cattle (6852.) and milch cows (6863.) require continued attention to food, cleanliness, and moderate exercise. Working horses must be kept in good condition; if they fall off now, they will not recover themselves for several months. Potatoes may now be cut into sets preparatory for next month.

4. *Live Stock.* (6216.)

Sheep now drop their lambs freely; and none pay better than such as are turnip fed at this time, and finished off in April, on forward pasture. As turnips begin to run to flower about this time, they are apt to prove more than usually laxative, and therefore the stock supplied with them should have an extra supply of hay.

5. *Grass Lands.* (5643.)

Meadows intended for mowing (5768.) should now be shut up, their surface having been freed from stones or other extraneous matters, the furrows or water gutters made completely effective, and, if the weather will permit, the surface bush-harrowed, and rolled. Meadows which have been flooded during winter will, in favourable situations, show a considerable crop of grass by the beginning of this month. Turn off the water a week or ten days, till the surface gets firm; then feed with ewes and lambs, giving a little hay in the evening. Calves may also be turned on these meadows, but nothing heavier. The best mode is to hurdle off the grass in strips, in the manner of eating turnips or clover in the places of their growth. Moles (7631.) and worms (7704.) are best destroyed at this season.

6. *Arable Lands.* (4925.)

There are few hardy seeds, whether of agriculture or gardening, that may not be committed to the soil during this month. Spring wheat of the common kind (5004.) may still be sown; but if possible, not later than the middle of the month; oats (5120.), rye (5069.), barley (5080.), canary corn (5169.), buckwheat (6111.), beans (5222.), peas (5121.), tares (5257.), &c.

Clover and rye grass (5521.) may now be sown among young wheats after naked fallows, or among spring corn in lands in good heart and fine tilth.

Field beet (5482.), carrots (5443.), parsneps (5471.), and Swedish turnips should be sown the last fortnight of the month, provided the land is dry enough to be sufficiently cleaned, and pulverised to the depth of at least a foot. It more frequently happens that this cannot be got done till the beginning of April, and hence this class of seeds is seldom got in before the middle of that month. The carrots should be first sown, and the Swedish turnip will bear to be the latest. Lands intended for potatoes, carriages, turnips, transplanted Swedish turnip, and other plants of the *Brássica* kind should be brought forward by such ploughings, cross ploughings, and workings with the grubber, as their nature and state may require. It is one great advantage of the common white turnip, that it admits of two months more time for preparing the soil than other root or *Brássica* crops. Summer or wheat fallows require at least one furrow in course of the month.

7. *Fences* (2960.) *Roads* (3523.), *and Drains.* (4213.)

Thorns and other hedge plants may be put in, but the earlier in the month the business is completed the better. This is an excellent season for making or repairing roads (3727.), drains, ponds, embankments, &c., the ground being still moist, and the days sufficiently long to admit of a man's labouring ten hours, or from six to six. In January, the ground is often too wet, or frozen, or covered with snow, and the days too short for advantageous day labour. In July and August the ground is too dry and hard for spade work, and day labour high on account of the proximity of hay-time and harvest.

8. *Orchards* (4079.) *and Hop Grounds.* (5997.)

Finish pruning fruit-trees (4111.), and also digging round their stems, if that is practised. (4119.) Where young orchards are grazed, see that the guards or fences to the single trees are in repair.

Form plantations of hops (5997.), and open up and dress the hills of established plants, returning the mould to their roots. (6025.)

9. *Wood-lands and Plantations.* (3906.)

In the tree nursery, finish sowing acorns, keys, nuts, mast, berries, stones. Sow also the lighter trees, as poplar seed (where it can be got), willow, birch, alder, elm, &c. Transplant from the seed bed, or from narrow to broader intervals, and attend to other parts of the usual routine culture.

New plantations may still be planted, endeavouring if possible to finish putting in deciduous trees with the month; using the puddle in dry weather (3940.), and fixing by water. (3952.) Where large trees are introduced, the latter generally require to be staked.

Evergreens of the harder kinds, as the Scotch pine, spruce fir, &c. may be transplanted in the last week of the month, but not safely before. They are often put in during any of the winter months, but the result shows the impropriety of the practice.

Fill up blanks (3983.) in young plantations and hedges, and fell timber, cut over coppice woods, and thin out young woods as in last month. When plantations are to be raised from seed where they are to remain for timber (3926.), this is the month for most seed, but April is better for the pine and fir tribe. Sow the others in the second or third week of the month; and if resinous trees are to be mixed, a sprinkling of their seeds can be sown over the others in April.

APRIL.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	49 9	3	29 77	1·460 inch.	The weather of this month is distinguished by the rapidity of its changes. It is generally stormy, interspersed with gleams of sunshine, hail, snow, some frost, and occasionally violent storms of wind. It is a month of the utmost activity to the cultivator of arable land, who during its course finishes the sowing of spring corns and grasses, and begins that of roots and leaves.
Edinburgh	46 3	- -	29 873	2·414	
Dublin -	51 125	-	32 909	2·561	

1. *Calendar of Animated Nature round London.*

In the first week: the viper (*Cóluber bèrus*) and woodlouse (*Onìscus Aséllus*) appear; the misseltoe thrush (*Túrdus viscívorus*) pairs; frogs (*Ranæ*) croak and spawn, and moths (*Phalænæ*) appear.

Second week: the stone curlew (*Charàdrius Œdicnèmus*) clamours; young frogs (*Rana temporària*) appear. The pheasant (*Phasiànus*) crows, the trout (*Sálmo Trútta*) rises, and spiders (*Aràneæ*) abound.

Third week: the crested wren (*Motacílla Régulus*) sings; the blackbird (*Tùrdus Mérula*), raven (*Córvus Còrax*), pigeon (*Colúmba doméstica*), hen (*Phasiànus Gállus*), and duck (*Anas bóscha*) sit; various insects appear; and the feldfare (*Túrdus pilàris*) is still here.

Fourth week: the swallow (*Hirúndo rústica*) returns; the nightingale (*Motacílla Luscínia*) sings; the bittern (*Ardea rotellària*) makes a noise; the house martin (*Hirúndo úrbica*) appears; the blackcap (*Motacílla Atricapílla*) whistles; and the common snake (*Cóluber Nàtrix*) appears.

2. *Calendar of Vegetable Nature round London.*

In the first week: the daffodil (*Narcíssus Pseùdo-narcíssus*), the garden hyacinth (*Hyacínthus orientàlis*), the wallflower (*Cheiránthus Cheìri*), the cowslip (*Prímula officinàlis*), the periwinkle (*Vínca*), sloe (*Prùnus spinòsa*), and various other herbs and trees in flower.

Second week: the ground-ivy (*Glechòma hederàcea*), gentianélla (*Gentiàna acaùlis*), Pulmonària virgínica, the auricula, *Ibèris sempervìrens*, *Omphalòdes vérna*, and most of the common fruit-trees and fruit-shrubs in flower.

Third week: some *Robíniæ*, *Andrómedæ*, *Kálmiæ*, and other American shrubs; *Dáphne Laurèola*, *Ulmus campéstris*, *Chrysosplènium oppositifòlium*, *Mercuriàlis perénnis*, and other plants in flower.

Fourth week: the beech (*Fàgus*) and elm (*Ulmus*) in flower; ivy-berries drop from the racemes; the larch in leaf, and the tulip and some white narcissi and fritillaries in flower.

3. *Farm-yard.* (2902.)

This month will in most situations terminate the wintering of cattle in the straw-yard. Straw is now very dry, therefore turnips, or other green food or roots, should be added in proportion.

Horses should be kept in high order, on account of the hard work and extra exertion often required of them during this month. If there are carrots or potatoes to steam for them once a day, that will greatly aid hay and corn; if not, steam a part of the hay.

The accidental supplies of food for store pigs and poultry are less abundant during this month, because less time can be spared for threshing. There are fewer wintering cattle, and the yards are generally now cleaned out for the field dunghills.

4. *Live Stock.* (6216.)

The end of this month is a good time for mares to foal (6629.), and they should have the horse accordingly. (6631.) Attend at the proper periods, first to moderate working, and then to entire ease before foaling time. (6641.)

Cows must still be well fed with roots or steamed food, within doors, letting them taste the grass occasionally towards the end of the month. (6863.)

Sheep and lambs generally require a good deal of artificial food during the first half of this month. When the turnips are expended, clover hay, grains of barley which have been malted, rape cake, or linseed cake, are the next resources. (6094.) About the end of the month they may be turned on the pastures, and then it is that mutton generally drops in price:—a hint to the farmer to sell all he can in the early part of April.

Where there are water-meadows, the sheep and lambs will have been fattening on these during the whole of the month, —an immense advantage to a farmer.

Poultry of most kinds have now hatched their broods, and require looking after, to see they do not injure one another, nor are attacked by stronger enemies.

5. *Grass Lands.* (5643.)

See that the fences are kept up, and the gates regularly shut and fastened; as cattle newly let out are very apt to wander, and more ready to break through fences than when the herbage is more abundant.

Water-meadows (4371.) are generally shut up for hay about the end of the month, the ewes and lambs being then turned on young artificial grasses, or common provincial pastures, in a sufficiently for yard state.

Mowing-meadows of the common kind (5768.), and clovers, and mixed grasses for hay, should be hand-picked, bush-harrowed, and rolled, early in the month, and then shut up for the scythe.

6. *Arable Lands.* (4925.)

Finish *sowing* all the spring corns (5080.), peas, tares, lucerne (5574.), saintfoin, and all other herbage, plants, and grasses. (5643.)

Summer wheat (5004.) may be sown during the whole of the month, also barley in late situations (5080.), peas for late podding, and under peculiar circumstances, tares for cutting green in October and November.

Manufactorial plants, as woad, madder, flax, hemp, mustard, &c.; oil plants, as rape, poppy, and such plants as are grown for medicinal purposes or peculiar uses in domestic economy, as rhubarb, liquorice, buck or beech wheat, cress, &c. may all be sown or planted from the middle of last to the middle of this month. The first week in April will, in the greater number of seasons, soils, and situations, suit the most of them.

Carrot (5443.), field beet (5482.), parsnep (5417.), and Swedish turnip (5409.), if not sown the last week of March, should be finished during the first ten days of April. A bed of Swedish turnips should be sown in the garden for transplanting in the field by the end of the month, or the first week in May.

The last fortnight of the month is the best season for planting potatoes (5316.); in the earliest situations this is soon enough for a full crop; in the latest, the middle of May will answer better. For very early crops for the supply of summer markets, dry rich sheltered fields may be planted in March. In the moors of Scotland they often plant in June, and still have a crop; there the potato is alike obnoxious to late spring and early autumnal frost.

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)

All these should have been put in order before, so as to leave the hedger of the farm (7714.), and the labourer of all work (7711.), time to assist in getting in planted crops, as potatoes, cabbages, &c. in the fields, cropping the garden, mowing, or otherwise dressing the orchard, shrubbery, lawn, or such ornamental or enjoyment ground as the farmer indulges in round his house.

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)

In some cases fruit-trees may be so over-run with insects towards the end of the month as to make it worth while to burn wet straw under them; but this rarely happens before the middle of May, and even then farm orchards may almost always be left to the birds and vigour of the trees. Hops are generally poled in this month, and the ground between the hills afterwards stirred with the cultivator or nidget as it is called in Kent. (6026.)

9. *Wood-lands and Plantations.* (3906.)

All planting and pruning of deciduous trees should be finished the first week of the month. Afterwards the planting and pruning of evergreens may commence; first the common pine and fir, and afterwards the holly, yew, and other forest evergreens. (3937.) If these can be watered, and staked, so much the better. Barking oaks may in some warm situations be felled the last week of the month, but May is the more general time. (4050.)

MAY.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	56 61	2 5	30 02	0·794 inch.	Vegetation now goes on with great vigour, though there are often very cold and even frosty nights, which materially injure the blossoms of fruit-trees, and sometimes the young shoots of the hop and potato. Man, in common with other animals, being now full of life and vigour, the consummation of animal desire is frequent; but marriage is better deferred till September, when the offspring will be born in the May or June following, a season of the year when the poor man can better support the expenses of an accouchement than in the cold month respondent to marriages in May.
Edinburgh	50 4	- -	29 585	1·915	
Dublin .	52 193	- -	30 061	1·812	

1. *Calendar of Animated Nature round London.*

In the first week: the titlark (*Alaúda praténsis*) sings, the cuckoo (*Cúculus canòrus*) is heard; the gudgeon (*Cyprinus Gòbio*) spawns; the redstart (*Motacílla Phœnicùrus*), swift (*Hirúndo Apus*), whitethroat (*Motacílla Sylvia*), and stinging-fly (*Cònops cálcitrans*) appear.

Second week: the turtle-dove (*Colúmba Túrtur*) coos; the red ant (*Formìca rùbra*), the laughing wren (*Motacílla Currùca*), the common flesh-fly (*Músca vomitòria*), the lady-cow (*Coccinélla bipunctàta*), grasshopper lark (*Alaúda Locústæ vòcis*), and willow-wren (*Motacílla Salicària*) appear.

Third week: the blue flesh-fly (*Músca vomitòria*) appears; black snails (*Hèlix nìgra*) abound, and the large bat appears.

Fourth week: the great white-cabbage butterfly (*Papílio brássicæ*) and dragon fly (*Libéllula 4-maculàta*) appear; the glow-worm shines, and the fern-owl, or goat-sucker (*Caprimúlgus europæus*), returns.

2. *Calendar of Vegetable Nature round London.*

In the first week: *Gèum urbànum*, *Artemísia* campéstris; lily of the valley (*Convallària majàlis*), water-violet (*Hottònia palústris*), tulip-tree (*Liriodéndron tulipífera*), and numerous other plants in flower.

Second week: the oak, ash, sweet chestnut (*Castànea vésca*), hawthorn (*Méspilus Oxyacántha*), the common maple (*Acer campéstre*), horse-chestnut (*Æsculus Hippocástanum*), barberry (*Bérberis* vulgàris), and the *Ajuga réptans* in flower.

Third week: the water scorpion-grass, or forget-me-not (*Myosòtis scorpiöìdes*), lime-tree (*Tília*), milk-wort (*Polýgala* vulgàris), nightshade (*Atropa Belladónna*), and various American shrubs in flower, and rye (*Secàle hybérnum*) in ear.

Fourth week: oaks, ashes, and beeches now generally in leaf, and the mulberry (*Mòrus nìgra*) beginning to open its buds. The cinnamon rose and some other hardy roses in flower; and also the bramble (*Rùbus fruticòsus*), moneywort (*Lysimàchia Nummulària*), columbine (*Aquilègia vulgàris*), and various other trees and shrubs in blossom.

3. *Farm-yard.* (2902.)

Feeding and wintering on straw and roots generally ends, and soiling (5542.) or pasturage (5562.) commences, in the first fortnight. Where high-flavoured milk and butter are preferred to quantity, then pasturage on dry-bottomed uplands is to be preferred; but where quantity and richness is the object, soiling with clover and tares, and two or three hours' pasturage per day, for the sake of exercise, is the preferable system. Even on farms where there is nothing to mow but old meadow, soiling with that will be found more economical than pasturing it. A field of meadow in good heart, mown and eaten green, will, at a rough estimate, produce treble the quantity of milk it would have done if pastured, and four times as much as it would do in the form of dry hay.

The *yards* and *pits* are generally cleared of dung, urine, &c. at this season; and if no soiling goes on, they should be kept clean during the summer, excepting what room is required for the dung of the few stock which are there constantly, as pigs and poultry, or occasionally, as horses while harnessing, &c.

4. *Live Stock.* (6216.)

In turning *cattle* to grass, consider the different systems of pasturing (5816.); adopt what suits your circumstances, and pursue it regularly. See that water is not wanting to each field (4463.); nor shade, rubbing posts, and shelter. (5838.)

Lean stock are generally dear during this month, from the number of persons who buy in and feed off on grass. When cattle or sheep are very numerous, they are found to feed better, and do less injury to the grass, in small herds or flocks, than in large ones.

Mares may have the horse during the first week, but not later considering the season of parturition. (6637.)

5. *Grass Lands.* (5643.)

As most grasses send up their flower-stalks during this month, it is of importance so to stock pastures, as to eat these down. This is only to be accomplished in recently sown down lands by overstocking, and not then completely if rye grass prevails. When grass lands are to be mown, the best crop of hay will be obtained by not pasturing after the middle of April. Some may think that where cattle and sheep are fed till May or June, the stalks left will come in as hay; but as such fields cannot be mown till the end of July, the stalks have long before shed their seed and become dry, and so shrivelled as to be unfit for food.

Where *paring* and *burning* are wanted, this is a favourable season. (3209.)

Water-meadows, having been eaten down in April, are generally watered for the first three or four weeks of this month, to bring forward the crop of hay. (4429.)

6. *Arable Lands.* (4925.)

Summer wheat (5004.) and *grass seeds* (5873.) may still be sown, but not profitably after the first week or ten days. Swedish turnip (5409.), marygold, and yellow turnip may be profitably sown, and also early crops of common white turnip where the soil is clean and duly prepared. (5394.)

The preparation of *turnip fallows* is the great business of this month, and next the stirring of naked fallows (4944.), and the culture, by horse and hand hoes, of corns and pulse in drills. In late situations potatoes may be planted during the whole month (5316.); and hemp and flax sown during the first fortnight. (5880. and 5922.) Tares for successional supply. (5257.)

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)

Clean young *hedge-rows.* (2982.) Drains may now be advantageously designed, as the springs show themselves more conspicuously during winter. The rest in this department is mere routine.

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)

Grafted trees should be looked over occasionally, and any that the clay has dropped from re-covered. Remove suckers and superfluous side shoots.

Stir and clean the *hop-plantations*; place the poles, tie the vines where necessary; and towards the end of the month, when the number of shoots wanted have taken the lead; cover the stool or centre of the plant with a small hill of soil, to prevent it from sending up more shoots.

9. *Wood-lands and Plantations.* (3906.)

Continue to bark *oak trees*, and also the larch, and such others as are adapted for the farmer (4044.), but finish, if possible, by the middle of the month. Keep newly planted large trees properly staked, and all kinds of cultivated ground clear of weeds.

JUNE.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	63 22	2	29 93	0·332 inch.	The weather is sometimes cold at the beginning, but is generally agreeable and steady towards the middle of the month. By observing the columns indicating the greatest variation of the thermometer in each month, it will be seen that it varies, in London, only two degrees in June, which is less than in any of the preceding months. In July and August the variation is the same; but in March and October it is twice as much.
Edinburgh	57 2	- -	29 666	1·935	
Dublin -	58 76	- -	30 06	0·860	

1. *Calendar of Animated Nature round London.*

In the first week: the sedge-sparrow (*Passer arundinacea*), the fly-catcher (*Muscicapa Atricapilla*), the wasp (*Vespa vulgaris*), and several species of the bee and butterfly appear.

Second week: the burnet moth (*Sphinx filipendulæ*), and forest-fly (*Hippohosca equina*) appear; bees swarm.

Third week: several flies, butterflies, moths, beetles, and other insects appear.

Fourth week: insects abound; and singing-birds begin to retire to the woods, and leave off singing.

2. *Calendar of Vegetable Nature round London.*

In the first week: water-lilies (*Nymphæa* et *Nuphar*) flower; also *Iris* Pseud-acorus, *Anthemis Cotula*, *Polygonum Persicaria*, *Malva rotundifolia*, and numerous other plants.

Second week: the vine, raspberry, and elder in full flower; also various Scotch roses (*Rosa spinosissima*), broom (*Spartium*), nettle (*Urtica*), and wheat in the ear.

Third week: the *Orchis*, *Epilobium*, *Iris Xiphium* and *xiphioides*, the hardy *Ixiæ* and *Gladioli*, and a great variety of garden and field plants in flower; also the wheat and many of the pasture grasses.

Fourth week: some black and red currants ripe, strawberries in abundance; young shoots of trees and shrubs have nearly attained their length. Oats and barley in flower; blue-bottle, scabious (*Centaurea Cyanus*), and numerous others in bloom.

3. *Farm-yard.* (2902.)

Soiling is the principal operation now going forward (5542.), and requires the utmost attention to the cleanliness of the animals, whether fatting cattle, feeding milch cows, or horses.

4. *Live Stock.* (6216.)

Wash and shear sheep (7201.); examine flocks individually as to the fly (7173.); see to shade for every description of stock when the weather is hot. Bees swarm during this and next month.

5. *Grass Lands.* (5648.)

Hay-making is now a principal business (5544. and 5792.) Any tussocks or flower-stalks (bents) which appear, notwithstanding the close feeding of April and May, should now be mown (5772.); thistles and similar weeds cut out close by the root (6202.); pare and burn as in May (3209.); clean out ponds, water-courses, wells, &c. See that clovers, tares, or other soiling crops are mown close to the soil.

6. *Arable Lands.* (4925.)

Great part of the turnip process goes on during the three first weeks of this month and the latter half of May. (5373.) Dung fallows and otherwise bring them forward (4568.), draining (4213.), levelling, altering ridges, &c. as the case may require; weed broad-cast crops, and stir the soil between such as are in rows. Warping, where it can be practised, may now be commenced (4450.); thin out the first sown turnips. (5406.)

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)

Weed hedges, but avoid clipping them, which only creates a close surface of feeble shoots, that in the end becomes so thick as to exclude light and air from the central stems, and occasions their languishing and death. (2985.)

Dig and otherwise prepare materials for roads (3635.) and drains. (4284.)

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)

Insects, or other effects of what are called blights, can seldom be destroyed on so large a scale as that of the farm-orchard or hop-garden. Burning weeds or wet straw, litter, &c. will do something; and on a small scale, washing with lime-water, soap-suds, tobacco-water, or a mixture of these, will prove effectual. (6056.) Those who tie the binds or vine of the hop to the poles, instead of leaving them to nature, have generally completed the operation by the middle of the month. In some early spots the superfluous shoots are cut off about the end of the month.

9. *Wood-lands and Plantations.* (3906.)

The woodman is now chiefly employed in trussing up the branches of barked trees, and otherwise disposing of what is unfit for timber purposes. (4049.) Old copses or stools of trees, woods, or hedges, may now be advantageously stocked up, stacked, and when dry, charred for fuel. (4068.)

JULY.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	66 3	2	29 89	2·194 inch.	This was called *hay month* by the Saxons; and though hay-making near London is generally finished in June, yet in places where manure is less abundant, it is chiefly made in this month. The farmer's prospects as to crop may now be determined as to almost every article cultivated.
Edinburgh	60 6	- -	29 445	2·546	
Dublin -	61 13	- -	29 929	2·614	

1. *Calendar of Animated Nature round London.*

In the first week: the cuckoo (*Cuculus canorus*) leaves off singing; the stone-curlew (*Charadrius Œdicnemus*) whistles occasionally late at night, and the golden-crested wren (*Motacilla Regulus*) now and then chirps.

Second week: the quail (*Tetrao ferrugineus*) calls; the cuckoo-spit, or frog-hopper (*Cicada spumaria*), abounds.

Third week: young frogs migrate. Hens moult.

Fourth week: the great horse-fly (*Tabanus bovinus*) appears; and partridges fly.

2. *Calendar of Vegetable Nature round London.*

In the first week: enchanter's nightshade (*Circæa lutetiana*) and lavender (*Lavandula spica*) in flower, and pinks and carnations in full bloom.

Second week: the fallen star (*Tremella Nostoc*) appears; also puff-balls (*Lycoperdon Bovista*), and sometimes the common mushroom (*Agaricus campestris*).

Third week: raspberries and gooseberries ripe, potatoes in flower, asparagus in berry, the liliums in perfection.

Fourth week: the truffle (*Tuber cibarium*) now hunted or dug up in commons and forests; nightshade (*Solanum nigrum*), devil's bit (*Scabiosa succisa*), burnet saxifrage (*Pimpinella Saxifraga*), and a great number of plants in flower.

3. *Farm-yard.* (2902.)

As in June; between hay and corn harvest is generally a very good time for the farmer to make a tour to observe more extensively the practices of his own district, and to witness those of other districts.

4, 5. *Live Stock* (6216.) *and Grass Lands.* (5648.)

Lambs are now weaned (7161.) when not fattened off; at first they require the richest keep. As green food will now be abundant, every animal about a farm that can live and thrive or answer its end by the soiling system, should be so treated. The weather being hot, cattle or sheep in fields must be frequently looked to, as to shade, water, and abundant keep. Suffering from thirst, or a want of food, they are very apt to break through fences, which at this season is more than usually injurious, on account of the state of the corn crops.

6. *Arable Lands.* (4925.)

Attend to weeding, hoeing, and otherwise moving the soil between rowed crops, more especially potatoes and turnips. Towards the end of the month, the first-sown white turnips will be in a state to thin out; and a farther thinning may be advantageously given to field beet, carrots, &c., at this season. Where peas are sown for podding, they will now be in abundance for gathering; in warm situations sooner. Buck-wheat may now be sown for autumnal food for game. (6111.)

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)

As in June.

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)

Cherries, strawberries, gooseberries, &c., where grown as field-crops, are now in gathering, and towards the end of the month, fallen apples and plums for tarts. Hop-grounds are looked over, and the superfluous vine pruned off, &c. In Kent

and other places these prunings are often a perquisite of the pruner, who lays them aside as fodder for cows.

9. *Wood-lands and Plantations.* (3906.)

As in June; and prune the gean, which at other seasons is apt to bleed. (3995.) This season answers perfectly for pruning all sorts of trees; and if their leaves and spray were an object for fodder, as in Sweden and Italy, no doubt it would be preferred. (3994. and 3996.) Wounds in trees do not now bleed as they sometimes do in spring and autumn; and they heal, and are in part covered over with bark, before the approach of winter. (3993.)

AUGUST.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	65 85	2	30 06	0·824 inch.	This is the barn or *harvest month* of the Saxons; and, as every body knows, the busiest month of the agriculturist. It is, in consequence, the most profitable season for the labourer and his family, who are generally in full employ, and at an increase of wages, or perquisites, for four or six weeks at this season.
Edinburgh	60 6	- -	29 828	1·996	
Dublin -	62 82	- -	30 172	5·858	

1. *Calendar of Animated Nature round London.*

In the first week: flying ants (*Formica*) appear; bees kill their drones; and the swallow-tailed butterfly (*Papilio Machaon*) appears.

Second week: young martins (*Hirundo urbica*) and swallows (*Hirundo rustica*, begin to congregate, and swifts (*Hirundo Apus*) to depart; the whame, or burrel-fly (*Œstrus bovis*), lays eggs on horses.

Third week: the black-eyed marble butterfly (*Papilio Semele*) appears. Various birds re-assume their spring notes.

Fourth week: the nuthatch (*Sitta europæa*) chatters, the stone-curlew (*Charadrius Œdicnemus*) whistles at night, the goat-sucker (*Caprimulgus europæus*) and young owls (*Strix Ulula*) make a noise in the evening; robin-redbreast (*Motacilla Rubicola*) sings; and rooks roost on their nest-trees.

2. *Calendar of Vegetable Nature round London.*

In the first week: melilot (*Trifolium officinale*), rue (*Ruta graveolens*), yellow succory (*Picris hieracioides*), burdock (*Arctium Lappa*) in flower; the bread-corns ripe.

Second week: wild clary (*Salvia Verbenaca*), meadow-rue (*Thalictrum flavum*), ploughman's spikenard (*Conyza squarrosa*), and various other natives in flower.

Third week: the mallow (*Malva Lavatera*), hollyhock (*Alcea rosea*), and lobelias, among the garden-flowers; and the polygonums and potamogetons among the wild plants now in blossom.

Fourth week: the autumnal crocus (*Colchicum autumnale*), *Aster* Solidago, *Senecio paludosus*, teasel (*Dipsacus fullonum*), and various other plants in flower. The earlier varieties of all the hardy kernel fruits ripe.

3. *Farm-yard.* (2902.)

The *rick-yard* should now be attended to (2906.); stack-stands repaired or put in order: bottoming of faggots, and straw or rape haulm got together; thatch in readiness, and ropes made. (3184.)

At any spare period the teams may be employed carting out the summer-made dung to the wheat fallows, or to form field dunghills for spring crops, &c.

4. *Live Stock.* (6216.)

Select the stock of *lambs* to be kept as breeders. (7170.) Swine commonly bring their second litter of pigs in this month; which, owing to the dropping corn, is generally one of abundant keep, both for them and poultry. Farmers in some places look to the stubbles as a source of good food for their cows, as others do to the fallows for keep for their sheep. Where either is the case, the culture must be of a very inferior description.

5. *Grass Lands.* (5643.)

Where *meadows* are manured, that operation generally goes on after the hay is removed, or during winter; the surface in the former case being hard with drought, and in the latter by frost. After grass should in general be shut up and reserved for later keep, and in some cases as a winter resource. Keep down weeds, tussocks, ant-hills, &c. Turn the water on meadow-lands as soon as the hay is removed, and let it remain till a third crop is in forwardness. (4387.)

6. *Arable Lands.* (4925.)

Weed and stir among green crops, earth up potatoes (5336.), but by no means turnips, unless the soil is very dry indeed, as that operation only prevents them from attaining a full size. Reaping commences in all the southern districts in the first week of this month, and in some by the middle of July. When the operation is executed by day-work, the most unremitting inspection of the master is necessary; and even when the greatly preferable mode of reaping by the acre is adopted, he should be continually in motion from one party to another, to see that the operation is performed low and clean.

Naked fallows in late situations receive the seed furrow during this month, excepting in cases where the seed is ploughed in, an operation generally deferred to the middle of September. Sow cabbage-seeds (4497.) for plants to put out in April next. Sow turnips after early peas which have been podded (5209.), or early cut wheat, tares, cabbages, &c., or after hemp and flax, which are generally pulled by the middle of this month. (5880. and 5922.) Grass seeds sown alone at this season (5692.) will generally succeed better than at any other; they germinate as well in spring; but the heats of July often burn up the tender plants.

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)

As in the two preceding months.

8. *Orchards* (4099.) *and Hop-grounds.* (5997.)

Apples and plums of some sorts are now ripe. Grafts may in general be untied. Budding performed, and pruning, if desirable, as observed last month under woods and plantations.

9. *Wood-lands and Plantations.* (3906.)

See last month.

SEPTEMBER.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	59 63	3 5	30 09	0·482 inch.	The temperature begins now to decline and to vary; the nights begins to lengthen, and heavy dews and diminished transpiration and evaporation promote the growth of grass, herbage, plants, and especially turnips. This is still a busy month with the agriculturists; in the warmest situations he is finishing harvest-work, and in the latest commencing it. Animals of most sorts are now fat; fruits are ripe; honey abundant; and most produots of the earth in perfection and plenty.
Edinburgh	54 3	- -	29 759	3·470	
Dublin -	59 35	- -	30 239	3·021	

1. *Calendar of Animated Nature round London.*

In the first week: young broods of goldfinches (*Fringilla Carduelis*) appear. The linnet (*Fringilla Linota*) congregates. The bull (*Bos Taurus*) makes his shrill autumnal noise; and swallows (*Hirundo rustica*) sing.

Second week: common owls (*Strix flammea*) hoot. The saffron butterfly (*Papilio Hyale*) and willow red under-wing moth (*Phalæna picta*) appear. Herrings (*Clupea Harengus*) are now cheap.

Third week: the ring ouzle (*Turdus torquatus*) appears. The fly-catcher (*Muscicapa Atricapilla*) withdraws.

Fourth week: the stare (*Sturnus vulgaris*) congregates. The wood-lark (*Alauda arborea*) sings. The woodcock (*Scolopax rusticola*) and fieldfare (*Turdus pilaris*) appear; and the swallow (*Hirundo rustica*) departs.

2. *Calendar of Vegetable Nature round London.*

In the first week: some fungi and *Ballota alba* appear, traveller's joy (*Clematis alba*) and *Parnassia palustris* in flower.

Second week: catkins of the hazel and birch formed; blossoms, and green, red, and black berries found on the bramble at the same time. Leaves of the sycamore, birch, lime, mountain-ash and elm, begin to change colour.

Third week: the ivy (*Hedera Helix*), laurel (*Prunus Laurocerasus* and furze (*Ulex europæa*) in flower.

Fourth week: hips, haws, and nuts ripe. Leaves of plane-tree (*Platanus*) tawny; of the hazel, yellow; of the oak, yellowish-green; of the sycamore, dirty brown; of the maple, pale yellow; of the ash, fine lemon; of the elm, orange; of the hawthorn, tawny yellow; of the cherry, red; of the hornbeam, bright yellow; of the willow, hoary.

3. *Farm-yard.* (2902.)

The *rick-yard* is now the chief scene of operations, in getting earlier crops thatched (3185.) and later ones stacked. (3276.) In all operations in this department attend, as far as circumstances will permit, to neatness. In the case of a proprietor or amateur, neatness, order, and high keeping are essential in every department.

4. *Live Stock.* (6216.)

There is generally abundance of fat cattle and sheep in the market during this and next month. Lean stock, especially crones and wedders, are now brought in, and wintered or fed off on turnips. Wintering cattle (6855.) also about the end of the month. Poultry and pigs are now fat, and honey may be taken from bee-hives.

5. *Grass Lands.* (5643.)

As in August. Newly sown grass lands should now be sparingly fed, in order to strengthen the plants for the winter.

6. *Arable Lands.* (4925.)

This is the chief season for sowing winter wheat, whether on naked fallows or after clover, tares, rape, or early crops of peas and beans. Potatoes are generally not taken up till the end of the month, in which case the sowing after that crop is later. (5015.) Sow tares to stand the winter (5257.), and grass seed, for permanent pasture; or a hay crop next season will succeed on good soils, if sown before the middle of the month. (5533.)

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)

Routine operations of mending, &c. as before.

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)

Gather *fruits* for immediate sale, the keeping sorts not being yet ripe. (4085.) Walnuts for pickling not later than the first week. (4102.)

Hop-picking and drying, in the districts where this plant is much cultivated, is the great business of the month. (6036.)

9. *Wood-lands and Plantations.* (3906.)

Routine operations as in the two or three preceding months Plant evergreens during the three last weeks, and deciduous trees the last ten days. (3937.)

OCTOBER.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	52 81	4	29 69	2·027 inch.	The weather of this month is very uncertain. Before those rains, snows, or frosts which constitute the practical commencement of winter, there is generally two or three weeks of settled weather; sometimes these weeks are in October, sometimes partly in November. These weeks afford a last resource for bringing forward neglected operations.
Edinburgh	49 7	-	29 339	3·334	
Dublin -	51	- -	29 76	2·798	

1. *Calendar of Animated Nature round London.*

In the first week: the red-wing (*Túrdus iliacus*) arrives. Snakes and vipers bury themselves.

Second week: hooded crows (*Córvus Córnix*) and wood-pigeons (*Colúmba Palúmbus*) arrive; hen-chaffinches (*Fringílla cœlebs*) congregate, and prepare for migration, leaving their males in this country.

Third week: the snipe (*Scólopax Gallinàgo*) appears in the meadows. Wild-geese (*Anas sylvéstris*) leave the fens, and go to the rye-lands.

Fourth week: the tortoise (*Testùdo græca*) begins to bury himself in the ground; and rooks visit their nest-trees. Some larks (*Alaúdæ*) sing, and the woodcock (*Scólopax rustícola*) returns. Spiders' webs abound.

2 *Calendar of Vegetable Nature round London.*

In the first week: strawberry-tree (*Arbutus Unedo*), holly (*Ilex Aquifólium*), China hollyhock (*Alcèa chinénsis*), and China aster (*Aster chinénsis*), in bloom.

Second week: catkins of some species of *Sàlix* formed; leaves of the asp almost all off; of the Spanish chestnut, yellow; of the sugar-maple (*Acer saccharínum*) scarlet; of the common birch, yellow and gold; and of the weeping-birch, gold and bright-red coloured.

Third week: Clématis calycìna in flower. Some horse-chestnuts and acacias quite denuded of leaves.

Fourth week: various plants, especially annuals, continue in flower. Leaves of marsh-elder (*Sambùcus Ebulus*), of a fine pink; of stag's-horn sumach, of a purplish-red; of the American oaks, of fine shades of yellow, orange, red, and purple.

3. *Farm-yard.* (2902.)

This is the season of rural plenty, affording an opportunity, both to men and animals, for laying in a large stock of health, to enable them to support the severity of the coming winter. Operatives should now buy in their winter stores of potatoes, fuel, &c. and ridge up their garden ground, not under crop, for the winter.

Corn crops being generally in the rick-yard by Michaelmas, and the root and herbage crops not taken being at or near maturity, the first of October is the most suitable season for a farmer to take stock and ascertain his annual profit or loss. Michaelmas being also the most general term of entry and removal, especially in the case of arable farms, is another reason why agricultural accounts are conveniently made up to this period. (4883.) Examine your household accounts, and if your expenses have exceeded your income, or even come up to it, look over the particulars with your wife or housekeeper, and see on which you can retrench. This is an essential process for all who would proceed in life with any thing like peace of mind, or the permanent respect of their neighbours. (4921.) Remember that very small indeed is the net income of a rent-paying agriculturist.

Michaelmas is also the general term for hiring farm-servants by the year; but the seldomer agricultural operatives are changed the better, unless in the case of senseless, indolent, or viciously inclined persons, who degenerate unless frequently removed.

4. *Live Stock.* (6216.)

Cattle and sheep not sufficiently fatted on grass or herbage, whether by pasturage or soiling, should now be put on other food, to complete them for the butcher. Oil-cake, grains, turnips, carrots, or, in default of these, bruised corn may be used. The same observations may be applied to hogs, which are generally in good condition at this season. (7315.)

Hog porridge. A mixture of oatmeal and water, or any other meal and water, left till it becomes sour, as practised by the millers in the northern counties, will feed hogs rapidly; but milk and peas meal make the finest pork in the world.

The *teams* which have been soiled during summer, may now be put on hay, straw, and carrots, or other roots, by degrees. (6752.)

5. *Grass Lands.* (5643.)

Where these are manured, this is a good season for the operation (5782.); choose dry weather.

6. *Arable Lands.* (4925.)

Potatoes (5291.), carrots (5443.), field beet (5482.), parsneps (5471.), and Swedish turnips, may now be taken up and housed, and the ground sown with wheat. This grain (5001.), rye (5069.), barley (5080.) in some situations, and tares (5257.) may still be sown in the milder districts. Embrace every opportunity to give the first furrow to fallows (4944.), whether for green crops or otherwise. In general all lands that are to have two or more furrows before they are sown or planted, should be ploughed as soon as possible after harvest; but not so lands that are to be sown on one furrow, which are better ploughed in January and February. It is a great mistake to suppose that ploughing land in autumn destroys the eggs or larvæ of insects (7695.), or the seeds of weeds; on the contrary, it may often, by giving them a deeper covering, preserve them better from the winter's frost, or what is much more destructive, from being devoured by birds. There are few subjects less generally understood than the economy of nature in regard to the eggs of insects and worms. (Turn to 7644. and 7704.) See that water furrows and drains run freely, and that fences and gates are in repair.

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)

Hedges may now be advantageously planted (2978.), grown ones pruned (2983.), old ones plashed (2989.), and imperfect ones repaired. (2993.) The Northumberland practice as to hedges (7809.) well deserves the study of the more southern agriculturalist. Roads and drains may be made or repaired at this season, and in spring, with better effect than during the heat and drought of summer. Road materials now bind better, and land-springs show themselves more distinctly.

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)

The *winter fruits* may now be gathered, and either spread in an airy loft or upper floor, there to remain till used, or sweated in heaps, to extract a part of their moisture, and then buried in dry sand, or packed in close boxes or casks, to be kept in a cool and dry cellar. (1834. and *Encyc. of Gardening*, 2d Edit. 2289.)

Fruits trees of every kind may now be planted (4105.) and pruned. (4111.)

Hop-picking is generally completed the first week of the month; and as soon afterwards as convenient, the vine and poles removed, and the latter stacked till next spring. (6047.) Young hop plantations may be formed (6005.), and the soil among established grounds manured and ploughed. (6019.)

9. *Wood-lands and Plantations.* (3906.)

Hedges and plantations of evergreen trees may be made during the first week of the month; and no period of the year is better for transplanting all kinds of hardy shrubs.

Timber and coppice may be felled, and in general every operation preparatory to planting, as well as the operation itself, may go forward.

NOVEMBER.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	44 44	4	29 68	2·527 inch.	This is the *windy month* of the Saxons; it is generally also cold and moist, and one of the most disagreeable for the labouring agriculturists; but he may console himself with the shortness of the day, and hail the approach of evening, when he may lay aside his wet dress and fortify his mind by converse with books, or enjoy the comforts of his fire-side, and the solace of his wife and children; reading to or otherwise instructing them, or mending his boots or shoes.
Edinburgh	41 1	- -	29 638	4·514	
Dublin -	43	- -	29 74	0·394	

1. *Calendar of Animated Nature round London.*
In the first week: the buck (Cérvus Capréolus) grunts.
Second week: the golden plover (Charàdrius pluviàlis) appears.
Third week: snails (Limax) and slugs (Hèlix) bury themselves.
Fourth week: greenfinches (Fringilla Montifringilla) flock. The winter moth (Geómetra brumària *Sam.*) and the common flat-body moth (Geómetra applàna *Sam.*) appear in gardens about the end of the month.

2. *Calendar of Vegetable Nature round London.*
In the first week: a few plants in flower, by accident, chiefly annuals, according to the season.
Second week: the fungus Helvélla mìtra appears. Laurustinus in flower.
Third week: Chimonánthus frágrans in flower.
Fourth week: some primroses show flowers at this season; and some plants, unnaturally in flower, still continue if the weather is temperate.

3. *Farm-yard.* (2902.)
Wintering cattle are now introduced to the straw-yards (2902.) or hammels (2831.), and others to stalls for feeding or fatting. Live stock in general ought to be kept in good condition at this season, otherwise they are apt to fall off towards spring. Threshing goes on at intervals to supply straw. (3198. and 2773.)

4. *Live Stock.* (6216.)
See Farm-yard.

5. *Grass Lands.* (5643.)
Manure in dry weather (5782.); turn the water on meadows adapted for irrigation (4387.); destroy ant-hills (5775.); drain by surface gutters, or other means, where that operation is requisite; clear out water furrows for the same purpose; admit cattle and horses only on the driest pastures; see that sheep have shelter, and especially Dorset ewes likely to lamb next month.

6. *Arable Lands.* (4925.)
See that water furrows and drains run unobstructed; plough and cart out manure, as weather and other circumstances permit.

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)
As in last month; and see that they are in effectual repair, and fairly used.

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)
Complete the operations of last month, where interrupted, deferred, or neglected.

9. *Wood-lands and Plantations.* (3906.)
As in last month, excepting when the weather is unfavourable. Felling all kinds of timber and coppice not adapted for barking for the tanner, may now go on freely, (4044.) Willows for baskets may be cut over (4042.), and baskets, hampers, crates, and hurdles, made by the woodman and hedger.

DECEMBER.

Weather at	Average of the Thermometer.	Greatest Variation from the Average.	Average of the Barometer.	Quantity of Rain.	REMARKS.
London -	41 4	3	29 64	1·124 inch.	*Winter month*, Sax. Cold but dry. The agricultural operations are chiefly of the laborious kind; but the days are short and the nights long. In the last week the young operator should examine himself as to his professional and intellectual progress during the bye-past year, and form plans for further improving himself for the year to come. Knowledge is a lever by which a man may raise himself as high as he desires.
Edinburgh	38 9	- -	29 66	2·598	
Dublin -	36 34	- -	29 723	2·916	

1. *Calendar of Animated Nature round London.*
The mole (Tálpa europæ'a) throws up hillocks. The December moth (Eriogáster pópuli *Sam.*) appears about the beginning, and the yellow-line quaker (Nóctua flavilínea *Sam.*) about the end of the month.

2. *Calendar of Vegetable Nature round London.*
Some of the last month's plants continue in flower, according to the weather.

3, 4. *Farm-Yard* (2902.), *and Live Stock.* (6216.)
Threshing, and otherwise preparing corn and straw for the market, and the use of the working, fattening, wintering, and store stock are the main operations. Next, the regular supply of live stock with food, and cleaning and littering them. Fatting stock should be particularly attended to, especially house lamb (7227.) and calves. (6855.)
The supply of turnips for cattle and sheep is liable to be interrupted by severe frosts, if the precaution of housing a quantity (5420.), or setting them (5421.), is not taken in time. Where oil cake, rape cake, or dust (6094.), brewers or distillers' grains (5112.) are used, supplies must be secured; and where hogs or cattle are fed on meal and water mixed and soured, a quantity must always be kept in mixture; as a week or ten days in temperate weather, and a longer period during frost, is requisite to induce the fermentation.

5. *Grass Lands.* (5643.)
See that they are not poached: that water furrows, gutters, drains, and ditches are in repair; and where manuring is practised, cart it out in frosty weather where there is no danger of injury from the feet of horses or cart-wheels. Unless labour is very cheap, carting earths or earthy composts on grass lands will not pay the expenses; they produce more effect on arable lands.

6. *Arable Lands.* (4925.)
See that all the modes of drainage are effective. (4278.) Plough and cart out manure according to weather and other circumstances.

7. *Fences* (2960.), *Roads* (3523.), *and Drains.* (4213.)
Plant hedges (2977.) and build walls only in temperate weather, as frosty air injures the roots of plants, and freezes humid mortar, thereby effectually preventing its setting. Roads and drains may be made and mended in all weathers that admit these operations.

8. *Orchards* (4079.) *and Hop-grounds.* (5997.)
Clear old trees of moss or misletoe; but prune only in mild weather. Dig and dung at any time.

9. *Wood-lands and Plantations.* (3906.)
Fell timber or copse of sorts not adapted for barking. (4044.) Stock or grub up tree roots, stacking them for fuel or charcoal. (4068.) Trench, dig, or otherwise prepare ground for planting; but lift plants from the nursery, and re-insert them in plantations only in mild weather, and when the soil does not poach by treading, &c. The rest as in November.

Evergreens, as Mr. M'Nab has ably shown and proved by experience, may be planted at any period during winter, when the weather is mild. He says, "I have planted evergreens at all seasons of the year with nearly equal success, except from the middle of June to the middle of August, and even during this period I have planted some: but unless the weather is very dull and moist, and even with such weather, it is difficult to prevent the plants suffering considerably, and in many cases it is years before they recover. Although, however, I have planted evergreens ten months out of the twelve, with little difference in the success, yet one season has a preference over the others with me; and when there is the power of choice, I would recommend late in autumn, winter, or early in spring; that is, any time from the middle of October to the middle of February, and in general the beginning of this period is the best; that is, from the middle of October to the middle of December, always providing that the weather and the ground are favourable; that is, supposing there is no frost, no drying wind, nor much sunshine, and that the ground is not too much saturated with wet, either from continued rain, or from the nature of the soil. One of the principal things to be attended to in planting evergreens is, to fix on a dull day for winter planting, and a moist day for spring and autumn planting. There can be no secret in the proper treatment of evergreens; if there were, I should say, that it is in preventing their roots becoming dry when out of the earth; to choose moist and cloudy weather for planting; and still better, if we had the power, by foresight or otherwise, to secure a continuance of such weather some time after they have been planted." (*M'Nab's Hints on the Planting and General Treatment of Hardy Evergreens in the Climate of Scotland, &c.* p. 17.)
Mr. Cruikshank has shown that poor waste ground, which, if trenched or ploughed would not bear a crop of grain, will, after being planted and kept under wood for some years, become fit for every purpose of agriculture. "On a rising ground, not far from the village of Ellon, a piece of ground of a dry gravelly nature, which has lately been cleared of a crop of full-grown Scotch firs, was trenched in a very partial and imperfect manner, the roots of the trees being scarcely eradicated. It was then sown with oats, without receiving lime, dung, or manure of any other description; yet the crop was so luxuriant, that a great part of it lodged. The following spring, the ground was again sown with the same species of grain, without receiving any enrichment; and, when harvest arrived, the crop was unequalled by that of the richest fields, in a neighbourhood which is generally considered fertile. The experiment was tried a third time, still without manure, and the return was again considerably above an average. The soil, as has already been remarked, was dry and gravelly, and far from possessing any natural qualities that could have been the cause of such extraordinary productiveness. When planted, it had been covered with heath, and in that state had not been superior to those waste lands which we occasionally see improved at a vast expense, and which will produce no kind of crop till they receive a great quantity of manure." (*Cruikshank's Practical Planter, &c.*)

GLOSSARIAL INDEX.

D.

E.

F.

G.

H.

Ha-ha, a sunk fence, p. 474.
Hacking and picking. See *Picking.*
Hainault mowing, explained, s. 3172. p. 515.
Hammel, a small shed, with a yard for feeding one, or at most two animals, p. 469.
Hands of tobacco, leaves tied up by their footstalks, so that the leaves spread out like the hand, s. 3945. p. 641.
Hangs, slopes, s. 3945. p. 641.
Harled, p. 497. See *Lipped.*
Hash, explained, s. 2716. p. 419.
Hatches, flood-gates, p. 726.
Hatted kitt, explained, s. 7105. p 1048.
Hattocks, shocks, s. 3173. p. 515.
Haulm, the base of the stalks or stems of all crops, after the seeds are reaped or gathered. The haulm of peas is in some places called pea ryse.
Head and heel of gates, explained, p. 500.
Heading down trees, lopping or cutting off the heads of trees, p. 651.
Heading sheaves, the hood sheaf or sheaves of shocks of corn, p. 515.
Headmain, explained, s. 4411. p. 726.
Heckles, iron combs, p. 923.
Heckling flax, combing, p. 916.
Helmets, a variety of pigeon, p. 1095.
Hepatic affections, affections of the liver, p. 1037.
Herbage plants, forage plants, such as clover and other plants cultivated chiefly for the herb, to be used either green or made into hay.
Hide-bound, a disease in horses and cattle when the skin cleaves to the sides, s. 6425. p. 977.
Hink, explained s. 5171. p. 832.
Hinny, explained, s. 6768. p. 1013.
Hirsel, a Scotch term of the same meaning as the English term "herd," s. 6793. p. 1017.
Hoars, thick mists, p. 772.
Holmes, small islands, but larger than aits.
Hood-sheaf, a sheaf placed on the summit of other sheaves for a covering, p. 516.
Hook bones, bones in the hind quarter of cattle, s. 6799. p. 1018.
Horny frog of the horse, the prominence in the hollow of a horse's foot, p. 976.
Horsemen, a variety of pigeon, p. 1095.
Horses, pieces of wood used in barking trees, p. 659.
Hot fur, explained, s. 5906. p. 824.
Hot yellows, explained, s. 7256. p. 1065.
Hove, explained, s. 7254. p. 1065.
Huckaback, a kind of cloth, s. 5933. p.917.
Hùmerus, the arm bone, p. 965.
Hummelling machine, explained, p. 440.
Hunger rot, explained, s. 7264. p. 1066.
Hungry soil, barren soil needing much manure, p. 773.
Husbandman, one who farms generally; that is, who both produces corn and cattle, and attends to the dairy, the poultry, the woodlands, and the orchard. A farmer may confine himself to grazing, or to breeding or haymaking or milking or raising green crops for the market, &c., but in none of these cases can he with propriety be called a husbandman. This term husbandman, therefore, is not exactly synonymous with farmer.
Husbandry, the culture of arable grass and woodlands, the management of live stock, the dairy, poultry, &c., and, in general, what constitutes the business of the head of a family living by agricultural industry in the country.
Hybrid, bastard or spurious, p. 1013.
Hydatid, the *Tæ`nia* glóbulus, an insect occurring in the skull of the sheep, p. 1049.
Hydropic rot, explained, s. 7261. p. 1065.
Hygrometer, an instrument for ascertaining the degree of moisture in the atmosphere, p. 773.

I.

Imàgo, the perfect state of insects, p. 1112.
Impinge, to strike against, s. 4361. p. 719.
In and in system of breeding, p. 301.
Incision of objects on roads, the marks, traces, tracks, or ruts made, s. 3571. p. 575.
Increments, proportional rates of increase, s. 3552. p. 572.
Indigenæ, peculiar to, springing out of the nature of, p. 1012.
Induration, hardening, p. 717.
Infield, an obsolete Scottish term for enclosed lands near the farmstead, as opposed to such as are at a distance from it, and uninclosed, s. 802. p. 130.
Ings. See *Saltings.*
Iris, the coloured circle in the eyes of animals, s. 6371. p. 970.
Isometrical perspective, explained, p. 472.
Isosceles triangle, a triangle which has only two of its sides equal, p. 503.
Itinerating libraries, libraries, the books of which are carried from one place of deposit to another, and thence issued, p. 756.
Jacobines, a variety of pigeon, p. 1095.
Jumper, a tool used by masons for boring holes in land stones to be reft by gunpowder, p. 743.
Jumping pole, a long stiff pole, by which persons in the fens are enabled to jump across ditches or drains twenty feet wide, by planting the pole towards the middle of the drain, and springing from bank to bank: a small piece of board, called a quant, is fastened to the bottom of the pole to prevent its sinking into the mud. See *Quant.*

K.

Kelp, the ashes of any description of *Fùci* or other seaweed, p. 1205.
Knees for ship-building, crooked pieces of timber, having two branches or arms, and generally used to connect the beams of a ship with her sides, s. 3034. p. 491.
Knuckering, explained, s. 6387. p. 972.
Kyloes, the name given to the cattle of the Hebrides, s. 6796. p. 1018.

L.

Lachrymal gland, the gland which secretes or supplies the *lachrymæ* or tears, p. 970.
Lacteals, the absorbents of the mesentery, which originate in the small intestines, and convey the chyle from thence to the thoracic duct, p. 968, See *Crabb's Tech. Dict.*
Lactometer, explained, s. 7008. p. 1037.
Lampas, a swelling of the wrinkles or ribs in the roof of the horse's mouth; analogous to the gumboils in man, p. 980.
Land, a term employed in Cambridgeshire and other counties, to designate what more generally is termed a ridge; that is, one of those compartments which lie between gutter and gutter in arable fields. The ridge, in Cambridgeshire, is the highest part or central line of the lands, just as the ridge of a house is the highest part of its roof. In Scotland, a ridge includes the whole of the surface between gutter and gutter. Land appears the fitter term.
Land, ground, earthy surface in opposition to water or rocks. The term ground is generally applied to a comparatively limited extent of surface, as garden grounds, hop grounds, &c. in opposition to arable lands, wood lands, &c.
Land-fast stones, stones fixed or imbedded in the soil, p. 483.
Land-reeve, explained, s. 4638. p. 760.
Larvæ, the grubs, maggots, or caterpillars of insects, 803.
Laryngeal sonorous sacs, hollows in the windpipe which modulate the voice of animals, s. 6764. p. 1013.
Larynx, the windpipe or trachea, p. 972.
Lateral shoots, shoots emitted on the sides of branches; laterally; quite distinct from latter shoots, with which they are occasionally confounded, p. 478.
Laying in hedge-planting, laying down the sets or plants horizontally on the bed prepared for them, s. 3944. p. 640.
Laying an old hedge, explained, s. 3026. p. 490.
Leaping ill, explained, s. 7253. p. 1065.
Leasehold, property held on lease, p. 552.
Legget, explained, s. 3193. p. 518.
Leguminous crops, crops of the various kinds of pulse, as peas, beans, tares, saintfoin, lucern, clover, &c., p. 800.
Levelling, explained, p. 535.
Leverage, the act of using levers, or the power acquired by the use of them, p. 575.
Light-layered, the dew-lap of a light colour, s. 6798. p. 1018.
Ligneous plants, woody plants, as trees or shrubs, p. 476.
Lipped and harled, a wall built of stones without mortar, but which has the joints afterwards filled with mortar, and the whole wall plastered over with what is called rough-cast, or harling in Scotland. The mixture used for harling is lime, sand, and small stones about the size of peas. Dashing in England is the forcible casting of small stones

SUPPLEMENT.

2789 *a* and 7790 *a*. *Threshing machines.* One of the most complete in England has been erected at the Duke of Gloucester's farmery at Bagshot Park; for the following description and drawings of which we are indebted to Mr. Anderson, an experienced agricultural engineer. This machine threshes the corn, hummels barley, winnows, sifts, and cleans corn, grinds it into flour, cuts the straw into chaff, and grinds bones for manure; and any one of these operations can be performed without the other. The different parts of this apparatus are chiefly taken from machines already in existence, but some also are original. It may be mentioned as a singular and melancholy sign of the times, that the parties who have the chief merit are afraid of giving their names to the public. The agriculturists of a future and, we trust, no distant day will hardly believe it possible that the destruction of threshing machines should have been popular in England in 1830. It is worthy of notice as an argument in favour of the diffusion of knowledge among the labouring classes, that, so far from threshing machines being destroyed in Scotland, they are so much in repute among the labourers of that country, that a farmer who is without one is obliged to pay higher wages to his servants. This fact is well authenticated by a correspondent in the *Examiner* newspaper of February 13. 1831. See the examination of Joseph Forster in No. 1. of *The Working Man's Companion*, and also in *Mech. Mag.* vol. xiv. p. 323.

The mechanical part of the machinery was executed and erected chiefly by Mr. George Miller, now residing near Bagshot. *Fig.* 1139. is partly a section, and partly a side view; *fig.* 1140. is partly a cross section, and partly an end view; and *fig.* 1141. is partly a vertical section, and partly a vertical profile. The same letters are applied to the same parts in all the figures.

Description of the machinery. (*figs.* 1139. 1140. 1141.) *a* is an overshot water wheel 15 feet diameter, which makes from six to eight revolutions per minute according to the supply of water; on the arms of the water wheel is fixed a bevel wheel *b* of 128 cogs (seven feet four inches diameter), working into the pinion *c* of 26 cogs (twenty inches diameter), on the upright shaft *d*: these wheels are below the ground floor, and entirely hid from the view.

On the shaft *d* are two driving wheels *g* and *f*: *g* is a spur wheel of 119 cogs (six feet two inches diameter), driving the pinion *e* of 22 cogs (14 inches diameter) on the shaft *h*, which leads to the floor above, and turns the upper millstone; *f* is a mitre wheel of 40 cogs (two feet diameter), working into two wheels *i* and *k* of the same dimensions.

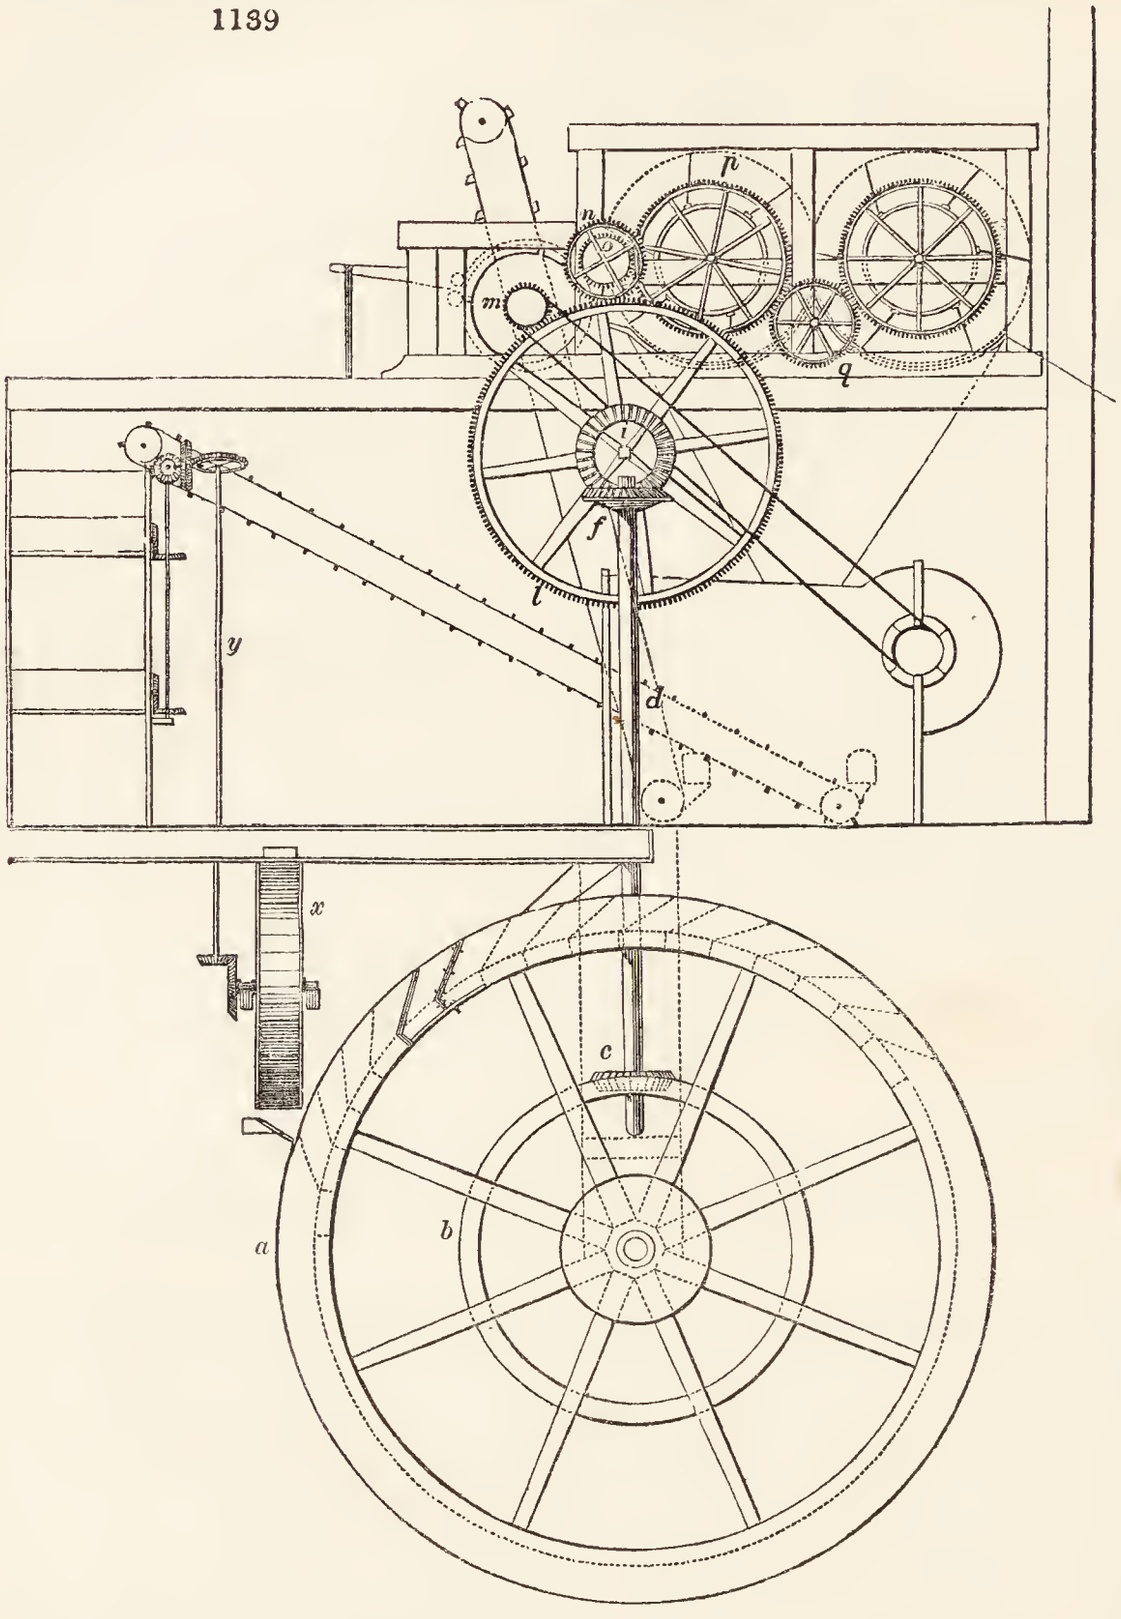
On the same shaft as the mitre wheel *i* is a spur wheel *l* of 200 cogs (six feet eight inches diameter) working into the threshing machine drum pinion *m* of 20 cogs (eleven inches diameter); the spur wheel *l* also drives a wheel *n* of 39 cogs (22 inches diameter), on the same axis of which is a small wheel *o* of 26 cogs (ten inches diameter), working into the wheel *p* of 121 cogs (three feet four inches diameter), on the axis of the first rake or shaker: the wheel *p* gives motion to the intermediate wheel *q* of 72 cogs (two feet diameter), which works into the second shaker wheel of the same dimensions as the first shaker wheel *p*.

On the spindle on which the wheel *n* is mounted is a small shifting pinion *r* of 17 cogs (seven inches diameter), working into the faced wheel *s*, on which are two rows of cogs, one of 20 and the other of 30 cogs each. On the same axis as the faced wheel *s* is a bevel wheel *t* of 20 cogs (eight inches diameter), working into the wheels *u* and *v* of 40 cogs (sixteen inches diameter), on the lower feeding roller spindle; these two wheels are not fixed on the spindle, but revolve freely on turned parts of the shaft, and give motion to it by means of the clutch and handle *w*. When the machine is at work the clutch is in the wheel *v*, giving to the feeding rollers the required motion; should it be necessary to stop the rollers, the handle *w* is moved from the feeding board, and the clutch disengaged from the wheel *v*. Should the handle be moved farther from the feeding board, the clutch is thrown into the wheel *u*, and the rollers turn the reverse way.

The winnowing machine under the shakers is driven by a sheave on the drum axis, and a rope leading to a sheave on the fanner spindle; to dress the grain thoroughly, it is conveyed from this machine, and passes through two winnowing machines, one placed above the other: this is effected by means of a canvass cloth on which are strips of wood half an inch in thickness; the cloth revolves on two rollers, and is set in motion by a rope leading from a sheave on the shaft *i* to a sheave on the upper roller spindle.

As it is absolutely necessary to have a steady and uniform motion to produce the best possible sample from a winnowing machine, and as the velocity of the threshing machine is subject to vary, from irregular feeding and other causes, the winnowing or dressing machines are set in motion by a small water-wheel *x*, five feet diameter, on the axis of

1139

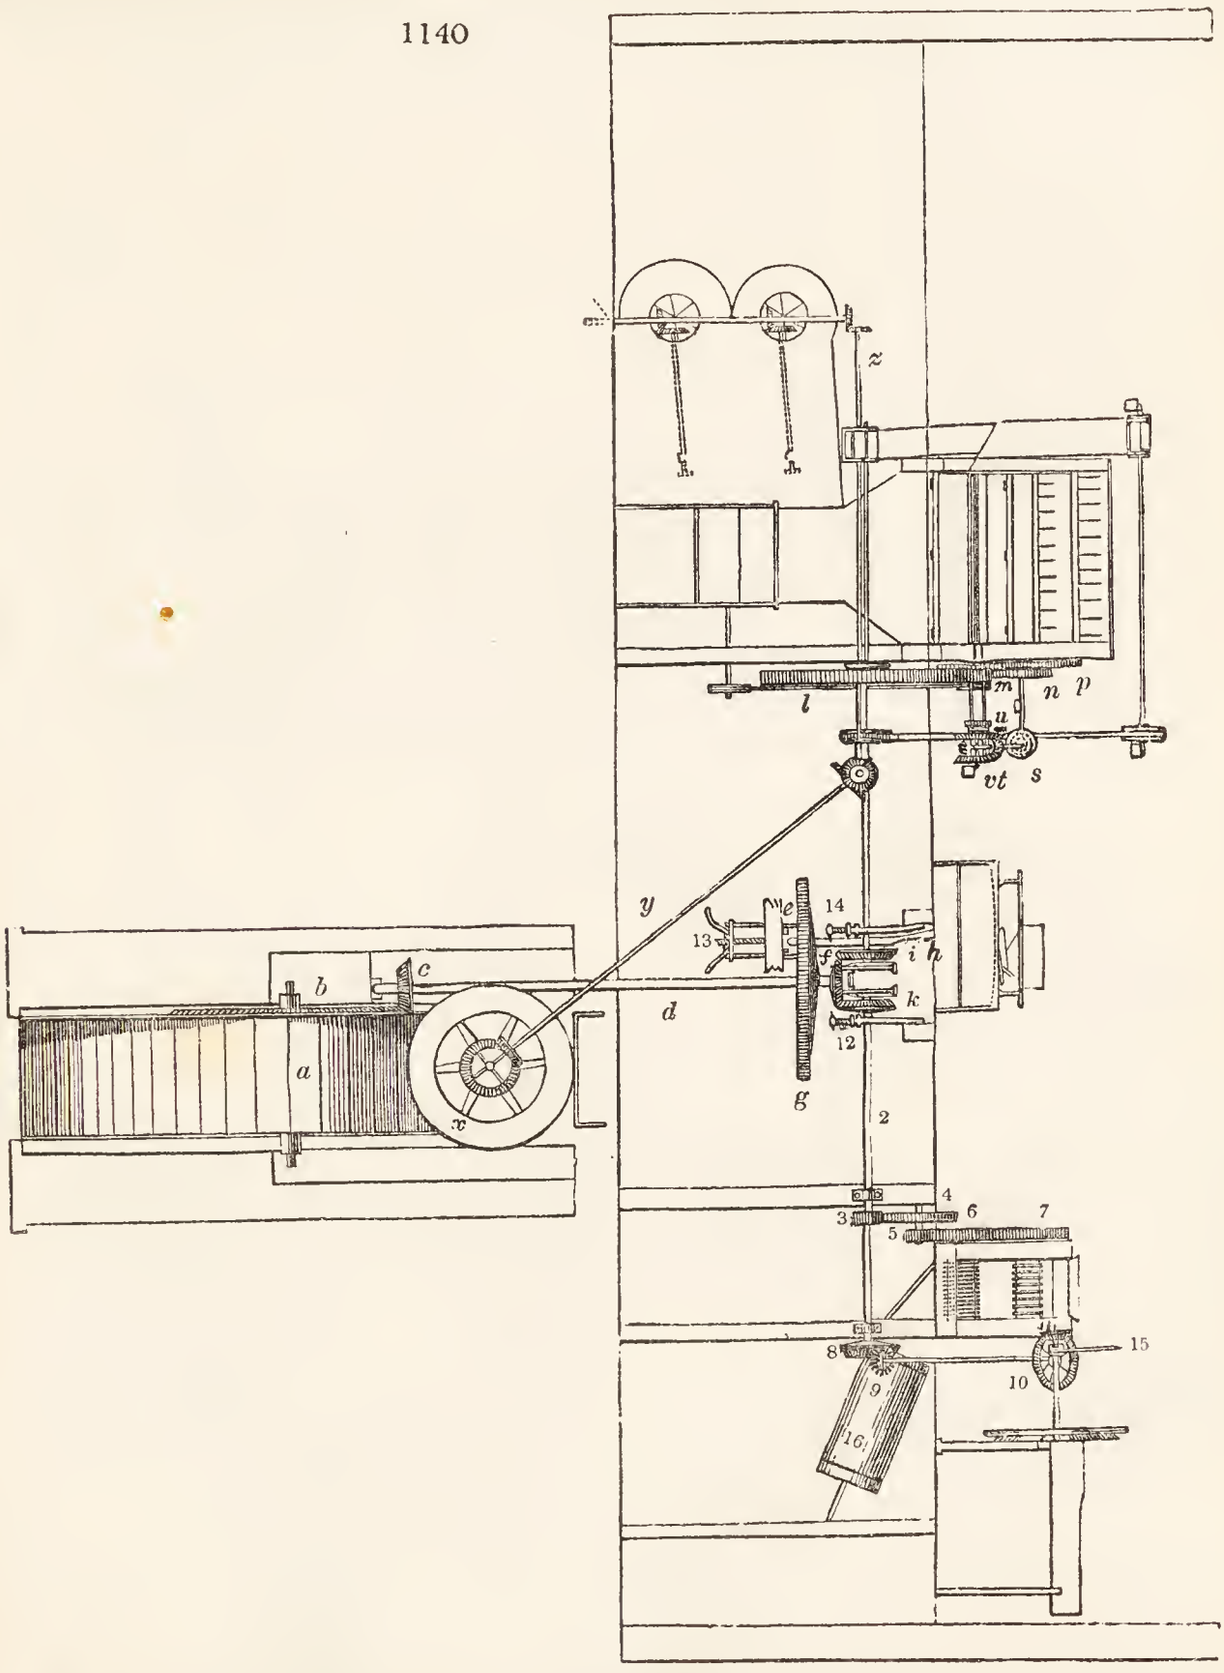


which is a bevel wheel twenty inches in diameter, working into a pinion on an inclined shaft *y*. On the upper end of the shaft *y* is a bevel wheel working into a pinion, on the axis of which is another bevel wheel giving motion to the shaft *z*, which turns the fanners by means of small mitre wheels.

The bone-mill and chaff-cutting machine are driven by the mitre wheels *f* and *k*. On the shaft 2 is a shifting pinion 3 of sixteen cogs (ten inches diameter), working into the wheel 4 of 49 cogs (two feet four inches diameter), on the axis of which is a pinion 5 of 16 cogs (ten inches diameter), driving the wheel 6 of 49 cogs (two feet four inches diameter), in the axis of one of the lower crushers: the upper pair of crushers are driven by the wheel 6 working into a wheel 7 in the upper crush or spindle. The crushing rollers are set to or from each other as the nature of the work may require. When the bones are large, the upper pair of crushers only are used in passing the bones the first time through, an inclined board being placed to prevent them from falling into the lower set; this board is removed at the second time of grinding, and the bones pass

through the two sets and fall into the revolving circular screen 16: any bones that will not pass through the mash of the screen are again put into the mill. The screen is set in motion by the wheel 6 working into a pinion, not shown in the drawing, and by a shaft and universal joint connecting with the axis of the screen.

1140



On the shaft 2 is a bevel wheel 8 of 46 cogs (21 inches diameter), driving the pinion 9 of 19 cogs (nine inches diameter), on an inclined shaft leading to the floor above; on the upper end of this shaft is a bevel wheel 10 of 52 cogs (twenty inches diameter), driving a pinion 11 of 17 cogs (nine inches diameter,) on the spindle of the chaff-cutting machine.

When the threshing machine only is at work, the mitre wheel *k* is thrown out of geer by the lifting screw 12; the pinion on the flour mill spindle is raised above the spur wheel *g* by the screw 13.

When the threshing machine is not at work, the mitre wheel *i* is thrown out of geer by the lifting screw 14.

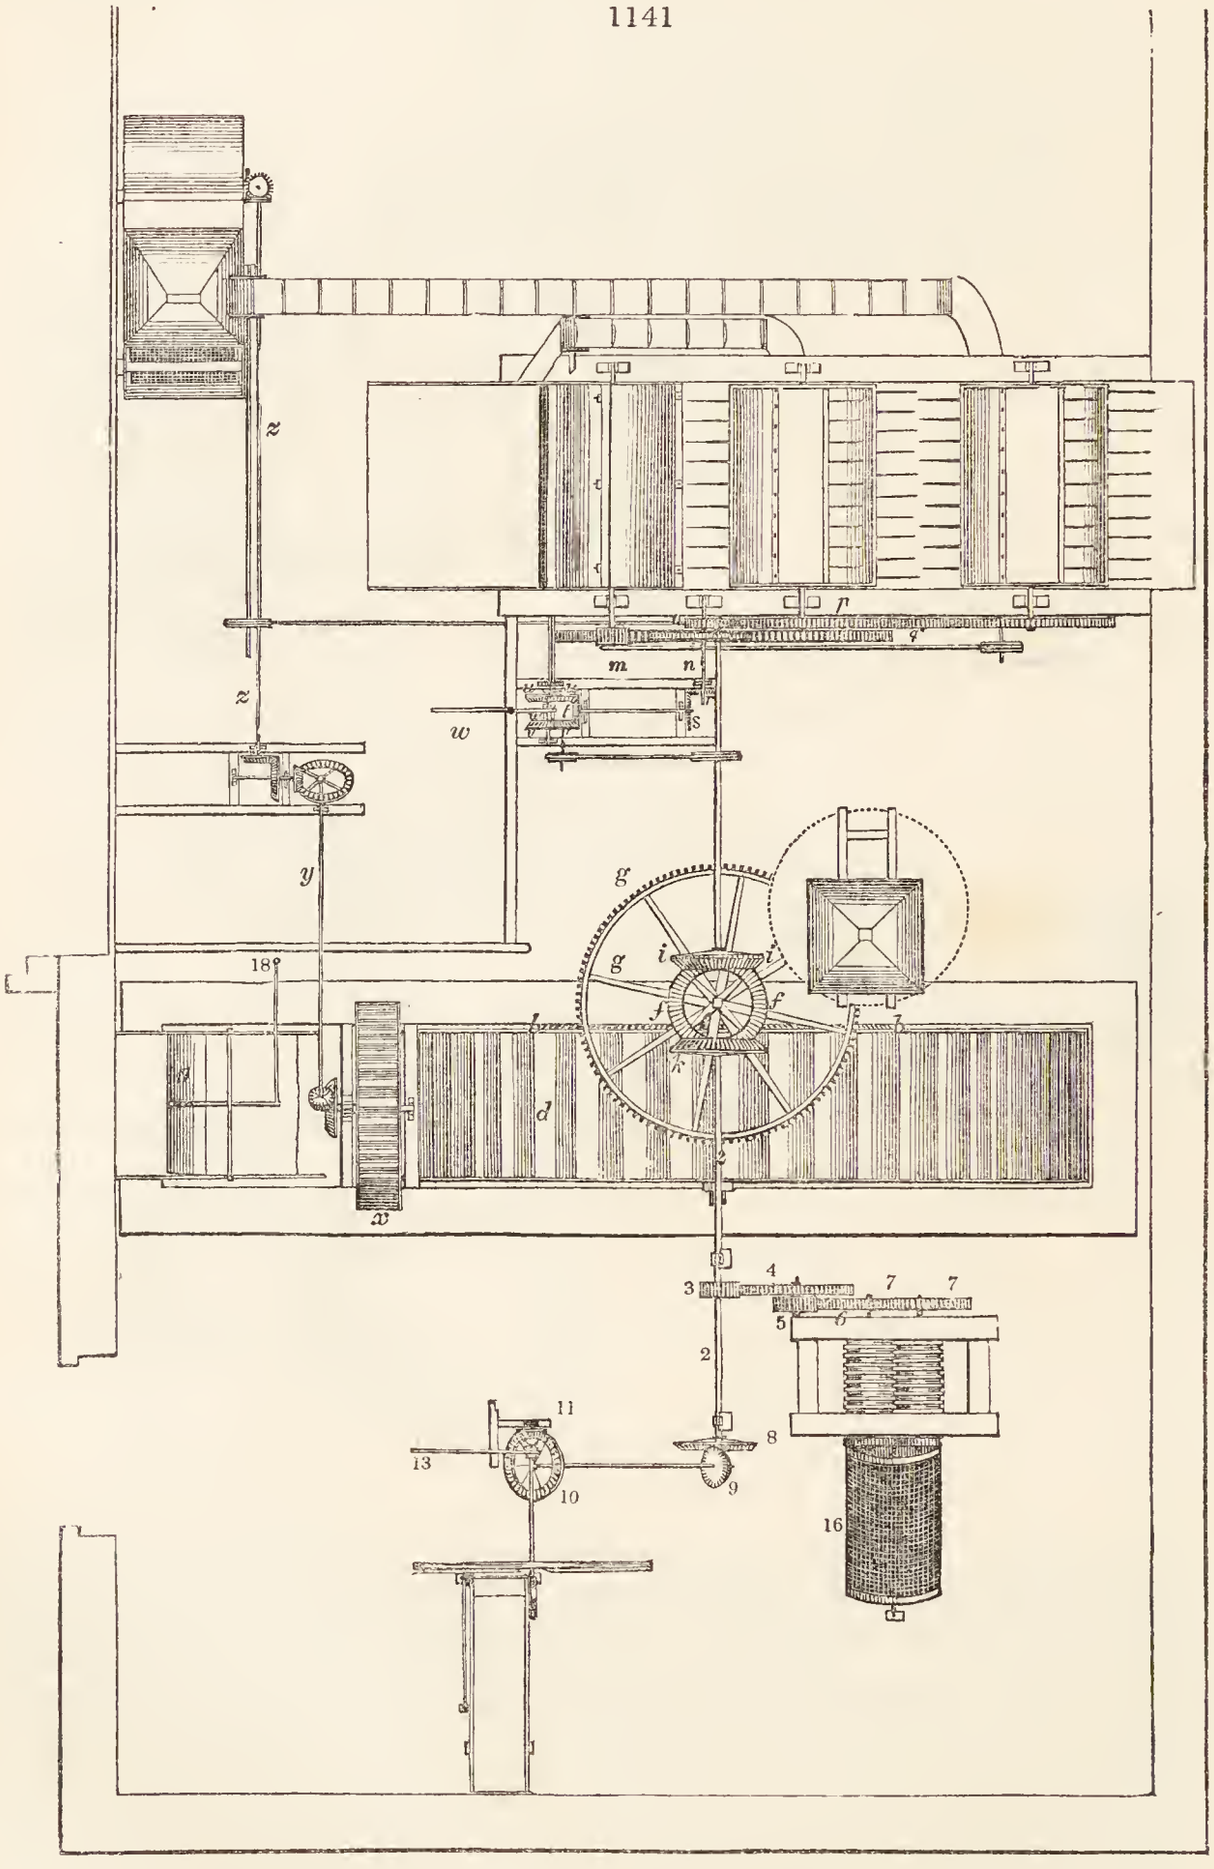
The pinion 3 is kept in its place on the shaft 2 by a key; when the bone-mill is not at work, the pinion is slided along the shaft clear of the wheel 4.

There are three cogs dovetailed into the pinion 9; when the chaff-cutting machine is

not at work these cogs are removed, and the vacant part turned towards the bevel wheel 8; the person attending the chaff-machine can also stop it by the clutch and handle 15.

To stop the water wheel the ring and lever 18 is raised by means of a chain leading over a pully at the upper part of the building; this raises the sluice board 17, and allows the water to escape clear of the wheel. The water which drives the small wheel *x* is also conveyed by a dash-board under it on to the large water wheel; as this water falls above the centre of the large wheel, the loss of power sustained is not great.

1141



The velocity of the particular parts is found by dividing the product of the number of cogs in the driving wheels by the product of the number of cogs in the driven wheels, and the quotient will be the number of revolutions made by the last moved part, for one of the first moving part. The drum will, therefore, make 49·2 revolutions for one of

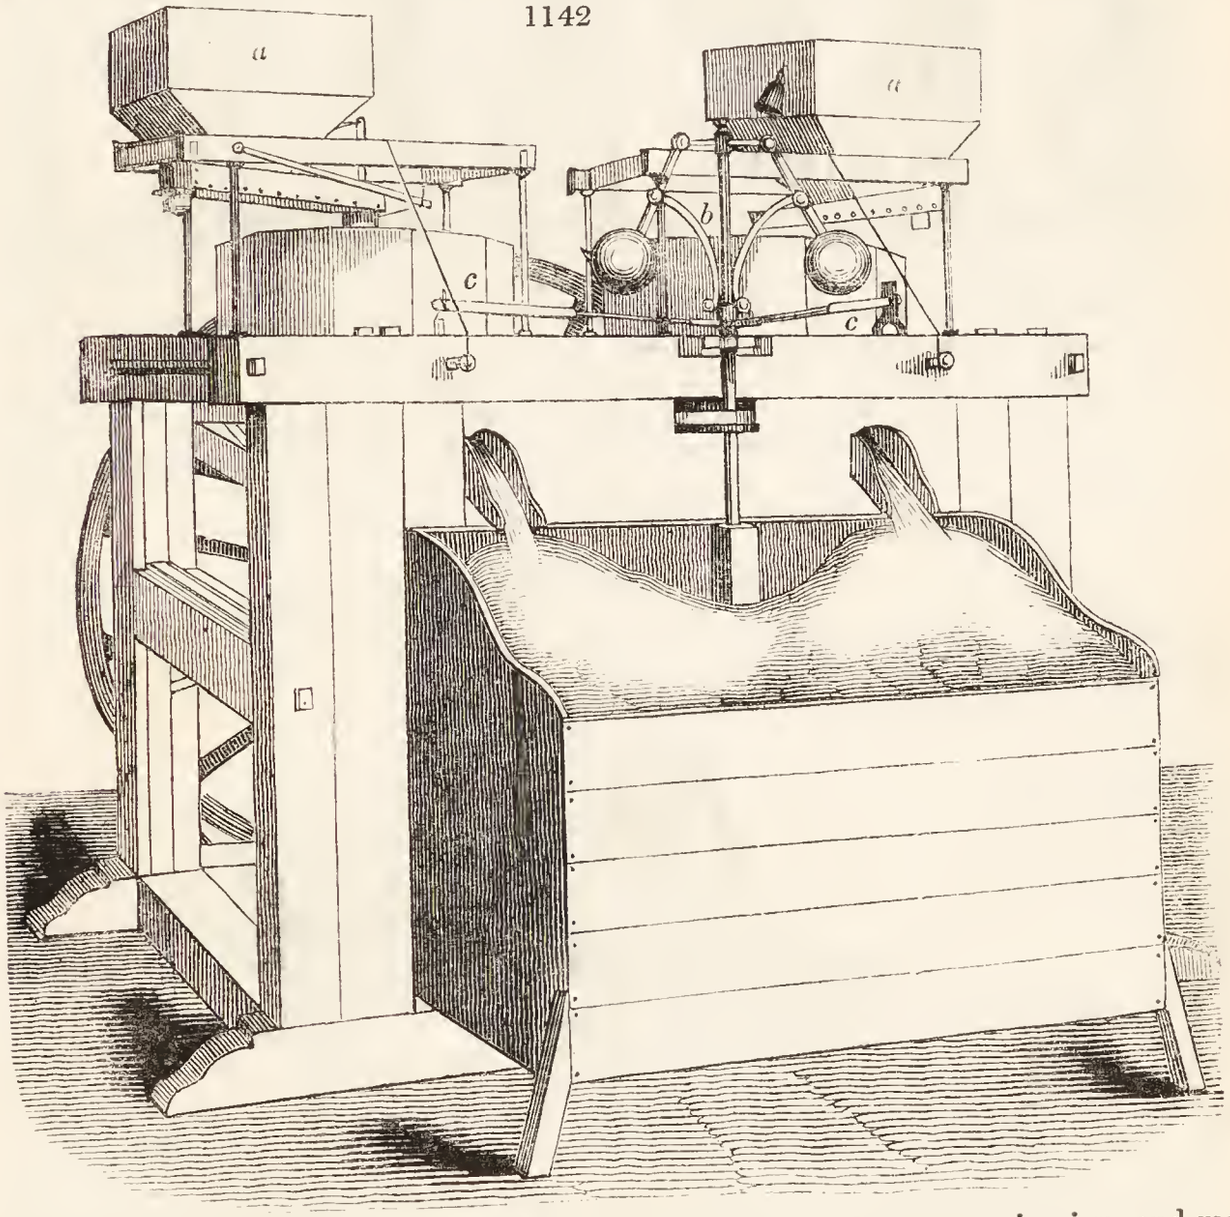
the water wheel; which, multiplied by 7, the medium revolutions of the water wheel per minute, will give 344·4 revolutions of the drum per minute; as the diameter of the drum is three feet, the circumference will be 9·42 feet, which, multiplied by 344·4, will give 3244 feet, the velocity of the beaters or switchers on the drum per minute. By following the same rule

The shakers will be found to make	5·42	revolutions for one of the water-wheel.
The feeding rollers, quick motion	10·7	
slow motion	7·1	
The upper stone of the flour mill	26·6	
The chaff-cutting machine	36·4	
The bone mill	·52	

The operative part of erecting the machine was done by a Mr. George Millar, now residing near Bagshot.

2551 *a*. *A flour mill for a parish workhouse*, upon a new and improved principle, (*figs.* 1142. and 1143.) has lately been erected at the Islington parish workhouse, by

1142

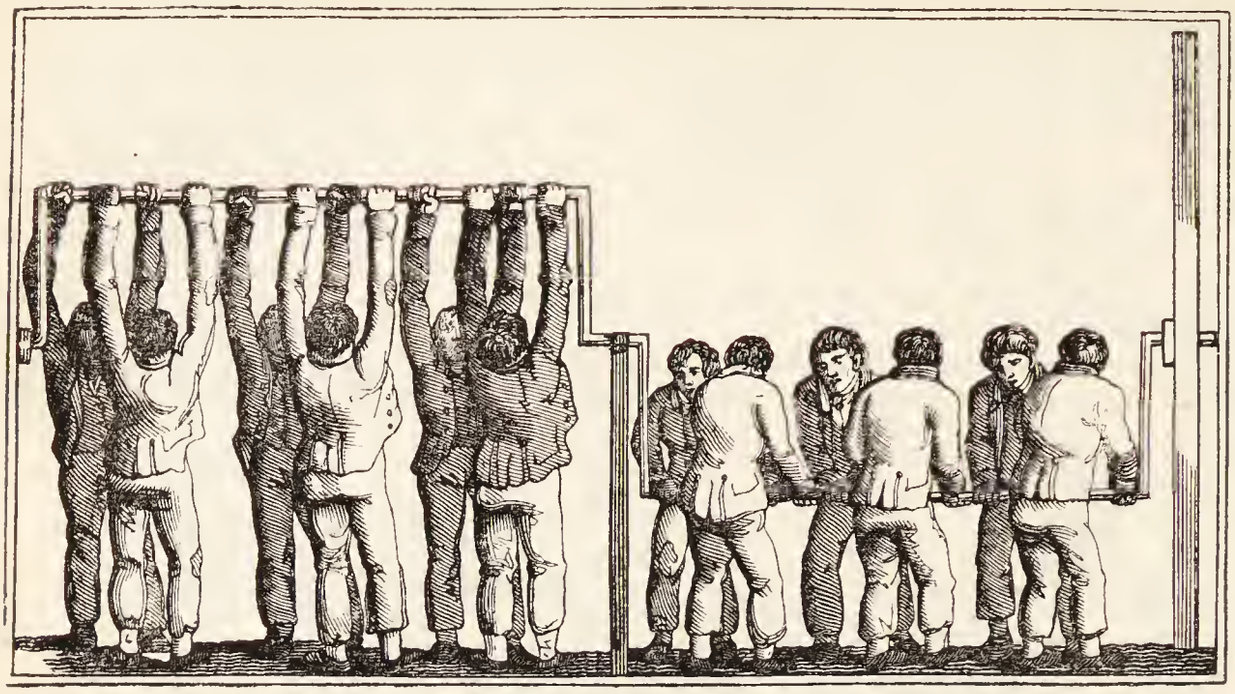


Weir, Oxford street; and as it is admirably calculated for the purpose in view, and may be adopted in many similar cases, we have deemed it well worth a place in this Supplement. It consists of two pairs of stones; one pair of which can be worked separately by six men, or both together by twelve men. The moving power is a crank (*fig.* 1143.), on the spindle of which is a large fly wheel; and beyond which is a pinion, working into a spur wheel on an upright shaft: this last wheel works into the pinions on the spindles that set the stones in motion. Either of the pinions is of course easily thrown out of gear by a lever.

There is a hopper (*a*, *a*) to each pair of stones, and one governor (*b*) which, by means of steel yard bars (*c*, *c*) reaching to each pair of stones, regulates their motion. Each pair of stones grinds a bushel and a half of wheat an hour, and the work is performed in as perfect a manner as by any water mill whatever. There is a bolting machine, (see 2552.) worked by a crank and fly wheel, and set in motion by four men. The expense of a flour mill of the above description depends chiefly upon the size of the burr stones; these when large being very expensive. The improvements in this machine are the invention of Mr. Malpas, the foreman at Weir's establishment, a very intelligent

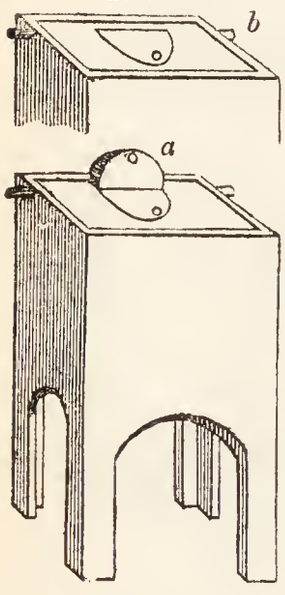
mechanic, and the author of various improvements on the implements and machinery manufactured there, which do him the highest credit.

1143

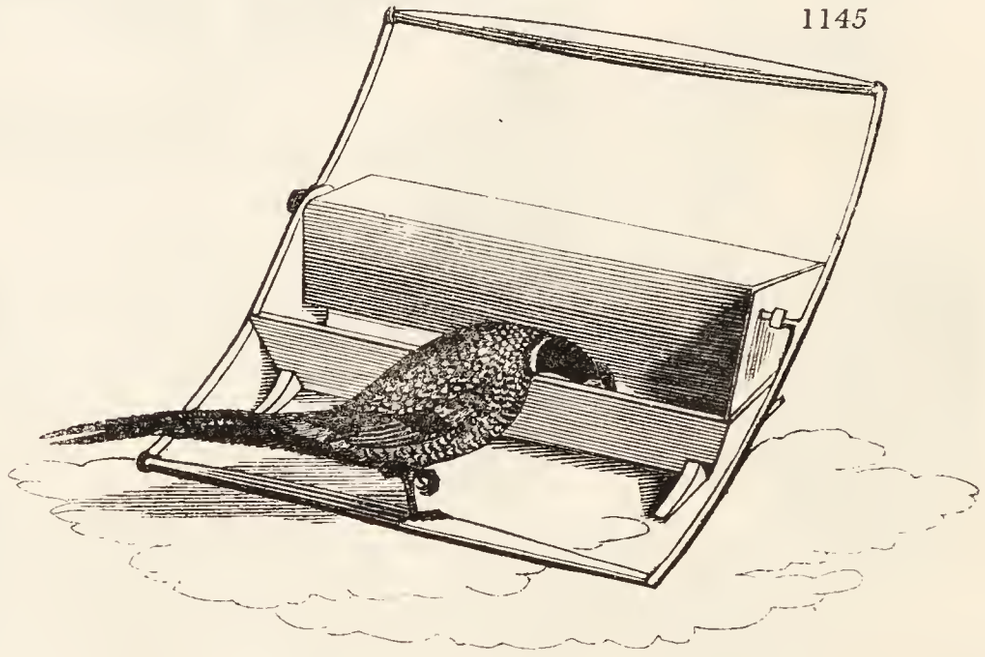


3088 *a.* *A fall-down gate-stop* (*fig.* 1144.) has lately been invented, which deserves adoption wherever double gates are fastened in the middle by a bolt, attached to the lower bar, and entering a hole in a stone or other body fixed in the road. This gate-stopper is formed of cast iron, and is sunk in the ground till its upper surface is level with the road, its lower end being placed on a stone to prevent its sinking too deep. The gate stop has an ear (*a*) which is raised up when the gate is shut, so as to form a stopper and a hole for the bolt; and it is put down (*b*) when the gate is open, so as not to present an obstruction to the feet of horses. Sold by Messrs. Cottam and Hallen.

1144



1145



7548 *a.* *The pheasant-feeder.* (*fig.* 1145.) This ingenious invention is manufactured of iron by Messrs. Cottam and Hallen, and seems the best utensil of the kind that we have seen. There is one of tin, lighter and cheaper (see *Gard. Mag.* vol. v. p. 589.), sold by Messrs. Bailey, 272. High Holborn, and by Weir in Oxford street, but it is by no means so durable.

THE END.

Printed by A. SPOTTISWOODE,
New-Street-Square.

FIRST ADDITIONAL

SUPPLEMENT

TO

LOUDON'S ENCYCLOPÆDIA OF AGRICULTURE;

BEING

NOTICES OF ALL THE PRINCIPAL IMPROVEMENTS

WHICH HAVE TAKEN PLACE IN AGRICULTURE IN BRITAIN,

WITH HISTORICAL NOTICES OF ITS PROGRESS IN OTHER COUNTRIES

SINCE THE PUBLICATION OF THE SECOND EDITION OF THE ENCYCLOPÆDIA OF AGRICULTURE, IN JANUARY, 1831.

By J. C. LOUDON, F.L., H., G., and Z.S., etc.

This Supplement is published in conformity with the intention expressed in the Preface to the second edition of the *Encyclopædia of Agriculture*, p. v. The additions, corrections, or variations, are given in paragraphs, each preceded by two numbers. The first of these numbers is a continuation of the series given in the second edition (which terminates with 7980.), for the sake of reference; and the second number is that of the paragraph, in the second edition of the Encyclopædia, to which the correction, addition, or variation refers; to which paragraph, in future impressions, a star will be affixed, in conformity to the plan laid down in p. v., above referred to.

In the compilation of this Supplement we have been guided by the same principles which influenced us in the composition of the original work; namely, that of laying before the reader a great variety of opinions and practices, and leaving him either to generalise on them for himself, or to particularise them, and to adopt such of them as may appear to him most suitable to his individual case. If we had adopted a different mode of proceeding; viz., that of generalising the opinion and practices of others, and giving the result as our own, our work must necessarily have exhibited our own opinion only; whereas, the former mode exhibits all the most valuable opinions and practices, on every subject that it treats of, which have hitherto been published, more particularly in Britain. The young reader is thus induced to think for himself, and to refer his opinions and practices to fundamental principles; while the experienced practitioner may adopt the opinions and practices of those authors in whom he has most faith.

A little reflection will, we think, convince every unprejudiced mind that this method of compilation is calculated to be the most useful in all general works on the practical arts; and, that it is more especially so in the arts of agriculture and gardening will be at once allowed, when it is considered how much the practice of these arts must vary with variations of climate, soil, and other geographical circumstances. How, for example, on any other plan than that which we have adopted, could we have treated on the culture and management of plants and animals, so as to have rendered our Treatise alike suitable for England and Scotland: or how else could we so easily have enabled the reader, who inhabits neither England nor Scotland, to deduce from the practices of those two countries a practice suitable to his own country; say, for example, North America? All knowledge, to be truly useful, must be gained by experience; and the next best thing to gaining experience from personal practice, is to observe and reflect on the practices of others. Our great object throughout, both in the Encyclopædia and in this Supplement, has been to instruct—not to lead.

J. C. L.

LIST OF CONTRIBUTORS.

Mr. Blackadder, p. 1328; Mr. Burness, p. 1366; Mr. Capper, p. 1371; Mr. Crosskill, p. 1309; Mr. Gladstone, p. 1310; Mr. Gorrie, p. 1330; Mr. Howden, p. 1305; Mr. Lawrence, p. 1323; Mr. L. of Wilga, p. 1282; Mr. Mackenzie, p. 1324; Mr. Mallet, p. 1367; Mr. Milne, p. 1327; Mr. Philips, of Albany, p. 1296; Selim, p. 1320; Mr. Swainson, p. 1371; Mr. Thompson of Sydney, p. 1295; Mr. Wilds, p. 1321; Mr. Wrigg, p. 1377.

To these, and to any other contributors whose names may have been inadvertently omitted, we return our best thanks; and we invite them and all our readers to send us whatever farther corrections and additions may occur to them. These will be used in a Second Additional Supplement.

FIRST

ADDITIONAL SUPPLEMENT.

PART I.

HISTORY OF AGRICULTURE.

7981. — 1. *The period which has elapsed since the historical part of the Encyclopædia of Agriculture was written,* may be described as one of general peace throughout the world. In the past history of the useful arts, it has always been observed that after nations have been for some years engaged in war, when peace arrives, their energies are directed to the useful arts with redoubled force. Accordingly, we find that in Europe those nations who were longest and most ardently engaged in arms, France and England, are now the most earnestly employed in domestic improvement. At present the attention of all ranks in France is directed to the advancement of agriculture and commerce; and this may be said, in a greater or less degree, of all the other nations on the Continent. The result is rendered evident to travellers by the improved appearance of the country, and by the numerous new buildings in the towns and cities; and to those who pay any attention to foreign politics, by legislative enactments, and by the establishment of agricultural, commercial, and statistical societies. Perhaps the most extraordinary improvement which has taken place on the Continent since the peace of 1815, is the establishment of a national system of education in Prussia in 1819; and, next to this, the attempt at the establishment of a similar system in France. (See Mrs. Austin's translation of Cousin's *National Education as it exists in Prussia.*) According to this system, all the inhabitants of both countries, without exception, would be not only taught all the most useful branches of knowledge, moral, intellectual, and physical, but even initiated into the practice of gardening and agriculture, in school gardens and fields; the boys into the practice of carpentry in school workshops, and the girls into the more useful branches of housewifery. Systems of national education, more or less perfect, have for upwards of thirty years been established in Wirtemberg, Baden, Bavaria, and Austria; but that of Prussia seems by far the most comprehensive, and equally likely to improve agriculture with the system of Bavaria, according to which system also agriculture is taught at the schools. In countries like Bavaria and France, where the farms are small, and the great mass of the population labouring cultivators, the education of all must be of greater importance, in an agricultural point of view, than in countries where farms are large; and where, if the farmer himself is enlightened in his arts, the ignorance of his labourers is of less consequence, since they act under his direction. Hence, with reference to national wealth, a national system of education would be of much greater consequence to Ireland, or any other country possessing but little capital, than it could be to England, or any other country abounding in capital. There are, however, other objects than the immediate acquirement of wealth, to be attended to by the legislator; and, taking the most comprehensive view of these objects, there appears to be no measure equal in importance to that of educating all classes, without exception.

7982. *The historical part of the Encyclopædia of Agriculture* was prepared in the beginning of the year 1829, and it cannot, therefore, be expected that we should have much to add in the way of bringing down the history of each particular country from that period to the present time. The details would be of too minute and temporary a nature to be considered as history; and they would occupy far too much space for this department of our Supplement. We have confined ourselves, therefore, to giving corrections or elucidations of former statements, whether these referred to remote periods of the agriculture of a country, or to descriptions of its present state. Among the latter, the most useful will be found the account of the Dutch dairy husbandry, from § 8001. to § 8019.

Italy.

7983. — 288. *The olive*, we are informed by Manetti, is most expeditiously propagated by cuttings, by seedlings, and by grafting. By cuttings is the most valuable mode when the soil is good, as the plants come soonest into a bearing state. Where the soil is poor, and especially if it be rocky, seedlings are to be preferred, because they send down their tap-roots into the crevices of rocks, and thus derive nourishment and support, where plants raised from cuttings would not live. In Tuscany, the olive is very generally raised from seed, and in many situations it is grafted. In Lombardy, on the Larian Hills, trees raised from cuttings are always used, and this is the reason Manetti alleges why these trees have their trunks perpendicular to the sides of the hill, instead of perpendicular to the horizon. Some interesting discussion on this very singular appearance will be found in *Gard. Mag.*, vol. viii. p. 68. to 70.

7984. — 290. *The foliage of the vines* supplies green food for cattle. Persons mount into the trees and gather the leaves into bags, exposing, at the same time, the ripening clusters to the sun. (*Blunt's Italy*, p. 212.)

7985. — 299. *The cause of malaria*, in this and other pestilential districts of Italy, has generally been supposed to be the decomposition of vegetable matter on a moist surface. This, however, is to confound the malaria with the marsh fever. The former is now thought to proceed from a very different cause, and to be analogous to what in England is called the hay fever. It is found that, while the corn or hay crop is in a growing state in the pestilential districts, they are as healthy as any part of Italy; but that the moment the crop is cut down, or withers on the ground, the malaria commences, and continues through the autumn and winter, till vegetation becomes vigorous in the following spring. The neighbourhood of Rome, where malaria is so prevalent, " is very hilly, dry, and entirely without vegetation. For days together, one sees nothing but desolate dried-up cornfields without trees, bushes, or wood of any description. In early times, Rome was surrounded by extensive sacred woods, which were not suffered to be destroyed. At that period malaria was unknown, though intermitting fevers were well known in the Pontine marshes. The avarice of the popes, however, converted these sacred woods into gold, and so desolated the region that not a tree or wood is to be met with around Rome. With the commencement of this system of extirpation the malaria appeared, and has at length reached such a height that, yearly, many are carried gradually off by it; and in the summer months strangers and respectable inhabitants quit Rome. When we take into consideration all the phenomena of marshy districts, the conclusion does not lie far distant, that the atmosphere is in different degrees rendered unfit for human organisation, not by the passage of the water to the air, but by the decomposition and solution of vegetable substances; and that thus those various intermitting fevers, and even the plague itself, are produced. In the case of real malaria, in opposition to marsh fevers, the circumstances are different. So long as the earth is covered with living vegetables, as, for example, with corn, the air of the most suspected district is pure and healthy, and no one fears being attacked by the disease; but when the prodigious crops, which in those volcanic, loose-soiled districts are speedily brought to maturity, are removed, does the surface of the earth become dead at the warmest and most energetic period of its functions? or does not rather a portion of those substances, which were consumed by the leaves and roots of plants, now go to the atmosphere, and render it unfavourable for the breathing of man, until all is again restored to an equilibrium in higher or more distant regions? That carbonaceous matter is beneficial to the vegetable kingdom, is as well known as that it is prejudicial to the breathing process in animals. No educated person in Germany doubts the organic function of the earth, to which also the cholera itself has been ascribed; and when a more general regard to nature advances to the south, the sacred woods will again gradually surround Rome, large vine branches entwine themselves round the elms, the hills be thus again covered, and the malaria reduced within limits. The fact is not without interest, that all real malaria districts are of volcanic formation, and that they are often to be found at the boundary of volcanic and non-volcanic rocks." (*Jameson's Journ.*, vol. xvii. p. 167.) In several districts in England, the country people are liable to attacks of fever immediately after the removal of the hay crop, some individuals much more so than others. This may be considered as a species of malaria of a comparatively mild description.

7986. — 301. *Lupines* are here (Vale of Poli) chiefly sown for the sake of manuring the land. When they are full grown, they are ploughed into the earth and left to rot. On some occasions they are boiled, and laid to the roots of orange and lemon trees, and even to those of olives and vines. (*Graham's Mountains near Rome*, p. 46.)

7987. — 302. *The single stale* or *funis* of the Roman plough is invariably adopted; the *binæ aures*, which are two strips of wood attached to the share (which also is often made of the same material), about eighteen inches long, diverging a little from each other, and inclined to the earth at a convenient angle for laying open the furrow. (*Blunt's Italy*, p. 205.)

France.

7988. — 380. *The backwardness of agriculture in France* " is mainly attributable to the very partial spread of education in the rural districts, there being out of 40,000 communes, according to M. Dupin, 15,000 destitute of teachers; and out of 25,000,000 inhabitants who have reached a teachable age, 10,000,000 only are able to read. Now as the small independent proprietors of land amount to 4,000,000, and their families to 12,000,000 or 14,000,000 more, it is obvious that this state of ignorance must, under such circumstances, be attended with far more prejudicial effects upon production than if it existed in England, where the labourers are under the orders of about 32,000 large proprietors, and the success of cultivation consequently does not so mainly depend upon the general diffusion of knowledge. It is gratifying to find, however, that the large proprietors in France are universally desirous for the instruction of the rest, and that societies, rural schools, and model farms have been established under very favourable auspices." (*For. Quart. Rev.* 1829.) A national system of public instruction was established in 1832, and the various details will be found in the *Bulletin de la Société pour l'Instruction Elémentaire*, for that year.

7989. — 381. *Present state of French agriculture.* In *L'Agronome*, a monthly agricultural journal published in France, at the low price of five francs a year, it is stated in the first number, published in January, 1833, that in France " the colonies afford no longer the means of making a fortune; the convents do not provide a remedy for the want of foresight of parents; the system of peace, which is every day procuring more advocates among the most highly civilised of the people, no longer offers a brilliant prospect in the profession of arms; commerce and manufacture suit only particular characters; the sciences and the professions only minds privileged by nature; while agriculture alone offers unlimited scope for employment and for improvement." After enlarging on this subject, the writer goes on to state, that the business of a farmer must no longer be that of men who are not fit for any thing else; but it must be adopted by men of education, and pursued assiduously and systematically. It appears, from this and other French publications, that extraordinary exertions are making in France for the territorial improvement of that country. Among other points to which the attention of the cultivator is directed, is the necessity of feeding his men well, no less than his horses. As a proof of the advantages of doing so, it is stated that when Messrs. Manby and Wilson, from England, established their iron works at Charenton, the French workmen were not able to support labour for the same number of hours as the English did, till they adopted, like them, the practice of eating butchers' meat. Exactly the same thing has been proved respecting the Irish labourers, as compared with the English.

7990. — *Agricultural Societies in France.* This, and some of the following paragraphs are taken from a very interesting article, understood to be by Professor Macculloch, which appeared in the *Foreign Quarterly Review*, just after the historical part of our 2d edition of this Encyclopædia was printed. "The Agricultural Society of the Seine and Oise, which comprises many extensive landed proprietors, bestows, annually, medals and prizes on the small cultivators who turn their hereditary estates to the most profit, and upon the hired labourers and servants employed in large farms, who perform their work with the greatest intelligence and fidelity. A model-farm has been lately established at Roville, in the Valley of the Meurthe, about six leagues from Nancy, by M. de Dombasle, a skilful practical agriculturist. It comprises clay, sand, and gravelly soil; and the proper modes of culture are applied to each. By the improvements in ploughs and instruments of husbandry, five horses and nine oxen now accomplish at Roville more work than thirty-five beasts of burthen used to do on the same ground. With the aid of the Scotch threshing-machine, M. de Dombasle beats out, with three horses, three hectolitres and a half (upwards of an imperial quarter) of wheat, and other grain in proportion. Potatoes are cultivated with attention, and a distillery has been established for extracting their spirit. M. de Dombasle has proved what will, we think, excite some surprise, that land of a middling quality, planted with potatoes for fattening beasts, will be more productive than the richest meadow. No stronger encomium can be made on the skill of M. de Dombasle, than the fact that he has more than doubled the produce of the land: the average annual return of Roville being 59 francs per hectare (of $2\frac{1}{2}$ acres), while that of the rest of the department of the Meurthe is but $28\frac{1}{5}$ francs per hectare. At Moneey, in the department of the Moselle, the model-farm of M. Bouchotte is famous for its breed of horses." (*For. Quart. Rev.*)

7991. "*The Agricultural Society of Strasburg* in 1828 commenced an experimental plantation of fruit and forest trees in Alsace; a want observable not merely in that department, but throughout the whole country, except, perhaps, Normandy and parts of Britany. In Franche-Comté, and the department of Doubs, the government has taken the breeding of cattle under its peculiar care, and established annual exhibitions and prizes. In these parts, as also in Montbéliard, the useless practice of feeding off the land is beginning to be discontinued, it being ascertained that a hectare of inclosed ground produces one third more if not subjected to this ceremony. The arrondissement of Montbéliard has abandoned the system of fallows in use in the rest of the department, and cultivates with success both flax and the turnip. In Franche-Comté the very beggars are becoming industrious; they go about collecting manure till they have accumulated a certain quantity, when they take it to a proprietor, who allows them in return to plant on his soil, and receive the crop of a proportionate number of potatoes. In Picardy, the increase of the sheep-flocks, and the improved system of manuring, have added to the fertility of the soil. At Nouvison, in the department of the Aisne, the farms have been ornamented by hedges and plantations, in imitation of the adjoining country of Hainault. It is here that the making of sabots, and wooden utensils called bois-jolis, is chiefly carried on; the supply sent to Paris annually is valued at 17,000*l.* At Origny, in the neighbourhood of Vervins, the children of the husbandmen are employed in fan-making, baskets, &c. of willow, to the value of 40,000*l.* per annum. In Champagne, the example of M. Richardot, a small proprietor, has given an impulse to planting, and to a systematic irrigation of the land." (*Ibid.*)

7992. — 390 & 414. "*The culture of the vine* is a department of their husbandry of which the French have, perhaps, a right to boast more than any other people. The same grape, when tried in countries under the same latitude as the south of France, has never been brought to an equal degree of perfection. The plantations of vines have been and are subject to severe discouragements, but have, nevertheless, increased very considerably over their extent in 1789. In that year their surface was estimated at 1,200,000 hectares of land; in 1808, it amounted to 1,600,000; and in 1824, it covered 1,728,000 hectares. In 1828, the vines occupied about 2,000,000 cultivators, and their annual produce was computed at 40,000,000 hectolitres; the value of which, at fifteen francs per hectolitre, is 600,000,000 francs, or about 24,000,000*l.* sterling English money." (*Ibid.*)

7993. — 391. *The olive climate.* Strabo (lib. iv.) says, that the line of the Cevennes, in Gallia Narbonensis, was the northern limit, beyond which the cold prevented the growth of the olive. The limit is still in the same position. (*Jameson's Jour.*, April, 1834, p. 233.)

7994. — 398 & 399. *The breed of cattle and sheep in France*, "with the exception of parts of French Flanders, Normandy, and Alsace, is yet very degenerate. But their improvement, like that of mankind, depends upon their rearing; and, if the example of the Roville and other studs be followed, there seems no reason to doubt that the French horses may one day equal those of England or Spain. The company lately formed for recovering the 4,000,000 hectares of marsh land now uncultivated, and converting them into pasture, will greatly further the amelioration of the cattle, as well as the augmentation of their numbers. 2,500,000 horses, 7,000,000 horned cattle, and 42,000,000 sheep and goats, are certainly not a large stock for a country covering 53,500,000 hectares of land. The most experienced of the agriculturists have shown that the fleeces may be brought to almost any desired degree of perfection. When the merinos of Spain first appeared in France, the partisans of the coarse mattress-wool were continually alleging that Spanish sheep would never thrive in the French climate; their success has, however, been complete. The celebrated M. Ternaux (deceased in 1832) imported wools of what are called the electoral race, and placed the goats of Thibet in his park of St. Ouen, near Paris. The rugged declivities of the Jura have been adorned with the magnificent naz breed of MM. Girod and Perrault, and their rams are now attesting in New Holland the march of science in the management of flocks in France." (*For. Quar. Rev.*)

7995. — 403. "*The French pigs*, although they have excited many facetious observations from travellers, and have not unfrequently been compared to greyhounds, may be fattened, we are assured, at a small expense; and the method of doing this is now beginning to be better understood. The Chinese and English breeds are also getting into use for crossing. The fact that 4,000,000 pigs are killed yearly in France, shows of how great importance they are to the small agriculturist." (*Ibid.*)

7996. — 407. *The most extensive of the branches of French agriculture, as connected with the manufactures*, "are the culture of beet-root for sugar; of oleaginous plants, particularly at Lille and Dijon; and of the mulberry for silk-worms, in Languedoc and the southern provinces. It has been the habit in England to consider the former of these as merely a fanciful amusement of national vanity; but it appears by the amount of its consumption (between 7,000,000 and 8,000,000 lbs. a year), that at all events it is become an article of some practical magnitude." (*Ibid.*)

Holland.

7997. — 426. *The greatest part of the land in Holland*, it is observed by Mr. Aiton, of Hamilton, being under the level of the sea, and of the great rivers and canals which intersect that country, and, consequently, being unfit for arable culture, is generally kept in meadow. "Part of the grass produced is cut for hay, to supply the stock in winter and spring; and the rest of it is eaten off by a few sheep and horses, but chiefly by cows. Some of the cows are fattened for the shambles, but most of them are kept as dairy stock. In those parts where the surface of the ground is above the level of the water, it is cropped with wheat, rye, rape, beans, oats, flax, hemp, and potatoes: and even where the soil is a little lower than the level of the sea and rivers, part of it is dug up in some places, and cropped with potatoes, hemp, &c. But the greatest part of North and South Holland is so often overflowed with water, as to render it improper to raise winter wheat crops to a great extent." (*Quart. Jour. of Agr.*, vol. iv. p. 328.)

7998 *The soil* "being generally rich, the herbage is luxuriant; but, owing to the moist condition of

the land, which is frequently inundated in winter, the herbage it produces is rather coarse, and many moist plants arise from the richer natural grasses." (*Ibid.*)

7999. *There are few large estates in Holland*, and "but few large farms. The land being remarkably level, it is generally divided and subdivided by ditches, or narrow canals, that receive the surface water, and serve the purposes of a fence." (*Ibid.*)

8000.—428. *The farm-houses in Holland* "are of dimensions suited to the extent of the land in the farm, and they are more or less elegant or comfortable, as the wealth or taste of the occupant may dictate; but they very much resemble each other. They are generally of only one story in height, but placed on so broad a base, as to afford accommodation not only for the boor, or farmer, and his family, but also their live stock, dairy, cheese-house, threshing-floor, the whole crop, and fodder for cattle. In short, the whole farmstead is frequently comprehended under one roof. Besides a kitchen, in which the family sit and eat, as well as cook their food, and from which they can see their cattle during winter and spring, these houses contain at least one elegant and well-furnished room, with a bed-room or two, into which they seldom enter, except on days of festivity. Their kitchens are much more tastefully fitted up than those of the farm-houses in Scotland. They have a stove of an elegant figure, which is kept wonderfully clean. The wall near to the fire-place is covered with plates of flowered earthenware; and the mantel-piece is richly, though rather heavily, fitted up. There are some concealed beds and closets in this part of the building; while a pump-well, and a horse-gin for washing and churning the butter, are both at hand, near the centre of the building. The floor of the kitchen generally consists of marble; the rest of the building is of brick. The gincourse is laid with sand, and is covered with boards when the horse is not in yoke. The whole building is roofed with tiles, and the roof rises in a somewhat pyramidal form. The walls are generally built of brick, but sometimes of mud or boards; but the roof is supported on frames of wood, round which the walls form only a covering. There is no urine tank as in Belgium. Indeed, little attention seems to be paid to manure in Holland, probably on account of the soil being naturally rich." (*Ibid.*)

8001. *The cow byre* is "paved with hard bricks, or clinkers, as they are termed, set on edge; and the stakes to which the cows are bound are made to be removed in summer, when the cattle are turned out to pasture. A passage before the cow's head is convenient for giving them their meat, and a trough of clean water is placed before the cows, from which they can drink at pleasure. The water is let off once a day by means of a plug, and a new supply from the well pumped into the trough. A passage behind the cows serves to remove the dung." (*Ibid.*, p. 330.)

8002. *Dutch cows.* "The Vriesland and Groningen cows are the largest and most esteemed races in Holland. They are short-necked, broad and deep-chested, deep-bodied, and broad-backed, with well-made limbs, fine small horns, and stand well upon their feet. The greatest number of these cows are either black or white, or dark brown and white." (*Highland Soc. Trans.*, vol. x. p. 169.)

8003. *The general practice in Holland* is, "that the cow should calve in her second year. The bull is employed when it is two years old, and is fatted and sold to the butcher when four or five years old, and the cow at seven or eight. Some cows are, however, kept for milking till the tenth year." (*Ibid.*)

8004. *The most improved method of treating the calf in Holland.* "It is immediately after its birth taken from the cow, put in a separate place, and laid on dry straw. A little salt is given, and the tongue and mouth are rubbed with it. It is also rubbed clean with straw. After the lapse of six or eight hours, the first beasting of the mother cow, diluted with one third water, is given to the calf to drink, and this treatment is continued for some days, the liquid being given thrice a day. Thereafter, during two or three weeks, they give the calf the milk as it comes from the cow, diluted with one fourth water, in which now and then a small handful of salt is put; then buttermilk is gradually given, and it is supplied with hay; at the age of ten weeks it is brought out into the meadow, where it is also supplied with skimmed milk, buttermilk, or whey. In this way each farmer raises the proper number of heifer calves to fill up vacancies; but calves fattened for sale have milk from the cow three times a day. For some days after calving the cow is milked thrice a day, after which they return to the usual practice of milking twice a day." (*Ibid.*)

8005. *Treatment of milch cows in Holland.* "The cows are turned out to grass generally by the end of March, or the beginning of April. They are, when first sent out, furnished with a very thick cloth of tow, covering the back and sides, from the shoulders to the tail, to prevent diseases from cold. They remain out, night and day, about thirty weeks. In the winter months the general food is hay, and most farmers give their cows nothing else: distillery grains are sometimes given, when they can be obtained. At the great establishment of Baron Van Palink, near Leyden, boiled beans, with rape cake, spread over the hay, were given at night, and ground linseed cake in the morning, which, it was stated, enabled the cow to give more and better milk than hay alone. Raw potatoes and dry linseed cake are also sometimes given, and most farmers give the buttermilk, either diluted with water or not, to the cows, as well as to the calves and pigs. Mangold-wurtzel is also given, but turnips never." (*Ibid.*)

8006. *The byres or cow houses in Holland* "are generally lofty, airy, paved with large square bricks [Aiton says "clinkers," *see* § 8001.], and kept perfectly clean. The roof is generally about ten feet high. There are no racks or mangers. The cows stand in two rows, generally facing the centre, and sometimes the sides of the byre, along which is a brick pavement slightly elevated in the middle. On the edges next the cows, and on a level with them, is a trough, perfectly clean, into which the meat or drink is put, and the hay laid down. Each cow has about five feet of space, and is tied to a railing of three small posts in front, which separate them from one another. There is little straw used for bedding: on the place where the cows stand, there is a hollow part at the fore feet, into which are now and then put dry horse dung and straw; at the hind feet, generally nothing is laid but a little dry sand. From the narrowness of the space divided into stalls, the back always projects so far as to cause the dung droppings to fall into a gutter about eighteen inches deep, and eighteen inches wide, which is regularly and carefully swept and cleaned, so that there is very little trouble in clearing away and collecting the manure. The cows are always kept quite clean; and, to prevent the tail occasioning filth, the lower end is always tied up by a string attached to the ceiling." (*Ibid.*)

8007. *Process of milking in Holland.* "The cows are always milked by the men, and the butter and cheese made by the women. One man is considered necessary for every ten cows. At Ter Leide, the well-managed dairy establishment of Baron Van Palink, there are ninety milch cows, nine men, and a *Boerinn* (or female farmer), the maker of the butter and cheese, who has a female assistant. At Klinkenburgh, near Sasenheim, there are forty cows; the farmer and three grown sons do all the milking, and his wife and one female servant make all the butter and cheese. At Schoote, near Haarlem, there are twenty cows; the father and son milk, and the wife and a female servant make the butter and cheese." (*Ibid.*)

8008. *Butter.* "There are three distinct kinds of butter manufactured in Holland; the butter made from the cream, when the cow is at grass in the summer, called grass butter; the butter from the whey of the new milk cheese, called whey butter; and the butter made in winter, when the cows are in the cow-houses, called hay butter." (*Ibid.*)

8009. *Grass butter.* "The cows being carefully milked to the last drop, the copper pitchers lined with brass, or pitchers entirely of brass, which contain the milk, are put into an oblong water-tight pit, which they call a *roelbak*, built of brick or stone, about six feet in length, three feet in breadth, and two feet in depth, into which cold water had been previously pumped; there being generally a pump at one end of the pit. In this pit or cooler, the pitchers stand two hours, this milk being frequently stirred. The cooling process is of great advantage in causing the cream to separate rapidly and abundantly from the milk. After this, the milk, being run through horse-hair sieves or drainers, is put into the flat milk-dishes,

which are of earthenware, copper, or wood, as will be afterwards described; it remains in a cool dairy or cellar for twenty-four hours. It is then skimmed, and the cream is collected in a tub or barrel. When soured, if there is a sufficient quantity from the number of cows, they churn every twenty-four hours, the churn being half filled with the soured cream. A little boiled warm water is added in winter, to give the whole the proper degree of heat; and in very warm weather the cream is first cooled in the *roelbak* or cooler. In many small farm-houses, or when the cows give little milk, the milk is not skimmed; but the whole, when soured, is put into the churn. The butter, immediately after being taken out, is put into a shallow tub called a *vloot*, and carefully washed with pure cold water. It is then worked with a slight sprinkling of small salt, whether for immediate use, or for the barrel; there being none made entirely without salt, as in Scotland. When the cows have been only eight or ten days out, the difference between grass and hay butter is slightly perceptible; but the grass butter, after the cows have been three weeks at grass, is delicious. This new butter is highly esteemed in Holland: it is made in fanciful shapes of lambs, pyramids, &c., or stuck with the flowers of the polyanthus, &c., and sells very high. If intended for barrelling, the butter is worked up twice or thrice a day with soft fine salt, for three days, in a flat tub, there being about two pounds of this salt allowed for fourteen pounds of butter; the butter is then hard packed in thin layers into the casks, which casks are previously carefully seasoned and cleaned. These casks are always of oak, well smoothed inside; and, before being used, they are allowed to stand three or four days, filled with sour whey, and are then carefully washed out and dried. Each cow, after being some time at grass, yields about one Dutch lb. (seventeen oz. and a half) of butter per day." (*Ibid.*)

8010. *Hay butter* "undergoes the same process as grass butter; being, of course, the butter made in winter, when the cows stand in the cow-house. But, although inferior in flavour and colour, it has none of the disagreeable taste which the turnip imparts to the winter butter of Britain." (*Ibid.*)

8011. *Whey butter* "is made from the whey of the new milk cheeses. The whey, being collected from the curd and the pressed cheese, is allowed to stand three days or a week, according to the quantity; the cream is either skimmed off and churned, or the whey itself is put into the churn, and the butter is formed in about an hour. In winter the butter obtained by this process is about one lb. per cow per week; and in summer about one lb. and a half per cow per week." (*Ibid.*)

8012. *Cheese.* There are four kinds of staple cheese made in Holland: the round or bullet cheeses, called Edam (from their having been first principally made in that neighbourhood); Stolkshe (so called from the village of Stolkwyk), which are called in Britain, Gouda, and are flat, and broader and larger than the Edam, both kinds being made of unskimmed milk; Leidsche or Leyden (being so called from this kind of cheese being principally made near Leyden), which is made of milk once skimmed; and Graawshe, which is made in Vriesland, of milk twice skimmed. Both the latter kinds are called Kanter cheese in Britain, and are larger and flatter than the two first named." (*Ibid.*)

8013. *Edam cheese.* "The process of manufacture of the Edam cheese is as follows: — The rennet is put into the milk as soon as it is taken from the cow; when coagulated, the hand, or a wooden bowl, is passed gently two or three times through the curd, which is then allowed to stand a few minutes; the bowl or finger is again passed through it, and it is permitted to stand some minutes longer. The whey is taken off with the bowl, and the curd is put into a wooden form of the proper size and shape of the cheese to be made. This form is cut out of the solid wood by a turner, and has one hole in the bottom. If the cheese is of the small size (about four lbs.), it remains in this form about fourteen days. It is turned daily, the upper part, during this time, being kept sprinkled with about two ounces of purified salt of the large crystals. It is then removed into a second box or form of the same size, with four holes in the bottom, and put under a press of about fifty lbs. weight, where it remains from two to three hours, if of the small size; and four to six hours, if of the large size. It is then taken out, put on a dry airy shelf in the cheese apartment, and daily turned for about four weeks, when Edam cheeses are generally fit to be taken to market. Alkmaar, in North Holland, is the great market for Edam cheese. It is not uncommon to see 800 farmers at this market, and 470,000 cheeses for sale on one day." (*Ibid.*)

8014. *Gouda cheese.* "This kind of cheese is also made from the milk, immediately on its being taken from the cow. After gradually taking off the principal part of the whey, a little warm water is put upon the curd, which is left standing for a quarter of an hour. By increasing the heat and quantity of the water, the cheese is made harder and more durable. All the whey and water is then taken off, and the curd is gradually packed hard into a form, cut out by the turner, flatter and broader than the form for the Edam cheese. A wooden cover is placed over it, and the press, with a weight of about eight lbs., put upon it. It it here frequently turned, and remains under the press about twenty-four hours altogether. The cheese is then carried to a cool cellar, and put into a tub containing pickle, the liquid covering the lower half of it. The water for the pickle is boiled, and about three or four handfuls of salt are melted in about thirty imperial pints of water. The cheese is not put in until the water is quite cold. After remaining twenty-four hours, or, at most, two days, in the pickle tub, where it is turned every six hours, the cheese, being first rubbed over with salt, is placed upon a board slightly hollowed, having a small channel in the centre to conduct the whey, which runs off into a tub placed at the one end. This board is called the *zouttank*, and several cheeses are generally placed upon it at a time. About two or three ounces of the large crystallised salt is then placed upon the upper side of the cheese, which is frequently turned: the side uppermost being always sprinkled with salt. It remains on the zouttank about eight or ten days, according to the warmth of the weather; it is then washed with hot water, rubbed dry, and laid upon planks, and turned daily, until perfectly dry and hard. The cheese-house is generally shut during the day, but must be open in the evening, and early in the morning. Each cow at grass in Holland is calculated to give about three or four lbs. of new milk cheese per day." (*Ibid.*)

8015. *Kanter cheese.* "The skimmed milk is poured out of the stone, copper, or wooden milk dishes, into a tub or tubs, in which it remains to settle half a day. About the fourth part is gently poured over into a copper boiler; which boiler, by the most careful farmers, is oiled with sweet oil, to prevent burning the milk, or giving it a singed taste. This is heated till the hand can hardly bear the heat, and then taken out and mixed with the other three fourths, the whole being stirred about; the rennet is then put in, and when coagulated, the whey is taken out with a wooden bowl, the curd is hard worked and pressed with the hands, and then put into a cloth, the four corners being folded on the top, and the whey pressed out. The curd is next put into a broad tub, called a *porteltobbe*, and hard worked, and trodden upon by the bare feet; for although there has lately been a plan introduced to obviate this disagreeable practice, this is generally the mode used in making common or kanter cheese. The next process is to mix among the curd a shut handful of soft fine salt to every thirty lbs. of cheese. The curd is then put into a strong circular form (of staves, and hooped, about three inches thick, with holes bored in the bottom), with the cloth round it. It stands in this form twenty-four hours, the cloth being taken off and wrung dry three or four times a day during these twenty-four hours: this form is placed upon a hand-barrow, or open standard, over a tub, which receives the whey; a cross plank is laid over the lid of the cheese form, and it is frequently pressed by the weight of the body. The cheese is then taken out and put into a cheese-well, or form, equally strong, having a cover called a *volgirt*, and put under a heavy press, the weight being about 360 lbs., where it remains twenty-four hours more. After this process, or when taken out of the press, the cheese is washed, and in some places it is smoothened by rubbing it frequently with sour skimmed beastings preserved for the purpose; it is then rubbed with a reddish-coloured substance, called *kaasverf* or *kaassmeer*, which the apothecaries sell in Holland, for the purpose of giving it a smooth outside, and good colour. The cheese is then put into a cool cheese-house or cellar, and frequently turned, until brought to market. It is into this kind of common or kanter cheese that various spices are put, although few of the spiced cheeses come to this country. This operation takes place when the curd is put into the first form: the curd is put in in layers; the first layer has no spices in it, but upon it is sprinkled

some cummin seed, and then follow regular layers, with cloves intermingled, until the upper layer is placed, which has no spices in it." (*Ibid.*)

8016. *Graawshe kaas, or inferior kanter cheese.* "This inferior kanter cheese is made of milk twice skimmed, in Vriesland and Gröningen; and is prepared in a similar way to Leidsche, or the best common or kanter cheese, to which it is much inferior. The Dutch farmers reckon that thirty cows at grass will give from 100 to 200 lbs. of fine butter, and about 300 lbs. of kanter or common cheese, per week." (*Ibid.*)

8017. *Dairies, or milk-houses.* "There is great variety in the arrangements of the milk and cheese-houses; but the most frequent form is this: — Between the dwelling apartments and the cow-house, and of the breadth of the house, is a square apartment for churning and other similar operations; at one corner is the cooler, built of brick, as already described, and generally having a pump at one end, for the purpose of introducing the cold water to cool the milk. This apartment is airy, roomy, and paved with square bricks. Descending a few steps from it, is the milk-house, or rather cellar; it is always three or four steps below the level of the house, paved with brick, and having an arched ceiling, almost always of brick or stone, and two or four windows, according to size. The milk dishes, or pans, which are daily first hand scrubbed and washed with boiling hot water, and then with cold, are ranged along the floor (not on shelves), in such a way as each pan may be reached by the dairy-maid. The windows are opened or shut according to the state of the weather, to which particular attention is paid." (*Ibid.*)

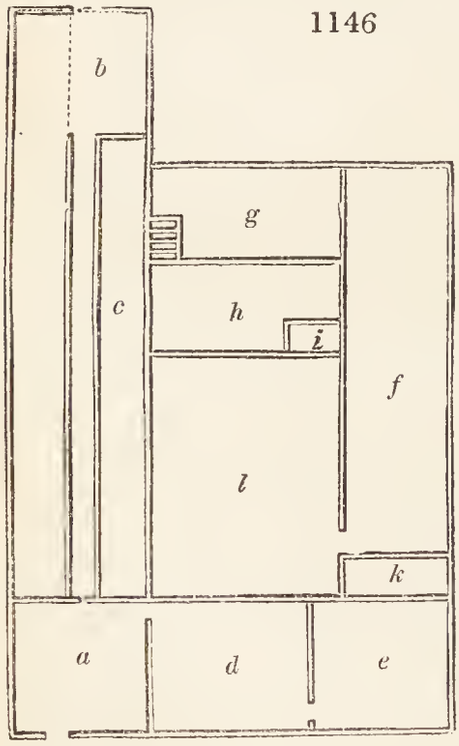
8018. *The cheese-houses* are also generally cellars, and adjoining the milk-houses; but in summer the byres are used for the Leidsche or kanter cheese; the floor being kept quite clean. All the windows and doors being open, abundant air is afforded. In winter the windows of the cheese-houses are generally kept shut; and, if any intense frost exists, they put in one of the wooden boxes, containing a pan with burning turf. The cheeses are placed in rows on the wooden shelves." (*Ibid.*)

8019. "*The sweet and delicious flavour of the Dutch butter* is said to be principally owing to the excellence of the Dutch salt. The butter, though salted, is always well flavoured, and hardly tastes of that acrid quality which the muriate or sulphate of magnesia frequently imparts to butter in this country. This acridity will be found very obvious, when comparing the Dutch salted butter to the best salted butter of Britain. It appears that in the manufacture of salt more time is allowed for evaporation and crystallisation, and that the crystals are nearly an inch square. In Britain the process of evaporation is hurried on by artificial heat, so that the crystallisation is never perfect. This is owing to our excise laws, which it is to be hoped will be removed, or regulated in such a manner as to admit of applying the modern improvements in chemistry in this manufacture." (*Ibid.*, vol. x. p. 184.)

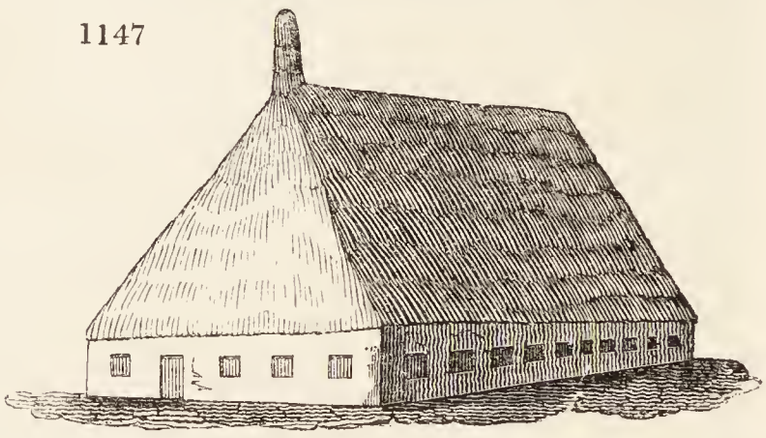
8020. *The great cleanliness everywhere observable in the farmeries of Holland* is "another cause of the general excellence of the dairy produce. This seems to be the result of a well-regulated division of labour. The men attend to milking and feeding the cows, and the women to making the butter and cheese. As to cleanliness, every dwelling-house is a model and a pattern; the inhabitants seem to vie with each other on this point. The cow-house is pure and clean, not a particle of filth being to be seen in it; the cows are as clean as if they were in a dining-room; the milk and cheese-houses, and, in short, every part of the house, are free from dust and dirt of any kind; the manure is placed at a convenient distance from the cow-house, behind the house, and every particle is carefully collected together. The whole apartments, even the byre and hay-house, are generally under one roof; and the cleanly system, and the admirable arrangements, give that comfort and pleasure which are too often wanting in Scotland.' (*Ibid.*)

8021. *As an example of a Dutch dairy farmery*, we copy the plan and elevation, *figs.* 1146 and 1147. In *fig.* 1146., "*a* is the kitchen or living-room of the family, during the greater part of the year; *b*, a temporary apartment in which the family take their meals during the warmest weather in summer; *c*, the cow-house, in which the cows are seen from both apartments; *d*, a large room used for various purposes; *e*, bed-room; *f*, shed; *g*, dairy; *h*, dairy scullery; *i*, cooler; *k*, a place for drying cheese; and *l*, hay and straw room in the centre of the building." The farmeries in Holland are generally of one story, and thatched with reeds, as in *fig.* 1147., one immense, lofty roof covering the whole. The highest part of this roof is in the centre, over the hay and straw room. (*Ibid.*) Mr. Aiton of Hamilton, who also visited Holland with a view of studying its dairy husbandry, gives a similar account of the Dutch farm-houses. See § 8000.

1146



1147



Germany.

8022. — 567. *The Agriculture of Prussia.* The system of national education established in this kingdom in 1819 has been already mentioned, and the reader will find the details, which have reference to the manner in which agriculture is taught in the school gardens or fields, in Cousin's work already (§ 79. 81.) referred to.

8023. — 573. "*The farmers about Bonn,*" says Williams, "have neither a good plough, nor a good cart, and their hay-fork is like Neptune's trident." (*Williams's Travels*, &c.)

8024. — 624. *Screens or narrow barns* are used in many parts of Carniola for hanging buck-wheat upon. The screen is composed of two upright posts, twenty feet in height. Through holes in the upright posts, horizontal poles are placed, reaching from one upright to the other. On these poles, the buck-wheat and other kinds of fodder are placed. A narrow roof of boards covers the whole, passing from one upright to the other. The sheaves of buck-wheat are also sometimes fixed on an upright post. (*Cadell's Travels*, p. 24.)

8025. — 625. *Gourds* are cultivated in considerable quantities in Carniola and Styria: cut in slices, they are given to the hogs and cows. (*Cadell's Travels*, vol. i. p. 25.)

Russia and Poland.

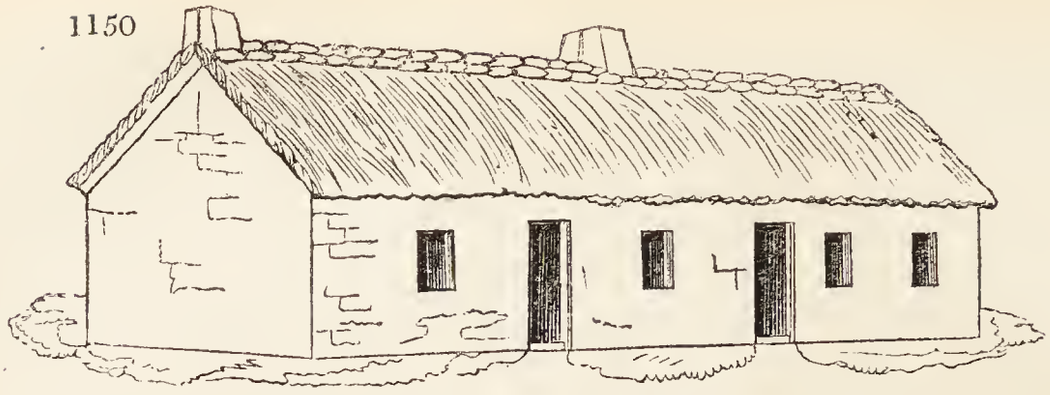
8026. — 662. *Roads in Poland.* By far the best specimen of that kind of road usually called macadamised, for want of a more explicative term, is to be found between Warsaw and Kalisz, a distance of thirty-three and a half Polish, or one hundred and fifty-six English miles. Throughout this distance it is uniformly hard, level, and as smooth as a billiard table, quite straight, planted with a double row of trees on each side, and with very tolerable inns at each post station. It is doubtful whether a better road is to be found in England; certainly not on the Continent, except, perhaps, between Milan and Cremona, or even as far as Vicenza. The Warsaw road is perfectly new, and owes its existence to the grand duke Constantine, whose efforts to improve the internal communication of the country in every direction were incessant. One feature of the Polish road in question deserves notice, because it tends to give it the appearance of a carriage-road in a gentleman's park kept in the highest order; namely, the manner in which the sides are dressed all along with green turf, which looks like mossy banks, cut smooth, and perfectly level. This method of flanking a macadamised road that has been cut through hills, or prominent undulations in the ground, offers, besides its neat appearance, a great advantage; for it prevents, in a great measure, the carrying away of the loose earth and denuding of the roots of trees during heavy rains, both which inconveniences, very injurious to the road itself, takes place when the sides are not covered with turf. (*Granville's Russia*, p. 580.)

8027. *British farmers in Poland.* Since the peace of 1814, some Scottish farmers have settled in different parts of Poland, and chiefly in the neighbourhood of Warsaw. The soil and the climate are found much more favourable, both for agriculture and gardening, than might naturally be imagined. Though the winters are more severe than they are at Edinburgh, yet the summers are much warmer, and corn and fruits ripen much sooner and better. The cucumber grows freely, and bears abundantly in the open air during the summer months. The estate or farm of Wilga, on the river of that name, a view of which is given in *fig.* 1148., consists of 1800 acres, and was purchased by a near relative of the author

in 1832. The buildings consist of a dwelling-house (*a*), with a detached kitchen (*b*), a brewery (*c*), a distillery (*d*), a machine for raising water to supply both (*e*), a corn-mill (*f*), sheds for feeding cattle (*g*), an ice-house (*h*), in which ice is kept above ground by means of thick double walls and doors; and large barns, a threshing-machine, coach-house, stabling and all other offices, including a carpenter's shop and house, blacksmith's shop and house, bailiff's house, &c. Besides these there is a small colony of cottages for the common labourers. These cottages are generally of the kind called log houses, and, with their draw-wells attached, present the appearance of *fig.* 1149. The Germans who are settled in Poland, as agricul-

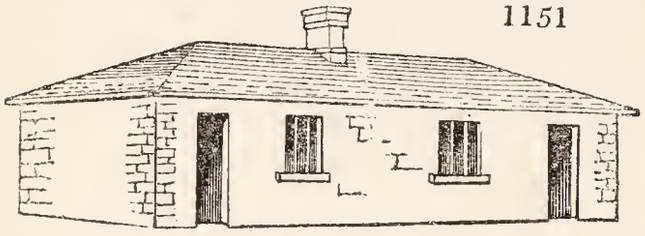
1149

1150



turists, generally build thatched cottages in the style of *fig.* 1150; and the English in the neighbourhood of Warsaw adopt the style shown in *fig.* 1151. Behind the house there are a large garden and orchard, with summer-house, green-house, &c., the estate having been the property and residence of a Polish nobleman, considered a man of taste. The situation of this property is about thirty miles from Warsaw, in a flat country, and there is good communication between it and that city, both by land and water. The soil is light in most places, but in others it is loamy. About half the surface is covered with wood, chiefly birch, poplar, and Scotch pine, which is felled at stated intervals, and is floated down the Wilga and the Vistula to Warsaw, where it is sold as fuel. The culture pursued on the arable land is the convertible system of—1. turnips; 2. corn, chiefly barley and wheat; 3. clover; and 4. oats. The turnips and clover are consumed in the feeding-houses by milch cows, or cattle for the butcher. The corn is either ground into flour, or malted and brewed into beer, or distilled into spirit; for both of which there is an ample market at Warsaw. Butter and cheese are made, for which there is also a great demand. Pigs are fattened, but the Polish towns being chiefly occupied by Jews, and trade of every kind being chiefly in their hands, it is found that pigs cannot be driven to market, and sold there alive as in Britain; but the carcasses are salted, or cured as bacon, and sold in that state, to Christian consumers. The fattened cattle are sold by private contract to Jewish dealers, who dispose of them, either to their brethren in Warsaw, Cracow, and other towns in Poland, where they are killed in the manner peculiar to the Jews; or to Christian butchers either in Poland, Prussia, or Russia. Numbers are sent to Dantzic and other sea-port towns. An unlimited supply of manure may be obtained from Warsaw at present, though it cannot be expected that this will long continue to be the case; but bones are abundant not only in Warsaw but all over the country, and the supply of this manure will, probably, for many years, exceed the demand. A crushing-mill has been, or is about to be, added to the corn or flour-mill on the estate. It is also in contemplation to establish a steam-boat between Wilga and Warsaw, which will add greatly to the rapidity of conveyance between the two places. The flour might then be converted into bread, and the cattle, for Christian consumption, slaughtered on the farm; for it is chiefly by manufacturing farm produce, that it can be at all disposed of to advantage in such a country as Poland. The great drawback to farming in Poland, is the want of moral principle in the labourers, who require continual watching both to keep them at work, and from stealing and drinking; but as this has arisen from the harsh treatment to which, as slaves, they have been subject from their masters through many generations (see § 650.); it may be diminished by kindness to the adults, and the education of the children.

1151



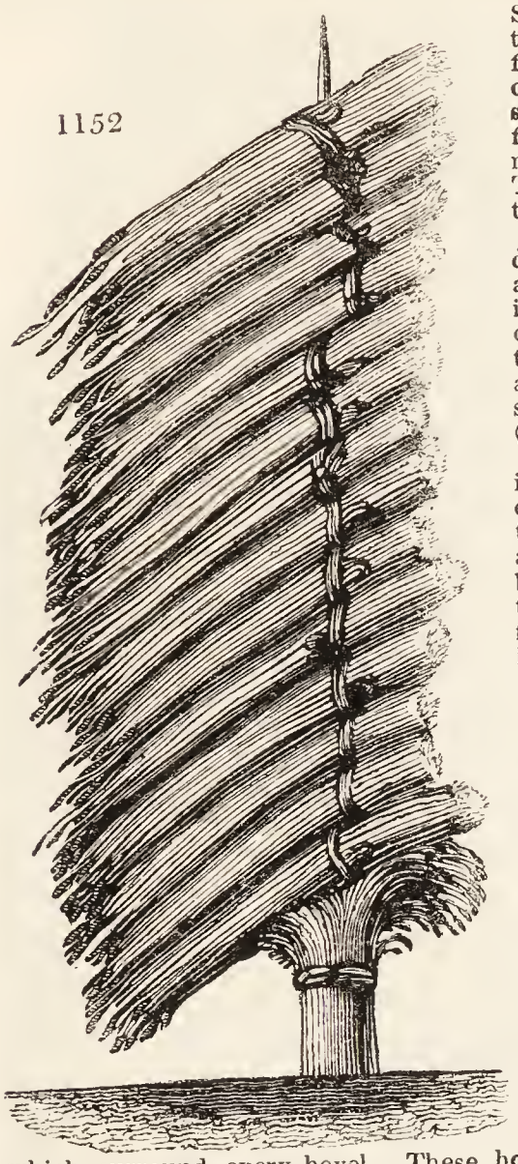
8028.—672. *Food of the peasantry in Russia.* Rye bread is the chief support of the peasants in the north of Russia; but, in order to save the rye flour, and to make it last the longer, the inhabitants, when compelled by necessity, mix with it fine ground oatmeal, the meal of buck-wheat, and the husks of the field mustard seed (*Sinàpis arvénsis*). Brandy is, in general, distilled in Russia from rye meal, with a more or less additional quantity of barley, oatmeal, and barley malt; but very seldom from wheat, or buck-wheat. The Russians also distil brandy from potatoes, juniper berries, and *Sórbus aucupària*, at all times with an addition of meal and malt. They distil, in Astrachan, a sort of French brandy from damaged wines, prunes, kernels of cherry-stones, and wild almonds (*Amýgdalus nàna*). Some of our distillers make use of the skin and stalks of pressed grapes, raisins, and the waste in sugar refineries, with which they make good brandy. To the worst and common sorts of brandy belongs the dram of Kamtschatka, of *Heraclèum Sphondýlium*, and another used by the Kalmucks, made from sour distilled mare's milk, which is spirituous, but rather of a disagreeable flavour. (*Com. Board Agr.*, vol. i.)

8029. *Agriculture in Livonia.* The country, before reaching Volima, offers a tolerable specimen of the present state of agriculture in this part of Livonia. Forests, both old and new, in considerable numbers, are met with here and there, succeeded by corn fields; barren heaths; farm-houses, consisting of one or two wooden buildings, and a yard, in tolerably good condition; small horses, and diminutive horned cattle; no inclosures, except a kind of palisade, marking the divisions of property or protecting the farm-houses from intrusion; and extensive buildings serving as granaries to hold the crops. These are the most prominent agricultural features of the country. The Livonians have the reputation of being good farmers. (*Granville's Russia*, p. 397.)

8030.—673. *Agricultural products of Russia.* The hop is indigenous in the district of Petersburg; a few are also cultivated in gardens, and the crop gathered the end of September. Hemp is sown about the middle of May, and pulled up in the beginning of September. Flax is sown in the beginning of June, and pulled in the middle of August. Both these plants are grown only in small quantities for private use. Red clover is sown along with barley and oats, and cut the following year, about the end of June, and the second in September; the plants are frequently destroyed by the early frosts. The farinaceous plants grown in the district of Petersburg are the following:—Some winter wheat upon good soil, sown in the latter end of August and the beginning of September, is reaped about the middle of August. Spring wheat is sown on newly cleared lands in the beginning of May, and reaped about the middle of August. Rye is sown, more extensively than any other grain, on most descriptions of soils, and in the latter end of July and the whole month of August; it is reaped the latter end of July and the beginning and middle of August. Spring rye is sown upon high and sandy ground in the beginning of May, and reaped the latter end of August. Barley is sown in the beginning and middle of May, and reaped about the middle of August. Oats are sown the latter end of April and beginning of May, and reaped from the middle of August to the beginning of September. Buck-wheat is sown upon high sandy lands in the month of May, and reaped in the beginning and middle of September. No oleaginous plants are cultivated, except the sesamum and the white mustard in a few gardens. The following are the leguminous plants of the same district:—White and gray peas are sown in the beginning of May, gathered green the latter end of July, and ripe the latter end of August. Beans are sown in the beginning of May, and reaped in the middle of August: French beans are sown in gardens, but they seldom do much good. (*Com. Board Agr.*, vol. i.)

Sweden.

8031. — 688. *General appearance of the country in Sweden.* A bishop of Bergen is said to have given the name of Northern Italy to some districts of Norway and Sweden. The pine forests are very beautiful, especially when the pale green of the young shoots contrasts with the older foliage. From the appearance of some of these trees on lofty cliffs, it is easy to perceive how in alpine countries the descent of the roots of the pine and the mountain ash, through fissures, contribute to the splitting of the rocks. The Swedish milestones are raised on plinths to keep them above the snow. The roads, winding through extensive pine forests, are picturesque in the extreme. (*Brooke's Travels in Sweden.*)



8032. — 693. *The cottages of the peasants* in Norway have double fronts. This additional protection renders them warm and secure against the blasts of winter. The manner of building these cottages is the same as in Sweden: and on the roof of each, a luxuriant crop of grass was generally growing, though some were loaded with a thick coating of pebbles, and above them were two or three large fragments of rock, to secure the whole from being blown away by the winter storms. (*Brooke's Travels*, p. 105.)

8033. — 704. *Stakes for drying newly-cut corn* are also used in Sweden. They are generally made of young pine trees, eight feet long, about one inch and a half in diameter at the top, and four inches at the bottom. Both ends are pointed, and the thick end is let into the soil by the aid of an iron crow bar. The first sheaf is put on the stake with the root ends of the corn downwards, and the other sheaves, to the number of fifteen or sixteen, are placed in an inclining position, as shown in *fig.* 1152. (*Quart. Journ. Agr.*, vol. iii. p. 638.)

Persia.

8034. — 864. *The general appearance of the country in Persia* is characterised by its chains of rocky mountains, its long arid riverless valleys, and its still more extensive salt or sandy deserts. The northern provinces form an extensive table land, which rises from a lower plain, and is interspersed with numerous clusters of hills, chains of rocky mountains, and barren deserts. The lower ground, under the name of Dushtistan, or the level country, exhibits a succession of sandy wastes, where the eye is occasionally relieved by a dark plantation of date trees, and a few patches of corn, in such places as are blessed with a freshwater rivulet or a copious well. On the banks of the Tigris this tract becomes more fertile. Wherever water abounds, vegetation is most luxuriant; but the country generally suffers from excessive drought. The mountains present masses of grey rock, and the only trees that are found in abundance are the tall poplar and stately chinar (*Plátanus orientàlis*), and the fruit trees which surround every hovel. These hovels are clean and comfortable; and wages are high, while food is cheap. (*Fraser's Persia*, *Edin. Cab. Lib.*, vol. xv.)

India.

8035. — 893. *To give some idea of the present state of agriculture in India*, Mr. W. Carey, one of the missionaries, states, in the *Transactions of the Agricultural and Horticultural Society of India*, vol. ii. part 1., 1832, that, in many parts of the country, the same crop is invariably raised on the same ground year after year; hay is never cut till the grass has died or withered on the ground; scientific rotation of crops is a subject to which Indian cultivators are strangers; and the manure produced by animals is generally consumed for fuel. No attempt to improve stock appears ever to have been made in India; though there is every reason to believe that all the animals used in the husbandry of Europe are capable of as high a degree of improvement in India as they are in more temperate regions. The quantity of waste lands in India is said to be so large as almost to exceed belief. Extensive tracts on the banks of numerous rivers are annually overflowed, so that they produce little except long and coarse grass, seldom turned to any useful account. During the rainy season, these tracts are the haunts of wild buffaloes, which in the night come up from them and devour the crops of rice on the high lands. In the cold season, wild hogs, tigers, and other noxious animals, unite with the buffaloes in occupying these extensive tracts of alluvial soil; which, though now so pernicious, might, by embanking and draining, become the richest lands in the country, and contribute greatly to the improvement of the climate. Similar observations might be made respecting immense tracts now wholly covered with wood, and producing nothing whatever to civilise man, but, on the contrary, proving a nuisance to the surrounding districts by affording a shelter to noxious animals. The oppression of landowners, and petty officers, on the cultivator is so great, that in some parts of the country no farmer can reasonably promise himself security for a single night. "Thus," concludes Mr. Carey, "one of the finest countries in the world, comprising almost every variety of climate and situation, diversified by hills and valleys, intersected in every part by streams (most of which are navigable six months in the year, and some of them through the whole year afford every facility for carrying manure to the land, and every part of the produce to market), is, as far as respects its agricultural interests, in a state the most abject and degraded." (p. 10.) This is a most forbidding picture; but it is incident to all countries in a particular stage of their progress in civilisation. Time was when the low districts of England were ravaged by the wolves and bears from the mountain forests, and when the crops on the alluvial vales of her rivers were annually swept away, or at least greatly injured, by floods. As to oppression by superiors, and thieving from others, there will always be abundance of such evils, till mankind are brought to something like equalisation in point of knowledge, and consequently power; till, in short, the mass of society become fit for self-government. (*Trans. Agr. Soc. of India.*)

Australia.

8036.—1037. *The whole territory of New South Wales*, Dr. Lang, writing in 1834, informs us, "is divided, like that of Great Britain, into counties and parishes; but these divisions are scarcely ever referred to in the common intercourse of colonial life. Except in government deeds or legal docu-

ments, the grand natural divisions of the country are the only ones recognised by the colonists." These divisions are the districts of the Hawkesbury, of Hunter's River, of Bathurst, of Illawarra, and of Argyle. The district of the Hawkesbury, which is let out in small farms of from 30 to 100 acres each, has been long considered the granary of the colony, from the extreme fertility of its soil, though the system of agriculture practised in it is as slovenly as can be well imagined. The surface of the ground is "for the most part merely scratched; and nothing like a proper rotation of crops is ever dreamt of. Wheat, year after year, for twenty years together, and sometimes wheat and maize in succession off the same ground during the same year, is the Sangrado system of husbandry that prevails on the Hawkesbury." The district of the Hunter's River is let out in farms of from 500 to 2000 acres each. "Dairies are frequent throughout this extensive district; and large quantities of butter and cheese, of superior quality, are forwarded regularly by the steamboats to Sydney." The vast plains of the Bathurst are chiefly tenanted by black cattle and sheep, and the farms are generally 2000 acres each. This may be considered the wool district. The cultivated land of the Argyle district is almost all in pasture, but there are interspersed extensive tracts of the most barren country imaginable. The district of the Illawarra consists of a narrow strip of arable land of the first quality, let out to "small settlers, who cultivate grain, potatoes, pumpkins, &c., for the Sydney market, their produce being conveyed to the capital by water in small coasting vessels." This is also the timber district, great numbers of the red and white cedar trees growing here, and that wood being generally used for cabinet and joinery work all over the colony. Besides these there are several large tracts of pastoral and alluvial land, which cannot be properly classed in any of the above-named districts; and a very great extent of country remains unexplored. The rich alluvial land on the banks of rivers is called interval land. It is very productive, but is difficult to clear. Norfolk Island, has a soil of the richest vegetable mould, even to the tops of the highest hills, and appears well adapted for the culture of coffee, if not sugar. It is now (1834) occupied as a penal settlement for the colony of New South Wales. (*Dr. Lang's Historical and Statistical Account of New South Wales*, vol. i.)

8037. *General aspect of the country.* The principal town, Sydney, is beautifully situated on Sydney Cove, one of the romantic inlets of Port Jackson, about seven miles from the entrance of that harbour, the headlands at the mouth of which constitute one of the grandest and most interesting features in the natural scenery of the country. Many of the most interesting localities on the shores of Port Jackson, between Sydney and the headlands, are in the hands of private proprietors. On Woolloomoolloo Hill (*fig.* 1153.), which is an elevated projection of the land, about a mile from Sydney, most of the officers of the colony have houses. The second town of the colony is at present Paramatta; but Maitland will, probably, soon supersede it, as the latter place is situated at the head of Hunter's River, in the centre of the most extensive agricultural and grazing district in the colony. Between Sydney and Maitland there are two steam-boats, and a company has lately been formed, called "The Hunter River Steam Navigation Company." With the exception of the large open plains in the interior of the country, the territory of New

South Wales is, in its natural state, one vast forest. On the banks of the rivers, and especially on the alluvial land within the reach of their inundations, this forest becomes what the colonists call a thick brush or jungle. Immense trees of the genus Eucalýptus, such as the stringy bark (*fig.* 1154.), the Blue gum, E. piperìta (*fig.* 1155.), and the Iron bark, E. resinífera (*fig.* 1156.), tower upwards in every direction, to the height of 150 or 200 feet; while the cedar, and other trees of inferior elevation, with innumerable wild vines and other parasitical plants, fill up the interstices. In the sterile region, the trees are stunted in their growth, and of a most forbidding aspect; their trunks and naked branches being frequently blackened by the action of fire, as in the Eucalyptus (*fig.* 1157.). The soil of these regions is a white sand, and nothing can exceed the loneliness and desolation of the scene. (*Ibid.*)

1154

8038. *The settled portion of New South Wales*, in 1833, Sturt tells us, extended from the 36th to the 32d parallel of latitude. The population of the colony is said to consist of 45,000 free settlers, and 25,000 convicts. Its imports, in the year ending January, 1833, amounted to 602,032*l.*, of which 144,793*l.* was the value of commodities imported from foreign states, the rest being the produce of Great Britain and her colonies. The exports amounted to 384,344*l.*, of which 81,969*l.* consisted of British and foreign merchandise re-exported, and the remainder was the produce of the colony, the New Zealand fisheries, and the South Sea Islands. The chief articles of export, which were shipped to the mother country, were:— New Zealand flax, 806 tons, value 15,393*l.*; sperm and black oil, 3186 tons, value 142,921*l.*; and wool, 1,515,159 lbs., value 73,559*l.* In 1831, no less than 150 vessels entered the harbour of Port Jackson from foreign ports, the amount of their tonnage being 31,259 tons. (*Sturt's Expedition into the Interior of Australia.*)

1155

1157

OLD GUM, 70 FT.

rocks of jasper; and beautiful agates, opal, and chalcedony, besides innumerable petrifactions, are found on its banks. (*Hist. and Statist. Acount, &c.*)

8040.—1040. *Natural productions of New Holland.* A peculiar character is given to the woods of the extratropical parts of New Holland, and to the woods of Van Diemen's Land, by the species of trees of the order Proteàceæ. These are numerous, and the leaves of the generality of them have a vertical position, and a similar aspect on both surfaces. These surfaces, a close inspection teaches, are distributed, by a reticulation of the fine veins of the leaf, into numerous small compartments or areolations, within each of which, on one face of the leaf, and very generally on both faces, is lodged a minute gland. (See *Brown's Supp. prim. Flor. New Holl.*)

1158

HONEYSUCKLE.

1159

APPLE TREE, 60 FT.

8041. *The vegetable productions of New Holland.* Some of the most common trees in the neighbourhood of Sydney are several of the different kinds of Eucalyptus (*fig.* 1154. to 1157.); what is there generally called the honeysuckle (Bánksia integrifòlia) (*fig.* 1158.), the apple tree (Angóphora lanceolàta) (*fig.* 1159.), the forest oak (Casuarìna torulòsa) (*fig.* 1160.), and the grass tree (Xanthorrhæ'a arborescens) (*fig.* 1161.). The last is particularly beautiful. There are also the broom (Jacksònia scopària) (*fig.* 1162.), which is called the dogwood at Port Jackson, and the wood of which is very difficult to burn, and the tea tree (Melaleùca

1160

FOREST OAK, 70 FT.

1161

GRASS TREE.

linariæfòlia) (*fig.*1163.). The name of tea tree is given almost indiscriminately to several kinds of Melaleùca, and Leptospérmum, because it is supposed that the first colonists made tea from the leaves of some of the species of these genera. The terms blue, red, or white gum trees, as applied to different species of the genus Eucalýptus, refer to the colour of the bark. The wood of trees of this genus is very durable; as a proof of which, Dr. Lang informs us that a stump of a species of Eucalýptus (blue gum tree) remained quite sound for thirty-five years in the ground, after having been cut down. When it was

1162

BROOM, OR DOGWOOD, 12 FT.

1163

TEA TREE, 20 TO 30 FT.

necessary to remove it, it took a fortnight to burn out the root. The circumstance of this trunk remaining quite sound for such a great length of time is very remarkable; and reminds us of what Dutrochet states respecting the stump and roots of the silver fir (*Gard. Mag.*, vol. x. p. 408.); viz., that they will continue to live, and even grow, during a great number of years after the tree has been felled. (*Lang's Hist. and Statist. Account.*) All these cuts of Australian trees, and also the view (*fig.* 1153.) are from drawings kindly sent to us by our friend, John Thompson, Esq. of Sydney, a gentleman whose taste in landscape is not unknown to the readers of the *Gardener's Magazine.*

8042.—1041. *Agriculture in Australia* appears to be making considerable advances, from the more frequent influx than formerly of emigrants with capital. Some Scotch farmers have settled in the interior of New Holland; a good many have located themselves in Van Diemen's Land, and there are some even on the Swan River. In 1830, the Cashmere goat was imported into the colony by Mr. Riley, and about the same time a German gardener, that Mr. Riley took with him from England, established vineyards in different parts of the country, which, from accounts received in 1834, have already produced wine. (See *Gard. Mag.*, vol. x. p. 159.)

8043. *The principal agricultural products of New South Wales* are wheat and maize. The cost of clearing heavily timbered alluvial land is about 5*l.* an acre, but sometimes a single crop of maize clears the expense. The return of wheat varies from 15 to 40 bushels an acre, and in the Argyle district it has reached 45 bushels; but the system of husbandry is, generally speaking, wretched in the extreme. The staple article of Australian produce is wool, of which Dr. Lang says, 1,515,156 lbs., and Sturt, 2,500,000 lbs., were exported in 1833. It is generally supposed that John Macarthur, Esq. was the first to introduce fine-woolled sheep into the territory; and, though the honour is also claimed by another individual, there is no doubt that Mr. Macarthur had the merit of having demonstrated their adaptation to the climate, and the capability of the colony to produce wool to almost any extent. This has been effected in comparatively a very short space of time. About 1792, Mr. Macarthur commenced sheep-farming, and in a year or two, he had an opportunity of crossing his coarse-fleeced sheep with merino blood. So prolific was the mixed breed, that in ten years, a flock, originally consisting of not more than seventy Bengal sheep, had increased to 4000. In 1803, Mr. Macarthur went to England, carrying samples of his wool, which was so much approved of by a committee of manufacturers, that government were induced to encourage him in his attempts to produce fine wool in the colony, by directing that he should receive a grant of land for that purpose, in the low pastures, which is now named the district of Cambden. In 1806, Mr. Macarthur returned to New South Wales with two ewes and three rams, purchased by him from the merino flock of George III.; his flock was removed to the low pastures, and since that period, the wool of New South Wales has been rapidly increasing in value in the home market. (*Dr. Lang's Hist. and Statist. Account*, and *Sturt's Exped. into the Interior of Australia.*)

8044. *Fruits and other vegetable products cultivated in the colony of New South Wales.* Vines, which are the most important of the fruit-bearing plants to a young settlement, have only been cultivated a few years to any extent. "There are now, however, many acres of vineyard throughout the country;" and wine and brandy have been manufactured from grapes grown by Mr. Macarthur's sons at Cambden. The wine is very similar to the light wines of France and Germany. Tobacco has been grown to great extent, particularly on the rich alluvial lands, and is only inferior in point of manufacture. Olives, hops, indigo, and opium, are beginning to be cultivated: the castor-oil tree (*Ricinus communis*) grows luxuriantly, and oranges and all the genus *Citrus*, and figs and peaches, bear abundantly. The hedges to the fields are generally formed of quince or lemon trees. There are several orange orchards, producing annually from 12,000 to 20,000 dozen each. The fruit of the loquat (Eriobótrya japónica) is sold in great quantities in the Sydney market. Cotton, coffee, tea, and sugar have been tried, and found to answer, though their cultivation has not yet been attempted on a larger scale. (*Hist. and Statist. Account*, vol. i. p. 375.)

8045.—1042. *As a country for emigrants.* During Sir Thomas Brisbane's administration, any respectable person, who pledged himself to government to maintain and employ ten or twenty convict servants, could obtain 100 acres for each such servant. This occasioned a great demand for convict labourers; and, instead of government being obliged to establish penal settlements in order to employ them, there was, during the government of General Darling, "applications for no fewer than 2000 convicts lying unsatisfied at the office of the principal superintendent of convicts." There is no doubt that New South Wales is an excellent country for the agriculturist; but it is subject to some drawbacks. A season of drought, which continued three years, began in 1827, and it appeared from the statements of old natives, that the country was subject to periodical visitations of that nature. It is also subject to inundations, particularly from the Hawkesbury River. From the imperfect state of husbandry throughout the country and the fertility of the soil, much may, however, be done by an experienced agriculturist. For eight months in the year, from March to November, the climate is delightful; but during the Australian summer, the heat is considerable. The most unpleasant part of the year is during the prevalence of the hot winds. "These winds occur on an average four times every summer, and continue from twenty-four to thirty-six hours at a time;" the atmosphere feeling like a current of heated air from a furnace, and the thermometer generally standing at from 90° to 100°, and sometimes even reaching 112° of Fahrenheit. The extreme dryness of the air, however, prevents this degree of heat from being so intolerable as it would be in a moist climate like England. The hot wind is generally succeeded by a violent gust from the southward, and very often by a shower of hail. (Vol. ii. p. 186.) Very few persons live to attain old age; but they generally enjoy excellent health and spirits while they do live. In short, observes Dr. Lang, "the lamp of life in the salubrious climate of New South Wales is like a taper immersed in a vessel filled with oxygen gas; it burns more brightly than in the common air, but it is sooner extinguished." To persons possessing property to the amount of from 2000*l.* to 5000*l.*, "New South Wales presents a most eligible prospect for effecting a comfortable settlement. They may put out part of their capital at interest for ten per cent. on excellent security, and 1000*l.* will not only purchase 1000 acres of land at 5*s.* an acre (the selling price in 1833), but will be amply sufficient to stock it." (*Lang's Hist. and Statist. Account*, vol. ii. p. 200.)

8046.—1044. *Van Diemen's Land.* This colony may be considered as the most prosperous in Australia, and the suitableness of its climate for Englishmen is every year more and more confirmed. "The colony," Mrs. Prinsep observes (*Journal of a Voyage from Calcutta to Van Diemen's Land*), "contains every source of wealth and health, in short, every thing but money. Interest on mortgages, with the very best securities, is 15 or 20 per cent. Bank shares pay 16 per cent. There is no immediate prospect of any check to that rise in the value of land which is now observable. Money well invested in land here, and allowed to accumulate, will be tenfold its original value in fifteen years. 200*l.* would purchase a noble property here. 1000*l.* will buy a fine, healthy, and beautiful estate of 1200 acres, 200 of them already in cultivation, and the whole becoming more valuable every year. Corn and potatoes are exported to Sydney; and wool to England. Wool averages 6*d.* per pound. The whole colony is on the advance, and its resources remain to be developed. Fresh lands are granted in square miles, in the proportion of the square mile, or 640 acres, for every 500*l* sterling of capital; which is the largest grant that is made to any settler without purchase, as the smallest is 320 acres. The total territory in acres is 15,000,000, of which about one half is rocky, or thickly wooded; the rest arable and pasture: the proportion of arable being as one to six of pasture. The total number of acres granted to individuals, up to December, 1829, is 1,323,523; consequently, there are 13,676,447 unlocated acres."

8047. *The wool of Van Diemen's Land* is of peculiar softness, and, from the greater attention now paid to cleaning and packing, the price is rising. Wheat is of a very superior quality, weighing generally about sixty, and sometimes as much as sixty-five pounds per bushel. Oats are beginning to be raised; barley has not yet succeeded; peas, and other species of pulse, are plentiful. Skins are also valuable; seal-skins the most so, being worth about 25*s.* each in England. Kangaroo skins are essentially useful in the colony for hats, and also for shoes, which are remarkably durable: when well packed, and of a good size, these skins fetch nearly 6*d.* a pound in London. Shoemakers make 100 per cent. on the raw material. (*Cape of Good Hope Lit. Gaz.*, vol. iii. p. 187.)

Egypt.

8048.—1077. *Egypt, under the government of the present pasha,* is undergoing extensive political improvements, among which agriculture, Mr. St. John observes, is not altogether forgotten. The culture of cotton has been commenced on a large scale by government; and an extensive tract of country round Cairo, which was long rendered useless by prodigious mounds of rubbish, many of them exceeding seventy feet in height, has been cleared, the mounds having been levelled, and planted with olive trees, which bore fruit the second year. The teak tree has been introduced from India, and is found to thrive near Cairo as well as in its native country. The mango, the pine-apple, and other tropical fruits, have been tried; and there is an English garden of naturalisation, under the direction of Mr. Trail, an English botanist. On the whole, there can be no doubt, that, if the present comparatively liberal policy of the Egyptian government be continued for another generation, the face of the country, and the condition of its inhabitants, will be entirely changed. Nature has supplied an excellent soil, and abundance of water, under a climate sufficiently hot to produce the produce of tropical countries, and yet not so much so as to prevent the grains of temperate regions from being profitably cultivated. (*Egypt and Mohammed Ali*, p. 443.)

Morocco.

8049.—1098. *Agriculture in Morocco.* The farmers plough and sow at the same time. The ploughing is performed by one man, who, while he guides the plough, which has a single handle, with his right hand, holds the reins, which are made of the palmetto twisted, and a long, thin, pointed stick to goad the oxen, in his left. When he sows, he leaves the plough, scattering the grain very sparingly with his right hand, and harrows it in by passing the plough again over the surface, the furrows being straight, narrow, and very shallow, without any ridge. The ploughshare has merely a simple tip of iron, which is taken off when the husbandman ceases to work, to prevent its being stolen. (*Brooke's Travels in Spain and Morocco*, vol. i. p. 303.)

Cape of Good Hope.

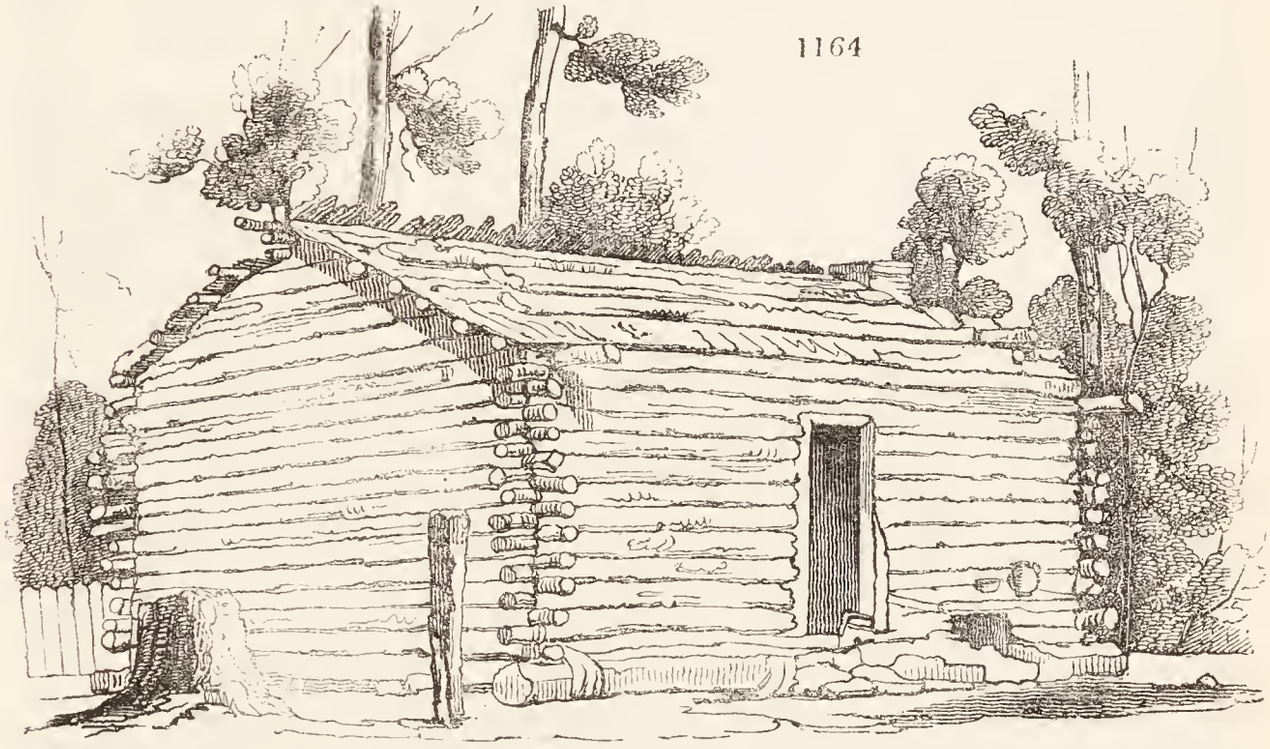
8050.—1133. *Albany.* At the close of 1824, when this new settlement was hastening to dissolution, the commissioners of enquiry removed certain political evils, and the country at once commenced a march of success, which John Centlivre Chase believes "the most unparalleled in the history of colonisation." In August, 1833, the Caffre trade, chiefly in ivory, amounted to about 34,000*l.* annually; and the exports increased from 32,273*l.*, their amount in 1829, to 51,290*l.*, their amount in 1832. Hides, horns, skins, tallow, butter, salted provisions, and ivory, formed the principal items. Cultivation is extended. Oats, barley, and oat-hay are the chief commodities; wheat has also been raised, and Indian corn, fruit, and vegetables grow most luxuriantly. Cattle, sheep, and horses are abundant, and every necessary of life is extremely cheap. There are about 26,000 sheep, the wool of which sells at upwards of 1*s.* per pound. Graham's Town has increased from 22 houses to 600; and eight villages, eleven places of worship, and fifteen schools have been built. Hat, blanket, and tile manufactories, numerous limekilns, three water and six wind mills, two tanneries, and two breweries, have been established. There is an infant school, a savings' bank, a public reading-room, and a commercial hall. A newspaper was commenced in January, 1832, and it is prospering. The population, in 1833, was 9913; and, as a proof that the country is favourable to human life, only 24 out of 248 persons, who landed in 1820, had died in 1830. "Such," says Mr. Chase, "is the result of thirteen years' settlement, nearly five of which were those of

failure and distress. From what has been related, it may be seen, whether success has attended the efforts of the immigrants or not, their only difficulty, in as far as my own knowledge goes, is that of a want of additional labourers to gather in the harvest of growing prosperity; and, as a proof of this want, I refer to the many and frequent appeals to the home government, successively made since 1825, for a new emigration." (*The Cape of Good Hope Lit. Gaz.*, vol. iii. p. 182.)

America.

8051. — 1153. *Climate of North America.* Over the whole extent of North America, it is universally admitted that the clearing of the country has modified the climate; that this modification becomes every day more manifest; that the winters are now less severe, and the summers less hot; and, in other words, that the extremes of temperature observed in January and July annually approach each other. (*Jones's Jour.* Ap. 1834.)

8052. — 1159. *The soil of the United States* is adapted to almost every species of culture. Wheat grows everywhere; and tobacco, hemp, and flax between the Potamac and Roanoke and Mexican Gulf. All the grains flourish in the valley of the Mississippi; but it is particularly in the delta of that river (which, like that of the Nile, is the work of the waters) that the sugar-cane and indigo succeed best. Almost everywhere, the earth abounds in pasturage, but is not adapted to the growth of fruit trees, or only produces fruit tart and without flavour. The most productive kinds of culture are those of colonial articles and vegetables; a species of cultivation for which the Americans are indebted to the French of St. Domingo, who have taken refuge among them. They are also indebted to them for some seed and kernel fruits. The territories of the United States, with regard to agriculture, may be divided into two parts, perfectly distinct from each other. The lands bordering on the Atlantic are generally bad or middling; but those on the other side of the Alleghanies, in the basins of the St. Lawrence and the Mississippi, are not exceeded by the best lands in Europe; and have, besides, the advantage of being nearly all virgin, and easily cultivated. Vegetation is hardy, but prompt, which is occasioned by the humidity of the soil. (*Beaujour's Sketch of the United States*, p. 81.)



1164

8053. — 1192. *Climate of the Canadas.* John Young asserts, "that, 2000 years since, the climate of Europe was precisely similar to that of British America at the present day; in support of which he quotes many authors of antiquity. He attributes the change, first, to the extirpation of the forests and the draining of the morasses; secondly, to the increase of population, and consequent evolution of animal heat, and the warmth communicated to the atmosphere by the fires within the houses; thirdly, to the extension of tillage, the process of putrefaction alone generating considerable heat." (*Brit. Farm. Mag.*, vol. vi. p. 196.) *Fig.* 1164. is a specimen of the Canadian log houses, which have been well represented in the *Sketches*, &c., of Captain Hall, from which our cut is taken.

8054. — 1195. *Emigration to British America.* Mr. Ferguson, who visited Canada in 1831, says, "that Upper Canada certainly is blessed with all the solid appearance of human happiness, independence, and comfort." The notes of this gentleman are given at length in the *Quarterly Journal of Agriculture*, vol. iii., and well deserve to be consulted by all emigrants. In a work on *Emigration to British America*, by John M'Gregor, Esq., published in 1831, the British possessions in North America are stated to be the Island of Newfoundland, Cape Breton, and Prince Edward Island; the province of Nova Scotia, New Brunswick, and the Canadas; the region of Labrador and the territory west of Hudson's Bay. Newfoundland bears a striking resemblance to the Western Highlands of Scotland, and is chiefly adapted for the rearing of cattle and sheep. Prince Edward Island possesses an excellent climate and soil, and is, taken altogether, a most desirable spot for emigrants. "The society in the island is good, and the inhabitants consist of Europeans from all nations, but particularly from Scotland. Cape Breton is a small island, peopled by between twenty-five and thirty thousand souls, chiefly from the Western Highlands of Scotland." The climate, though humid, is salubrious; the general aspect of the country romantic and mountainous, and covered with forests; and the valleys contain extensive tracts of excellent soil. Nova Scotia is an extensive country, fitted to receive "thousands, perhaps millions, of emigrants." The winters are severe, but the air at that season is generally dry. This peninsula abounds with extensive fields of coal, with ironstone, with gypsum, and, it is believed, with rock salt. New Brunswick has a climate particularly suited to the constitution of Britons. The country is covered with immense forests of evergreen and deciduous trees, and it is everywhere intersected by rivers fit for navigation. Coal, iron, gypsum, and sandstone abound. The Canadas include an extensive territory, with a climate which is on the whole salubrious. The thermometer, in summer, rises as high as 80° in the shade, and in winter sinks below zero. The winter in Lower Canada is two months shorter than that of Upper Canada. The geology of Canada is little known; the principal rocks appear to be trap and limestone. There are soils of every description, but the largest tracts are either alluvial, or of a lighter character, approaching to sand. Labrador, and the territory west of Hudson's Bay, Mr. M'Gregor does not consider as suitable to emigrants. We can only refer the reader, who is desirous of emigrating, to Mr. M'Gregor's book; or to a very copious abstract of it which will be found in the *Quarterly Journal of Agriculture*, vol. iii. p. 880. to 924.

PART II.

AGRICULTURE CONSIDERED AS A SCIENCE AND AS AN ART.

8055. — 1285. *In the arrangement* of this division of the Encyclopædia of Agriculture, we endeavoured, in the first three books, viz., those on plants, animals, and the soil, to establish the science of agriculture; and in the succeeding two books, on the mechanical agents of agriculture, to describe the tools, instruments, machines, and other engines, and operations performed by them, which constitute the art. In this Supplement the chief additions to the scientific part will be found to be some paragraphs on mildew; some on the new theory of the rotation of crops (according to which plants are supposed to injure the soil by their excretions, instead of exhausting it of specific kinds of nutriment, as was heretofore conjectured); and some on humin, and on the management of manures. The additions to the mechanical part, or the art of agriculture, include a number of new implements or machines, and buildings; among which are, one of the most complete threshing-machines that has ever been erected; a very superior description of farmery; a hop kiln of a new and superior contruction; and some excellent designs for labourers' cottages.

8056. — 1294. *A plant*, Dr. Lindley observes, "is to be understood as a mass of individuals, each having its own peculiar system of life, growing together in a definite manner, and having a common organisation, but nevertheless capable of vegetating independently, and not unfrequently separating spontaneously from each other. These individuals are buds, each of which is perfect in itself, and exactly the same as all the others of the same plant. They are combined by means of a fibro-cellular substance called bark, which is to be understood as being composed of the cellular integuments of as many individuals as the plant may have developed buds. As the act of vegetation consists in the developement of a germinating body in two opposite directions; the one upwards, as stem, the other downwards, as root; every bud, when it begins to grow, must be subject to this law, provided it is the independent being which it has been represented to be. And, in fact, if a bud is separated from the system to which it belongs, it does follow this law of developement, as is well known to gardeners from their practice of propagating plants by buds and eyes. Now, if buds, when in a state of combination, undergo the same kind of developement as when isolated, as it is reasonable to suppose they do, it will be found that the fibrous and vascular tissue of the wood and bark, which always descends from the buds, really constitutes their roots: and that, consequently, the concentric circles of the wood and bark of dicotyledonous trees are congeries of roots formed by the annual developement of buds upon the surface of the plant." (*Jour. R. Institut.*, May, 1831, p. 479.) To those who are desirous of keeping up their knowledge of the physiology of plants, with the rapid progress making in that department of science, we would strongly recommend, as scientific works, *De Candolle's Physiologie Végétale* and Lindley's *Introduction to Botany;* and as popular works on the same subject, Mrs. Marcet's *Conversations on Vegetable Physiology*, *Main's Illustrations of Vegetable Physiology*, and Lindley's *Lady's Botany.*

8057. — 1515. *Influence of temperature on the germinisation of seeds.* Seeds in general will not vegetate in a temperature of 9° or 10° above zero. But, from some experiments lately related to the Royal Academy of Sciences at Paris, it appears that seeds of wheat, barley, rye, and beans, have been submitted for fifteen minutes to the temperature of the congelation of mercury, and yet germinated afterwards. The same seeds which lost their germinating power at 122° in water, preserved it to 143° in vapour, and 173° in dry air. The limit of germinisation varies with the duration of immersion. Thus, not more than one fifth of the seeds of wheat, barley, and rye would germinate after being kept for three days in water at 95°; the same seeds will germinate in sand slightly moistened at 113°. The germinative principle of cerealia and legumes is destroyed at 173° in fifteen minutes. In most seeds 122° will destroy the vital principle. In hot countries where the temperature of the soil is as high as 118°, and even 122°, the cerealia disappear; first the barley, then the wheat, and finally the rye. (*L'Institut.—The Printing Machine*, vol. i. p. 107.)

8058. — 1526. *Nitrogen gas.* Cruciferous plants exceed all others in the quantity of azote (nitrogen) which they contain; and, on account of this quantity of azote, ammoniacal principles are frequently obvious in their fermentation or putrefaction. To the same cause are, perhaps, to be attributed these two phenomena; first, that the cruciferæ yield more of nutritive matter than most other esculent vegetables; and, secondly, that they require, to produce them in perfection, a soil well imbued with animal matter, or a station contiguous to the residence of man. (*Dec. Syst.*, vol. ii. p. 142.)

8059. *Presence of azote in seeds.* M. Guy-Lussac remarks, "that some seeds contain azote is a well-known fact, since a substance of an animal nature may be extracted from them, as gluten from wheat flour; but he observes that he has nowhere seen it stated that all seeds contain animalised matter. To be satisfied that this is the case, however, it is requisite only to submit any seed to distillation, either in its natural state, or, what is better, deprived of its ligneous envelope. Nevertheless, ammoniacal products are not always immediately obtained by distillation. Rice, for example, gives a very acid product; but the presence of ammonia is easily proved by the addition of lime. Kidneybeans and many other similar seeds give a very ammoniacal product. In general, any grain, deprived of its envelope, may be considered as composed of two parts; one vegetable, which gives an acid product by distillation; and the other animal, yielding ammonia; so that the acid or alkaline character depends upon the predominance of one or other of these matters. M. Guy-Lussac submitted all grains which came in his way to distillation, and all of them gave ammonia, the greater number immediately, and the others after the addition of lime; and he considers that this circumstance will explain the nutritive quality of grain, and the astonishing fertilising property of seeds as manure, after the oil has been extracted from them." (*An. de Chim. et de Phys.*, May, 1833; and *Phil. Mag.* for May, 1834.)

8060. — 1534, 1535. *Fertility of soils.* The theory promulgated in these two paragraphs is, to a certain extent, at variance with the new doctrine of soils becoming poisonous by the deposition of excrement, which will be found given at length, in the section on the rotation of crops, § 2217. in the *Encyclopædia*, and § 8069. in this *Supplement.*

8061. — 1694. and 1708. *Blight and mildew.* The term blight is indiscriminately employed by empirical cultivators, and by the unscientific public generally, to plants injured either by fungi, or by insects, and sometimes even to diseased plants. If it is to be used at all, it would be more correct to use it adjectively in connection with the cause of the injury; as, for example, blighted by insects, by fungi, or by disease.

8062. *Mildew*, one of the greatest enemies that the agriculturist has to contend with, is nothing more than several species of parasitical fungi, which attack different kinds of plants, varying in their nature and appearance, according to the plants attacked; or, in technical language, being specifically different on different plants. The fungi, commonly called mildew, are divided into three classes: 1. Those which grow, or rather lie, on the surface of leaves, and which, perhaps, do not derive nutriment from the plant; 2. Those which are formed in the interior of the stem or leaf, and protrude themselves from it when ripe; and, 3. Those which only attack the roots. All are extremely simple in their organisation, and very minute in their forms; they seldom appear in the open air, but in autumn.

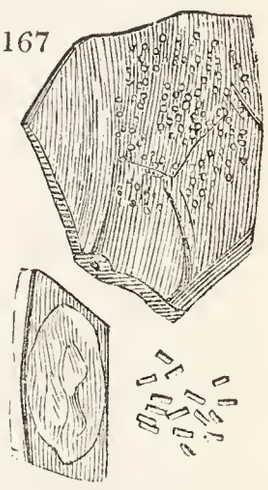
8063. *The first class, or mildew composed of those fungi that live on the surface of leaves*, injure a plant by preventing its respiration, but do not appear to draw any nourishment from it. One of the most common of these fungi is that called Sporótrichum, from *sporo*, a sporule, and *thrix*, hair, in allusion to the filamentous nature of its sporules. This is a very destructive parasite, and it is found upon a great variety of plants. The leaves and even fruit of peach trees are often attacked by it, and it is frequently mistaken by gardeners for an insect. Another very destructive superficial fungus is called Acrospòrium moniliöìdes (*fig.* 1165.), and it consists of a number of globules, attached to each other, which, when magnified, appear like the beads of a necklace, and in many cases are found standing upright. When ripe, these globules fall; and, taking root, form fresh strings, or necklaces, like the first. Sometimes little tufts of these globules appear fixed to stalks; and, from some fancied resemblance to the brushes used for sprinkling holy water, are called Aspergíllus. (*fig.* 1165.) The superficial mildew which infects the onion, and is very fatal to that plant, is called Bótrytis. Its name signifies a bunch of grapes; and it is thus called from a fancied resemblance between that fruit and its clusters of little globular seeds and seed-vessels. All these and many other superficial mildews are known by gardeners by the popular name of blight, and their devastations are frequently mistaken for those of insects.

1165

8064. *The second class of fungi, viz., those which spring from the interior of leaves and stems, are by far the most fatal.* These fungi generally appear in a sort of bag or case, which is supposed to be formed of the cuticle of the affected leaf; and they may be called hypodermous fungi, or internal mildew. One of the most common of these, is that which attacks the common cabbage (*fig.* 1167.), Cylindrospòrium concéntricum *Grev.* These very destructive fungi have the appearance of small white patches, or specks, of frosty incrustation, which, when magnified, are found to consist of a number of small cylinders, lying end to end, or across each other. These cylinders are all filled with seed, and burst when it is ripe, scattering it in every direction: wherever it falls upon the leaf it takes root, and thus the fungus spreads rapidly. The mildew which attacks rose trees and many other flowering shrubs is a kind of *Ure*̀do. This name, derived from *uro*, Lat., to burn or scorch, is applied to those occasional discolorations of the surfaces of plants which were formerly attributed to blights, or injuries from the atmosphere, and which have the appearance of a brown powder. *Ure*̀do effùsa *Grev.* (*fig.* 1168.) generally shows itself on the under sides of the leaves of the *Ro*sàceæ, and spreads rapidly. *Ure*̀do *Ro*̀sæ *Pers.* is another kind, which also attacks rose trees. The bean and pea are affected by a kind of mildew (*Ure*̀do *Fa*̀bæ *Pers.*, *fig.* 1169.), which spreads along their leaves, like white roots curiously interlaced. From these roots spring a number of branch-like shoots, each bearing a ball-like head or brown berry, which, when ripe, bursts and discharges seed. An internal mildew, which infects corn, is highly injurious to the farmer. It is vulgarly called the pepper brand; and, when corn is attacked by it, it gradually consumes the substance of the grain, leaving in its stead only a dark powder, which has a very offensive smell. This fungus is found only on barley, and in this respect differs from the *Ure*̀do *Se*́getum, or smut, which is destructive not only of barley, but also of wheat and oats. The *Ure*̀do *Se*́getum, or smut, has been the subject of many interesting experiments by Mr. Bauer of Kew, whose discoveries will no doubt throw very considerable light upon the subject. It not only destroys the grain, which it converts into a kind of jelly, but it attacks the leaves and stems, always forming in the interior of the plant, and bursting forth when ripe. Corn is also attacked by a species of Puccínia; a very fatal kind of fungus, which always appears divided into cells. Puccínia *Grá*minis (*fig.* 1172.), which attacks corn, forms in the interior of the stalk; and, when ripe, bursts forth in clusters, like bunches of grapes, of a dark brown colour. Puccínia *Ro*̀sæ *Grev.* (*fig.* 1173.) appears on the leaves of rose trees in little brown tufts, which, when opened and magnified, are found divided into extremely minute cells. The ergot on the rye (Spermœ̀dia clàvus *Fries*) is a well known and very destructive species of internal mildew. It partakes of the nature of the truffle, and grows out of a spike of corn like a prolonged kernel. It is long, horny, and cartilaginous; and it consists of fibres closely interlaid. This disease evidently originates in the centre of the stem. It affects maize, various species of corn, and grass, and is often found in plants of yellow gentian, &c. Hawthorn trees are attacked by a species of Æcídium, which at first appears merely a point made by an insect, but afterwards looks like fungi (Æcídium laceràtum *Dec.*, *fig.* 1170. *d*). The sycamore fungus is a black spot consisting of oblong purplish bodies, yellow inside, and containing tubes filled with seeds. Æcídium Grossulàriæ *Dec.* (*fig.* 1170. *b*) attacks gooseberry bushes, and Æcídium cornùtum (*fig.* 1170. *e*), the mountain ash: both spread rapidly, and are very difficult to cure. The oak is attacked by a species of Æcídium, different varieties of which are found on many kinds of forest trees. The Æcídium *Pi*̀ni (*fig.* 1170. *a*), found on pine trees, has, when magnified, the appearance of a number of ninepins. When ripe, the cuticle which covers the fungus bursts, and emits a powder of a bright orange colour, which is the seed. It is a vulgar error to suppose that a berberry tree (*Bérberis* vulgàris *L.*), if planted in a cornfield, will, if infected with mildew, communicate the disease to the corn. This cannot be the case, as the mildew which attacks the berberry (Æcídium *Berbéridis* Pers., *fig.* 1170. *c*) is quite different from any of the fungi which are found on corn. The berberry mildew, when magnified, is found to consist of a number of small orange cups with white films over each. When ripe, these lids burst, and the top of the cup assumes a ragged uneven appearance, like white fungi. Each cup has within it a number of little boxes containing seeds. The mildew on the pear tree is called Æcídium cancellàtum.

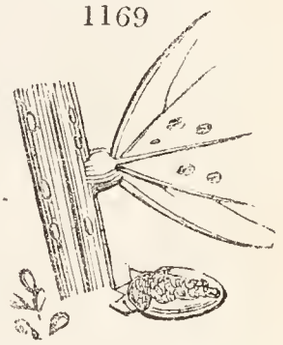
1166

1167



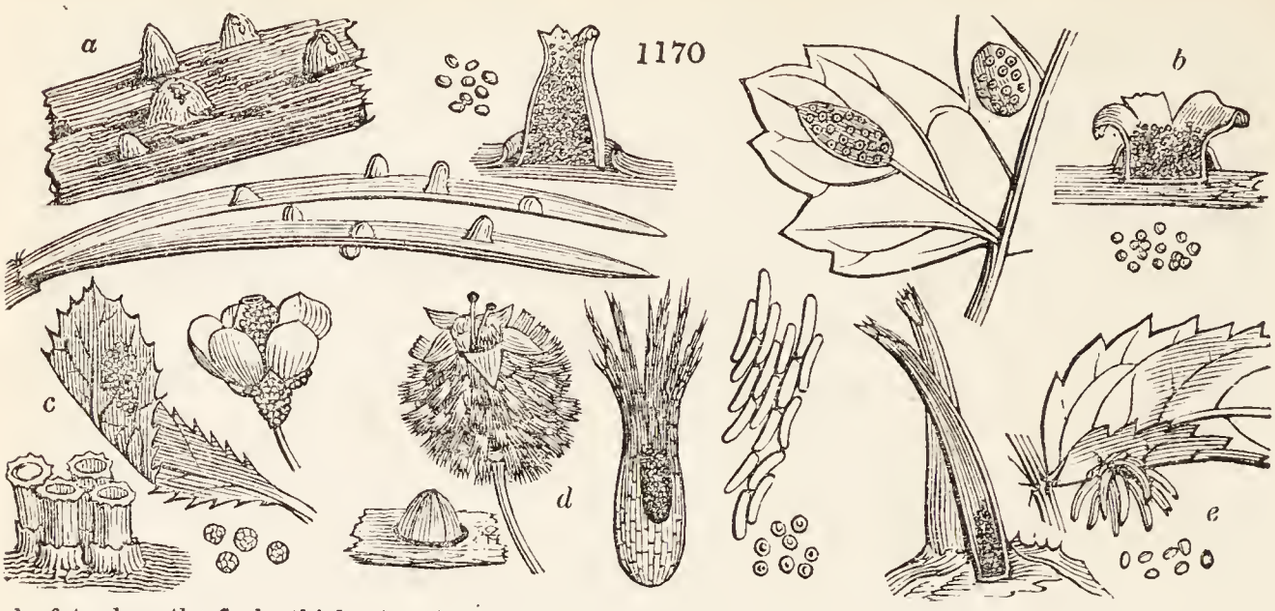
1168

1169



(*fig.* 1171.) In this figure, *a* is a leaf with the Æcídium becoming developed; *b*, a leaf bearing the Æcídium fully developed; *c*, portion of a leaf with the Æcídium farther developed; *d*, section of a

1170

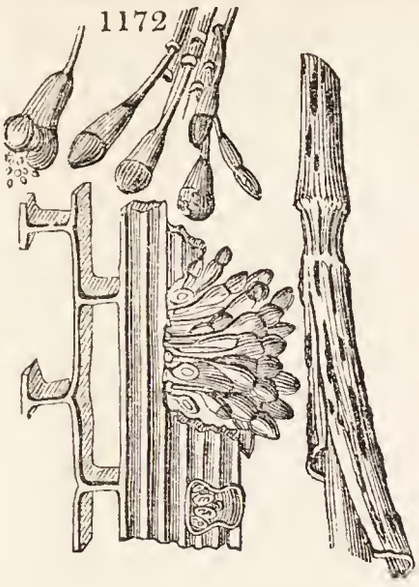


leaf, to show the fleshy thickening that accompanies the developement of the Æcídium; *e e*, seeds of the Æcídium: a seed is called a sporidium; in the plural, sporidia; *f f*, plants of the Æcídium: each is

1171

called a peridium; in the plural, peridia. The Æcídium cancellàtum first appears like mucus, but consists of a number of hairy substances. These hairs, when magnified, appear like a collection of granules of a bulbous shape, each containing a number of balls connected by strings. The balls, though so minute as to be scarcely perceptible by the eye, are yet only receptacles for seed. This is a most destructive fungus: it always seizes on the veins of the leaves, which afterwards turn yellow, and fall off; the branches next wither, and in two or three years a whole orchard is destroyed. Mr. Knight, in 1832, suffered severely from this fungus, and has tried many experiments respecting its cure.

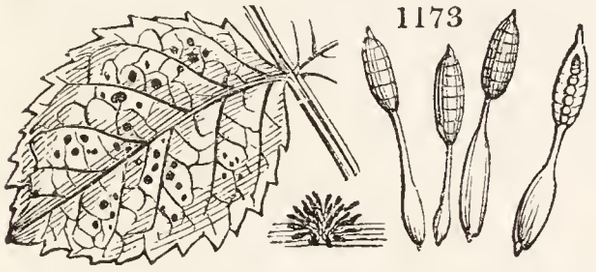
1172



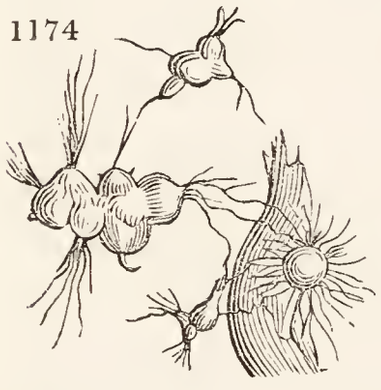
8065. *The principal fungi of the third class, or those which attack the roots of plants*, are two; and both closely resemble truffles. One of these (Rhizoctònia *Crocòrum*, *fig.* 1174.), which is of a brownish yellow, attacks crocuses; and, in those countries where the crocus is cultivated for its saffron as an article of commerce, it makes great ravages. It is called by the French *la mort du safran*, and soon destroys a whole crop. The other fungus (Perìola tomentòsa) is found on the potato, lucern, &c. It turns the roots, which are naturally white, of a purplish hue. Its ravages are often attributed to grubs. Both these fungi appear to be propagated by spawn, or fibres which spread through the earth, and cling round the roots which they find in their way.

8066. *Remedies for mildew.* All these mildew fungi are very easily propagated, from the rapidity with which they arrive at maturity, and the immense numbers of seeds which they produce. Most of them require only twenty-four hours from the first springing of the plant to the ripening of its seed; and the number produced by each may be guessed from the circumstance of one mushroom being sufficient to propagate 250,000,000. The extreme minuteness of the mildew fungi renders them still more numerous. The first class, or the superficial mildew, appears to be communicated by the air, the seeds when ripe being carried by it from one plant to another, and establishing themselves wherever they touch. They destroy a plant by covering the surface of its leaves, and thus preventing respiration. Plants are generally most affected by superficial fungi after a long drought, when the fibres of their roots are unable to imbibe sufficient moisture from the soil, and the plant thus becomes debilitated, and affords an easy prey to the parasite which attacks it: as a proof, in Scotland, where there are heavy night dews, this fungus is unknown. The cure for this species of mildew seems evidently to be abundant watering. Some onions attacked in a dry season by Bótrytis were nearly cured by abundant watering; and the progress of the disease was effectually checked. The internal mildew requires diametrically opposite treatment. This mildew evidently cannot be communicated by the air, since it always appears to spring from the interior of the plant, and to be at first covered with a thin skin, from which it does not burst till it is ripe. It is impossible, therefore, that this kind of mildew can be communicated externally, and yet the fact that it is contagious is so clear as not to admit a doubt. The only manner in which it appears probable that it can reach the interior is through the roots. The seeds, when ripe, fall upon the earth, which becomes contaminated by them, and they are sucked up by the spongioles of the roots. The correctness of this hypothesis is proved by sowing clean seeds in infected soils; and the young plants from these seeds springing up with the disease upon them. The circumstance of its always attacking the most vigorous plants is thus also explained, as it is evident that, the more rapid the circulation, the greater is the probability of extraneous substances being drawn up with the moisture imbibed by the roots. It is also clear that, in this case, water must aggravate the disease; as, by exciting the plant to suck it up, it would increase the danger of the seeds of the fungi being drawn in with it. The only cure for this fungus seems to be that adopted by Mr. Knight with his pear trees; viz., taking them up, washing the roots quite clean from every particle of soil, and then replanting them in quite a different part of his grounds. Red plants are said to be more liable to mildew than any other. Red is, indeed, supposed, by some, always to indicate a morbid action, as it shows that the plant is unable to absorb carbonic acid gas from the atmosphere, which is necessary to its perfect health; at all events, it is a proof of disease when leaves, or any other parts of a plant, not naturally red, assume that colour. Other experiments have been made for curing, or at least preventing the spread of, the internal mildew; and Mr. Bauer has found that steeping grains of corn in limewater will produce the desired effect. There appears no cure for mildew in the roots, but by cutting a deep trench round the infected plants, and cutting off all communication between them and the rest of the field. (*Gard. Mag.*, vol. ix. p. 332.)

1173



1174



8067. — 1732. *Elevation*, by occasioning a material difference in atmospheric pressure, has a considerable effect on mountain plants; and, according to Professor Dobereiner, is the chief cause of their diminutive size. Experiments have been made to prove this by placing seeds of barley in vessels, containing soil, water, and air, under different degrees of atmospheric pressure; and the result has been, that, where the pressure was greatest, the vigour of the plants was greatest also. (*Ency. of Gard.*, edit. of 1834. § 1746.)

8068. —1832. *Cross impregnation of the different kinds of corns is an important operation with a view to produce new varieties.* It is thus performed with the gramineous plants: — The first day "that wheat, oats, or barley comes into ear, let the farmer select a few stalks, as breeders; and, with the forefinger of his left hand, pressing gently on the point of the chaffy cover, let him force it open; and, with a pair of small pointed scissors in the right hand, let him cut out the three yellow anthers, not yet opened, and let the chaff spring back to protect the stigma and embryo grain. After four days, let him return to the same stalks with the male flowers, or parts of the flowers, of the variety with which he means to cross, open up the glumes as formerly, and dust the stigma gently with the pollen. One stalk of barley, oats, or wheat, treated in this manner, and the grains carefully sown, may produce several new improved varieties. Peas and beans, too, have their parts of fructification concealed by the papilionaceous corolla, and by similar treatment may produce similar results." (*Quart. Jour. Agr.*, vol. iii. p. 666.)

8069. — 2217. *A new theory of the rotation of crops* has recently been promulgated by M. De Candolle and others. The originator of this theory appears to have been M. Brugmans, who, having placed some living plants in dry sand, saw some small drops of water exude from the extremity of the radicles. It appears that exudations of this kind are, if not always, at least frequently, excretions, or parts of the

juices, which, not having served for nourishment, are rejected by the inferior parts of the vessels of plants. This idea first suggested to M. De Candolle a new theory of the rotation of crops, which has been confirmed to a certain extent by the experiments of M. Macaire. M. De Candolle assumed it as highly probable that the exuded matter from the roots of plants may be considered as their excrement, and that it would be as unreasonable to feed plants on their own excrements, as to feed animals on theirs. The particles which have been delcterious to one genus of a tribe or family of plants, cannot, he thinks, be it prove injurious to all the individuals composing that tribe or family; while at the same time he thinks it probable that these excrements might not only be innoxious, but even nourishing, to others. If this opinion be founded on fact, it will easily account for the circumstance of one kind of corn crop being injured by immediately succeeding another.

8070. *M. Macaire*, to subject these theoretic views to the test of experience, has made many experiments to prove that vegetables exude matter from the roots; and these are related by him in a memoir inserted in the *Mémoires de la Société de Physique et d'Histoire Naturelle de Genève.* (See *Edin. New Phil. Jour.*, No. xxviii. p. 215.) After various attempts to raise plants in pure siliceous sand, pounded glass, washed sponge, and on white linen, he decided upon pure rain water. After cleansing and washing the roots thoroughly, he placed them in vials with a certain quantity of pure water. After they had put forth leaves, expanded their flowers, and flourished for some time, he ascertained by the evaporation of the water, and the use of chemical reagents, that the water contained matter which had exuded from the roots. He satisfied himself that this is the fact with respect to nearly all those plants which display their flowers. Several plants of Chondrílla muràlis, perfectly clean, were placed with their roots in pure water. At the end of a week, the water was yellowish, it emitted an odour like opium, and had a bitter taste. Subacetate and acetate of lead produced a brownish flocculent precipitate, and a solution of gelatine disturbed its transparency. As a proof that this matter was an exudation from the roots, it was found that neither pieces of the root, nor of the stem, when macerated in the water during the same time, occasioned either taste, smell, or precipitate. To prove that plants employ the excretory power of their roots, in order to get rid of hurtful substances which they may have imbibed, the following experiments were made: — Some plants of the *Mercuriàlis* ánnua were washed in distilled water, placed so that one portion of their roots dipped into a weak solution of acetate of lead, and another branch of the same root into pure water. Having vegetated in this manner very well for several days, the water was tested by hydrosulphuret of ammonia, which proved, by the black precipitate which it formed, that a notable portion of the lead had been absorbed, and deposited by the branch which dipped into the water. Groundsel, cabbage, and other plants, gave the same results. Some plants grew very well for two days in acetate of lead. They were then withdrawn, their roots well washed with distilled water, which, being afterwards tested, was found to contain no lead, and then placed to vegetate in rain water. In the course of two days this water was found to contain a small quantity of acetate of lead. The same experiments were made with limewater, which, being less injurious to plants, is preferable to lead. The roots being partly placed in limewater and partly in pure water, the plants lived well, and the pure water soon showed the presence of lime by the oxalate of ammonia; and the plants which had grown in lime, and then been transferred with every precaution to pure water, soon disgorged into it a portion of lime. Similar trials were made with a weak solution of marine salt, and with a like result. There can be no doubt, then, that plants have the power of rejecting, by their roots, soluble salts which are injurious to vegetation. Experiments also proved that the roots exuded a greater excess of matter during night than in the day. As it is well known that the light of day causes the roots to absorb their juices, it is natural to suppose that, during the night, absorption ceases, and excretion takes place.

8071. *The inferences which M. Macaire would deduce from his experiments*, are, that the greater number of vegetables exude by their roots substances unfit for their nourishment; that the nature of these substances varies according to the families of plants which produce them; and that some being acrid and resinous may be injurious, and others being mild and gummy may assist in the nourishment of other plants. (*Quart. Jour. Agr.*, vol. ii. p. 320.; *Gard. Mag.*, vol. x. p. 12.)

8072. *The reasonableness of this theory of the rotation of crops* seems to be generally allowed by vegetable physiologists; and it is even alleged that it had occurred to the mind of Lord Kaimes, who remarked that plants exhaust or defile the soil chiefly when forming or ripening their seeds. "Culmiferous plants," this writer observes, "when not allowed to come into flower, draw little nourishment from the soil; but by the time they have begun to ripen their seeds, all their leaves are withered, and they depend entirely upon the soil for a supply of nutriment." Mr. Towers, an English writer on gardening, seems also to have hit upon something like this theory, when he noticed that two crops of raspberries, in immediate succession, cannot easily be maintained, even with the assistance of abundance of manure. An ingenious writer in the *Quarterly Journal of Agriculture* (vol. iv. p. 880.) is inclined to think that plants exude matter from their roots only when they display their flowers, when they form or ripen their seeds, or when they die. Onions, he says, and all garden vegetables which are not permitted to produce seeds, may be cultivated in the same plot of ground year after year, without the assistance of manure; but not peas, beans, kidneybeans, &c., because they are required to form their seeds. This writer accounts for the raspberry defiling the soil from its wood dying every year after having yielded its fruit. However, there are difficulties in the way of this theory when it comes to be applied to trees and shrubs, and such plants as the saintfoin and lucern, that it will require time to overcome. (See *Gard. Mag.*, vol. x. p. 12.) We are informed, that Professor Daubeny of Oxford is engaged in a series of experiments on this subject; and, from the acknowledged eminence of that philosopher, both as a chemist and as a vegetable physiologist, the result to which he arrives will probably determine the value of the hypothesis, for theory it can hardly with propriety be called, since it has not yet been proved to be generally applicable. Notwithstanding this, however, a writer in the *Quarterly Journal of Agriculture* (vol. v. p. 1.) has endeavoured to explain the advantages derived from fallowing, paring and burning, irrigation, and draining, on the principle of freeing the soil from the excrementitious matters deposited in it by plants; an hypothesis too absurd to need contradiction.

8073. — 2226. *A new theory* of the operation of animal and vegetable manures has lately been promulgated by some German philosophers. According to this doctrine, before putrescent manure can be absorbed by the spongioles of the roots of plants, it must become *humin*, which appears to be carbon in a particular state of decomposition.

8074. *Humin.* Of all the different ingredients of which manures are composed, carbon is supposed to be that which holds the first rank as a food of plants; but it is only in a state for this after it has united with the carbonic acid of the air, and the compound so formed, on being dissolved, is taken up by plants as food. This substance was called *ulmin*, on account of its being first found in the diseased part of an elm; but M. Sprengel gave it the more general term of *humin*, because he found it to exist in soils. Humin is a substance not unlike carbon, for which it has hitherto been mistaken. It is very soluble in spirits of wine, concentrated sulphuric acid, ammonia, and by heat in acetic acid; but it is insoluble in water, and water throws it down in all its solutions. It combines with all the salifiable bases, and forms the *humic acid:* but it has no acid taste; does not redden vegetable blues, &c.; like the gallic acid, it contains only carbon and water, without excess of oxygen. There is a strong analogy between humin and other nutritive substances, such as gum or fecula. It forms a humate with an alkali, which is very soluble in water. All substances which contain carbon are dissolved in the water of vegetation, through the means of humin; and the dissolved mass is taken up by plants as food. Humin in combination with lime, ammonia, or potass, also becomes soluble in soils or dung. (*Quart. Jour. Agr.*, vol. iv. p. 260.)

8075. — 2241. *Noir animalisé.* The charcoal obtained from wood, coal, or peat, by burning in close vessels, after being powdered, is found to act like chloride of lime in absorbing bad smells. In consequence

of this, it has been mixed by the French with those descriptions of manures which give off the most offensive odours, and the manure so formed, which is said to be highly fertilising, is sold under the name of *Noir animalisé*. This discovery was made by M. Salmon in 1831, who has obtained a patent for it, and manufactures it on a large scale. M. Bella, of Grignon, an eminent French agriculturist, tried this manure against the *poudrette* (dried night soil), and found it one fifth part more powerful. (*L'Agronome*, vol. i. p. 126.) An improvement has been made in this manufacture by M. Damart-Vincent, by which it is sold cheaper than the *poudrette*, or at about five francs for nearly two cwt.. (*Ibid.* p. 251.)

8076.—2243. *Dutch ashes* are procured by burning bricks made from the mud found at the bottom of ponds, from which peat has been dug. According to an analysis by Professor Brande, they contain, in every 100 parts, siliceous earth, 32 parts; sulphate of lime, 12 parts; sulphate and muriate of soda, 6 parts; carbonate of lime, 40 parts; oxide of iron, 3 parts; and impurities, &c., 7 parts. These ashes are extensively used in Flanders, especially as a top-dressing for clover, at the rate of nineteen bushels per imperial acre. They are also sown on wheat and pastures in March and April; on oats and beans in the beginning of May; on rye in October and November; and in gardens at most seasons. A bushel of these ashes weighs forty pounds; and, as they can be sold in British seaports at 3*l.* per ton, the expense of manuring an acre with them will not exceed 1*l.* (*High. Soc. Trans.*, vol. x. p. 110.)

8077.—2248. *Bone dust* is usually applied at the rate of two quarters per imperial acre; but by mixing it with finely sifted coal ashes one quarter per acre, it is alleged, may be rendered nearly as effective. When bone dust is used in any quantity above two quarters per acre, it does not produce a corresponding increase in the bulk of crops. The energies of bone dust as a manure is thus explained. The decomposition of the dust in the soil, which is rapid, disengages the phosphoric acid, and the lime and animal carbon is left to be acted on by the air; and these substances being converted into humin readily form a soluble mass, which is taken up by the water of vegetation, and becomes the food of plants.

8078. *Bone manure as compared with stable manure.* By an experiment conducted on a soil somewhat clayey, it appears that, while a Scotch acre manured with sixty bushels of crushed bones produced twenty-four tons of Swedish turnips, an adjoining acre manured with thirty cart-loads of stable manure produced twenty-nine tons. (*Quart. Jour. Agr.*, vol. iv. p. 636.)

8079.—2270. *Application of recent manure.* The opinion and practices of British farmers have always been at variance with the theory of Sir Humphry Davy on this subject; though it would appear that Sir Humphry believed the farmers to have been converted. "Many," he says, "who have doubted, have been lately convinced; and perhaps there is no subject of investigation, in which there is such a union of theoretical and practical evidence." (*Lect.* VI.) It appears, by two articles lately published in the *Quarterly Journal of Agriculture*, that the Scotch farmers are as much opposed to Sir Humphry's theory as ever. "In theory," it is there stated, "dunghills should be kept dry and cool till they are applied to the land; because, if dung cannot be immediately applied to crops, the destructive fermentation should be prevented very carefully; and, if dung has been fermented till it becomes a mere soft cohesive mass, it has generally lost from one third to one half of its most useful constituent elements. In practice, on the other hand, dunghills are quite exposed to the weather, because all dry litter which has been even decomposed a little, such as that under sheds, in which the cattle are accustomed to lie all night, or an unmixed mass of horse dung, is found to be of itself a worthless application to any crop. These substances should be mixed by turning them over among the wetter cattle dung, so that the whole mass may be fermented to an equable consistency. Practice has also discovered, that the crop of turnips will be risked altogether, if well-fermented dung be not employed. Indeed, many farmers maintain that it cannot be too much fermented for the turnip crop. Two years' fermented dung is kept on purpose, by many who have abundance of straw, to apply to the raising of Swedish turnips; and, certainly, the shorter the dung is, the more quickly will the plants push through the ground, and the more healthy and heavy are the turnips likely to be. Fermented dung is more and more applied every year, even to the potato crop, which was for a long time supposed to do best when immersed among rank dung. In true potato soils, the crop is decidedly better when it is raised with fermented dung. Fermentation is also found useful in killing the vegetative power of the seeds of weeds, or grains of corn, that may have passed away among the straw. 'Thus we see from the evidence' which we have adduced, that there is not only no 'union,' but a decided opposition between the theoretical and practical methods of treating and applying putrescent manures." (Vol. iv. p. 78.)

8080. *There are other objections to the use of recent farmyard manure*, of a less important nature: such as the difficulty of burying it, and, when buried, its liability to be dragged up by the harrows; but principally the tendency which littery dung has to render the land on which it is laid too open, and thus subjecting it to the danger of being burnt up in dry weather. (*Quart. Jour. Agr.*, vol. iv. p. 78.)

8081. *The practical farmer*, in consequence of these reasons, and notwithstanding the experiments made by Sir Humphry Davy, and detailed in § 2238. and § 2239., continues to prefer using manure in a highly fermented state, so as to be what in practice is called short muck. In defence of the practical man, it is contended, that the decomposition of a dunghill does not throw off the most valuable and the most efficient parts of the dung, but chiefly vapour of water. It is allowed by those advocates, that when the texture of the fibrous part of farmyard manure begins to decompose, there will be an evolution of some of the gases which constitute the food of plants: "but what harm," it is asked "occurs to the dung as a manure from the escape of these gases? None whatever. We are told that the gases constitute the food of plants; and that, if they are permitted to be dissipated by decomposition, the quantity of nourishment in the heap of manure will of course be so much diminished; and that, if the bulk of the dunghill be lessened one half, or one third, by excessive fermentation, the quantity of nourishment to the crops will be diminished in a greater ratio." Still it is contended, that, though some of the gases which constitute the food of plants are disengaged from fermenting stable manure, yet that it does not follow that plants will receive them as food directly that they are disengaged. On the contrary, it is considered that they would either reject food in that state; or, if they could not avoid taking it in, that they would be injured by it. "Accordingly, we invariably find that plants suffer from their contact with fermenting dung, and it is this well-known fact, more than any other circumstance, which deters farmers from applying dung in an unprepared state." What has experience determined as the least injurious state in which dung can be applied to any crop? The cultivator answers, in the state of short muck, that is, "a soft cohesive mass," capable of being cut with a spade. What state has the cultivator determined to be the best for putrescent manure to be in when applied to soil not under crop, but which is to be sown or planted some days or weeks afterwards? A determinate answer to this question, founded on experience, has not yet been given. Farmyard manure is sometimes applied to fallows in an unprepared state, but always a considerable time previously to the seed being committed to the soil.

8082. *The propriety of the farmer's practice in applying dung in the state of short muck* is thus given in the work above quoted:—"In 1802, the celebrated Klaproth received from Palermo a substance which exuded spontaneously from the bark of a species of elm, and to which Dr. Thomson gave the temporary name of *ulmin*. It dissolves speedily in a small quantity of water, in which respect it is like a gum: but when the solution is very much concentrated by evaporation, it is not in the least mucilaginous or ropy; nor does it answer as a paste, and in this respect it differs essentially from a gum. When a few drops of nitric or oxymuriatic acid are added to the solution, it becomes a gelatinous mass; which, when slowly evaporated to dryness, and heated with alcohol and again evaporated, leaves a light brown bitter and sharp resinous substance. Thus it appears that ulmin, by the addition of a little oxygen, is converted into a resinous substance. In this new state it is insoluble in water; and that a substance soluble in water should assume the resinous form with such facility, is very remarkable." (*Thomson's Chemistry*, vol. iv. p. 696.) "Berzelius has found this curious substance in all barks; Braconnot, in sawdust, starch, and sugar. But, what is more to our purpose, Sprengel and Polydore Boullay have found it to constitute

a leading principle in all soils and manures. Sprengel appropriately calls it *humin* from its existence in all soils, *ulmin* being given to it by Dr. Thomson as a temporary name." (*Quart. Jour. Agr.*, vol. iv. p. 620.)

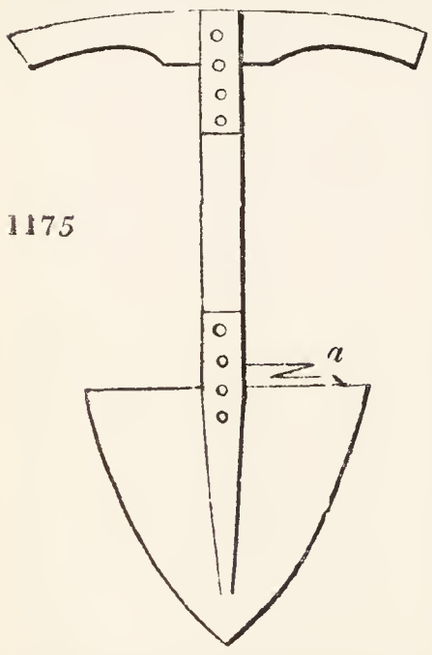
8083. *Humic acid and carbonic acid gas*, mixed with water, constitute, according to this discovery, the chief food of plants. Every description of manure is only valuable in proportion as it contains these substances. Humic acid is found in abundance in putrescent manure when it is so far rotted as that it may be cut with a spade. It has been proved that rotted dung contains much more carbonic acid gas and humic gas, weight for weight, than fresh dung. Fresh dung is injurious to vegetation in consequence of its ammonia; which, from its acridity, in practice is said to burn plants. Ammonia becomes concentrated in stale liquid manures, and such manures are, therefore, mixed lightly with water, "in order to dilute the ammonia, and allow the proper action of the humic acid, which exists in large quantity in them." Covering a dunghill with soil in hot weather "is now explained, not as it has hitherto been, viz. by asserting that the earth absorbs and prevents the escape of the carbonic acid gas, which it could no more do than a balloon made of gauze could prevent the escape of hydrogen gas (*Grisenthwaite*); but that a violent fermentation in the dung is checked by the earth partly excluding the atmospheric air and rain water, the oxygen in either of which is indispensable to continue the process of forming carbonic acid gas by uniting with the dung. With regard to composts, it is found that to mix lime with fresh or rotten dung is to waste it; because the lime takes up and renders useless the carbonic acid gas which it contains. In like manner, a compost of fresh dung and weeds, green leaves, grass, turf, and green vegetables, without lime, is valuable; because all these substances supply abundance of *humin*. On the other hand, lime promotes the fermentation of peat earth, dry leaves, and every thing which contains hard woody fibre and supplies *humin* in quantity." (*Quart. Jour. Agr.*, vol. iv. p. 623.)

8084. *Such are the two leading theories* of the operation of putrescent manures; in the application of which, the farmer must take especial care not to err on the side of over-fermentation. It is a fact well known to gardeners that the black spit dung of old hotbeds, however moist, is not nearly so powerful a manure as dung in a comparatively recent state from the farmyard. For our own part, we are inclined to place the happy moment of appliçation in a middle point between littery dung, which can only be lifted with a fork, and rotten dung, which can be easily cut with a spade. It will thus appear that we neither agree entirely with the theory of Sir Humphry Davy, which is also that of M. Chaptal in the edition for 1820 of his work entitled *La Chémie appliquée à l'Agriculture*, nor with the theory of *humin* of Klaproth, Sprengel, Thomson, and others.

8085. — 2306. *Common salt as a manure.* Much as has been written on this subject, a pamphlet has recently appeared by Mr. Kemp, *On the Important Discovery of the Decomposition of Common Salt, for the Purposes of Manure: whereby an acre of land is prepared for the reception of any crop, at a cost of* 10*s. only.* The author states that, while farmyard dung produces twenty bushels of wheat per acre, decomposed salt will produce from thirty-five to forty bushels. He anticipates the whole produce of the kingdom increased fully one third by his discovery; but, before he makes it known, he expects to be remunerated by a handsome subscription, or by parliament. (See *Gard. Mag.*, vol. x. p. 233.)

8086. — 2307. *Universal compost.* The following ingredients and quantities, it is said, will afford a sufficient dressing for an acre of land: — Fifty pounds of vegetable alkali, viz., English, Russian, or American potash; thirty-six pounds, viz., four gallons of oil of any kind; one hundred and twelve pounds, viz., two bushels of common salt; fifty pounds, or about a bushel, of quicklime. Mix the whole together, the alkali and salt having been previously dissolved in water, and reduce the whole to such a degree of liquidity that it may be poured from the rose of a watering-pot on as much light porous soil as will absorb it. After this compost has lain some time, it may be carted out, and spread over the acre to be manured; but if there is a proper water cart (*fig.* 348.), this manure may be sprinkled over the land in its liquid state. (See *A Dissertation on Soils and Manures.*)

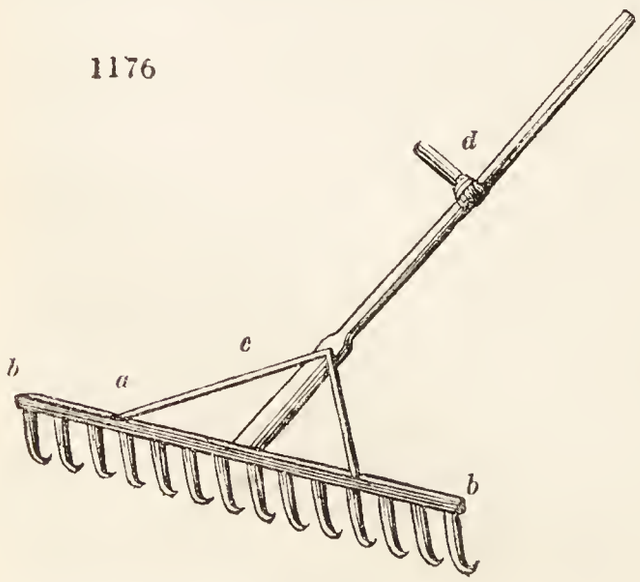
1175



8087. — 2308. *Saltpetre* has been tried on wheat, grass, and oats at the rate of 1¼ cwt. per Scotch acre. It was sown on grass land, on the 28th of March, 1829; and in ten days afterwards the grass was of a deep green, and was fit for pasturage before the rest of the field. It appeared also to improve the quality of wheat and oats by producing the more green vegetation. It ought to be applied when the land is moist. (*Highland Soc. Trans.*, vol. viii. p. 195.)

8088. — 2444. *The under-foot spade* (*fig.* 1175.) should be made very strong; the shaft, or handle, should be square, with the angles rounded off, and strongly plated over where it is joined to the cross-angle at top, and to the blade below. The blade is about fourteen inches across, and twelve inches deep; quite perpendicular, with sharp cutting edges, and a hilt or piece of iron (*a*) riveted on for the feet. For the stuffing up of hedges, taking the top sods off drains, and various uses where strength is wanted, this spade will be found a most powerful instrument. (*Gard. Mag.*, vol. vii. p. 86.)

1176



8089. — 2452. *The corn rake* (*fig.* 1176.), for using after the scythe, differs from the common rake both in form and dimensions. The head (*a*) of the corn rake should be made of fine ash; as light as possible, but strong enough to bear the driving in of a number of iron teeth; and it should be at least five feet in length, and feruled with iron at both ends (*b b*). The teeth should be seven inches in length, and four inches apart, and so curved at their points, that the weight of the rake may rest upon the curve, with the points of the teeth quite free of the ground, when the rake is held in a working position. The points of the teeth should be thin and broad. The handle of the rake may be of light fir, and it should be full six feet in length. An iron (*c*), passing from the handle on each side to the head, will prevent the latter from being twisted out of its position. A short handle, *d*, like the left handle of the scythe, and fastened at a convenient spot on the shank with an iron wedge, will facilitate the passage of the rake over the ground. (*Quart Jour. Agr.*, vol. iv. p. 363.)

8090. — 2462. *The Spanish hoe.* A modification

of this instrument has been made by Lord Vernon, to which he has given his name. (See *Gard. Mag.*, vol. ix. p. 508.) The hoe is manufactured at Sheffield of different sizes, and is an excellent implement for stirring the soil; because, from the pointed form of its blade, it goes much deeper with the same exertion of force than any of the thrust or draw hoes. It is, in fact, a kind of pick, like the hoe picks used in France and Spain in stirring the soil among vines.

8091. — 2481. *The reaping-hook.* It is observed by the author of an excellent article on reaping with the scythe, published in the *Quart. Jour. of Agr.*, vol. iv. p. 350., as a remarkable circumstance in the history of mechanical science in Britain, that the art of cutting down corn crops should be so inadequately supplied with instruments. The reaping-hook, unlike every other mechanical instrument, depends entirely for its efficacy on the physical powers and dexterity of the labourer. The knife and the spade are as simple in their forms as the reaping-hook; and yet the former has been displaced by many mechanical contrivances, while the reaping-hook remains in all its primitive simplicity. Its continued use in the field is attended with immense loss of time and money; and, therefore, till an efficient reaping-machine is invented, it is proposed to substitute, in many cases, the scythe in its stead. The scythe is used, for this purpose, in France, Switzerland, and in many parts of Aberdeenshire, and it appears to be gaining ground everywhere.

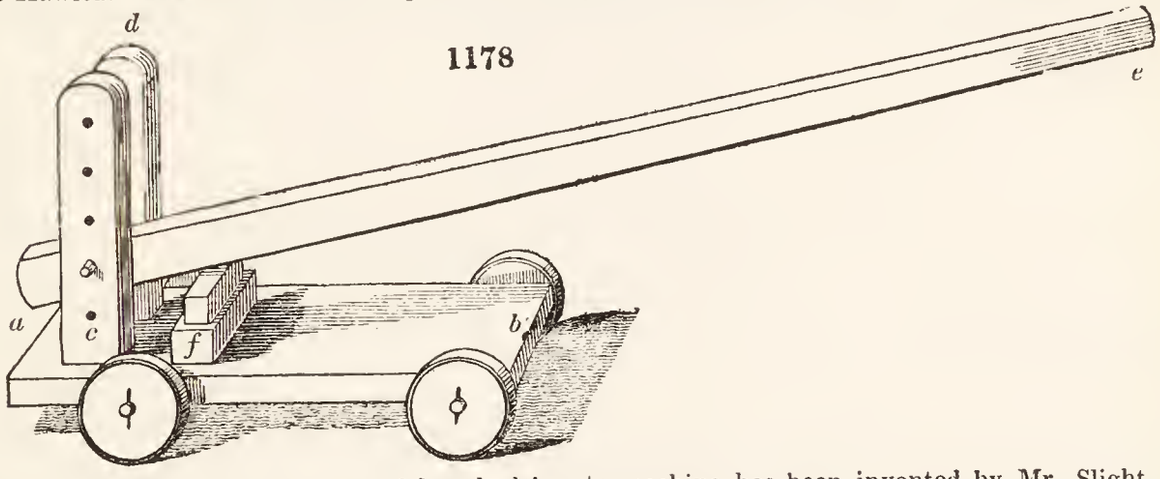
1177

8092. — 2489. *Howden's two-edged bill-hook.* (*fig.* 1177.) This hook is something like the letter S; it is all round sharp, and combines the powers of the carpenter's axe, the gardener's knife, the hedger's hook, the Highlander's broadsword, and the joiner's chisel. The blade is twelve inches in length, and three inches broad; the socket is eight inches long, and serves instead of a wooden handle when the instrument is used as a knife, bill-hook, or axe; when it is to be used as a chisel, it must be placed on the end of a long handle; and will then, either by pushing or drawing, remove small branches from the stems of tall trees. The long socket is made a little oval in the direction of the two edges, in order to let the operator feel where the edges are. The chief use of this instrument, however, is for dressing hedges, and for that a wooden helve, or handle, of about two feet in length, is best. (*John Howden, April* 30. 1830.)

8093. — 2551. *A press for compressing flour or meal into casks* is employed in North America, and it will be found described in the *Quart. Jour. of Agr.*, vol. iii. p. 559.

8094. *A machine for compressing peat* (*fig.* 1178.) has been invented by Mr. Walter Tod, of Longhope, near Hawick. The same machine might also be employed for compressing earth for building walls, and

1178

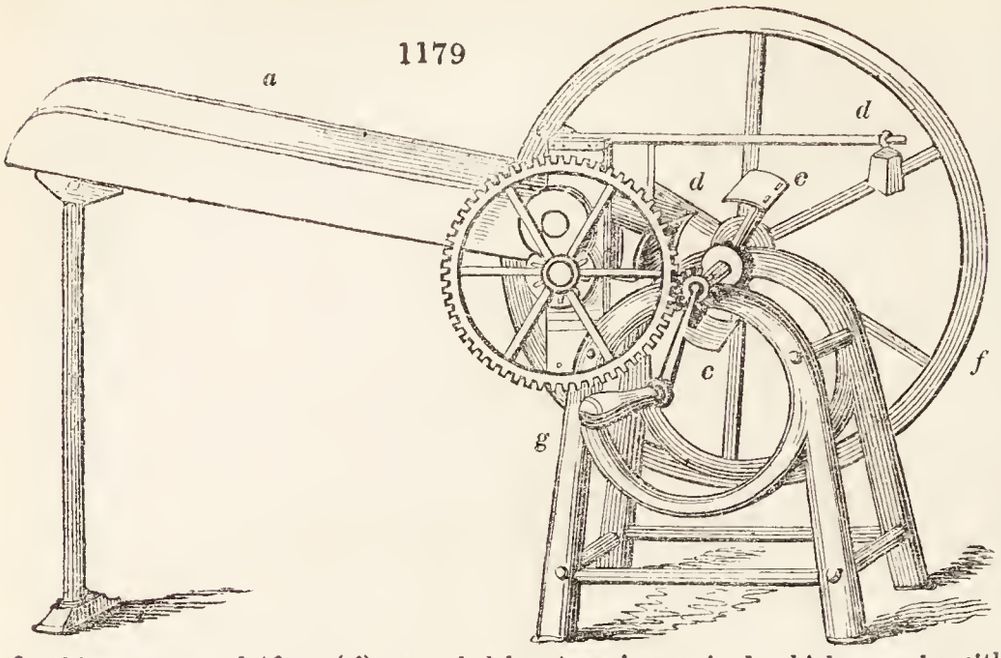


for other purposes. A more powerful and elaborate machine has been invented by Mr. Slight, the Curator of the *Highland Society's Museum of Models*, and figured and described in the fourth volume of their *Transactions;* but the simple machine of Mr. Tod, we think, will be more useful in countries where the fuel is peat; and in new countries, where the emigrant might think it advisable to build the walls of his house of dry earth. This machine consists of two strong planks of wood fixed together at each end by cross bars, and mounted upon four wheels. Two pieces of wood (*c*, *d*) at the distance of two inches from one another, are mortised into the plank (*a*, *b*) at the end *a*, and at right angles to *b*. Between the upright posts (*c*, *d*) there is inserted a strong beam (*a*, *e*) twelve feet long, and secured with an iron bolt passing through the pieces (*c*, *d*), which have numerous holes to admit of raising and depressing the beam (*a*, *e*) at pleasure. Two boxes are then made, one of wood, and one of sheet iron fourteen inches in length, three and a half in breadth, and three and a half deep. These boxes have lids which just fit them, about three inches in thickness, to allow them to sink in the boxes by the pressure. Each box is to be alternately filled with peat newly dug, the lid adjusted, and the box placed in the machine at the point *f*; a man stands at the end (*e*) of the beam (*a*, *e*); and, as each box is placed in the machine at the point, *f*, he bends his whole strength and weight upon the end of the beam. By this means, an immense pressure is applied to the box by a single effort, and in an instant of time. Two women may fill and remove the boxes. In this way a man and three women could compress about eight cart-loads of peat in a day. One man digging, and a woman throwing out the peats, could keep the machine in full operation. The peats, when taken from the machine, are built up like small stacks of bricks, but so open as to admit a free circulation of air. The stacks put up in this way become perfectly dry, without being moved till they are taken home. If the machine just described were to be adopted for compressing earth, boxes of cast iron, full of small holes, would answer the purpose best. The pressure is so great, that the wooden boxes frequently give way, though strongly made, and secured with iron at the ends; and even the one of strong sheet iron has been bent. (*Highland Soc. Trans.*, vol. ix. p. 374.)

8095. — 2560. *Slight and Lillie's straw-cutter* (*fig.* 1179.) is considered to be the most perfect machine of this description that has hitherto been invented. In most of the other machines, the oblique position of the cutters, relatively to the hay or straw which they have to pass through, is found to be attended with difficulties to the workmen when replacing them after they have been taken off for sharpening. Messrs. Slight and Lillie have obtained the advantages of passing the knives in an oblique direction through the body of hay, without occasioning the slightest difficulty when these knives are removed to be ground. This is done by elongating the cutting-box into a nozzle, which is twisted until its orifice assumes an angle of about thirty degrees. By this arrangement, the entire efficiency of the machine is retained, while its construction and keeping in order are simplified, and its price is proportionately reduced. The framing is made entirely of cast iron: *a* is the feeding-trough, the rollers being only partially seen; *b* is the nozzle or cutting-box; *c c*, the cutting bearers, with the cutters attached by their bolts; *d* is a lever and weight, which, through the medium of the bridge *e*, keeps a constant pressure on the feeding-rollers to counteract any inequality of feeding; *f* is the fly-wheel for equalising the motion; and *g*, the handle to which the power is applied. The small pinion on the fly-wheel shaft gives motion to the spur-wheel, which is mounted on the shaft of the lower feeding-roller, and carries also the lower feeding-pinion. This last pinion works into the pinion of the upper roller; and, both being furnished with very long teeth, they thereby admit of a limited range of distance between the rollers according to the quantity of feed. With one of these machines, a man, assisted by a boy to feed in the hay or straw, can cut

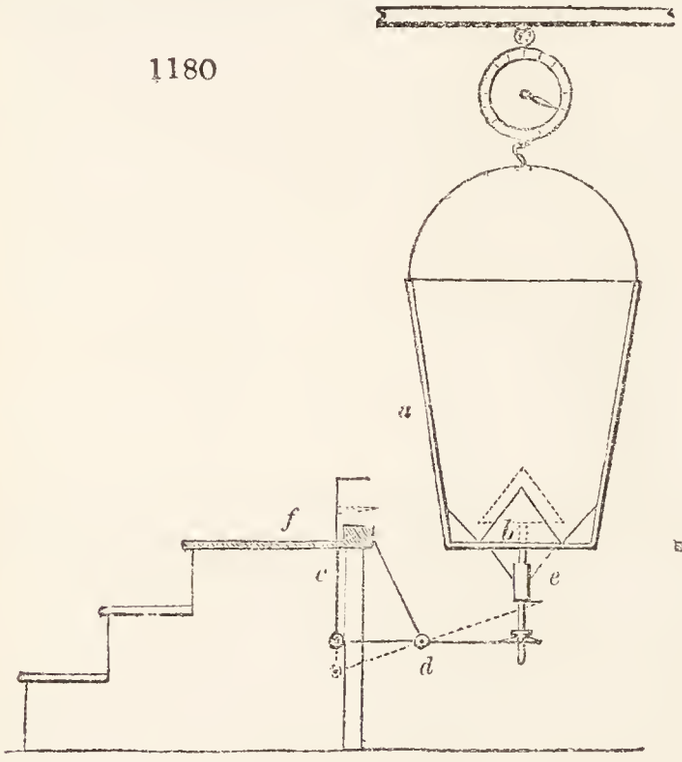
at the rate of eight stones per hour; and that quantity of cut hay is found to be sufficient for sixteen horses for twenty-four hours. (*Quart. Jour. Agr.*, vol. iv. p. 349.)

1179

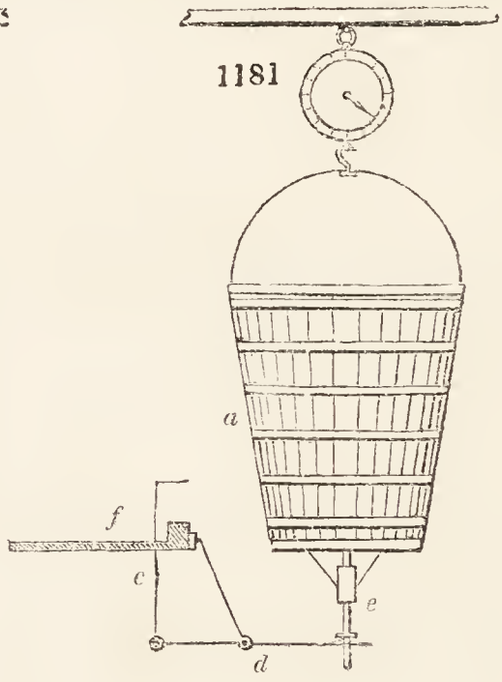


8096. — 2568. *Taylor's tub for measuring and weighing corn* represented in *figs.* 1180. and 1181. The tub (*a*) has a movable bottom (*b*), which, when it is desired to let the corn drop out, is raised by putting the foot on the pedal (*c*), which operates on the lever (*d*). The valve is worked by a spindle, which passes through the collar (*e*). The angles at the bottom of the tub are bevelled off to allow of the free egress of the corn into the sack below it. Of course the tub should be suspended high enough above the floor to allow the corn to escape; and for this purpose a platform (*f*), ascended by steps, is required, which may be either fixed or movable. Up this platform the man walks who bears the sack of corn; and, the mouth of the sack being previously

1180



1181



untied, he shoots the contents very gently and gradually into the tub. The precaution of shooting the corn into the tub gently and gradually is essentially necessary, as otherwise there will not appear to be full measure. The mode of weighing may be either by Marriott's dial engine, or by a steelyard beam; the former is the most simple. This tub was invented by Mr. Samuel Taylor, and is used in the extensive malting establishment under his care at Stokeferry, Norfolk. (*Gard. Mag.*, vol. viii. p. 467.)

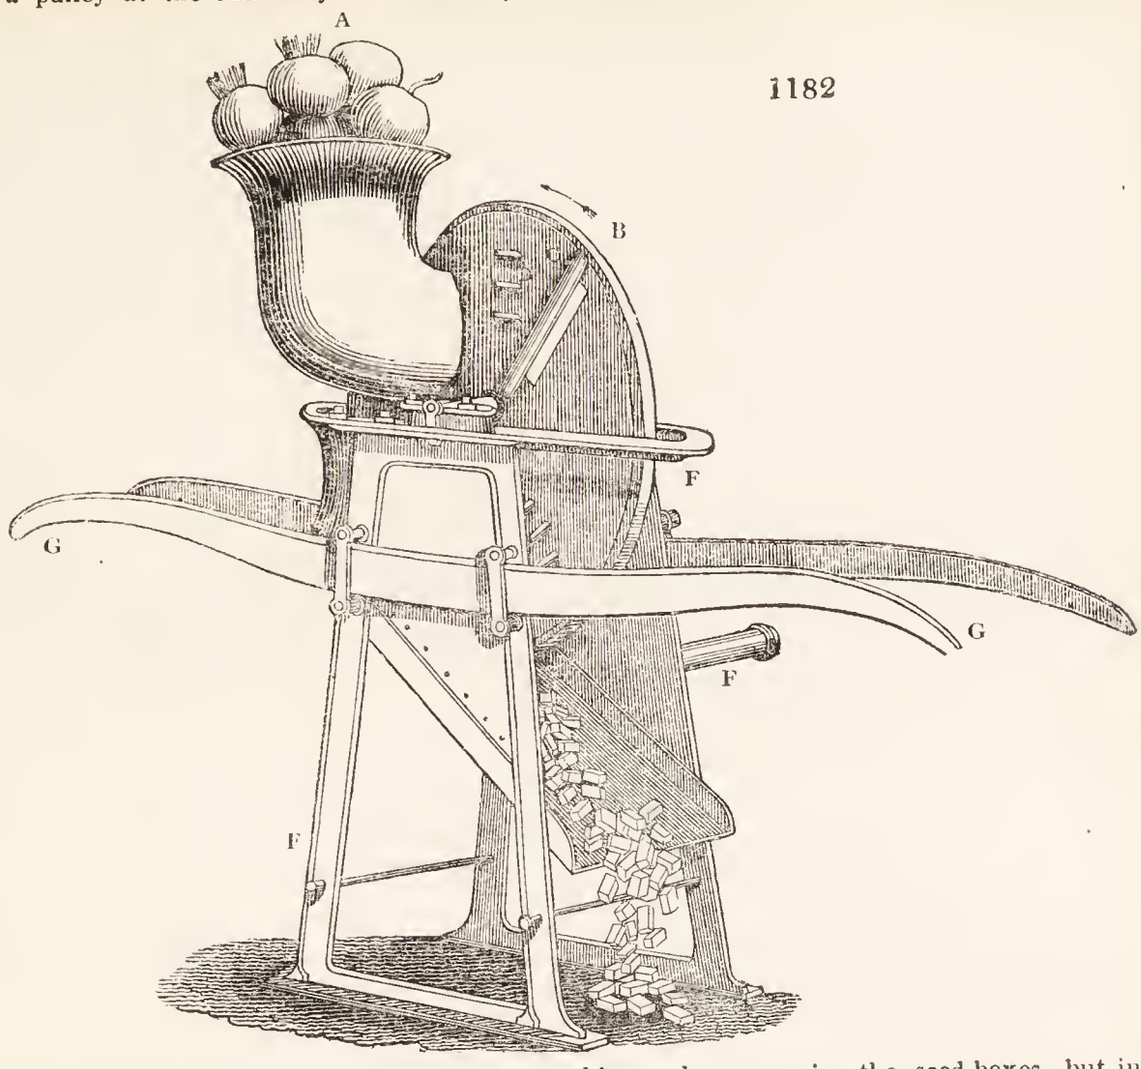
8097. — 2571. *Baird's turnip-slicer. Fig.* 1182. is considered one of the best turnip-slicers in use in Scotland. It is made, when of full size, entirely of cast iron, and consists of a standard or frame to which is attached a hopper; the frame bearing a circular plate of cast iron mounted on a horizontal axis, to which the winch-handle is attached. This plate is cast with a thickened edge or rim, which gives it, when in motion, the effect of a flywheel. It carries two thin cutters or knives, set parallel to the face of the plate, and radiating from the centre. The thickness of the slices is regulated by the distance of the knives from the face of the plate. Each knife is preceded by three or more lancet-pointed studs, which, by slitting the turnips in passing, prepare the slices for falling in pieces when they are detached from the knives, at each revolution of the plate. This process goes on so long as the hopper is replenished with turnips, their own weight being found sufficient to hold them within the stroke of the knife. When potatoes are to be sliced, the disc above described is to be removed, and another substituted, differing from the first in having the cutting studs set closer together. In the figure, A represents the hopper filled with turnips; B, the disc of cast iron that carries the cutters; C, one of the cutting knives, the opposite one being concealed by the framework; D, the lancet-pointed studs; E, the winch-handle, partially seen from behind the machine; F F, the framework of the machine; G G, two bars which slide into staples, and serve as handles by which it can be removed from one place to another. (*Highland Soc. Trans.*, vol. x. p. 51.)

8098. — 2578. *A turnip-sowing machine*, which sows two rows at a time, and deposits along with the seed a regular train of bone dust, is described in the *Quarterly Journal of Agriculture*, vol. iii. p. 718.

8099. *A machine for sowing carrots* was invented in 1833, by Mr. Daniel M'Naughton, farmer, near Irvine, in Ayrshire. *Fig.* 1183. exhibits the general appearance of the machine, which is similar to those in common use for sowing turnips; the essential difference lying in the apparatus adopted for discharging the carrot seeds from the seed-boxes. To the lower part of the framework is attached, in the usual manner, the great roller (*a*) serving to compress the prepared ridgelets, and also to communicate motion to

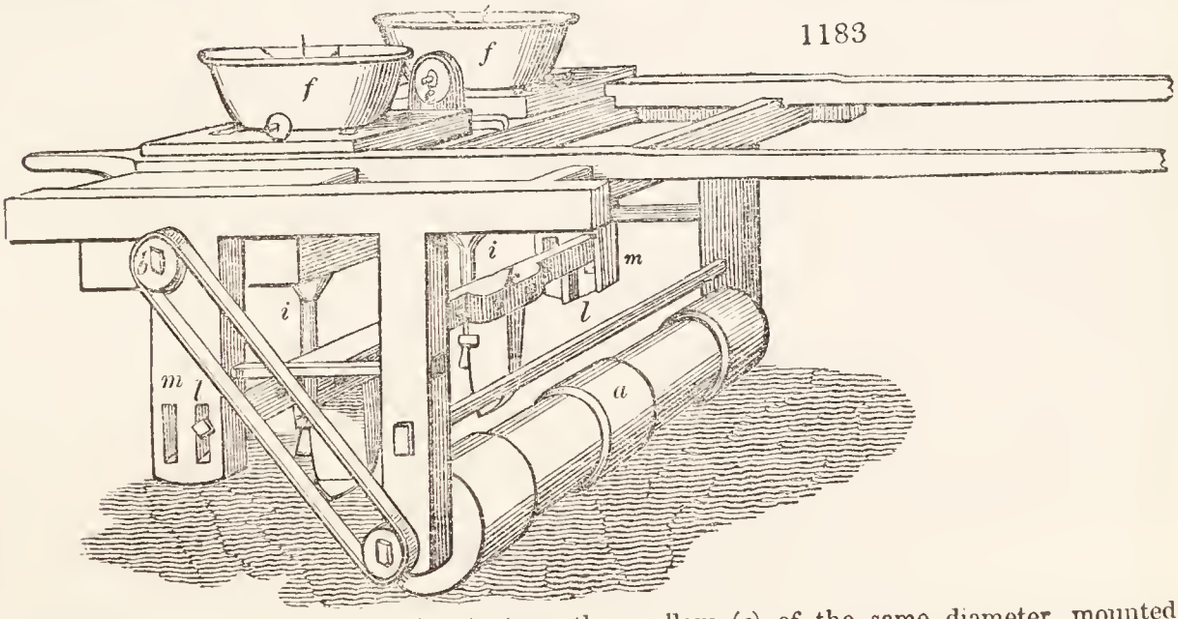
the other parts of the machine. This is effected by means of a leathern belt or a pitch chain, passing over a pulley at the extremity of the roller, and another of the same diameter at the extremity

1182



of the axle (*b*); which last, in the common machines, always carries the seed-boxes, but in this performs a double purpose. The first of these purposes is, that by means of two pulleys, which are

1183

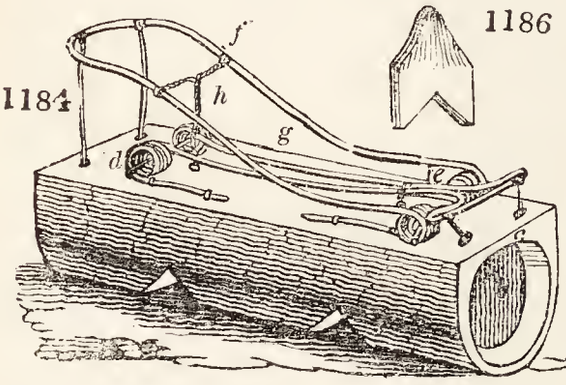


not seen in the figure, it gives motion to two other pulleys (*e*) of the same diameter, mounted on small axles, which pass through the seed-boxes, and are each mounted with three plain wooden pulleys; the middle one is about six inches diameter, one inch thick at the centre, and is diminished to about half an inch thick at the edges; the other two are three inches in diameter, and of proportional thickness. The middle pulleys, unseen, are armed with six stout wire prongs, the extremities of which describe a circle of twelve inches in diameter; while the smaller pulleys (at *e*) are similarly armed with five prongs, extending to seven inches in diameter. The revolution of these armed pulleys keeps the seeds in continual agitation preparatory to their being propelled from the box. The second purpose to which the axle (*b*) is applied is, to carry a small wooden cylinder, placed immediately under each seed-box, of five inches in length, and three inches in diameter, armed with four prongs or claws, extending to a radius of three inches. In the revolution of these claws they penetrate successively into the orifice of the seedbox, and perform an operation of picking or scratching out the seeds in a regular succession. The seeds are received into the funnels (*i i*), and pass from thence down the tubes in the usual manner to the ground, where a rut is prepared for them by the coulter. The seed-boxes are made of sheet iron, or of tin plate of an elliptical form in the mouth; the diameter being about eighteen inches and twelve inches, with a depth of twelve inches; the cross section, taken either longitudinally or transversely, being also elliptical. The bottom of the box terminates in an oblong orifice of about six inches long by half an inch wide in the clear; the latter dimension being capable of extension, or diminution, by means of two pinching screws. Each box is covered with a movable lid, to prevent the seeds from being thrown out by the agitators. The funnels, with their seed tubes, are attached to the hind part of

the coulters, and are provided with an adjustment, by means of the slits and pinching screws in the collar bar (*k*) of the framework, enabling the operator to regulate the distance between the rows, while, by means of the slits and pinching screws (*m m*), he can regulate the depth of the rut for the seed-bed. The machine is convertible into a turnip drill by a very simple alteration. The seed-boxes and the claw cylinders are removed; and, in place of the latter, two barrel-shaped seed-boxes of the common construction are substituted upon the axle (*b*). It is then a complete turnip drill-machine. When, again, it is required for sowing onions, the turnip seed-boxes are removed, as also the collar bar (*k*). The axle (*b*) is then mounted with five barrel-shaped seed-boxes, similar to, but smaller than, those for turnips. A collar bar, with five permanent coulters, is placed in the slits (*ll*) of the frame. The coulters are perforated from top to bottom for the passage of the seed, terminating in the hind part of the lower extremity. Five funnels, corresponding to the seed-boxes, are inserted, one into the upper orifice of each coulter, and thus the machine is prepared for sowing five rows of onion seed. (*Highland Soc. Trans.*, vol. x. p. 203.)

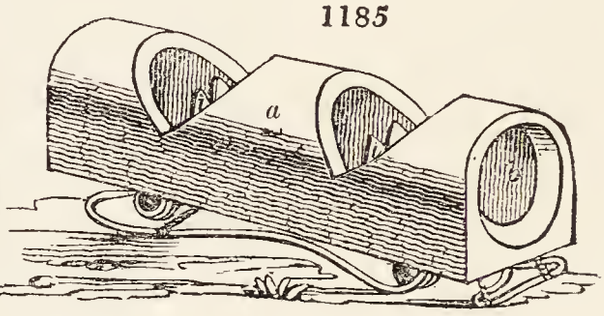
8100. — 2581. *A moletrap in use in the north of Scotland* (*fig.* 1184.) consists of a block of wood (*a*)

1184



1186

1185



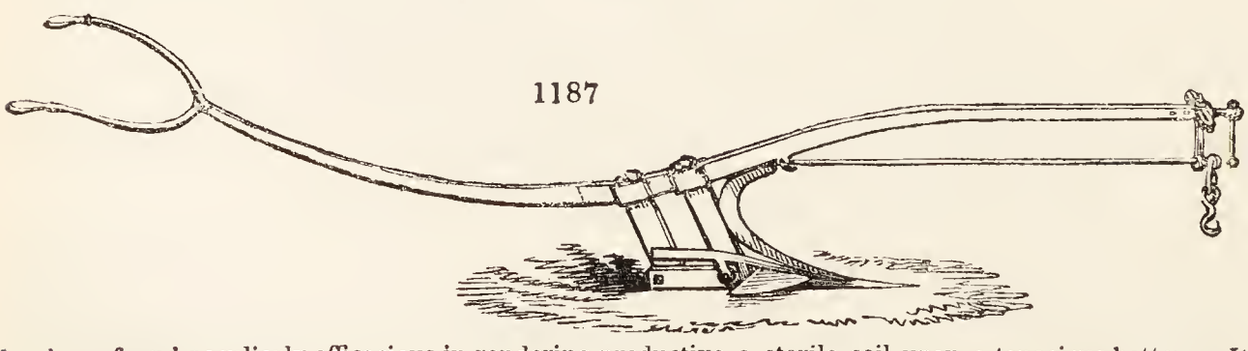
ten inches long, three inches broad, and three inches and a half deep; with a hole (*b*) two inches and a half in diameter, bored lengthwise through both ends. In the inside, half an inch from each extremity, is a groove for a wire loop to fit into, as in the common moletraps, only that the grooves are here cut quite through, having a small nail or pin of wire driven in through the middle, to keep the wires from rising above the wood. In the upper side of the hole, close by the grooves, three blunt-pointed pikes of wire (*c*) are fixed, so as to stand a quarter of an inch out of the wood. The holes for the triggers are bored in the centre of the upper side three inches from each end: in the lower side, opposite each trigger hole, is a small piece cut out, as in the common trap. The springs are made of iron wire, of about one eighth of an inch in diameter (*d* and *e*); and are exactly of the same form as those of the common mouse-trap, having a cross wire fixed one inch and a half from the top of each spring (*f* and *g*); from which the catches, which are likewise made of wire, are suspended. These catches are retained by the plug or trigger (*i*) till it is displaced by the mole. *Fig.* 1186. shows the trigger separately. (*Gard. Mag.*, vol. viii. p. 299.)

8101. — 2691. *Mr. Small*, in the county of Berwick, and who removed to the Lothians, improved considerably on the English or Rotherham plough. But Mr. Wilkie, in the vicinity of Glasgow, has made far greater improvements on Small's plough, than Small did on the English one, or than that was an improvement on the old Scotch plough. The ploughs are now all constructed of iron in the western counties of Scotland, and are beginning to be made there by many country smiths, who always form them on Wilkie's, and not Small's model. (*Brit. Farm. Mag.*, vol. vi. p. 304.) In the *Mechanics' Magazine*, vol. xxi. p. 283., a table is given showing the mechanical analysis of a ploughing match held at Aylesbury in Buckinghamshire, in May, 1834; by which it appears that a furrow nine inches broad, and four inches and a half deep, required a power of draught of six cwt. and three quarters. The plough was the common sowing-plough of Buckinghamshire, called the foot plough, with a wooden mould-board, and drawn by two horses; and the soil was a stiff clay. The horses walked at the rate of two miles an hour. Now, with one of Wilkie's iron ploughs, the same furrow would have been turned over with a drawing power of four cwt. or less; and the horses, if of the proper kind for farm labour, would have walked at the rate of two miles and a half an hour.

8102. *The universal adoption of the common two-horse plough throughout England* would, Laidlaw asserts, add more than 3,000,000 quarters of wheat to the resources of the country. (*Quart. Jour. of Agr.*, vol. iii. p. 713.)

8103. — 2616. *The subsoil plough* (*fig.* 1187.), as designed and used by Mr. Smith on the farm of Deanston,

1187



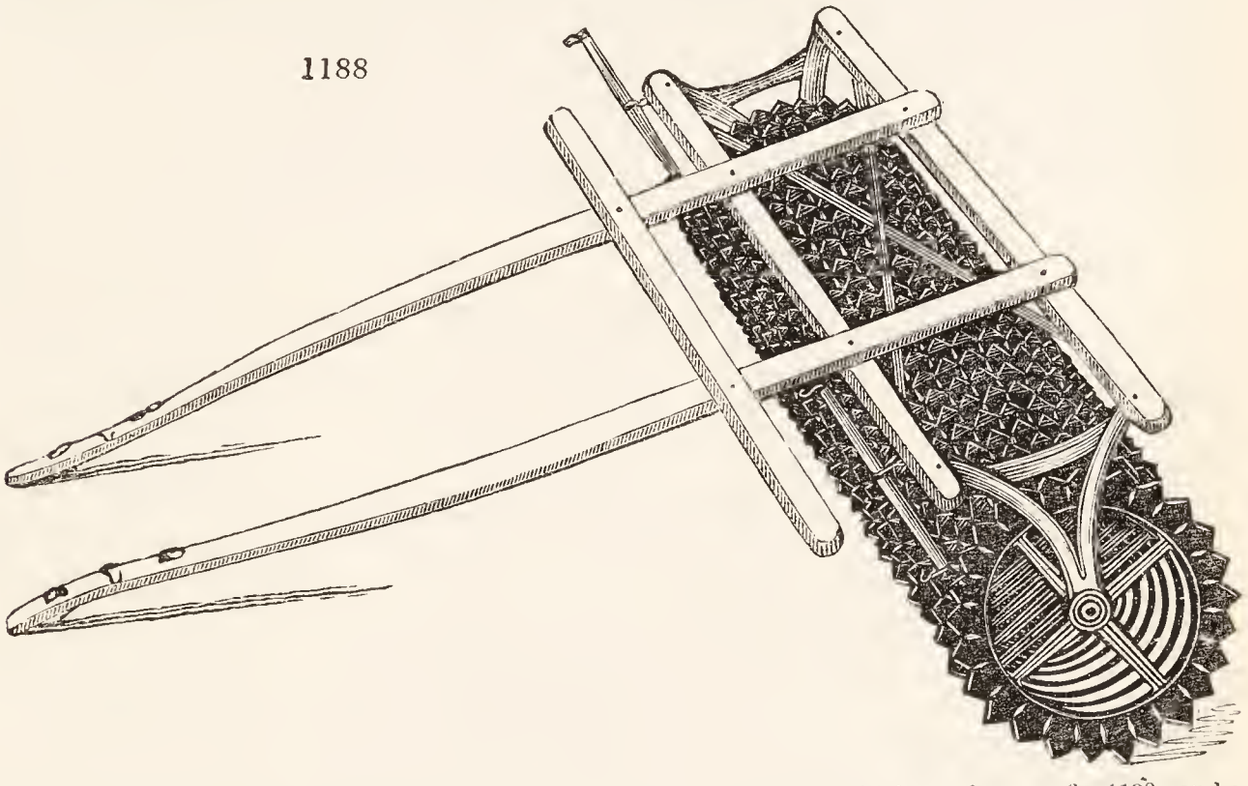
has been found peculiarly efficacious in rendering productive a sterile soil upon a tenacious bottom. It has been constructed so as to be of easy draught, and to penetrate to a depth of from sixteen to eighteen inches from the surface. It has no mould-board, and is intended merely to break and stir up the subsoil, without bringing it to the surface, or mixing it in the first instance with the incumbent soil. It is, in fact, a *horse-pick*, and readily loosens and throws out all stones not exceeding seventy pounds weight. It is drawn by four horses, two and two abreast, and it is held in the usual way by one man. In working, the common plough goes before it, taking a furrow ten inches by six inches, the subsoil plough following in the bottom of that furrow, and going deeper by ten or twelve inches. When this plough is applied on a tenacious bottom, and in conjunction with parallel drains about two feet and a half deep, and distant from twelve to twenty feet from each other, it produces wonderful effects in attaining a deep and dry soil; and, even on gravelly and sandy bottoms, its effects are considerable, and are especially apparent in the succeeding pasture. The cost of such a plough, with a soam, or main chain for the leading horses to draw by, is about 9*l*. The ordinary swingle-trees and harnessing suit, with straps over the quarters of the leading horses to bear up the swingle-trees to their buttocks, and a chain from the collars of the hind horses to bear up the soam-chain. This plough, with four horses, a ploughman, and a lad to drive, will do about an acre imperial per day, at a cost of about 1*l*.; no charge being made for the common plough, as the land would require a furrow at any rate. Such ploughs are made by Robertson Smith, at Drip (by Stirling), on the estate of Blair-Drummond. (*Highland Soc. Trans.*, vol. viii. p. 206.)

8104. — 2637. *Wilkie's improved friction wheel plough for two horses.* The invention of the friction wheel plough is claimed by Mr. Morton, an implement manufacturer of Leith Walk, Edinburgh, who "conceived the idea of introducing a wheel into the body or bosom of the common plough, about fifteen inches in diameter, to act as the sole," so far back as 1813. The average draught of the ploughs when the wheel was applied was reduced about one fifth, or to about two cwt. and three quarters. He manufactured a number of these ploughs both for home and foreign use; but in a short time, the farmers in the neighbourhood of Edinburgh left them off, giving as a reason for so doing, that they required more attention from the ploughman to grease the axle of the wheel, than the latter were willing to give. (*Gard. Mag.*, vol. vi. p. 209.) We may notice it, as a remarkable circumstance, that Professor Low, in his *Elements of Practical Agriculture*, published in 1834, describes only Small's plough, without mentioning Morton, Wilkie, or any other improver, and without once introducing the subject of wheel ploughs of any kind. The invention of the friction wheel is also claimed by Mr. E. Elliott, who lately managed a farm near Shepperton, in the county of Middlesex. In the *Farmer's Journal* for August 1. 1831, an account of an experiment is given in which Wilkie's improved plough without a friction wheel, was tried against the same implement with a friction wheel, and both against the common swing plough in use in Middlesex. Wilkie's plough, without the friction wheel, required four cwt. two quarters; with a friction wheel, three cwt.; and the common Middlesex swing-plough, six cwt. Notwithstanding experiments of this kind, it is an undeniable fact, that the old, heavy, clumsy Middlesex plough, which it appears requires twice as much strength to draw it as Wilkie's friction wheel plough, is still that commonly used in the county! We cannot suppose that any class of men would persist in a practice which they knew to be decidedly opposed to their own interest, and therefore we unavoidably conclude that in ignorance, or prejudice, or both, we must seek for the cause of these men so obstinately adhering to the practice of their forefathers. The truth is, as we have elsewhere observed, the farmers are the only class of Englishmen who do not read.

8105. — 2655. *The grubber, as compared with the plough*, Professor Low observes, will go over five or six times more ground in the same time; and to this extent there will be a saving by the use of it, where it can be substituted for the plough. It will go to the depth to which the land has been originally ploughed, or to any lesser depth which may be required. (*Elements, &c.*, p. 99.)

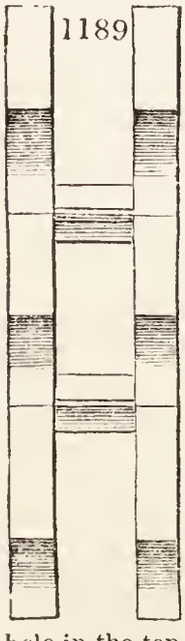
8106. — 2709. *Crosskill's clod-crusher roller* (*fig.* 1188.) is intended to effect the same objects as the

1188



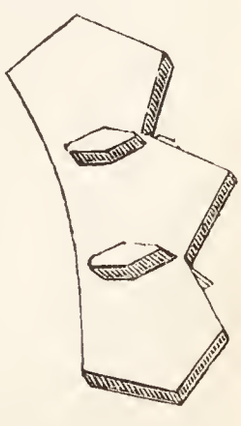
spiky roller. It consists of a number of segments, a perspective view of which may be seen *fig.* 1190., and a vertical elevation of the same segment *fig.* 1189., fixed on an iron axle six feet six inches long. Ploughed land once rolled by this machine is said to be reduced to a finer state than by two or three rollings and harrowings with the ordinary machines. It is drawn by three horses, and cleans itself, even when land is in the very roughest state. A number of these machines have been manufactured by the inventor at Beverley, and used by the farmers of the surrounding country. The price of a machine, including two iron road wheels to attach to it when not in use, is from 17*l.* to 19*l.* delivered in Hull.

1189



8107. — 2711. *A cheap and useful watercart* is thus described by Mr. Donaldson in the *Farmer's Magazine*, vol. viii. p. 81.: — A barrel, holding 100 to 200 gallons, is placed on a pair of wheels and shafts in the usual way. A pump, three inches in diameter, is placed close by the side of the barrel; and to the under end of the pump is made fast a leather pipe of indefinite length, with a rose copper end, and in the pipe small copper or tin rings are placed, two inches distant, to prevent the external air from pressing together the sides of the pipe, and thus excluding the water. The cart being placed on the bank of a river, brook, or pond, and the pipe thrown into the water with the rose end immersed, a man will pump 150 gallons in ten minutes, without the trouble of having a road into the bottom of the river, and with the great advantage of the horse standing dry, and not plunged into three feet of cold water on a winter day, in the usual way of filling by ladle and standish. A stopcock is fixed behind for discharging the water. When the cart is travelling, the leather pipe lies over the barrel, fastened by two iron catches. The barrel being filled, and driven to the place required, the leather pipe is immersed in the barrel by a hole in the top, sufficient to admit the rose end. A small iron rod screws down by the side of the piston rod, upon the upper valve, and shuts in fast. A rising main, with a cheek valve, is opened between the two buckets in the pump, upon which is screwed fast a leather pipe with a copper tube on the end. One man directing this pipe, and another pumping, converts the cart into a sort of fire engine, that may be

1190

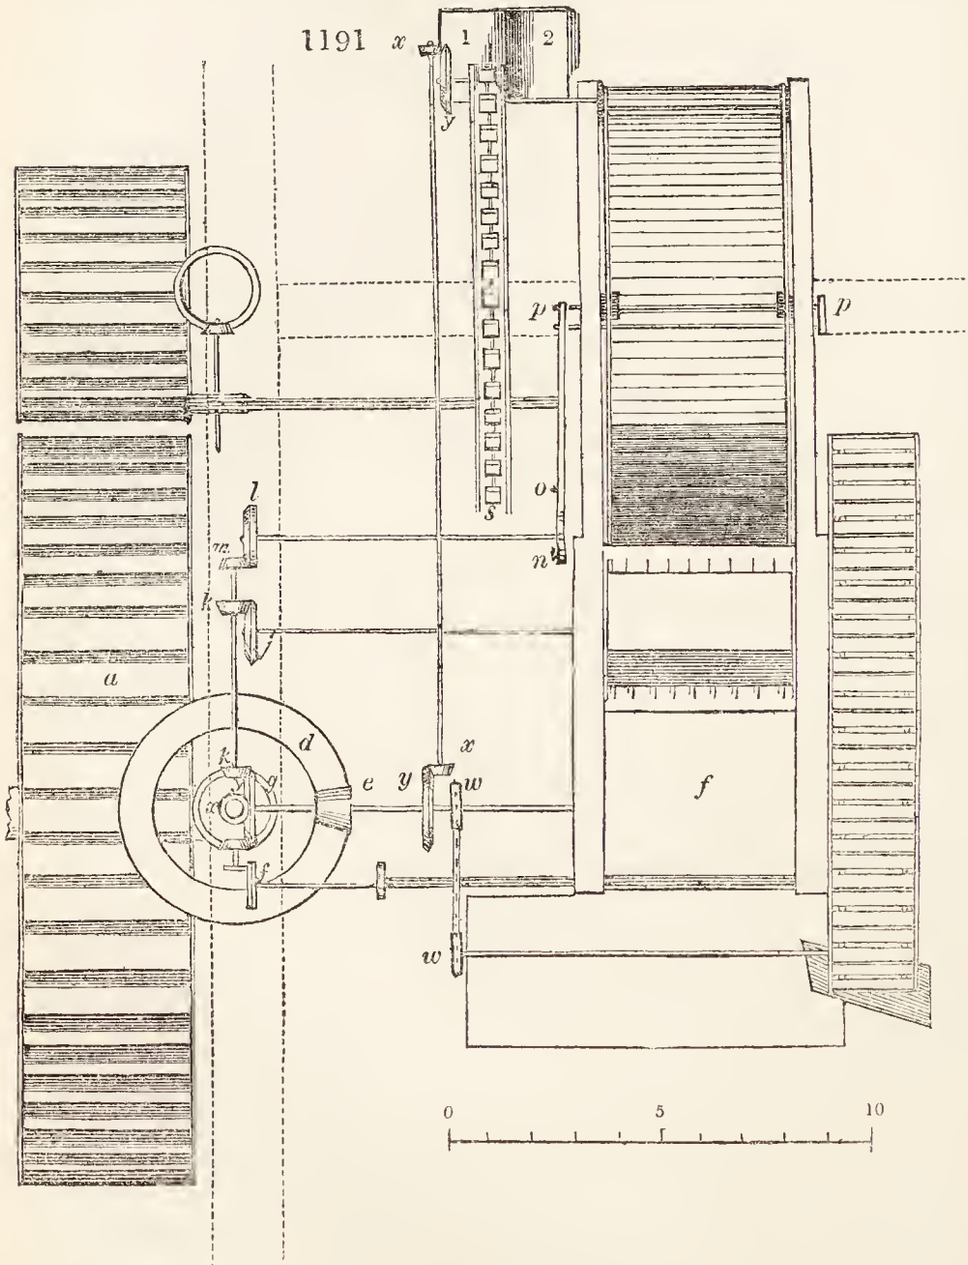


very useful in cases of emergency, throwing the water forty feet horizontally, and over any house of two stories, any haystack or corn-rick; it is also very useful for garden walls and fruit trees. By increasing the size of the barrel, and by applying more power, a very sufficient engine may be made, and answering othe purposes at the same time.

8108. — 2731. *Mann's reaping machine* was invented in 1820, but neglected till 1826, when it was improved; and in 1832 it was exhibited at an agricultural meeting at Kelso. It differs from Bell's reaping machine in being drawn instead of being pushed, and in depositing the corn in a continuous swathe nearly at right angles with the line of direction, and on the side opposite to the standing corn. Both these are advantages which we hope will not be lost sight of by the mechanist who may at some future time make such a reaping machine as shall come into general use. An engraving, with descriptive details, of Mann's reaping machine will be found in the *Quart. Jour. Agr.*, vol. iv. p. 250.

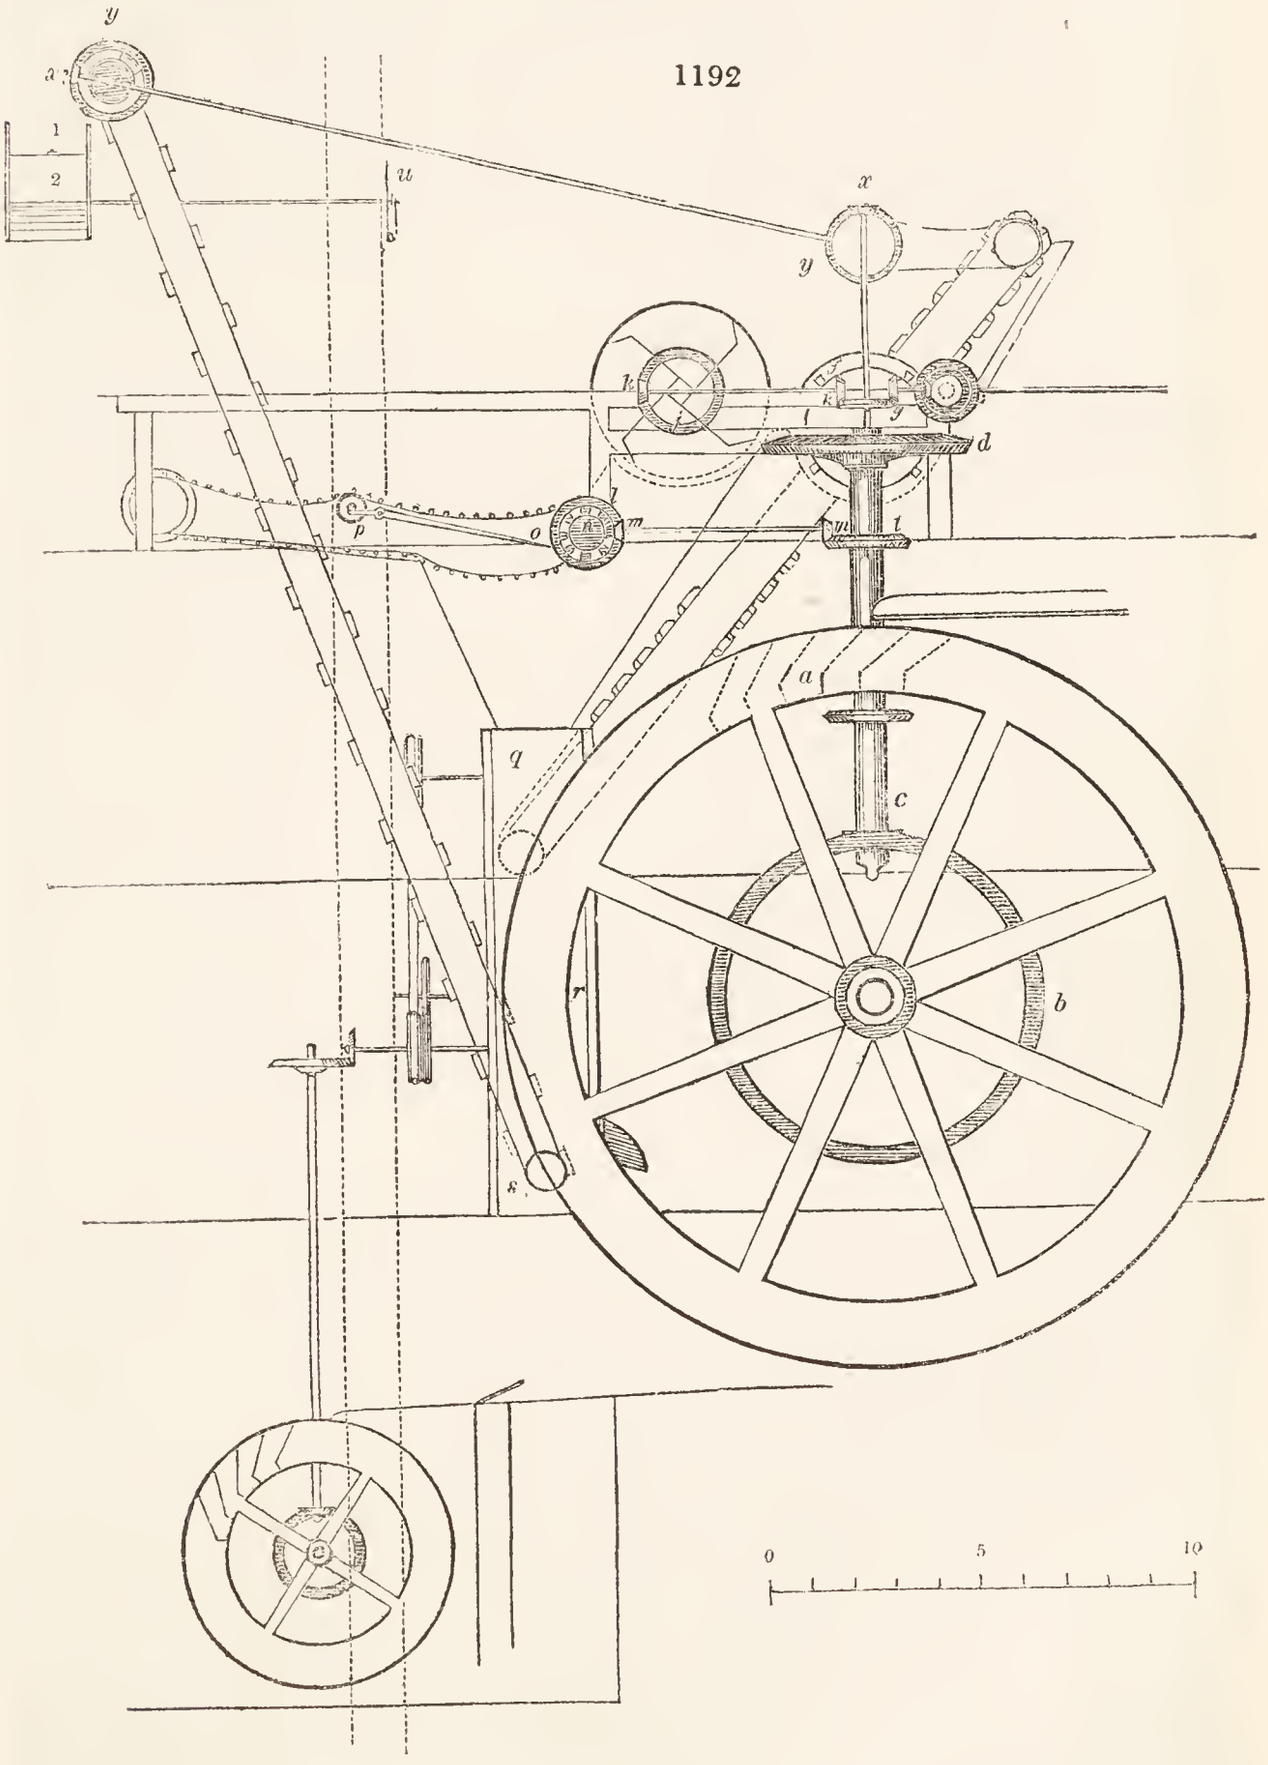
8109. — 2773. *The construction of threshing machines* is everywhere very imperfect, even in Scotland, where they were first invented, and where machines of the largest power, impelled by water or steam, are erected at great expense. The editor of the *Quarterly Journal of Agriculture* has the following judicious observations on this subject: — "Were threshing machines constructed on correct and unerring principles, like the machinery of a timepiece or of a steam-engine, or even of a flour mill, the advantage to the farmer would not only appear in the shape of cleaner threshed straw, and of economy of time and labour, but the millwright himself would derive great advantage in the certain possession of *materials*, which would enable him to erect threshing machines that would suit the particular localities in which they were to be placed. There is no way of arriving at this perfection, but by the institution of experiments to ascertain what may be the simplest construction of the threshing machine, and the best mode of applying the least quantity of moving power to execute the desired work satisfactorily. These desiderata would produce the advantage of threshing the corn at the least cost. Threshing machines are of so durable a nature that they are not often renewed; but for that very reason they should be constructed in the best manner at first. A set of patterns could be made from the results of these experiments, and lent out to those makers in the country who could grant security that they would only erect machines which were conformable to these patterns. In the course of time the country would be stored with efficient and easily moved threshing machines. The ill-judged desire of the farmer to have a machine that will not cost much money often leads the millwright to adopt expedients in its construction which he is conscious are not suited to work well together. This is one reason, among many others, to prove the propriety of landlords erecting threshing machines at their own expense, upon their farm-steadings, and of giving the tenants the use of the mills, as well as the steadings, and of obliging them to keep the machines in repair, as in the case of the buildings." (*Quart. Jour. Agr.*, vol. iii. p. 986.)

8110. *The threshing machine at Wynnstay*, the seat of Sir Watkin Williams Wynn, Bart., is considered one of the most complete in Britain. It was erected by the late Mr. John Gladstone, of Castle Douglas, Kirkcudbrightshire, about the year 1812. This machine separates the corn from the straw, and delivers both straw and corn into their proper places, without the assistance of manual labour, with the exception of feeding. The site of the mill is on a declivity, and the barn has three floors or stories; the uppermost of which opens into the stack-yard, making it very convenient for carrying in the sheaves: the second one contains the first winnowing machine; with a chaff-house, partitioned off under the stair, and descending to the floor below, with a door into the straw-house, and one into the cattle-yard. When the corn is only to be passed through the first winnowing machine, the corn elevators and second machine are thrown out of geer, and the corn delivered on the second floor, where the bruising machine is fixed. The under floor contains the second winnowing machine with the lower end of the corn elevators. If necessary, the clean corn may be delivered on this floor, instead of into the elevator trough: the ends of both machines are inserted in the chaff chamber. The corn is put between two grooved rollers, when the grain is beaten out of the ear by four beaters fixed on the threshing cylinder, and thrown into the rake or first shaker, when it falls through the sparred bottom into the winnowing machine hopper, while the straw is raked forward and thrown upon the travelling shaker, where it is thoroughly shaked, and conveyed into the straw-house. The corn passes through the first winnowing machine, when it is cleared of its chaff, short straws, &c.: the latter is thrown into a set of elevators which carries them up to the feeding-table, to be



threshed over again with the unthreshed corn. This is a very useful appendage to a threshing-mill; it takes all the refuse from the fanners, which generally accumulates about a barn floor (or is carried up by hand), whereas the elevators carry all away, and thereby leave a clean barn. The corn passes through another pair of fanners, and from thence into the corn elevator trough, and is carried from thence into the granary and thrown into the weighing machine, which is connected with an index in the barn on the partition walls facing the man at the feeding-table, which shows the quantity threshed very nearly. The machine occupies part of three floors. The water-wheel is in a house beside the barn, and in a room above the wheel is a Scotch barley-mill, and beyond it is a very complete saw mill, both driven from the same wheel, which can be detached when the threshing part is at work, and the threshing part, when the saw or barley mills are wanted. In the middle floor is an oat bruiser driven from the upright shaft: it can be put out of geer if wanted.

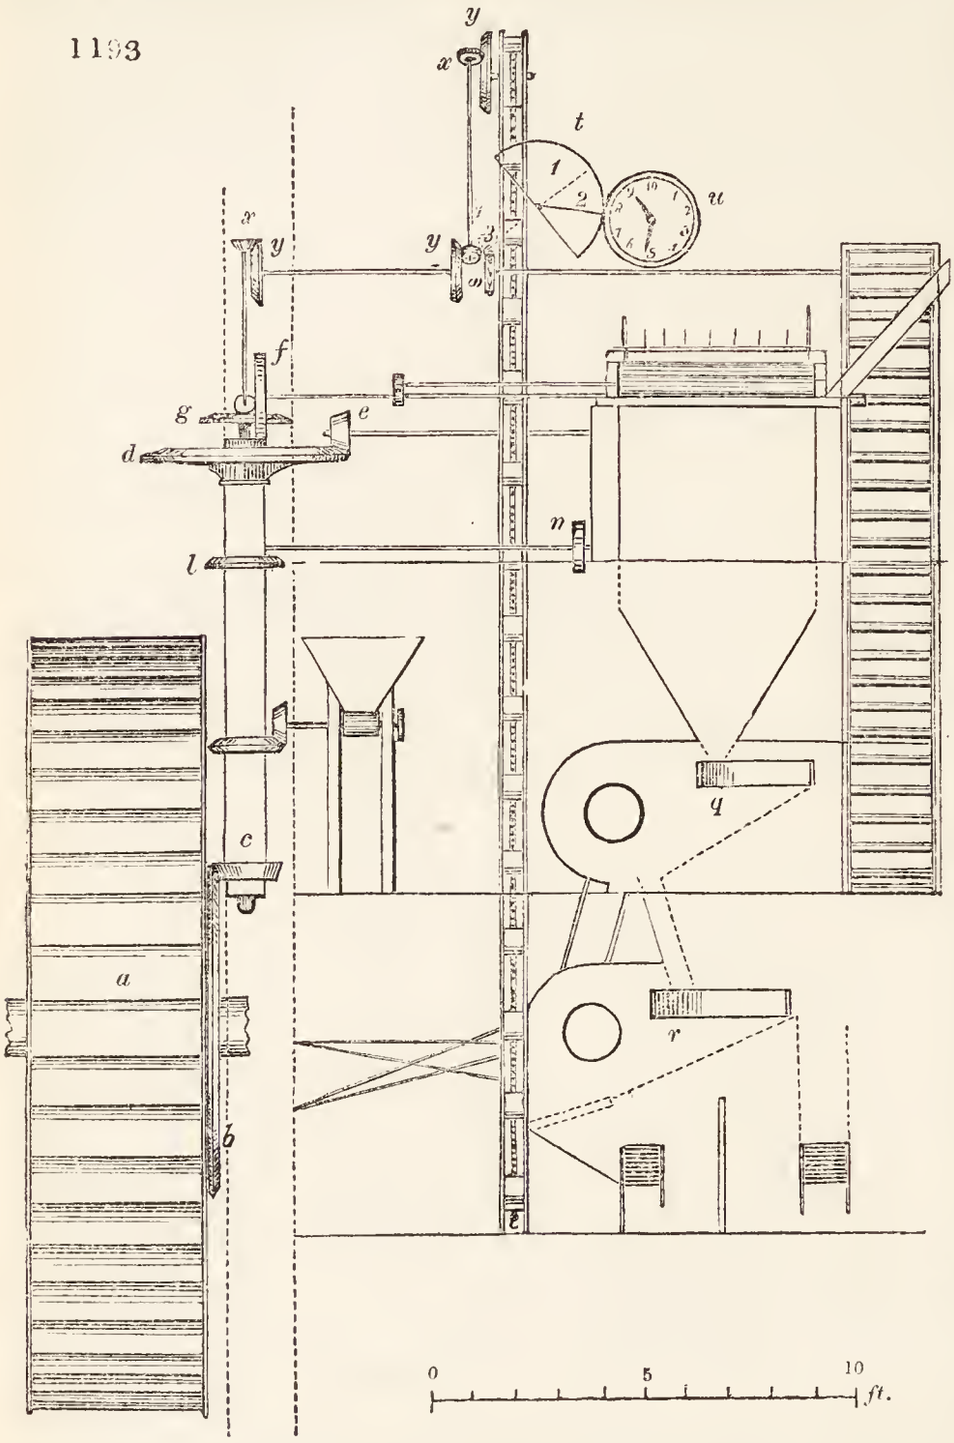
8111. *Description.* In *figs.* 1191, 1192, 1193., *a* is the water-wheel, eighteen feet in diameter by four feet wide; *b*, a pit wheel, eight feet in diameter, which works into a pinion, *c*, of fifteen inches in diameter fixed on the upright shaft; *d*, a bevel wheel, five feet in diameter, which turns the drum pinion, *e*, of nine



inches in diameter; *f*, the drum, or threshing cylinder, three feet four inches in diameter outside of the beaters, and four feet and a half long, with four beaters turning upwards with a velocity of 300 revolutions per minute; *a*, a bevel wheel, twenty-one inches in diameter, turning a pinion of five inches and a quarter diameter, on the axle of which is another pinion five inches in diameter, working in the face wheel, *i*, with two rows of teeth, one of thirty and the other twenty-four teeth; this pinion slides along its axle into either sets of teeth; for instance, into the one of the smallest number if the straw is long, and into the other if it is

short, loose, and irregular. The rollers are about three inches and a half in diameter; the wheels *g* and *j* are each twenty-one inches in diameter, working into the pinions *k k*, five inches and a quarter in diameter, which gives motion to the rake or first shaker at the rate of forty-five turns per minute: it is four feet in diameter to the extremity of the teeth; *l l*, two wheels, each twenty-one inches in diameter, with pinions, *m m*, five inches and a quarter each, which drive the travelling shaker that receives the straw from the rake, and conveys it into the straw-house. This shaker is composed of two endless pitch chains, worked by two stud wheels ten inches in diameter, with eight studs on each, on the same shaft as the wheels *m* and *n*, revolving at forty-five times per minute. These chains are kept stretched by two smooth wheels at the farther end in the straw-house: between the chains are fixed round wooden rods about two inches apart. *m* is a wheel with large teeth on its circumference, which, as it turns round, depresses the point of the lever *o*, and raises the end *p*. The lever is fixed on an axle which passes through to the other side of the shaker, with a short lever fixed on it to correspond with the lever *p*; on these levers, *p p*, rests a small shaft, on which is fixed on each end, under the chains, a small drum four inches in diameter, which supports the shaker in the middle, as the wheel, *n*, moves round. The point of the lever, *o*, strikes from tooth to tooth, and thereby keeps the small shaft, at *p p*, in motion up and down, which shakes the loose corn out of the straw, which is drawn back by the under returning rod into the winnowing machine hopper; *q* is the first winnowing machine; *r*, the second winnowing machine; both driven by a small water-wheel, six feet in diameter, and four feet wide: the water from the large wheels supplies this one. The motion of the machine requires to be uniform, which cannot be the case if connected with the threshing part. It answers better to have a separate wheel for the machines. The clean corn passes into the elevators *s*; from thence it is carried up into the granary, and delivered into the weighing machine, *t*, by small elevators made of sheet iron, with wooden backs and bottoms fixed to a pitch chain, revolving round a studded wheel ten inches in diameter, and with eight studs at the upper end, and a small wooden roller at the bottom, at eleven turns per minute. The corn is delivered into the weighing-machine box, 1, and accumulates until there is the weight of a measure, when the box turns on its axle, and the corn is emptied into the spout which conveys it into whatever binn it may be wanted in. At the same time the part 2 turns up, and is filled as the other, and, when full, descends as the other, and so on, while the threshing is going forward: 3 is a weight which slides up and down a rod fixed at right angles from the bottom of the weighing machine: if the corn is heavy, slide this up until it will balance a bushel of corn similar to what is to be threshed; if light, slide it downwards. From the axle of this box, a small rod proceeds to two small wheels behind the index, *u*, which turns two fingers that revolve round the face of this index; it is figured from 1 to 10. For every movement the weighing bucket makes, the longest finger moves over the space of one, and for every ten, the other finger moves one. At the end of the threshing, this finger will denote pretty accurately the quantity threshed: for instance, were the long finger at 5, and the short one at 9, there would be ninety-five bushels of corn in the binn; *x x x* are pinions five inches and a quarter in diameter, each working in wheels (*y y y*) twenty-one inches in diameter each, which give motion to the corn elevators, and likewise to the tail elevators by a pitch chain revolving round the stud-wheel *w w*, giving motion to the shaft of the elevators at eleven times per minute. The buckets are made of thin boards fixed on two pitch chains turned by two stud wheels ten inches in diameter at the upper end, and a wooden roller at the lower. (*J. Gladstone, Lead-works, Chester, Oct.* 29. 1831.)

1193



8112. *Mr. J. Gladstone, civil engineer, Chester*, to whom we are indebted for the foregoing plans and description, with reference to the improved form of the threshing machine, says, "I have always understood that it was to my father we are indebted for it in its improved state. In 1788, Mr. Andrew Meikle produced the first machine of the kind, for which he took out a patent. (See *Repository of Arts*, vol. x. No. 58.) This was simply a threshing cylinder with the beaters turning downwards, throwing straw and corn

into a moving screen, which separated them in a very imperfect manner; so much so, that I have heard the machines were given up, or going into disuse, simply on account of the beaters striking downwards; if the ears escaped the beaters immediately on passing through the rollers, they were bent under them, and laid close to the interior of the cylinder case, and thereby evaded the stroke of the beater. In 1793, my father made his first machine, similar to that of Mr. Meikle, with this difference, that the threshing cylinder turned upwards, and as the corn came through the roller, it lay upon the cylinder, and, being exposed to the stroke of each beater, none escaped being threshed." (See *The Stewartry of Kirkcudbright Agricultural Report of* 1810.)

8113. *The late Mr. Gladstone, of Castle Douglas*, added the shaker to the threshing machine in 1794, and what he called a fetterer, for breaking off the awns of barley, soon afterwards. In 1798, he made a threshing machine, to be driven by windmill sails. In 1799, he invented the draught chains used in threshing machines, to equalise the pressure of the draught on the horse's shoulder. In 1805, he added a travelling shaker to the threshing machine, and soon after, a contrivance for conveying the corn from the fanners into the granary, and weighing it at the same time. By another piece of machinery the corn may be accurately measured. "On reviewing the whole," the writer, in the *Report of the Stewartry of Kirkcudbright Agricultural Society for* 1810, observes, "it is impossible not to perceive how vastly superior the machines of Mr. Gladstone are to those first contrived by Mr. Meikle, and what distinguished services he has thus rendered to the interests of agriculture. The machine is now competent to the threshing not only of one, but of every, species of grain. It is adapted of itself to separate the straw from the corn, and convey it perfectly shaken into the straw-house; to clean the corn effectually to weigh and measure it accurately; and to lodge it securely in the granary. If driven by water, the adoption of the chain bucket outer wheel saves an inner one, formerly deemed indispensably necessary, and simplifies the machinery; if by horses, the person feeding it can manage without a driver from within, and assign to each horse an equal share of the draught, or such a proportion of it as may be supposed adequate to his strength. Much diminution in the expense, as well as much improvement in the mode, of farm management has thus taken place. What was the work of several months, can be performed more perfectly, and with more ease, in as many weeks; and the labour of the winter season can now be devoted to more valuable purposes, to the collecting and formation of manures, and the better preparation of the land for the reception of the seed."

8114.—2811. *Edifices in use in agriculture. In the Encyclopædia of Cottage, Farm, and Villa Architecture*, we have gone into this subject in greater detail than could with propriety have been done in a work embracing so extended a view of agriculture as the present volume. In that work we have not only given a great variety of the very best plans for farmeries, or farm-houses, which have been executed in Britain within these few years; but we have given detailed plans, sections, and specifications of all the component buildings of a farmyard, and of their fittings-up, fixtures, and furniture. In the *Architectural Magazine*, which may be considered as a perpetual supplement to the *Encyclopædia of Architecture*, all the improvements which may be made in architectural buildings will be recorded as they occur. We have given in this Supplement, § 8157., a plan of a farmery from the former work, which embodies all the latest improvements.

8115.—2847. *Barn floors*, to be proof against the ascent of rats from beneath, should be formed of wood. "The sleepers upon which the floor is laid, should rest upon stone and lime building, raised two feet from the ground, close to the barn wall; and the mortar and stones must be packed close to the upper edge of the sleepers, up to the deals of the floor. According to the width of the barn, the sleepers should rest also upon one or two supports of stones, so hewn as to permit no footing to any vermin; and which will support the middle of the floor. By this contrivance, the space from the floor to the ground is made too deep to permit any small animal standing on its hind legs and gnawing the floor, while dogs or cats can easily pass under it." (*Quart. Jour. Agr.*, vol. iii. p. 995.)

8116.—2876. *Labourers' cottages*. Having entered on this subject at length in our *Encyclopædia of Cottage, Farm, and Villa Architecture*, and there given numerous plans, accompanied by descriptions, specifications, estimates, and critical remarks, we shall not here repeat any thing which has appeared in that work. Nevertheless, as the improvement of the dwellings of country labourers is what we have most at heart, next to the education of their offspring, we cannot let pass this opportunity, without contributing something farther to the subject: we shall, therefore, give one article, entitled the *beau idéal* of an English labourer's cottage, by a most benevolent and enlightened clergyman, who adopts the signature of Selim; and another on building cottages with mud walls, by a professional man, Mr. Wilds, of Hertford, who, having been in North America, is deeply impressed with the importance of this kind of knowledge to emigrants, who, at present, too frequently build their houses of wood, and who, consequently, sooner or later, suffer from accidents from fire, or, what is almost as bad, live in continual fear of doing so. To these we shall add the design of a stone-walled agricultural labourer's cottage, recently built, along with a number of others of the same kind, on the estate of William Lawrence, Esq., in Gloucestershire.

8117. *The beau idéal of an English labourer's cottage*. The leading feature in the exterior of a labourer's cottage, should be a picturesque simplicity, which is a sort of medium between superfluous decoration and unmeaning plainness. This appears to be the only character of which a cottage is susceptible; for, as plainness is uninteresting, so it offends our sense of propriety to see a building of this description bedecked with costly fantastic ornaments, which are evidently unsuited to the simple unrefined habits of humble life. But a picturesque simplicity is seldom the pervading character of modern ornamental cottages. They are often decorated with turrets and battlements in the castellated style of Gothic, or in the monastic style, with elaborate painted windows, crosses, and pinnacles; nay, instances have occurred where the two styles have been united in the ornaments of a cottage dwelling. It cannot be denied, that a picturesque effect is produced by this mode of embellishment; all I contend for is, that such ornaments are altogether unsuited to a dwelling of the lowest order. Should it be objected, that, if we reject this mode of decoration, we must have recourse to ruin and decay to produce a picturesque effect; I answer, that as much of this effect as we may require may be produced, I think, by irregularity of form and outline; and irregularity is, in fact, the only effect aimed at by the use of Gothic ornaments. But as my object would be only a picturesque simplicity, I should discard useless and inconvenient irregularity. In so small a building as a cottage, a slight irregularity would be sufficient to give it a picturesque character, and the simplest embellishments would give it an ornamental effect; and this, I conceive, is all we require to produce what I understand by picturesque simplicity. Though I am an advocate for simplicity, however, in cottage architecture, I would in some measure sacrifice even simplicity to the picturesque; because the beauty of a neighbourhood frequently depends upon the style of the labourers' dwellings. These are the prevailing buildings in all rural scenery. They are occasionally so placed and associated with surrounding objects, that they present the most striking features in the landscape; and the effect of particular scenes is not unfrequently produced by the forms and situations of the cottages. Hence, a picturesque exterior is one of the chief requisites in an ornamental cottage; but it should be a simple pleasing style of picturesque, which does not interfere with internal comfort and convenience; produced by slight irregularity of form, and by unobtrusive and appropriate ornaments. I am not at all disposed to sacrifice internal comfort to outward effect. I think a picturesque exterior may always be united with a comfortable interior; and I now proceed to give the description of a cottage in which I shall endeavour to exemplify the union above alluded to.

8118. *Site of the cottage*. As the comfort of the inmates and the general effect of a building depend materially on its site, the situation of a cottage is the first thing connected with it that requires consideration. A general rule for the situation of a cottage is, that it should be properly supplied with water; be

dry, airy, and sheltered; and admit of a sufficient allotment of garden ground adjoining the house. And I am an advocate for rather a scattered village, because, among other advantages, it affords an opportunity of erecting the cottages in proper situations. A damp situation is the principal thing to be avoided. It is a nuisance in all cases; but especially to a labouring man, who cannot afford to spend any thing in draining, or much in fuel; whose health is his only source of wealth, and to whom it is necessary, both for health and comfort, that he should have a dry home to come to, after long exposure and severe exertion in the open air. Besides being dry, the site of a cottage should be airy and sheltered. Every dwelling should have a proper circulation of air around it, or it cannot be dry; and a cottage should be sheltered, that it may be warmed with less expense of fuel: the shelter should be so placed, however, as not to interfere with a full exposure to the sun. We will, therefore, suppose our cottage placed on a gentle eminence in the neighbourhood of other dwellings; and sheltered, in part, by higher ground at a distance, by a wood, or by groups of trees, and in part by its own orchard and outbuildings; some of these so placed as to appear above the roof, but leaving it fully open to the south. The situation would be more desirable if a stream of water happened to run near, or if it adjoined a common, or a public road; and it would thus possess the advantages of dryness, shelter, and cheerfulness, besides others which are of consequence to the general effect of the building to be erected upon it.

8119. *Style of the cottage.* Having fixed upon the site of the cottage, the next thing to be considered is, in what style is the building to be erected; for even a cottage, I think, should present some appearance of architectural style. I have already contended that the Gothic is inappropriate to a dwelling of this description, and a building in the Grecian or Roman style, upon so small a scale as a cottage, must be plain and formal, and deficient in picturesque effect, unless it be an elegant and costly edifice. There remains, therefore, only what is called the old English style, which is, I think, the proper style of architecture for an ornamental cottage. It admits of great irregularity and variety of form; and is suited to houses of all dimensions. Its ornaments may be adapted to the smallest dwellings; the irregularity it allows in the exterior, may be made conducive to internal convenience; and it has this peculiar advantage, that we have many beautiful models of old English cottages in all parts of the kingdom. It has, also, this additional recommendation, that it is not an expensive style, and may be executed in almost any kind of material. A cottage in this manner may be built of stone, brick, flint and chalk, or even of wood and plaster; and the building may be so formed, and the materials so disposed, as to give a picturesque and decorated effect, without the use of any expensive ornaments. The desired effect will be given by the tall chimneys; by the high pointed gables, with, perhaps, small pinnacles at the angles; by the mullioned windows and the labels over them; by a projecting porch of one or two stories; and by the stringcourses round the building. In this style much of the ornamental work might be of wood. For instance, the whole of the upper story might be formed of a wooden framework, filled in with brick or plaster. This wooden framework would project beyond the wall which supported it, and produce a pleasing effect of light and shade, and a variety of ornament might be given by the form of the frame itself, which shows on the outside, and by the arrangement of the bricks, or by the patterns impressed upon the plaster, with which the interstices of the frame are filled up. In these half timber houses might be introduced a kind of wooden oriel window, which is one of the most striking ornaments in many old cottages. The gables over such a building might have handsome barge boards, with carved pinnacles at the points. These pinnacles, if small and in good proportion, would be in keeping with a mode of building which admits of a great variety of embellishment, and is well suited to a district where stone and other substantial materials are scarce and expensive. As it possesses these recommendations, we will adopt the old English style for our present purpose, and suppose the cottage erected on a dry, airy site, well protected from the prevailing winds, and surrounded by its garden, orchard, and out-buildings. It would, of course, present one regular front. This we will suppose divided into two equal parts by a porch of two stories in the centre: in the ground story of the porch might be an arched entrance; in that above, a neat mullioned window of two lights, with its proper label; and over this a low gable terminating in a simple ornament. On each side of the porch might be a mullioned window of three lights, placed immediately under the stringcourse, which divides the house into two stories; the low wall above these windows would be plain, as the windows of the rooms in the chamber floor would be most conveniently placed in the gables at the ends of the house. In the centre of the roof, behind the porch, would be the stack of chimneys, which should be tall, and rather the handsomest member of the building. It is the most conspicuous part of it, and the general effect of the whole would depend materially upon the form of the stack of chimneys. This front would afford an example of what I understand by picturesque simplicity. There would be a certain symmetry and unity about it; it would present no superfluous ornaments, nor any unmeaning irregularity. But still it might be made a highly ornamental cottage, and might contain many internal conveniences which are not always found in buildings of more pretension; and it would possess enough of the picturesque character to make it harmonise with the surrounding scenery.

8120. *Interior accommodation.* Such, then, would be the exterior of the cottage: what are the accommodations it should contain within? A comfortable labourer's dwelling should, in my opinion, consist of an entrance porch, kitchen, washhouse, pantry, and small cellar, a parlour or spare sitting-room, and at least three bedchambers. These apartments are all necessary for the comfortable accommodation of a family, even in humble life; and, as we are attempting to describe the *beau idéal* of a cottage, we must suppose it to contain all these conveniences, which we proceed to describe in their order. A porch, besides being an important ornamental appendage to a cottage, is necessary for the comfort of the inhabitants, to which it contributes by sheltering the entrance from wind and rain, and thus assisting to warm the interior. A cottage porch should be of small dimensions, the floor on a level with the rooms within, and raised a step or two above the surrounding surface. It should be paved and ceiled; and if it had a seat on each side, it would form a kind of summer-house, where the females would often sit at work in fine weather. Over the seats might be shelves, on which small tools might be put away, and seeds, onions, &c., placed to dry. There should, of course, be a scraper at the steps, and a mat within the entrance.

8121. *Kitchen.* From the porch you should pass through a small lobby to the kitchen, or common sitting-room of the family, which should be a sufficiently spacious, light, and airy apartment. The object of the lobby is, that there may be two doors between the living-room and the outer air, which will assist in keeping the room warm with a less expense of fuel. There are some defects, usually found in the interior of old cottages, which ought to be avoided when new ones are erected. I allude to the lowness of the rooms and doorways, damp floors, and smoky chimneys. If we were to judge of the people by the houses they inhabited, we might suppose the former generations of our "bold peasantry, their country's pride," to have been absolutely a race of dwarfs. For, if you would avoid a broken head, you must actually creep through the doorways of ordinary cottages; and, after escaping the perils of the doorway, a man of good stature can seldom stand upright in the house without being in danger of knocking his head against the bare rafters of the floor above, or against the bacon-rack, the scythe-blade, the reaping-hooks, and twenty other things commonly suspended from the ceiling. Now, these low rooms and doorways must be a continual source of annoyance to the inhabitants; and, therefore, I would lay it down as a general rule, that no cottage kitchen should be lower than eight feet, and every cottage doorway above six feet. Another common defect in cottages is, the dampness of the ground-floor. In the case of old cottages, the ground-floor is usually much below the level of the surrounding surface, and you generally descend into the house; and, even in modern cottages, the floors of the lower apartments are seldom sufficiently elevated. The consequence is, that, in many situations, the cottages are damp and uncomfortable for five or six months in the year; indeed, I know several cottages in which springs of water regu-

larly break through the kitchen floors during the winter season. To avoid this inconvenience, I would propose, as another general rule, that the ground-floor of every dwelling of this description should be eighteen inches or more above the surface, and that the earth on the outside should be the same distance below the level of the floor. Under every brick or stone floor there should be a substratum of broken stone or flints, varying in thickness according to the nature of the soil and situation. On a damp site, it may be necessary to have this substratum two or three feet deep, with drains and air passages through it; and the earth should have a good slope from the walls on every side, so that the water from the roof may escape rapidly, and not sink into the foundation. Another prevailing misery in cottages is, a smoky chimney. This is a proverbial nuisance to every one; but it is especially so to a cottager, because, over and above the dirt and discomfort occasioned by the smoke, half the fuel is wasted in a fireplace which has not a proper draught. This nuisance in cottages generally arises from the large size and straightness of the flue, and from the lowness of the chimney on the outside, or from the currents of air occasioned by the bad positions of the doors and windows, which seldom fit close. From whatever cause it arises, a smoky chimney is a prevailing misery in labourers' dwellings, which a judicious builder may generally contrive to avoid; and I refer the reader to some sensible observations upon this subject in the *Encyclopædia of Cottage, Farm, and Villa Architecture*. After this digression, let us return to the cottage kitchen. As this is the common sitting-room of the family, in which most of the household operations are to be performed, it should be a light warm apartment, of a good size. We will suppose it sixteen or seventeen feet square, and eight feet high, having a window in the east and one in the west side. It would thus have the benefit of the morning and midday sun; an important advantage to a cottager, in whose domestic expenditure coals and candles are considerable articles. Stone is, I believe, the best material for the floor, as being most durable and easily kept clean, and in these respects greatly to be preferred to brick. Boards, besides that they are liable to occasion accidents by fire, could scarcely be kept clean in a cottage living-room, and would soon be worn out by the iron-bound shoes of the inhabitants. Of course the walls and ceiling should be neatly plastered and whitewashed, and there should be a proper skirting-board round the room, and attached inside shutters to the windows. The fireplace should be so situated as to be well lighted by one of the windows; and it might be a close or open fireplace, according as wood or coal happened to be the common fuel of the district. I observe that the old-fashioned open fireplaces are generally preferred by cottagers, on account of the snug warm seats they afford in the chimney corner, as it is called, and which is too often the only warm place in the house. I am aware that these fireplaces do not economise fuel, or afford the best means of warming the room; but they present some advantages to the cottager; that is, they are capital places to dry bacon in, and wet clothing. Either wood may be burnt in them on the hearth, or coal in a movable grate; and, as the fire is on or near the ground, it certainly diffuses a considerable heat around it. The mouth of the brick oven also generally opens in the back, or side, of the chimney, so that all the ashes and litter, together with the heat produced, are confined to one place; and, should this place be near the centre of the building, the mass of warm masonry must have the effect of raising the general temperature of all the apartments. In the coal countries these open fireplaces are not usually met with; but, where wood is the principal fuel of the peasantry (as it is in the district from which I write), I would indulge their prejudice in favour of an open chimney, and will suppose one in the cottage kitchen, with the mouth of the oven on one side of the back, and on the other a small copper set in an arch, having a flue through the arch by which the steam might escape up the chimney. It would be tedious to describe minutely the various articles of useful and ornamental furniture found in the kitchen of a thriving cottager; indeed, to those unacquainted with rural life it would be difficult to convey an idea of the multifarious collection often displayed in a room of this kind. A tidy labourer's wife is sometimes as fond of knick-knacks, and as proud of displaying her various stores, as the richest lady in the land. The peasantry have, in fact, many of the prevailing tastes of their superiors in wealth and refinement, and love to ornament their houses with plants and flowers, prints, and plaster casts, and ornamental china. The kitchen is frequently as much crowded with useful and ornamental furniture as a modern drawing-room. The mantel-shelf displays a range of flower vases, images, and painted busts of the favourite heroes of past and present times, mixed with some of the bright cooking utensils. The walls are sometimes thickly hung with coarse engravings, ballads, and printed papers, moral, religious, and political, and with various other things; among which are conspicuous the labourer's club rules, and his staff, or some peculiar implement denoting his occupation, such as the polished head of the shepherd's crook, the market-day carter's whip, or the spare flail of the thresher. The window is seldom without its collection of exotics, thriving surprisingly, some of them in spoutless teapots and other discarded vessels; and on the window seat, or on a shelf near, a little heap of books; the bible, in a neat cover, reverently placed apart from the rest. Even the ceiling is usually furnished with that desirable ornament, a well-stored bacon-rack, shoes, tools, bags of seeds, and a host of other things. But the pride of the cottage housewife is her dresser and shelves. Here she displays her little store of glass and earthenware of the better kinds, with her best plated spoons, her bright pewter plates, and clean wood trenchers, frequently arranged with considerable taste and effect. Some of the conspicuous articles will not, perhaps, bear a close examination; and are, in fact, useless; though "wisely kept for show:" but she contrives to hide defects, and the shelves often exhibit specimens of old glass and china, which a collector of such rarities might covet. There are, indeed, few more picturesque interiors than that of the well-kept kitchen of a thriving labourer who happens to have a tidy wife; and I have often been much pleased at the air of decent comfort, and at the decorated effect produced by the miscellaneous collection seen in a room of this description.

8122. *Furniture of the kitchen.* Among the more prominent articles of furniture in a thriving labourer's kitchen, the clock, I think, takes precedence of the rest in the owner's estimation, and its well-polished case is generally a conspicuous object. Next to this we may rank the best dining-table, often one of those interesting old oak tables with rounded leaves, and as many curiously-turned legs as a spider. The best tea-table, turned up, with its pillar and claw, in a corner; and the dough trough, with its clean white cover, would next attract attention. To these we may add the great arm-chair, with a patchwork cushion in the bottom, for the *man*, as he is emphatically called here, in which he sits in the evening in a sort of rustic dignity, surrounded by his wife and children, forming, in many cases, a happy, interesting group: the wife and elder girls at work, perhaps, while one of the boys is standing by the father, reading, or repeating what he has learnt at school during the day. I hope there are many such evening groups still to be found in our cottages, in spite of politics and the beer-shops. This reminds me of another piece of furniture which I should wish to see in every cottage; I mean, a shelf of useful and instructive books. You seldom enter a cottage without finding some books; indeed, as far as my observation extends, I should say that a taste for reading is becoming more general among the labouring classes; and it ought to be encouraged, as a source of instruction and enjoyment, which has a tendency to improve the morals and better the condition of the peasantry. What a wide field of knowledge and enjoyment is cut off from the labourer who is unable to read, or who has no taste for reading! Half the leisure time of such a person must be spent in drowsy indolence, or in the debasing scenes of the alehouse, to which he is almost driven in self-defence, to relieve the tedium of idleness and the oppressive vacancy of his mind: the want of this resource and comfort is severely felt by the uneducated labourer in times of sickness and old age, when a long active life is necessarily exchanged for a state of total inactivity. There are few of the rising generation entirely without education. The stores of knowledge will therefore soon be opened to all the labouring classes, and they should be encouraged to use them to their own advantage, by having their attention directed to useful and improving books. "A little learning," if not properly directed, "is a dangerous thing."

8123. *Back-kitchen and washhouse.* Besides the kitchen, or common living-room of the family, every

complete cottage should have a small washhouse, in which the brewing and washing, the dirty and all work of the family, may be done. Here I would have shelves for the saucepans, and other unsightly articles, used in cooking; also a set copper; and a proper sink, communicating, by a drain, with the dung pit or a cess-pool. Most cottages are without a washhouse; but a small place of this sort is absolutely necessary to every dwelling; as, without it, the living-room can never be tidy or comfortable, and, I may add, wholesome. For want of a washhouse, the cottager is compelled to hang up his dead pig, and even to salt it, in the living-room; and as there is no other place in which to do the dirty work, and put away the dirty things which must be used in every family, the room is generally in a litter, and has an unwholesome, disagreeable smell, which must be prejudicial to the health of the inhabitants. But what I would chiefly insist upon in the washhouse is a proper sink to receive the slops and dirty water. Very few cottages have any convenience of this kind; and consequently all the slops are thrown out at the door; and, you can scarcely approach a cottage, in many cases, for the abominations that surround it. Besides this, the entrance is commonly surrounded by a sort of impure air, which is extremely offensive and must be injurious to the inmates. No cottage, therefore, should be without a sink, communicating with a drain, which may carry the dirty water to a sufficient distance from the house. Even a pretty cottage will have a squalid, miserable appearance, when the door is surrounded by filth; and I have seen villages, with the houses built on each side of a narrow road, which were absolutely disgusting in consequence of the nuisance referred to.

8124. *A small larder or pantry*, having a window in the outer wall, should communicate with the kitchen or wash-house. This is a necessary convenience not often found in labourers' dwellings, in which the provisions are generally kept in nasty close cupboards, or on shelves in the living-room, where they are liable to get spoilt, and are exposed to dust, smoke, and all sorts of impurities. For want of a better place, even the beer or cider barrel is kept in the warm kitchen, and in such a situation the liquor, of course, soon becomes sour and unfit to drink. No cottage, therefore, should be without a cool airy larder; and a small place of this kind might be easily contrived in every dwelling, with little or no addition to the cost of building. As I am describing the *beau idéal* of a cottage, the owner of which might keep a cow, I will, in the present case, suppose the larder of a sufficient size to contain both the milk and provisions. We can scarcely expect a distinct place for each in a labourer's cottage, and it would be unnecessary. There might be separate shelves for the milk and provisions, &c.; hanging shelves for the small cheeses, which a managing woman would of course make during the summer season, even from her single cow.

8125. *Cellar.* If the floor of the larder were sunk the depth of a yard below the surface, the beer might also be kept in it; but a cottage would not be quite complete without a small cellar, to contain the beer, and the potatoes and other roots. A cottager with land would grow a large supply of potatoes and other roots, for his cow and pigs; and it would save a great deal of time, and prevent waste, to have the roots always at hand in the cellar, instead of burying them out of doors in pits, which, when once opened, are not secure against frost and wet. I would also recommend a cellar in every new cottage; because I look forward to the time when every labouring man will be able to brew his beer at home. A hard-working labourer requires a certain quantity of wholesome beer; and if he has not this at home, he is sure to go to the alehouse, where he gets into the worst company, spends in intemperance what is required for the maintenance of his family, and in many cases becomes a confirmed drunkard. It would be a work of charity, therefore, to encourage brewing among the labourers; and, as a means of promoting it in country villages, I would suggest a plan of having a small set of brewing utensils, for the use of the cottagers, in the care of a fit person, who would lend them, in the parish, under proper regulations. The cost of the tubs &c., would be inconsiderable, and might be easily raised by subscription among the wealthy inhabitants, or even among the cottagers themselves. A penny or two paid for the use of the tubs would be sufficient to keep them in repair. The want of tubs is one of the chief obstacles in the way of cottagers brewing, which this plan would remove. And I am persuaded it would succeed, as I find that even a whitewashing brush, kept to lend out, has been a great promoter of cleanliness.

8126 *The parlour.* Should this paper ever fall into the hands of a labouring man, he would probably smile when he came to this part of it, in which I am to speak of the parlour. Many persons will consider a parlour an unnecessary luxury in a labourer's dwelling: it would be seldom used perhaps as a sitting-room, but as a spare room it would be a great convenience in the case of a large family, and should not be omitted in an attempt to describe a complete cottage. Most thriving labourers are in the habit of receiving their distant friends and relations, at certain seasons, such as the village feast, at "the tides," at christenings, &c. The parlour would be useful on such occasions, both as a sitting-room and additional bedroom, as it would be also in case of sickness, or death. If for no other reason, I should be an advocate for a spare room of this kind in every cottage, as a receptacle for the dead. As cottages are at present, there is seldom any possibility of separating the dead from the living, when one of the inmates dies: when such a calamity occurs, the corpse must be placed either in the sitting-room or bedroom; and I have known instances of a large family sleeping for several nights together in the same room with a corpse, even when death has been occasioned by an infectious fever. To my feelings there is something unspeakably terrible in this dreadful mixture of the living with the dead; and if the idea be so appalling what must the reality be to those who suffer it! A small parlour, therefore, containing an occasional bed, would prevent the necessity for this most disgusting consequence of death in a labourer's family; as, with the possibility of making up an extra-bed for some of the inmates, one of the bedrooms might generally be appropriated for the reception of the body, between the death and the funeral. I would have the parlour a plain comfortable room, ceiled and plastered, with a stone or boarded floor. It should, of course, have a small fireplace, and attached inside window-shutters. Besides the chairs and table, the furniture should comprise a closet bed complete, as the room would probably be more used as a bedroom than as a sitting-room. A corner cupboard to receive the best china and glass, a few groceries, &c., would also be useful; and a chest of drawers for the linen of the family would not be out of place. I should whitewash the walls, because it could be done by the cottagers themselves when requisite, and colour-washing is, of all things in this way, the most difficult to do well to the uninitiated. The cottager's wife would decorate the walls and the room generally with some of her best knick-knacks, books, flowers, &c.

8127. *Staircase.* As we proceed to the upper story, we must say something of the staircase. This, in old cottages, is generally the most awkward thing possible, and placed in the most awkward situation; a narrow, twisting, dark, and, to a stranger, a dangerous ascent, compared with which a common ladder would be luxurious, and usually leading into a bedroom which is a passage room to another, when there happens to be two. Our cottage must have a proper light staircase, ending above in a small landing, to which all the bedroom doors should open.

8128. *Bedrooms.* Every cottage for a family should have at least three bedrooms, so that the parents, and the children of each sex, might sleep in separate apartments. The rooms need not be large, but they should be light, airy, comfortable, each having a window that will open. They ought to be ceiled, plastered, and whitewashed; with boarded or plaster floors; and, if possible, a fireplace in each, in case of sickness, or merely for ventilation. I am rather an advocate for the plaster floors used in the north of England for cottage bedrooms, as they are a security against accidents by fire; and, when properly made, are more comfortable, and have a more cleanly appearance, than the rough ill-joined boards commonly found in cottage chambers. I have seen these floors nearly as hard as stone, and, when washed over with pipeclay, they have a very neat effect. It is unnecessary to describe the furniture, which, of course, should comprise the requisites for comfortable repose and cleanliness in a humble way. You seldom find bed-curtains in a cottager's chambers; I have heard them express a dislike to bed furniture; and, in a

tolerably warm room, it is, I think, a luxury we might all dispense with, as being rather prejudicial to health than otherwise. Cottagers generally use stump bedsteads, with head-boards; and I have observed in cottages ancient specimens of oak bedsteads, with curiously carved head-boards and legs. Old carved oak clothes-chests are also frequently met with, which would be valued by the antiquary. There are few things connected with labourers' dwellings which so much need reform as the bedrooms. In this neighbourhood half the cottages have only one chamber, and this sometimes a low miserable apartment in the roof, open to the thatch; with the walls unplastered, and without a window that will open; in fact, a place little better than a hay-loft. And here the whole family sleep; old and young, married and single, without even a curtain to separate the sexes. Can we wonder at the gross immorality which is so lamentably common among the young peasantry, when the sense of delicacy is destroyed even from infancy? I would therefore press this subject on the attention of all benevolent owners of cottages, and especially on our great landed proprietors, who are generally well disposed to contribute to the improvement of the peasantry. The first step towards the improvement of their morals must be to increase the number of bedrooms in cottages. Let me then urge this upon those whom it concerns, in the words of "Nature's sternest painter, yet the best," the poet Crabbe: —

"These thoughtless people part,
Nor let the ear be first to taint the heart."

8129. *General remarks on the interior.* Having described the interior of the cottage, let me pause and enquire, whether there is anything in the description which can be justly considered superfluous, and not absolutely necessary for the comfortable accommodation of a labourer with a large family. I am not aware of any thing to which a reasonable objection can be offered, unless it be the parlour. The idea of a cottage parlour may lead some to exclaim, "The man must be a fool! Who is to do the work, if labourers are to be fine folks, and sit in parlours?" My friend, are you not offended at a name? Let us change the high-sounding title of this room of all works, and perhaps you will not object to it. Call it the spare room, for instance; a place to be used for all sorts of purposes: for such it would be, in fact. Unless when the wife was confined, or any of the family happened to be recovering from illness, I will answer that it would not be used as a parlour above six times in the year. It would frequently be let as a lodging to an occasional labourer in the parish. In rainy weather, it would be degraded into a drying-room, and be filled with wet linen; and the floor would often be found half covered with onions and seeds laid there to dry. Do not the various uses to which such a room may be applied make it a desirable addition to a cottage, even though it may be called a parlour? If such an apartment would have a tendency to give the peasantry fine notions, I should be the last to recommend it. For I hate fine people of all sorts, and fine *poor* people above all others, because they have not even an excuse for finery. But though I would not give them notions unsuited to their station, I should be glad to see their habitations improved, and I know, from painful observation, that our cottages stand in need of improvement. They are, in fact, behind the times; and while the houses of every other class of society have been gradually increasing in comfort and convenience, the dwellings of the labourers are little better than they were a hundred years ago. Many improvements and conveniences in cottages have been suggested by others, which I forbear to notice; for this reason, that, while such conveniences are unattainable by persons of small independent property, it is in vain to expect that they will be provided for cottagers. My object has, therefore, been to describe the accommodation required in what would be called a comfortable labourer's dwelling, and to suggest practicable improvements which are likely to be effected; and I hope that there is nothing in the foregoing description which can be considered impracticable.

8130. *External appendages to a labourer's cottage.* I am next to speak of the external appendages to a complete labourer's dwelling, including the yard and outbuildings, the garden, orchard, and allotment of land. To account for some of the outbuildings which will be mentioned in the following description, I must remind the reader that, as I am speaking of a cottage of the first class, I must, of course, suppose the cottager to keep a cow; and that, besides a quarter or half an acre of land, for spade husbandry, (the quantity should be proportioned to the spare time of the labourer, and the quantity of manure he can collect), he would also be the occupier of about three acres of pasture. I am of opinion that it would have a beneficial effect upon the general conduct of the agricultural labourers, if there were a certain number of cottages, with land attached to them, in every parish, to act as a sort of stimulus to industry and frugality. Formerly the small farms presented this stimulus. The industrious, saving cottager had then a chance of rising a step above his original station in society; and a natural desire to improve his condition would act as a constant inducement to carefulness and activity. But now he has no such inducement. In most parts of England, parishes which were once divided into ten or twelve farms, of various extent, are now thrown into two or three large ones; the waste lands are enclosed or appropriated; and even the bare-worn common is, in many cases, denied to the hard-working frugal labourer, who happens to have saved enough money to set up a cow. How can we wonder, then, at the careless, improvident habits of the peasantry, when they have scarcely an inducement to be otherwise? But, under all their disadvantages, there are still a few labourers who save money; and is it not rather hard that they should be deprived of the opportunity of employing it profitably in the only business with which they are acquainted, that is, agriculture? Let us suppose a working man to be possessed of 50*l.* Almost the only way in which he could invest it safely, would be in a savings' bank, where it would produce him an interest of about 2*l.* a year. Now this is all very well; the principal sum is secure, and a certain 2*l.* a year is a desirable addition to a labourer's income. But it would take nearly his whole life to save up 50*l.*; and half that sum would produce a much greater income, and much improve his condition, if employed in some sort of business. In short, though the savings' banks have been a great benefit to the working classes, the small income produced by a sum of money placed there does not afford a sufficient stimulus to frugality. The interest upon their savings can add little to the comforts of the depositors; and, as to having a sum of money against the time of sickness or misfortune, they know that the parish must then support them; and though they might be induced to save, if by saving they could materially improve their condition, we must not expect them to save for the relief of the parish. But let us suppose a man to have saved only 25*l.*, and to have an opportunity of taking a cottage, with land enough attached to it to support a cow. He would probably invest his little capital in a cow, a couple of pigs, some poultry, perhaps, and a hive or two of bees; and, if he had tolerably good luck, and were a good manager, he would soon be placed in circumstances of comparative affluence, and would be infinitely better off with his 25*l.*, *thus invested*, than the other would be with his 50*l.* in the savings' bank. The great improvement in his condition would also be apparent to all around him, and would act as a general spur upon the carefulness and industry of his neighbours. Money in the savings' bank would not produce this consequence, because its effects are less apparent; in short, its effects are unimportant when compared with the comforts derived to a labourer's family from keeping a cow. But, besides being prizes to excite the diligence and reward the good conduct of the labourers, a few cottages, with land attached, would be a general convenience to the villagers, as a means of supplying them with milk; a luxury which, in my neighbourhood, is seldom tasted by the poor. Though living in the country, they are worse off than townspeople in this respect, as they cannot get it for money, unless on some particular occasion. The cause of this inconvenience is the large farms, and the want of cottagers' cows. A rich farmer is, of course, above selling milk, and there is no one else to sell it, unless there happens to be a small farmer in the parish, or the rich farmer lets his cows to the farmer or dairyman. It would not answer to sell milk in small quantities, and, as we have no cottage cowkeepers, the peasantry are deprived of a nutritious article of food, which it is almost impossible to do without. Wherever there are no cottagers' cows, the peasantry in general must be ill supplied with that important

necessary, milk. I offer these reasons for the opinion I have ventured to advance, that in every village a few cottages, with land to keep cows, would be desirable on many accounts. I do not say that every cottager should have a cow. Perhaps it would be better if all had them who can manage them; and it would be found, upon trial, that the number of these would not be large. A cow would be thrown away upon dirty, indolent cottagers, and there are many respectable ones so situated, that it would be more an inconvenience than an advantage to them to keep a cow. But I think there should be a few cottages with land in every parish, that the steady and industrious, and those who have an opportunity, may at least have a chance, of improving their condition.

8131. *The yard.* After this long digression, let us proceed to speak of the yard, a very necessary convenience to a labourer who keeps a cow. The wash-house should have a door opening into the yard, which ought to contain the pump, dung-pits, and all the out-buildings. The pump I would place as near the washhouse door as convenient; the dung-pit in the corner of the yard, farthest from the house; and to this pit the surface of the yard should have a gentle fall. It should, of course, be properly drained.

8132. *The fuel-house.* The first out-office to be mentioned is the fuel-house, a place in which the coals and dry wood may be kept, if necessary, under lock. The tools, and hogwash tubs, and many other things, may also be placed in this building, which is a necessary appendage to every cottage. It would be most conveniently placed joining the back part of the house, so that it might be approached under cover from the washhouse door.

8133. *The cowhouse and pigsty* should be near the dung pit, that the drains from both may be laid into it at little expense, and to save the cottager's time in cleaning out the cow stall, &c. The cowhouse need only contain one roomy stall and a calf-pen, with a small loft over both for the hay brought in for use. The pigsty to a cottage where a cow is kept should be divided into two, that the store pig, which a good manager would never be without, might be separated from the fatting pig.

8134. *If a poultry-house* should be required, I would place it either over or adjoining to the cowhouse, for the sake of warmth. But I am not sure that it would answer to a cottager to keep much poultry, unless in situations where there is a ready sale for eggs and chickens, and where poultry can be kept without being a nuisance to the owner and his neighbours. In a widely scattered village this may sometimes be the case, but where the houses are near together, the cottager's fowls are a continual source of dispute and annoyance. They are ill fed at home, and cannot stray anywhere in search of food without trespassing upon a neighbour's ground, where, in the absence of the family at work, they may devour or destroy half the produce of the garden. Where the houses are scattered, and a cottager has land of his own, or is near a common, on which they could have a run without trespassing upon others, perhaps it would answer his purpose to keep a few fowls; that is, if he can keep them out of his garden, but not otherwise. If water is near, ducks would be most profitable to a labourer, and more easily managed than hens.

8135. *Privy.* I do not recollect any other outbuilding actually necessary for the cottager's convenience, unless it be the privy, which might be either in the yard or in the garden, and, if desired, I see no objection to one in each place. But it is useless to talk of a separate convenience of this kind for males and females, till every labourer's dwelling has one. I believe that nearly half our cottages are without any place of the kind; at least it is so in my neighbourhood. For instance, out of sixteen dwellings near me, six only have the convenience alluded to, and three of the six conveniences have been erected within these two years. The want of such places must be a terrible nuisance to the cottagers; and I particularly recommend the subject to the attention of cottage owners.

8136. *General observations on exteriors.* As the fence of the yard and the outbuildings would add something to the cost of the cottage, I choose here to meet objections that I suppose, and recommend only the least expensive outbuildings, such as the cottagers, with trifling assistance, would very frequently erect themselves. The cowhouse would be the chief expense, and that would be little better than a common shed, walled up with any thing on three sides, and open to the south. But I would have a strong fence and gate to the yard, to be fastened well at night, that all the stock may be secure, as it would probably cost the owner at least a day's work when his cow or pig happened to get astray. I do not mention any place for pigeons in the yard, because a cottager could not keep them without constantly trespassing on his neighbours. There is an increasing prejudice against pigeons, which are certainly very troublesome to the farmer at certain times in the year. Dovecots are now much less frequently seen in farmyards than they were formerly, at least in the corn-growing districts: and if the farmers can no longer keep pigeons, of course the labourers must not. Where the cottage stands near a common, or among open green lanes, it would answer the cottager's purpose to breed a few geese, which are a profitable kind of stock, because, after a certain age, they almost take care of themselves. They would require to be secured at night; and, if the cottager keeps geese, he must add a house for them to his outbuildings in the yard.

8137. *The garden,* if well managed, is commonly the most striking feature about a labourer's dwelling, and there are many reasons why it should adjoin the house. In the present case we will suppose the cottage to be surrounded on two sides by the garden, and I would approach the front of the house through a narrow part of the garden which divides the house from the road; and this part of it I would devote chiefly to flowers and shrubs. I would train some ornamental climbing plants against the walls of the house, and a vine or pear trees, if there were proper situations for them, where the fruit would ripen and be out of the reach of the children. I observe, however, that excepting vines, fruit trees seldom thrive much against the walls of cottages; there are few labourers who know any thing of the art of pruning, and, being improperly pruned, the trees bear little, and seem not worth the time and trouble they require. Vines, however, do remarkably well against the cottage walls in this neighbourhood, and bear profusely in many situations, apparently with very little care or pruning. I am not qualified to lay down rules for the management of a cottager's garden, but I would venture to suggest, that it should not be too large; a small garden, well cultivated, being more profitable than a large one half cultivated. In fact, if he have an allotment of potato ground elsewhere, the cottager has no use for a large garden, as he grows and uses none but the commonest vegetables, which take up little room. He does not ever cultivate much small fruit. Strawberries and raspberries are very seldom seen in a cottage garden; and currants and gooseberries are not often abundant; so that a large garden is not requisite. I used to wonder formerly why the cottagers did not cultivate the small fruits in greater abundance, as they require so little trouble, and are so extremely useful. The reason for this neglect, given me by several labourers, is, that the children devour the fruit before it comes to perfection; in fact, they begin upon it as soon as it is formed, and very little is left to ripen. As cottage children are, of course, left a great deal to themselves, I believe it would be useless to attempt growing fruit where there is a large family, or in a closely built village. Where a cottager, therefore, cannot grow fruit, he ought, I think, to keep bees as a substitute for the profit of fruit. Indeed, no cottage garden should be without bees, placed in some warm retired corner, at a short distance from the house, for they are not agreeable neighbours. Bees are, I believe, the most profitable of all stock for a cottager, as the whole of their produce is valuable, and, except at swarming times, they are no trouble.

8138. *Orchard.* Besides the garden, it is desirable that every cottage with land should have a small orchard attached to it, especially in the cider countries; and, in extensive allotments of land, there are generally rough places, which, being of little value for any other purpose, might be converted into small orchards. Where there is no waste place of this description, I would plant the orchard immediately behind the garden, and contiguous to the house, that it may be easily overlooked by the owner; I would also rear a good hedge round it to keep out intruders, for young cottagers are as fond of sour apples as

they are of sour gooseberries; and though they can scarcely clear an orchard of apples as they would a garden of small fruit, they will do a great deal of mischief, if not guarded against. As it is scarcely possible to have too much fruit, and a peasant's orchard is not likely to be large, I would plant some fruit trees in the hedges of the garden and fields. Damsons and cider apples, and other common fruit trees, would do very well in the hedgerows, and would be very ornamental. I think a cottage orchard should produce apples, pears, and plums of various kinds, but chiefly apples. Fruit will sell every where; and it is desirable that a cottager should have as many ways as possible of making a little money. The landlord ought to furnish the cottage grounds with fruit trees, and a gentleman of landed property would do this at a very trifling expense, by having a small cottage nursery, in which his gardener might graft, and rear fruit trees of good kinds, to transplant, when fit, into the cottagers' gardens and orchards. Many labourers are fond of grafting; and, if the ground were planted with fruit trees at first by the landlord, the tenants would generally keep it stocked. I wonder our landowners do not see the advantages of planting their cottage grounds with fruit trees; by which they would increase the value of them, and place in the hands of the tenants the means of paying the rent. They would also give their cottagers an additional comfort, and greatly increase the beauty of our villages, by surrounding the houses with fruit trees, which are the most interesting of all trees. What can be more beautiful than a handsome apple tree covered with rosy blossoms in the spring, or loaded with golden fruit in autumn? It is picturesque even in winter, when its rugged massy stem and irregular branches are exposed to view. Indeed, a village with many small orchards about it is generally a pretty village.

8139. *Potato-ground.* The next thing to be spoken of is the allotment for potatoes, &c., without which no cottage would, in these days, be thought complete. But, of course, this allotment would be much smaller in the case of a cottager keeping a cow, than in that of a labourer with only a garden to attend to The cowkeeper would have many little odd jobs to do connected with his cow and land, which would leave him not leisure enough to cultivate an extensive potato-ground besides his garden. Nothing pays a labourer so well as working for a master; consequently, a garden cannot answer to a cottager if he is obliged to lose time, as they express it, in order to cultivate it. A cowkeeper's ground for potatoes, &c. should therefore be smaller than that of another labourer, because the man will not have much leisure, and the wife will have less, as she will have the produce of the cow to manage, in addition to the ordinary cares of the family. But if the cowkeeper have not constant employment with a master, the case would be altered, and he would require as large an allotment as other labourers. He would probably cultivate his ground on a different plan from that followed by ordinary cottagers. He would not have space for a plot of corn, and it would answer his purpose better to grow cabbages, Swedish turnips, mangold wurtzel, or something that would be useful for the cow, on that part of his ground not occupied by the potato crop; indeed, a man who has a cow and pigs should consider their wants in his gardening almost as much as he does those of his family, and his pigs should nearly live on vegetables during the summer.

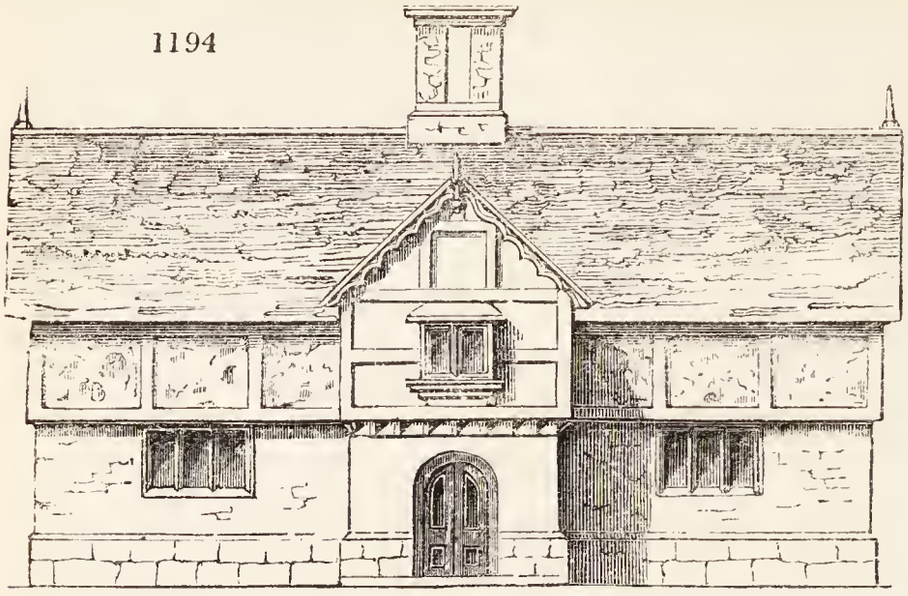
8140. *Grass land.* We conclude with a few observations upon the grass land which the cottager is to occupy for the use of his cow. This should be about three acres, divided into two enclosures. I believe three acres of fair grass land are generally considered the quantity required to summer and winter a cow; but, if a less quantity would be sufficient, of course the cottager would not desire more, as it would cause an unnecessary addition to his rent. He had better have rather too much land than too little, as the profit of a cow depends in a great measure on its being well fed. He would probably mow his fields for hay alternately, as he would not be able to manure very freely. He must, however, manure a portion of his grass land every year, or it would go back; and, if he were a good manager, he would be able to do this; for it is surprising what a heap of compost a managing person will collect who keeps a cow, and two or three pigs, and gathers every thing that can be converted into manure from the garden, the yard, the drains, and the roads about the premises. If he had not too large a potato-ground, a cottager, situated as I have described, would not be a good manager if he could not contrive to dress over an acre of his grass with compost every year; and this would be sufficient to keep it in heart if it were mowed every alternate year. There is one thing connected with allotments of land to labourers, which I would press on the attention of cottage owners, that whatever land is let to a labourer should be adjacent to his house. It should be remembered that the cottager's land is to be cultivated during the leisure time he has after having done an honest day's work for his master. His land, therefore, should be near his abode, that he may make use of all his time, half of which would be wasted in walking backwards and forwards if his land happened to be at a distance. If, also, his land were at home, he would spend many a half hour spudding thistles, or spreading dung in the field, or doing many little odd jobs, which would be left undone if the field were some way off. Moreover, it works a man too hard to have to walk a quarter of a mile, or more, to his extra-labour, after, perhaps, walking a much greater distance from the place where he works for a master. He would do half as much more work, and do it with more pleasure to himself, if he could do it at home, where he could immediately retire into the house when he felt fatigued. In short, if a cottager is to do any good with land, it should be within an easy distance of his home. Imagine the extra-labour occasioned to the cottager when he has to wheel out the manure, and bring home the produce of his land, distant, perhaps, a quarter of a mile from his house. Where the cottages belong chiefly to one proprietor, who is the principal landowner in the parish, it may generally be contrived that the allotment of land may adjoin the cottage, or be at least a convenient distance from it. A cottager can generally afford to pay as good a rent for land as an ordinary farmer; and, if he can afford to pay for it, he may reasonably expect to have it conveniently situated.

8241. *General observations.* I believe I have noticed most of the conveniences, internal and external, which in these times would be thought requisite to form a complete labourer's cottage. I am aware that the description given goes very far beyond the ordinary run of cottages, as they are at present. My aim has been to make it so; but I hope I have suggested nothing but what is absolutely necessary for the decent comfort of a family. My aim has also been to speak of practical improvements; and to show how the domestic accommodations of the peasantry may be increased at a moderate expense. There are many desirable improvements and luxuries suggested by writers on cottage architecture, which I have forborne to mention for this reason; because costly improvements are not likely to be applied to cottages; and it is useless to recommend luxuries for labourers' dwellings, which are not found in the houses of wealthy farmers and tradesmen, and even in those of the smaller gentry. Our peasantry, however, have no desire or taste for luxurious habitations. They wish for comfortable cottages; that is, dry, warm, and, above all, sufficiently roomy dwellings, in which their families may be conveniently accommodated, without violating the common decencies of life. If they had houses of this description, they would have every reason to be satisfied, and would be so, without unnecessary luxuries. And I hope the time is fast advancing, when the improvement which has taken place in the habitations of all classes above them will be extended to labourers' cottages.

8142. *As an example of an English labourer's cottage*, applicable to the above description, our correspondent has sent us the design shown in *figs.* 1194. to 1196. *Fig.* 1194. is the elevation; *fig.* 1195. the ground plan; and *fig.* 1196. the chamber plan. In *fig.* 1196. *a* is the oven; *b*, a small boiler; *c*, a closet for bacon or other things which require to be kept dry; *d*, stairs; *e*, a lobby; *f*, kitchen fireplace; *g*, parlour fireplace; *h*, washhouse; *i*, dairy; and *k*, shed for fuel, hog tubs, &c., opening into a yard, *l*. In *fig.* 1196., *m* is the parents' bedroom; *n*, spare bedroom, or bedroom for young or sick children; *o*, bedroom for girls; *p*, bedroom for boys; and *q*, a closet entered from the landing-place, *r*. The lower story of this cottage is supposed to be built of stone, or of brick with stone mullioned windows. The upper story to be a wooden framework, filled in with brick or plaster ornamented. The framework projects at the ends, and the gables have ornamented barge-boards. The window in the porch gable is an imitation of the old projecting wooden windows, of which there is a great variety, and they

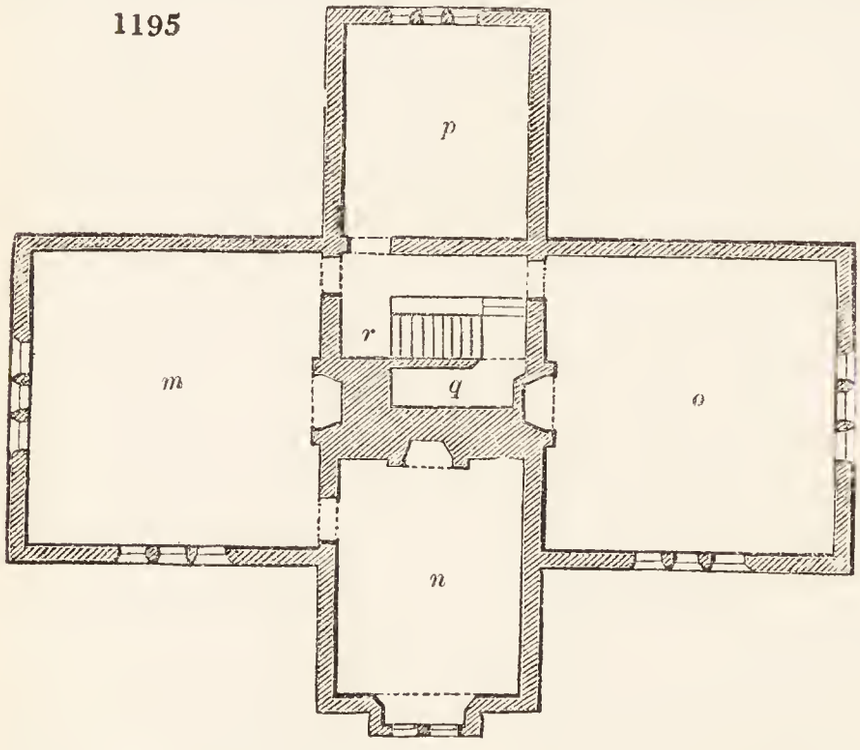
are all ornamental. There is a window in this form (see *fig.* 1194.), supported below by an ornamental bracket, which would have a good effect over a porch. These projecting windows are generally small, but they give more light than a common window of the same size. They are only proper for wooden houses, or in such parts of a house as are built of wood. The upper story in this design is supposed to be of wood and plaster, as being more picturesque, and in some places cheaper, than bricks; but in stone countries the cottage may be altogether of stone; or, both stories may be built of brick, with string-courses and copings to the gables. The chimney-stack consists of four slender separate shafts,

1194



with plain stone or brick cornices. The roof is tile or slate stone. The side walls of the chamber floor are to be five or six feet high, and the flat part of the ceiling is to be raised still higher in the roof. The bedrooms will thus be lofty and airy. (*Selim. Wiltshire, July,* 1834.)

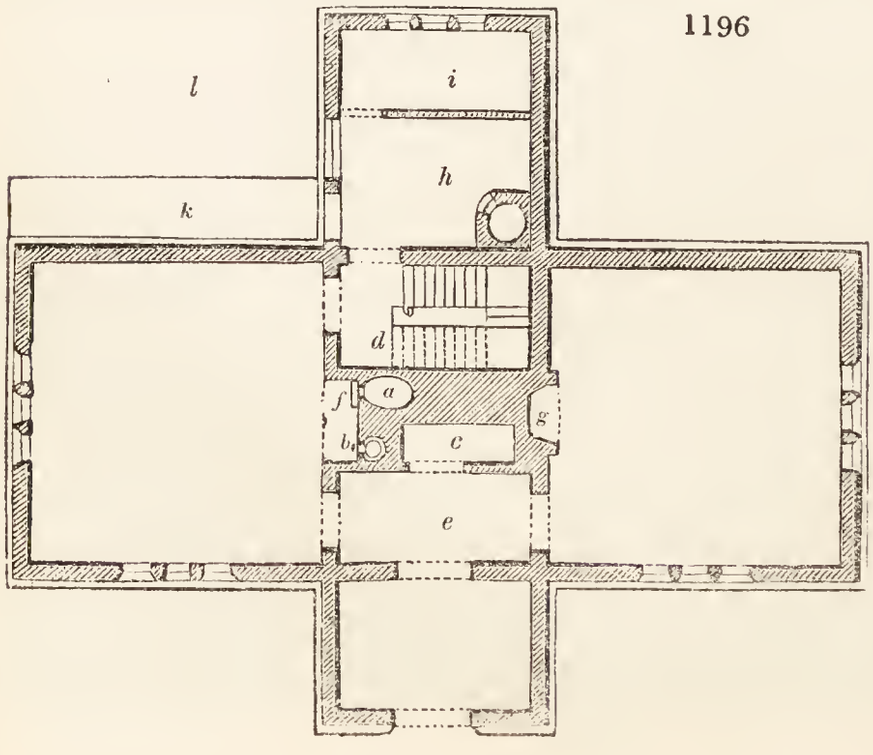
1195



8143. *A group of four cottages* (*figs.* 1197,1198.), represented as two, suitable for labourers with small families, comprising living-room, bedroom over, and washhouse to each. Privies are attached for the use of the two middle cottages; those of the two end ones are supposed to be detached. They may either be placed on a platform or terrace, according to the manner recommended in the *Encyclopædia of Cottage, Farm, and Villa Architecture*, or not, according to circumstances. In *fig.* 1198., *a a* are the sitting-rooms, twelve feet by ten feet; *b b* washhouse, one eight feet by six feet, and the other nine feet by six feet; *c*, water-closet; *d d*, entrance lobbies; and *e*, staircase.

8144. *Earthen walls.* It is proposed to erect the walls of these cottages with compressed earth; which method of building is termed *pisé*, and is very suitable for cottages of this description, being a very good substitute for brick, and reducing the expense of the walls one half. The chimneys must be of brick, with which the *pisé* firmly and readily unites; and, if the soil on which the cottages are to stand is not perfectly dry, the foundation must be carried above the ground-line in rough brick or stone work. I shall, however, proceed to describe the manner of executing the whole of the cottages in *pisé*, the chimneys and arches over apertures always excepted.

1196



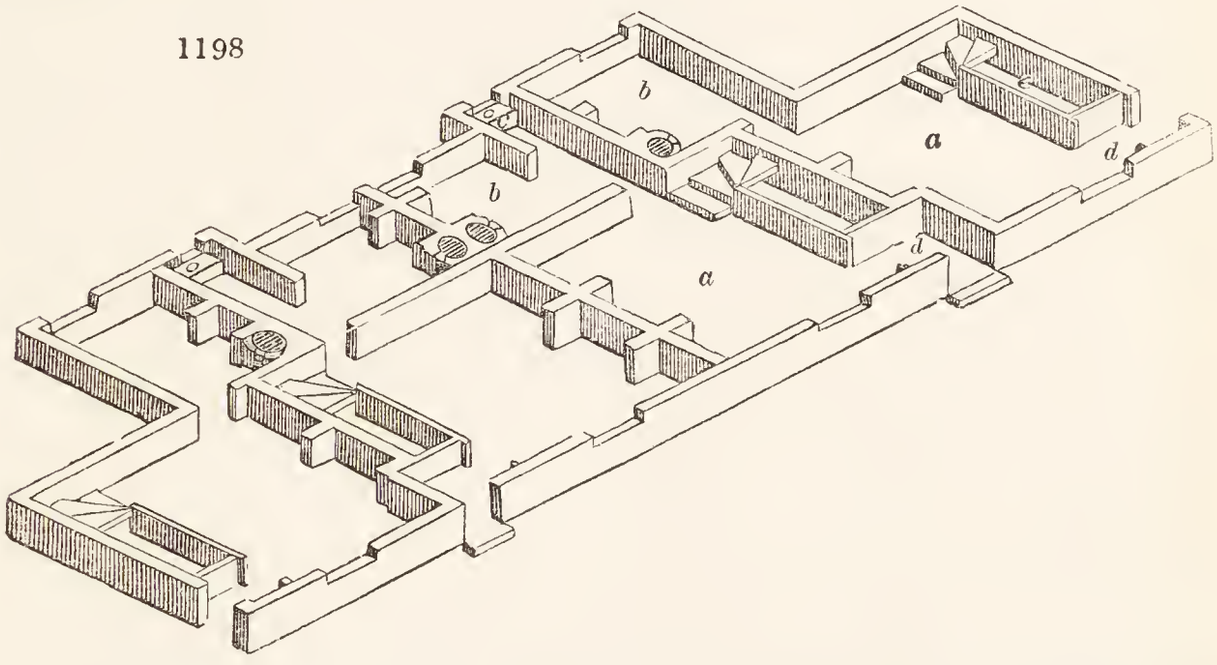
8145. *The sort of earth* most likely to be met with is common gravel, containing a small portion of clay; and this will answer the purpose as well as any that can be found. Where clay is not found combined in sufficient quantity with the gravel in its natural state, a small portion of common clay, or of loam, which is too

light for making bricks, may be procured, and mixed with the earth previous to its being used. On the other hand, if the clay be too strong, it will not do, but must be reduced to the proper quality by

1197

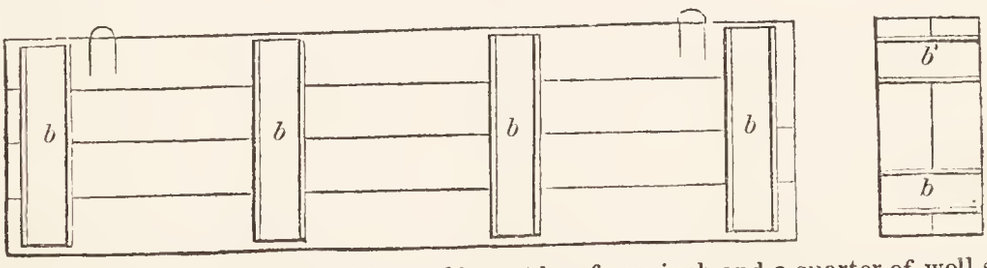
the addition of gravel or other coarse earthy rubbish; always carefully excluding all vegetable and animal substances.

1198



8146. *Mould for forming the blocks in.* For the purpose of erecting walls of this description, a mould (*fig.*1199.) is required, which may be made by any country carpenter, being very simple, although con-

1199



sisting of several parts. The two sides of this mould must be of one inch and a quarter of well-seasoned deal, smoothed and rabbeted, each about ten feet long and two feet nine inches wide when finished, and each having four ledges, *b*, of the same substance, nailed or screwed on the back, with iron handles to lift them by. Two heads to fit in between the sides must be made in the same way, and must be as wide as the thickness of the wall. Four bearers, mortised through at each end, receive the tenons of the upright posts. Eight upright posts stand upon these bearers, and are kept in their places by tenons at the bottom, and at the top by a line wound round each pair and twisted tight with a stick, one end of which is kept fast by being passed over a nail or peg in the post. Wall gauges, or pieces of timber cut to the width of the wall, will also be necessary to fit in between the sides of the mould, so as to prevent their coming over towards each other at top, which they will have a tendency to do during the operation. Two rammers should also be prepared, of hard heavy wood; and if formed of the root of the tree they will answer the better, being less liable to splinter off.

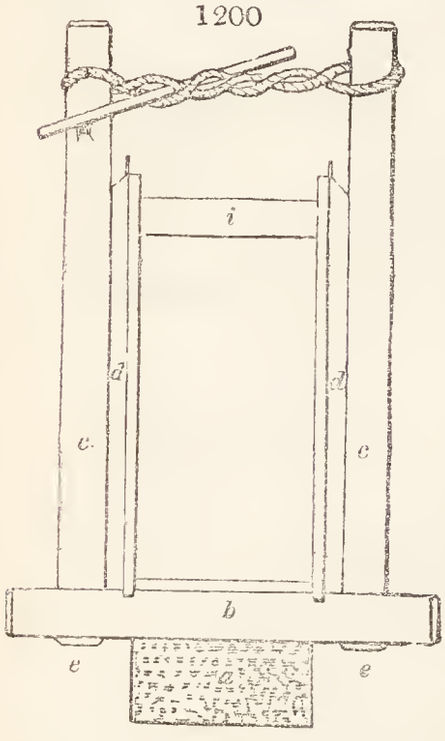
8147. *Mode of laying the foundation.* These things being in readiness, and the spot fixed on for the supply of earth, which should be as near to the intended building as may be convenient, the first step is to dig out the ground for the foundation in the usual manner. When trenches are opened of equal depth all round, for the outside, as well as for the partition walls, beginning at one end, fill in about six inches in depth with the ground that was taken out, and, after having trodden it well down, ram it with a heavy rough piece of timber (not with the rammers to be used in the mould), till it leaves no impression; fill in for another length; and, when the whole is covered with this first course, begin a second, and proceed in like manner till the foundation is brought up to the ground line. Large stones, or any coarse rubbish that can be conveniently procured, may be thrown into the foundation, but it should be thoroughly mixed with the earth, and, if it be very dry, a slight sprinkling of water may be

given to it, from a watering-pot, before it is put in. The wall mould will not be required at this stage of the proceedings, for the sides of the trench will form a mould; but as the edges will be somewhat broken away, the ground must be well rammed up to the foundation on both sides. Having proved the work with a level, some precaution must here be taken to prevent the damp from ascending the wall, which it would otherwise be sure to do, more or less, according to the nature of the soil. In some cases, a bed of cement, spread all over the work just above the ground line, will be sufficient; in others, a course of slates must be added, and over that another bed of cement. The chimneys should be built first, and with sound bricks and good mortar, which will allow of the earth being well rammed up to the brickwork.

8148. *Mode of fixing the mould.* The bearers are now laid on at proper distances for one length of walling, level in themselves, and with each other; the sides of the mould are then set in their places, as are also the uprights, and the end and the wall gauges are put in. The line is next passed round each pair of posts, and tightly twisted with a stick; one end of which is brought over a nail or peg in one of the posts, and kept there, by which means the whole is braced firmly together.

8149. *A section of the mould as fixed,* is seen at *fig.* 1200.; in which *a* is a portion of the wall underneath; *b*, the bearer; *c c*, posts with their tenons passing through mortises in *b*, at *e e*; *d d* are sides of the mould; and *i* is the wall gauge. The twisted line and stick are also seen at top.

1200



8150. *Mode of forming the wall.* The turf having been pared off all round the spot whence the supply of earth for the walls is to be obtained, and as much immediately under it removed as is unfit for use, proceed to dig the same with a pickaxe, and throw it up in a heap, breaking the large lumps or clods, and drawing away the largest of the stones, which will roll to the bottom, with an iron-toothed rake. This rake, however, must not be too fine, as all stones not larger than a hen's egg may be used in the wall. Care must be taken to pick out every little bit of root, twig, or other vegetable substance that is to be found, and to throw them aside; for, if worked up in the wall, they would in a short time rot, and thereby affect its stability. If the earth be very dry, it should be wetted a little; but this must be done very sparingly and equally, and before it is put into the mould. Being thus prepared, the earth is carried to the wall in baskets, and put into the mould, at which there should be two other workmen with their rammers: one of these men gets carefully into the mould, and, spreading the earth evenly with his feet, treads it well down. A layer of about four inches in thickness being thus spread over the bottom of the mould, the men, one on each side, proceed to work it with their rammers, crossing their strokes in every direction. This layer being sufficiently rammed, others are added, and proceeded with as before, till the mould is filled within three inches of the top. The mould is then taken to pieces and fixed for the next length of walling, and one course is completed all round, including the partition walls up to the chimneys. Small wood-bricks for nailing skirting, linings, &c., to, should be put in vertically. Binders or ties of oak or other hard wood are put in at the angles, rough from the saw, about five feet long, an inch thick, and of such a width as to allow about four inches of earth on each side of them. One of these is put in at each angle on the top of every course, the alternate ones turning different ways, and the ends consequently crossing each other. Similar ones are put in to tie the partition walls to the front and back walls.

8151. *Laying the second course.* The first course being completed, the second should be worked the reverse way: thus, if the first was from left to right, the next should be from right to left. When the walls are built up high enough for the arches to the apertures, the skew-back of the arch may be formed by chipping away the rammed earth with a pickaxe or chisel, and the arches may be turned with sound bricks in cement or good mortar, the centres being made rather stronger than usual, as well as the supports under them; and these should be left in till the wall is completed. The lintels, joists, &c., are laid in the same way as in brick walls; and these, as well as the timbers of the roof, may be laid on immediately, which is one of the many advantages which this method possesses over "cob" or mud walling.

8152. *The roof.* The roof is intended to be slated, and furnished with eaves, trough, &c.; and the outer walls stuccoed, or a still cheaper coating may be given of roughcast.

8153. *Finishing.* The holes in the walls left by the bearers of the mould may remain open for a short time, which will occasion the walls to dry the quicker; and the plastering should not be laid on till a few weeks after they are finished, or the sweat of the walls will cast it off again. The roof, however, should be covered in, and eaves-troughs fixed as soon as possible. When the walls are ready for plastering, they should be covered all over with small holes, picked in with the sharp point of a hammer, or some such instrument, which will give a hold to the plastering; the loose dirt being brushed away with a stiff brush, and the walls then slightly sprinkled with water. The plastering is done in the usual way of rendering on brickwork; which, however, requires rather more wetting than *pisé*.

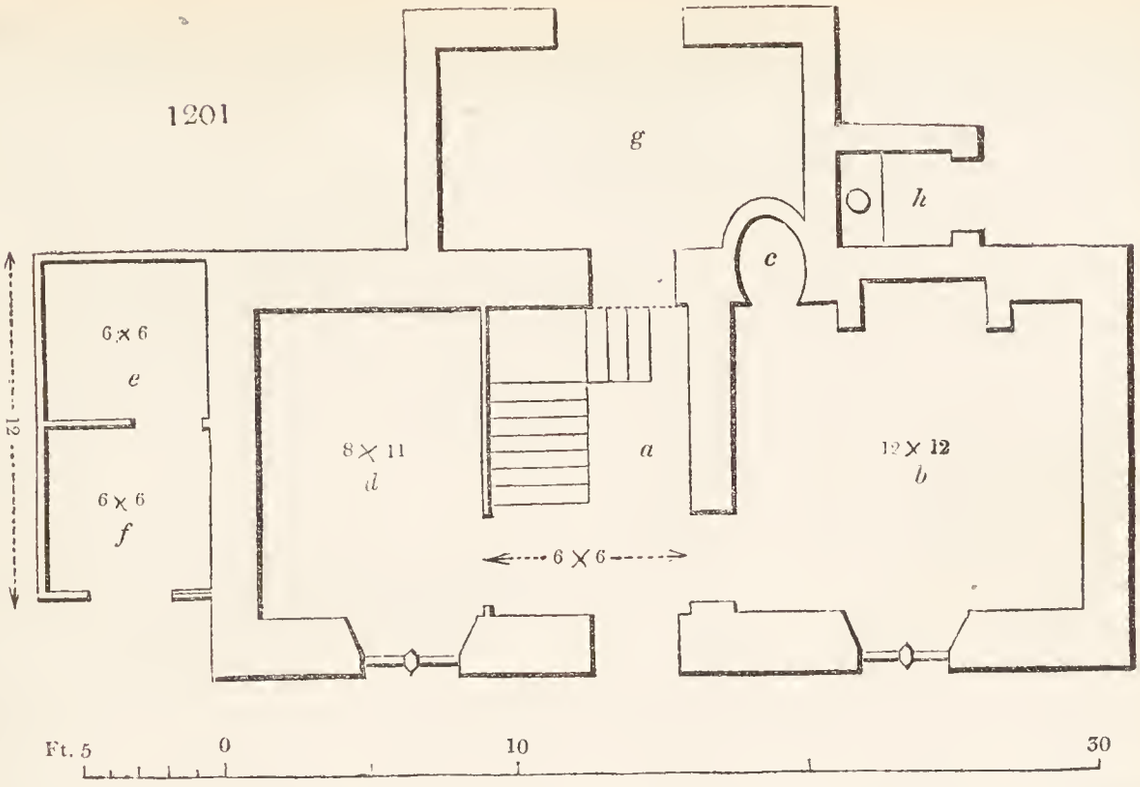
8154. *General remarks.* This will be found an economical, easy, and expeditious manner of erecting cottages, farm or other ordinary buildings, and, if properly executed and protected, will soon become as hard as stone, affording the comforts and convenience of a brick building, at nearly half less expense, and being vastly superior to those miserable hovels, put together with mud and sticks, which still disgrace many parts of the country as human habitations.

8155. *Estimate.* The expense of erecting the four cottages represented in *figs.* 1197. and 1198. according to the above plan, and finished according to the usual cottage style, will probably amount to the sum of 250*l.*, supposing the supply of earth to be conveniently placed, and of tolerably good quality.

8156. *The Gloucestershire agricultural labourer's cottage* is represented in *figs.* 1201, 1202, and 1203. *Fig.* 1201. shows an entrance, *a*, with a staircase down to the cellars, and up to the bedrooms; a living-room or kitchen, *b*, with an oven, *c*; a back kitchen or room for washing kitchen utensils, *d*; a covered pigsty, *e*; a yard to the pigsty, *f*; a shed for fuel, *g*; and the privy, *h*. There are bedrooms over *b* and *d*; and cellars under them. The lobby, and the space under the ascending stairs, are sufficiently large to admit of being used as a place for the family to sit in, in the summer season, when the heat of the kitchen might render it uncomfortable. *Fig.* 1202. is the front elevation of this cottage, and *fig.* 1203. the back elevation. These cottages, of which a number have been recently built on Mr. Lawrence's estate, by his brother, Charles Lawrence, Esq., who acts as agent for him, have each a quarter of an acre of good land attached as a garden; and, though they are well worth 5*l.* or 6*l.* a year, they are benevolently let by Mr. Lawrence for 52*s.* each. In order to teach labourers how to cultivate their gardens, Mr. Charles Lawrence has composed one of the best tracts on the subject of cottage gardens for country labourers, which has yet appeared, and has distributed it among them. It is entitled *Practical Directions for the Cultivation and General Management of Cottage Gardens*, &c.; and we would strongly recommend it to all who wish to teach country labourers how to make the most of their gardens.

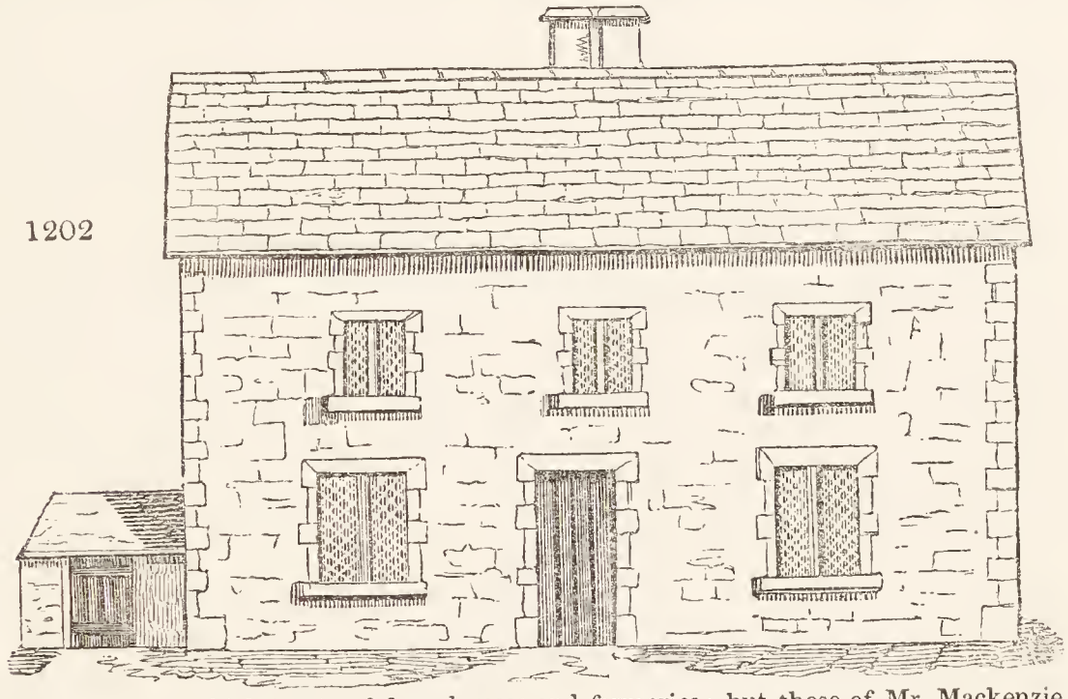
8157.—2919. *Farm buildings.* The greatest improvement which has been made in these, since the

1201

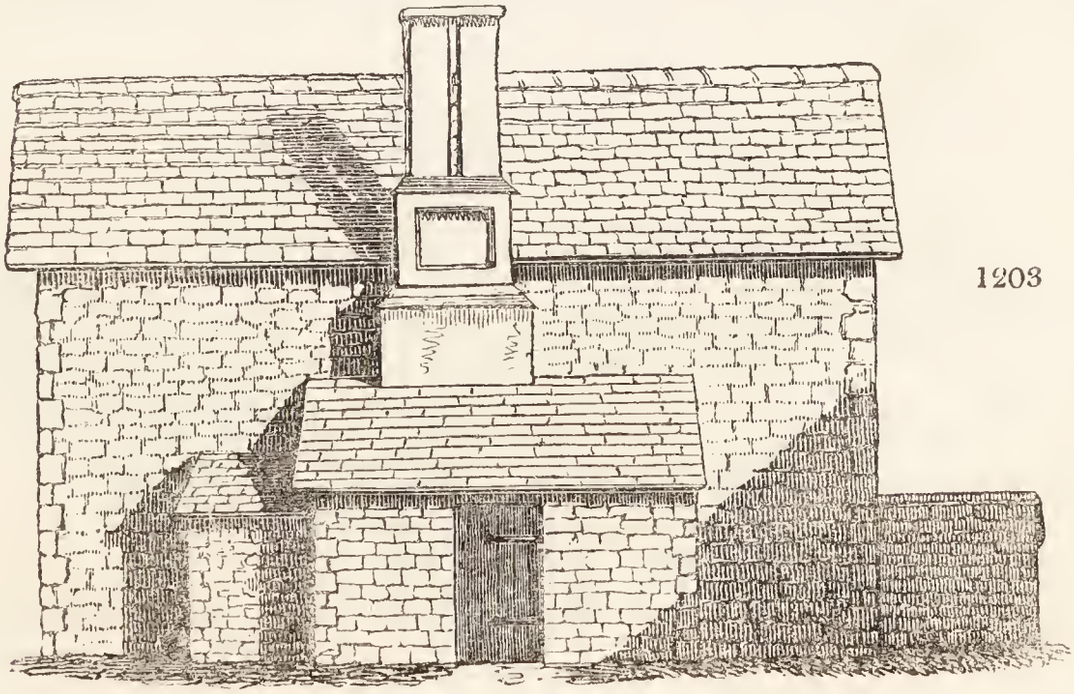


publication of our second edition, is by W. M. Mackenzie, Esq., an architect of Perth. A number of minor improvements, by different Scotch architects, will be found delineated in that part of our *Architectural Encyclopædia* which treats of farm-houses and farmeries; but those of Mr. Mackenzie far surpass all the others. In the *Encyclopædia of Architecture*, p. 537., will be found a design for a farm of

1202



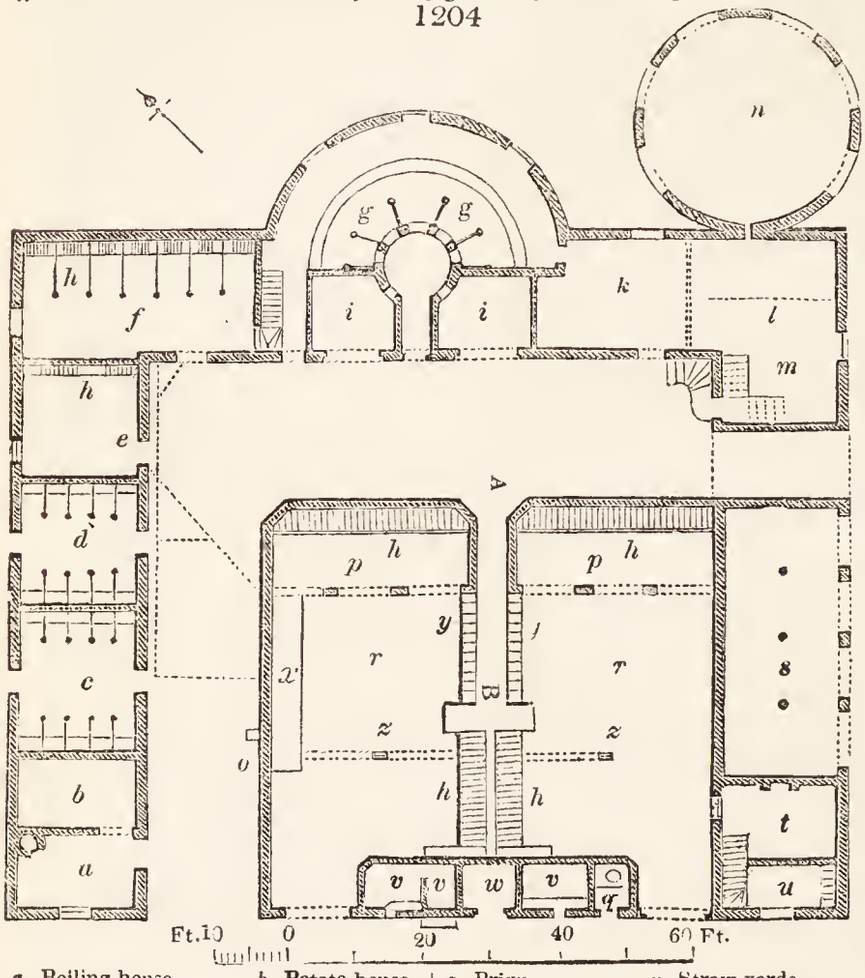
1203



six ploughs, in which all Mr. Mackenzie's improvements are introduced, and described in detail; and in our *Architectural Magazine* (vol. i.) will be found another design by Mr. Mackenzie for a three-plough farmery; which, embodying all the improvements alluded to, and being of very general application, we shall here quote in the first place, and subsequently give two other designs, one by J. Milne, Esq., an Edinburgh architect, and the other by J. Blackadder, Esq., a land-surveyor of Berwickshire; both eminent professional men.

8158. *Design for a three-plough farmery, by Mr. Mackenzie of Perth.* *Fig.* 1204. is a ground plan; *fig.* 1205. an isometrical view; and *fig.* 1206., a vertical profile. This three-plough farmery is understood to be built upon level ground; with the straw-yard cut out hollow in the centre of a basin figure; that being the best form for retaining the moisture among the manure. In fixing the position of the different ranges of the buildings, the highest are put down to front the north and east, as best suiting the purposes to which those parts of the farmery are to be applied; and at the same time adding to the comfort of the cattle in the sheds and straw-yards, by sheltering them in the directions which are generally the coldest.

1204

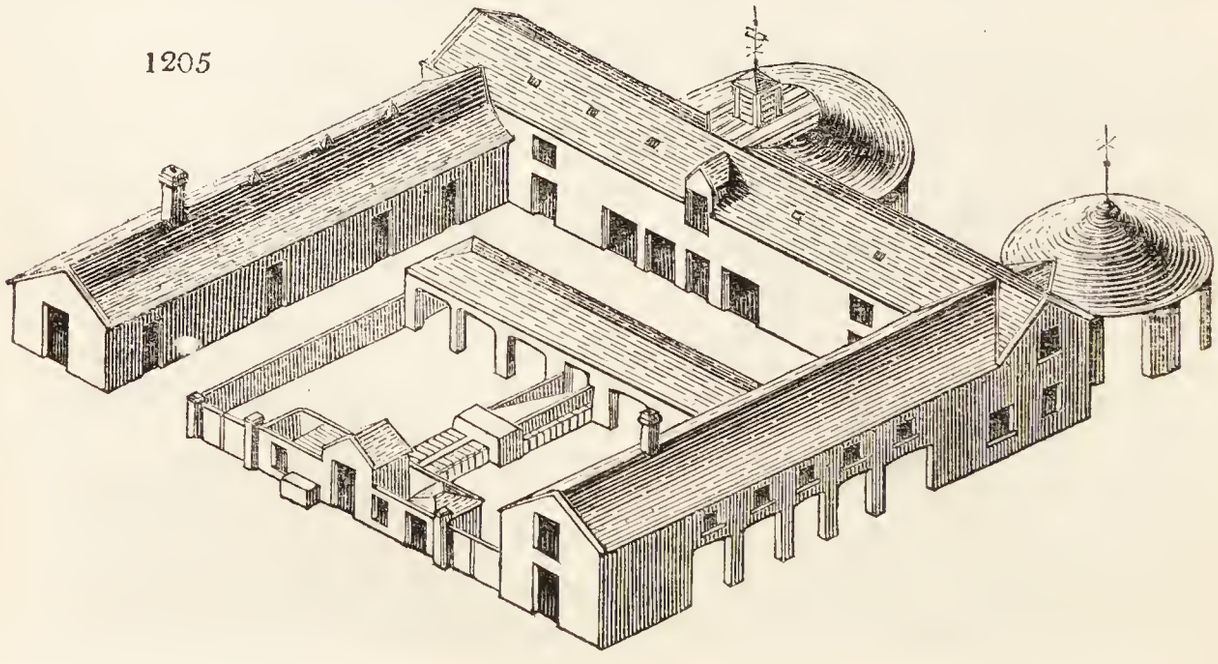


a, Boiling-house.
b, Potato-house.
c, Cow-byre.
d, Calf-byre.
e, Saddle-horse stable, and double stall enclosed for a mare and foal.
f, Common farm stable, with hay and straw-chamber above.
g, Feeding-byre, with straw-chambers above.
h, Racks for hay or straw.
i, Turnip-sheds: straw-chambers over.
k, Straw-house with upper floor.
l Threshing-machinery.
m, Clean corn-room, unthreshed corn above.
n, Horse-shed for threshing-machines.
o, Pump for liquid manure tank.
p, Cattle-sheds.
q, Privy.
r, Straw-yards.
s, Cart-sheds, with granary above, carried over the carriage entrance to the farmery, and communicating with the clean corn-room.
t, Boothy for men servants, with beds in the upper-floor extending over the poultry-house.
u, Poultry-house.
v, Piggeries.
w, Water-house.
x, Tank for liquid manure.
y, Turnip-boxes.
z, Gratings over the drains leading to the liquid manure tank, to prevent the straw from the yard from choking up the drains.

8159. *The byres* (*c*, *d*), which are low buildings on the west, and the pigsties (*v*), which are on the south, do not shade the straw-yard and cattle-sheds, but admit the rays of the sun to all parts of them. The farm-house is supposed to be situated on the south-west of the farmery, with the kitchen court adjacent to the cow-byre, calf-yard, &c.; thus keeping the offices which are managed by the house servants in one division, and those under the management of the farm servants in the other division of the establishment.

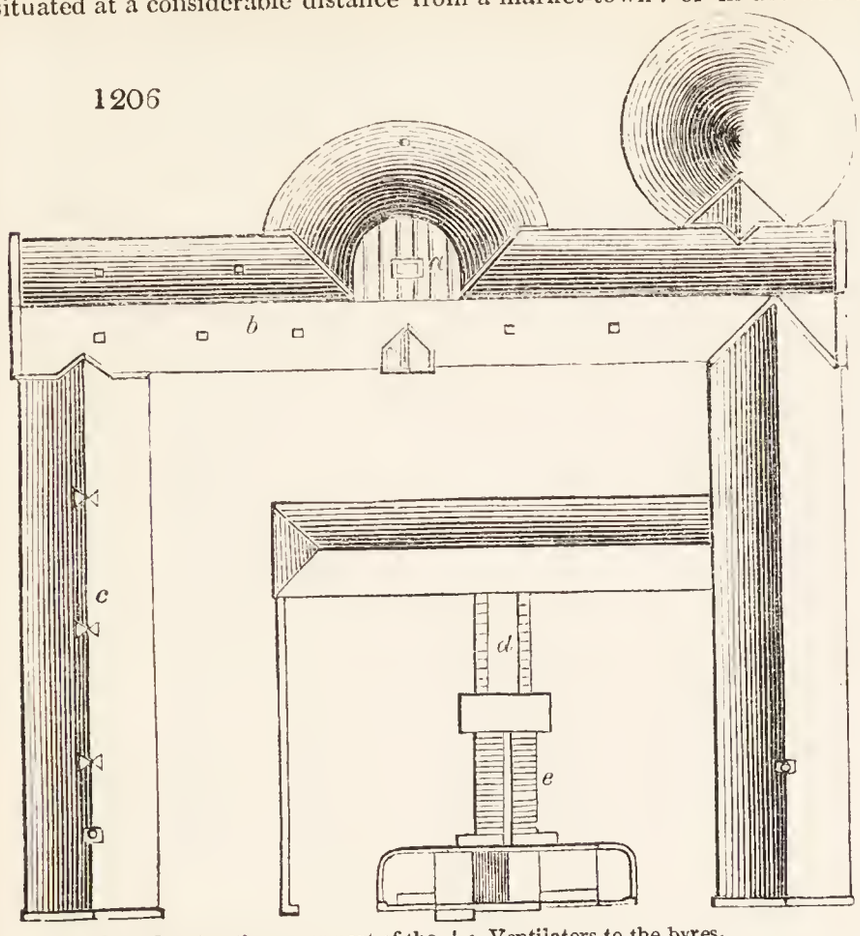
8160. *The threshing machinery* (*l*), being placed in a corner of the square, discharges the threshed corn into the clean corn-room (*m*), in the direction of the granary, which occupies the upper story of that side of the square; and the straw is thrown from it into the straw-house, which is in the direction of the straw-chambers, over the feeding-byre, stables, &c., on the other side of the square. The clean corn-room thus communicates with the granary, which extends from this point over the cart-shed. In this way the clean corn-room and granary occupy a side of the square apart from the offices allotted for the cattle, and the other apartments connected with them; and, as the corn-room can be locked up the moment the operation of threshing is finished, no opportunity is left for the grain being pilfered or injured. The granary in this situation has not only the advantage of the ventilators in the side walls, but it has also the benefit of the free air from the open cart-shed under it, which acts upon the grain through the joints of the floor. The cart-shed

1205



under the granary, besides being beneficial to it for air, is convenient, particularly where a farm is situated at a considerable distance from a market-town: or in the winter season, when the carts require to be loaded on the evening preceding the market-day; as it can be done before yoking (putting the horses in), and without moving the carts from under their cover, by means of the trap-door in the centre passage of the granary: which passage must at all times be kept clear from grain. In the straw-house, a trap-door is placed over the straw-rack; and, when the lower part of the house is packed full, this trap-door can be shut, and the straw carried along the upper floor to the straw-chambers over the stable and feeding-byre. These apartments will contain the straw of two ricks, which will enable the farmer to keep different kinds of straw under cover, and in separate divisions. A door is placed opposite the passage which extends along the centre of the straw-yard for taking out straw for the cattle-sheds, cow-byres, &c., if at any time required; but in general these are supplied from the low straw-house. The threshing-machine is one of six horse-power, and is impelled by horses; but where water can be had, it is a great improvement, as the men may be employed threshing, while the horses are resting: this is advantageous in a still greater degree at certain times, when the field operations exhaust all the horse power.

1206



a, Platform forming the upper part of the roof of the feeding-shed.
b, Ventilators to the stables.
c, Ventilators to the byres.
d, Inclined plane between turnip boxes.
e, Racks for hay or corn.

8161. *The circular byre* (*g*), which will contain ten head of cattle, is by far the most commodious and convenient arrangement; and, for a farm double this extent, the same form may be introduced, with equal advantage, by carrying the stalls wholly round the circle where the sheds are. The figure of the stalls, being broad behind, gives more space for the cattle when lying down; and, as a greater quantity of litter is requisite, more manure, of course, will be made: at the same time it admits from behind a more abundant supply of fresh air, and has also the advantage of one large ventilator in the centre of the circle serving the whole. The ten head of cattle are put up in double stalls in pairs; they are bound up one on each side of the partition, which is made high enough to prevent the horned cattle from touching one another; at the same time keeping the heads of each pair at such a distance apart, as to prevent them from injuring each other, or eating each other's turnips. The bends, or cow-ties, are fixed to upright iron rods about three quarters of an inch in diameter, which are screwed together through the partition. The lower part of the windows in the back wall of the byre are filled with luffer-boarding, which can be opened to any degree for admitting air, or shut altogether at pleasure. The feeding-ports, or openings which surround the feeding-chambers, have small doors hung with pulleys, lines, and weights, similar to those of a common window, which, by moving upwards, do not interfere with, or occupy, any part of the chamber. The wall at the heads of the cattle surrounding the feeding-chamber is built to the full height of the joists; which keeps the turnip barrow out of the view of the cattle, and does not disturb the one division of them, while the man is in the act of feeding the other. This is important, as the quieter cattle are kept the better, quietness being, no doubt, essential to quick fattening.

8162. *A commodious straw-chamber* is obtained over the byre, in a connected range with the straw or hay chamber over the stable: the roof, which is of considerable width, serving the double purpose of covering the feeding-byre, and of containing a very large quantity of straw immediately over it. Racks are placed over the several stalls, which are filled from the straw-chamber above. By this arrangement, the cattle have it in their power to eat straw and turnips alternately, if inclined. The access to the straw-chambers over the byre and stables is by a stair, which is common to both; and upon the plate (first landing-place) of this stair is placed a door, which divides the stable from the feeding-byre; the upper flight of the stair is understood to be a hanging one, having a useful space under it for holding the byre implements. By the whole arrangement much labour in feeding and attending the cattle will be saved.

8163. *The stabling* (*e*, *f*) consists of ten stalls, three of which are separated from the general farm stable, but are so situated as to admit of the racks being supplied from the general straw or hay chamber over the common farm stable. They are understood to have two sets of racks; the upper are for hay or straw, and the under one for grass. Although the under racks appear the most natural for the horses to eat from, it is found that they do not eat the straw or hay so clean out of them, as they do out of the upper racks; but these under racks are the most convenient for the grass, as it should always be put in from the stall below, without passing through the hay-chamber; being, in its damp state, very hurtful to the wood floor above. Part of the three-stall stable is set apart for a mare and foal.

8164. *The turnip-shed* (*i*), adjoining the feeding-byre, is also conveniently situated for supplying the cattle in the straw-yard; and, as it is not required for turnips in summer, it may be used for and serve the double purpose of a turnip-house and a grass-house.

8165. *Ventilators.* The cow-byres have ventilators placed over each line of heads; these cross the ridge, and are formed of lead of a triangular figure; the sill piece being overlapped by the sides far enough to prevent the rain from getting in. (See *c* in *fig.* 1206.)

8166. *The calf-house* and ward, and the cow-byres (*c*, *d*), which fall under the class of offices more immediately connected with the farm-house, have doors facing the kitchen-court, which makes the access to them convenient and clean. The opposite doors are used for driving out the cattle, and for wheeling the manure into the straw-yard. The causewayed court, in front of the byres, besides being convenient for carting in the turnips, affords space for the cows to move about in, or to stand in for a short time; and, as the cattle always dung when they are driven out, by allowing them to remain for a few minutes in this passage or court, the manure, that might otherwise be wasted on the roads, is preserved, and thrown into the straw-yard.

8167. *The several drains* leading from the byres, stables, and straw-yard, have such declivities as are sufficient to discharge the liquid manure into the tank, which is constructed on one side of the straw-yard in a central situation for the byres, stables, &c. It is thirty feet long, three feet broad, and seven feet deep; and, if the nature of the soil be porous, it should be plastered with Roman cement, to prevent the thin liquid manure from escaping. Being of this long and narrow figure, the tank can easily be covered with flagstones, which are much cheaper than arching, and take up less space. The drains should have holes fitted with cast-iron plugs, placed about fifteen feet apart; so that at these openings a jointed rod fifteen feet long could be put into the drain, with a hoe, or a piece of plate iron the shape of the drain, fixed to the one end of it. By these means the drains may be cleaned without breaking up any part of the causeway; but, if the drains are properly constructed, they will not require cleaning for several years. They should have a fall, towards the tank, of at least four inches to the ten feet, and be nine inches wide, six inches deep at the sides, and nine inches in the centre. By having this kind of triangular bottom, the smallest quantity makes a current, and forces everything along with it. The drains through the straw-yard should have openings with grates (*z z*) over them, situated in the lowest part of the straw-yard, to draw off the surplus water after heavy falls of rain or snow. When these drains are not required, the grates may be easily covered over with dung; and if, at any time, the manure is found too dry, movable spouts may be attached to the pump which is placed in the tank, by which means the liquid manure can be regularly spread over the whole straw-yard. A waste drain extends from the tank to an open ditch near the buildings; by which means, the liquid manure in the tank, if neglected, is carried off when it rises to that level, and is thus prevented from injuring the drains.

8168. *The cattle-sheds* (*p*), from their situation, face the south, which is of great advantage to the cattle, though often overlooked in laying out farm buildings, and they are divided in the centre by a passage adjoining the turnip-shed, and opposite the straw-house. This passage rises like an inclined plane four feet from A to B: the sides or parapets may be of wood, two inches thick (which forms a back to the turnip boxes), and be four feet in height, forming a fence to both yards. All the manure from the feeding-byre and stable is wheeled into the straw-yards by this passage: which, from its central situation, admits of the stable dung being equally distributed through both yards, and this by the rising passage can be done without opening a door, which prevents the one class of cattle from intermingling with the other, or getting out. Straw-racks (*h h h h*) are placed in the sheds; but, by also having them in the centre of the yard, and connected with this passage, they can be conveniently filled, and the cattle are induced to divide, which mixes the dung more generally through the yards

8169. *The piggeries* (*v*), from their situation, may be conveniently supplied from the kitchen or boiling-house, and are in both yards. Pigs are very beneficial to the manure, from their turning it over, and mixing it; they also eat up any particles of corn among the horses' dung that may not have been digested. One small enclosure is provided with a trough for feeding young pigs, and they are thus protected from the cattle while eating; but they have no house or sty, that they may be induced to go out among the cattle, and to lie down about the sheds. By this arrangement, they have healthy exercise, and are enabled at the same time to provide a part of their food, and to be beneficial to the manure in both yards. Another sty is provided for putting up a pair to feed.

8170. *The gates to the straw-yard* may either be of the common form, or be hung, like sash windows, with stout ropes, pulleys, and weights. This last is perhaps the best plan, as it secures them from the risk of damage when the dung is being carted out of the yard; and also enables them to be raised as the straw in the yard rises.

8171. *The cistern-house* (*w*) is of such a height that pipes may be taken from it to the dwelling-house, boiling-house, calf-ward, &c. It may be either supplied from a spring, if one is to be found in the neighbourhood; or a well may be dug, and a pump placed within the cistern-house. A water-trough is placed in the division wall between the straw-yards; and a ball-cock is fixed in the centre of the said trough, and shut in by boarding, overlapped by the upper part of the wall, which thus protects it from injury by the cattle. By this self-acting supply, the cattle at all times have the command of water, and none of it is wasted: if supplied from a spring, no attention is necessary, as the supply may be regulated by having a ball-cock in the cistern. Two troughs are placed on the outside, for the horses and the milch cows, and are also supplied with ball-cocks. The roof water, in the inside of the court, is carried round with eave-spouts, and with rainwater pipes at the south extremities, leading it into drains. It is a material object to carry off the roof water, without allowing its admixture with the manure in the courts.

8172. *Estimate.*

	£	s.	d.
Masonwork, excavations, and paving	373	0	0
Carpenter's, glazier's, and smith's work	470	0	0
Slater's and plumber's work	145	0	0
Plaster work	5	0	0
	£ 993	0	0

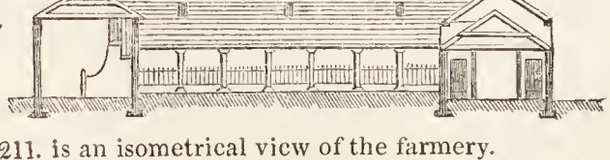
The above estimate is made out upon the supposition that stone may be got for the working, at a distance not exceeding one mile from the building; and that the land carriage of the timber (which is all foreign) and of the lime should not exceed from five to ten miles, and that of the slates from ten to fifteen miles.

8173. *Design for a set of farming offices, and farm-house, for a low-country farm, employing two ploughs, by Mr. Milne of Edinburgh.* In the ground plan of the farm-house (*fig.* 1210.), there are an entrance lobby, *a*; staircase and stairs to attics, *b*; passage, *c*; kitchen, *d*; kitchen and dairy scullery, *e*; family bedroom, *f*; dining-room, *g*; bedroom, *h*; farmer's room, *i*; coal-house, *k*; back entrance, *l*; parlour, *m*; laundry and maid-servant's room, *n*; scalding-room, *o*; dairy or milk-house, *p*; entrance to the dairy, &c., *q*. The ground-plan of the farmery (*fig.* 1209.) consists of the calf-house, *a*; yard for airing cows, *b*; dung pit and liquid manure tank, *c*; seed potato-house with hay-chamber over, *d*; stable for five horses, *e*; tool-house, *f*; cart-shed, *g*; straw-barn, *h*; house for threshing-machine, *i*; feeding-byre for eight fattening cattle, *k*; byre for ten milch cows, *l*; cleaning passages, *m m*; root and potato house, *n*; boiling-house, *o*; feeding-house, *p*; feeding-place for pigs, *q*; pigs' sleeping place, *r*; privy, *s*; pump from the liquid manure tank, in the centre of the dung-yard, *t*. The double dotted lines indicate the various drains leading to the liquid manure tank.

Fig. 1207. represents a section through the farmery offices on the line A B.

Fig. 1208. is a geometrical elevation of the front of the farm-house.

1207

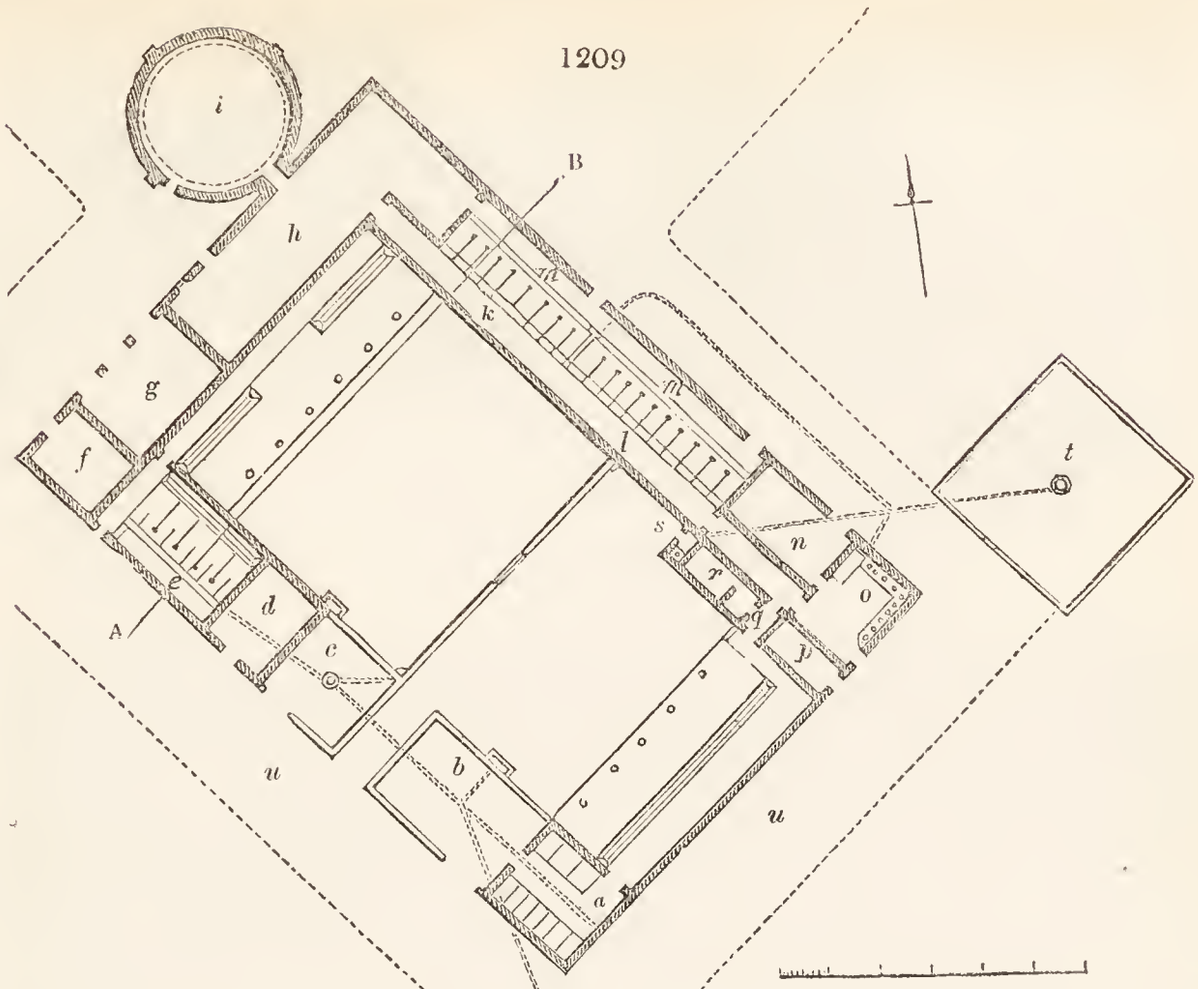


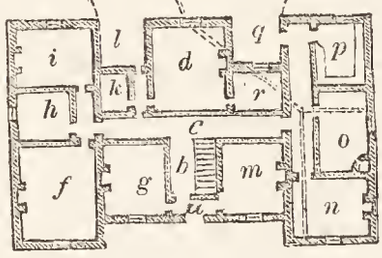
1208

Fig. 1211. is an isometrical view of the farmery.

8174. *Remarks on the arrangement of the farmery.* In designing a farmery, the object in view is to secure that disposition of the buildings which shall be the most convenient, at the least expense; and, in order to attain this object, the arrangement of the various apartments in this plan is very different from that which is usually adopted. Economy in the number or strength of the servants, together with such a plan as shall prevent the provender from being blown about by every gust of wind, and also pre-

1209

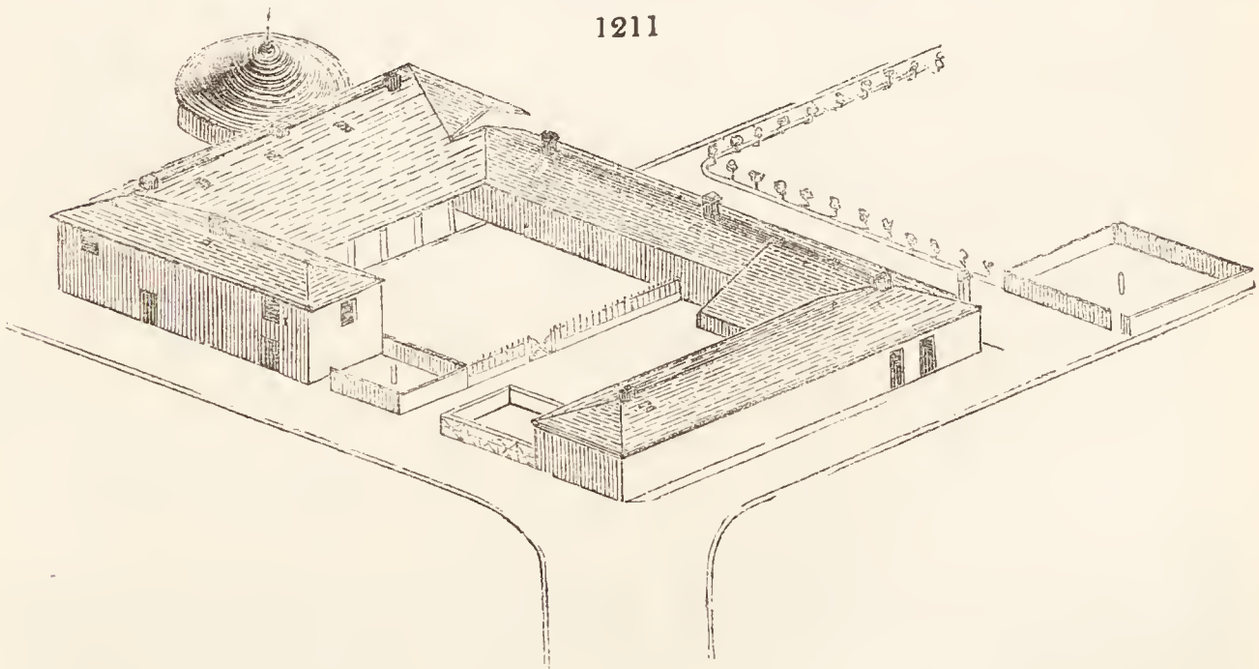




1210

vent the necessity of dragging it over urinous pools of water and wreaths of snow, and which offers a number of courts for wintering cattle of different ages, is alike profitable for the proprietor and farmer. While making a design, however, without reference to any particular farm, a considerable difficulty presents itself. By assuming only that so many ploughs are to be employed, no adequate idea can be formed of the site of the buildings; which, were it known, might lead to a difference of construction. Even a seemingly untoward piece of ground can, in the hands of a skilful architect, be turned to advantage for

1211



this or for any other purpose. The nature of the soil, too, its local situation, and capability for and extent of pasturage, would determine the number of cattle to be housed, &c., none of which data can be given on this occasion. But, assuming that a two-plough farm is capable of raising every year 67 imperial quarters of wheat, and of oats 280, of barley 67, and of peas 24 quarters; and that, collectively, these would yield about 7000 stones (of 16 lbs. each) of straw: then, for making butter and cheese for the market, there could be kept ten milch cows, five one year old cattle, five two years old, and seven three years old,

to be kept through the winter, and fattened for sale in the spring; and accommodation for this number of cattle is provided in the design, *fig.* 1210.

8175. *Estimate for the farmery.* —

	£	s.	d.
Masonry of the offices	172	3	2
Carpentry	93	19	4
Covering the roofs, slating, and furnishing lead	83	4	9
Amount for the offices	£ 349	7	3

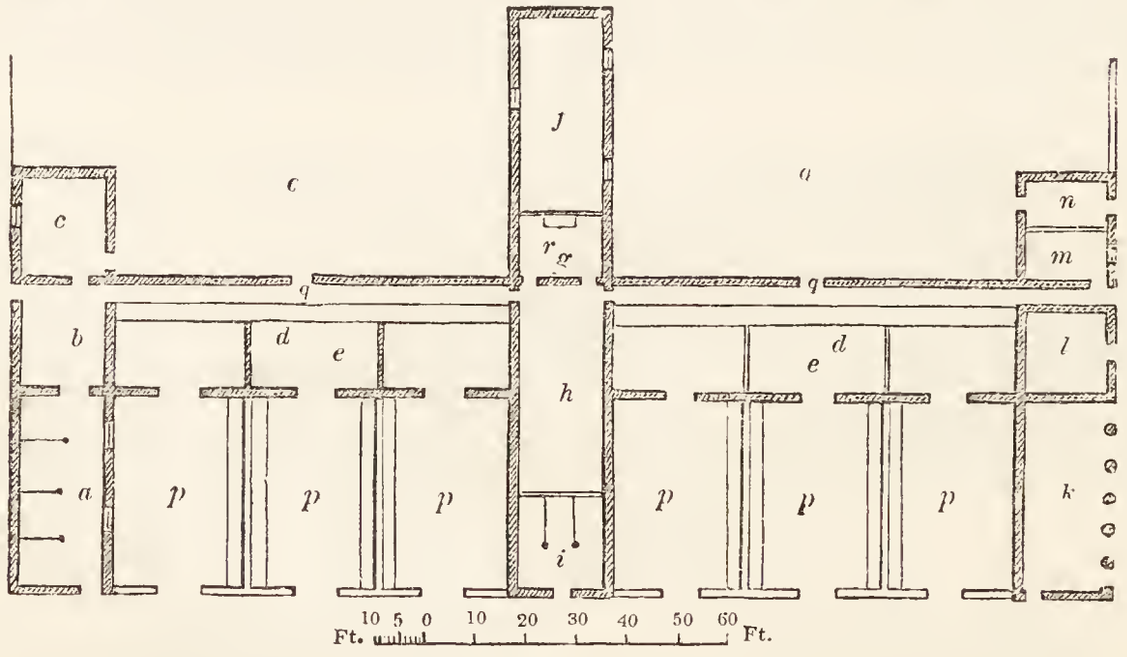
8176. *Farm-house.* The relative situation of the house to the offices claims particular attention. It is here placed, so that the farmer can see two sides of the farm-yard at once, and that at the greatest distance possible, without requiring an extensive paved court between it and the buildings. Where the operations of a dairy are carried on within the house, it is better to make it one story high than two: the heated vapours which ascend from the process of butter and cheese making, combined with the peculiar gases which are evolved from the apartments where such operations are carried on, render an upper story uncomfortable; and this evil is sufficiently great to counterbalance the extra expense of a little more roofing.

8177. *Estimate of farm-house*, &c. —

	£	s.	d.
Masonry	83	12	7½
Carpenters' and joiners' work	87	18	9
Covering of roof	35	15	6
Amount for the house	207	5	10½
Add amount for the offices	349	7	3
The whole amount	£ 556	13	1½

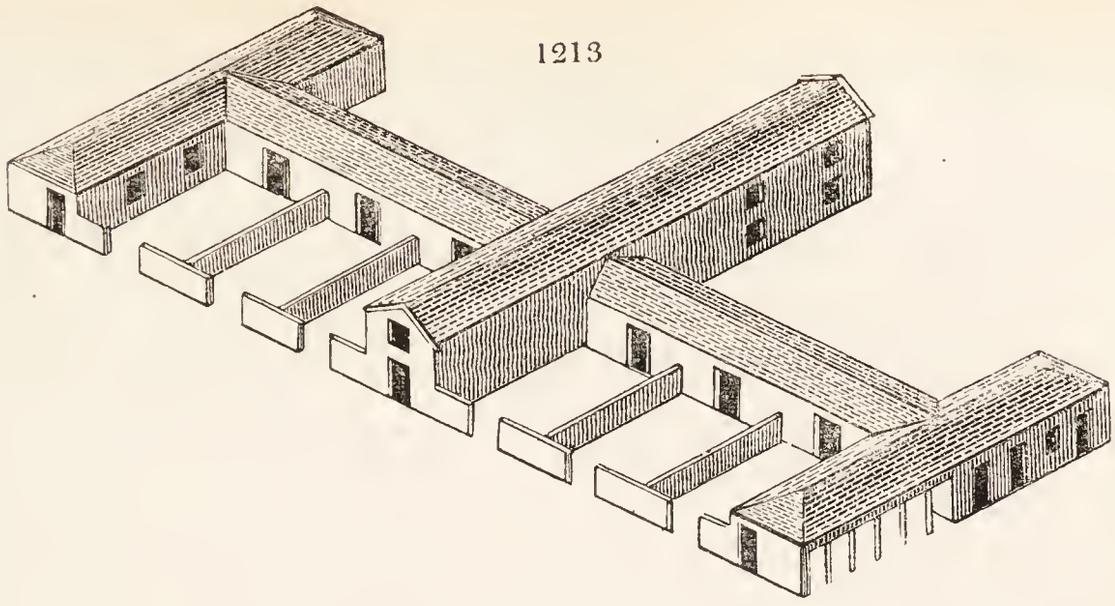
8178. *General remarks.* The practice of tossing the dung out of the byres (cow and cattle houses) through a hole in the wall should be discontinued; as by this practice the house is kept in a most unsightly state, the groop (gutter) and walls are abominably bespattered, and a current of offensive gas is continually evolved from the putrid mass at the door. It is a mistaken notion that cattle will thrive equally well in a tainted atmosphere as in pure air. The best practice is to drag the fulzie (filth) to a urinal pit at some distance, and occasionally to pump the liquid manure upon it. A horse-course is shown for the threshing machine, which almost requires an apology, as steam power is now very generally used; and the farmers in East Lothian are even said to be improving their high-pressure engines, by condensing the steam, and not using an air-pump. A valve is attached to the bottom of the condenser that opens to the outside; the effect of which is, that, when a blast of steam gets into the condenser, it pushes open the valve, thrusting out by it any air and water which had collected in the condenser during the previous stroke of the machine. As soon as the air and water have been pushed out, the jet valve is opened, the steam condensed, and the stroke effected, when the blast of steam again forces the air and water out of the condenser. The valve at the bottom shuts close by the pressure of the atmosphere, as soon as the condensation of the steam within begins to take place. By this cheap contrivance seven pounds per inch of the working piston is said to be gained. Skylights in stables and byres are preferable to windows, which are liable to be broken by the farm servants; in which cases currents of cold air enter, till they are at length closed with an old hat, or some other opaque material, by which the air and light are both shut out at the same time. When the currents of air are not stopped, they bring diseases upon the horse, which are often difficult, if not impossible, to cure; and, by excluding the light, his vision is weakened when he is taken out, and, if he is predisposed to "moon blindness," the disease is called forth. Many are the evils to which the horse is liable by subjecting him to sudden changes of light and temperature; but, by placing the windows of the stable in the roof, and by thoroughly ventilating the whole building, he has some chance of escaping from them. Indeed ventilation is essential, not only for the health of the cattle, but for the preservation of the building; yet, strange it is, that it is seldom if ever attended to. From the humid air in stables and byres, fungi may be frequently seen upon the rafters and other timbers of buildings, which are also often attacked by dry rot.

8179. *Plan, elevation, description, and estimate of a farmery, by Mr. Blackadder of Berwickshire.* In the ground plan (*fig.* 1212.), *a* is the work-horse stable, measuring eighteen feet by forty feet; *b*, stable



incidentals, places for keeping stable utensils; *c*, storehouse for turnips, &c.; *d*, straw-racks; *e*, shelter sheds, with open courts in front; *f*, is the dressing-barn (over which is the threshing machine), measuring eighteen feet by forty feet; *g*, chaff-house; *h*, straw-house, with granary above, eighteen feet by forty feet; *i*, riding-stable, with granary over it; *k*, cart-shed, eighteen feet by forty feet; *l*, wheelwright's shop and storehouse; *m*, piggery; *n*, hen-house; *o*, stack-yards; *p*, six open courts in front of the sheds, each measuring twenty-five feet by forty feet; *q*, passage through which to pass to serve the racks with straw; *r*, situation of the fanners. *Fig.* 1213. is an isometrical view of the farmery.

1213



8180. *Specifications.* The height of the side walls for the barn and straw-house to be fourteen feet, and the side walls of the other buildings to be nine feet. The dressing-barn to have seven feet, and the straw-house and riding-stable ten feet of head room. The shelter sheds to be joisted and covered with loose boards, and used as an additional straw-house. The back of the racks along the open passage to be close boarded up six feet in height, and the front laid with horizontal spars ten inches apart: the bottom of these racks to be laid with cross spars, sloping from the back down to the front, so as to send forward the straw as the rack is cleared out by the cattle; and this bottom to be laid at such a height as will allow the pigs a free range throughout the whole, and also to have liberty to go into each courtain (stall). The water to be had from the mill-head, or from pumps or wells, put down in one or two different places, according to the local situation.

8181. *The site of the farm-house* to be at any convenient distance in front of the farm-stead, allowing at least a complete cart road all round the latter; and the cottages that may be required, to be placed on the right and left side of the road opposite the cart-shed and work-horse stable. Each of these cottages to lodge two families only, and to have a pig-house and garden behind it: this will add much to the comfort of the cottager, and encourage a desire to cleanliness.

8182. *General estimate.* The walls of these buildings are supposed to be erected of stone, and the following are the estimates for Berwickshire: —

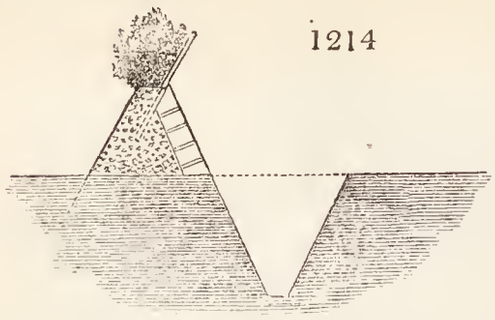
	Yds.	£	s.	d.
8183. *Rubblework.* — Barn and straw-house	537 at 4*s.*	107	8	0
Stable	269 at 4*s.*	53	16	0
Cart-shed	269 at 4*s.*	53	16	0
Shelter-sheds	355 at 4*s.*	71	0	0
Courtain walls	320 at 4*s.*	64	0	0
Total of the rubblework		350	0	0
8184. *Hewer's (stonecutter's) work.* — 540 feet, at 6*d.*		13	0	0
8185. *Roofing.* — Barn and straw-house	440 at 5*s.*	110	0	0
Stable	291 at 5*s.*	72	15	0
Cart-shed	291 at 5*s.*	72	15	0
Shelter-sheds	582 at 5*s.*	145	10	0
Racks and feeding-troughs in the shelter-sheds		40	0	0
Barn floors	188 at 5*s.*	45	0	0
Granary floor	109 at 5*s.*	27	5	0
Stalls in the stables	42 at 3*s.* 6*d.*	7	7	0
Racks and mangers	30 at 3*s.* 6*d.*	5	5	0
		525	17	0
8186. *Slater's work. Pantiles.* — Stable	284 at 2*s.*	28	8	0
Cart-shed	284 at 2*s.*	28	8	0
Shelter-shed	570 at 2*s.*	57	0	0
Barn	426 at 2*s.*	42	12	0
		156	8	0
8187. *Estimate of the amount of the whole.* — Rubblework		350	0	0
Hewer's work		13	0	0
Roofing		525	17	0
Slater's work		156	8	0
Total.		1045	5	0

East Blanerne, Jan. 1833.

8188. — 2968. *Ditches and drains.* "The bank of earth with upright facing of turfs, with a bank behind." This sort of ditch or fence, Mr. Gorrie observes, is only effective where the ditch lies between the bestial (cattle), and the faced dike (wall faced with stones), surrounding strips of plantations, orchards, or such enclosures as are not subjected to pasture. In such a case, this ditch, in waste lands, where the turf is well matted with the roots of grasses, and where the breadth occupied is not a considerable object, can be rendered a more effective fence than any other at so cheap a rate. Suppose the ditch to act in the capacity of an epen drain, as well as a fence for sheep and cattle, it should be five feet wide at top, nine inches wide at bottom, and three feet deep. The turf should be cut in small squares of about nine inches, and about four inches thick, laid with the earth side uppermost, breaking joint every layer, and continued to the height of two feet nine inches, including the coping, with the

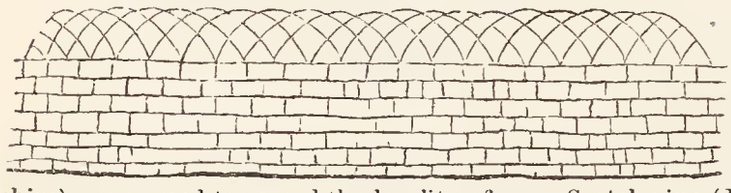
green side uppermost. The faced dike (*fig.* 1214.) will require to have nearly, but not altogether, the same inclination as the sides of the ditch, and the earth taken out of the bottom must be rammed in firmly at the back of the turf in course of the work: this form of fence prevents rubbing by cattle either with their sides or horns, a practice of which they are mischievously fond, when they can reach mud fences. If sheep are to be warded off, little or no scarsement (set back) should be made, as they would get up and walk the set back, though it might be only five or six inches in breadth, and from thence they would easily effect a passage over the faced dike: in this case, a single paling rail, about nine inches above the coping, will be necessary, to serve till a hedge of plants, suited to the soil and climate, has reached the height of two or three feet above the coping and become permanently effective. A

1214



good and neat, as well as cheap, substitute for a rail, which requires sawing, posts, and nails, will be found where old larch plantations abound, and where branches about one inch and a quarter in diameter at the thick end, and six inches in length, can be got in sufficient quantities. These, having both ends sharpened, and stuck into the ground in the form of basketwork (*fig.* 1215.), will make a neat and effective fence. The larch branches so bent will last ten years, and will form an open wickerwork-like structure, which will serve as an efficient fence, impervious even to the attacks of black-faced sheep, the most troublesome dike-leapers of the breed. A fence of this nature surrounds a part of a small plantation at the west end of "Loudon's Howe" (in the parish of Kilspindie, Perthshire); so named to record the locality of some Scotch pine (*Pinus sylvestris*), seeds of which, furnished by Mr. Loudon from the forest of Hagenau, were sown in the spring of 1829, and, having been thinned out, are now in a prosperous state.

1215

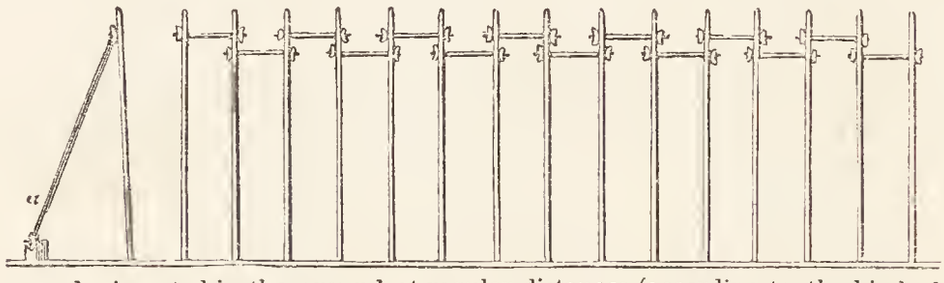


8189.—2991. *Cutting down old hedges.* In wastes, where ground is not of much value, and where it is not necessary to keep the ditch clean, a substantial hedge or live fence may be easily formed by cutting the plant halfway through, or rather more, near the root, and laying the shoots horizontally outward, at right angles with the line of fence. The side branches grow upward; and vigorous shoots spring from below the cut, forming in a short time a broad, dense, and impenetrable thicket. This practice is of advantage when hedges around plantations are necessary; and where, in the ordinary practice, they are liable to be overtopped, drawn up weak, and rendered inefficient. Some hedges have been treated in this manner by Mr. Beattie, an eminent horticulturist and forester, of extensive and successful practice, at Scone Palace, Perthshire.

8190.—3047. *Hurdle-making.* A detailed account of this operation, including descriptions of all the requisite tools, is given by Mr. Main in the *Quart. Jour. Agr.*, vol. iii. p. 647. to p. 653.

8191.—3039. *Fences composed of palings.* In the *Architectural Magazine* (vol. i. p. 79. and p. 235.) will be found two descriptions of wooden fences, which may be constructed without the use of nails, bolts, or iron, in any form. The details would occupy too much space to be introduced here; but the execution is simple enough; and the fences are suitable for countries where timber is more abundant than manufactured iron. *Fig.* 1216. is a description of fence recommended by Menteath. It consists of young

1216

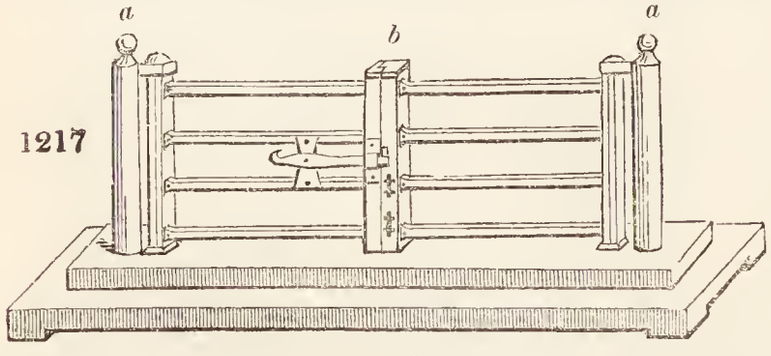


larch poles, or rods, inserted in the ground at regular distances (according to the kind of animals to be excluded or separated), and joined together at top either by wires, short iron rods, or short slips of wood. At every twelve or fifteen feet, there may be a brace on one or both sides, or alternately, as shown at *a*.

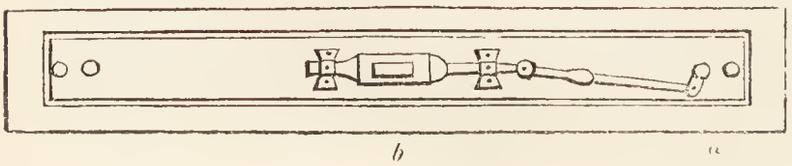
8192.—3075. *Gates.* In the *Encyclopædia of Cottage, Farm, and Villa Architecture* will be found figured and described at length, some gates of a very superior description. That called Buchanan's Gate, which is formed entirely of iron, is remarkably strong and cheap; and Cottam's Gate is equally cheap, and nearly as strong. There are several gates for park entrances, with machinery attached for the gate-keeper to open them in the night-time without getting out of bed.

8193.—3088, *b* (3088, *a*, is a gate-stopper given in the first Supplement). *Russell's gate-stopper* is thus described in the *Highland Society's Transactions*, vol. xi. p. 236. *Fig.* 1217. is a view of two leaves of a gate fixed in the pivots *a a*. The centre, *b*, is formed of two uprights, checked into each other, and fixed together by a latch, and perpendicular bolt, which is drawn up by the hand. On the gate being opened, one of the uprights, *a*, having communication with a cast-iron box (*fig.* 1218.), gives motion to the connecting rod between *a* and *b*. When the leaves of the gate are opened, the connecting rod is shortened by means of the crank at *a*; and, when shutting, it is lengthened by pushing an inclined plane, or wedge, under the stopper, which is thus raised above the surface when the leaves are closed, and depressed when the leaves are opened. The iron box is intended to be sunk a few inches under ground, and covered with gravel. The posts and gate may be wholly of iron, or

1217



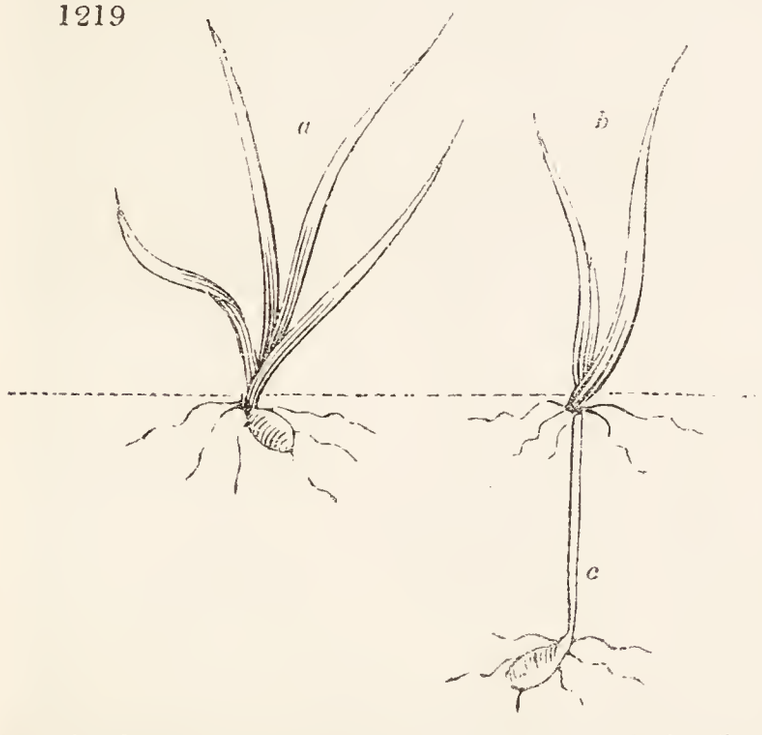
1218



of stone and wood. The advantage of this construction is, that the danger and annoyance resulting from a raised stopper in the middle of a pathway are obviated; for the moment the leaf of the gate is opened, the stopper begins to be lowered, and when the gate is wholly opened, it is level with the ground. (*Highland Soc. Trans.*, vol. xi. p. 236.)

8194. — 3148. *The due depth at which seeds should be deposited in the soil* is a very important subject, which has been discussed by Baron Voght, of Flotbeck, near Hamburgh, in the *British Farmer's Magazine*, vol. iv.; and the following comment has been made on his paper by Mr. Main:—"If seeds be placed by accident or design at such a depth in the earth as to be out of the influence of the air, and though they may be surrounded by the requisite degrees of heat and moisture, they will nevertheless remain dormant. We have many instances of the truth of this in every-day practice, and of the imperishable properties of some kinds of seed when excluded from the influence of the air. If seeds are dropped on the bare surface of the ground, they will remain uninjured and unaltered so long as the air is perfectly dry; but in moist air germination commences, and the point of the root will quickly be protruded and find its way into the soil. This is the ordinary process of nature; but experience has taught us, that though nature distributes grain and other seeds generally on the surface of the spot where produced, yet there is a proper depth at which all seeds should be deposited, and which is specially suitable. This depth is obviously that which, while it yields the necessary degrees of heat, moisture, and darkness, is yet within the requisite influence of air. In the ordinary proceedings of farmers in the business of sowing, our implements, more than any thing else, regulate the depth at which we lay in the seed. The drilling system is approved, not only from its equal distribution of the seed, but because by it seeds are also laid in at an equal depth; this last circumstance being regarded as one of the principal advantages of the machine. Now our author has endeavoured to show that seeds may be deposited too deep even by the drill; and in all cases when seed is sown before harrowing, much of it will be laid deeper than it should be. Of this there can be no doubt. Every one acquainted with sowing must allow that seed may be buried; and every body acquainted with the structure of culmiferous plants, and their manner of growth, must be convinced, by what the Baron has shown, that, if seeds are but just covered, so as to be sufficiently shaded from the sun's rays, it is enough. As proof of this, our author quotes several eminent authorities, who argue from the physical structure of the plants, as well as from the qualities contained in the seed, and which submit to the chemical action of the elements in the act of germination, that deep sowing is highly detrimental, and opposed to the provisions of nature. Explanatory of these assertions, the Baron has appended to his paper figures of five different kinds of corn in five different states of growth, caused by the different depths at which they had been deposited in the earth. Two of these are given in the annexed cut. (*fig.* 1219.)

1219



The dotted line is the surface of the ground: *a* represents a healthy plant of wheat from a seed laid in at the proper depth, viz. one inch beneath the surface; *b* shows the growth of a plant from a seed which has been laid in too deep. This last, it will be observed, vegetated, although two or three inches under the surface; threw out its seminal or first roots, and sent up its first shoot, bearing two leaves, into the air; but, as the first joint of the culm rises therewith, and remains near the surface, it also throws out roots, and entirely supersedes those that were first produced from the grain. Now, as this is only a provision of nature to accommodate herself to circumstances of accidental position, many cultivators have been of opinion that the placing of the seed at irregular depths makes but little or no difference to the ultimate strength of the plant, or to the crop. To this the Baron is decidedly averse, affirming that this unnecessary waste of vegetable power is both hurtful and unnatural. We think, and indeed we may venture to say we know, that he is right: for, without mentioning the needless waste of vigour, the young plant must be more liable to accidents from the changes of the weather, slugs and insects, during the ascent of the first shoot, and before the principal roots are formed, than if it started from its natural position at once. To guard against over deep sowing, therefore, the Baron advises to sow nothing before harrowing; and, moreover, that great pains should be taken to pulverise the surface with fine harrows before the seed is sown, lest the corn should rise in rows, which, in broadcast husbandry, he condemns. Very different this from the custom of sowing wheat in this country, where the dexterity of the ploughman is often judged of by the regular exactness in which the ranks of corn appear on first coming up. This idea of the Baron's, though it be condemnatory of the drilling system (unless the machine be made to deliver very thinly), is, notwithstanding, very reasonable. The numbers of inferior ears, and the inequality of our samples of wheat, is mainly owing to the plants being too much crowded together in the dips between the furrows. Admitting that the principle of shallow sowing and equal distribution on a well-harrowed surface is in general right, still, as we have in this country very often a showery seedtime, it would be running a great risk on a clayey soil to harrow it down so finely as Baron Voght advises; and if a naturally loose and dry one, such an operation would probably bring up such a crop of weeds as would greatly injure, if not destroy, the crop. But on early-sowed fallows, all kinds of lent corns and small seeds, we think, from what we know of the nature of seeds generally, as well as from this writer's opinions, that the farmer cannot do wrong in following the Flotbeck manner of sowing broadcast." (*Brit. Farm. Mag.*, vol. iv. p. 290.) On the subject of this paragraph, and generally on all that respects the operations of agriculture considered scientifically, we would recommend to our young readers the careful study of the following cheap works: viz., *Mrs. Marcet's Conversations on Vegetable Physiology; Main's Illustrations of Vegetable Physiology; Lindley's Outlines of Horticulture;* and *Hayward's Inquiry into the Causes of the Fruitfulness and Barrenness of Plants and Trees.* The advantage which we propose to be attained by the study of such works, is the power of independent thinking, and of proceeding farther in scientific knowlege by observation and reflection. Many excellent practical agricultural works have a tendency altogether to preclude reflection, by describing and recommending only one practice, which has been found successful, without assigning any reasons why it has been so: instead of either assigning the reasons as the foundation for the practice; or giving different practices, and leaving the reasons to be discovered by the reader.

PART III.

AGRICULTURE AS PRACTISED IN BRITAIN.

8195. — 3385. The principal addition which we have made to this part of the work, is an abridgment of Sir Henry Parnell's *Treatise on Road-making;* which it was the more necessary to give, since, in the body of the work, the system of M'Adam may be considered as placed in a more prominent point of view than is warranted by its merits. There is also a valuable article on the frequent-drain system, and the plan and description of a machine for draining fen and other low lands by steam by Mr. Capper, Engineer, of Birmingham; and the engravings and description of a very complete apparatus for steaming food for cattle, by Mr. Mallet, of Dublin.

8196. — 3523. *Formation and management of roads.* The whole subject of road-making, road management, and road repairs, has lately been discussed by Sir Henry Parnell, in a *Treatise on Roads, wherein the Principles on which Roads should be made are explained and illustrated, &c*, as practised by that distinguished engineer, the late Mr. Telford. In this *Treatise*, a number of received opinions which we had adopted are controverted, and we have therefore thought it advisable to give the essence of the work in a continued series of paragraphs.

8197. *In the introduction*, the author, after setting forth the advantages of good roads, describing the roads of the Romans, and noticing the present state of roads in the principal countries of Europe, speaks of those of England. Little attention was paid to English roads previously to 1629, when a proclamation was issued for preserving roads by limiting the weights to be drawn over them. The first turnpike road was established by law in 1653, through Hertfordshire, Cambridgeshire, and Huntingdonshire. Nothing, however, of importance was done to raise the character of English highways, till after the peace of 1748. In Arthur Young's *Six Months' Tour*, published in 1770, a frightful picture is given of the roads in Lancashire and Cheshire, and travellers are cautioned to avoid them "as they would the devil, for a thousand to one they break their necks or their limbs, by overthrows or breakings down." The ruts on these roads are described as in some places four feet deep, filled with floating mud, with here and there a loose stone, which serves no other purpose than that of jolting a carriage in a most intolerable manner. Between 1760 and 1764, 452 turnpike acts were passed; and in twenty-four years, from 1785 to 1809, upwards of 1000 have been passed, and nearly 20,000 miles of road formed, or improved. But, notwithstanding this progress, the operations have been directed with such negligence or ignorance, "that at this moment there is not a road in England, except those recently made by some eminent civil engineers, which is not extremely defective in the most essential qualities of a perfect road." (p. 26.) The crookedness and steepness of almost every great road, is owing to its being made on the lines of the footpaths of the aboriginal inhabitants, which afterwards became the horse tracks; and, finally, as society advanced, the only legal line left for carriages. This state of things is not only dangerous, but "disgraceful to the national character." (p. 26.)

8198. *The true principles of road-making* have not yet been followed in this country. "The breadth of a road is seldom defined to a regular number of feet by straight and regular boundaries, such as fences, footpaths, mounds of earth, or side channels. The transverse section of the surface, when measured, is rarely to be found of a regular convexity. The surface of all the roads, until within a few years, was everywhere cut into deep ruts, and even now, since more attention has been paid to road works, though the surface is smoother, the bed of materials which forms it is universally so thin, that it is weak, and consequently exceedingly imperfect. Drainage is neglected; high hedges and trees are allowed to intercept the action of the sun and wind in drying the roads; and many roads, by constantly carrying off the mud from them for a number of years, have been sunk below the level of the adjoining fields, so that they are always wet and damp, and extremely expensive to keep in order, owing to the rapid decay of the materials which are laid upon them." (p. 27.)

8199. *Road-makers in England* have hitherto been wholly ignorant of the scientific principles on which the making of good roads depends. Even government is ignorant on the subject, as appears evident from recommending the M'Adam system as the perfection of road-making. Notwithstanding the extent to which science is displayed in our canals, docks, bridges, and other public works, it was not till 1830 that land proprietors began to understand the value of good roads, and to be aware, that large funds, considerable science, and constant attention, are necessary to bring them into, and keep them in, a perfect state. (p. 29.)

8200. *In Scotland and Ireland*, however, a better system has been followed for some time. In 1790, Lord Daer introduced the practice of laying out roads with a spirit level, and having no greater inclination than one in forty, even in the most hilly country; and this practice has been generally followed. In Ireland, the system of statute labour was abolished in 1763, and, the business of making roads being committed to the grand juries, improvements soon became so general, that Arthur Young, about 1777, found everywhere better roads than in England. The British legislature made a great effort for improving the roads of the Highlands of Scotland in 1803; and 875 miles and 1117 bridges, were constructed under the direction of Mr. Telford.

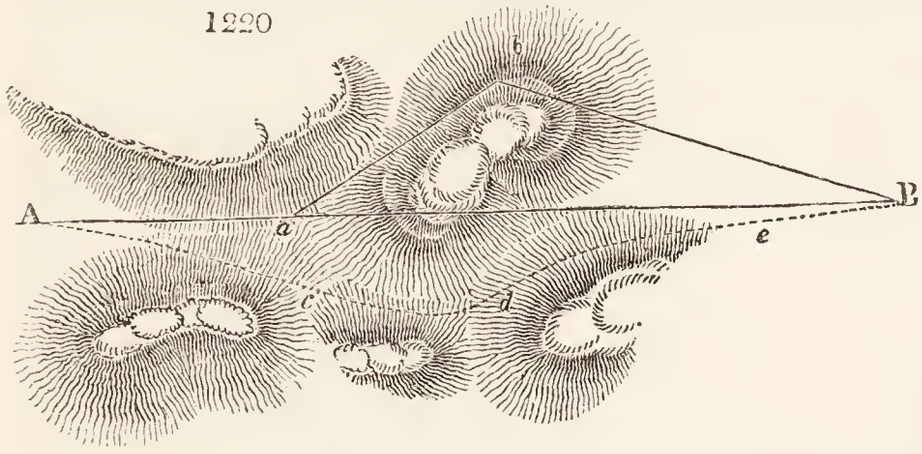
8201. *In England, a great advance in road-making was made, in* 1815, by the employment of Mr. Telford, by parliament, to improve the Holyhead road, which is now "acknowledged, by all persons competent to form a correct judgment on works of this kind, to be a model of the most perfect road-making that has ever been attempted in any country." (p. 35.) The following passage at once points out the use of the treatise, and the grounds on which the practice recommended are founded.

8202. *The obvious utility of a work on road-making*, "explaining the principles on which this business should be carried on, and containing an illustration of those principles by a reference to the plans, specifications, and contracts which have been made use of in constructing this extent of new road, through a country presenting every kind of difficulty, has suggested the present publication. The object of it is to point out, in a clear and concise manner, the best method of tracing out and constructing roads, under every variety of circumstances; and it is confidently expected, that the course which has been pursued of proceeding on experience by referring to the identical plans, specifications, and contracts by which so great an extent of perfect road has been successfully made, will be found to have attained this object."

8203. *Rules for tracing the line of a new road.* Surveys and levels should previously be made, and plans, and vertical sections, transverse and longitudinal, should be laid down on paper. The scale for the plan should be sixty-six yards to an inch, and for the sections, thirty feet to an inch. The depth of rivers to be passed, and the height of their highest floods; the depth of bogs or morasses; the natural drainage;

situation of gravel-pits or quarries, should all be marked on the plan. As a general rule, a straight, level, and cheaply executed line is the best; subject, however, to modifications arising from the comparative cost of annual repairs, and present and future traffic, &c. When a deviation is made from a straight line, proceed in a direct line from a new point, and if another interruption occurs, again change the direction, always keeping in view the imaginary straight line between the extreme points of the road, so as to deviate from it no more than is absolutely necessary. "Thus, for instance, if it be decided to have no greater rate of inclination than one in thirty-five, on a new line of road, from A to B in *fig.* 1220., and the surveyor, when he arrives at the point *a*, finds a greater inclination than this, he must incline from the direct line to *b*. Having then gained the summit of the hill, he does not endeavour to get back into the original straight line A B, but pursues the direct line *b* B, unless he is again obliged, from a similar cause, to deviate from it. This part of the survey being accomplished, it will then become necessary to examine the practicability of making a direct line of road, between A and *b*, instead of going to the point *a*. When hills are high and numerous, it sometimes appears, from a perambulation and inspection of the country, to be advisable to leave the straight line altogether from the beginning, in order to cross the ridges, at lower levels, by a circuitous course, in the way represented by the dotted lines A *c d e* B, in the above figure."

1220



8204. *The saving of perpendicular height to be passed over by a road* has not received that attention from engineers which it deserves. When the inclination of a hill is not greater than one in thirty-five, it may be driven down with perfect safety at the rate of twelve miles an hour; but if the road is so steep as not to admit of going faster than six miles an hour, there is a loss of half a mile in distance for every half mile down the hill; besides rendering necessary the use of the drag, which is at all times more or less dangerous. "An inclination of one in thirty-five is found by experience to be just such an inclination as admits of horses being driven in a stage coach with perfect safety, when descending in as fast a trot as they can go." (p. 45) "A perfectly flat road is to be avoided, if it is not to be raised by embanking, at least three or four feet above the general level of the land on each side of it, so as to expose the surface of it fully to the sun and wind; for if there is not a longitudinal inclination of at least 1 in 100 on a road, water will not run off." (p. 47.) The great fault of all roads in hilly countries is their constant ascent and descent before they gain the highest point of the country they have to traverse; by which the number of feet ascended is increased to an extent far greater than would have been the case, if each height when once gained were not lost again by the succeeding descent. Thus a horse must ascend upwards of 1300 feet between London and Barnet, though the latter is only 500 feet higher than the former, while a horse going from Barnet to London must ascend nearly 800 feet, instead of descending 500 feet. (p. 48.) In carrying a road across a deep valley, the descent and ascent, and the quantity of material wanted, will be diminished by inclining the line upwards, where the bottom of the valley rises, rather than downwards where it falls. Where valleys are narrow and steep, the road may be more economically carried across on viaducts; some of the finest of which in Britain have been erected by Mr. Telford, at Mousewater, Birkwood Burn, the Menai Straits, &c. Hills may sometimes be passed through by means of a tunnel instead of deep cutting.

8205. *Rivers have been allowed to direct the line of a road too readily*, from timidity about incurring the expense of bridges, &c.; but if even a quarter of a mile of road be saved, by expending several thousand pounds on a bridge and its embankments, the saving to the country in annual repairs and horse labour will soon pay off the original cost.

8206. *Bogs and marshes* being elastic, the foundation of an intended road over them requires to be drained and loaded with earth to destroy the elasticity of the subsoil; which, by destroying the momentum of a carriage passing over it, greatly increases its draught.

8207. *A proper exposure to the sun and winds* is of great importance to a road. The north side of a valley running east and west, ought always, if possible, to be preferred, and trees, high walls, and every thing on the south margin of a road, which obstructs the united action of the sun and wind, removed. Damp roads, of whatever material they may be composed, wear away rapidly under the weight and pressure of heavy carriages. Open roads afford free respiration to horses, in consequence of which they can perform much more work; a fact which those farmers are well aware of, that have confined horse-tracks for their threshing mills. The expediency of causing a road to deviate from its straightest direction, in order to pass through a town, must depend on the principal object of the road. In general, little attention should be paid to the opposition of inhabitants of towns to new roads, and still less to the proprietors of parks and gardens.

8208. *Principles of road-making.* A beaten track of knowledge is but a bad guide, when, amongst several ways, the best is to be preferred. The most important, and the most obviously correct principle of road-making is, that it should be of such a degree of substance as to bear the weight and number of the carriages that are to pass over it. This principle is almost universally violated, and the crust of roads will be found generally not to exceed more than three or four inches, instead of a coating of six inches, of the hardest kind of stone, broken into small pieces, and laid on a regular foundation of rough pavement. The external forces which counteract the momentum of carriages passing over roads are collision, friction, gravity, and air.

8209. *Collision* is produced by protuberances, and friction by a soft or elastic surface. Smoothness and hardness, therefore, are the chief qualities of a perfect road. That a road may be hard, it is not sufficient to lay upon a prepared bed of earth merely a coating of broken stones, for the carriages passing over them will force those next the earth into it; even if a coating of from sixteen to twenty inches were laid on. Mr. Telford's plan, of making a regular bottoming of rough, close-set pavement, and covering it with six inches of broken stones, secures the greatest degree of hardness that can be given to a road. "By laying the stones in making the bottoming with their broadest face downwards, and filling up the interstices closely with stone chips well driven in, the earthy bed of the road cannot be pressed up so as to be mixed with the coating of broken stones. This coating, therefore, when consolidated, will form a solid uniform mass of stone, and be infinitely harder than one of broken stones when mixed with the earth of the substratum of the road. It is by proceeding in the way here recommended that the friction of wheels on a road will be reduced as much as possible."

8210. *Friction.* "Experiments have proved that, on a well-made pavement, the power required to draw a waggon is 33 pounds; on a road made with six inches of broken stone of great hardness, laid on a foundation of large stones, set in the form of a pavement, the power required is 46 pounds;

on a road made with a thick coating of broken stone, laid on earth, the power required is 65 pounds; and on a road made with a thick coating of gravel, laid on earth, the power required is 147 pounds." These experiments, it is shown, correspond with results deduced from the laws of science, and are in direct opposition to the doctrines laid down by Mr. M'Adam, viz.: "That a foundation or bottoming of large stones is unnecessary and injurious on any kind of subsoil. That the maximum strength or depth of metal requisite for any road, is only ten inches. That the duration only, and not the condition of a road, depends upon the quality and nature of the material used. That freestone will make as good a road as any other kind of stone. That it is no matter whether the substratum be soft or hard."

8211. *As gravity* acts in a direction perpendicular to the plane of the horizon, it neither accelerates nor retards the motion of a body moving on a road which is perfectly horizontal. When, however, a road is not horizontal, the action of gravity becomes a positive impediment.

8212. *The resistance of air* to a body moving along a road is variable, and has no relation to the state of the road. Wind travelling at the rate of fifteen miles an hour has a force of one pound per square foot; at twenty-five miles an hour, or a very brisk gale, three pounds; at thirty-five miles per hour, or a high wind six pounds; at fifty miles an hour, or a storm, twelve pounds. A very little reflection will show, that the resistance offered by wind to any body moving against it will be as the motion of that body, and that driving stage-coaches at a rapid rate against high winds is attended with a ruinous waste of horse labour.

8213. *Forming a road.* The great art, in carrying a road over a high elevation, is to lay it out so as to prevent it having any fall from the point of departure to the highest point. This can only be done by lowering heights and raising hollows, and the engineer will show his skill in effecting this by the least quantity of cutting and embanking. In cutting through hills, the slopes of the banks should in general not be less than two feet horizontal to one foot perpendicular; but on the south side of a road which runs east and west, the inclination may be three to one, in order to secure the action of the sun and wind from the road. No person should be intrusted to form high embankments who has not had considerable experience as a canal or road maker; "for, if the base of an embankment be not formed at first to its full breadth, and if the earth be not laid on in regular layers or courses of not exceeding four feet in thickness, it is almost certain to slip. In forming high embankments, the earth should be laid on in concave courses; for, when laid on convexly, the courses are for ever slipping." (p. 83.) "In forming embankments along the sides of hills, or what is called side forming, the rule that should be followed is that the slope to be covered should be cut into level slips to receive the earth, otherwise it will be very liable to slip down the hill: in such cases, the earth should be well compressed, and great care should be taken to interrupt all the land springs about it by proper drainage. For this purpose, a drain should be cut on the upper side of the road, and open drains should be made on the side of the hill above the road, to catch the surface water of the hill." Rocks of different kinds, and chalk, will stand at a steeper slope than common soils; chalk or chalk marl will stand at one to one; hard sandstone at a quarter to one, or nearly perpendicular; while plastic clay requires a slope of three to one.

8214. *Drainage.* On flat and wet surfaces, there should be a drain at each side of the road, at least three feet deep below the substratum of the latter. Where main drains cannot be formed, as on the side of a hill, near houses, &c., then covered drains, substantially built of stone or brick, must be resorted to. If springs rise in the centre of the road, drains must be made to them so as completely to dry the bed of the road. In cuttings, that is, where a road is cut through or along the side of a hill, it becomes necessary, in almost every case, except that of solid rock or gravel, "to make drains of small dimensions from the centre of the road to the side drains. These drains should form an angle in the centre of the road, in the shape of a V, technically called mitre drains: the angle or splay of these drains should depend upon the inclination of the road; it should not make the inclination of the drains exceed an inch in 100; for if it be greater, the run of the water will undermine the sides, and injure them. These mitre drains should be 9 in. wide at bottom, 12 in. wide at top, and 10 in. deep. These drains should be placed at about sixty yards from each other, or about thirty in the mile; but if the soil be wet, this number should be considerably increased. They are to be filled with rubblestone, or cleansed gravel. If gravel is used, a draining tile should be laid along the bottom before the gravel is put in. The upper part of these mitre drains should communicate with the road materials, so as to draw the water from them. According to the inclination of a road, and the form and wetness of the country through which it passes, cross drains of good masonry should be built under the road, having their extremities carried under the road fences. One of these drains should be made wherever the water would lie on one side of the road, and can only be got rid of by carrying it to the other side. When the road passes along the slope of a hill or mountain, a great number of these drains are necessary to carry off the water that collects in the channel of the road on the side next the high ground. They should be placed at from 50 to 100 yards' distance from each other, according to the declivity of the hill; so that the side channels may not be cut by carrying water too far. In these situations inlets should be built of masonry, to carry the water from the side channel of the road into the cross drains." After every precaution in respect to draining has been taken, injury from water should be farther secured by convexity of surface, and by side channels. "These side channels will be formed by the angle where the slope of the side parts of the surface of the road abuts against the edge of the footpath, or other defining bounds of the roadway. They will be capable of carrying off a great quantity of water, without being made into the form of a square-sided drain." The reduced particles of the materials of a road, when wet, assist the wheels in rapidly grinding down the surface, in the same manner as a lapidary cuts his jewels with the powder of the same kind of stone mixed with water.

8215. *Different kinds of roads, and modes of constructing them.* — *Railways* of wood were first introduced about 1602, and cast iron seems to have been first employed in them in 1667. A railway with a declivity of 1 in 96, or 55 feet in a mile, will admit of one horse drawing from 12 to 15 tons down the declivity, and 4 tons up it. On a level railway, a horse can draw 12 tons. In some situations, where all the traffic is one way, the loaded carriages descend by their own gravity, and pull up the empty ones. In others, the loaded waggons drag with them another waggon or truck, containing the horses which are to pull up the empty waggons. This is the case on the Darlington railway, where the rest which the horses receive while riding from one point to another, is found to renew their vigour. (p. 105.) "The expense of constructing railways depends upon the nature of the ground they are made over, and the purpose for which they are intended. In many situations, where the trade is altogether a descending one, and water scarce, they are preferable to canals, and may be constructed cheaper; but for general traffic, over a wide extent of country, they do not afford as cheap a means of conveyance as canals. The expense of carrying goods by locomotive engines on railways much exceeds that on canals, or on railways with horses."

8216. *The plan of constructing a railway* "should be arranged so as to be adapted to the purposes for which it is intended. If for local or private purposes, the same expense is not necessary as when the railway is for general and public traffic. In the former case, the rails should not be so heavy, so strong, or so expensive, as when employed for the latter, and the blocks may be of much less weight, and the fastenings less perfect. To form a perfect railway for general traffic, on which locomotive engines are to be employed, the surface of the ground over which it is to be made should be reduced, by cutting, filling, or tunnelling, to rates of inclination not exceeding 1 in 300. The rails should be of wrought iron, of not less than fifty pounds to the yard and they should be laid on blocks of hard solid stone, each of not less than five cubic feet. These blocks should be set on a firm, solid foundation of hard broken stones, at least two feet thick, technically called ballasting. The space between the blocks should be filled up with rubble stones, and the whole should be covered with gravel up to the level of the bottom of the rails

What has been said relating to the draining of a turnpike road, should be strictly attended to in constructing railways. Railroads on which locomotive engines are employed should not be carried across a turnpike road on the same level with the road, but by tunnels or viaducts. When horses are employed, it is not so objectionable to cross roads on the same level; it should, however, if possible, be avoided: when it is impossible, great care should be taken to keep the top of the rails on a level with the surface of the road, or rather below it, and the space between the rails should be kept always filled to the same level. Notwithstanding it seems to be universally believed that the practicability of making use of locomotive engines on railroads has been established by what has taken place on the Manchester and Liverpool railway, there are many competent judges who are of opinion that it would not have succeeded had it not been for the peculiar circumstance of its forming a direct communication between two such very populous, opulent, and enterprising trading towns as Manchester and Liverpool." (p. 116.)

8217. *Paved roads*, where there is much traffic, will be found better for conveying goods than turnpike roads, constructed as they usually are. "On a smooth, well-made pavement, quite horizontal, it appears, from the experiments made with Mr. Macneill's machine, that the resistance to draught is not more than the hundredth part of the weight of the carriage and its load, when the carriage is properly constructed, and mounted on straight and cylindrical axles. According to this, a horse of great power would be able to draw on such a road, if horizontal, 6¾ tons; and if with no greater inclination than 1 in 50, 2¼ tons. A common opinion prevails, that because paved streets have almost everywhere been suffered to be rough and imperfect, all pavements must necessarily be rough and bad; but a slight degree of consideration will show that this opinion is without foundation, and that, in point of fact, the cause of rough and bad pavements is bad management, arising from the ignorance of those employed to make them, or the want of sufficient funds for executing good work." (p. 120.)

8218. "*The first object to be secured is a good foundation.* For this purpose, a bed should be formed with a convexity of two inches to ten feet, so as to admit of twelve inches of broken stones being laid upon it. These should be put on in layers of four inches at a time. After the first layer is put on, the street should be kept open for carriages to pass over it. When this first layer has become firm and consolidated, then another layer of four inches should be put on, and worked in as before, care being taken to rake the ruts and tracks of the wheels of carriages, so that the surface may become smooth and consolidated. The same process should be repeated with the third layer of stones, by which means a solid and firm foundation will be established, of twelve inches in thickness, for the dressed paving-stones to lie upon. The next thing to be attended to, is to provide proper paving-stones. These should be cut into a rectangular shape, and of the hardest quality that can be procured; granite is the best, but whinstones, some descriptions of limestone and freestone, will answer the purpose." (p. 133.)

8219. *With regard to the size of the stones*, that should be regulated by the intercourse. The streets should be divided into three classes, according as the thoroughfare is greater or less. For streets of the first class, or greatest thoroughfare, the stones should be ten inches in depth, from ten to fifteen inches in length, and from six to eight inches in breadth on the face. For streets of the second class, the stones should be eight inches in depth, from eight to twelve inches in length, and from five to seven inches in breadth on the face. For streets of the third class, the stones should be six inches in depth, from six to ten inches in length, and from four to six inches in breadth on the face.

8220. *After having prepared a proper bottoming*, the greatest care must then be bestowed in setting the stones. Fine gravel must be provided, cleansed from all earth, to form a bed over the bottoming of two inches thick, for the stones to be set in. Strong mortar must also be provided; and, besides the common tools, each pavior should have a wooden maul, the head of which should be made of beech or elm, and should weigh about fourteen pounds. The stones should be selected so that they may be laid in even courses, and so as to match, as nearly as possible, in each course, with regard to breadth and depth.

8221. *In paving*, the pavior should first set a stone on the gravel bed, by striking it strongly downwards with the maul, and then on its sides. Then he should lift it out of its berth, and put mortar on the sides of the two adjoining stones; after which he should again place the stone in its berth, and strike it as hard as he can, downwards and sidewise, with the maul, till it is fastened in the position in which it is to remain. Each stone should be set in this manner; and, when the pavement is finished, it will be so firm as not to require ramming.

8222. *The crossings for foot passengers* should be raised above the level of the pavement, by giving a moderate convexity to the bottoming. They should be made with stones of the size for streets of the first class, more accurately dressed.

8223. *The pavement should be formed with a regular, but very moderate, convex surface*, by giving the bed for it the convexity already mentioned. There should be no gutter or other channel but that which will be formed by the angle made by the surface of the pavement abutting on the kerbstone. The kerbstone of the pavement should be made of long blocks of stone, of a quality sufficiently hard to resist the shocks of wheels striking it. These blocks should be bedded in gravel, and joined with cement: they should be sunk four inches at least into the ground, and be six inches above the pavement.

8224. "*The foot pavements* should be made of well-dressed flags; each flag to have its sides rectangular, and to be set in mortar, with a very close joint, upon a strong gravel bed, of six inches in depth. The flagstones should be at least two inches and a half thick; the surface of the foot pavement should have a declivity at the rate of one inch in ten feet, towards the street."

8225. *The paving and repairing of paved streets* should be done by the superficial yard, and by contract; the specifications ought to be drawn up with the greatest care, and accompanied by all necessary plans and sections. Repairs require to be made the moment they are discovered to be necessary. As soon as a single stone gets out of its proper bearing, it should be taken up, and relaid with new bottoming; and a complete bottoming should always be laid down over pipes when the pavement is broken up in order to get at them. The paving-stones should be laid on loose at first, and left till the bottoming is consolidated, and then they should be taken up and carefully set in mortar.

8226. *Paved streets have been objected to*, on account of the noise made by carriages passing over them. The noise chiefly arises from the boxes of the wheels striking the arms of the axle-trees; and, therefore, when a paved street is exceedingly rough, the strokes of the axles are frequent and violent. But when a paved street is properly made, the surface of it will be comparatively smooth, and then both the number and force of the strokes of the axles on the boxes will be greatly reduced, and consequently the noise made by carriages. When a carriage passes from a rough to a well-made pavement, the difference of sound is immediately perceivable. It is supposed by some persons, that, if the streets were paved in the way proposed, their surface would be too smoooth for horses to go safely over them; but this supposition is not well founded, except when that kind of stone is used which becomes polished by wear. Scotch granite and some other kinds of stone do not become polished, and, therefore, pavements made with them will never have so smooth a surface as to be unfit for horses. A horse properly shod will seldom slip on a pavement, or fall, unless when thrown down by being turned too short, or other careless management. The enormous expense which has been incurred by adopting the plan of broken-stone streets in London, in place of pavements, is fully established by the returns which were presented to the House of Commons in the year 1827. By this return it appears that the first cost of converting 1 mile 250 yards from a pavement into broken-stone road was 12,842*l.*; and that the annual expense of maintaining this 1 mile 250 yards has been 400*3l.*, being at the rate of 1*s.* 9*d.* per superficial square yard.

8227. *Roads partly paved, and partly made with broken stones.* "Whenever the traffic of a road is so great as to wear down three inches of hard broken stones in a year, the middle part of it should be paved. At this rate of wear half a cubic yard of materials will be requisite for every lineal yard of eighteen feet of the breadth of the road. This will make the expense of new stones alone, for a road thirty-six feet

wide, per mile, per annum (supposing the cubic yard of broken stones to cost 12*s.*), amount to 1056*l.* If the middle twenty feet of the broken-stone streets in London, where the traffic is very great, were paved, a great expense would be saved; at the same time that the convenience of broken-stone roadways would not be taken away." (p. 146.)

8228. "*A road with a foundation of pavement, and a surface of broken stones.* The following specification of the manner of constructing a road of this kind, of thirty feet in width, is taken from a contract for making a part of the Holyhead road. Upon the level bed prepared for the road materials, a bottom course or layer of stones is to be set by hand in form of a close firm pavement. The stones set in the middle of the road are to be seven inches in depth; at nine feet from the centre, five inches; at twelve from the centre, four inches; and at fifteen feet, three inches. They are to be set on their broadest edges lengthwise across the road, and the breadth of the upper edge is not to exceed four inches in any case. All the irregularities of the upper part of the said pavement are to be broken off by the hammer, and all the interstices to be filled with stone chips firmly wedged or packed by hand with a light hammer; so that, when the whole pavement is finished, there shall be a convexity of four inches in the breadth of fifteen feet from the centre. The middle eighteen feet of pavement is to be coated with hard stones to the depth of six inches; four of these six inches to be first put on, and worked in by carriages and horses, care being taken to rake in the ruts until the surface becomes firm and consolidated; after which the remaining two inches are to be put on. The whole of this stone is to be broken into pieces as nearly cubical as possible, so that the largest piece, in its longest dimensions, may pass through a ring of two inches and a half inside-diameter. The paved spaces on each side of the eighteen middle feet are to be coated with broken stones, or well-cleansed strong gravel, up to the footpath or other boundary of the road, so as to make the whole convexity of the road six inches, from the centre to the sides of it; and the whole of the materials are to be covered with a binding of an inch and a half in depth of good gravel, free from clay or earth." (p. 150.)

8229. *The work of setting the paving-stones* must be executed with the greatest care, and strictly according to the foregoing directions, or otherwise the stones will become loose, and in time may work up to the surface of the road: when the work is properly executed, no stone can move. If the work be executed by contract, the inspector should see all the operations as they are going on; he should walk over the pavement when it is completed, and try whether the stones be firmly fixed; and he should not allow any broken stones to be laid on over the pavement till it has undergone an examination of this kind.

8230. *In breaking stones*, the workmen would be required to break them as nearly cubical as possible: when this rule is not attended to, a great quantity of materials is wasted by first splitting the stones into thin slices, and then breaking them into pieces that are too small and too thin. If the stones or top metal are not broken very small, the proper degree of smoothness of surface will not be obtained. When stones are very hard, they never make a very smooth surface; limestone will make a much smoother surface than whinstone and other harder stones, but they should not for this reason be preferred to harder stones; for these will wear longest, carriages will run lighter over them, and the expense for scraping and repairing will be less. All the soft kinds of stones make heavy roads in wet weather; and in dry weather there will be more friction upon roads made with them, because there will be more dust on their surface.

8231. *With respect to the convexity of a road*, it should be so arranged that it should be slight in the middle. In giving a convexity of six inches to a road of thirty feet in breadth, the convexity at four feet from the centre should be half an inch; at nine feet, two inches; and at fifteen feet, six inches. This will give the form of a flat ellipsis.

8232. *The binding*, which in the foregoing specification is required to be laid on a new-made road, is by no means of use to the road, but, on the contrary, injurious to it. It is, however, unavoidable, when a long piece of new road is to be opened; for, without it, the wheels, by sinking into the new materials, would make the draught of the carriages much too heavy for the horses. This binding, by sinking between the stones, diminishes the absolute solidity of the surface of the road, lets in water and frost, and contributes to prevent the complete consolidation of the mass of broken stones. In a district of country where any sort of coarse stone can be got for making a pavement, it will be cheaper to make a road with a pavement and six inches of broken stones, than with ten inches of broken stones without a pavement.

8233. *Roads made with foundations of rubblestones, and a surface of broken stones*, will answer for cross roads and others, that do not communicate between large towns, collieries, or quarries. The rubble-stones should be reduced so as none of them exceed four pounds in weight; they should be laid in a regular bed, seven inches deep in the middle of the road, and four inches at the sides, and a coating of small broken stones, not exceeding an inch in diameter, should then be laid over them.

8234. *A road made wholly of broken stone*, of twelve inches in thickness in the middle, and six inches at the sides, may be found suitable for light carriages and little traffic. The stone should be laid on in layers, allowing each layer to be worked in and consolidated, before a fresh one be laid on. "This plan of road-making, however, having of late been recommended, as greatly superior to all other plans, by persons who profess to be experienced and scientific road-makers, a number of turnpike trustees have adopted it; but experience has fully established its unfitness for roads of great traffic, in comparison with roads made with a proper foundation. In point of fact, there is nothing new in this plan; for all the roads of the kingdom have been made in this way, and the universal defect of them, namely, their weakness, is the result. A road made on this plan will require, for two or three years after it is said to be finished, the expending of large sums in new materials, to bring it into anything like even an imperfectly consolidated state; and, after all that can be done, such a road will always run heavy, and break up after severe frosts; for as the natural soil on which such a road is laid is always more or less damp and wet, it will necessarily keep the body of materials, of which the road is made, damp and wet; in consequence of which, the surface of the road will wear down quickly. Hard frosts will penetrate through the materials into the under-soil; and, when the thaws take place, will break up the whole surface. It is in this way that the ruinous state of most roads, after severe frosts, is to be accounted for."

8235. *Roads made with gravel.* The bed being prepared, a coating should be laid on four inches thick and carriages allowed to pass over the road, the ruts being filled in as soon as they appear. When the first coat has become firm, a second coat once screened, that is, freed from the larger stones and the smaller gravel, should be laid on three inches thick, and treated as before. A third coat of well-riddled gravel should afterwards be put on, taking care to break all pebbles exceeding an inch and a half in diameter; and this process of putting on layer after layer, allowing a considerable interval between, should be continued till there is a body of gravel on the road sixteen inches thick, declining convexly towards the sides, where the thickness may be ten inches. The strongest and best part of the gravel should, of course, be put in the middle part of the road. A road made with gravel in the way here recommended will be much stronger than gravel roads usually are; but it will be much inferior to one made with stone materials. The roundness of the gravel stones prevents them from becoming consolidated by pressure, so as to form a perfectly hard road surface; and when the gravel consists of limestone, flint, freestone, sandstone, or other kinds of weak stone, it is so rapidly pulverised that the friction produced by wheels passing over it adds greatly to the labour of horses."

8236. *Fences.* Walls are preferred to hedges, because they require less room; and at once give a neat and finished appearance to a road. Hedges are to be planted on banks, and the ditch is always to be on the field side of the bank. All road-fences should be kept as low as possible, in order that they may not intercept the sun and wind. Hedges should be trimmed every year, in August and September, applying a line and templet (mould) to insure regularity.

8237. *Road masonry.* — *Bridges* ought to be placed in a direct line with the road which is to pass over them, and, if possible, at right angles to a straight reach of the river or stream. The width of bridges on turnpike roads near large towns should not be less than forty feet, and on other roads thirty-six, thirty, twenty-four, or twenty feet. The inclination of the sides of bridges should never exceed one in thirty. The waterway of the bridge should be ample, so as to allow the highest floods to pass away freely.

8238. *Retaining walls*, or those which are built on the hill side of a road in a rugged and precipitous country, require to have a secure foundation, and to be carried up with a curved batter (slope) on the face or side next the road, at the rate of one inch and a half of curve for every foot in height.

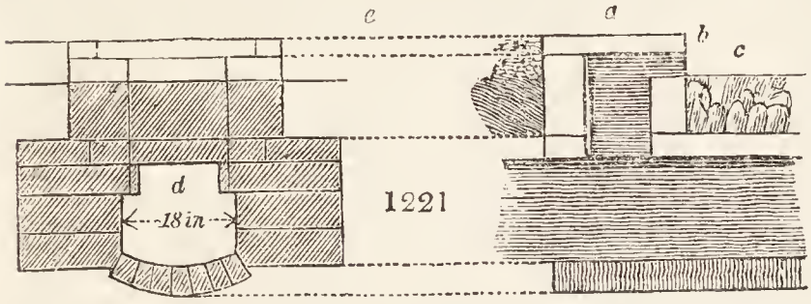
8239. *Breast walls*, or those which support a road on its lower side, should be built in the same manner as retaining walls; and, like them, they should increase in thickness downwards, at the rate of two inches and a half for every foot in depth, by a regular slope on the outside.

8240. *Fence-walls* may be built without mortar if the stones are flat-bedded.

8241. *Cross drains* should be built of good masonry, eighteen inches in the clear.

8242. *Inlets* or openings for the water from the side-channels of a road should be in stone masonry, ten inches by sixteen inches, covered with sound flagstones, the top of which would be at least six inches above the level of the channel, as in *fig.* 1221., in which *a* is the flagstone, *b* the opening for the water, *c* the channel of the road, *d* the cross drain, and *e* the surface of the footpath. Inlets may likewise be made along the channels, and should be covered with iron gratings.

1221

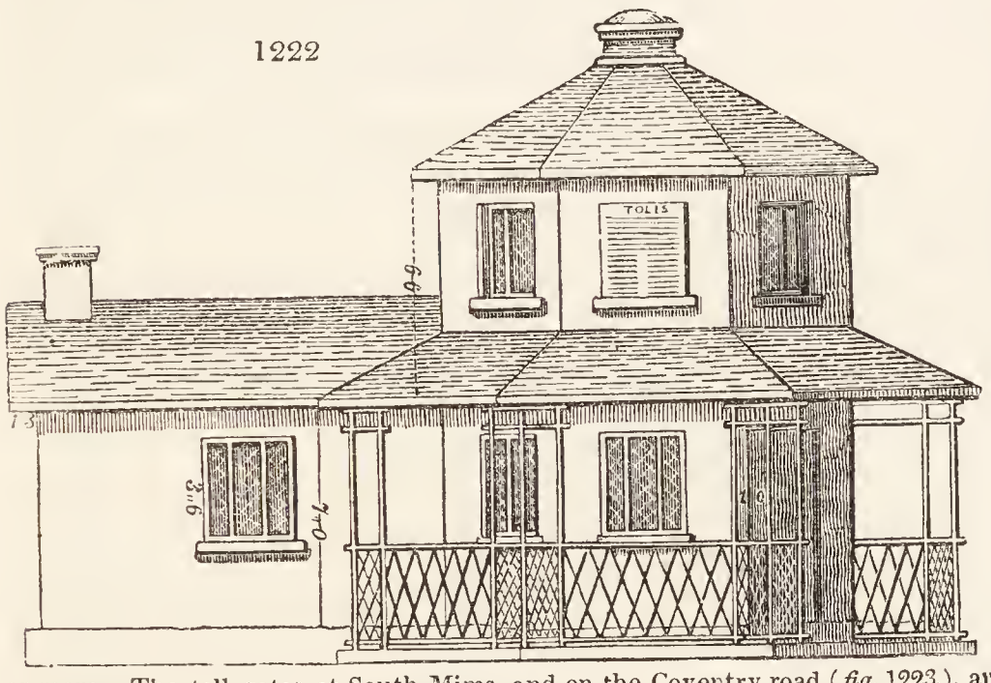


8243. *Outlets* may be built of brick or stone, about a foot square, for the purpose of carrying the water from the channels under the footpath or fence into the outside drains, or to the cross drains, as the case may be.

8244. *Depôts* are made along roads for holding materials for repairs; they are rectangular recesses, with back and side walls, the former twelve, and the latter each two yards and a half in length. This space will hold twenty-five cubic yards of materials; and four depôts on a mile, at 428 yards apart, will contain 100 cubic yards. Depôts should never be farther apart than a quarter of a mile, so as to admit of the materials being moved from them in barrows.

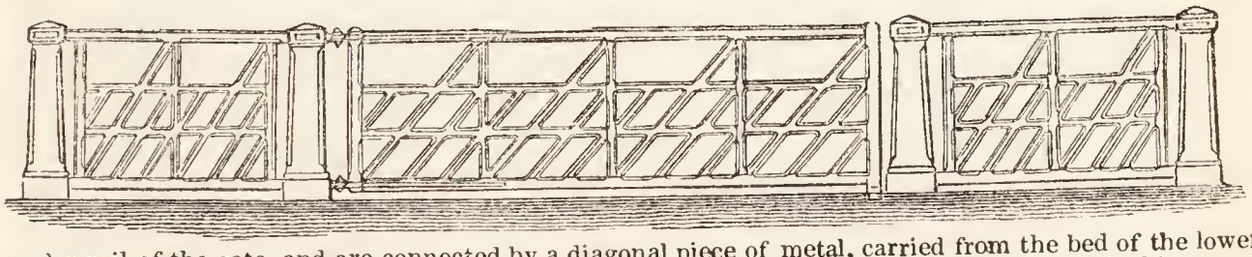
8245. *Toll-houses* are recommended to be built in a strong substantial manner, and to be made suitable and comfortable for the persons who are to inhabit them. "Many instances might be mentioned, in which the tolls on a road have been much increased by building good houses." (p. 212.) *Fig.* 1222. is the elevation of a toll-house at Llanfair, in Anglesea, built by Mr. Telford.

1222



8246. *Tollgates and bars* should never be placed on the summit of a hill, or at the bottom of one, for obvious reasons. Gates should be painted white, and not made higher than four feet six inches. The width of the carriage-way may be sixteen feet or more. The toll gates at South Mims, and on the Coventry road (*fig.* 1223.), are hung on "Collinge's patent hinges, which are particularly fit for this purpose: they run about five feet along the upper and

1223



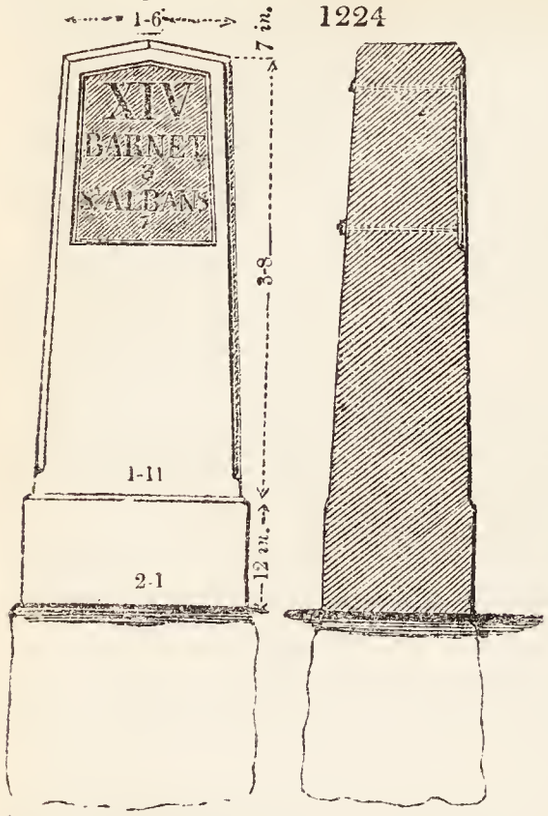
under rail of the gate, and are connected by a diagonal piece of metal, carried from the bed of the lower hinge to the point of the upper one, in order to prevent the gate from sinking. The balls of the hinges are cast, with the caps and plinths of the posts, so that the posts are not weakened by holes or mortises, as in the usual manner of hanging gates. The caps and plinths of metal are also a great security to the posts by preserving them from the effects of the weather, and by preventing the wheels of carriages from chafing their angles.

8247. "*Flapping-posts* are set in the ground at proper places, to prevent the gates from opening too far, and straining the hinges; these posts are about two feet and a half above the ground, and two feet in it. Catches or clicks are let into these posts, to hold the gates open when thrown back: these catches project about two inches from the side of the posts, and turn on a pin within the post; the inner end of the catch being made heavier than the outer, it always throws that end up, and by that means it takes hold of the bottom of the lower bar of the gate, by a notch cut in it for that purpose: by making the catches in this way, they are out of the reach of injury. In the common way they are put on the top of the posts, from which they project six or seven inches; in consequence of which they are frequently torn off by wheels of carriages and waggons." (p. 224.)

8248. *Lamps* are required for all tollgates; they should be made similar to the best coach lamps, with powerful reflectors, and large airholes; they may be nine inches high, and six inches wide in the clear

8249. *Milestones* should be made higher than they generally are, and of very hard stone of a light colour. *Fig.* 1224. is the form used on the Holyhead road.

1224



8250. *Management of roadwork.* As soon as the precise line is determined on, the following circumstances should be attended to: — I. Drawings to show, 1st, the natural surface of the ground; 2d, the longitudinal inclinations of the proposed road; 3d, the slopes of the cuttings and embankments; 4th, the form of the bed of the road, and footpath; and 5th, the courses of materials to be laid on, and the thickness of each course. Drawings should also be made, describing the plans of the bridges, culverts, cross drains, inlets, outlets, depôts, and fences which are required to be made. II. A specification should be prepared, to explain in detail the precise method of executing every part of the work. III. After the specification has been settled, an estimate should be made of the expense to be incurred. IV. Next a contract is to be entered into, which, if the plans, specifications, &c. have been properly made, will be found the most safe and satisfactory mode of execution. Select a contractor of skill, integrity, and capital, and rather overpay than underpay him. V. In preparing a deed of contract, refer to the drawings and specifications, and provide a clause to prevent all deviations from them, except by agreement in writing. VI. Before the work is commenced, an inspector should lay out the work, settle the levels, and see that everything is done agreeably to the specifications. The inspector should be a person of considerable experience as a civil engineer; and it is on the skill of the chief engineer, in engaging men of this kind, that his success in accomplishing great works will very much depend. VII. The mode of paying the contractor should be as the work proceeds: for which purpose it ought to be measured by the inspector every fourth week.

8251. *Improving old roads.* Here nearly the same objects are to be attended to as in making new ones; "such, for instance, as the direction, the longitudinal inclinations, the breadth, form, and hardness of the surface, the drainage, and the fencing. For the purpose of ascertaining in what respect an old road is complete or defective in these points, the following queries have been prepared. The answers that can be given to these will at once show what is the state of a road: —

1st, Is the direction of the road in the shortest line that can be found, without having to pass over steep hills, or other obstacles?

2d, What are the rates of inclination of the hills? Is there no more ascent in the road than is necessary for reaching the heights of the country which must be crossed?

3d, What is the breadth of the road? Is it everywhere the same? Is it defined by side channels, having along them kerbstones, or borders of grass sods?

4th, Are the channels on each side of the road on the same level? Is the convexity of the surface uniformly the same in every part along the whole length of the road?

5th, Is there a footpath? What is the height of it above the side of road? What is its breadth? Of what materials is it composed?

6th, Is there any waste land between the road and the fences of the road? In what state is it?

7th, Is the surface of the road higher than that of the adjacent fields?

8th, Of what materials does the crust of the road consist? What is the depth of them in the centre of the road, and at a distance of five feet on each side of the centre?

9th, Are there sufficient drains for carrying off all rain and other water?

10th, Are the fences low? Are they raised on ground of the same level on both sides of the road? Are they of the same height on both sides, and parallel to each other?

The answers which can be given to these queries will show what the defects are of any road to which they are applied, and what is requisite to be done to improve it."

8252. *Repairing roads.* This ought always to be managed on a regular plan, more especially with reference to, "1st, The quality of materials. 2d, The quantity to be put on per mile per annum. 3d, The preparation of the materials. 4th, The method of putting them on the road. 5th, The number of labourers to be employed." (p. 270.)

8253. *The materials used* should always be the hardest; for it has been ascertained by experience, that hard stones brought from a distance are cheaper in the end than soft stones got near the road at a much lower price. It is also a fact, that in proportion to the softness of the stones is the labour of the horses on the road, in working the often-renewed coatings of them into a smooth surface. The best description of stones for roads are, basalt, granite, quartz, syenite, and porphyry. Schistose rocks are rapidly destroyed, more especially when wet; and they occasion great expense in scraping, and constantly laying on new coatings. Limestone is liable to the same objection. Sandstone is very well adapted for the foundation of a road, but much too weak for its surface. Flints vary very much in quality as a road material. The hardest of them are nearly as good as the best limestone; but the softer kinds are quickly crushed by the wheels of carriages, and make heavy and dirty roads. Gravel, when it consists of pebbles of the hard sorts of stones, will make a good road, particularly when the pebbles are so large as to admit of their being broken; but when it consists of limestone, sandstone, flint, and other weak stones, it will not; for it wears so rapidly, that the crust of a road made with it, always consists of a large portion of the earthy matter to which it is reduced. This prevents the gravel from becoming consolidated, and renders a road made with it extremely defective with respect to that perfect hardness which it ought to have."

8254. *The quantity of materials* to be put on the road in the course of a year will be regulated by their durability, and the traffic on the road. The materials should be quarried, carted, and broken by contract, and, when ready to be put on the road, placed on the depôts till wanted.

8255. *With respect to preparation*, stones should be broken "to a size of a cubical form, not exceeding two inches in their largest dimensions." Gravel should be sifted at the pits, so that no stone larger than one quarter of an inch in diameter should be carried to the road. The road labourers should again sift it, so as to separate the pebbles that are less in diameter than the rest; and the large pebbles which exceed one inch in diameter should be broken.

8256. *The materials should be laid on in small quantities at a time*, taking care to fill up ruts or hollows as soon as they appear. "In those places where the surface of the road has become much worn, a coating of one inch and a half of materials should be laid on: that is to say, a coating only a single stone in thickness, when stones are used; and when gravel is used, a coating not exceeding one inch in thickness. If more materials are necessary, they should be laid on after the first coating is worked in. The work of repairing roads, by laying on new coatings of materials, ought to be done between the months of October

and April, and when the surface of the road is wet. By laying on the materials at this season of the year in thin coatings, they are soon worked into the surface, without being crushed into powder, and without producing any great distress to horses drawing carriages over them." (p. 274.)

8257. *In arranging the labourers* on a road, it should be divided into "districts of four miles each; and a foreman, with three labourers, should be appointed for each district. The foreman and one or more of the labourers should be daily on the road, taking care that the side channels of the road are kept clean, and making good any injury to the road, as soon as it appears. The foreman should work with the men: he should take care that the orders of the surveyor are attended to, and be able to measure roadwork." (p. 274.) The water channels and drains should be particularly attended to, and in October in every year they ought to undergo a general repair. At that season, also, the surface of the whole road should be scraped, "all ruts and hollows should be carefully filled with materials, and all weak parts of the surface coated with materials; that is to say, the road should be put, in every respect, into a complete state of repair, so as to preserve it from being broken up during the approaching winter. A road should be scraped, from time to time, so as never to have half an inch of mud upon it. This is particularly necessary to be attended to, when the materials are weak; for, if the surface is not kept clean, so as to admit of its becoming dry in the intervals between showers of rain, it will be rapidly worn away." Hedges should be kept clipped, and branches of trees lopped. The superior condition of roads which cross unenclosed lands, and of those which run south and north, rather than east and west, shows the great benefits of a free exposure to the sun and air.

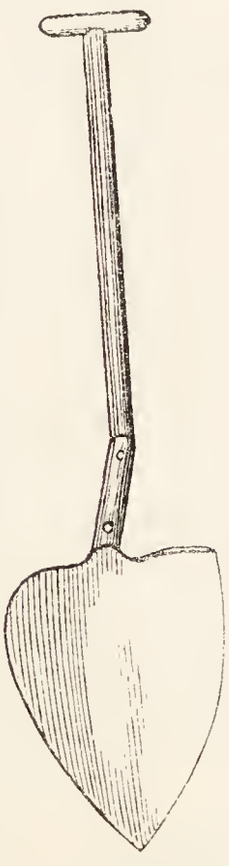
8258. *The trustees of a turnpike road* should require the surveyor to lay before them, at the commencement of every year, an estimate of the work he proposes to perform in that year; and he should make up a monthly account, as well as an annual account.

8259. *Road instruments and tools.* The principal instruments are theodolites, spirit levels, and sextants, which are used in laying out roads. Road tools are spades, *fig.* 1225.; shovels, *fig.* 1226.; trucks, or small waggons, for removing earth; hammers for breaking stones, *figs.* 1227. and 1228., the handles of which should

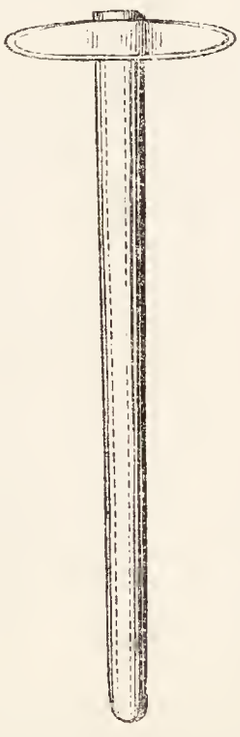
1228

1225

1226



1227



be flexible, and made of straight-grained ash; the small hammers having a chisel face, and the larger ones a convex one, about five eighths of an inch in diameter. The hammers should be made of cast steel, which wears much longer than wrought iron, and seldom breaks at the eye. Pronged shovels are useful for filling broken stones into carts or barrows: a man will not only lift more stones with them, but he will lift them without taking up earth. Scrapers for scraping off dust or mud should be made of wood shod with iron, or of plate iron, six inches deep, and from fourteen to eighteen inches long. The best scrapers are made of old saw-plates, stiffened on the back by a nib of wrought iron, or a piece of elm board. Hedging-knives are required for trimming hedges, which they do much more expeditiously than shears. Working levels, which resemble a common bricklayer's levels, are absolutely necessary in laying out new works. On the horizontal wooden bar should be placed four gauges, made to move perpendicularly in dovetail grooves, to the lower edge of the bar. Each of these should have a thumb-screw, in order that, when adjusted to its depth below the level line, the gauge may be fixed in the desired position. "Levels for laying out slopes are best made of a bar of wood, three inches deep, one inch thick, and six feet long; on the centre near the middle of the rod, a triangular piece of wood of the same thickness is nailed; the sides of this triangular piece are so formed, that when the rod is placed upon a slope of one to two, or one to three, a small pocket level placed on one side of the triangle will be horizontal, and the bubble will remain in the centre."

8260. *Ring gauges* are required for ascertaining the size of broken stones.

8261. *Road legislation.* The turnpike system is considered as so far good, as, by putting the management of roads into the hands of local proprietors as trustees, a larger road revenue has been raised than the country would have been willing to pay to government for their management. Great errors have, nowever, been committed in carrying the turnpike system into operation. The government is not to blame for this, because the business has not been in its hands; nor the civil engineers, because they have not been consulted by turnpike trustees. "The country gentlemen of England, in point of fact, are alone responsible for the defective state of the roads, because the business of managing them has been vested, by the legislature, exclusively in their hands." (p. 291.)

8262. *More than double the money necessary is raised,* and the works are performed in the most slovenly manner, or not at all. The trustees on each trust are by far too numerous; they ought to be reduced, and rendered responsible to a board of control, appointed by government. Under such a board, the Holyhead road was improved, and the late Mr. Huskisson, who was chairman of this board, observed, that all the roads in the kingdom ought to be placed under similar control.

8263. *Parish roads* are, in general, much worse than turnpike roads. The private interests of a vestry lead it to be satisfied with very imperfect roads. The surveyor is appointed to act only for one year; a proceeding founded on the vulgar notion that the management of roads is something that requires no education, skill, or science. These roads ought to be managed by county commissioners, as in Scotland. (p. 312.)

8264. *Scotch roads* are superior to the turnpike roads of England. The road management of every county is vested in trustees, which is attended with the following advantages:— "1st, A more efficient governing authority is provided. 2dly, The obstacle to a uniform and efficient management of the roads, which the small divisions of parishes occasion, is obviated by giving the general management of all the roads of a county to the general meetings of the trustees. 3dly, The funds for maintaining the roads are derived from a regular assessment on the lands, instead of statute labour. 4thly, The surveyors are appointed permanently, and with fixed salaries."

8265. *Irish roads* are under the management of grand juries; the defects of which plan is, that the governing authority is insufficient, because it does not represent the interest concerned in road affairs, and because there is a want of "correct moral principle" and "pure habits" among Irish grand juries. (p. 318.) The Scotch, therefore, is recommended to be introduced into Ireland.

8266. *Appendix. No. I. is a description of Macneill's road indicator,* which Mr. Telford has declared to be, "for practical purposes on a large scale, one of the most valuable that has been lately given to the public." (p. 328.) It may be described as a dynamometer of an improved description, attached to a carriage (a light phaeton), in such a manner that no part of the moving power is communicated to the carriage, except through the agency of the instrument. The indicator may also be attached to the fore part of any carriage, cart, or waggon. Besides pointing out the distance passed over, it marks the power of draught at every ten or twenty yards, and the rates of acclivity or declivity on every part of the road.

8267. *Macneill's road indicator* may be applied to the following important purposes:— 1st, It affords the means of ascertaining the exact power required to draw a carriage over any line of road. 2dly, It can be applied to compare one line of road with another, so as to determine which of them is the best, and the exact amount of the difference, as regards horse power, both for slow and fast coaches. 3dly, The comparative value of different road surfaces may be determined with great exactness. 4thly, It affords the means of keeping a registry, in a most accurate manner, from year to year, of the state of a road, showing its improvement or deterioration, and the exact parts in which such improvement or deterioration has taken place.

8268. *Practical examples explanatory of the foregoing statement.* 1st, Let it be required to determine the expense of working a four-horse coach over the line of road from ——— to ———, at a velocity of ten miles an hour. Suppose the instrument has been run over the road, and that it has been found that the average power required to draw a four-horse coach over the whole line amounts to 350 lbs., and the distance equal to twelve miles. Let the average power which a horse should exert for eight miles a day, with a velocity of ten miles per hour, be assumed equal to 60 lbs.; then $160 \times 8 = 480$ lbs., raised one mile in the day; and taking the daily expense of a horse equal to six shillings, we have 480 lbs. : 6*s*. : : 1 lb. : ·15, the expense of horse power exerting a force of 1 lb. over 1 mile. Thence $350 + \cdot15 + 12$ miles = 630 pence, or 2*l*. 12*s*. 6*d*., the expense of horse power required to work a four-horse coach per day over such a road.

8269. *The most important and useful application of the instrument* is, perhaps, that of being able to ascertain with accuracy and precision the state of any road, from time to time, as regards its surface; and the state of repair in which it has been kept.

8270. *The public advantages* to be derived from such a system of road inspection would probably be very great. It would show not only where the best plan of repairing roads has been followed, and point out where there are good and bad surveyors, but it would also show if the money of the trust is improperly applied or wasted on any line of road; and it will enable trustees, who let the repairs of their roads by contract, to determine whether or not the contractors have done their duty, and kept the road in the same state of repair as at first, or whether they had improved it, or suffered it to become defective."

8271. *Appendix II. contains a report respecting the street pavements, &c. of St. George's, Hanover Square,* in which the present system of macadamising streets is condemned as in every respect bad.

8272. *Appendix III. is a notice of Mr. Walker's plan of paving roads along the sides,* by which the carmen on footpaths or sides of the roads could be close to their horses without interruption, or being in danger of accidents from light carriages; and the unpaved, being the highest or middle part, would be more easily kept in repair. This plan was adopted in the Commercial Road, Middlesex, in 1820, and has been subject to the heaviest traffic ever since: it has cost very little for repairs, and is now, 1834, in excellent order.

8273. *Appendix IV. Report respecting the expense of the Holyhead and Liverpool roads.* It occupies a number of pages, and will be useful to young engineers, by showing them the forms in which business is transacted, and assisting them in committing their ideas to paper.

8274. *Appendix V. The principal clauses of a Scotch act of parliament respecting roads,* which it is thought might be imitated in English and Irish acts.

8275. *Appendix VI. Tables respecting turnpike road trusts,* extracted from the reports of the Lords' Committee on that subject.

8276. *Note A.* Investigation of the best plan for improving the road through Stowe Hill Valley. By John Macneill. This is a most valuable paper for the young engineer; it contains arguments, comparative views, specifications, and estimates, full of instruction.

8277. *Note B.* Proofs of the resistance produced by collision.

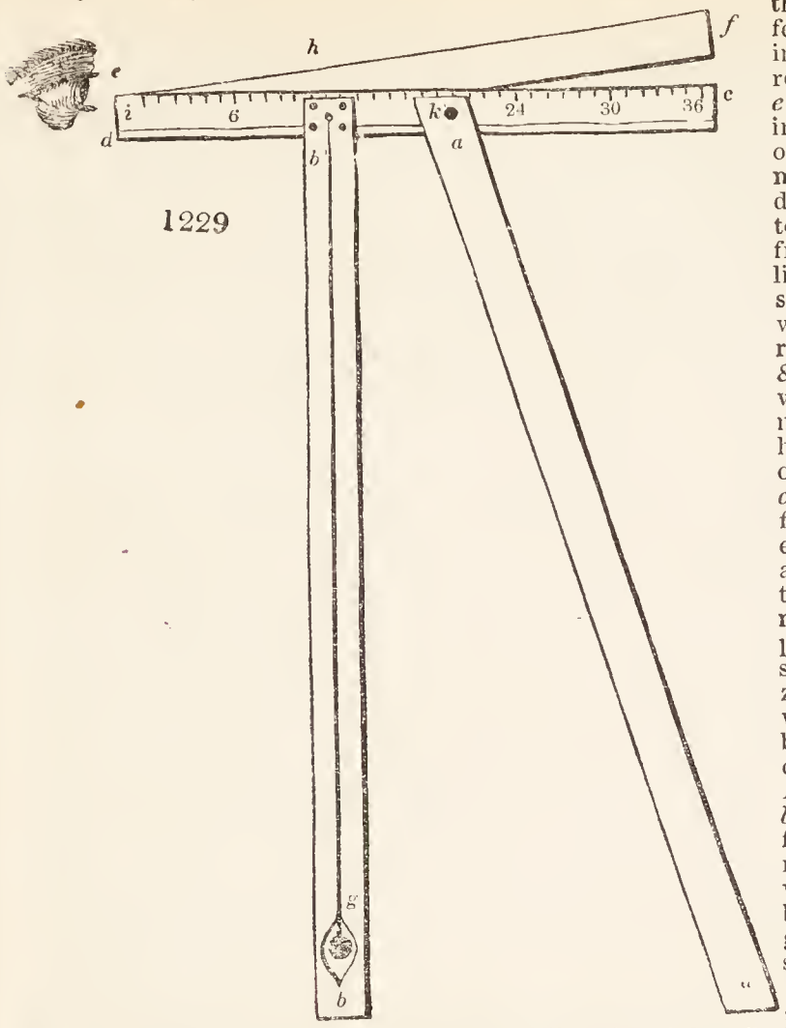
8278. *Note C.* Proofs of the resistance occasioned by friction.

8279. *Note D.* Proofs of the resistance from the force of gravity, when a road is not horizontal. We have already occupied so much space, that we cannot afford room to give the substance of these notes; but the book itself will soon find its way into the library of every civil engineer, road-maker, and country gentleman. We need hardly say that it is by far the best work on the subject which has appeared in England.

8280. *An instrument for measuring the inclination of roads* (*fig.* 1229.) is thus described in *Trans. Highland Soc.*, vol. viii. p. 62.:—"A slip of wood must be procured, measuring three inches broad by half an inch thick, and sixteen feet nine inches long, which must be cut into four lengths of five feet three

inches, five feet, three feet three inches, and three feet three inches, marked as follows:—*a a*, five feet three inches; *b b*, five feet; *c d*, three feet three inches; *e f*, three feet three inches: six thick screw nails are also required, one inch long. Join *c d* and *e f* by a screw nail, inserted about two inches from the end of each, and exactly one inch from their upper surfaces, as marked *a*. From the point *a*, upon *e f*, draw a line, measuring thirty-six inches, towards *f*, and exactly one inch distant from the upper surface, and divide this line into thirty-six parts or inches. It is self-evident that each of these points, when elevated above *c d*, will show a rise of one in fifteen, twenty, thirty-four, &c., as the case may be, provided *c d*, which should be divided into inches numbered on the upper edge, shall be horizontal; and *e f* shall point to a pole or mark, as high above the ground as *c d* is; this is effected by fixing *b b* firmly upon *c d*, at right angles, and either having a plummet *g* suspended, as in the figure, or a spirit level fixed on the top of *c d*. I prefer the plummet made of bobbin or small cord, with a pierced bullet at the bottom. The instrument is retained in a level or horizontal position by the assistance of *a a*, which is upon a movable pivot, made by one of the screw nails at *b*. The distance of *a a* from *b b* is immaterial. A small stop is fastened at the back of *b b*, for the purpose of preventing *e f* from falling below *c d*. The rise of a road is shown by looking from *e* towards *f*; the fall of a road, of course, by looking from *f* towards *e*, and, if great correctness is required, the observation should be reversed."

1229

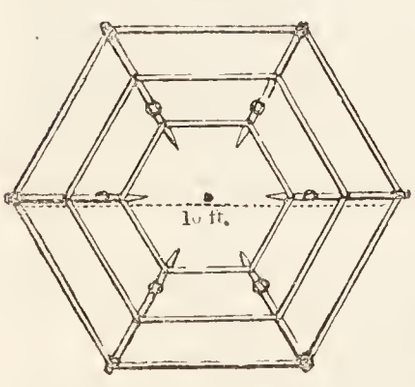


8281.—3862. *Burning of lime, and making of bricks.* A variety of forms of limekilns, and of kilns for burning bricks, will be found described in the *Encyclopædia of Cottage, Farm, and Villa Architecture.*

8282.—3918. *Succession in the kinds of trees.* "There is reason to fear that a judicious rotation of crops in arboriculture is not, as yet, well understood; doubts are entertained, for instance, that the Scotch pine, as a previous crop, is unfavourable to the growth of larch, having a tendency to produce rot at an early stage of growth. It is well known that the Scotch pine is an excellent preparation for the oak, producing rapid growth where that plant would not previously have prospered, although it may be injurious as a forcgoing crop to other resinous plants; and as the Scotch pine and the larch, as a mixture (3958.), are known to prosper tolerably well together without engendering disease from their proximities, it may be inferred that it is not so much from the excrementitious matter exuding from the growing roots of Scotch pine that larch receives injury, as from the poisonous matter, absorbed by the spongioles of the growing larch, proceeding from the decaying roots of Scotch pine in the soil. It therefore becomes a matter of importance for the forester to consider how far it may be advisable to mix larch with Scotch pines in plantations (a practice of frequent occurrence); as, in the process of thinning, a process more or less necessary in every plantation, many roots will be left to rot in the soil, and these, in a state of decomposition, may prove seriously hurtful to living plants on the same spot. It may be safer practice to plant each sort in masses (4012.), observing not to plant larch on an open dry loam, incumbent on a ferruginous subsoil." (*A. G.*)

8283.—3923. *A new guard for single trees in parks and in lawns* is described in the *Gard. Mag.*, vol. vi. p. 48. It consists of low stakes with rails nailed to them in such a manner as to form a hexagonal platform of paling, ten feet in diameter, and about eighteen inches high, round each tree, or group. The advantage is, that it keeps horses and cattle off as effectually as a high paling, and yet is not offensive to the eye. This invention has been termed a dendrophylacton; its vertical profile is seen in *fig.* 1230., and its elevation, or rather section, in *fig.* 1231.

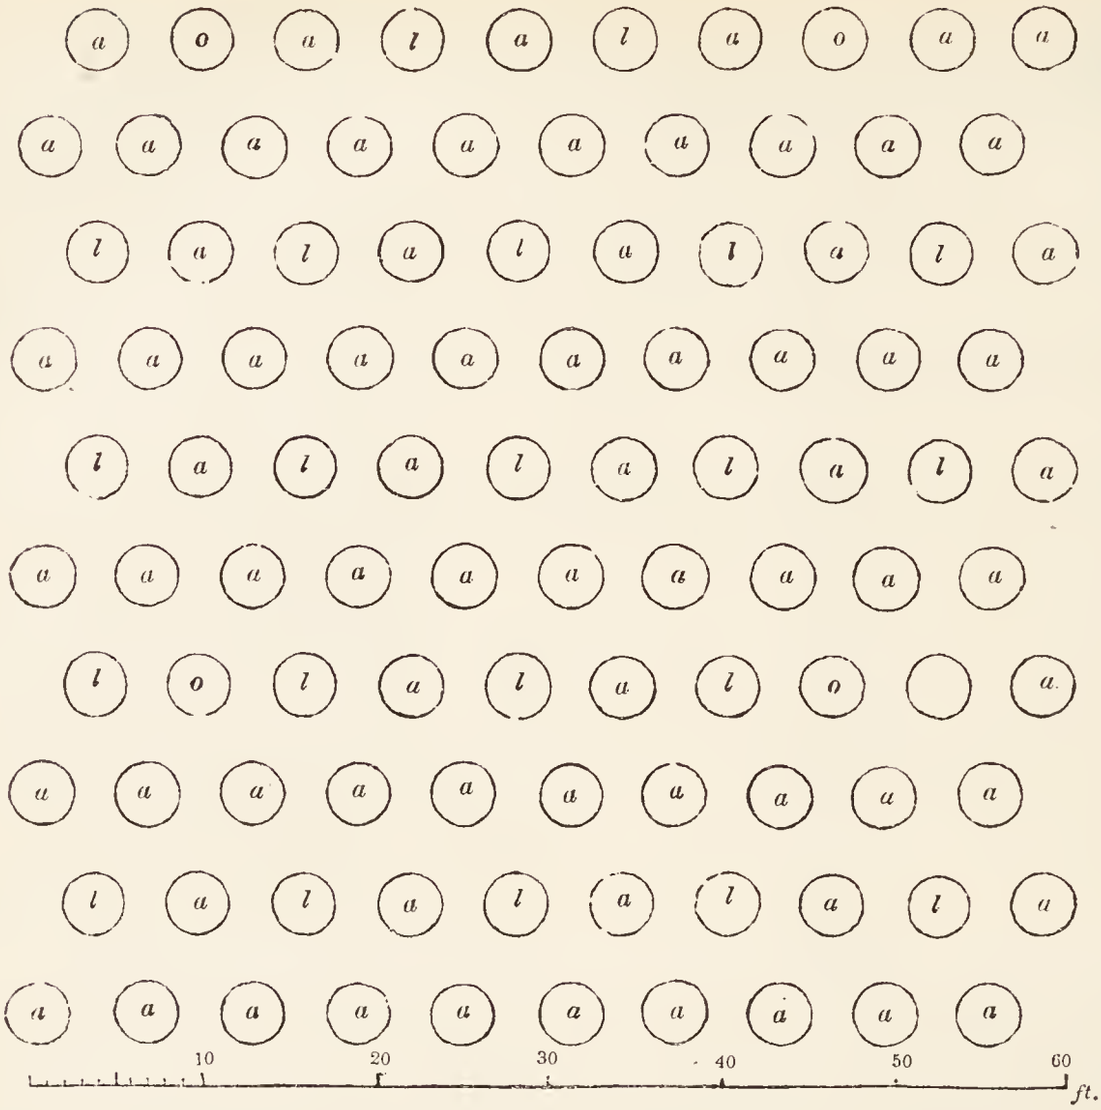
1230



1231

8284.—3928. *Disposing of trees in plantations.* Mr. Lawrence, under ordinary circumstances, prefers a mixture planted at regular distances; and he gives, as an example, a square plantation (*fig.* 1232.), formed of oak, ash, and larch. The great advantage of this regular disposition of the trees, both in regard to distance and kinds, is, that the future management of the plantations can be predetermined, and, as it grows, regulated with perfect ease and accuracy. For example, the trees in this plantation being six feet apart, no thinning will be required until the ash attains a sufficient size for hurdles, hoops, &c., which will be from twelve to fifteen years' growth, according to the quality of the land; or even eighteen years' growth, if the land is very poor. At this period cut off every other ash, in the rows composed exclusively of ash, with a blow in an upward direction, from two to three inches above the ground, in order that the stools should shoot again. The next year cut off all the ash between the larch and the oak in the same manner. The following year cut out the remainder of the ash with a downward blow, under the ground, to prevent them from shooting again. The ash left for stools will produce, in the summer after cutting, several shoots; these should be thinned out, leaving not more than three or four of the best placed for a crop. When these have attained sufficient growth to be crowded by the larch, the

1232

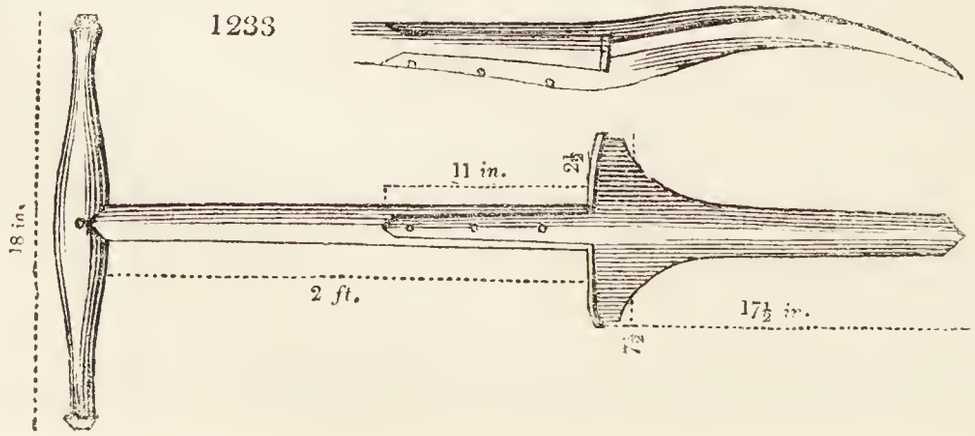


latter will be from twenty to twenty-five years' growth, and should be cut out as soon as the sap is sufficiently in action to admit of their being barked; as, though their bark does not bear a price in proportion to that of the oak, with reference to the tan it yields, it will pay for the stripping. Upon this plan it is obvious that any labourer could effect the necessary thinning without any superintendence: he could not make a mistake. If a variety of timber be desired, a sweet chestnut may be substituted for every other oak, as both thrive well, generally, on the same soil; or any other timber trees may be planted, more suitable to the particular soil, keeping them in the places assigned in the plan to the oak. The underwood may also be varied, by the introduction of the oak, wych elm (*Ulmus montàna*), *Sàlix càprea*, hazel, &c., all of which form excellent coppice wood, but they must be introduced in regular order, with reference to future thinning. (*Gard. Mag.*, vol. x. p. 30.)

8285. — 3929. *To grow the best and most valuable timber*, the trees should stand rather closely together, and be regularly pruned, from the time they are five feet high, until a clear stem is obtained of at least twenty feet. Clearness of grain, undeteriorated by knots or flaws, constitutes prime timber; and it is impossible to have it so, unless the trees be carefully trimmed when young. The leading shoot of the stem should always be allowed to have pre-eminence, by cutting off lateral branches which act as rivals; and such branches should be cut off close to the bole, when they are not more than one inch in diameter. If allowed to exceed this size, the wound made by the removal, though it will be shortly afterwards covered with new wood and bark, will always remain a flaw in the timber when cut up for use. Small spray growing on the trunk does no injury to the grain of the timber; and if all branches, as they arrive at the size mentioned, be pruned off, till a bole of sufficient length be obtained, very fine round timber will be the result. It must be remembered, however, that the trunk is not enlarged by pruning, but rather the reverse; but, as length of bole, clearness of grain, and perfect soundness, cannot be had without pruning, and paying attention to the trees in the early stages of their growth, a portion of their girth must be sacrificed for the more valuable properties of length of bole and excellence of timber. (*J. Main, in Brit. Farm. Mag.*, vol. vii. p. 162.)

8286. — 3950. *The perforator* (*fig.* 1233.) is used as a substitute for the spade, in planting young tap-rooted trees in rough ground. It was invented by Mr. Munro of the Bristol Nursery, and, in that

1233



neighbourhood, in 1828, cost about eight shillings. In using it, one man employs the instrument, while another man, or boy, holds a bundle of plants. The man first inserts the instrument in the soil, holding it up for the reception of the plant; round which, when introduced, he inserts the iron three times, in order to loosen the soil about the roots; he then treads down the turf, and the plant becomes as firmly set in the ground as if it had been long planted. Two men may set from five hundred to six hundred plants in a day with this instrument. (*Gard. Mag.*, vol. iii. p. 215.)

8287. — 3954. *The subject of preparing large trees intended to be transplanted by cutting or shortening their roots* has been treated upon, in a very masterly manner, by Mr. M'Nab of the Royal Botanic Garden, Edinburgh, in the *Quarterly Journal of Agriculture*. The following is the essence of the article alluded to: — The practice of cutting the roots of large trees, at a certain distance from the stem, a year or two previous to removal, is excellent, where time is allowed for the operation, or its necessity foreseen; but the opinion, that the chief advantage derived from this operation arises from the formation of young roots, or fibres, is denied. The principal consequence of this mode of mutilation, is the check given to the growth of the tree; by which it is, to a certain extent, stunted. Every large deciduous tree receives a check when transplanted; and, by beginning the operation of checking a year or two before transplanting, it is rendered more gradual.

8288. *The economy* of Mr. M'Nab's mode is thus shown: — "Let three trees of the same kind, and as much alike as possible as to age, size, health, situation, soil, and exposure, be selected, each about three feet in circumference at about a foot from the ground, and from thirty-five to forty feet high. Let a trench, eighteen inches wide, be cut round each, at the distance of eight feet from the stem, and down to the subsoil, so as to divide every horizontal root at the inner side of the trench. Let this trench be left open round the first tree till the period of transplanting, but round the other two let it be filled again with the earth which had just been taken out of it. At the period of transplanting, let the three trees be removed with equal care, and planted in similar situations and soils, the whole operation being conducted in the same manner, with this difference only: in the first, let any new roots which may have formed at the cut extremities, in consequence of earth having accidentally fallen into the trench, be disregarded; in the second, let all the new roots which have formed in this situation be cut off; in the third, let them be preserved with as much care as possible. At the end of two or three years (and we can rarely judge sooner of the ultimate success of our operations), we shall find the whole to have succeeded alike; and it is evident that the first and second will have been removed with a saving of labour, and, therefore, at a cheaper rate, than the last. The length of time which should be allowed to elapse between the cuttings of the roots and the transplantation will vary with the season; after one wet season the trees will be as fit for removal as after two dry years."

8289. *Two bad methods of transplanting trees* are next described by Mr. M'Nab. By both these methods manure is applied to the roots of the trees previous to their removal. In the one case, the manure or compost is placed in a trench, cut round at three or four feet from the stem of the tree, and by the other it is laid on the surface of the ground all round the stem. Both methods are bad, from their producing an excess of vigour in the tree. By this, the constitution of the tree is brought into an artificial state, and therefore it is much less able to bear the shock of removal, than if it had been left alone. Enriching the soil about trees, after they have been removed, in order to assist them in regaining their previous vigour, is to be recommended; but, if this artificial enrichment is continued many years after transplanting, the tree will be thrown into an unnatural state of growth, which it could not continue without the continuation of the manuring. "There cannot be a doubt that a tree, taken up and transplanted without any previous preparation (even although the roots and branches are deficient), will make a better appearance, at the end of four or five years after removal, than one that has got the top-dressing will do in the same period, supposing all other things alike, both in transplanting and in subsequent treatment. We may be assured that it is a good practice to starve and stunt trees before removal, and to feed and encourage them, for a time, after they have been transplanted."

8290. *The truth of this doctrine* every gardener has experienced who has been in the habit of taking up plants growing in the open ground and putting them into pots or tubs. If the roots are cut at some distance from the stem some days previous to removal, the plant will receive no great check; but if, on the other hand, a vigorous plant be taken up at once without having its roots previously cut, it will suffer considerably, and, in all probability, lose a number of its leaves, and also its flowers. "Now this difference can only arise from the first plant having been checked in its growth, not from any advantage which it could derive from the formation of young roots between the preparation of the plant and its removal, because the roots are scarcely ever cut so short, at first, as to go into the pot, lest the check should be too sudden, but require either to be shortened a second time, or bent round in the inside of the pot; and, even in this last case, it is hardly possible to preserve any tender rootlets which may have been formed at or near the extremity of the old roots. The principal advantage of following this practice (which I know from experience to be a good one) must, therefore, arise from checking the plant in its growth before it is taken up. Were it necessary, other facts might be adduced to prove that, at least, one great advantage of cutting the roots of large trees previous to removal is derived from the check thus given, and, by consequence, that every measure taken to promote that vigour, previously to removal, must be injurious." (*Quart. Journ. of Agr.*, vol. ii. p. 828.)

8291. *The practice of Mr. Monro of Brechin* may be adduced as confirmatory of Mr. M'Nab's theory. During the winter of 1824, having occasion to transplant a number of trees, and being dissatisfied with the mode of preparation by opening a trench round the tree and filling it with loose soil, Mr. Monro selected an oak about twenty-five years old, large for its years, and prepared it in the following manner: — He formed a circular trench round the tree, and dug out the earth; but, instead of filling the trench with loose mould, he left it empty, and roofed it over with boards, covering over any opening between them with withered grass, and then putting over the whole one inch deep of earth. The tree remained a year in this state, and was transplanted in the winter of 1825. On reducing the ball of earth to proper dimensions for removing the tree, the old roots were found furnished with fibres, matted sufficiently to retain enough of earth to protect them during removal. The object which Mr. Monro had in view was, instead of encouraging the growth of fibres at the extremities of the amputated roots, as is done when the trench is filled in with loose soil, to have them formed within the ball of earth, and not on the outside of it. This he considered would enable him to remove the tree with a ball, which he never could accomplish by the other method, though he had practised it for five years, on from three to five hundred trees annually. When the trench dug round the tree is filled with loose earth, the young roots form in clusters round the ends of the old roots, and the tree, on removal, generally loses the whole of the earth which forms the ball. (*Gard. Mag.*, vol. ix. p. 218.)

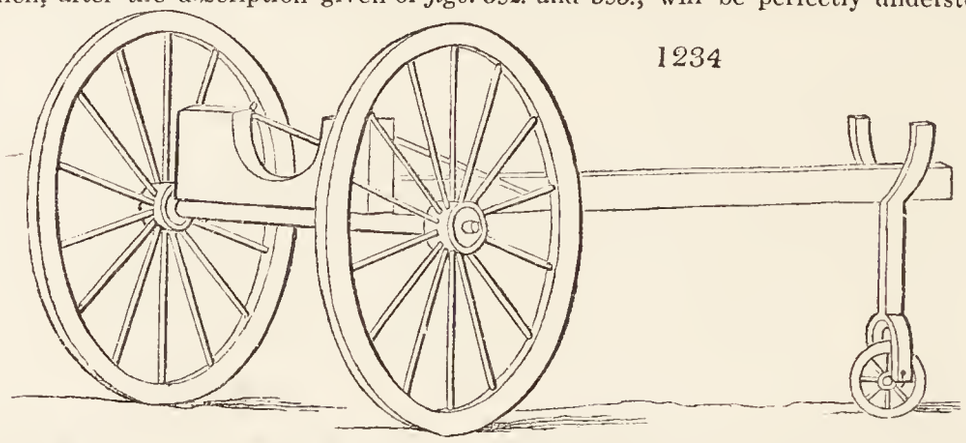
8292. *The opinion of Mr. M'Nab is further confirmed* by the practice which prevails in Belgium and France of planting large trees by the roadside. These trees are always of considerable size, and generally between two and three inches in diameter. When planted out, the head of the tree is cut off, leaving the trunk a bare pole. This bare pole is suffered to grow untouched for one or two years, after which all the branches are cut off below the strongest leading shoot, which is left to form the head of the future tree, and which, in a few years, becomes as straight and handsome as one not headed down, and far more vigorous. (*Gard. Mag.*, vol. ii. p. 226.) The trunks of trees so treated, observes Mr. Joseph Knight, become generally as straight as the mast of a ship, to the height of from thirty to forty feet. (*Ibid.*, vol. x. p. 8.)

8293. *Our opinion on this subject* is, that the mode of previous preparation by digging a trench round the tree, and filling it with rich mould, or by manuring the surface of the soil in which the tree grows, is worse than useless; and that checking the growth of the tree a year before removal, and heading it

down to the height of eight or ten feet, when removed, is the cheapest and best of all modes for general purposes where the trunk of the tree does not exceed from five to eight inches in diameter at the surface of the soil. For larger trees, or for trees which are short-lived, or for any description of tree where immediate effect is an object, we would still do nothing more than check the growth of the tree by cutting its roots a year before removal; and only make this difference after removal, that we would not cut off any, or, at all events, not many of the branches. With regard to trees which may be considered old, in the case of the beech, and in that of all the pine and fir tribe, and of most evergreens, we would cut off no branches whatever. We ground this recommendation as to old trees, the beech, resinous trees, and evergreens, chiefly on experience; it being found that these trees do not bear amputation well, either of their tops or roots.

8294.—3957. *The machine for transplanting large trees, in general use in England*, is represented by *fig.* 1234.; which, after the description given of *figs.* 592. and 593., will be perfectly understood by inspection.

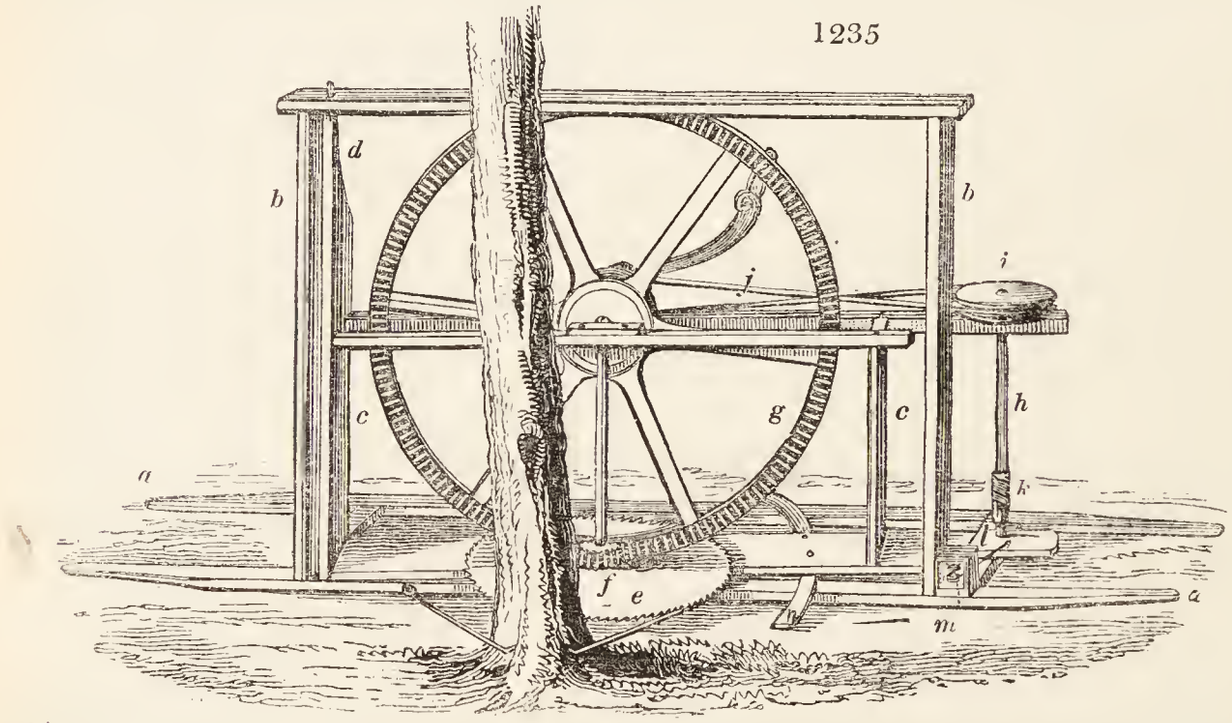
1234



8295.—3983. *Filling up blanks in plantations.* In Cambridgeshire, where the willow is grown extensively for basket rods, deaths take place occasionally among the stools. The mode of filling up the blanks thus occasioned is not, as might be supposed, by sticking in a cutting, as in the case of new plantations, because the shoots from that cutting would soon be choked by the surrounding shoots from the stools; but by inserting a rod at its full length, and allowing it to grow undisturbed for a year or two; when, having acquired an abundance of roots and a thick stem, it is cut down. Empirical practice is here in beautiful accordance with science. (*J. D.*)

8296.—4062. *Sawing machines for felling timber*, of four different kinds, will be found described in the *Highland Soc. Trans.*, vol. ix. p. 275. The most powerful of these appears to be a circular saw (*fig.* 1235.)

1235



which consists, first, of a ground frame (*a a*), in form of the common hand-barrow, eight feet and a half in length by two feet and a half in width; on one side of which is erected a vertical frame (*b b*), of three feet and a half in height. The second compartment comprehends a traversing frame or carriage (*c c*) about five feet in length, and two feet in height; the vertical bar (*d*) being prolonged upward, and having its top and bottom ends formed into pivots, on which the carriage, carrying all the working machinery, is made to swing. The saw (*e*), of twenty-four inches diameter, is fixed on the lower end of a vertical spindle, and immediately above it a bevelled pinion (*f*), which is driven by the wheel (*g*); the winch handle, by which the power is applied, is fitted upon the same spindle. The saw pinion and the wheel (*g*) are in the proportion of one to five, so that, when the handle is turned with the ordinary velocity of forty revolutions a minute, the saw will make 200 revolutions in the same time. In order to keep the edge of the saw in contact with the saw-draft, a vertical spindle (*h*), carrying the pulley (*i*), of one foot in diameter, is placed at the outward extremity of the carriage; the pulley (*i*) is put in motion by the band (*j*) passing over a smaller pulley on the winch axle. On the spindle (*h*) there is also fitted a small drum (*k*), capable of being disengaged at pleasure from the motion of the spindle by means of a clutch. The cord (*l*), which passes round the pulley (*m*), in the ground frame, has one end attached to the carriage; while the other end, being attached to the drum, is coiled upon it when revolving along with the spindle, thereby carrying forward the saw with a slow and uniform motion. When the operation is completed, the small drum is disengaged, and the cord is allowed to uncoil, while the carriage is moved backward to prepare for the next cut. For the support and guidance of the carriage, an iron segment (*n*) is fixed upon the lower part, which slides through eyes in the ground frame; and the machine is kept steady while at work, by two iron dogs (grappling irons), the hooks of which are driven into the roots of the tree. The certificates accompanying the model of this machine bear ample testimony to its successful application on the large scale; and show that it can be worked, and carried from tree to tree, by two men. The machine here described is calculated for felling trees from eight to twelve inches in diameter. (*Highland Soc. Trans.*, vol. ix. p. 276.)

8297. *Species and varieties of the larch.* That extensively cultivated by the Duke of Athol is the common white larch, *L*àrix europæ'a *Dec.;* but the following other species or varieties were tried: — 1. The Tyrol larch, with white flowers; those of the common variety being pink flowers. 2. The Tyrol larch, with white flowers; the cones also remarkable for their whiteness, and for being erect, not cernuous. The shoots of the Tyrol larch are generally stronger than those of the common larch; but the foliage of both kinds is similar. 3. The weeping Tyrol larch, a variety of the common, with pendulous branches; but distinct in botanic characters from the *L*àrix péndula, or black larch of North America. 4. The red larch of North America, or *L*àrix microcárpa. This species is remarkable for the great specific gravity of its wood, which is so ponderous that it will scarcely swim in water. Its cones are shorter or smaller than those of the common larch, its branches weaker, and its leaves narrower. 5. The Russian larch, raised from seed procured by the Duke from Archangel, about the year 1806. The bark is cinereous, not yellowish-brown; the leaves come out so early that they are liable to be injured by spring frosts. The *L*àrix péndula, or black larch of North America, and *L*àrix dàùrica of Dr. Fischer of Petersburgh, are distinct species, no examples of which exist at Dunkeld or Blair. (*Hort. Trans.*, vol. iv. p. 416.)

8298. As an *Appendix* to the chapter on Planting, we shall here give some account of the larch plantation of Athol and Dunkeld, from the *Transactions of the Highland Society*, vol. xi. p. 165. to p. 219. It appears that the late Duke of Athol planted 15,573 acres, which contained 27,431,600 plants. Of these 8,604,542 plants were larch. All these were planted in the slit manner, as by far the best. It is stated in that paper that the larch will supply timber fit for ship-building, at a great height above the region of the oak; and that, while a seventy-four-gun ship would require the oak timber of seventy-five acres, it would not require more than the timber of ten acres of larch; the trees in both cases being sixty-eight years old. The larch in the neighbourhood of Dunkeld grows at the height of 1300 feet above the level of the sea; the spruce at 1200; the Scotch pine at 700; and deciduous trees not higher than 500. The larch, in comparison with the Scotch pine, is found to produce three and three quarter times more timber, and that timber of seven times more value. The larch, also, being a deciduous tree, instead of injuring the pasture under it, improves it. It is remarkable that the woolly aphis, which affected the larch plantations in most parts of Scotland for a number of years about the beginning of the present century, never extended higher than about 600 feet above the level of the sea. The late Duke John the Second planted, in the last years of his life, 6500 Scotch acres of mountain ground solely with the larch, which, in the course of seventy-two years from the time of planting, will be a forest of timber fit for the building of the largest class of ships in his majesty's navy. It will have been thinned out to about 400 trees per acre. Each tree will contain at the least fifty cubic feet, or one load of timber, which, at the low price of 1*s.* per cubic foot, only one half of its present value, will give 1000*l.* per acre, or, in all, a sum of 6,500,000*l.* sterling. Besides this, there will have been a return of 7*l.* per acre from the thinnings, after deducting all expense of thinning, and the original outlay of planting. Further still, the land on which the larch is planted is not worth above 9*d.* to 1*s.* per acre. After the thinnings of the first thirty years, the larch will make it worth at least 10*s.* an acre, by the improvement of the pasturage, upon which cattle can be kept summer and winter. (*Highland Soc. Trans.*, vol. iii. p. 168.)

8299. *Soil for the larch.* It is an error to suppose that the larch will thrive in all soils and in all situations. There are many kinds of soils in which it will not thrive, and ought not to be planted. It has been found that, in soils which have been turned up by the plough, and which have borne white crops, the larch cankers. It cankers in wet situations also. In soils resting on a wet tilly subsoil, it decays at the heart, after arriving at forty years of age. In situations where water stands for a length of time about the roots, it becomes fogged, or covered with lichens. But in all rocky situations, and particularly those which are composed of mica slate, containing crystal of garnets, among the fissures and fragments of which they can push down their roots, larches thrive to admiration. The geognostic character of the country from Dunkeld to Blair is primitive. At Blair is gneiss, at Dunkeld clay slate, and the intermediate space is occupied by mica-slate: they lie conformably to one another.

8300. *Situation.* The advantages resulting from planting mountain ground appear at first sight, in the greater number of trees that may be supported on the acclivity of a mountain than on a surface equal to its base. Trees derive nourishment from the soil immediately around the place in which they are fixed; and, as the superficies of that soil must, of course, be greater on an acclivity than on the base, a greater number of trees will be there supported. Practically speaking, 100 trees, at six feet apart, can be planted on the hypothenuse of a right-angled triangle, whereas the base would only permit eighty at the same distance. Another and a great advantage derived from planting mountain ground is, that, on an acclivity, the trees expose a greater surface to the influence of the sun, and air, and rain, than they can do on a level surface. That trees derive much nourishment from the air, through the instrumentality of their leaves, there is no doubt. The experiment of taking the bark from fifty standing larches, in May, 1814, at Dunkeld, did not prevent their vegetation, and even forming wood for two years after. The outside trees in a forest are always the strongest. On an acclivity, they all possess the advantages of outside trees; and, at the same time, most of the shelter enjoyed by those in the interior." (*Highland Soc. Trans.*, vol. xi. p. 185.)

8301. *Nurses* were not used by the late duke in his larch plantation. The gardener, in the Duke's absence, planted some acres with a mixture of Scotch pine and larch; but so far were the former from nursing the latter, that at the end of seventeen years they had not attained a height exceeding three feet; while the larches which they were intended to nurse were from fifteen to twenty feet high.

8302. *The growth of the larch.* Taking the average height of an average larch, of eight years from the seed, at eleven feet, it will be nearly accurate to allow sixteen inches as the annual growth, till the tree is fifty years old, and after that only ten inches per annum for twenty-two years longer; as the length of the tree lessens in growth as the bulk of the wood increases. These data give a larch tree of seventy-two years of age a height of ninety-three feet four inches; a fair average, agreeing with actual experiment. The shoots of larches beyond thirty-five years of age are heavier, though they are not so long as those of younger trees. The larch, like the oak, puts forth two shoots every year, the one in spring, the other in autumn. The spring shoot has no lateral branches; the autumnal shoot pushes out like the spring one; but, at the time this process is going on, the spring one is throwing out lateral branches which are firm and woody.

8303. *In regard to the growth of the girth*, a larch tree, on an average, will acquire an inch in girth per annum, till it be twenty-four years old; and, from that time, till it has acquired the venerable age of seventy-two years, it will grow one inch and a quarter in girth every year; thus: —

In 24 years, it will be	2 feet in girth, at	1 inch per annum.
48 years more,	5 feet in girth, at	1¼ inch per annum.
In 72 years, it will be	7 feet.	

8304. *The larch begins to make wood* at twenty-four years of age.

At 50 years old it will contain		26 cubic feet of wood.
60	—	14 ditto more.
72	—	20 ditto more.
In all,		60 ditto, or one load of 50 cubic feet, and 10 feet more.

8305. *These results* correspond exactly with the quantities which the Duke obtained at these respective ages. Larch appears to be on its greatest increase for timber from fifty-seven to seventy-two years old. A larch containing fifty cubic feet, or one load of timber, is quite fit for naval purposes. At half that size it is suitable for every country purpose.

8306. *Thinning larch plantations.* The great object of the Duke, in planting the larch, seems to have been to raise timber for naval purposes; and, finding that larches grow to a great size at only twelve feet apart, he thinned accordingly. This distance gives 380 trees to the Scotch acre, or about one fifth of the 2000 originally planted. "The first thinning should consist of a light one of about one fifth of the whole, by removing only those trees that are of least value or worthless. After twenty-four years from the time of planting, the spines fall off the lower branches, which are, of course, no longer useful to the soil below. From twenty to thirty years old, then, the thinning is carried on so extensively, as to remove two thirds of that which was left standing by the first thinning. In thinning, it is necessary to observe that all the strongest and healthiest trees should be left, even if two or three of them should be closer together than twelve feet. These small clumps happening to light on a favourable situation, they will thrive well, as the air has access to each tree, around two thirds of its circumference. This thinning being delayed so long, the trees thinned out will be valuable for a variety of purposes. One of these purposes is the profitable use which may be made of the bark. The last thinning should be given when the trees are from thirty to thirty-five years old, which will leave from 380 to 400 trees per acre."

8307. *Pruning the larch.* Little or no pruning was used in the larch plantations at Dunkeld. The 380 trees left in the acre, it is observed, "will require a little pruning and trimming of the lower branches, in order to give head room to the cattle, which are to browse on the grass below. The whole prunings and thinnings will cost about 5*l.*, and their produce will fetch about 12*l.*, leaving a profit on them of about 7*l.* an acre." (*Highland Soc. Trans.*, vol. xi. p. 190.)

8308. *Thin planting the larch* is recommended by the late Duke of Athol, because it allows the lower branches to extend to a greater size; and on these depend the thickness of the base of the trunk of the tree, and the strength of its roots. He therefore seldom planted more than 2000 plants per acre, more especially in elevated regions.

8309. *The process of the thickening of the soil, and the improvement of the pasture, by the larch,* being very important in its results, it deserves to be particularly described. The lower and stronger branches meet together in six or seven years after planting, so as to form a complete matting over the ground. The air and light being excluded by them, all plants that are under them die. At the same time, the annual deposit of leaves from them, by means of decomposition, forms, in the course of time, a soil of considerable depth. At the age of twenty-four, the larches lose the spines on the lower branches altogether, and that is the natural mark of their being ready to be removed by thinning, to a considerable extent. On the air being readmitted by the removal of the trees, the surface of the new-made soil, wherever it has been formed, even among the rocks, becomes immediately covered with natural grasses, of which the *Hólcus móllis* and *H. nàtus* seem to predominate. These grasses continue to grow, and to thicken into a sward by the annual top-dressing which they receive from a continued deposition of leaves. The improvement of the natural surface of the ground for pasturage, by means of the larch, appears to be a property peculiar to this tree. This pasturage is quite capable of improving the condition of cattle either in winter or summer.

8310. *With regard to other trees effecting a change of the ground,* the following are the results of many experiments made by the Duke on the subject. In oak copses, the value of the pasture is only 5*s.* or 6*s.* per acre for eight years only in every twenty-four years, when the copse is cut down again. Under a Scotch fir plantation, the grass is not worth 6*d.* more per acre than it was before it was planted. Under beech and spruce it is worth less than it was before; but the spruce affords excellent shelter to cattle, either from the heat of summer or the cold of winter. Under ash the value may be 2*s.* or 3*s.* per acre more than it was in its natural state. But under larch, where the ground was not worth 1*s.* per acre, the pasture is worth from 8*s.* to 10*s.* per acre, after the first thirty years, when all the thinnings have been completed, and the trees left for naval purposes, at the rate of about 400 to the acre, and twelve feet apart. Nay, so impressed was the Duke of the value of larch as an improver of natural pasturage, that he makes a statement to show that the pasture alone, independent of the ship-timber on it, would increase the value of land, by increasing its annual rental, so that it itself would repay the whole outlay of fencing and planting, at five per cent. compound interest, thus: —

	£	s.	d.
3000 acres of land in its natural state, not worth above 1*s.* per acre, at 25 years' purchase, will give	3,750	0	0
Plants and planting, at 6*s.* per acre	900	0	0
2400 roods of fencing, at 5*s.* per acre	600	0	0
Sundry expenses, at 3*d.* per acre	37	10	0
	£5,287	10	0

5287*l.* 10*s.*, at five per cent. compound interest, for twenty-nine years, the period at which the land is fit to be begun to be depastured, gives 21,150*l.*; but 3000 acres, at an improved rent only of 6*s.* per acre per annum, at twenty-five years' purchase, yield 22,500*l.* (*Highland Soc. Trans.* vol. xi. p. 189.)

8311. *The value of larch wood,* exclusive of the value of the pasture under it, may be estimated in this manner: — Suppose the plantations are thinned out by thirty years to what they are to stand for ship-timber; that is, to 400 trees per Scotch acre; — suppose, after that period, the whole were cut down at the following respective ages; the value of the whole, per acre, at the different periods, would be as follows: —

	£
400 trees at 30 years old, at 2½ cubic feet each tree, = 1000 cubic feet, or 20 loads, at 1*s.* 6*d.* per foot profit, =	75 per acre.
400 trees at 43½ years old, at 15 cubic feet each tree, = 6000 cubic feet, or 120 loads, at 1*s.* 6*d.* per foot profit, =	450 —
400 trees at 59 years old, at 40 cubic feet each tree, = 16,000 cubic feet, or 320 loads, at 2*s.* 6*d.* per foot profit, =	2000 —
400 trees at 72 years old, at 60 cubic feet each tree, = 24,000 cubic feet, or 480 loads, at 2*s.* 6*d.* per foot profit, =	3000 —

The average of these prices would be 1381*l.* 5*s.* per acre; so that 1000*l.* per acre is not too high a calculation of the value of the Duke's larch plantations.

8312. *On felling large trees of larch,* care must be taken to use plenty of rope, and to take advantage of the direction of the wind; but a very windy day should be avoided. It was found, in digging the Scotch fir out by the roots from among the larch, that the ground was so much shaken about the roots of the larch, as to endanger their stability: ever after, the fir was cut over by the ground.

8313. *The seasoning of larch timber* is accelerated by stripping off the bark before felling. In May, 1815, the Duke experimented on fifty trees of larch at Dunkeld, that were growing in a situation, among other wood, that was nearly inaccessible for want of a road or path to it. In 1816 they were cut down and used for several purposes, and they appeared to be completely seasoned. They contained twenty-five cubic feet of wood each. Larch trees that had been only ten months cut down were built into a steam-boat in the river Thames, but they had not been seasoned enough, as the planks above water, near the deck, shrunk a little. In this case, however, the scantlings were made the same as of oak, which were of too slight dimensions for larch.

8314. *Uses of the larch.* These are very various. Larches have been grown by the Duke as nurses to spruce firs. The thinnings of larch plantations, "which take place from twenty to thirty years of their age, supply useful materials for various purposes. Posts and rails for fencing may be made either out of the tops or the trunks of young trees. While fir-posts and rails last only about five years, and are worm-eaten after that period, the larch-posts stand for twenty years, and never get worm-eaten.

But the trunks of young trees are preferable for this purpose to the tops, as they have less sap-wood In 1807 the Duke fenced a nursery-ground with young larch trees cut up the middle, made into a railing seven feet high. In three years after, the sawn side assumed a leaden grey colour, and in 1817 the whole railing was quite sound. Larch tops which had lain cut for four years, and were, of course, well worn, were found useful in filling drains where stones were at a distance, and they continued sound in them for many years. The larch was used for axles to different kinds of mills, from 1793 to 1802, and up to 1817 they continued quite sound, though constantly in water.

8315. " *For buildings*, too, the larch is found equally desirable. In 1779, the Duke built the shooting-box in Glentill, called Forest Lodge, the floors and joints of which were made of larch. The wood was under forty years old, and, as an experiment, some of the deals were cut up narrow, and others as broad as they could be wrought. In 1817 the narrow boards continued quite close together. After the bridge was thrown over the Tay at Dunkeld, the Duke altered the course of the great northern road to Inverness, which caused him to build a new porter's lodge, stables, and offices to Dunkeld House, near the new line of road. The whole wood-work of these buildings was executed with larch. They were finished in 1812. In 1813, part of Athol House was burnt down, and the repairs of wood, consisting of joists, floors, doors, and windows, were all made of larch. This wood was so red in colour that it looked like cedar. Several houses were also repaired in the town of Dunkeld with larch. At Dunkeld 271, and at Blair 170, larch trees had been used by 1817 for building purposes.

8316. " *The first attempt to use the larch for the purposes of navigation* was in the construction of fishing-cobles on the Tay in 1777. In 1809, 8491 cubic feet of larch timber were sent to Woolwich dockyard. The greatest quantity which was employed was in the repair of the *Serapis* store-ship, and the state of its soundness was favourably reported on in 1817. One beam of it was put into the large frigate *Sibylle*, in 1816, after it had lain six years in the dockyard. The next trial of larch in shipbuilding was in the Sir Simon Clerk, merchant vessel, of 375 tons register, built by Messrs. Symes and Co. of Leith, in 1810. They got eleven trees, containing 1066 cubic feet, and they were formed into the first four or five planks, of three inches and a half in thickness, on the bottom of the vessel from the keel upwards. This vessel was soon afterwards taken by the Americans, and no account could therefore be got regarding the durability of the timber."

8317. *The elasticity, durability, strength, and resilience of larch timber, relatively to oak and Baltic fir*, has been determined by experiment. The details, in a tabular form, will be found in the article quoted; and the following are the general results: — The Riga timber and American white pine are about one fifth part less strong than the larch. The larch is superior to the oak in stiffness, in strength, and in resilience, or the power of resisting a body in motion; and it is inferior to Memel or Riga timber in stiffness only. The larch tree, while growing, may be uprooted by wind, but it seldom breaks over by the stem, either by wind, or a weight of snow lodging on its upper branches. The durability of the timber, in every stage of its growth, is superior to every other, even to oak itself. When speaking of all the above properties as belonging to the larch, it is always to be understood to be grown in an alpine region on dry soil. In low rich soils the wood is of a very inferior character.

8318. *The large roots of larch trees fit for ship timber* may be used as knees; and this was first done at Leith in 1811. These roots have been used for the same purpose on various occasions since that time.

8319. *The larch has been tried for masts;* but, the vessels which were fitted up with them having left the Tay, it is uncertain how far larch timber will answer for that purpose. It was the Duke's practice " to plant spruce in all the wet parts of the ground, which he planted to the amount of about one tenth, expressly for the purpose of raising masts and spars, for which he conceived the spruce peculiarly well adapted."

8320. *The larch as piles.* Two hundred and twenty-three trees, forty-two years old, were converted into piles, and driven into the river Thames in the front of the works of the Woolwich dockyard in the year 1810. A report on their state was made in 1817, when they were found to be as fresh as when they were driven in. It is impossible to peruse this paper without being strongly impressed with the patriotic views entertained by John, the second Duke of Athol. Living in a period when the country was involved in a war with almost all other countries, he dreaded, in common with other patriots and statesmen, a scarcity of timber fit for naval purposes, and he contemplated the idea of planting so extensively as to provide against this scarcity for centuries to come. In all his plans and operations we see little or nothing of the merely selfish principle at work; his great object was to provide a regular yearly supply of ship timber, the commencement of which supply could not take place till many years after he was dead. The following table shows the Duke's own calculation of the supply which would be afforded by the woods of Athol, from 1832 to 1904.

12 years	cutting from	1832	to 1844	will give	1,250 loads	annually from	50 acres.
10	—	1844	- 1854	—	8,000	—	300
8	—	1854	- 1862	—	18,000	—	650
8	—	1862	- 1870	—	30,000	—	1050
16	—	1870	- 1886	—	52,000	—	2000
18	—	1886	- 1904	—	120,000	—	3000

8321. *The relative duration of timber* has been thus determined by M. Hartig, an eminent German professor of forestry. Small posts of lime tree, black American birch, alder, and trembling poplar, inserted in the soil, decayed in three years; the common willow, horsechestnut and the platanus in four years; the purple beech and the common birch in five years; the elm, the hornbeam, the ash, and the Lombardy poplar, in seven years; the acacia, the oak, the Scotch pine, the Weymouth pine, and the spruce fir, at the end of seven years were only decayed a little to the depth of a quarter of an inch; the larch, the common juniper, the Virginian juniper, and the arbor vitæ, were, at the end of the same period, untouched by decay. Thin boards of the same woods decayed in the following order: platanus, horsechestnut, lime tree, poplar, birch, purple beech, hornbeam, alder, ash, the maple, the spruce fir, the Scotch pine, the elm, the Weymouth pine, the acacia, the oak, and the larch. (*L'Agronome*, tom. i. p. 315.) It thus appears that the larch, whether as posts with the bark on, or sawn up into boards, is by far the most durable of our timber trees.

8322. — 4138. *Machinery and utensils necessary for cider making.* In the *Encyclopædia of Cottage, Farm, and Villa Architecture* this subject is treated at much greater length; and not only all necessary plans, elevations, and sections are given, but detailed specifications for the execution of the work, and detailed estimates of the cost of every part.

8323. — 4267. *The frequent-drain system.* The great importance of thorough drainage, and deep ploughing, has lately been placed in a striking point of view, by James Smith, Esq. of Deanston, in Stirlingshire, in an article contained in a *Report of the Exhibition of Agricultural Productions*, &c., published, in 1832, by Messrs. Drummond, seedsmen, of Stirling. Mr. Smith observes, " that the practical drainers of the old school cannot see how a field should be drained, unless by deep cross drains, to cut off the springs. The portion of land, however, wetted by water springing from below, bears but a very small proportion to that which is in a wet state from the *retention* of the water which falls upon the surface in the state of rain; and a vast extent of the arable land of Scotland and England, generally esteemed dry, is yet so far injured by the tardy and imperfect escape of the water, especially in winter, and during long periods of wet weather in summer, that the working of it is often difficult and precarious; and its fertility is much below what would uniformly exist under a state of thorough dryness. A system of drainage, therefore, generally applicable, and effecting complete and uniform dryness, is of the utmost importance to the agricultural interests, and, through them, to all the other interests of the country. By the system here recom-

mended, this is attained, whilst the expense is moderate, and the permanency greater than on any other system yet known. The drains, as applied in the carse, have been named *wedge drains*, from their form, and being filled with wedges or keys to preserve the opening in their bottoms. They are sometimes called *furrow drains*, from their being placed under the water furrows of the ridges; but these terms give no exposition of the principle upon which the effect of this mode of draining depends. The principle of the system is, *the providing frequent opportunities for the water rising from below, or falling on the surface, to pass freely and completely off;* and, therefore, the most appropriate appellation for it is *the frequent-drain system.*"

8324. *Main drains.* In proceeding to apply this system of drainage to land, the first object is to obtain a sufficient fall, or level, as it is commonly termed, for a main drain to receive the water flowing from the various smaller or ordinary drains. This drain should be directed along the bottom of the chief hollow or valley of the grounds, where the whole or greater portion of the drains can be led into it. If any lesser hollows occur in the extent of surface, they must also have their proportional mains or leaders. The bottom of the main should be at least three feet; and, if possible, three feet and a half or four feet under the surface where it passes along; and it should have throughout as uniform a fall as the nature of the ground will admit. It should be flagged at the bottom; or, where flagstones are expensive, built as an inverted arch, to prevent the possibility of rain, &c. washing away the earth under the side building. The dimensions necessary will depend on the fall or declivity, and the area of land from which the drain has to receive water. With a fall in no place less than 100 yards, a drain ten inches wide, and eighteen inches deep, will receive the rain water from 100 acres. It is of great importance to make the openings of such drains narrow and high; as they will thus require smaller bottoms and covers, and be less liable to give way; the current of water being also more confined, mud and sand will be less apt to settle in the bottom. Let the sides be smoothly and securely built with flat stones, either with or without mortar; and let strong flat covers be placed over the drain; or, where such are not to be found, a rough simple arch, with thin stones and mortar, may be built, packing the haunches of the arch well up to the sides of the cuts with earth beaten in firmly. Where lesser hollows occur, crossing the fields, it is necessary to cut submains along their bottoms, about three feet or three and a half feet deep, and having openings of suitable dimensions formed by stone couples (two flat stones placed together at the top and apart at the bottom, like the two sides of a triangle), or with drain tiles; or, where a very large flow of water has to be provided for, with inverted tiles, and covering tiles placed above the bottom one, or with larger tiles made on purpose.

8325. *Submain drains.* There should be a cross submain at the bottom of every field or stretch of drains, to receive the water from all the parallel drains; and such submain drain should always be cut six inches deeper than the drains running into it, that the water may have a free drop, which will prevent the lodgment of mud or sand at their junctions or mouths. Open cuts or ditches, either as mains or submains, should never, except from necessity, be adopted, being apt to get filled with mud and grass, by which the water is thrown back into the drains, and often chokes them; besides, the loss of land, annoyance in ploughing, constant expense of cleaning, and unsightly appearance of such drains, are serious objections.

8326. *Parallel or frequent drains.* Having thus provided a main drain, with submains flowing into it, matters are prepared for setting off and for executing parallel or frequent drains in the field. These drains can be executed at any season when the weather will permit; but spring and summer are most suitable for the work. It is best to execute the drains when the field is in grass, as they can then be cut in all kinds of weather, and in a more cleanly manner.

8327. *In setting out the drains,* the first object for consideration is, the nature of the subsoil: if it consists of a stiff strong clay, or a dead sandy clay, then the distance from drain to drain should not exceed from ten to fifteen feet; but if there is a lighter and more porous subsoil, a distance of from eighteen to twenty-four feet will be close enough. When the ridges of the field have been formerly much raised, it suits very well to run a drain up every furrow, which saves some depth of cutting. At whatever distances the drains are placed, they should be run parallel to the ridges, which is commonly in the steepest descent. They should always be run quite parallel to each other, and at regular distances, and should be carried throughout the whole field *without reference to the wet or dry appearance of portions of the field;* as uniform and complete dryness is the object, and land, which may be considered dry in its natural state, will show wet when compared with properly drained land. A three-feet drain should be carried along the ends of these drains at the top of the field, and at a distance of about nine feet from the fence, especially if it is a hedge fence. Such a drain is necessary for the growth of the hedge; but if made nearer than nine feet, the roots are apt to get into the drain, and choke it up by degrees. It is of importance to be accurate in setting out the drains as described, as it secures uniformity of dryness, and in all future operations, or at any time, it is easy to ascertain the line of any drain.

8328. *Excavation.* The lines of drains having been marked off in the field, the drainer begins by cutting with a spade on a line; then removing the first layer to the depth of a spitful of about thirteen or fourteen inches wide all along, another follows with a narrower and tapering spade, made for the purpose, taking out another layer; and, when picking becomes necessary, a third man follows with a pick; and a fourth with a large scoop shovel to cast out the earth, and a smaller scoop shovel is used to clean out the bottom, which should be cut as narrow as will allow the last drainer a footing, generally about three or four inches. From two to two feet and a half from the surface are the best depths for such drains; the latter always to be preferred. The bottom should be cut as straight and uniform as possible, so that the water may flow freely along at all places, and it is better to cut a little deeper when there is any sudden rise of the surface than to follow it; and where sudden hollows occur, the cutting may, on the same principle, be less deep: attention to this also admits of after straightening or levelling of the surface, without injury to the drains. The workmen, in cutting, should throw the earth to the right and left from each alternate drain, as that allows the plough to go regularly and fully occupied *boutings* (a Scotch term for a rotation or traverse of the plough) in filling in the earth, whilst each alternate ridge or space is left for getting in the stones free from the earth thrown out.

8329. *Filling.* The stones may either be laid down at intervals, by the sides of the drains, to be there broken; or, being broken in masses at some convenient spot, can be brought by the carts, ready to be filled in. No part of any drain should, if possible, be filled in, till the whole line is cut out and inspected, but the sooner drains are filled, after having been cut, the better. Sometimes, when there is much tendency of the sides to fall in, it becomes necessary to fill in going along. Cutting at the end of summer, when there is little water in the soil, or in a dry season, saves much of this. In soft or sandy bottoms, by cutting the drains to half the depth in the first instance, and allowing them to remain in this state until the water has drained from the upper stratum of the soil, the lower part may be cut out with more safety from falling in. The stones covering the drains should not be filled in nearer to the surface than eighteen inches, leaving sixteen inches free for deep ploughing.

8330. *Covering the stones.* The upper surface of the stones having been made straight and uniform, the whole should be neatly and closely covered with thin turfs, cut from the adjoining surface, or brought from some suitable place. Strict attention to the correct execution of this operation is of the greatest importance, as many drains are ruined at once, from the running in of the loose earth. Thick turfs are objectionable, from the difficulty of getting them to fit close. Straw, rushes, broom, whin, and other like material, are very objectionable, affording no certain or uniform security, and forming a receptacle for vermin. Peat may be used to advantage. Where the deepest ploughing has been executed, there should always remain a firm crust of earth undisturbed over the stones of the drain; and no surface water should ever have access to the free way of a drain by any direct opening, but should find its way, by percolation or filtration, through the subsoil, and should always enter by the sides of the drains. For this

purpose, it may be of advantage to tread or beat down closely the first two inches of soil put over the turf, in order to form the permanent crust.

8331. *The cost of executing such drains* varies, of course, according to circumstances: the cutting cost (in 1832) from 1*s.* 6*d.* to 2*s.* 6*d.* per rood of thirty-six yards, according to the hardness of the subsoil; the stones, if collected on the adjoining fields, will cost from 1*s.* to 1*s.* 6*d.* per rood, the breaking from 9*d.* to 1*s.* per rood; about one and a half cubic yard of broken stones will fill a rood of a well-cut drain; the putting in of the stones may be calculated to cost about 3*d.* per rood, and the turfing about 1*d.*; the filling in of the earth over the stones with the plough will cost about 1*d.* per rood. The whole cost, per rood, of common drains, may be taken at 4*s.* 8*d.*, or, including a charge to cover proportion of main drains, 5*s.*

8332. *The following table* exhibits the cost per Scotch acre of draining in this method, at various distances between the drains; and as this method of draining forms a permanent improvement of the land, it is presumed the proprietor should defray part of the expense. The table is constructed to show how much it will cost the landlord in money to do the cutting, carrying, and (when necessary) breaking of stones, filling in, and turfing; and how much the horse-work, &c., which can be performed by the tenant, will cost, charged at the ordinary rates: —

Subsoils to which the Distances are applicable.	Distance between the Drains in Feet.	Roods per Acre.	Cost per Rood to Landlord.	Cost per Acre to Landlord.	Cost per Rood to Farmer.	Cost per Acre to Farmer.	Total Cost per Acre.

8333. *Remarks.* In cases where time or capital are wanting to complete the drainage, each alternate drain may be executed in the first instance; and the remainder can be done the next time the field is to be broken up. After the drainage has been completed, a crop of oats may be taken from the field; and immediately after that crop is off the ground, the field should be gone thoroughly over with the subsoil plough, crossing the line of drains at right angles.

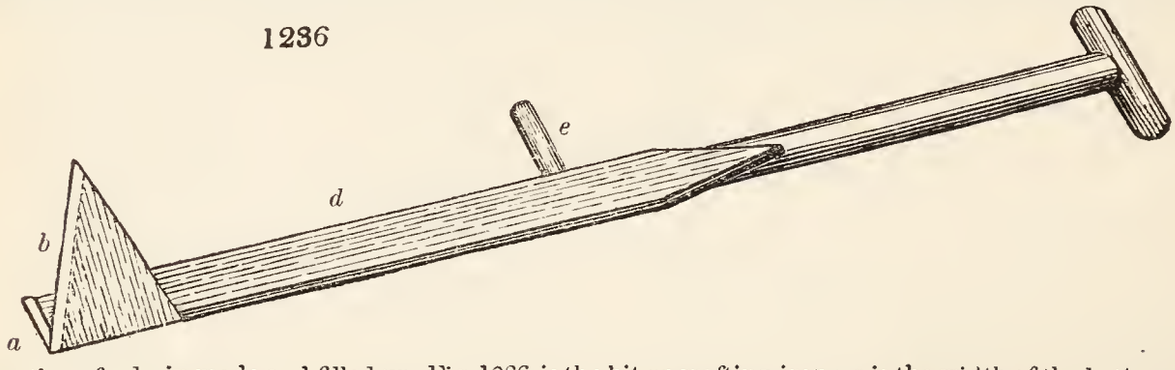
8334. *The subsoil plough* has been constructed on principles appearing the best fitted to break up the subsoil completely to a depth sufficient for most thorough cultivation, say fourteen to sixteen inches, allowing the active soil still to remain on the surface; to be of the easiest possible draught, in reference to the depth of furrow and firmness of the subsoil; and to have strength and massive weight sufficient to penetrate the hardest stratum, to resist the shocks from fast stones, and to throw out all stones under 200 lbs. in weight. All this has been accomplished, and practically proved, over an extent of at least 200 acres of various soils. This plough requires four good horses, an active ploughman, and a lad to drive the horses and manage them at the turnings. Six horses, yoked three and three abreast, may be necessary in some very stiff or stony soils. A common plough drawn by a pair, goes before the subsoil plough, throwing out a large open furrow of the active soil. The subsoil plough following, stirs up thoroughly and breaks the bottom, when the next furrow of the active soil is thrown over it; the stones brought to the surface by the subsoil plough being thrown aside, on the ploughed part of the land, by a boy or lad; and so on, till the whole field is gone over. The boy should carry a bag of wooden pins, that he may mark the site of the large fast stones which the plough cannot throw out, and which must afterwards be dug out with the pick, and, perhaps, blasted. This large plough is a sort of horse-pick, breaking up without raising to the surface the subsoil. Channels are thus regularly formed for the water to flow from all parts towards the drains. The atmospheric air being also by this means freely admitted to the subsoil, the most sterile and obdurate clay becomes gradually ameliorated, and the common plough may ever after be brought to a depth of from fourteen to sixteen inches without obstruction; and with the power of three horses yoked abreast, and managed with ease by the ploughman, without any person to drive. By being thus yoked together, and near the point of resistance, the horses have great power; and, the furrow turned over being broad in proportion, nearly as much ground will be gone over in a day, as with a plough and a half drawn by a pair of horses. The cost of subsoil ploughing an acre may be estimated at 30*s.*, being one sixth of what a similar depth would cost with the spade; and, upon the whole, as effectually done. A subsoil plough with apparatus cost, in 1832, from 7*l.* to 8*l.*

8335. *The effect of this mode of draining and deep working on close-bottomed land* is quite wonderful. After one turn of green cropping, with the usual application of lime and dung, the formerly scanty sterile surface soil becomes a deep rich loam, carrying, without fail, crops of wheat and barley, producing from nine to twelve bolls per acre of wheat, and from eight to twelve of barley; the hay and pasture following being also very fine. When fields have been thus dried and worked, it is recommended to plough them at all times without ridges, or water furrows, preserving one uniform sheet of soil over the whole field.

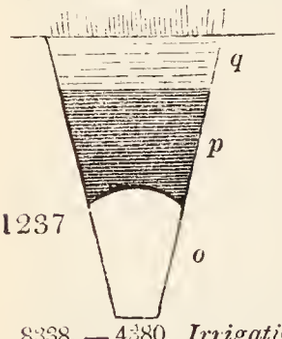
By this means every superficial inch is allowed to be productive. There is no carrying away of the surface by accumulated currents of water; and the water falling as rain, is left to percolate through the soil where it falls, thereby uniformly enriching the whole extent. There is a powerful process of nature much facilitated by complete draining and deep working, viz., the constant circulation of air to and from the bottom of the soil, produced by the constantly varying relative temperatures of the atmosphere and the earth. When heavy rain falls, the air is completely expelled from the interstices of the soil, the water taking its place. Also, when the rain has ceased to fall, the water gradually subsides to the level of the drains, or, at all events, to the level of the bottom of the subsoil that has been moved by the plough, and fresh air takes its place throughout the soil; thereby promoting doubly a chemical action vastly conducive to the decomposition of the soil and the manure it contains; and, of course, to the nourishment of plants. When land is uniformly and completely dry and deep in the soil, it is more easily wrought; it can be wrought at any time when it does not rain; it comes to a state proper for sowing earlier, and more uniformly; a circumstance of great importance in our climate: it affords a wide and uninterrupted range for the roots of plants; it resists the evil effects of long droughts, as well as of long periods of wet; it never honeycombs, as it is called; it seldom throws out plants of any kind in frosts: it never suffers from the treading of cattle in removing the green crop; for, although apparently puddled or poached on the surface, yet, being dry below, a single ploughing restores the soil to a proper tilth; and it gives an earlier harvest, and affords a dry bed for cattle when in pasture. In the conclusion of his article, Mr. Smith observes, that the subject of thorough under-draining, and of deep ploughing, is one of so much importance, and so extensive in its parts, that volumes might be written on it to the advantage of the country. (*Report of Drummond's Agricultural Exhibition, &c.*)

8336.—4295. *Plug or clay draining* is performed chiefly in pasture land, by first digging out a drain from eighteen inches to two feet deep, two inches wide at the bottom, and about one foot wide at the top. In the bottom of this drain is placed what is called the suter, or plug, which may be two or three feet in length, one inch and three quarters wide at the bottom, and four inches wide at the top. To one end of this plug is attached a chain, about two feet in length, which is connected with a lever for drawing the plug forward. The drain being dug out, and the plug being put in its bottom, the excavated clay is then firmly rammed over it; when this is done, the plug is moved forward by means of the lever, and the same operation of ramming is repeated, till the whole length of drain is filled in. The drain is completed by replacing the surface turf as it was before the drain was dug out. This mode of draining is described in the *Quart. Journ. of Agr.*, vol. iv. p. 501., by W. J. Evans, Esq., who says "that he has executed in this manner, during three years, more than 400 miles of clay drains, to his entire satisfaction." "Pasture land," he says, "which had been before deluged by surface water, has undergone an entire change of character." The implement, *fig.* 1236, is used in clearing out the bottom of these drains; and *fig.* 1237. is

1236



a section of a drain made and filled up. Fig. 1236. is the bit or grafting-iron; *a* is the width of the bottom, one inch and three quarters; *b*, the side bit, length of cut six inches; *c* is the width of the back of the side bit, worked out of the main bit, which must be of the best tempered steel, four inches and a half; *d* is the length of the main bit from the step to the bottom, one foot six inches; *e* is the treading step; and *f*, the handle, which is about the length of a common spade handle. Fig. 1237. is a section of a main drain, two feet deep, filled up again; *o* is the waterway left open, eight inches and a half high; *p* is the rammed clay above the suter, or plug, nine inches deep; and *q* is the returned turf, with the grassy side uppermost, six inches and a half thick. (*Quart. Jour. Agr.*, vol. iv. p. 503.)



1237

8337.—4320. *Embankments.* An essay will be found in the *Highland Soc. Trans.* (vol. viii. p. 97.), in which are enumerated all the books, or articles, which have appeared on the subject in the English language up to 1828, the period at which the essay was written. In the same work (vol. viii. p. 91.) will be found a section and description of an embankment formed by rows of piles, filled in between by furze, and employed to direct the course of a river.

8338.—4380. *Irrigation.* An excellent practical work on this subject, and on draining, *Stephens's Practical Irrigator and Drainer*, has reached a second edition since the publication of this Encyclopædia. Any thing new in such a work was not to be expected; but, being entirely of a practical nature, and by a practical man, it may safely be recommended as one of the best books on the subject.

8339.—4406. *Sluices, trunks, and valves for embankments* are now made of cast iron, on an improved principle; and, when properly fixed in by a mass of masonry and cement, they are found to retain the water of a pond, and admit it at pleasure, with as much accuracy and ease as a brass cock does the contents of a beer barrel.

8340.—4485. *Artesian wells*, or those produced by boring, are so named from their having been first used in the neighbourhood of Artes in France. Upon a review of the appearances observed in these wells, it is quite evident that they must always succeed where an inclined stratum of a fissured or porous limestone, or other porous stone, is included between two waterproof beds of clay; one of which sets a limit to the sinking of the water downwards, and the other prevents it from rising above the surface. The existence of such a cover is evinced by all boring works. A waterproof stratum of clay must always be penetrated, before reaching the spring water: and it may easily be conceived that the undermost layer is never wanting. Although, for the most part, some thinner strata of limestone supply its place, yet the strata, which conduct the water, always contain it in crevices, which are much more numerous on the surface than in the centre of the beds. Thus there is a demonstration, as in a boring work at Blengel, that, even in the limestone itself, beds of clay occur. From these circumstances it is easily explained how we can never hope to sink Artesian wells in granite, gneiss, porphyry, serpentine, &c. Even in schistose mountains, it would not be advisable to sink these wells, because, if water were found there, it would be very easily impregnated with sulphuretted hydrogen, from the abundance of pyrites occurring in these strata, and thus be unfitted for many uses. Limestone, on the contrary, which is very insoluble, experience teaches us, yields a very pure water. These observations especially relate to the Pas de Calais.

8341. *Other districts*, where water has been bored for, show a similar geognostic constitution to the Pas de Calais. M. Garnier, in his *Manuel du Fontanier-sondeur, &c.*, notices this, with regard to Boston in America, and Sheerness in England. London (where many sugar-works, distilleries, and breweries

have, for a long time, been principally supplied with water from Artesian wells) lies in the middle of a basin-shaped hollow, the fundamental rock of which is a limestone belonging to the chalk formation; which also forms the heights in the vicinity, and which is covered with clay, though at times not immediately. The wells, which are not sunk to this London clay, give abundance of clear, but mostly very hard, water; while those which penetrate through the London clay, into the subjacent plastic clay, a formation immediately covering the chalk, and consisting of alternating beds of sand, clay, and boulders, yield a very soft and pure water, which, on piercing this clay, often ascends with such violence that the workmen have scarcely time to escape. Here the plastic clay seems to be either the conducting medium, or the reservoir of the water yielded by the chalk. Paris is known to be situated in a district whose geognostic relations are almost identical with those of London, and therefore we cannot wonder that there, as well as in many other parts of the north and east of France, Artesian wells may everywhere be sunk; nor can we doubt of the extension of this very useful discovery. (*Jameson's Phil. Journ. for July*, 1830.)

8342. *We must not, however, expect to be able to sink Artesian wells in every description of country*, as has been thoughtlessly asserted. On the one hand, the nature of the ground sometimes absolutely prevents it, as in granite districts; and, on the other hand, it is possible that a perforation, if made too near a bored well affording water, may not yield any; should the latter, for example, be fed by a subterranean current, in place of being supplied by a sheet of water; or should the perforation be made upon the extremity of a basin with inclined strata, resting upon a formation of a very different nature. M. Garnier's *Manuel du Fontanier-sondeur* contains all that can be desired on the subject of boring these wells. (*Ibid.*)

8343. *General observations on Artesian wells.* Great subterranean sheets of water exist at various depths. These sheets are more commonly met with in the plane of superposition of strata of different formations. They, however, frequently occur at various heights in the great masses of earth; such as those of clay, chalk, and even marine limestone containing cerithia, when these masses are entire, and of great thickness. According to the slope, the undulations, or the declivities which are presented by the plane of superposition of the permeable deposits in which the waters flow between impermeable strata, these great sheets of water are met with at all depths; but it is impossible to lay down any constant rule with respect to them. (*Ibid.*)

8344. *In order that these waters may be capable of ascending*, it is necessary that the formations among which they occur be entire, in the state in which they were originally deposited; and that they be not intersected by large valleys, or deep ravines, through which the waters would find a free and easy exit.

8345. *It would be in vain to search for springs in deposits which, at no great distance from the place of boring, are intersected by deep valleys*, or when the formations are internally crooked, filled with tortuous separations, and greatly disturbed, whether by the contraction attending the desiccation of the mass, of by internal shocks, swellings, or earthquakes; or, lastly, when these Neptunian formations, such as plastic clay, chalk, oolite, and shell-limestone, are raised up, and present precipices at the surface. In such localities, we need not expect success in boring for springs, unless by penetrating deeply into the mass of the chalk, in search of the sheets of water in its lower part; or even by traversing it entirely, in order to come upon those in the clays, oolites, and shell-limestones; or, lastly, unless by penetrating deeply into the latter, when they happen to be raised to the surface, and to present cliffs, or are intersected by valleys of greater or less depth.

8346. *In a country composed of elevated plains*, if, in place of boring to the necessary depths for reaching the different water-sheets which are commonly the most abundant, and, at the same time, those which rise highest, the boring is stopped at higher levels, less distant from the surface, it is more than probable that the ascending waters will stop more or less beneath the surface of the ground, according to the depth of the borings. When this occurs, we ought to be far from considering the operation as having failed; because in this case the water does not rise above the surface, and in most instances, according to the localities and the nature of the ground, steps may be taken to remedy the deficiency. Thus, for example, when the water of a boring only rises to within a certain number of yards from the surface, but in sufficient quantity, it might be conducted from the point to which it reaches, by a small gallery, into some neighbouring well, or into one dug on purpose; and there might thus be produced a kind of artificial fall, which might be employed to make the water ascend to the surface of the ground, and even beyond it, by employing for this purpose either the hydraulic ram (bélier hydraulique), which would always give a third of the volume of water, or a wheel, which might be placed at the point of the fall, and which, working a pump suitably placed, might raise the third, or perhaps even the half, of the volume of water; or, in short, any other hydraulic machine of the kind. But these means would be practicable, only in so far as the wells into which the waters should be precipitated, might not allow them to run off into strata of permeable deposits.

8347. *Circumstances which it is necessary to examine and appreciate before resolving upon boring a well.* It is necessary to examine the physical constitution or the nature of the ground, and the disposition of the surface of the country, with reference to the mountains which overlook it, the valleys by which it is intersected, and the springs which rise in those valleys. The latter it is particularly necessary to examine, before deciding upon boring a well, as many of them are natural wells. It is of importance to select a fit person for boring; the art not being merely mechanical, and such as can be practised by *any borer*. Besides attending to these circumstances, it is necessary to be possessed of perseverance and courage, which will lead us to disregard the delays and difficulties often unavoidably connected with the operations of boring. (*Héricart de Thury, as quoted in Jameson's Journal for July*, 1830.)

8348. *Boring for water in deep sand.* Mr. David Greenley of London has been lately (August, 1834) very successful in obtaining "an abundant supply of pure water," at Diss in Norfolk, at a depth of upwards of 600 feet below the surface. A well had been previously sunk in the same place; but, in consequence of an immense quantity of sand rising whenever the pump was worked, it was almost useless. (See *Arch. Mag.*, vol. i. p. 210.)

8349.—4524. *Rending rocks or stones.* A newly invented apparatus for this purpose has been brought into notice by Mr. D. Millar, road contractor and builder in Edinburgh. The apparatus appears to be a more efficient boring instrument than any hitherto in use. It is calculated to bore or tap to the depth of 100 feet or upwards, and may be put in operation either by manual labour or steam. (*Scotsman*, Feb. 22. 1834.) An instrument for the same purpose was invented by Mr. Mallet of Dublin in 1832. Mr. Mallet's object was to split all rocks that could be separated into laminæ, by the application of male and female screws; instead of blasting, as heretofore practised, with gunpowder. The process is as follows:—Jumper holes are formed in the direction of the proposed fracture, as at present; but, instead of filling them with gunpowder, a split female screw is inserted in each hole, and the fracture is effected by the insertion of a conical or male screw. (*Arch. Mag.*, vol. i. p. 93.)

8350.—4541. *Draining and bringing into cultivation moss-lands or peat-bogs.* The Liverpool Agricultural Society having awarded its premium to Mr. Reed, late of Chat Moss, but now a professional drainer, we give the following as the essence of his paper. We may premise that we had the pleasure of inspecting Mr. Reed's farm at Chat Moss, near Liverpool, in August, 1831, and were much gratified and instructed by what, when there, we saw and were told by Mr. Reed.

8351. *Draining.* The water, to a considerable depth from the surface, being held in a great degree by capillary attraction, drains should be frequent, and more or less distant according to their depth. Open drains to divide the fields may be placed at any distance not exceeding 100 yards. The covered drains should run at right angles to the divisional drains. Sixty-six yards, or three chains, Mr. Reed has

found the best width between the open drains; and, consequently, as the covered drains are at right angles to these, their length will be sixty-six yards. The open drains may be four feet wide at the top, from three feet six inches to four feet deep, and fourteen inches wide at the bottom. The covered drains should not be more than five or six yards apart, and three feet deep. No material is wanted to cover them but the moss itself. "The form should combine the principle both of the shoulder and the wedge drain, and the somewhat square clod, which is first taken out, when dried to a certain extent by the weather, becomes the cover."

8352. *Preparing the surface.* "Moss, or peat bog, is not a soil, but an accumulation of dead, dying, and living plants growing in water." To form a soil, therefore, it is necessary to destroy, to a certain depth, the original structure of the moss, both for the purpose of destroying vegetation, and facilitating the passage of the water to the covered drains. Digging is perhaps the best mode of destroying the structure of the moss, and afterwards, a cutting machine formed by fixing circular knives on the cylinder of a common roller, may be applied. In due time, the surface may be harrowed, and afterwards manured, and sown with a crop. Any description of earth is useful, as tending to consolidate the moss, and to facilitate its decomposition; but, to obtain a good crop the first year, putrescent manure in a considerable quantity is absolutely necessary.

8353. *After cultivation.* "Manure of some sort being applied, almost any description of crops may be had; but potatoes are perhaps the best article to begin with; 2d, wheat; 3d, clover, without grass seeds; 4th, oats. The rotation may be varied, so as to include almost every crop."

8354. *The preparation of coke or charcoal from peat or moss* has been effected in different parts of Scotland, and in Ireland, and the charcoal thus produced has been found superior to many kinds of coal for smelting iron, and the use of smiths' forges. This arises from the total absence of all sulphuric matter in the peat, which renders it almost equal to the charcoal of wood, to which it is well known the Swedish iron owes its principal excellence. The charring of peat for use in smelting iron has been strongly recommended as a means of giving employment to the labouring population. (See *Brit. Farm. Mag.*, vol. v. p. 360.)

8355. — 4557. *In improving moist lands where manure cannot be obtained*, covered drains are unnecessary; but open drains are made at distances of from ten to twelve yards. The stuff taken out of the drains is spread on the intervening spaces, on which also clayey earth is laid, in quantity varying from thirty to fifty yards per statute acre. The land is afterwards pared with a breast plough by men; or with a plough constructed for the purpose, drawn by a horse; then partially burned, the ashes distributed pretty equally over the surface, the seed sown, and ploughed in with a slight narrow furrow. Tolerable crops of oats may be obtained in this manner; and, sometimes, inferior crops of clover are made to follow the oats: in others, oats follow oats, year after year; the paring and burning being a necessary preliminary to each crop. This is certainly better than nothing, and is, perhaps, the best practice where manure cannot be made or procured at a moderate price. (*Brit. Farm. Mag.*, vol. viii. p 42.)

8356.—4688. *The question of corn rents* has been discussed at considerable length, but nothing has been said as to the *modus operandi* of converting money into a grain rent. In a cultivated district, where the farm proceeds arise chiefly or wholly from the sale of grain, an experienced farmer, in offering for a farm, forms an estimate of the quantity of grain he may expect to raise for the market, and what proportions thereof he can afford to pay as rent, after allowing for interest on capital, profits, and expenses. In this estimate, price forms a most important ingredient; and it is the fluctuation in the price of grain which has occasioned the adoption of grain rents. From the commencement of the present century till the conclusion of the war, the generally high prices of grain produced keen competition in farm-taking, and a rapid rise of rent was the consequence; but those who, chiming in with the spirit of the times, entered into leases at high rents, between 1810 and 1815, found, by 1821, that, in reckoning on a continuance of high prices, they had calculated without their host. About that period the cry for deductions of rent became loud and general; and that cry was in many instances responded to by the landlords giving temporary relief. This relief was, however, only temporary; and, in many cases, did harm, as it tended to keep up competition in farm-taking; and though a proprietor who had acquired a character of liberality felt little alteration in his rent roll on granting new leases, yet, as that liberality formed a very prominent ingredient in the farmer's estimate, it was naturally expected to be put in requisition where other sources failed. This unsettling of all covenants between landlord and tenant soon became disagreeable to all parties. The farmer had to become a humble supplicant, and the landlord to put up with a diminished income, without being altogether certain how far the claims on his generosity were well founded, or to what extent they might proceed. It therefore became a matter of necessity to make such arrangements as would restore the farmer to his original and proper state of independence, and the landlord to a state of certainty as to the extent of his income. Those farmers who had entered on nineteen years' leases during the last years of the war, or soon after its termination, had calculated on receiving, on an average of years, 35*s.* per boll for wheat, 25*s.* per boll for barley, and 20*s.* per boll for oats; but as prices soon fell, and continued below these rates, profits on farming became extinct, and capital began to decrease. Under these circumstances, farmers petitioned for permanent reductions of rent, suitable to the low prices; or craved leave to retire. Renunciations were written out by land agents, in which terms were proffered to the tenant less favourable than if his lease had expired, connected with an offer to convert the money rent into grain rent, payable in money by the county fiars price (the average price for the year) of grain for the current crop. Thus a tenant who had entered on his farm in 1815, and who grumbled at low prices in 1821, paying a money rent of 400*l.*, agreed to pay, under the new arrangement, during the currency of his lease, money to the amount of the highest fiars per 100 bolls of wheat, 100 bolls barley, and 100 bolls oats, these three bolls at 35*s.*, 25*s.*, and 20*s.*, amounting to 4*l.*; the maximum reaching to 85*s.* or 90*s.*, and the minimum to 60*s.*; thus giving a preference to the tenant in the fluctuation. When farmers entered into leases subsequently to 1821, on money rents, 75*s.* for the three bolls became the standard of conversion, because, warned by a succession of low prices, farmers had offered lower money rents; but in either case, wherever the plan has been adopted, it has been found to work well. Where money rents still exist, they are ill paid; the partial payments are entered to account, and the arrears press as an incubus on enterprise or improvement. The situation of the landlord is not enviable, and that of the tenant is deplorable; but, with the example before them, this state of things will soon rectify itself. In pastoral districts, something, too, might be devised to produce a fluctuating rent, regulated by the average price of sheep, wool, and cattle; and thus to place the grazier and his landlord on that same safe sort of footing now enjoyed by the more reflecting portion of the landlords and farmers in the cultivated districts. (*A. G.*)

8357.—4820. *On the capital required in farming*, an excellent paper will be found in the *Quart. Jour. of Agr.*, vol. iii. p. 450. To this paper is annexed a list of the implements of husbandry, live stock, seeds, lime, and expense of labour required for stocking a farm in Scotland, in 1831, of 500 acres. The total amount required was 3569*l.* 17*s.* 11*d.* The list is given in great detail, and well deserves the study of young men intending to become occupiers of farms.

8358.—4925. *Rotation of crops.* Independently of the benefit which a rotation of crops affords to the cultivator, by the greater variety of articles which it enables him to cultivate, there is less danger of his suffering in years of scarcity; because it seldom or never happens that the seasons are unfavourable for every description of crop. Thus, a very dry season is favourable for the production of corn, while a very wet one is unfavourable for corn, but produces abundance of herbage, roots, and grasses, which directly, or by means of nourishing or fattening animals, furnish a supply of human food.

8359.—4936. *For clays and loams of an inferior description*, the following rotation is recommended in the body of the work: —

1. Fallow, with dung. 3. Clover and rye grass. 5. Beans, drilled and horse-hoed.
2. Wheat. 4. Oats. 6. Wheat.

Here barley forms no part of the rotation, though inferior loams are often well calculated to yield fair crops of that grain; such loams are to be met with in many parts of Scotland at altitudes where wheat could not succeed. Another objection to this rotation is, that wheat forms the last and also the first crop of the course, with an intervening fallow: for inferior loams, such cropping is too severe; and in any case two crops of the same species in succession should, if possible, be avoided, even although a fallow or green crop intervene. The following rotation, which is practised on poor clays in the Carse of Gowrie, appears preferable, either on inferior clays, or loams, where wheat can form part of the rotation: —

1. Fallow, with dung. 3. Drilled beans. 5. Clover and rye grass.
2. Wheat. 4. Barley, with dung. 6. Oats.

On inferior soils, five successive crops, with only one manuring, cannot be expected to reach mediocrity. The general practice is to give rather less to the fallow crop, say fifteen tons per acre, and ten tons per acre, ploughed down in the end of autumn, on the bean stubble, for the barley. The growth of this plant is so rapid, that, on strong lands, where the dung has not been incorporating with the soil throughout the previous winter months, it is found to be of little benefit to the barley crop, and is therefore seldom applied at seedtime. In this rotation, too, five years intervene between each species of crop; the only drawback is, that barley after beans or peas is darker coloured than after a fallow or a green crop; but purchasers will make allowance for this, when they perceive that such colour does not proceed from damp in the stack. (*A. G.*)

8360.—4937. *The rotation for thin clays* in the body of the work is objectionable, from the land being continued too long in grass.

1. Fallow. 3. Grass. 5. Grass
2. Wheat. 4. Grass. 6. Oats.

On the thin clays in the Carse of Gowrie, of which there is a considerable breadth, the rotation generally followed is the same as that recommended above. Pasturing poor retentive clays will not pay. Such land is sufficiently tenacious without the tread of cattle, and the forage would be extremely scanty. Where the clay soil is so miserably poor as not to carry beans, a four-course shift might be adopted, keeping the grass only one year. On all clay lands it is often difficult to obtain sufficient mould for grass seeds in spring, among autumn-sown wheat; and, except in early situations, spring-sown wheat will not succeed on cold clays; hence a cross crop, that is, oats after wheat, is sometimes resorted to, for insuring a fair braird (sprouting, or plant) of clover and grass seeds. With this exception, the practice is not advisable. (*Idem.*)

8361.—4939. *In the "rotation for light soils,"* we have —

1. Turnips. 3. Clover and rye grass.
2. Spring wheat or barley. 4. Oats or wheat.

What I consider defective in this rotation is the possibility (although not clearly expressed) of following barley with wheat, after only one intervening green crop. It has been found, by dear-bought experience, that wheat succeeding to barley, with only an intervening fallow grass, or other green crop, is diminished in produce, from one third to one half in quantity on light lands: on strong retentive soils, the diminution is less perceptible; but on all soils, the practice should be avoided. (*Idem.*)

8362. *The land under regular rotation of cropping all over the country* has been rendered, by frequent repetition of the same sort of grass seeds, what is termed "clover-sick;" a state of the soil, according to De Candolle and others, produced by excrementitious deposit, hurtful to clover, but favourable to the growth of the cereal crops. On many farms a seven-course shift has of late been adopted, it being found that clover succeeds better after a cross crop, otherwise an objectionable mode of farming: the land requiring, as it would appear, two successive white crops to purify it from clover deposits, and to prepare it for producing that plant in a healthy state. Aware of this, the writer of this article, twelve years since, commenced the following rotation on light dry land, which, by frequent cropping, had become so "clover-sick," as to produce little else than rye grass.

8363. *Rotation of eight years*: —

1. Potatoes and turnips. 3. Grass after barley, peas after wheat. 5. Turnips and potatoes.
2. Half wheat and half barley. 4. Oats, on both divisions. 6. Barley and wheat, as before.
7. Grass after barley, and peas after wheat. 8. Oats.

Here the rotation is after the four-course method; only the potatoes alternate, as do the barley and wheat, and the peas and grass; so that each of these species of crops occurs only once in eight years on the same ground, with the exception of oats, for which each soil is well calculated, and which occurs once in four years. From this mode of cropping, a much heavier crop of clover is obtained from the half of the division than was formerly from the whole. The pea straw also adds to the horse fodder; and by it the dung is considerably augmented. The practice begins to recommend itself in the neighbourhood. The farm on which this course of cropping originated lies on the northern bank of the Carse of Gowrie, and at an elevation of from 400 to 500 feet above the level of the sea, consequently at the full limit where wheat can succeed (*Idem.*)

8364.—4944. *Fallows.* It is the opinion of some, that the mere exposure of soil to the drying influence of the sun during the summer season will contribute towards its fertility; but, assuming that the land is what farmers call sweet, that is, friable, and free from weeds, it will profit more by being covered with vegetation, or otherwise shaded from the sun and drying air, than by being exposed to it. This is shown by an able article in the *British Farmer's Magazine*, vol. iv. p. 10.

8365.—4955. *Kirkwood's grubber* has, subsequently to its first being made known, been greatly improved by the inventor, an ingenious mechanic, at Tranent, in East Lothian. (See *Quart. Jour. of Agr.*, vol. ii. p. 848.)

8366.—4965. *The use of fresh or unfermented dung* for turnips has, of late, been much recommended by several agriculturists, and has been advocated by Sir H. Davy, on chemical principles. But it appears that practice does not always support it. When Davy's lecture appeared, it was sent, by the then President of the Board of Agriculture, to a friend in Tweedside, who farms to an extent of several hundreds of acres of turnips yearly. This being in the turnip season, he directed an experiment to be made in two parts of a field with fresh dung from the fold-yards against the dunghill. The fresh dung failed by thirty per cent., and similar trials made on another farm led to the same result. It may be observed, however, that, in making experiments of this kind, something may be misunderstood. If the fold-yards were kept in a rough state, the fresh dung might be little better than wet straw, and containing little or no excrementitious matter; and if it were taken from near pigsties, or a chaff house, it might be nearly as much decayed as if it had lain in the dunghill. It is a long-established opinion, that dung fit for raising turnips must be thoroughly rotten and decomposed, so as to cut like a jelly; and though in this case a loss takes place, both of bulk and matter, the quality of the manure is undoubted. Perhaps dung in a state betwixt unfermented and total decomposition is preferable to either; and this opinion the following statement appears to confirm. During two succeeding years, the dung required for turnips on a farm was laid in a moist state on a dunghill about ten weeks before turnip sowing. A short time before sowing, it was turned, carefully shaken out, and laid lightly together. When laid on the land, it appeared to be in a most excellent state; the decomposition was going on, but had not ceased. A steam arose from the heaps of dung, and, the arrangement of the carts and ploughs being very close, ten minutes did not elapse

until the turnip-seed was sown, and pressed close to the dung by a roller. The braird (sprouting) of Swedes was everywhere most excellent; and, through the summer, grew with a rapidity seldom seen, and produced a crop rarely to be met with in the best turnip districts. The field was a sandy loam, of weak quality, but suitable for turnips. It is presumed that the heat which the dung possessed, and the subsequent decomposition that would take place, had infused life and vigour into the young plant, which thoroughly rotten dung does not possess; and, though it may ultimately raise us a good crop of turnips, it is at the expense of a great loss of bulk. The experience of the best cultivators in the northern parts of the kingdom is against the use of fresh dung; and neither Davy's lecture nor the recommendations of some of the greatest names of the day, have been able to alter that opinion. Fresh dung may answer on wheat fallows; but all dung will be the better for being laid together, turned, and fermented, so as to be easily separated and properly covered. (*Brit. Farm. Mag.*, vol. vi. p. 270.)

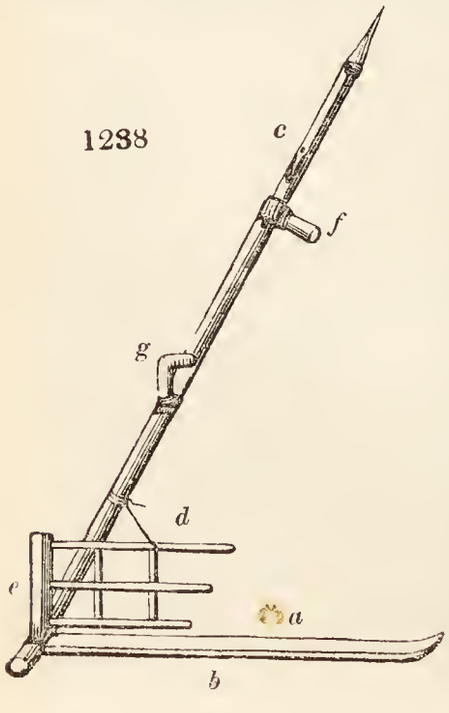
8367.—4990. *Meal from straw and hay* has been obtained by some French agriculturists, by cutting and afterwards grinding; and the meal, or rather bran, so produced, by facilitating mastication and digestion, is supposed to be better for old horses than straw or hay which is merely cut.

8368.—4992. *The advantages of cutting corn crops before they are dead ripe;* that is, when the straw immediately below the ear is just beginning to turn yellow, are thus summed up by Mr. Sheriff: — An increased quantity of grain, greater security from the weather, improved quality of straw, and an extension of the harvesting season. To these may be added, greater security against the effects of wind and rain, either as affects the shedding, discoloration, or germinating of the grain. The colour of grain which was not cut till it became dead ripe is generally of an opaque whitish hue; while that which was cut before it was dead ripe is transparent, and tinged with brown. The latter description of sample bears the highest price in most British markets. (*Brit. Farm. Mag.*, vol. v. p. 23.)

8369. *The period at which corn crops ought to be reaped* is best determined by examining the upper grains of the spikes. The cereal grasses, like all monocotyledonous plants, ripen the seeds on the upper extremity of their flowers, or even in the upper part of their seed-vessels, in the case of plants with pods containing many seeds; whereas dicotyledonous plants ripen their seeds equally throughout the seed-vessel, and in general rather ripen them first at the lower end than at the upper end. When the uppermost grain of a spike of corn has dropped out, the stalk may be considered as having stood rather too long, and the reaping point to be that when the uppermost grain is firm and plump. On the whole, the most improved practice of British farmers is in favour of reaping their crops at an earlier state of ripeness than they have hitherto been accustomed. (*Quart. Jour. Agr.*, vol. iv. p. 501.)

8370. *Cutting grain crops with a common scythe* has been generally practised in Aberdeenshire since 1818. The crops grown in this country are chiefly oats and barley. No change whatever is made in the common grass and clover scythe, for cutting heavy or lodged grain crops; but for light standing crops, a very simple addition is found of advantage. This consists of a small rod or shoot, nearly an inch in diameter, of green willow, or rowan (mountain ash), or broom, or any other flexible and tough young wood. It has its thick end twisted into the small iron rod, which aids in attaching the blade of the scythe to its handle, named provincially the grass-nail. Its small end passes over the upper side of the blade as far as the back, where it is bent upwards in an easy curve, and is brought backward, and tied with several rounds of strong twine to the handle, about fifteen inches above the blade. In cutting grain with a scythe, the swathe or cut corn is laid away from the standing corn. Every mower is attended by a gatherer; and, as the gathering is the part of the work that women can best perform, the gatherers are generally women. The grain is left by the scythe, having the stems forming an acute angle with the line of the standing corn, the root end of the stems pointing partly backwards and partly inwards towards the uncut part of the field. The gatherer places herself at the root end of the stems, so as to be able to stoop forward nearly in the line in which they are laid; and, by a succession of lifts with her hands, placing the corn on the rear over that which is more forward, stepping at the same time towards the right hand herself, she gathers into one heap what she deems sufficient for a sheaf, and, having carefully separated it with her right hand from the forward part of the swathe, then makes a band, in the ordinary way, of a part of the gathered heap, and lays the heap upon it. A binder is also attached to every mower, who is able to bind up all the sheaves cut by one scythe, and also to set them up in shocks; but there is no novelty in his operations. The gatherer and binder could generally, after a skilful mower, gather up all the corn sufficiently clean; but their labour would be greatly impeded, so as that they could not keep up with the scythe, were the cleanest gathering strictly enforced. That is, therefore, dispensed with; and a raker, generally a woman, follows the other operators, to collect the straggling ears and straws. (*Highland Soc. Trans.*, vol. x. p. 189.) The Rev. James Farquharson, speaking of this mode of reaping, says, — "In no branch of agricultural labour, not even in the substitution of the two-horse plough for the one drawn by ten oxen, or of the threshing-machine for the flail, has a more valuable advance been made, within our memory, from an old and inferior system to a new and better one, than in the adoption of scythe-reaping. It is calculated that double the work is done by the scythe, which could be performed in the same time by the sickle. It is also better performed; because the straw is cut off more closely to the ground, and consequently a better provision is made for cattle fodder during the winter, and for a larger quantity of manure. When the grain is over-ripe, much less is shaken out by the scythe than by the sickle. Another advantage, of which the magnitude can scarcely be believed, except by those who have learnt to estimate it by their own experience, is the quickness with which the mowed shock winns (drys or withers) thoroughly, and becomes fit for the stack; a matter of the utmost importance in our unsteady climate. The straws are not crushed, as they frequently are with the hand in reaping with the sickle; and the sheaf, although not more liable to break out of the band, is more elastic and open to the action of the atmosphere. It is perhaps not too much to say, that a sheaf of equal weight, cut with the scythe, becomes ready for the stack, under equal circumstances of weather, in half the time needed by one cut with the sickle. The most pleasing advantage is the total change of the character of the labour, as it affects the larger part of the workpeople. The mowers, gatherers, and rakers deem their work delightful in comparison with the labour of the sickle."

1238



8371. *The scythe for reaping corn* (*fig.* 1238.) should have its blade (*a*) of the best steel, four feet long, strengthened by a plate of iron along the back (*b*). The handle should be straight, because that gives the greatest command over the scythe. A well-seasoned young larch tree, reduced to the proper thickness, with a slight curve at the root end, for receiving the blade in a proper position, makes the best handle to a reaping-scythe. A hone, covered with fine sand, and a fine sandstone, to whet the edge of the scythe, are hooked on to the handle at *c*, near its upper extremity. There should be a cradle (*d*, consisting of three long teeth, fastened to an upright stem (*e*), formed of ash, and as light as the strength of the wood will permit. The upper tooth should be a little more than two feet in length, and the two under ones should be, the first three inches, and the second six inches shorter. The upright stem of the cradle is driven into a socket of iron. The height of the cradle is about thirteen inches; the left-hand handle (*f*)

is straight, and the right-hand handle (*g*) is crooked. For the construction of this important instrument, further details will be found in the *Quart. Jour. of Agr.*, from which our figure is taken; but the above outline will suffice for any one who can construct a common scythe.

8372. *Corn of every description may be reaped with the scythe.* Oats make the most perfect work, with the greatest ease to all the labourers. Barley, with new grass, is not difficult to cut; but the clammy juice from the barley straw lubricates the scythe with a viscid coating like varnish, which must be rubbed off frequently with the whetstone. The binders have always hard work among barley. Wheat is beautifully laid in swath when mown. The takers-up and binders have less labour among wheat than the mowers, who must be powerful men to continue a length of time at the work; but there are modes of equalising the labour, and, of course, of diminishing the fatigue. For example: when a field of wheat and a field of oats are nearly ready for reaping, it is an excellent arrangement to reap the oats in the dewy mornings, before breakfast, or as long as there is any dampness on the corn, and then to go to the wheat, or to the barley, if there be little wheat on the farm, during the dry period of the day. By this plan much valuable time can be saved in reaping the whole crop. Oats are not the worse of being reaped in a damp state. It is a remarkable fact, that oats reaped in a damp state, with the scythe, will be nearly as soon ready for the stack as when reaped dry. Not so with barley. Shocks of oats which are reaped dry, but have afterwards been soaked with rain, will be longer before they are ready for the stacks than oats that have been reaped in a damp state. It is a still more remarkable fact, that damp oats reaped with the scythe will be sooner ready for the stack than would the same oats, reaped in a dry state, with the sickle. Oats reaped with the scythe will be quite ready for the stack in eight days, whereas oats reaped with the sickle require at least a fortnight. Shocks that have been reaped with the scythe will keep off much more rain than those reaped with the sickle. (*Quart. Jour.*, vol. iv. p. 366.)

8373.—5003. *Cone wheat*, a variety of *Tríticum túrgidum*, has been found by Mr. Gorrie to be but little injured by the wheat-fly, as this insect appears in the fly state much sooner than the wheat blossom bursts from the spathe. The grain of this variety is coarse; but every spike generally yields from seventy to ninety grains, which is double the number of the common wheat, *Tríticum hybérnum*. It ripens about a week after the red wheat, and, when standing, is from a foot to eighteen inches taller than the common wheat. (*Quart. Jour. Agr.*, vol. iii. p. 641.)

8374. *Dantzig creeping wheat* is a variety cultivated on the borders of Scotland, which possesses the property of tillering, or throwing tap-shoots from the root in the autumn, in a remarkable degree. It originally came from Dantzig. (*Quart. Jour. Agr.*, vol. iv. p. 536.)

8375.—5042. *On the climate requisite to bring wheat to perfection.* Nothing is here said of altitude, latitude, or temperature. The highest altitude on which wheat will succeed on the banks of the Tay, is 450 feet above the level of the sea, where the mean temperature for the year is 46°. Wherever the annual mean temperature is below this, wheat cannot be raised with advantage. (*A. G.*)

8376.—5074. *Rye straw* is preferred to that of any other plant for littering horses; and rye is somewhat extensively cultivated about Newmarket for the sake of obtaining the straw for the livery stables. (*J. D.*)

8377. — 5121. *The Hopetoun oat* is an accidental variety brought into notice by Mr. Sheriff in 1824. It is chiefly remarkable for its long reedy straw, which, in a crop of twenty acres in East Lothian, has averaged six feet in length, while the grain is thin in the husk, and nearly as short and plump as the grains of the potato oat. (*Trans. of Highland Soc.*, vol. viii. p. 362.)

8378. — 5290. *The value of crops of Swedish turnips, potatoes, and mangold wurtzel, as food for cattle*, is not materially different, provided the crops are alike good of their kind. This is the opinion formed by an East Lothian farmer of great skill and experience, after having made a number of experiments to determine the value of these roots. (*Highland Soc. Trans.*, vol. ix. p. 273.)

8379. — 5307. *Soil for the potato.* In the peninsula of Kintyre, the soil is calcareous clay, in which there is found gypsum, an earth said to be congenial to the potato; and there, Mr. Stewart states, that the potato crops far surpass any he had elsewhere seen, either in Scotland or Ireland. (*Brit. Farm. Mag.*, vol. vii. p. 479.)

8380. — 5312. *Comparative produce of different modes of preparing the sets, and planting potatoes.* The following interesting experiments were made by the Messrs. Drummond of Stirling, with the Irish blue potato, on the same piece of ground, and under similar circumstances. The space which each experiment occupied was forty square yards, which were drilled and dunged at the rate of thirty tons the imperial acre. They were all planted on 28th May, and raised 12th October, 1832: —

8381. *The first plot* was planted on the plan recommended by Mr. Knight, Pres. Hort. Soc. The tubers were whole, weighing half a pound each, and were planted at the distance of six inches in the row, and the rows four feet apart, and lying north and south; forty square yards required nine pounds of sets, and produced 364 pounds of potatoes; being, per acre, 136 bushels of sets, and 550 bushels of produce: net increase, 414 bushels.

8382. *The second plot* was also planted with similar tubers to the last, at nine inches apart. The seed required weighed sixty pounds, the produce 326 pounds; being, per acre, ninety-one bushels of seed, and 493 bushels of crop: net increase, 402 bushels.

8383. *In both these plots* the plants were highly vigorous, and early in advance of others planted in the ordinary manner. The potatoes were not too large, but the crop contained a great proportion of small ones.

8384. *The third plot was planted* the same as the last, but the sets were cut of the common size. The seed required weighed only six pounds, the produce, 276 pounds; being, per acre, nine bushels of seed, and 417 of produce; nett increase, 408 bushels. The plants in this plot grew fast in the autumn, and produced by much the largest potatoes; but they did not ripen well.

8385. *The fourth plot* was planted with sets cut of the common size. The seed required weighed twelve pounds, and the produce 376 pounds; being, per acre, eighteen bushels of seed, and 568 of produce; net increase, 550 bushels. The potatoes in the produce of this last lot were the most equal sized.

8386. *The result of these experiments* (which were conducted with great care) is entirely contrary to Mr. Knight's theory, and consequent practice. (*Quart. Jour. Agr.*, vol. iv. p. 411.) In the *Transactions of the Horticultural Society*, second series, vol. i. p. 445. to 456. (published in August, 1834), an account is given of a number of experiments made with the greatest care and accuracy, under the direction of Professor Lindley, in the garden of the Horticultural Society, the result of which is conformable to that obtained by Messrs. Drummond. It also appears in the same work that Sir George Mackenzie made experiments of the same kind in Ross-shire, and found the produce decidedly better from sets than from whole potatoes. (See *Gard. Mag.*, vol. x. p. 433. 435. and p. 499.)

8387. — 5328. *The uselessness of earthing up potatoes* has been pointed out by Mr. Hayward; and, independently of the effect of earthing up, and other operations between the rows, in destroying weeds and loosening the soil, we should think his practice the best. He says, that a farmer who simply hoed the soil between the rows of potatoes in one of his fields, had a much larger crop than he had in an adjoining field, where the rows were earthed up with the greatest care. A potato placed an inch only under the surface of the soil will produce a greater number of tubers than one planted at the depth of a foot. "I have no doubt," says Mr. Hayward, "if potatoes are planted shallow, and placed wide enough apart to admit of the stems being laid down after the young potatoes are formed; and if the earth between them was then thrown over five or six inches thick, so as to form a flat surface, that it would increase the crop. But this is a very different operation from that which I object to." (*Gard. Mag.*, vol. ix. p. 323.)

8388. — 5337. *Benefit resulting from the removal of potato blossoms.* By a well-conducted experiment on a field of two acres, for which the honorary silver medal of the Highland Society was given, it appears that one third part of the field, being those drills from which the blossoms were plucked in the bud, pro-

duced thirty bolls, two bushels. One third part from which the blossoms were plucked when in full flower produced twenty-seven bolls, three bushels; and one third part, being those drills on which the plants were allowed to ripen their seed, produced twenty-six bolls. The difference here, in favour of plucking off the blossoms as soon as they appear, instead of allowing them to remain and ripen their seed, is nearly one sixth part of the produce. (*Highland Soc. Trans.*, vol. x. p. 237.)

8389.—5354. *Potatoes may be preserved* by being rasped or ground to a pulp, afterwards pressed into dry cakes by Bramah's or any other powerful press, and then dried like cheeses. Potato cakes of this sort have been found to keep for years perfectly sweet; and, as a great deal of nutriment is thus put into very little bulk, it is thought by some that ships bound for long voyages might find it advantageous to lay in their stock of potatoes in this form. (*Quart. Jour. Agr.*, vol. iv. p. 483.)

8390. *Potato flour* was shown at Messrs. Drummonds' exhibition at Stirling in 1832, which was thirty-eight years old. It was made from damaged potatoes, which, it seems, answer as well as sound ones, and was in the finest condition. (*Quart. Jour. Agr.*, vol. iv. p. 414.)

8391.—5360. *Potato haum* forms a rich and excellent manure for wheat, at the rate of four acres of haum to one of wheat, ploughed in green immediately before sowing the wheat. It is found decidedly superior to stable-yard dung. The mode of preparing it is simply to pull up the stems, and to avoid burying potatoes with it, however small they may be. (*A. Gorrie, in Country Times*, October, 1831.)

8392.—5363. *Good beer can be produced from potatoes* by grating them to a pulp, mixing it well with boiling water, and then adding ground barley malt. The liquid, being drawn off, is to be hopped in the usual way, yeast added, and fermentation induced. The liquor thus produced, after being bottled, was found greatly to resemble the Paris beer. (*Dom. Econ.* in *Lardner's Cyclopædia.*)

8393. *Beer may be made from parsneps* in a similar manner to that from potatoes.

8394.—5364. *The distillation of spirit from potatoes is thus practised in France:*—The potatoes are boiled by means of a steaming apparatus; and, where the apparatus is good, will be prepared sufficiently in ten minutes. As soon as they are in a proper state, they must be bruised when at as high a degree of temperature as possible, and then thrown, for the purpose of fermentation, into a tub or other vessel containing, for every 1000 pounds of potatoes, 416⅔ pounds of cold water; the temperature of which, however, should not be below 14° of Reaumur (63½° of Fahrenheit). The whole must then be covered up, and allowed to remain. There will be 750 pounds of sediment contained in the quantity of potatoes which has been mentioned; and this proportion, with the 416⅔ pounds of water, will be quite sufficient to produce a mass, of which the consistency will be that of pap or curdled milk, and the temperature from 48° to 50° Reaum. (140° to 144½° Fahr.) There are then taken 31¼ pounds of the malt of barley, which is steeped in 250 pounds of water that has been previously heated to the height of 60° Reaum. (167° of Fahr.), and the whole is allowed to remain until it shall have cooled to the temperature of 22° of Reaum. (81½° of Fahr.) There are then added 22½ pounds of yeast, which is mixed by being actively stirred, and the whole is then well covered and allowed to remain. When the mass of fermenting potatoes is cooled to the temperature of 38° of Reaum. (117½° of Fahr.), the fermentation is stopped by adding 416⅔ pounds of cold water, and the whole is well stirred together. This mass having fallen to the temperature of 25° Reaum. (88¼° Fahr.), the prepared malt, which has already begun to ferment, is added; the whole is again well stirred together, the vessel very lightly covered, and the fermentation allowed to proceed. This latter operation takes place very regularly, and terminates in from forty-eight to sixty hours. The fermented mass assumes a spirituous odour, and furnishes, on distillation, so abundant a quantity of spirit, that, for every 100 pounds of potatoes, there are obtained eight French pints of spirit, in which, according to the scale of Richter, there are thirty per cent. of alcohol. If, before carrying the fermented mass to the still, it is passed through a sieve of iron wire of close meshes, the pulp of potatoes is kept back, and the spirit is then more pure, and more pleasant to the taste and smell. This will be still more the case, if there be added to this mass half a pound of potash for every 100 pounds of potatoes, before submitting it to distillation. If it is wished to have a spirit analogous to that obtained from wine, it must be rectified accordingly. (*Moléon's Recueil Industriel*, and *Quart. Jour. Agr.*, vol. iii. p. 321.)

8395.—5377. *Dale's hybrid turnip* was originated, about 1828, by Mr. Robert Dale, of Libberton West, near Edinburgh. It is tankard-shaped, and resembles the Swedish or yellow turnip in colour. It is equal in size to the white globe, superior in size to most other varieties, whether of white, yellow, or Swedish turnips, and is found to produce a greater weight in a given space, and at a given expense of manure, than any other turnip hitherto introduced. It is not so hardy as the Swedish, and it runs to flower rather sooner in the spring; but, with these exceptions, it is the best of all field turnips. (*Quart. Jour. of Agr.*, vol. iii. p. 578.)

8396.—5432. *Fly on turnips.* The following mode of prevention has been resorted to with success at Green Hammerton, Yorkshire. A board, about eighteen inches in breadth, and sufficiently long to cover four ridges of turnips, was made to run upon wheels, high enough to allow the board to pass over the turnips without touching the tops of them. The lower side of this board was painted with white paint, which the men provided themselves with, and took into the field, and during the night (at which time the fly is more injurious and destructive than during the day) the instrument was wheeled from one end of the field to the other. The insects, on being disturbed, of course immediately fly or jump up, and stick to the paint; and at the end of every set of ridges the board was almost covered with them. (*Leeds Mercury*, and *Report Don. Agr. Association.*)

8397.—5453. *Carrot seed.* Messrs. Drummond, the eminent seedsmen of Stirling, state that the carrot crop in the field may almost always be insured, other circumstances being favourable, by bringing the seed to the point of vegetating before sowing. This is done by mixing it with sand or earth, kept moist, and turned occasionally for several days. They also recommend some nourishing compost to be placed under the seed in the drills, or sown along with it. They have made an experiment to prove that carrots may be grown to great advantage in peaty soil, and that they may be even grown in old worn-out garden soil, by mixing peat and dung together, and putting the compost thus formed in a gutter made by a wedge-shaped dibble, six inches wide at top, six or eight inches long, and at least a foot deep; the seed being sown immediately above the compost. (*Quart. Jour. of Agr.*, vol. iv. p. 410.)

8398.—5516. *Sýmphytum aspérrimum*, Mr. Gorrie observes, is assuredly liked by horses and cattle, and will soon recommend itself to the cottager and dairyman as a powerful auxiliary to clover, in summer and autumn. (*Highland Soc. Trans.*, vol. ix. p. 249.)

8399.—5527. *Trifòlium incarnàtum* is considered in Italy as the earliest of clovers; as particularly calculated for dry soils, and as preferring the mountain to the plain. It is an annual, and succeeds best when sown in the autumn, after the corn crop has been removed. (*Quart. Jour. of Agr.*, vol. iii. p. 729.)

8400. *Trifòlium élegans* is mentioned as worth culture, and seeds of it were shown at the Highland Society's exhibition in 1832. (*Farm. Jour.*, Oct. 4. 1830.)

8401.—5550. *Clover* is dried in the hilly parts of Germany by resting it, immediately after being mown, against portable tressels, as corn is dried in Sweden and Norway. (*L'Agronome*, vol. i. p. 136.)

8402.—5643. *Old pasture compared with new.* John Boswell, Esq. of Kingcausie, Aberdeenshire, has long been of opinion that permanent pasture, instead of being a good thing, is a bad thing. After recapitulating his experience during several years, and strongly recommending thorough under-draining, deep ploughing and manuring, he concludes thus:—"I maintain, that, except a few favoured spots, such as banks of rivers, &c., no ground can, without loss, be left long in pasture; and that it appears to me, four or five years is, generally speaking, the longest period land should be allowed to lie in grass. If pasture be the object, at the end of that time the ground should be broken up as arable land, and then returned to grass again. I maintain, that without grass severely cropped land cannot be restored to full fertility; and without cropping, grass cannot be made to continue at the maximum point of verdure and utility.

Lastly, I maintain, no land, under any circumstances, ought to be cut in hay, if intended to remain some years in pasture; and, if cut as hay, every kind of land ought to be directly ploughed, and again put through the rotation." (*Quart. Jour. Agr.*, vol. iv. p. 790.)

8403.—5647. *The great object of mixing different grass and herbage seeds together*, is to stock the surface of the soil at once so thickly with useful plants as to prevent weeds from rising up through them. Experience has proved that this cannot be done so effectually when only one or two species of grass or herbage seeds are employed, as when a greater number are made use of: and the reason appears to be found in the diversity of soils and situations. In general, the richer the soil the smaller will be the number of species which it will require. When the selection of grass seeds is judicious, there will be a constant succession of herbage kept up by them the whole year round, as grasses of several sorts grow at all times when the temperature is above the freezing point.

8404.—5656. *The Italian rye grass*, Mr. Lawson found to be the same variety as Stickney's rye grass. It is considered superior to any other grass in producing winter herbage, and to be more hardy than the common rye grass. (*Highland Soc. Trans.*, vol. x. p. 28.)

8405.—5717. *Number of kinds of grasses required in laying down permanent pasture.* A judicious writer in the *Quart. Jour. of Agr.* is of opinion that more of these grasses are brought into notice than their good properties will warrant. Independently of perennial rye grass and white clover, which must always occupy a large share of every permanent pasture, perhaps five or six of the others are all that are worth cultivation. It is true, many worthless grasses will grow up among our most carefully laid down pastures, and they, no doubt, assist in thickening the sward. But this is surely no adequate reason to sow them; and if it be necessary to sow a certain quantity of seed to cover the ground, that quantity should be composed of the best kinds. One reason for sowing a number of kinds is, that more plants will thrive closely together of different sorts than of the same sort. Allowing this to be the fact, there is still no necessity for incurring the trouble and expense of sowing worthless kinds, when a variety of them will grow naturally out of the soil to form a thick sward. Should the different kinds arrive successively at their greatest vigour, seeds of the best sorts can be selected on account of their coming to maturity at the different seasons when pasturage is required. It seems that 4½ bushels will just furnish as many fertile seeds, that is, seven to the square inch, as there are plants in that space in a natural pasture: but if even more are required to render the pasture better, more of the best kinds only should be sown to insure the requisite thickness of sward. (*Quart. Jour. Agr.*, vol. iv. p. 414.)

8406. *Kinds and qualities of grass seeds for laying down land.* The most valuable article which has appeared on this subject since the publication of Sinclair's *Hortus Gramineus Woburnensis*, will be found in the *Quarterly Journal of Agriculture*, vol. iv. p. 714—724. This article is by Mr. Lawson, an eminent seedsman in Edinburgh; who, for a number of years, has directed his attention to the subject, with a degree of success which has been acknowledged by the first agriculturists in Scotland to be pre-eminently great. After giving a short description of thirty species or varieties of proper grasses, and eleven herbage plants, of which he has seeds for sale, he enumerates six other herbage plants, all Leguminòsæ, the seeds of which are not yet articles of commerce, but which, he says, may be advantageously introduced into cultivation as soon as their seeds can be obtained. These are, *Lòtus màjor*; *Vicia Crácca*, sèpium, and sylvática; *Láthyrus praténsis*, and *Trifòlium mèdium*.

8407. *Sowing the seeds of grasses and herbage plants by weight*, instead of the general practice of sowing the grasses by measure, and the clovers by weight, is strongly recommended by Mr. Lawson. "For, although in grass seeds the greater weight of one variety is no criterion of its superiority over another variety of less weight, yet a greater weight in the same variety always denotes a superior quality. Thus, when seed is light, and consequently inferior, the greatest number of seeds is obtained by adhering to a given weight; and hence there is the chance of nearly an equal number of plants springing up as when the seeds are plump and heavy. But a given weight of measure of seeds does not indicate the relative number of plants that will spring up; because there is both a difference in the relative bulk and specific gravity of seeds, and there is also a difference in the number of seeds that grow from a given quantity." (p. 719.)

8408. *The weight of the seeds of grasses*, per imperial bushel, is next given by Mr. Lawson; and the differences between the seeds of different species in this respect is most remarkable. Of thirty species, the heaviest appears to be the common perennial rye grass, a bushel of which weighs from eighteen to thirty pounds; and the next heaviest appears to be the crested dog's-tail grass, which weighs twenty-six pounds. The lightest seed is that of *Avèna* [*Trisètum*] *flavéscens*, a bushel of which weighs only five pounds, and the next lightest is the meadow fox-tail grass, which weighs five pounds and a quarter. *Anthoxánthum odoràtum*, and *Alopecùrus geniculàtus* weigh each six pounds; *Aira flexuòsa*, six pounds and a quarter; *Poa glaùca*, seven pounds and a half; *Elymus arenàrius* and *Festùca duriúscula*, each nine pounds and a half; and the remaining species weigh from ten to sixteen pounds. Rye weighs 62 pounds the bushel.

8409. *The weights of clover and other herbage plants* are much less various. Burnet weighs twenty-four pounds and a half; saintfoin weighs twenty-six pounds; *Achillea millefòlium*, twenty-eight pounds and a quarter; ribwort, fifty-one pounds and a half; *Medicàgo lupulìna* (the nonsuch of English farmers, and the yellow clover of the Scotch) weighs sixty-three pounds and three quarters; and the different species of clover (*Trifòlium*) from sixty-two to sixty-five pounds.

8410. *With reference to the culture of grasses in Britain*, Mr. Lawson observes that, wherever land produces the cereal grains and other cultivated plants, the pasture and herbage grasses will grow with vigour. Plants of this kind, he observes, are improved by different kinds of soils, and more especially with relation to their states of dryness or moisture. As a convenient arrangement for practical purposes, he classes all soils under light, medium, and heavy; and he has composed twelve different tables, each containing the quantity of grass seeds, per Scotch acre, for these three divisions of soils. Whoever, whether in Britain or America, wishes to sow grasses on a large scale, will find it worth their while to correspond with Mr. Lawson, with reference to the subject of these tables; because every year he is adding to his experience, and in all probability improving the selection. We shall, therefore, not copy them into our pages in detail, but merely give their titles, with a few remarks, chiefly with a view of showing how much greater the number of species is which Mr. Lawson recommends than what is commonly sown, and yet how much smaller is the quantity of seed per acre.

8411. *Grass and herbage seeds for alternate husbandry.* For one year's hay, twenty-two pounds of annual rye grass, ten pounds of red and two pounds of white clover. For one year's hay and one year's pasture, eight pounds of annual and eighteen pounds of perennial rye grass; three pounds of *Phlèum praténse*, five pounds of red and five pounds of white clover, and two pounds of nonsuch. For one year's hay and two years' pasture, twenty-eight pounds of perennial rye grass, two pounds of *Phlèum praténse*, two pounds of red, six pounds of white, two pounds of cow clover, and two pounds of nonsuch. These proportions are for soils suited for the turnip husbandry; in heavy soils, from two to four pounds of *Phlèum praténse* may be added for one year's grass.

8412. *Grasses and herbage plants for permanent pasture.* Of proper grasses, seven species are employed; of proper clovers, three species, and also the nonsuch. The proportions are given for laying down without a crop and also with a crop; and it is worthy of remark, that in the latter case the quantity required is not much above half what it is in the former. Without a crop, seventy-five pounds are required for a light soil, and eighty-two for a heavy soil; while with a crop, forty-one pounds and a half in the one case, and forty-five lbs. in the other, only are required.

8413. *Grasses, &c., for permanent pasture in ornamental parks.* Of proper grasses, fourteen species are employed, besides the clovers mentioned in the preceding paragraph. It is added, that *Achillèa mille-*

fòlium may be added in dry soils; saintfoin in dry calcareous soils; wild endive in heavy soils; and from one to two pounds of parsley per acre on lands where sheep are apt to get the rot.

8414. *Grasses and herbage plants for lawns, bowling-greens, &c., kept constantly under the scythe.* Of proper grasses, fifteen species are employed, together with the common white clover. On each soil, Pacey's perennial rye grass, more than one fourth part of the proper grasses, and the quantity of white clover per acre, varies from six to twelve pounds.

8415. *Grasses and herbage plants for grounds much shaded with trees.* Twelve species of proper grasses and white clover.

8416. *Grasses, &c., for heathy and moory lands which have been pared and burned, or scarified, for the purpose of producing herbage.* The following cheap mixture is recommended: — Mixed hay seeds twenty-five pounds, and white clover, six pounds, with a crop; and forty pounds of mixed hay seeds, forty-five pounds of rye, and nine pounds of white clover, without a crop. When land of this description is situated 500 feet, and upwards, above the level of the sea, sheep's fescue and the two allied species, and *P*òa glaùca, may be added, at the rate of two pounds each.

8417. *Grasses for improved deep peaty ground intended to lie in grass.* Perennial rye grass, ten pounds; *P*hlèum praténse, eight pounds; *A*gróstis stolonífera, two pounds; *A*lopecùrus praténsis, two pounds; and *T*rifòlium rèpens, eight pounds, are recommended, when they are to be sown with a crop; when without a crop, the proportions are, eighteen, twelve, three, three, and twelve pounds.

8418. *Grasses for land in preparation for irrigation.* We shall take the liberty, in this case, of copying the table verbatim: —

	Light Soil.		Medium Soil.		Heavy Soil.	
	With a Crop.	Without a Crop.	With a Crop	Without a Crop.	With a Crop.	Without a Crop.
	Lbs.	*Lbs.*	*Lbs.*	*Lbs.*	*Lbs.*	*Lbs.*
Perennial rye grass	10	18	7	2	7	12
*A*gróstis stolonífera	2	4	2	4	3	6
*A*lopecùrus praténsis	2	4	3	6	4	8
Festùca praténsis	2	4	2	4	2	4
*Festùca l*oliàcea	4	7	4	7	4	7
*P*òa triviàlis	2	4	2	4	3	6
*P*òa flùitans	1	2	2	4	2	4
*P*hlèum praténse	4	6	6	9	7	10
	27	49	28	50	32	57

8419. *Grasses for lands which are occasionally subject to the overflowing of lakes and rivers, or which are always in a very wet state.* These are, *P*òa aquàtica, six pounds; *P*òa flùitans, six pounds; *Festùca l*oliàcea, four pounds; *P*hlèum praténse, six pounds; *A*lopecùrus geniculàtus, six pounds; *A*gróstis stolonífera, four pounds.

8420. *Grasses for rabbit warrens, or light sandy soils.* These are, perennial rye-grass, fourteen pounds; Anthoxánthum odoràtum, one pound; *Festùca* duriúscula, one pound; *Festùca* ovìna, one pound; *Festùca* rùbra, one pound; Cynosùrus cristàtus, two pounds; *P*otèrium Sanguisórba, four pounds; *A*chillèa millefòlium, half a pound; *T*rifòlium rèpens, six pounds; *T*rifòlium mìnus vel procúmbens, two pounds; Medicàgo lupulìna, two pounds. If this mixture be sown without a crop, a bushel and a half of rye grass may be sown along with it.

8421. *For drifting sands, which are to be consolidated, and have a sward produced upon them by sowing.* These are, *E*lymus arenàrius, ten pounds, which should be mixed with clay and straw ropes cut into pieces, and dibbled into the sand. After a sward has been produced, the mixture recommended for rabbit-warrens, or light sandy soils, may be sown.

8422. *For dry gravelly situations, which resist a sward from all ordinary means.* These soils may be sown with *A*gróstis vulgàris, two pounds; *P*òa ánnua, four pounds; *B*rìza mèdia, four pounds; *A*ìra flexuòsa, one pound; *T*rifòlium mìnus vel procúmbens. We repeat our strong recommendation of Mr. Lawson, as an agricultural seedsman, to all persons residing near Edinburgh who have lands to lay down in grass. We are not less anxious to recommend Messrs. Drummonds of Stirling; Messrs. Dickson and Turnbull of Perth; Messrs. Cormack and Son, and Mr. Gibbs, of London; and M. Vilmorin, of Paris, to all those similarly circumstanced in their respective localities.

8423. *Mixtures of grasses for the alternate husbandry.* From the result of an experiment made by Mr. Shireff of Mungoswells (*Quart. Jour. Agr.*, vol. ii. p. 242.), it appears decidedly preferable to use a mixture of seeds, even where a single crop of hay, to be succeeded by a year's pasturage, is to be taken. The grasses sown were cock's-foot, hard fescue, cat's-tail, rye grass, and red, white, and yellow clover. "The rye grass was conspicuous for growing early in spring as well as late in autumn, and remaining comparatively unproductive in the summer months. The cock's-foot, throughout the season, put forth new leaves with rapidity, after being cut with the scythe, and produced culms to the hay crop only; the fescue planted thinly, and also grew rapidly after being cut; the cat's-tail was later in producing flower-stalks than the other grasses used in the experiment, and, after being cut, did not put forth new leaves so rapidly as the cock's-foot and fescue; but, in every instance, it produced numerous culms, white blossomed, at the same time as the red clover; and, where a part of the field was four times mown, yielded a rich crop of culms to the last. The produce, as compared with that of clover and rye grass only, sown in the same field in the same season, was about a ninth part greater, and the extra-expenses of the seed about a fifteenth part. Had the clover failed to grow along with the rye grass, as it frequently does, the difference in the produce would have been much greater. The great advantage of a numerous combination of grasses is, that the failure of a crop is rendered next to impossible. It is also found that a mixture of grasses is less injurious to the succeeding corn crop than rye grass only. The family of grasses, Mr. Shireff observes, forms a useful class of machinery in the manufacture of productions for the dairy, the shambles, and the manufacturer of clothing; but, in order to take advantage of the raw materials, air and moisture, so bountifully supplied by nature, the most efficient machinery must be employed. The husbandman who clothes his fields only with rye-grass and clover employs a limited machinery, the former being unproductive in summer, the latter moderately so in spring; but when he, for this purpose, uses a variety of plants, differing in their habits of growth and periods of luxuriance, a numerous and powerful machinery is kept successively in full operation.

8424. *Pòa nemoràlis* was found by Mr. Taunton to produce a thick sward in plantations where every other grass was killed. He says, "its rich nutritive quality, its beautiful and perpetual verdure, and, above all, its quality of flourishing under a dense cover of trees, appear to me to render it peculiarly valuable for the particular purpose of rendering ornamental, and also of turning to a profit, the site of grown-up plantations and thick groves, which are, usually, in a state of complete nakedness." (*Quart. Jour. of Agr.*, vol. iii. p. 413.)

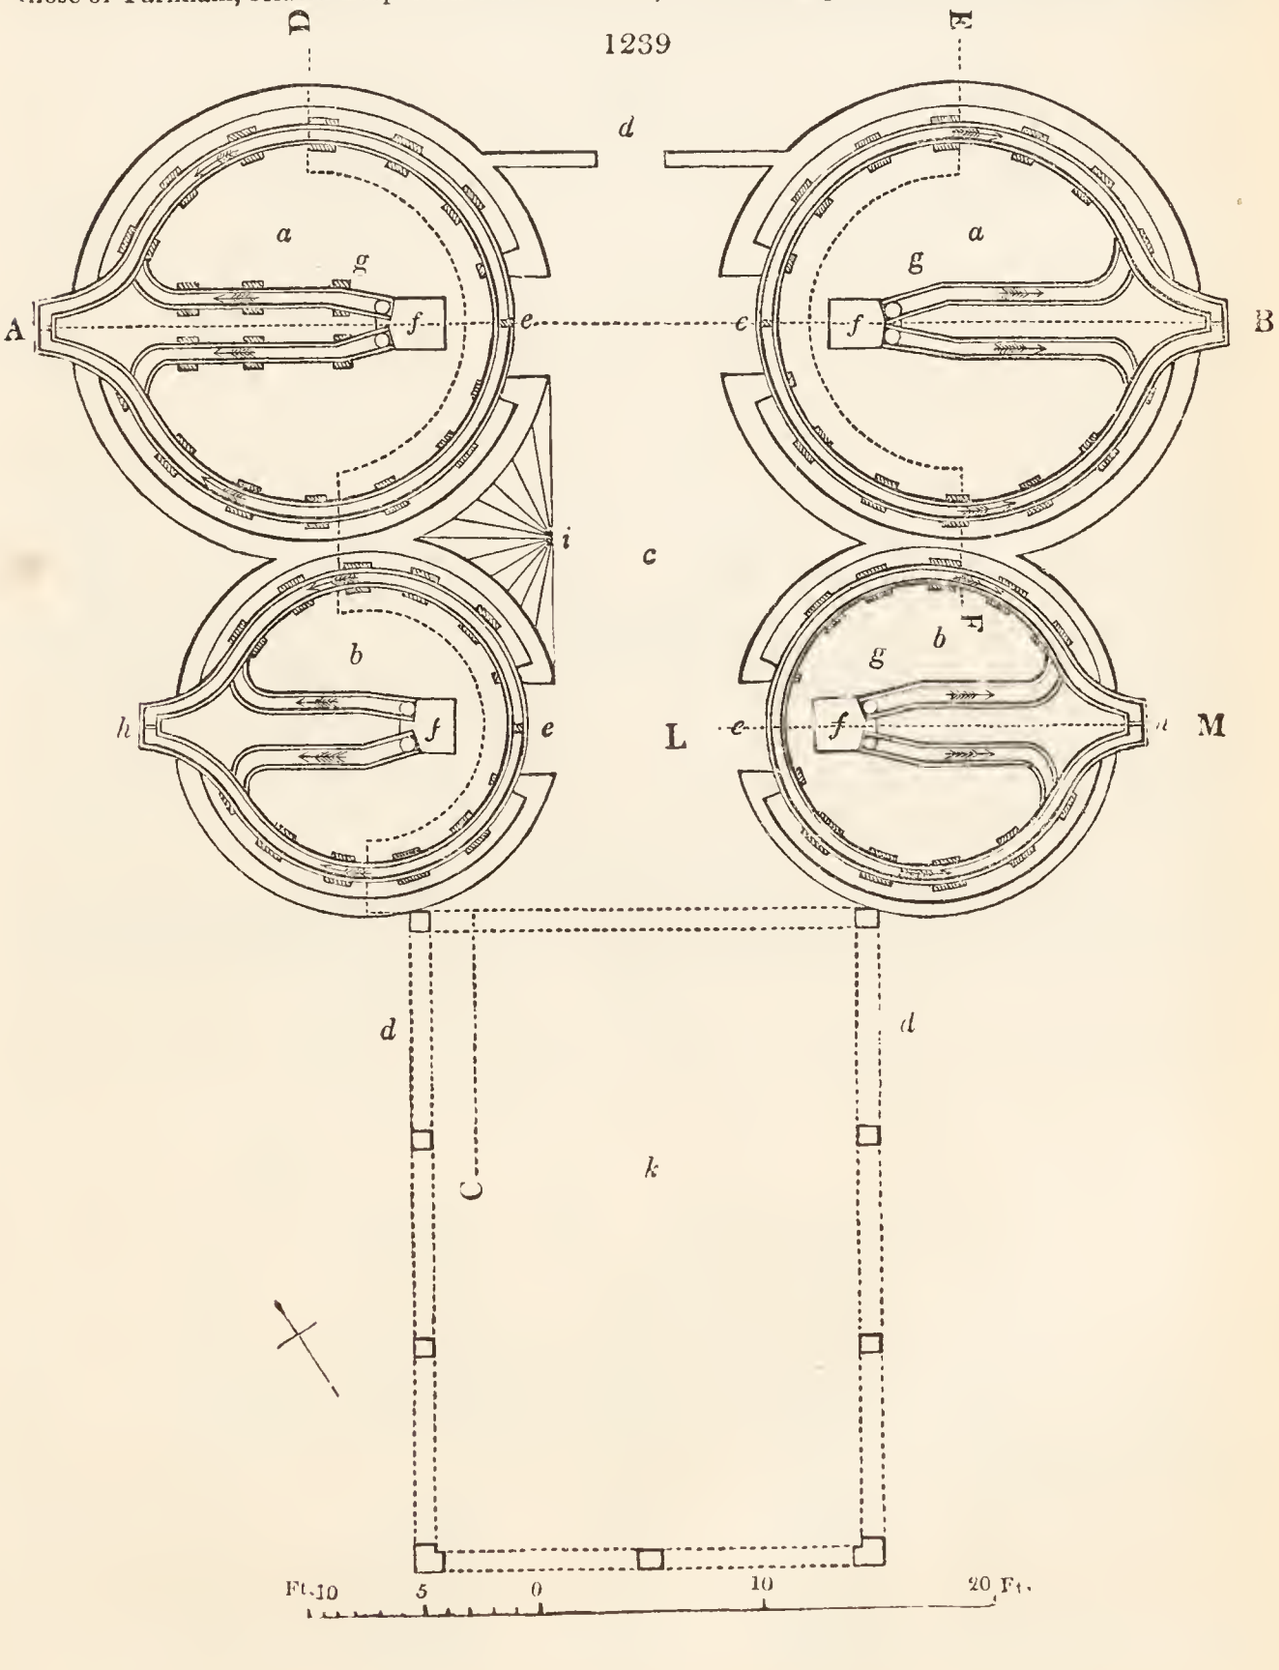
8425. — 5820. *To destroy moss in old turf.* "It is a singular fact, but not generally known to agriculturists, that by merely lifting the turf of an old pasture field that is overrun with moss, and ploughing and loosening the subsoil, and then laying the same turf down again, the whole of the moss will disap-

pear the first season, without applying either water or manure to the surface." (*Stephens on Irrigation and Draining*, p. 59.)

8426. *Renovating defective meadows.* The late Mr. Sinclair, of the New Cross Nursery, had perhaps more experience, as he certainly had more science and skill, in this department than any other man. In his excellent work the *Hortus Gramineus Woburnensis*, he recommends first ascertaining that the meadow is completely under-drained; then stirring the surface, by harrowing it, in all directions; the best harrow for which is unquestionably that of Finlayson. After this, he gives a thorough top-dressing of rich finely divided compost; he again harrows and cross harrows, and then sows from two to six pecks per acre of grass and clover seeds. For a meadow of low rich alluvial soil, he employs meadow fox-tail, meadow cats-tail, meadow fescue, rough-stalk meadow grass, crested dog's-tail grass, sweet-scented vernal grass, and perennial red clover. In two years such a meadow will be thoroughly renovated, and will bear abundant crops of hay.

8427. — 6041. *The process of drying hops* is as follows: — After being gathered from the bine, or stalk, the flowers are immediately carried in bags to the kiln, on which they are spread out to the thickness of from six to ten inches all over the surface of the kiln. The fire is then lighted, and kept burning briskly night and day, so long as there are any hops ready to be dried. It is found that a kiln of Mr. Read's construction may be charged once in every twelve hours. After the hops are dried, they are swept off the kiln into a cool ventilated loft adjoining, and generally attached to it; this loft being formed over a cart-shed, or some other building open on one or all sides. Being cooled here for a day or more, or according to convenience, the hops are bagged or pocketed; the bag weighing 200½ cwt., and the pocket 100½ cwt.; that is, packed in bags, which are suspended by a hoop from a round opening in the floor, and into each of which a man enters, to consolidate the hops by treading them down. When the bag is full, it is released from the hoop, and pulled up, still being retained over the hole, till it is beaten into shape, when it is sewn up, and let down into the shed, whence it is carried to market, or to the store loft, where it may be kept a year or more, if carefully excluded from the air. Hops dried on Mr. Read's kiln have been known to keep four or five years; but those dried by the common methods, and especially those of Farnham, seldom keep even twelve months, from the imperfect manner in which the process

1239



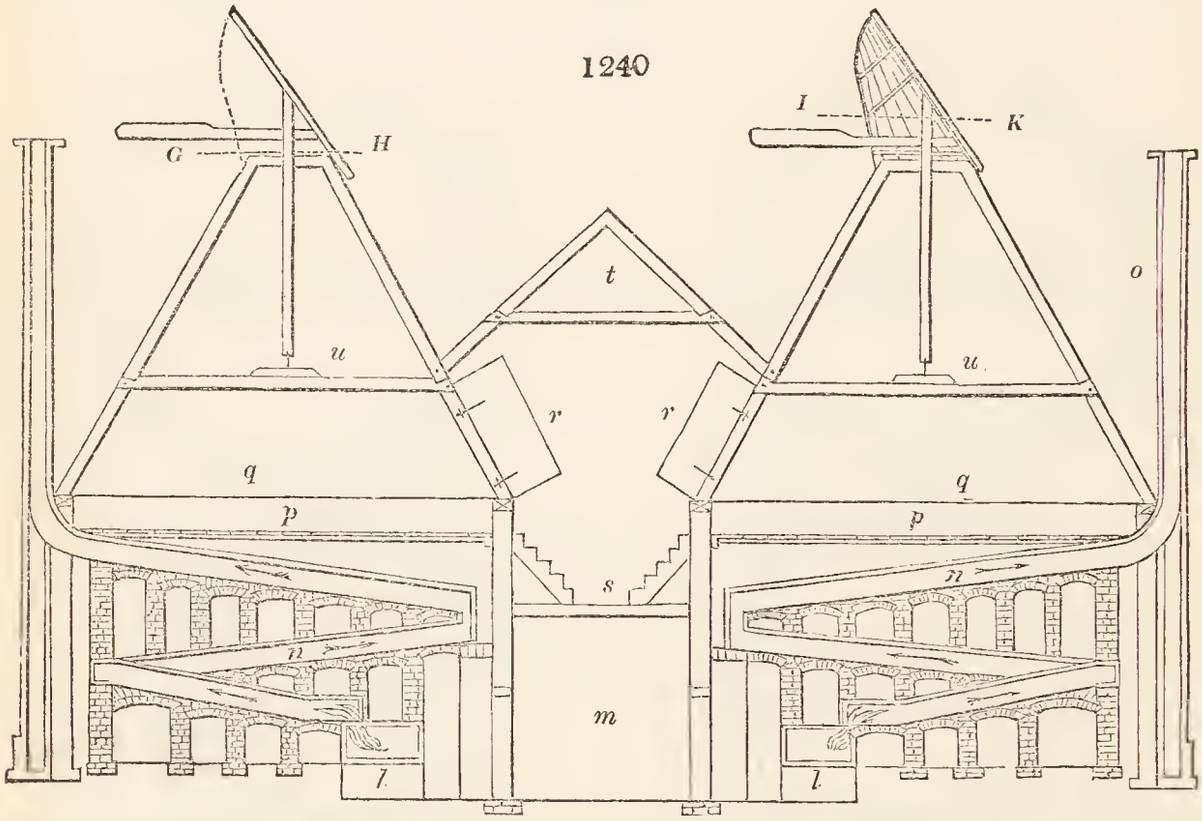
of drying has been performed. There are several excise regulations connected with the drying of hops in Britain, which we think it unnecessary to enter into a work intended for both hemispheres; more especially as we anticipate the entire removal of the excise duties, and the substitution of a graduated per centage or property tax for this and all other government taxes.

8428. *The situation of a hop-oast* ought to be airy; and the external opening to it, for the admission of the air, ought to face that point of the compass from which the wind blows most frequently at that season of the year when hops are being dried. In England, the hop harvest is in the month of September, and the wind in that month is generally in the direction of the south-west. When several kilns are built together, and not in a straight line, but so as to form two rows or a group, as in *fig.* 1239., this rule cannot be followed; but the next best rule is, to have the openings to the fireplaces facing the north-west and south-east, by which means they will catch a part of the current from the south-west as it passes.

8429. *The circular form* for the kiln has been adopted by Mr. Read, because it contains a greater area than any other figure with the same quantity of exterior walling; and, because both the walls and roof can be made stronger than they can in any rectangular form, with fewer materials. Hence, while the circular kilns possess more strength and durability than the rectangular ones, the expense of construction is less.

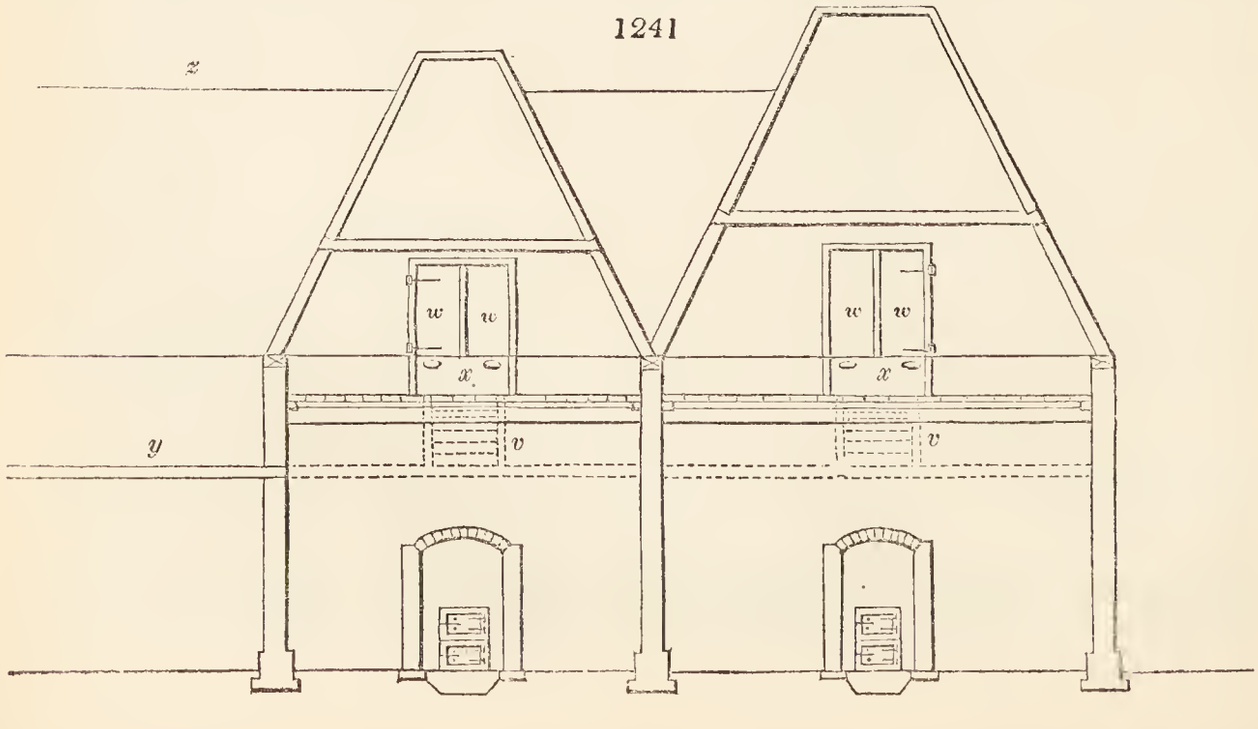
8430. *Details of the oasts* erected at Teston. Fig. 1239. is the ground-plan; in which *a a* are two kilns, twenty feet in diameter internally; and *b b* two other kilns, sixteen feet in diameter internally; *c* is an open space between the kilns, to which air is freely admitted by the openings to the south-east, south-west, and to the north-east, at *d d d*; *e* shows the openings to the dunge, and cockles or furnaces for the admission of air to the fire, and to be rarified by the flues, previously to its ascending and passing through the drying floor; *f*, the furnaces, made of cast iron, with doors to the fuel-chambers and ash-pits of the same material; *g*, termination of a portion, to the extent of one yard, of the flues next the furnaces, which ought to be built of fire brick, or which may be formed entirely of cast iron, as in this design. The remaining part of the flues to be built of common brick on edge three courses deep, and covered with bricks or tiles, twelve inches long by six inches broad; *h*, the situation of the chimney-shafts; *i*, the staircase for carrying up the hops to the drying-floor; and *k*, a cart-shed, over which is a floor on which the hops are cooled. Fig. 1240. is a transverse section on the line A B, or nearly so, in which *l* is the fuel-

1240



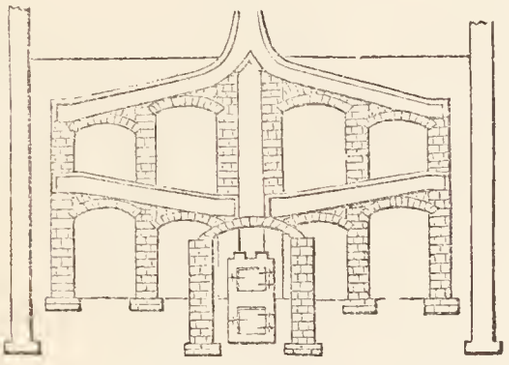
chamber, with the doors open; *m*, the thoroughfare between the two kilns; *n*, the flues; *o*, the chimney-shafts; *p*, the drying-floor; *q*, the situation of the wall-plate; *r*, the doors to the drying-floor open; *s*, the floor of the loft, with the movable stairs to the drying-floor; *t*, the roof of the cooling-loft; and *u*, collar beams for supporting the spindle of the cowl. Fig. 1241. is a longitudinal section on the line C D, in

1241

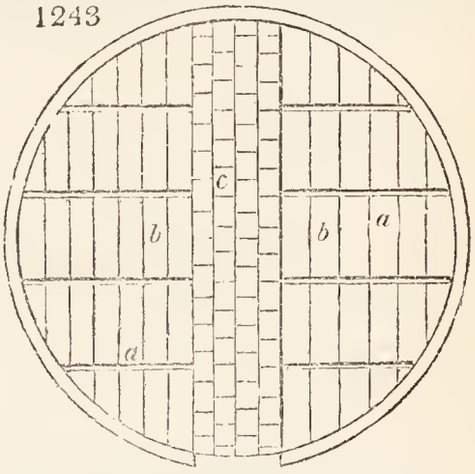


which *v v* show the situation of the movable steps from the common floor of the passage loft, and cooling-room, to the double doors, *w*, of the drying-floor; *x*, bottom boards of the doors, eighteen inches deep, which fit into grooves, and have two holes in each for lifting them up every time the drying-floor is to be emptied. While this operation is going on, the step ladders are removed, and the hops are swept through the door, and fall down into the passage loft, where they are swept along to the cooling chamber; *z* is the ridge of the roof from the cooling chamber and passage loft. Fig. 1242. is a cross section of one of the larger kilns on the line E F, for the purpose of showing the returns of the flues, from the centre to the sides in the lower part of the dunge, and from the sides to the chimney-shaft in the upper part of the dunge. Fig. 1243. is a dissected plan of the drying-floor, in which *a a* are the iron girders, the strength

1242



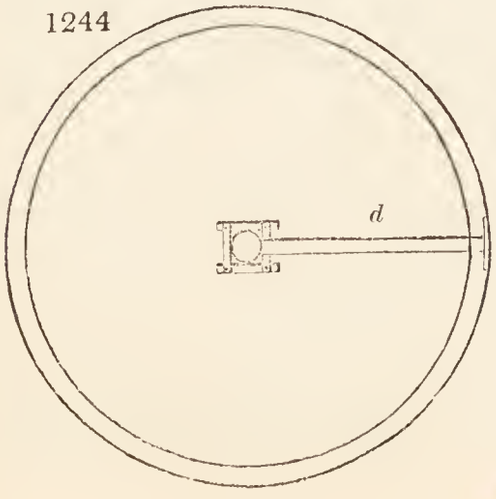
1243



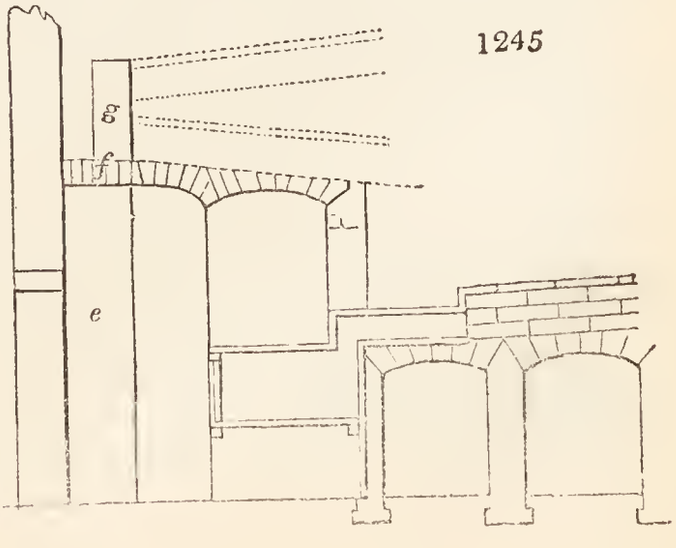
of which may either be such as to require no supports between the ends, or they may be so slight as to require one or more pillars as props between the extremities; when they are of cast iron, they may be in two lengths, four inches deep in the middle, and half an inch thick, each length of sixteen feet, supported by two iron columns: *b b* are the laths, which may be either of cast or wrought iron; when of cast iron, they are four feet long, roach-bellied, that is, forming the segment of a circle on the under side, two inches broad at top, and a quarter of an inch on the under edge; when they are of wrought iron, they are one inch and a half broad (that breadth being necessary to form a bed for the tiles), and half an inch deep; in this case the extended length across the girders is from one of the kilns to the other: *c c* are the tiles pierced with holes, in the same manner as the tiles of malt kilns.

8431. *Construction.* The exterior walls are of brick, with eighteen-inch footings, and are carried up a foot or more of the width of fourteen inches, after which their width is nine inches, up to the eaves of the roof, which are eighteen inches above the drying-floor. The rafters are four inches by two inches at the bottom; and three inches by one inch and a half at the top, where they shut against a circular curb or rim under the cowl. The furnaces or fuel-chambers are entirely of cast iron, and the ash-pits have iron doors. At the farther extremity of the fuel-chamber there is an opening six inches square at top, through which the smoke and heat ascend into the flue. The flue for the first three or four feet is either built of firebrick, or formed entirely of cast iron, six inches in diameter; after which its sides are formed of three bricks on edge, not plastered either outside or inside; and its top is covered with two courses of tiles, breaking joint, six inches by three inches. The reason why narrow tiles are chosen is, that duty is saved; and two courses breaking joint are employed, in order to prevent the risk of smoke getting through the joints into the dunge. The flues are supported by piers formed of open brickwork on edge, and joined by arches four inches in thickness, bevelled on the top, so as to form the base of the flue. Two flues proceed from each fireplace, ascending at an angle of 15°, or more if the height of the dunge will permit, in the direction indicated by the arrows, meeting at *e*, in the plan *fig.* 1239. and each there returning over itself, and again meeting at the chimney-shaft, *h*. These flues may be easily cleaned by the removal, at short distances, of some of the covering tiles; or, what is a simpler mode, by burning in the fuel-chamber a few handfuls of dry brushwood, or dried hop-bine, or any thing that will quickly create such a draught as will carry all the soot in the course of a few minutes out at the chimney top. About London the washerwomen clean the chimneys of their boilers on the same principle, by throwing in, in rapid succession, small quantities of gunpowder. The cowl should project about a foot on every side over the orifice in the summit. This orifice is, to that for the admission of air to the dunge, as one to one and a quarter. In the building of the walls of the kiln, in order to preserve them truly circular, an upright pole is fixed in the centre, and a guide-rod, *fig.* 1244. *d*, is framed on to it, of the requisite radius. The lower end of the central perpendicular pole is fixed in the ground, and the top kept steady by braces to other poles outside the circumference of the plan, so as not to interrupt the free evolution of the guide-rod. For every course of bricks laid on the wall, a course is also laid in mortar round the upright pole under the guide-rod, so that the latter is always kept level. So rapidly can bricks be laid in this manner, that Mr. Read finds such walling cost less than straight brickwork. The course of bricks immediately under the flooring tiles, twenty inches from the top, ought to project an inch inwards, for the tiles to rest on. The exterior opening to the dunge should be kept low, it being found that when this is the case the draught is always greatest; its height need never exceed four feet six inches, which is sufficiently high to admit a person to enter the dunge. When the manager of the furnace is once within, he immediately finds six feet of head-room; there being a pier, *e*, nine inches by eighteen inches, carried up on each side of the door, along with the outside wall, as in *fig.* 1245., which is a section on the line

1244

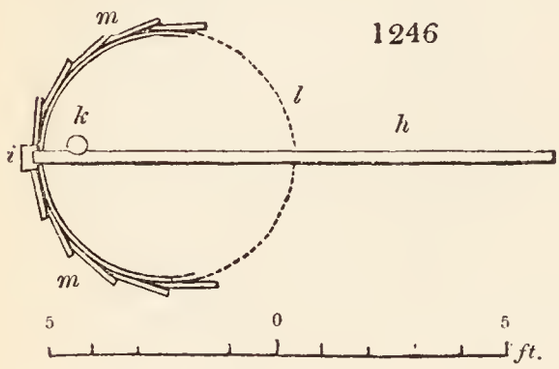


1245

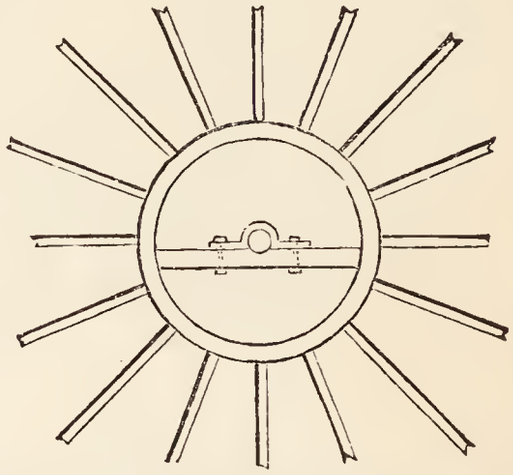


L M, for the purpose of forming abutments for the four-inch arch, *f*, which carries the double flue, the end of which, at the point where one returns on the other, is shown at *g*. The furnace and flues should be blackened exteriorly, in order to increase the radiation of heat, and the inside of the surrounding walls ought to be whitewashed, to prevent them as much as possible from absorbing it. The cowl moves altogether independently of the curb which forms the opening under it: it consists of one strong back piece, into which the upright spindle is framed, as may be seen in the section, *fig.* 1240, at I. Attached to the spindle and the back-board is the fly-board, *fig.* 1246. *h*, which serves, like a rudder, to keep the back of the cowl to the wind. The boards forming the cowl overlap each other from the back piece, or rib, towards the sides; and they are nailed to iron hoops, as indicated in the section I K, *fig.* 1246., and also in the section, *fig.* 1240. In the former section, *h* is the fly-board; *i*, the back rib; *k*, the upright spindle; *l*, the iron hoop; and *m*, the boarding. *Fig.* 1247., which is a section on the line G H, shows the

1246



1247



manner in which the upright spindle works against a collar-piece, which is fixed across the centre of the curb, at the kiln top. This piece being fixed, and the collar containing the spindle bolted on it, the bottom piece, in which the pivot of the spindle works, can, before it is fixed, be moved backwards and forwards on the collar beam, till the spindle is brought to a perfectly upright position and made to work freely.

8432. *Remarks.* The great superiority of the circular kiln to that described in the preceding design is so obvious that we only wonder, considering that it has been extensively used in Kent and Sussex for upwards of thirty years, that it has not found its way everywhere. It must be obvious that not only any description of fuel may be used in Mr. Read's kilns, but that, from the great length of the flues, a much greater quantity of heat will be rendered available for passing through the drying-floor. The circumstance of the flues ascending at a considerable slope is highly favourable for promoting a draught, and consequently for thoroughly consuming the fuel. Mr. Read informs us, that he has superintended the erection of some hundreds of these kilns; and that in one year he erected seventy, all within the counties of Kent and Sussex. This being the case, it strikes us with astonishment that Mr. Read's improvement has not been adopted by the hop-growers of either Farnham or Worcestershire, and the proprietors of malt kilns everywhere.

8433. "*Buckwheat* is ground generally into grits by means of handmills, or lever hammers, and is made either coarse or fine. The coarse sort is used for gruel, and the fine sort for cakes and biscuits. In some places they even make use of the first grinding with the bran, more or less, in addition to the finer flour, for baking household bread. It also serves to fatten hogs or poultry in a short time. The principal method to cleanse and separate the husk is, to pour boiling water on a given quantity of cleaned buckwheat, to stir the mass about with a stick, and draw the water off, then to pour cold water upon it, having first stirred it about well. In a quarter of an hour after, the buckwheat is taken out with the hands, and the water squeezed out. In the summer it is dried in the sunshine, and in winter in a warm room, and spread on the floor. As soon as it is quite dry, it is ground in a hand-mill or a stamping-machine into grits, in which state it is very clean and tasteful. The flour obtained from the sieve is dainty and very fit for cakes," &c. (*Com. Board Agr.*, vol. i.)

8434. — 6594. *A machine for fixing horses while being shod*, of a simple and effective description, has recently been invented by Mr. James Catcleugh, millwright in Haddington, a mechanic of very great genius; which will be found described and figured in the *Quart. Jour. Agr.*, vol. iii. p. 510.

8435. — 6684. *The following plan of feeding horses* has been practised by Dr. Sully of Wiveliscombe, in Somersetshire, for upwards of twenty years. In Dr. Sully's stables there are no racks for holding hay; for in his opinion a horse with a well-filled rack will consume and spoil upwards of thirty pounds of hay in twenty-four hours; whereas, if the hay were cut down, and mixed with a due proportion of cut straw, and bruised or coarsely-ground oats or other grain, ten pounds are sufficient. In the loft, above the horses, Dr. Sully has prepared proportionable quantities of the food with which his horses are daily supplied; and a very simple method has been devised to convey it, when mixed, to the manger of each horse. A wooden pipe is made to pass from the loft into each of the mangers, and close by the mouth of the pipe, in the loft, is placed a tub, of size enough to contain what is sufficient food for a horse for twenty-four hours. To prevent the horse, in searching for grain, from tossing out of the manger the mixed food which is dropped into it, oak crossbars twelve inches distant, are nailed over it; between these bars ample space remains for the horse to feed. As there can be no dependence on the measured quantities of grain or other food given to the horse, from the variation at times in the respective weights of equal quantities, Dr. Sully recommends, and, indeed, regards it as necessary, that grain of all kinds, and also the cut hay and straw, should be carefully weighed. When all the ingredients are so prepared, the proportions for each horse are allotted. From the following table will be seen the different articles of food, and the quantities and weight of each, which the horses should receive: —

	1st class. lbs.	2d class. lbs.	3d class. lbs.	4th class. 1 s.
1. Farinaceous substances, consisting of bruised or ground beans, peas, wheat, barley, or oats	5	5	10	5
2. Bran, fine or coarse	- -	- -	- -	7
3. Boiled or steamed potatoes, mashed in a tub with a wooden bruiser	5	5		
4. Fresh grains (boiled barley)	6			
5. Hay cut down into chaff	7	8	10	8
6. Straw cut down into chaff	7	10	10	8
7. Malt dust, or ground oilcake	- -	2	- -	2
	30	30	30	30

With two ounces of salt for each class. By this table it will be seen that each horse receives thirty pounds of food in the twenty-four hours, a quantity that will in all cases be found to be amply sufficient. The addition of two ounces of salt is necessary to assist the digestion of the food. Of the four classes into which Dr. Sully divides his ingredients for feeding, those two which contain the steamed or boiled potatoes are the most recommended. No food conduces more to the healthy working condition of horses than the steamed or boiled potatoes; and we may observe, with relation to this, as well as to other kinds of food, that, when the horse comes in weary and hungry, after a long day's work, it is necessary to fill his manger more copiously with the ingredients prepared for him. Dr. Sully and all the other persons who have devised improved methods of feeding agree in the practices of bruising or coarsely grinding the grain and beans, of cutting down the hay and straw, of giving no hay in the rack, of allowing salt, and of weighing each article separately before mixture, instead of adopting the fallacious guide of measurement. (*Quart. Jour. of Agr.*, vol. ii. p. 727.)

8436. *Road horses*, in some parts of Scotland, and more especially in the neighbourhood of Edinburgh and Glasgow, are fed on equal parts of oat-straw and hay, cut by a machine in the lengths of from one eighth to one sixteenth of an inch. The cut straw and hay so produced are intimately mixed together, and, when musty, sometimes sprinkled with a little salt and water. The drink given to the horses is water in which oats or barley have been boiled, and the grain so boiled is found to equal double its quantity of raw grain in keeping horses in condition.

8437.—6852. *Feeding horned cattle on raw, or on steamed or boiled, food.* Though boiled corn is found to be doubly nutritious to horses, yet, from a number of experiments made by practical farmers, with a view of obtaining the premium of thirty sovereigns offered by the Highland Society of Scotland, it has been given as an opinion, that, in the case of the ruminating animals, no advantage whatever results from cooking their food. (See *High. Soc. Trans.*, vol. x. p. 253.)

8438.—6856. *On the treatment of cattle in winter.* An excellent paper on this subject will be found in the *Quarterly Journal of Agriculture*, vol. ii. p. 228—241. Some difference of opinion exists among agricultural writers as to whether young growing cattle ought to be fed, or pampered as Dr. Coventry calls it, with rich food, or supplied with abundance of coarser food. The writer of the article referred to inclines to the former opinion, on the principle of its being the farmer's interest to treat his cattle in such a way as shall enable him to bring them soonest to market. Coarse food, he says, ought not to be found on a well-cultivated farm. Straw and water, in an agricultural sense, are not food at all. Straw given to cattle, with a view of being consumed as their only food, is just so much straw wasted, and time lost, in the forwarding of their condition. A limited supply of turnips will keep cattle alive, and may prevent them from falling off in flesh, but it will never bring them to a state of fatness, though they were to eat in that manner for any length of time; whereas a moderate quantity beyond this limited portion would constitute abundance. Scanty food renders cattle uneasy; whereas food in abundance renders them contented and able to endure every inclemency of weather. A farmer ought neither to rear nor purchase more cattle than he has food sufficient to keep in affluence; for though this might lessen the number, both on individual farms and in the country generally, yet the quantity of butchers' meat brought to market would be greater, and its quality better, than it now is. Hence, on the score of profit to the farmer, and ease and comfort to the cattle themselves, abundant nourishment ought to be given to the latter from the earliest period of their existence, until their growth is complete. Cattle may be fed in houses, and tied to stakes, or in what are provincially called "hammels," which are small open courts, with an open shed for shelter on the north side. Twenty calves, or ten yearlings, may be put into one of these hammels. A hammel with a shed seventeen feet in width, and fourteen feet in depth, with a court twenty-one feet by seventeen feet, will contain three large oxen, or four smaller-sized cattle. Every hammel must be supplied with pure water at the command of the cattle. Before the cattle are put into hammels or byres, the floors ought to be well littered, so as to form a sort of drain to carry off the urine to an underground tank, whence it may be pumped up for use. Cattle fed on turnips eat very little straw; and therefore, the first thing that should be given to them, in the morning, is turnips; the troughs for holding them having been previously cleaned out. In the byre, the first thing to be done in the morning is to draw the dung from behind the cattle into the urine canal; and while the cattle are eating their turnips, the dung can be wheeled to the dunghill. Fresh straw, for fodder, may be given about the time that the turnips are eaten up, a small quantity being placed before each beast in the byre, and in the racks under the sheds of the courts. Oat-straw is found to constitute the best fodder for cattle; potato oat-straw is, perhaps, better than that of the common oat, as the former is always cut down before it is quite ripe. Hay is, no doubt, better than any kind of straw; and those who have abundance of that desirable fodder may give it ungrudgingly to cattle, in the certainty of being soon repaid its value. Turnips should be given again about mid-day; and about three o'clock in the afternoon the mangers should be cleared out, and straw or chaff given. In the byre, after this allowance is eaten up, the mangers should be cleaned out before giving another foddering of straw. A trowel will be found a handy instrument for this purpose. At the hammels, the last foddering of straw can be given any time after the last allowance of turnips, which should be ample, as the cattle will come backward and forward to them even in the dark, and in moonlight they will feed as well as during the day. The calves should be served with turnips immediately after the feeding-beasts; and the year-olds can also get a few at this time, to complete their day's allowance. Between the allowances of turnips, litter should be sprinkled in the byres and hammels, to induce the cattle to lie down after repletion, to chew the cud, which they will invariably do. At eight o'clock at night, the byres should be looked at with a light, and the cattle supplied with the fodder necessary, and their beds made comfortable, for the night, by drawing back any dung that may be on them, sprinkling some more litter, and shaking it well up with a fork. At the hammels, if it is moonlight, some more turnips should be thrown, even at this time of night, into the mangers. During the day, the water-troughs should be all kept full of fresh water, and any filth that may have been blown into them by the wind should be removed. When the frost becomes so severe as to harden the turnips, they should no longer be brought from the field, but from the store formed of them in the beginning of winter, for the purpose of supplying the cattle with fresh turnips during the continuance of frosty weather; nor should any more be taken even from the store than what can be consumed in a day. Frozen turnips may be thawed by being placed in a tub of cold water; but this is a very tedious and troublesome mode of obtaining fresh turnips in frosty weather, compared to the excellent practice of storing a considerable quantity in open weather.

8439. *In the feeding of cattle*, it is of the utmost importance that the man who has the charge of them should be very attentive to his duty; and, in particular, that he should be exact, even to a minute, in supplying them with turnips: cattle know perfectly well when the time arrives for a fresh supply, even though the mangers in the hammels may not be empty, which they should never altogether be. When they are supplied with food at irregular times, they will either be always craving it, or become careless about it; and their uneasiness, arising from frequent disappointments, will prevent them from feeding so pleasantly and speedily as when their food is placed before them at exact periods. When the man thus regulates his different works by time, he will find leisure moments during the day to perform many necessary acts; which, though they may appear of little importance in themselves, nevertheless contribute greatly to the appearance of neatness and comfort in the farm-yard and its inmates. Thus, he might spread the stable-litter along the edge of the turnip-troughs of the year-old cattle, to keep any turnips clean that may have been pulled over by the beasts; for, when cattle are first put up to feed, the freshness and tenderness of the leaves induce them to eat these first, and in the anxiety of each to obtain another fresh bite, many turnips are necessarily turned over. The man can also shovel and scrape together any mud about the causeways, and the places on which the turnips have been laid down from

the field. He can frequently examine the skins of the cattle, and give immediate notice of any eruption; for cattle, after being a month or six weeks on turnips, get very itchy in the skin, the violent rubbing of which often causes ulcerated spots to break out, but which can easily enough be cured at first, by an application of a decoction of tobacco, with a little spirit of tar. He should rub those parts of the body which they cannot easily get at to lick with an old currycomb, and scrape off any dung that may adhere to the hair in the hinder and under parts of the body, with a large blunt knife; and this attention is more necessary at the beginning of the season than afterwards, as the freshness of the stems, and the juiciness of the roots of the turnips, and the greediness which all cattle evince for them at first, often cause a looseness in their bowels. He should observe the first indication of lice in their skins in the early part of the spring, when these may be easily destroyed, by applying to the affected parts a solution of mercurial ointment; but, if neglected, they will cause much uneasiness to the cattle, making their hair peel off, and exposing to view an unsightly skin; and he may handle them frequently on every part of their body, as they are very fond of being handled when they are rising in condition; and it is also serviceable to familiarise them with man; as cattle, when they have been accustomed to be handled, will stand better, and show themselves more satisfactorily to the buyer. There is something so winning in a gentle disposition in powerful animals, caused by good treatment, that a buyer will prefer them, when they have to be driven a distance upon the road; and the butchers in the neighbourhood will also prefer them, as they will walk peaceably to the shambles, without the risk of being raised to a frenzy. All these constitute the minutiæ of the business of feeding cattle on turnips in winter; and, trifling as they may appear, attention to them will be amply repaid, in the shape of prime beef and docile cattle. The whole may be easily accomplished by any man who regulates his movements by the watch; and the man who has the charge of cattle in winter that will do this, whether he is seen by his master or not, is an inestimable servant.

8440. *The quantity of turnips which feeding cattle will consume*, as stated by most writers, is about one ton every week, for an ox of from sixty to seventy stones, or about one acre of a fair crop of turnips in six months. Thirty-three double-horse cart-loads of turnips, each weighing from sixteen cwt. to eighteen cwt., are a good crop on light sharp lands.

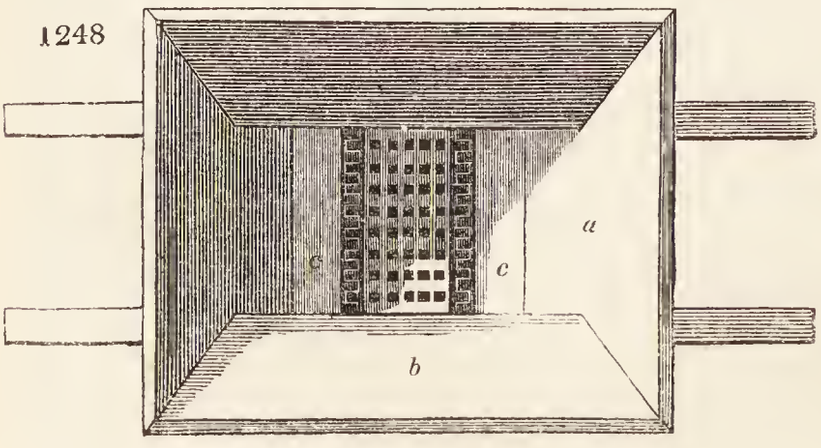
8441. *Time of putting up to feed.* If the second growth of grass has continued fresh till the latter part of autumn, cattle may be soon enough put up to feed by the 1st of November; but if the grass fail sooner, which it will in most seasons do, the middle of October is late enough for putting them up to feed. White globe turnips are an excellent juicy food for cattle till the commencement of the new year, after which should follow the yellow or green tops, for two months longer, and then the Swedish turnips will finish the season. If the Swedish turnips have been stored up before the second growth of the stem has made its appearance in spring, they may be taken out quite fresh till the beginning of June. Since the cultivation of the potato has increased so rapidly, many people feed their cattle on it in spring, either wholly or mixed with turnips. When cattle are fed on potatoes, attention ought to be paid to them after feeding, for fear of internal swelling. When observed at first, the swelling may be allayed by pouring down the throat a bottleful or less of common whale oil, which will check the fermentation, and operate as a purgative. Should any of the young cattle or the feeding beasts in the byre be choked with a piece of turnip, for those fed in hammels never or very seldom do so, the best expedient is to use the probang at once, rather than to permit the throat of the poor animal to be squeezed and consequently inflamed in attempting to push the piece of turnip up and down. The probang may be used with great success, by causing the animal to be forcibly held by superior strength, with its neck and mouth stretched forward, and while one is pushing the instrument gently down, another is directing the end of it down the gullet on the outside of the neck. When the piece of turnip is pushed down into the stomach, let the instrument be gently drawn out; and if, during the operation, the animal forcibly twists its head about, the instrument should instantly be let go. Feeding cattle will eat very little straw; but they ought to have abundance of litter at all times.

8442. *Comparative merits of feeding cattle in hammels and byres.* "Our decided predilection is in favour of hammels. In them the cattle are at perfect liberty to roam about, if disposed for exercise: they are exposed to all the sunshine there may be in a winter day; and the very rain which falls on their backs titillates the skin, and causes them to lick and clean themselves; they are comfortably warm in their sheds among an abundance of straw in the coarsest night, and cattle will never suffer from cold, when they have a comfortable shelter to which they can repair at will; they can come and go to their food whenever they please, night and day, and, their meat being constantly in the open air, it will be always fresh and sweet; and their feet and hair, when they come to travel, are quite able to bear the hardness of the road and the coldness of the air. These are all advantages which no byre can confer. Nor are the hammels so expensive in their original erection as many represent them to be. We have seen a range of them consisting of five divisions, capable of feeding twenty large oxen, erected for 20*l.*; but these had no regular roof. The roofing of all buildings is the most expensive part of them. The roof of those to which we refer, consisted of trees laid across as beams, about a foot asunder, the space between them being filled up with the branches of the spruce fir and Scotch pine. Such a place was a choice one for stacking pease or beans upon. To this purpose it was often appropriated; or it was covered with straw, roped down, which was used as bedding for the cattle in the first part of the succeeding season, when fresh straw was put in its stead. In the hammels which faced the south, the cattle were well fed and comfortably lodged; and no byre could have afforded so much accommodation at the same expense." (*Quart. Jour. Agr.*, vol. ii. p. 241.)

8443. — 6978. *Milk is preserved from becoming acid* by the addition of any alkali; because, when milk ferments, it developes an acid, which the alkalies neutralise. Hence alkalies prevent the curdling of milk. Alkalies applied to curd will turn it into milk: they are not unwholesome, but in large quantities give the milk a disagreeable flavour. (*L'Agriculteur-Manufacturier*, Mai, 1831.)

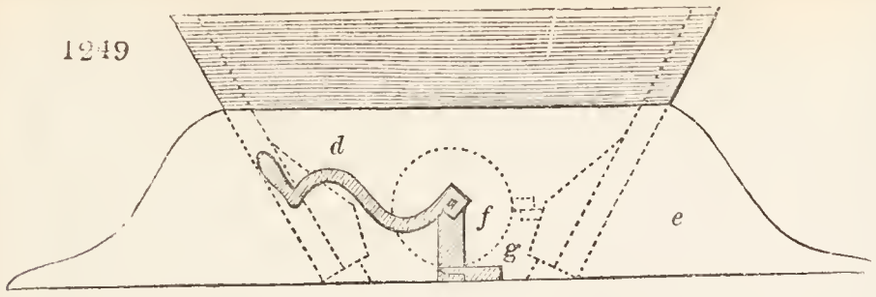
8444. — 7008. *A curd-breaker for skim-milk cheeses* (*figs.* 1248. and 1249.) has been invented by Mr. Robert Barlas, of Gilmour Place, Edinburgh. It consists of a hopper of wood (*fig.* 1248. *a*), seventeen inches and a half by fourteen inches on the top, and ten inches in depth; and a cylinder of hard wood six inches and three quarters (*b*) in length, and three inches and a half in diameter. The cylinder is studded with square pegs made of hard wood, each a quarter of an inch in the side, cut square at the ends, and projecting three eighths of an inch. There are eight teeth in the length, and fifteen in the circumference, of the cylinder, 120 teeth in all. It revolves on a round iron axle twelve inches in length, and is moved by the crank handle (*d* in *fig.* 1249.); *c c* are two wedge-shaped pieces of hard wood, made to fill up, in some degree, the space between the side of the hopper and the cylinder. These pieces rest on a slip of wood nailed to the lower

1248

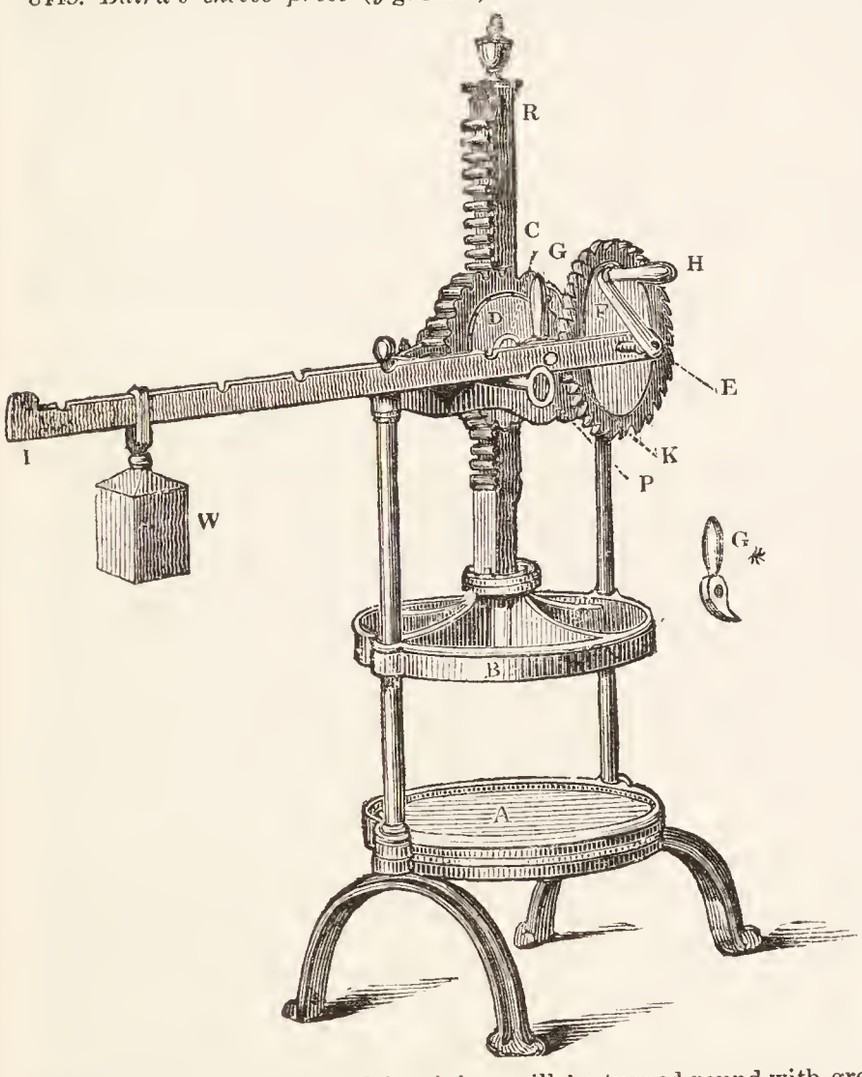


rim of the hopper, to keep them in their place. The face of these is studded with nine teeth of hard wood, similar to those on the cylinder, at opposite sides. The stand (*e*) (*fig.* 1249.) can be made of any length, to suit the breadth of the tub into which the curd is broken. The implement is used in this manner: — Place over it a tub, heap the hopper (*a*), with curd, and, on turning the winch (*d*) in either direction, the curd will fall, broken quite small, into the tub. While one hand is moving the machine, the other can press the curd gently down into the hopper. As cleanliness is a matter of the greatest importance in cheese-making, the internal parts of this machine, being loosely put together, can be easily taken to pieces to clean. The cylinder axle rests on two hard wooden blocks (*f*, *fig.* 1249.), one on each side, which slip out of their groove. They are held in their working position by the thumb-catch (*g*), sunk flush with the bottom of the stand (*e*), one over each block. The wedge-shaped pieces (*c c*, *fig.* 1248.) come out. To prevent the curd working out of the sides of the axle, the cylinder is set a little at both ends into the sides of the hopper. The dotted lines in *fig.* 1249. will give an idea how the internal part of the machine is constructed. Only one tooth is represented on the cylinder by the dotted lines, to show the position of the whole. (*Quart. Jour. Agr.*, vol. iv. p. 385.)

1249



8445. *Baird's cheese press* (*fig.* 1250.) is one of the most convenient in use. "The form containing the curd is put on the bottom plate, A, and the top plate, B, is made to descend and press on it. There are two ways of doing this: one quick and easy, until the resistance becomes great; and the other slower, but more powerful, and used for the conclusion of the operation. On the axis, C, of the wheel, D, there is a pinion of eight teeth (not seen in the engraving) which works in the rack, R. On the axis, E, there is another pinion of eight teeth (concealed by the other parts) which acts in the wheel, D, of twenty-four teeth. This axis, E, may be turned by the winch handle, H, three turns of which will make the rack descend through a space corresponding to eight of its teeth. In this way the plate, B, may be lowered to touch the cheese, and to commence the pressure; but when the resistance becomes considerable, the second method of acting on the rack must be resorted to. On the axis, E, besides the pinion before-mentioned, there is a fixed ratchet wheel, F: the lever, I, forked at the end, which embraces F, is also placed on this axis, but turns freely round it. In the forked part of F, there is a pall or click, G (better seen at G*), which, turning on the pin, K, may be made to engage in the notches of the ratchet-wheel, F. By means of this arrangement, when I is raised up, and G engaged in F, the axis, E, and its pinion, will be turned round with great power on depressing the end, I, of the lever; and by alternately raising and depressing I, any degree of pressure required may be given to the cheese; after which, if it be wished to continue the pressure, and to follow the gradual shrinking of the cheese, the lever is to be raised above the horizontal position, and the weight, W, hung on, which will cause it to descend as the cheese yields. By inserting the pin, P, this effect may be discontinued, and the farther descent of B prevented. (*Highland Soc. Trans.*, vol. x. p. 52.)



8446. *The pneumatic cheese press* (*figs.* 1251, 1252.) is the invention of John Robison, Esq., Sec. R.S.E. When of full size, this press may consist of a stand about three feet high, on the top of which may be fixed a tinned copper or zinc vessel, of any required capacity (say eighteen inches diameter, and eighteen inches deep), to contain the prepared curd. This vessel should have a loose bottom of ribbed work, covered with wirecloth, from under which a small tube, nearly twelve inches long, should communicate with a close vessel, capable of containing all the whey which may be drawn from the curd in the upper vessel. At one side of the stand there may be a small pump-barrel of about seven inches deep, from the bottom of which a suction pipe should terminate at its upper end in a valve opening upwards, and a piston, with a similar valve, should be placed in the pump-barrel, and be worked by a jointed lever, as shown in the model. The process is to be conducted as follows: — The curd being prepared, and salted in the usual way, a cloth is to be put over and into the upper vessel, and the curd put lightly into it, except round the edges, where it should be packed quite close to the sides of the vessel, so that no air may pass that way; the pump handle is then to be briskly worked for a few minutes, on which the pressure of the external air will force the whey to run down the tube into the whey-vessel; when it ceases to run, a few strokes of the pump may be repeated. The cloth and its contents are then to be lifted bodily out of the curd-vessel, and to be put into a mould of close wirework, with a weight placed over it until it become firm enough to be handled. The mould should stand on a sparred shelf (a shelf made of laths like a bacon rack) to allow the air free access to it on all sides of the cheeses. In *fig.* 1251., *a* is a vessel containing the curd; *b*, a vessel for containing the whey; *c*, a tube communicating from *a* to *b*; *d*, an air pump

for exhausting the air in *b*; *e*, tube communicating from *d* to *b*; *f*, a tub for letting off the whey from *b*

1251

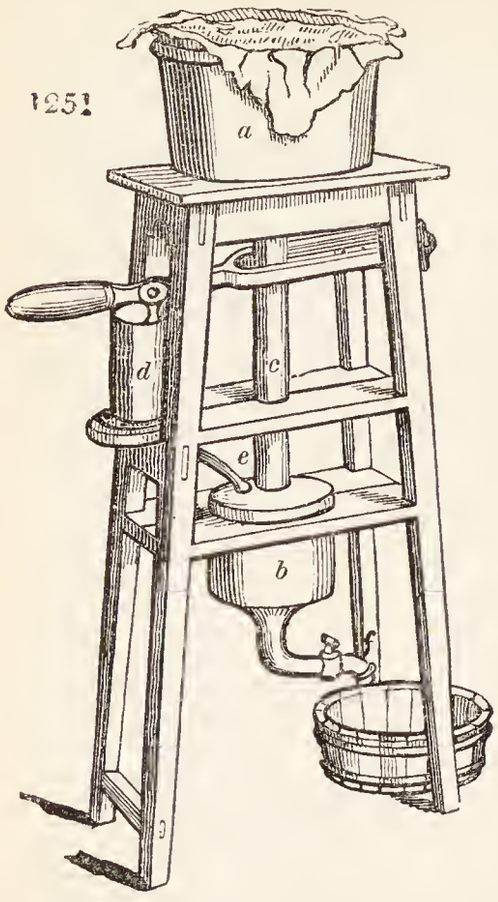


Fig. 1252. is a false bottom for the vessel *a*; *g*, wood frame; *h*, wirecloth. (*Highland Soc. Trans.*, vol. x. p. 200.)

8447.—7086. *New Stilton cheeses* may be made to acquire the flavour and appearance of old ones, by inoculating them with portions of the old, containing blue mould. The little scoop which is used in taking samples of cheese, affords a ready means of performing the operation, by interchanging ten or a dozen of the rolls which it extracts, and placing them so as to disseminate the germ of the blue mould all over the cheese. A new Stilton cheese, treated in this way, and well covered up from the air for a few weeks, becomes thoroughly impregnated with the mould, and generally with a flavour hardly to be distinguished from the old one. (*Highland Soc. Trans.*, vol. xi. p. 233.)

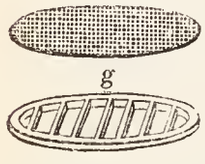
8448.—7184. *Management of the fleece in Australia.* In order to assimilate the Australian wool as much as possible with the German, in preparing it for market, the fleeces should not be broken, but merely divested of the breech and stained locks, and so assorted or arranged that each package may contain fleeces of the same character as to colour, length of staple, fineness of hair, and general quality.

8449. *If the washing* has been performed at the same time and place, and with an equal degree of care, the colour is likely to be uniform, and it will then only be necessary to attend to the separation of the fleeces as to length, fineness, and general quality; but if a large grower has flocks of different breeds, and fed on different soils, care should be taken that the fleeces be separated, first, as to colour, and then, again, as to length, fineness, &c.

8450. *Packing.* The fleeces, being assorted as already suggested, should be spread one upon another, the neck of the second fleece being laid upon the tail of the first, and so on alternately to the extent of eight to ten fleeces, according to their size and weight. When so spread, the two sides should be folded towards the middle, then rolled together, beginning at each end, and meeting in the centre; and the roll or bundle, so formed, should be held together by a slight packthread.

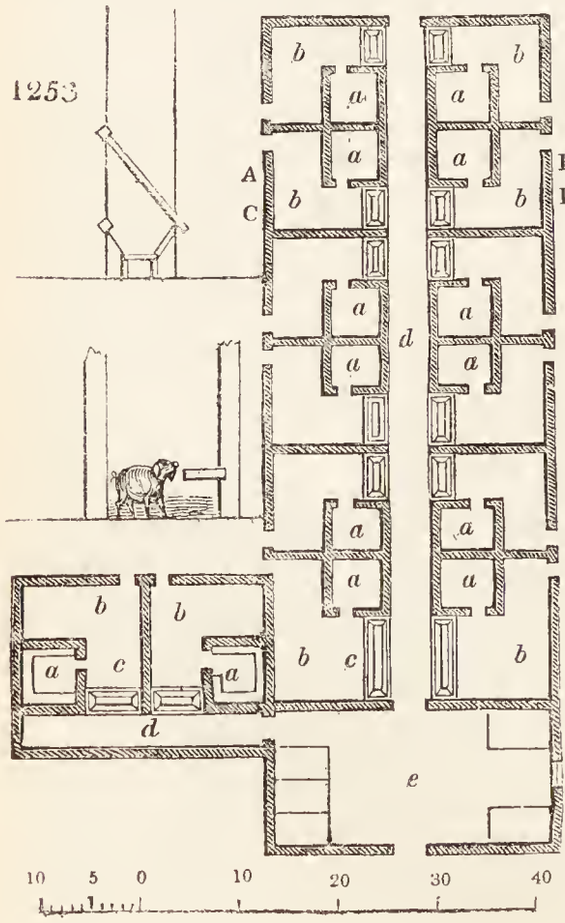
8451. *The bagging* should be of a close, firm, and tough nature. The material hitherto most generally used has been sail canvass, which very ill resists bad weather on a long voyage, and, when received here, even in favourable condition, is so dry and crisp, that it will tear like paper. A thicker, twilled, more flexible, and tough material would be preferable. The size and form of the package may be in length about nine feet, and in width four feet, sewed up on the two long sides, and at one end; the other end being suspended with the open end upwards to receive the bundles made up as before directed, which are to be put in one at a time, one of the flat sides of the roll or bundle being put downwards, and so on in succession; and the whole being well trodden down, until sufficiently filled for the mouth to be closed. This is the German mode of packing, but it is doubtful whether packages of the dimensions that have been hitherto sent from the two colonies may not be more convenient for so long a voyage.

1252



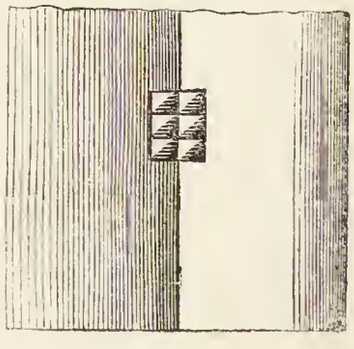
8452. *The operation of screwing* should be discontinued where it has been practised; as the pressure by the screw, and the remaining compressed during the voyage, occasions the wool to be caked and matted together in a manner that is highly prejudicial to its appearance on arrival. The practice, also, of winding up each fleece separately, and twisting a portion into a band, is productive, in a minor degree, of the same prejudicial effect; and it is to avoid this, that the making German bundles of eight or ten fleeces is suggested. (*Hobart Town Courier*, Jan. 8. 1834.)

1253

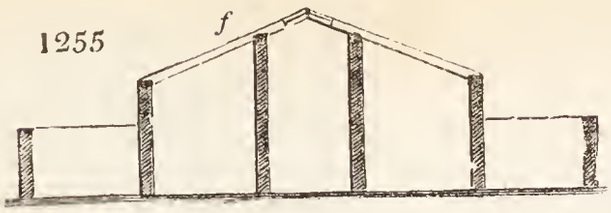


8453.—7274. *A pigsty* is a building which a general observer is in the habit of thinking requires no great care either in the plan or in the execution; but the experienced agriculturist is of a very different opinion. Pigs, to thrive, must be kept dry, warm, and clean, and this they cannot be without some contrivance. In general, a pigsty consists of two parts, a small open yard, and a small covered house, or shed; in the former, the animal eats and takes exercise, and, in the latter, he keeps himself warm and sleeps. As an example of a complete range of pigsties erected at Bagshot Park Farm, by Mr. Burness (see *Gard. Mag.*, vol. x. p. 332.), we refer to *fig.* 1253., which is a ground plan of a very complete building for breeding and fattening pigs. In this figure, *a* represents the lodging-houses; *b*, the exercise courts; *c*, the troughs into which food is put; *d*, passages for supplying food; and *e*, a house containing the food, in which there is a boiling and steaming apparatus, and three large tanks, for fermenting the food before it is used. *Fig.* 1255. is a section, on a larger scale, on the line A B, and *fig.* 1254. is a vertical profile, on a still larger scale, of part of the roof, showing the cover of one of the ventilators, marked *f*, in *fig.* 1255. *Fig.* 1256. is a section, on the line C D, on the same scale as *fig.* 1255.

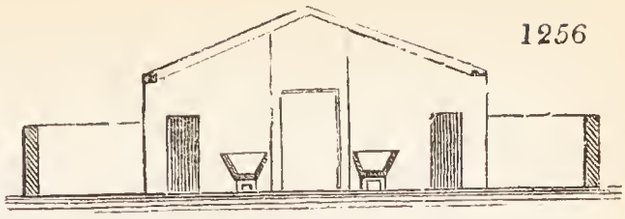
1254



1255



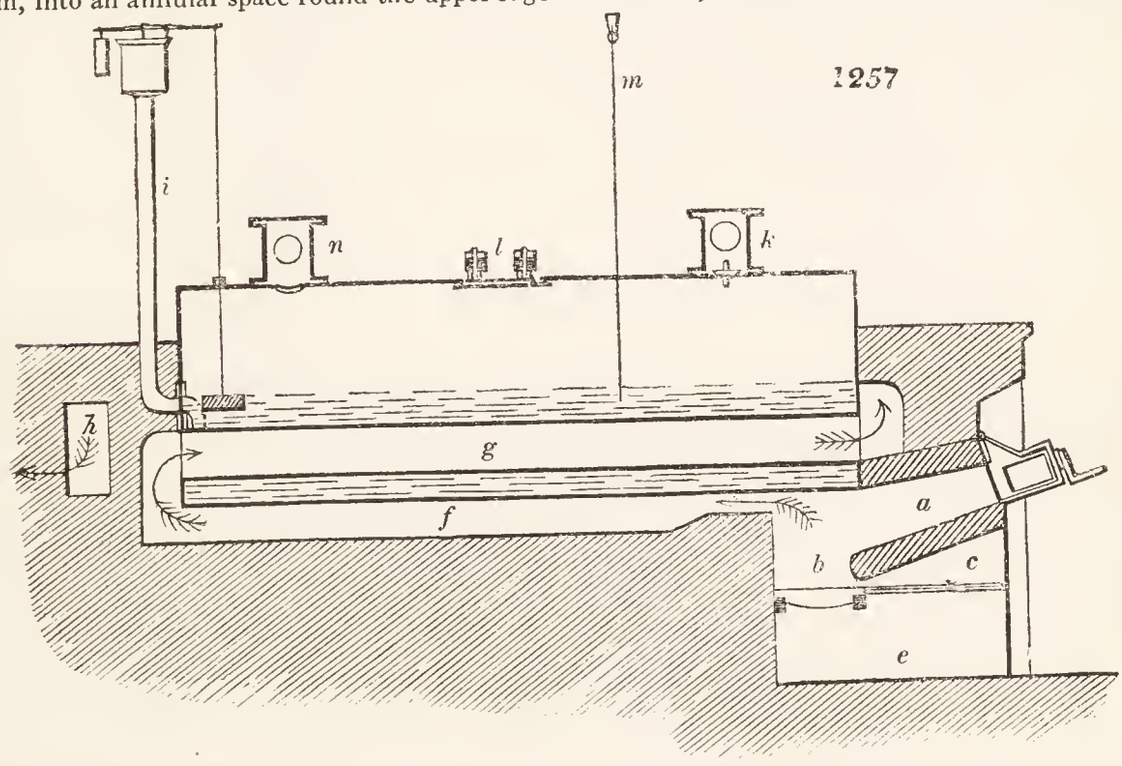
1256



8454.—7315. *Preparation of food for swine.* Mr. Bolton, who has fattened swine to an enormous weight, has the following observations on the subject in the *British Farmer's Magazine*, vol. vii. We consider them worthy of quotation, with a view of impressing on the mind of the reader the importance of fermenting food for this class of animals:—"I always feed my pigs on sour food, which I have invariably found to feed them faster, and to make the flesh firmer and whiter, than food given in any other state. The following is my method of preparing it:—As soon as the potatoes are steamed, I have them, while quite hot, beaten to a pulp, and mixed with bran, in the proportion of twenty-eight pounds of bran to a sack (240 pounds) of potatoes, and this mixture is put into a vat for ten or twelve days, till quite sour; this food makes the pigs fat enough for porkers or small bacons. When I require them more than commonly fat, I begin with fifty pounds of barley flour, instead of the bran, to each sack of potatoes, gradually increasing the quantity of flour till it amounts to half the weight of the potatoes; when the quantity of flour is greater than the moisture of the potatoes will absorb, I add a sufficient quantity of water to make it into a thick paste: I never give it until it has fermented."

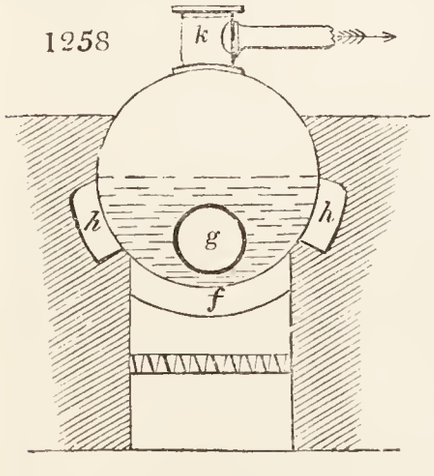
8455. *A description of Mallet's improved apparatus for cooking fodder for cattle by steam.* The simplest form of apparatus for this purpose usually met with, consists merely of a common open boiler, over which a tub, with its bottom perforated, is placed, and the junction rendered steam-tight by what is called a water-valve or water-lute joint; that is to say, by the lower edge of the tub projecting below its bottom, into an annular space round the upper edge of the boiler, filled with water. The tub is filled with

1257



the vegetable matter to be cooked; and the steam rising through the perforations of its bottom, from the water beneath (a fire having been lighted under the boiler), prepares it. This apparatus, excellent as it appears from its simplicity, has many disadvantages. The tub requires to be lifted on and off, by means of a crane, if of large size; a separate boiler is required for each tub; there is no mode of regulating the supply of steam, but by damping the fire, or urging it; and the boiler, to be supplied with the water spent in steam, needs the tub to be previously lifted off. Added to all, the boiler must be circular, and, therefore, of the worst possible form for economy of fuel. The next form is that in which several steaming vessels are supplied from one boiler, which may be of any form. Each of these vessels consists of a tub, as before, with a perforated bottom, and close but movable cover, which is placed on another shallow tub, with a close bottom, into which the steam from the boiler is conducted by a pipe from the boiler; the junction between the two tubs being made good, either by three or four thicknesses of felt, or by a gasket; a cock regulates the admission of steam to each lower tub, and a crane is provided, which commands the whole range, and lifts them on or off. The arrangement answers tolerably well, but has some inconveniences. But a comparatively small surface of the potatoes or other fodder is exposed to coction. The crane for lifting off the tubs, when each is capable of containing from four to six barrels of potatoes, requires to be a strong and rather costly piece of work; and the consumption of time and labour in lifting on and off, filling and emptying those tubs while hot, is very great, whereby a considerable loss in fuel accrues. All these considerations may be of small importance where the quantity of fodder cooked is small, and therefore the cost of labour and fuel slight; but where a large stock of cattle is to be fed with cooked food, and the apparatus is therefore nearly at constant work, every consideration of facility and economy becomes in the highest degree important. Accordingly, the following train of apparatus was designed for a gentleman, who is not only an extensive rearer of cattle, but one of the most distinguished agricultural improvers in Ireland.* It is conceived that it embodies most, if not all, that can be wished for the purpose. Fig. 1257. is a longitudinal section of the boiler, which is cylindrical, and four times its diameter in length. Witty's patent gas-furnace is applied to it

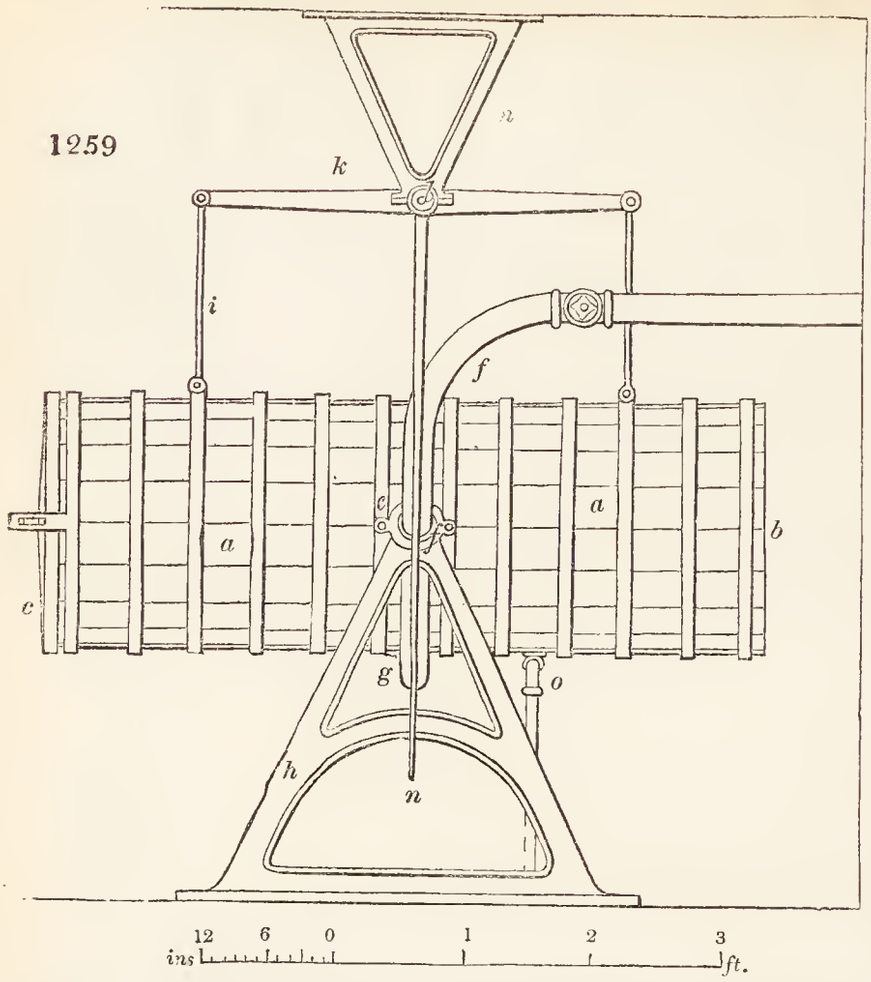
1258



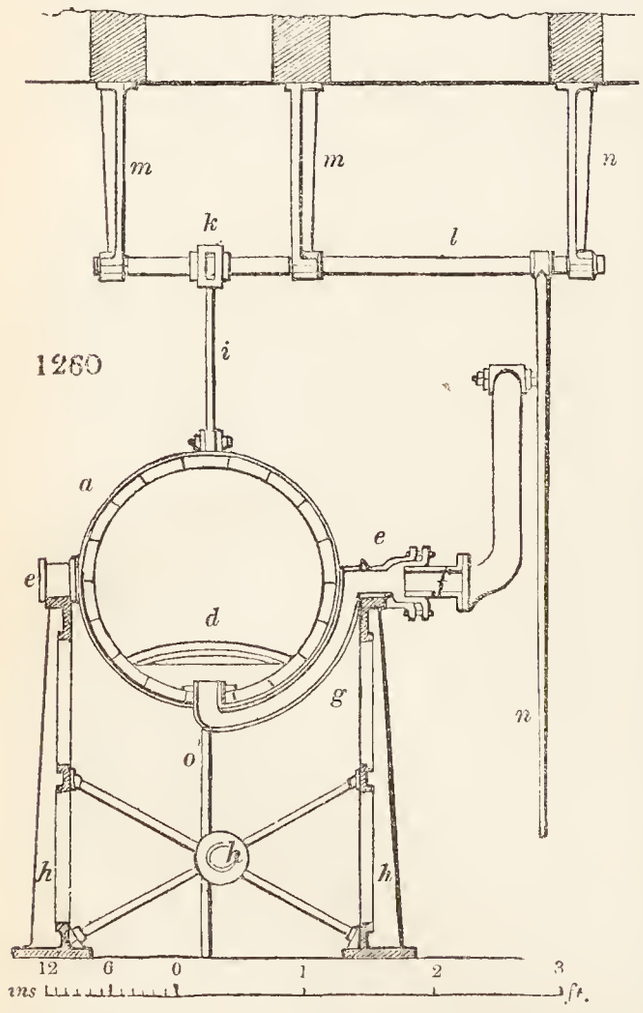
* Robert La Zouche, Esq., of Harriston.

a is the inclined plane; *b*, the fire bars; *c*, the dead plate; *e*, the ash-pit. The flame and heated air passes under the boiler, through the bottom flue, *f*, thence through the tubular flue, *g*, right through the body of water in the boiler; at the extremity of which it goes off, right and left, through two lateral flues, which join at *h*, and go into the stack or chimney: *i* is the feed head, supplied either from any sufficiently elevated source, or by a pump; it is adjusted, to supply the boiler at a pressure of 1½ lb to the square inch: *k* is the safety valve, loaded to the same pressure; the steam from it blows into the flue; *l* is the man-lid; *m*, a whistle, for the purpose of giving notice when there is a deficiency of water in the boiler, should such ever take place; boilers upon this construction being much more liable to injury in this respect than those which have no internal flues: *n* is the steam-pipe and stop-valve, which is connected with the steaming vessels. *Fig.* 1258. is a cross section of the boiler: the same letters refer to both figures. The top part of the boiler, above the masonry, is covered with a wooden jacket, one inch thick, and supported by segments of angle iron, at an interval of one inch and a quarter from its external surface; and for the same reason the walls of its setting are all built hollow. *Fig.* 1259. is a side elevation of the steaming vessel for cooking potatoes, carrots, parsneps, turnips, &c., or other such things; of which *fig.* 1260. is a cross section, through the centre of its length: the same letters refer to both. *a* is the external cylinder or outer case of the vessel, formed of oaken staves, one inch and a half thick, hooped together, and having a close end, staved in at the end, *b*. The other end is closed by a movable lid (*c*) of wood, fastened by cotters driven through two links formed in projections from the adjacent hoop, and made steam-tight by a gasket, soaked in bees' wax and tallow; it is capable of being very readily put on or taken off. In the lower segment of the cylinder, an arched wooden false bottom *d* is placed, stiffened by slight cross-ribs of cast iron, and perforated full of holes, five eighths of an inch in diameter; above, and supported by this, the matters to be cooked are placed until they quite fill the cylinder. The whole thing is hung upon two gudgeons or journals, *e e*, passing through the centre of gravity of the cylinder, when loaded; so that, by the arrangement about to be described, either end of it may be elevated or depressed. One of these journals is hollow, and immediately connected with the steam-pipe from the boiler by a stuffing-box, *f*; so that the steam enters the bottom of the cylinder through this journal and the curved pipe, *g*, the former having still free liberty of motion. Both journals move in brasses, resting on strong diagonal framing, *h h*, bolted down to a mass of masonry. *i i* are two wrought-iron links, connected by joints with the hoops of the cylinder at top, and with the extremities of the equibrachial lever, *k*; the centre of which consists of a Y shaft, *l*, supported by two or three slight frames, *m m m*, and having the long vertical lever, *n*, keyed on it at one end. These frames are bolted to proper timbers in the floor of the loft above. Now it is obvious that, by means of the vertical lever, *n*, either end of the cylinder may be elevated or depressed, and that the natural tendency of the whole system, when at rest, will be to remain horizontal. From the bottom or side of the cylinder at *o* proceeds a small tube, to take away the condensed steam; so made, that it shall permit the water to pass, and yet be steam-tight; and also that it shall remain vertical, whatever be the position of the cylinder. This is shown enlarged in *fig.* 1264. The upper end of the tube works in a steam-tight joint, *a*, like the pin of a common cock; but made so that there is a free passage through in all positions of the tube: the screw tail of this joint is secured into the bottom of the cylinder by a brass nut and felt washer; the joint being placed with its axis of motion at right angles to the axis of the cylinder. The lower end of the tube, *b* (shown only in part), consists of an inverted siphon, the returning limb of which is of such a

1259

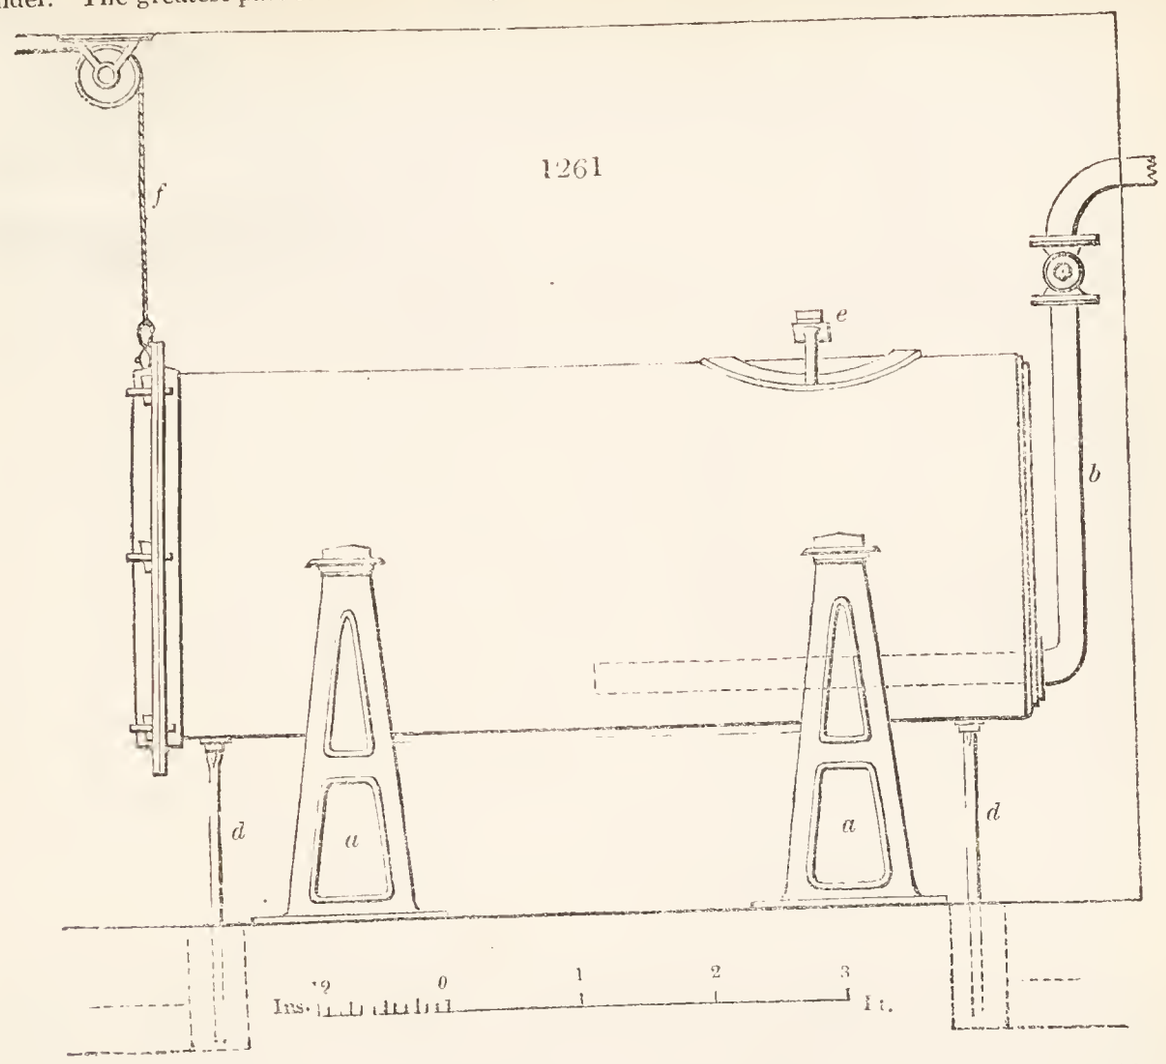


1260



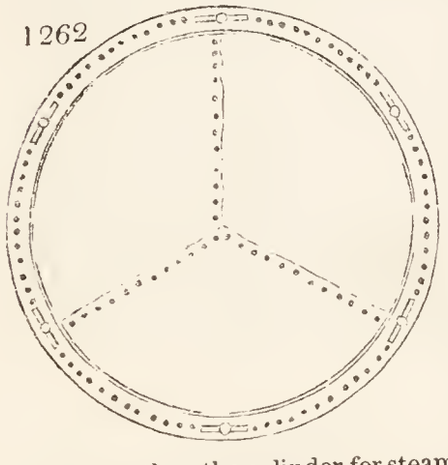
length that the column of water retained in it is equal in pressure to the density of the steam in the cylinder. The greatest part of this tube hangs freely in a square aperture, below the level of the floors

1261



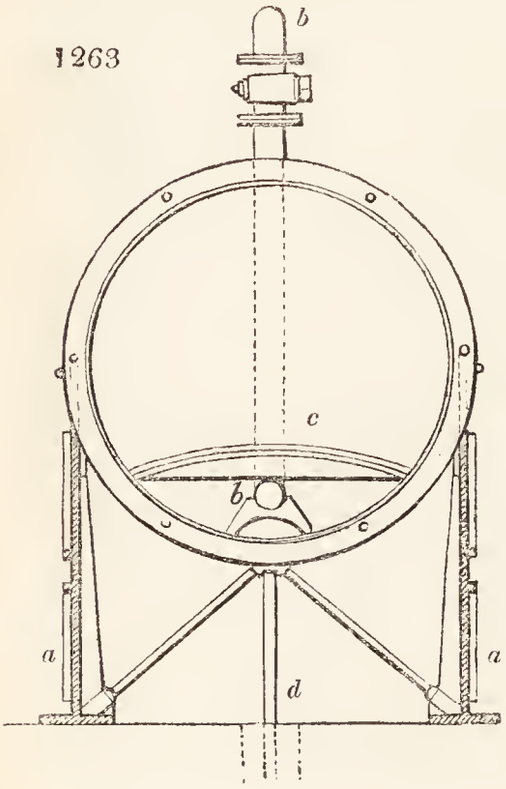
in *figs.* 1258. and 1259., where it is connected with a small sewer to take away the water. It is evident that, when the cylinder is moved, the tube will rise and fall vertically in the hole or upright trunk in the floor. Now for the mode of working this steaming vessel. The steam being up in the boiler, and the lid, *c*, removed, the end, *c*, of the cylinder is elevated to an angle of about 40°, when it comes just under a large wooden shoot or hopper from the loft above, close to which is placed a slicing machine, for dividing mangold wurtzel, turnips, or other large roots requiring to be steamed; from whence they drop direct through the hopper into the cylinder until it is full. Potatoes are either shot direct from a cart (if the situation permit of it) through the hopper, or from sacks from men's shoulders, into the cylinder. When it is full, the lid, *c*, is put on, and cottered tight; the cylinder again placed horizontally, and the steam admitted. When the steaming is complete, a low capacious truck, or a large square basket on wheels, or any other convenient receptacle, is brought under the end, *c*; the lid is removed, and the end, *c*, is now depressed sufficiently to cause the vegetable matter to fall out; the steam being previously shut off: the operation is then complete. The false bottom is now to be withdrawn; and it, together with the inside of the vessel, scraped and washed: the former is only necessary when potatoes are cooked in it. The objects proposed in this arrangement are, perfect ease in filling and emptying, without the necessity of handling either the heated vessel or food; nearly a maximum capacity with a minimum cooling surface to the vessel; perfect staunchness, durability, and readiness of examination and cleansing of the interior. If there be no other elevated supply of water to the steam kitchen, a pump should be fixed in it, both to supply the boiler and to wash the vessels: potatoes, especially, leave a kind of slime upon the inside of steam tubs, which soon putrifies. It is said the cattle are sometimes choked by small potatoes, which are not sufficiently steamed; this might be prevented by the addition of a pair of rollers, into the hopper of which the cylinder might discharge its contents; and they would bruise all to a given size, and deliver into the truck before mentioned. *Fig.* 1261. is a side elevation of the cylindrical vessel for steaming hay, chaff, bran, oats, clover, &c. It is of a much larger size than the cylinder for steaming more solid matters; and, therefore, is not made of wooden staves, but of iron plate riveted together like a steam boiler. *Fig.* 1263. is a cross section of the same: the letters of reference apply to both figures alike. The cylinder is supported on four vertical frames of cast iron, *a a*, properly connected by diagonal stays; one end of it is riveted in, and through it the steam-pipe, *b*, enters. The other end is movable, and closed by a circular lid or cover, also of boiler plate, secured by six cotter bolts, as shown in elevation, *fig.* 1261.; it is strengthened round its edge by a ring of two inches and a half angle iron riveted on, and is externally slightly convex: *c* is the convex false bottom, formed of sheet iron one eighth of an inch thick, punched full of round holes three tenths of an inch diameter, and stiffened by ribs of T iron, riveted to its lower side: *d d* are two siphon tubes for emission of condensed water, as before described: *e* is a man-lid for the purpose of filling in chaff, &c., or other such matters. The large end lid has got a counterbalance weight attached to the chain, *f*. The whole of this cylinder, and all the steam-pipes, are lapped over with slight haybands, which are lapped over with thick felt or dreadnought; and this, lastly, is sewed tightly over with strong sail canvass painted. This mode of uniting, as a coating, several bad conductors having different conducting powers, is found to resist the passage of heat much more effectually than an equal thickness, of even the worst conductor of the three. This fact, which, I believe, has not been hitherto noticed, will at once suggest to the scientific reader some curious

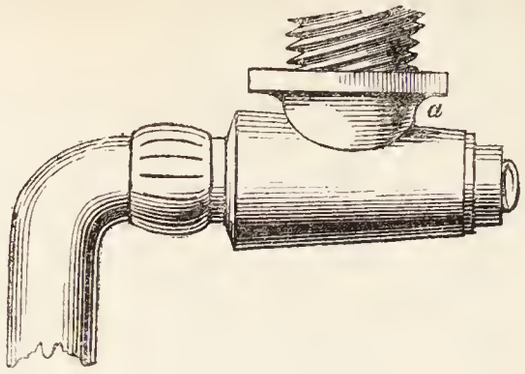
1262



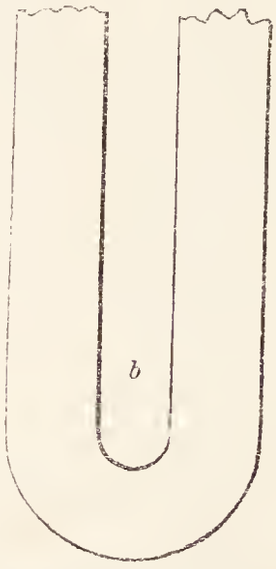
analogies to the passage of sound through media of different density; and which, indeed, caused the arrangement which has been described to be adopted. It will thus be seen that this second cylinder is

1263





1264

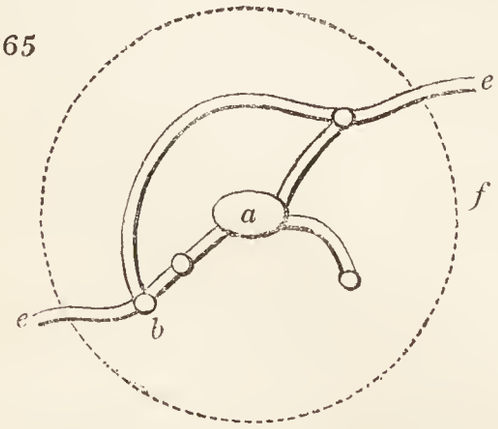


very similar in its general construction to that first described, except that it is not movable; which, from its magnitude, would be inconvenient, and is unnecessary for either hay or chaff, &c. Now of the mode of working it. In the loft above, immediately over the man-lid, *e*, is placed a chaff-cutter, and also a bean and oat bruiser, which both discharge by separate hoppers into the cylinder. The end lid having been put on and cottered up steam-tight, the vessel is thus filled with the desired material, which is spread uniformly with a fork through the man-lid. Steam is then turned on; and, when the operation is complete, the end lid is loosed and thrown up by the aid of the counterbalance above the cylinder end, and the contents drawn out by forks, or by a large but light and slender instrument like the worm of the ramrod of a gun. Before being used the first time, the inside of this vessel is given a coat of drying oil, and copal varnish mixed, which prevents subsequent oxidation. The general intent of the whole of the apparatus is to save labour and fuel, which it does effectually; and that portion of it for cooking potatoes is now about being erected in the new gaol of Mayo, the largest in Ireland. In some few cases, where the extent of the apparatus would be very great, and labour dear, it might be advisable to connect a small steam-engine with it, working from the same boiler, to pump water, slice turnips and mangold wurtzel, cut chaff, and bruise oats and beans, &c. Where a high pressure steam-engine pre-exists on a farmery for other purposes, the waste steam from it may be made fully available for steam-cooking apparatus, which thus would cost nothing; it requires, however, a particular adaptation, in order that the power of the engine may not be reduced, by driving the steam through any considerable resistance. Occasionally, but rarely, fluids may require to be boiled by steam, as stirabout for pigs, or wash for calves; for these, another form and construction of vessel altogether is necessary. (*R. Mallet.*)

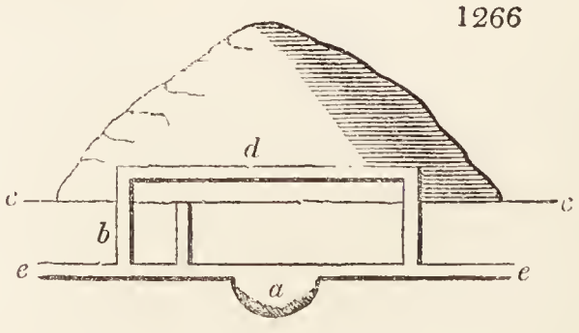
8456. — 7431. *Warmth* is strongly recommended for promoting the health of poultry. Cold, it is found, either produces inflammation of the lungs, or pulmonary consumption. Heat constantly prevents this, and alleviates the disease when it has taken place. (*Annales des Sciences Naturelles*, as quoted in *Quart. Jour. of Agr.*, vol. ii. p. 568.) Warmth, also, makes fowls lay. Every housewife knows that eggs are most abundant in warm weather; and all country housewives know that the only way to make hens lay in cold weather, when eggs are dear, is to feed them well and keep them warm — the latter being of very nearly as much importance as the former. Some excellent observations on the subject of rearing and feeding poultry will be found in our *Ency. of Cott. Arch.*, § 1325. to § 1329., and § 1356.

8457. — 7631. *The mole* may be extirpated without the use of traps by digging up the mole hills in the course of the month of March, which is the breeding season. In order to give an idea where the mole's nest is to be found, reference may be had to *figs.* 1265. and 1266.; the first of which is an underground plan,

1265



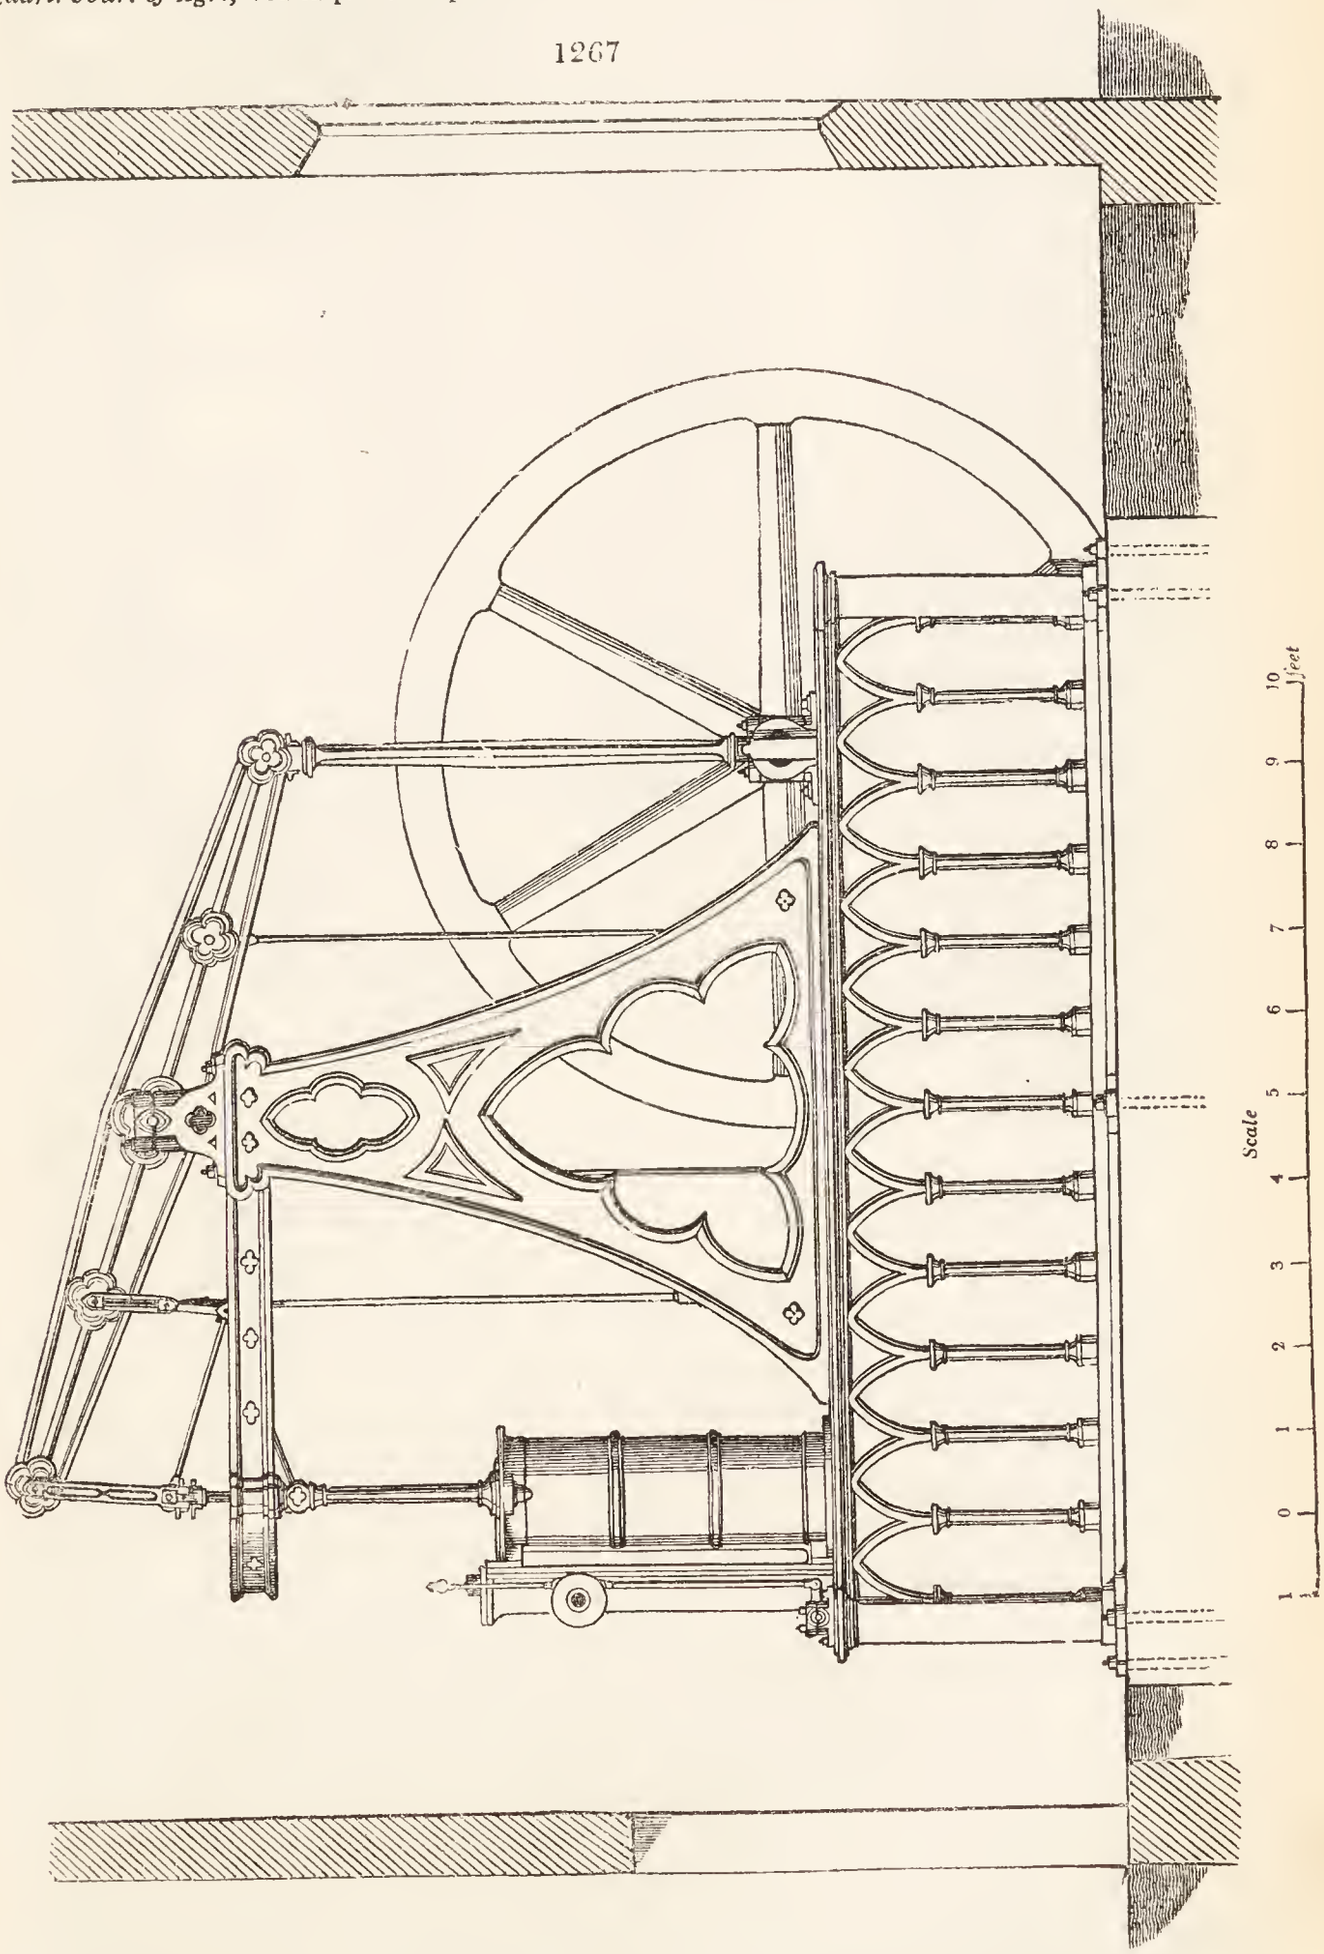
1266



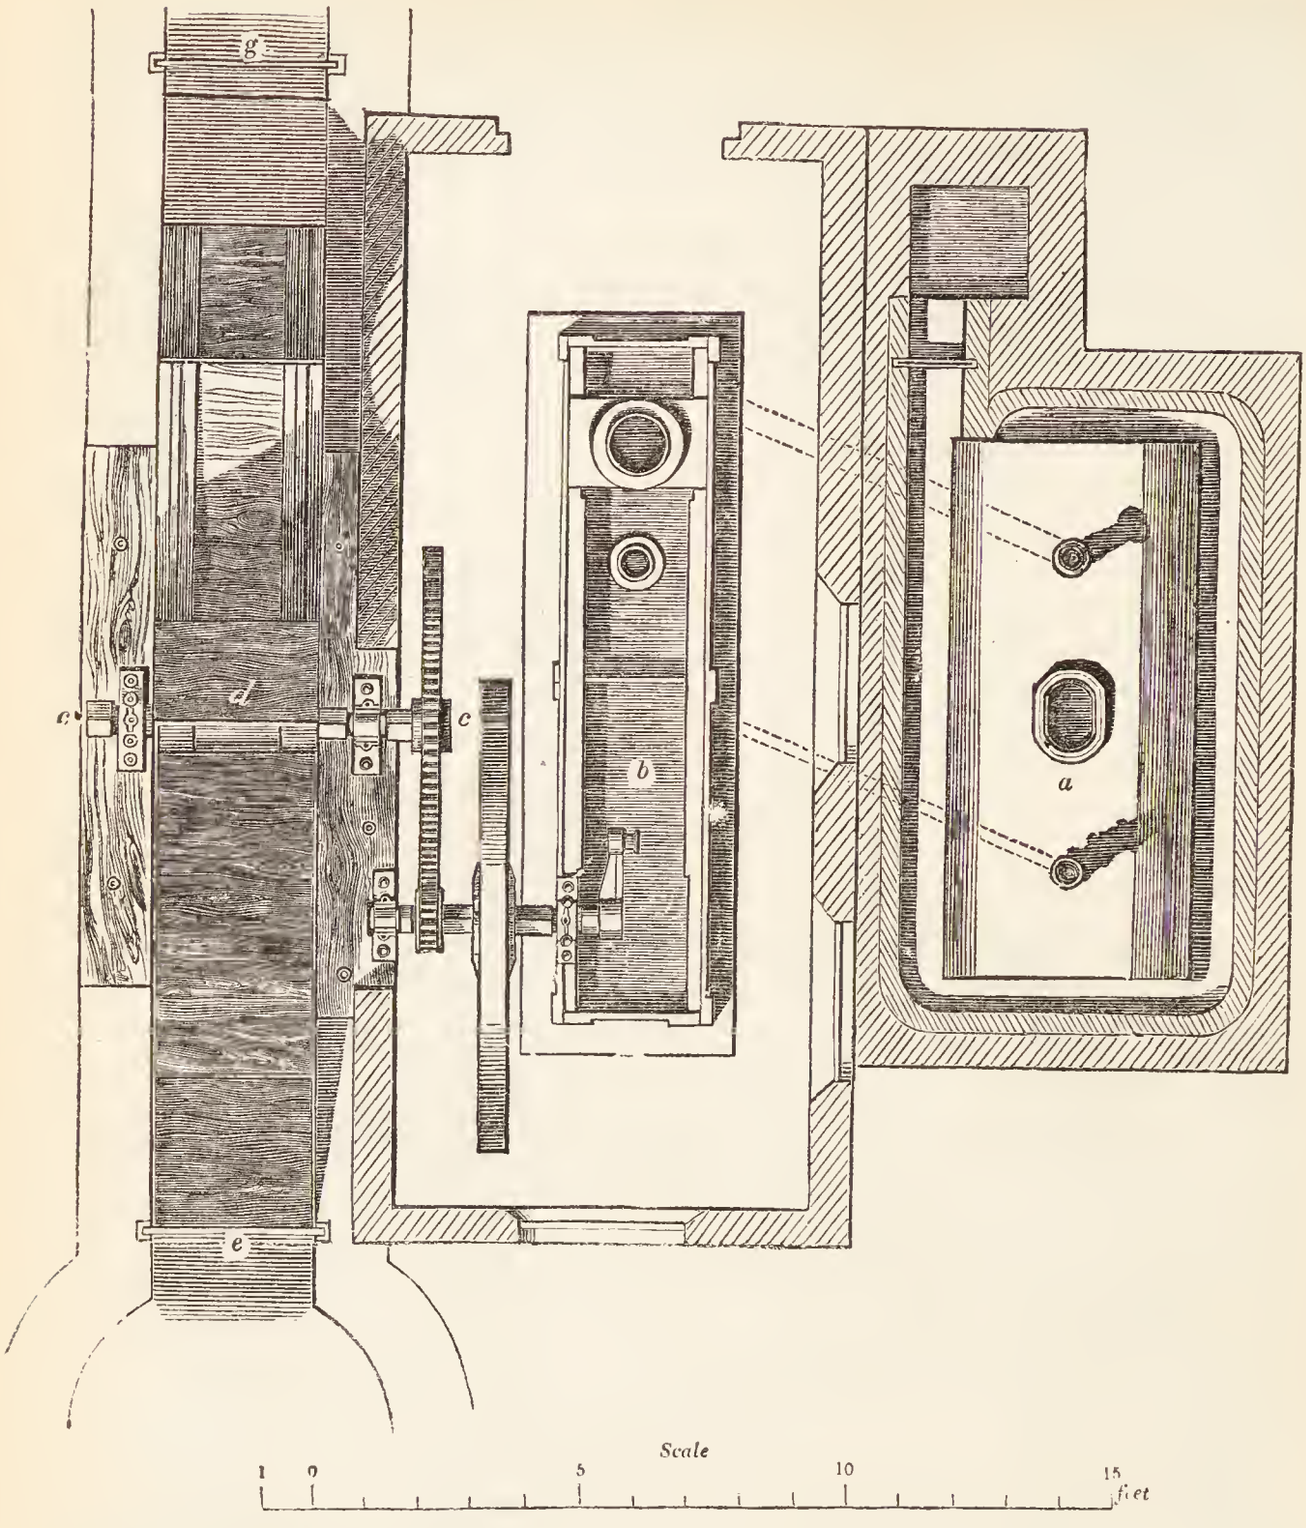
or horizontal section of a mole-hill, and the second a vertical section. In both these figures, *a* is the mole's nest; *b*, vertical tubes or runs, by which the mole ascends with the soil which it has excavated

from the place forming the nest, in order to raise a hill over it to protect it from the rain; *c c* show the surface of the ground; *d*, a tunnel above the surface of the ground, in the soil of the artificial hill; *e e*, the common run of the mole extended to an unascertained length on every side; *f*, line indicating the base of the hillock. After removing the hill, and destroying the young moles, by waiting a little without making the least noise, the parent will make her appearance, and may be also destroyed. (*L'Agronome*, vol. i. p. 220.)

8458. — 7632. *A mode of catching rats* by baiting the traps with ground pale malt scented with the oil of caraway seeds, and which is said to be very effective, will be found described, at great length, in the *Quart. Jour. of Agr.*, vol. ii. p. 319. to p. 331.



8459. — 7643. *Insects injurious to agriculture.* The following has been received from the writer of this article in the body of the *Encyclopædia*, W. Swainson, Esq. F.R.S. &c. — "Dear Sir, Although little disposed to notice the small critics, who love nothing so much as to be thought worthy of a reply, it is due to yourself that I should say something upon an attack made on the chapter regarding insects, written by myself in your *Encyclopædia of Agriculture*, and which attack I have just seen in an agricultural book,



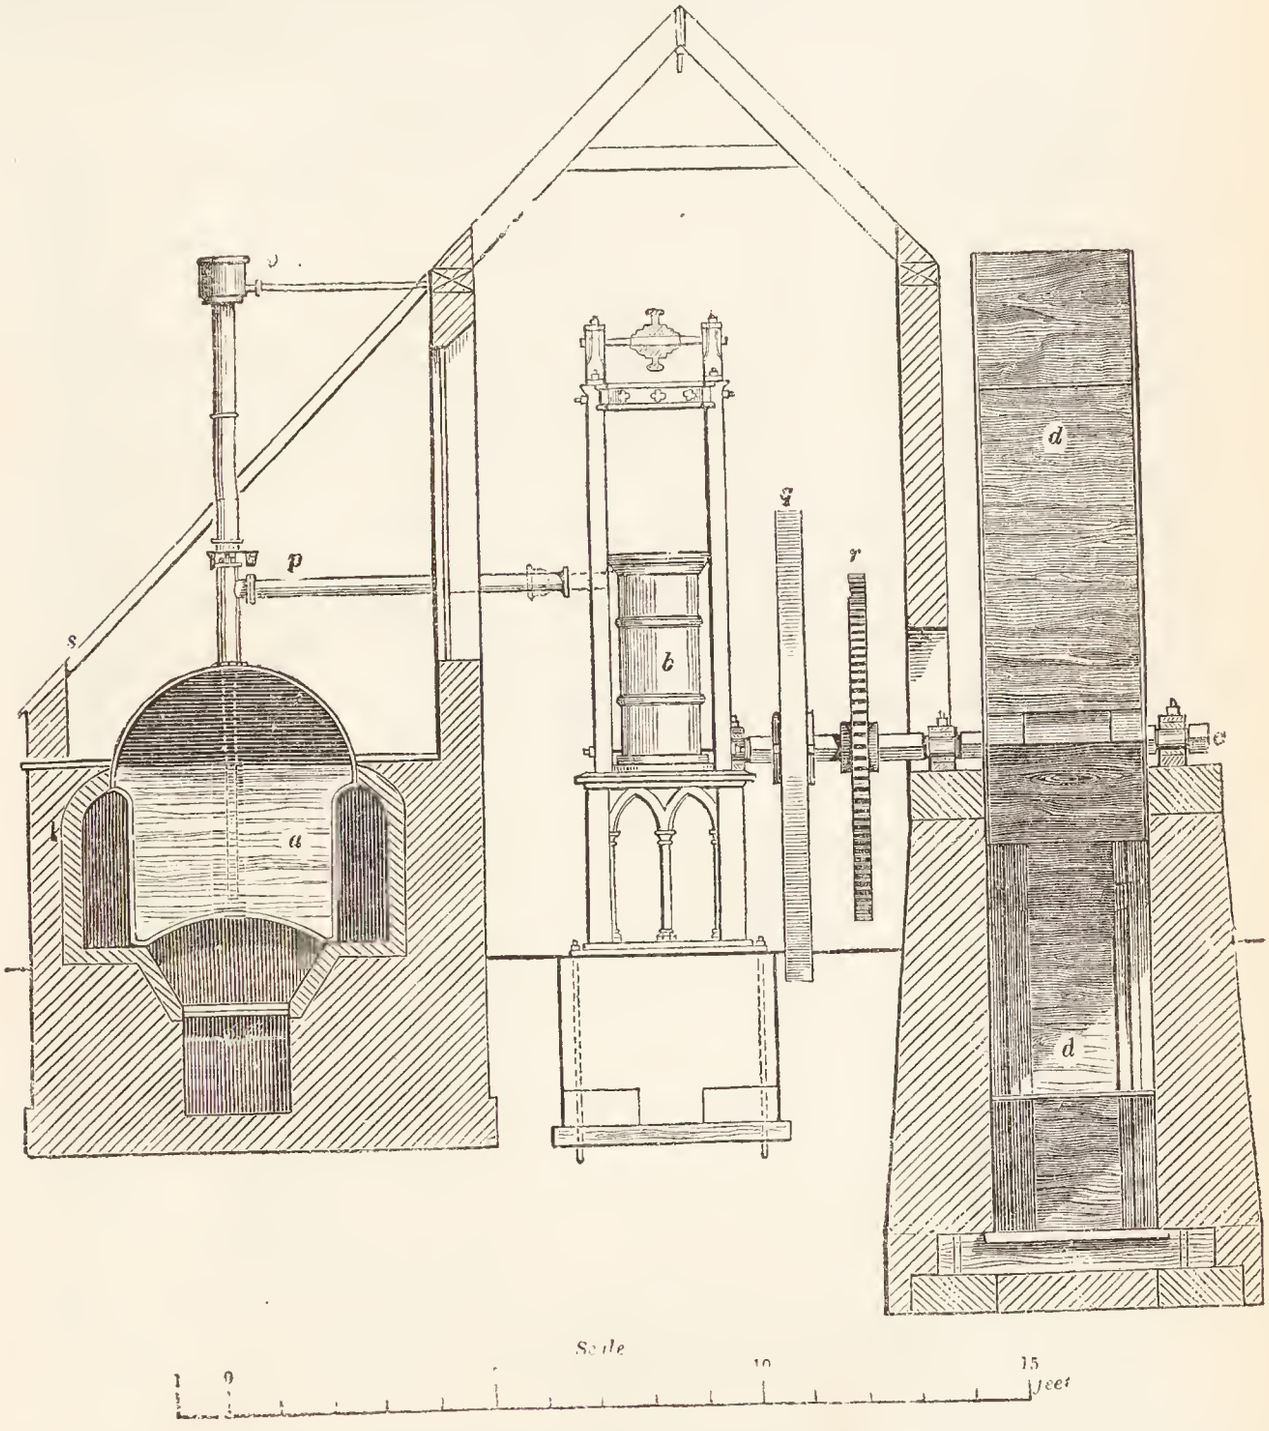
written in imitation of your excellent and useful work. It seems that I have said (p. 1113.), that, as the perfect suctorial insects (the Haustellàta of *Clairville*) 'are supported by suction alone, it is obvious that in this state they can do no injury to the agriculturist.' Yet, says the critic, 'in absolute forgetfulness of this extraordinary assertion, Mr. Swainson, in the very next pages, tells us of the extensively destructive ravages of these very suctorial insects, which he has just before pronounced to be incapable of doing any injury to the agriculturist.' So far for the charge: now for the inference. 'Such palpable blunders as these require no comment, but I (the critic) cannot help remarking that they are calculated to lead to extensive practical inconvenience, to puzzle the agricultural reader most inextricably, and to destroy very much his confidence in all book instructors.' Literary blunders are of two kinds. They either originate in the ignorance of the author with regard to the subject he is writing upon, or in the haste of composition; in which latter case they are usually, if not always, discovered on perusing the proof sheet. If, however, by any chance, the proof is not seen (and I have no recollection of this circumstance), and the mistake is a '*palpable* blunder,' it corrects itself; every one *palpably* perceives that it is an oversight, originating from the printer's omitting, perhaps, one or two words. It requires, indeed, no comment; for every one capable of reasoning sees at once that, by expatiating on the injury caused by the *Aphides*, I virtually correct the previous omission of those insects being an exception. So much for the 'palpable blunders,' the 'inextricable puzzlement,' the 'extensive practical inconvenience,' and the 'destruction of the confidence' of the agriculturist, the printer's omission has occasioned. 'The figures, indeed,' continues the critic, 'drawn by Mr. Swainson, prove his great accuracy as an artist; but the text equally proves that he knows little of insects beyond the atmosphere of cabinets and books, and that even his book knowledge is sadly deficient.' Now the figures in question *were not drawn by me*, but by Mr. Sowerby; and, in regard to the rest, who cannot help laughing at one of the oldest entomologists of England, who has, moreover, for years, lived under the temperate and tropical 'atmospheres' of both hemispheres, being gravely told that he knows nothing about insects beyond the precincts of his study! But when the same writer talks to us of the 'gross inaccuracy' of Linnæus, the 'credulous absurdity,' and the 'wild, mischievous, and absurd analogies' of Cuvier, the 'trash' of Mohs and Haidinger, the 'absurdity' of Savigny, and (to crown all) the 'flimsy productions' of Macleay and Horsfield (see the *Phil. Magazine*, Nov. 1831. No. lix.)*, need I add, that, to be associated in such a list (comprising, as it does, the

* The reader who wishes to know the entomological proficiencies of Mr. Rennie, will be greatly amused y turning to the *Entom. Journal*, vol. i.; and to the *Philosoph. Magazine*, for Nov. 1831. p. 372.

princes of science) will always be considered the greatest honour that can be conferred upon, dear sir, yours most truly—*W. S. Tittenhanger Green, Feb.* 12. 1834."

8460.—7776. *The agriculture of the different counties* in England, Wales, and Scotland, more particularly the grazing districts, will be found treated of in a work entitled, *The present State of the Tenancy of Land in the Highland and Grazing Districts of Great Britain*, by L. Kennedy and T. B. Grainger, published in 1829. This work contains a good deal of information on the subjects of sheep and wool, the great object of which is to show the difficulties under which the landowners and farmers are placed, in consequence of excessive taxation, as compared with the German baron who cultivates his own estate, or the agriculturist of Australia who possesses for nothing the right of pasturage over thousands of acres. The result of the whole is the "necessity of a protecting duty to the wool-growers." The time for protecting one part of capital and labour against another is, we trust, rapidly passing away.

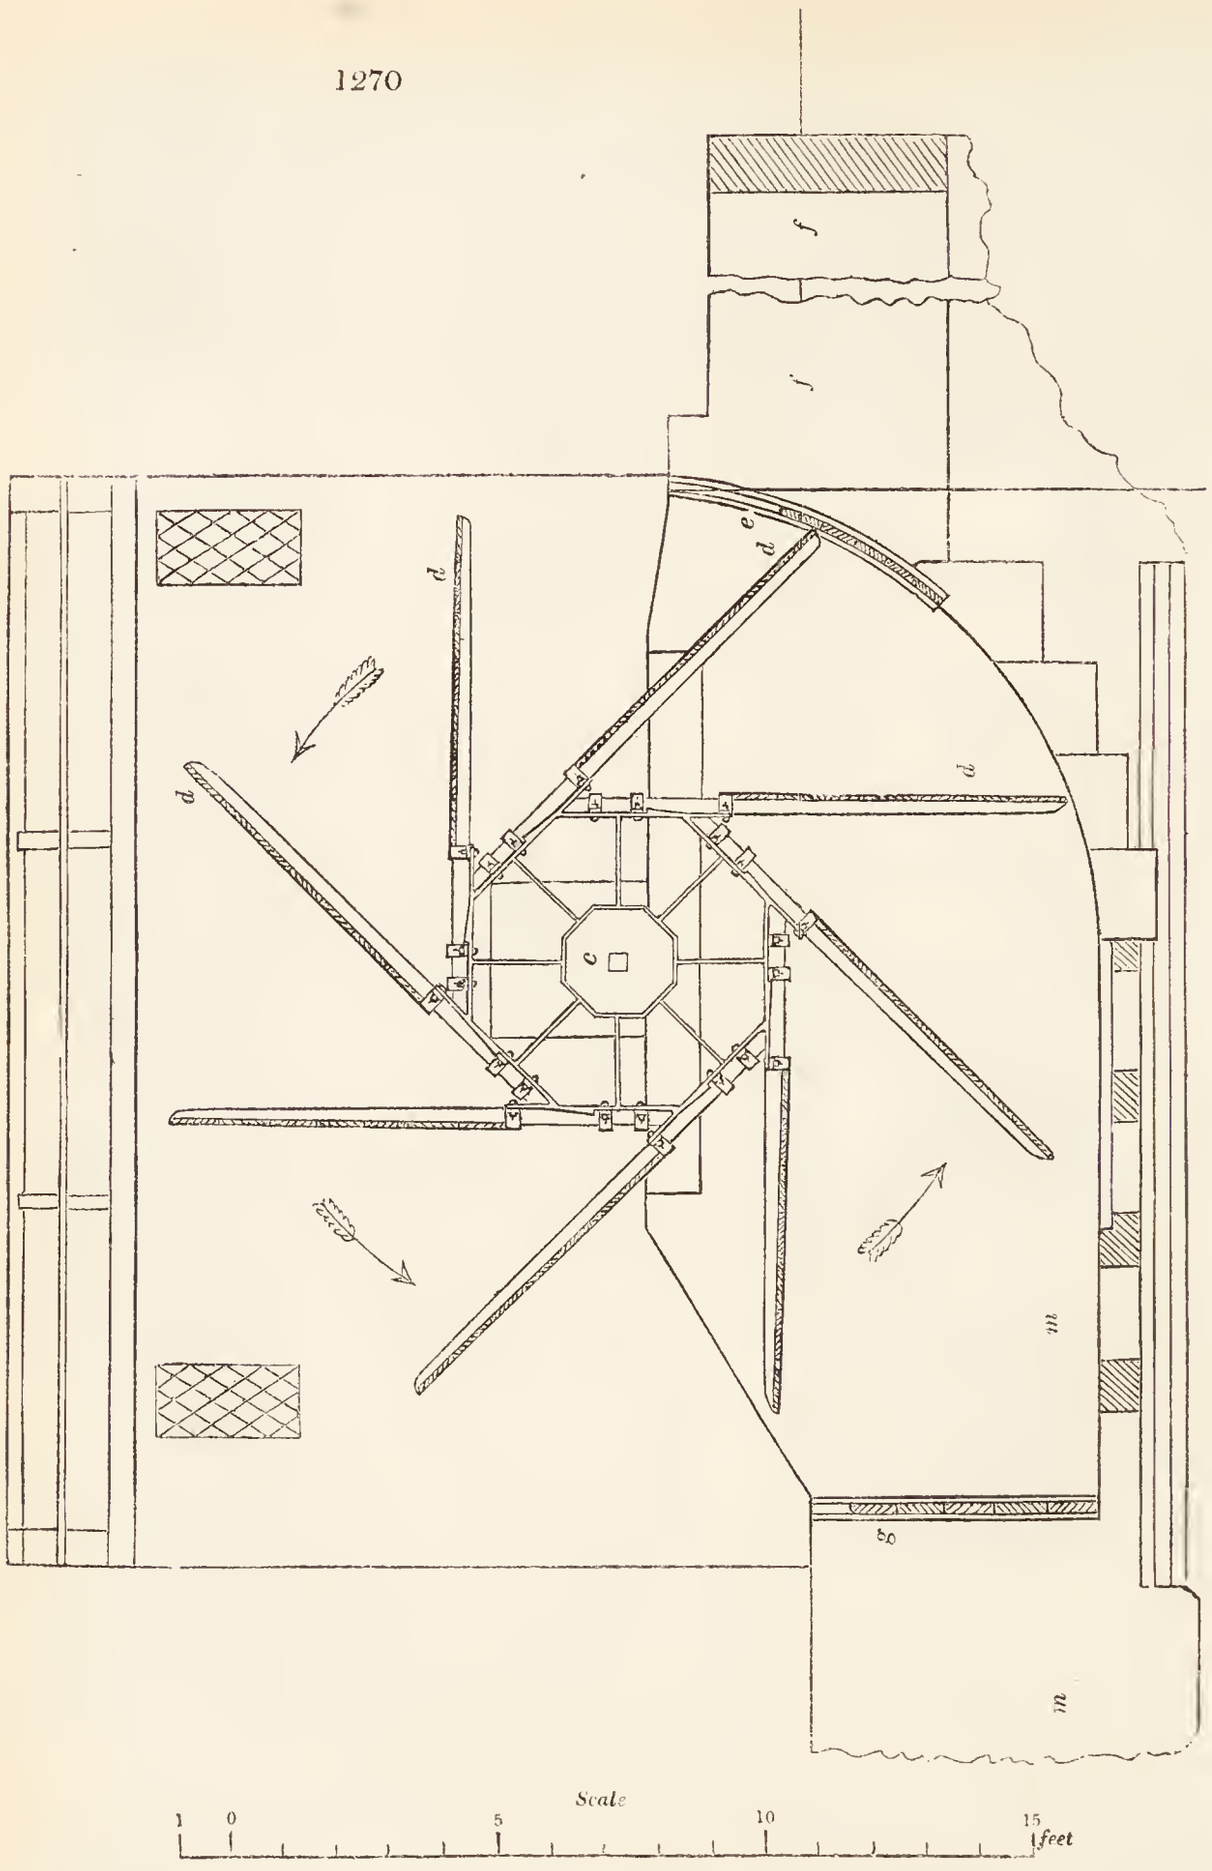
8461.—7784. 11. *The application of steam to machinery for raising the water from fen and low lands.* We have mentioned (§ 7786.), that steam had been employed for this purpose in Cambridgeshire; and we have since learned from the account of a trial, in the newspapers (see *Times* for July, 1834), that a gas engine has also been so employed in the Cambridge fens. We are now enabled, through the kindness of Mr C. H. Capper, engine-maker, Union Foundery, Birmingham, to figure and describe a steam-engine and



lifting machine of a very superior description, which that gentleman has erected on the estate of —— Drake, Esq., at Stainfield in Lincolnshire. "The great advantage," Mr. Capper observes, "of bringing fen and low lands (formerly rendered useless by floods) into cultivation, by a small outlay of capital, must be my apology for troubling you with so minute a description of the draining machine I have erected for that purpose; and, as the same may be of use to a few, I shall feel obliged if you will give it a place in your work; and at the same time add, that by the great improvements which the use of locomotive carriages has made in high-pressure engines, I am enabled to say that as effective an engine as the one described might now be completed for a much less amount,; or, if the landowners whose lands are subject to floods were to subscribe, a movable draining-machine might be made, at a very small expense."

Fig. 1267. shows the elevation of a six-horse portable condensing steam-engine, working a second shaft, marked *c*, in *figs.* 1268, 1269, and 1270. On this shaft, the large water-wheel *d d* is fixed. This wheel revolves in a brick or stone casing, similar to that formed for the wheel of a common water mill, but so accurately fitted as not to allow of any water passing by either of the sides of the paddles, or by the front; because this wheel acts by its paddles lifting the water from the bottom of the wheel race up against the breastwork, and then throwing it over the sluice *e*. This sluice is formed of movable boards, to admit of regulating the lift of water at pleasure, from 3 feet to 8 feet in height. The water, being raised and thrown over the sluice *e*, falls into the pond or receiver *f*, whence it is carried off at as high a level as it

1270



will run; in this case, at about 3 feet higher than the surface of the lands to be drained, and about 6 feet higher than the bottom of the drains. At the lower end of the trough there is a sluice, *g*, for regulating the quantity of water introduced into the lifting wheel; because, if this were too great, the power of the steam-engine might be insufficient to turn the wheel, or the machinery might be injured. The wheel, as it will be seen, consists of eight iron paddles, fixed to an octagon iron casing; each paddle acts by lifting up a portion of water from the bottom of the wheel-race, and raising it to the top of the sluice *e*. When the whole of the water, or nearly so, is lifted up, of course the boards composing the sluice *e* must be attended to, lest the water force its way back again upon the wheel.

Fig. 1268. is a ground plan of the boiler, engine, and water-wheel; in which *a* is the boiler; *b*, the engine; *c*, the water-wheel shaft; *d*, the paddles of the water-wheel; *e*, the upper sluice, over which the water is thrown; *f*, the pond or reservoir which receives the water; and *g*, the lower sluice, placed across the drain which conveys the water to the wheel-race.

Fig. 1269. is a section through the steam-engine and the water-wheel; in which *a* is the boiler; *b*, the engine; *c*, the shaft or axle of the water-wheel; *d*, the paddles; *o*, the tube for supplying water to the boiler; *p*, the steam pipe; *q*, the fly-wheel; *r*, the spur-wheels; and *s s*, the roof.

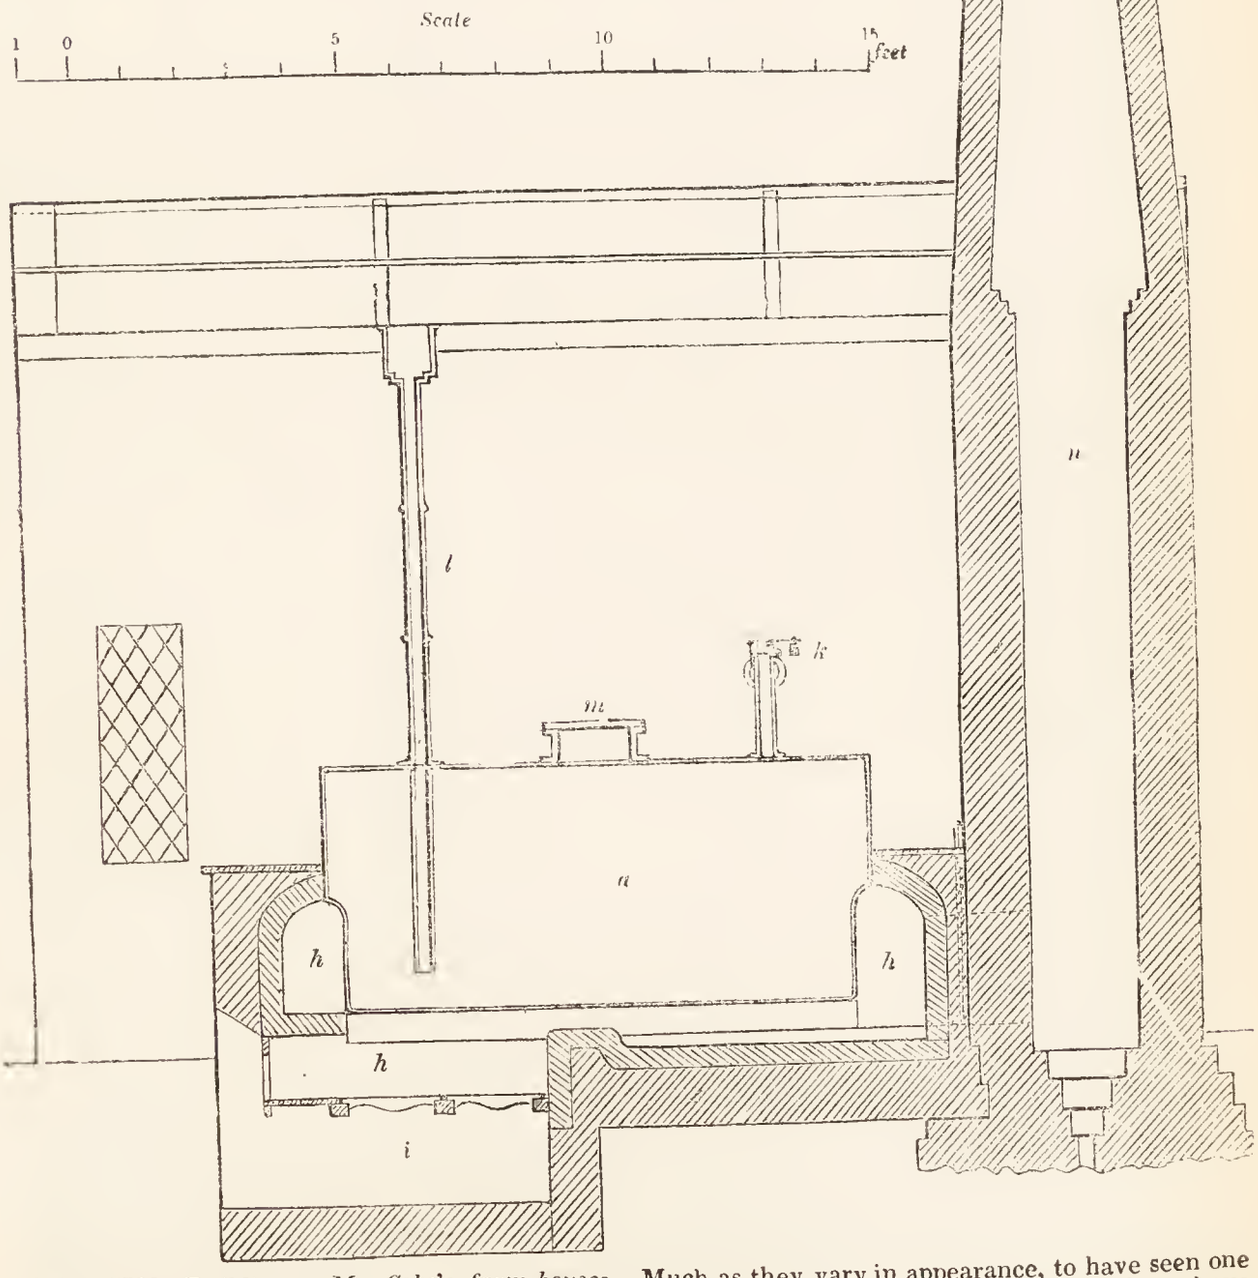
Fig. 1270. is a longitudinal section through the water-wheel, the trough, and the two sluices; in which *c* is the axle of the water-wheel; *d*, the paddles; *e*, the upper sluice, over which the water is thrown; *f*, the pond or reservoir to receive the water before it is carried off to the nearest river; *m* the trough or wheel-race; and, *g*, the sluice to regulate the admission of the water from the land to be drained.

Fig. 1271. is a section through the boiler lengthwise; in which *a* is the boiler; *h*, the fireplace, and flue round the boiler; *i*, the ash-pit; *k*, the safety valve; *l*, the tube for supplying water to the boiler, *m*, manhole for cleaning out the boiler; and, *n*, the chimney.

8462. *Action of the machine.* After these particulars, little description will be needed; for it must be evident that, when the engine is set in motion, it will, by means of the wheel and pinion *r*, turn the water-wheel, *d d*, about its centre, *e*; and that, when set in motion, each of the arms will lift a quantity of water from the trough, or wheel-race, *m*, over the sluice *e* (see *fig.* 1270.), at a higher level to the pond or reservoir, *f*, whence it may be taken away as circumstances may require.

8463. *The expense* of the portable steam-engine, exclusive of carriage, and putting up, was about 280*l.*; that of the fitting wheel, exclusive of the masonry, about 70*l.*; and the total expense of the whole about 450*l.*

1271



8464.—7788. *Buildings. Mr. Coke's farm-houses.* Much as they vary in appearance, to have seen one of Mr. Coke's farm-houses is to have seen all, as respects character. Of these, besides such as have undergone repairs and additions, not directed solely to the acquisition of perfect comfort, but of highly tasteful ornament, the liberal proprietor has erected fifty-two entirely from the ground. Landlords who grudge their tenantry even the repairs requisite to preserve a miserable hovel in safety above their heads, will find everything to censure in this part of the arrangements at Holkham; for, not only are these cottages tasteful beyond anything usually erected of the kind, but it is utterly impossible to imagine anything more commodious and replete with convenience. They are, in fact, suitable for the residence of gentlemen of moderate independent fortune. This may be considered superfluous, and certainly less might be made to suffice; but Mr. Coke's farms are all large, and his tenantry must be men of a certain capital. Independently of these considerations, Mr. Coke's is evidently the right system. He does not fail to reflect, when he builds for a tenant, that, in all probability, he has like notions of comfort (though more humble) with himself, and that without certain and ample conveniences he cannot employ the

produce of his farm advantageously to either tenant or landlord. In this spirit Mr. Coke has provided amply for the comfort of his tenantry, not only cultivating and improving their taste while he gratifies his own; but, which is infinitely more important, convincing them at the same time that all the requisites to their comfort and advantage are duly cared for. Though built in a style the most simple, these houses present a whole in accordance with the truest taste, and all has been accomplished by the most simple means. A sea shingle, of which grey is the predominant hue, embedded in plaster, and occasionally divided into compartments, gives a beautiful appearance to the walls; and where coping can be useful or ornamental, it is happily introduced in blocks of what appears beautiful stone, but is, in fact, a naked brick earth, produced on the estate. In this way the neighbourhood has been studded with a number of most tasteful structures, calculated to produce even a moral influence on the conduct of the occupants. Taste, neatness, cleanliness, are thus daily upheld before them, as a pattern set by their landlord; and they are continually silently, but expressively, reminded, that he who has done this for them expects, and has a claim for, a corresponding return. Such is the value of good example, no matter how directed to us; even a well-arranged house, with a cleanly and tasteful exterior, may teach its occupant excellent morality. (*Brit. Farm. Mag.*, vol. viii. p. 12.)

8465. *Mr. Coke's cottages.* "The village of Holkham is occupied, I believe, solely by Mr. Coke's servants and workmen, or by the superannuated members of both classes. The cottages are rendered highly picturesque and neat by the application of shingle, as in the case of the farm-houses; and to each is allotted a garden, sufficient for the occupation of leisure hours, and no more; it being Mr. Coke's opinion, that his labourers would not find their condition ameliorated, nor their capacity to do justice to their employer or themselves extended, were they converted into small farmers or market gardeners." (*Brit. Farm. Mag.*, vol. viii. p. 12.)

8466. *Lady Anne Coke's school* forms a pleasing structure in the village of Holkham, in which the children of the village receive, in the words of the Rev. Henry Berry, "an education suitable to their Christian vocation, and for the rank of life to which God has been pleased to call them." "I am happy," continues the rev. gentleman, "to be able to record the unquestionable utility of this establishment. There is a certain moderate degree of education, which has always been found adequate to raise an industrious and talented man to that consequence in his business, of whatever nature, which such characters are entitled to attain." (p. 14.)

8467.—7862. *Description of a machine for making subterraneous drains in bogs*, the invention of William Kersall Wrigg, C. E., Dublin. This invention may probably be considered impracticable; but we have given it a place on account of its ingenuity, and because it may lead to something better. In *fig.* 1272., A A′ are wheels, upon which the frame B B B is mounted; the wheels being made of such a breadth upon the sole as to prevent the weight they carry from sinking them in the bog. On the axle of the fore wheels, and revolving with them, is fixed a wheel, C, the teeth of which work in those of the bevel-wheel D, mounted on the shaft E; and upon the same shaft are affixed the bevel-wheels F and G, and a crank H; the shaft E revolving in a socket, *a*, fixed to the axle-tree *b*, and a socket, *a′*, fixed to the frame B. I K are bevel-wheels, working in those marked F G; L is a knife five or six feet long, according to the depth the drain is made under the surface of the bog, and whose cutting edge, C, is made of highly tempered steel, and whose back is an inch thick. M N are spindles, say of one inch diameter, revolving with their respective wheels, I K, to which they are attached; and at the bottom of these spindles, as at O and P, are affixed knives, made in the form of oyster-knives, and so placed that the vertical section of their contour shall be a circle, and that each knife be upon a different horizontal plane; so that, in revolving, they shall not move in the same track. This will be understood by referring to the figure: the knife *e*, for instance, is in a different plane to the knife *f*. Other knives may be placed upon the spindles at right angles to the first set, taking care that each blade shall move in a different track from any of the others. The saw L is pointed at the bottom to make its entrance into the bog easy; and the spindles M N are held in the required position, by the sockets in which they work, as shown in drawing. Let us now suppose the carriage is drawn forward in the direction from A to A′. As the wheel A′ turns, the machinery connected with it causes the crank H and the wheels F G to revolve; the crank giving an alternate motion up and down to the saw, which, being pressed against the fibres of the moss, by being obliged to follow the wheel A′ at a fixed distance, will cut those fibres, and in its progress divide the bog, so as to leave a passage for the spindles M N: but, at the same time the bog is being cut, or sawn through, the spindles M N will be revolving at a rapid rate; and as the several knives fixed at their extremities revolve with them, each one presenting its sharp edge to the fibres of the moss, upon a different plane to any other, it is evident that portion of the bog in which the knives revolve, will be divided into a number of minute parts, in proportion to the number of knives used, and the rapidity with which they revolve. We will trace the effect constantly dividing the mossy fibres of the bog will produce. First, for that of the spindle M. It will be seen by the drawing, the knives affixed to this spindle are not so close as those at P; and for this reason; the fibres of the bog would be cut into minute particles easier by two operations than by one; the action of the knives P being much more effective upon the moss previously separated from the large body to which it was attached, than they would before it was so detached; hence the knives at O are only designed to cut the fibres so as to separate that portion of the bog where the drain is about to be made, from the large body connected with it.

8468. *The knives* at P are intended to be an inch apart, and as there are four sets, and each knife moves in a different track, the tracks will be but a quarter of an inch asunder, and consequently the matter opposing them will be divided into portions of this length by the action of these knives alone; but the divisions produced by the revolving of the knives at O, make the particles still smaller, particularly so, as the spindles M and N move in opposite directions. This would be the effect if the knives acted upon a body of mere dry twigs; but upon the matter upon which it is intended to operate, the effect would be somewhat different; for the vegetable matter composing bogs is generally found, at a depth of five or six feet, to be in a state of decay, and so easily divided, that, upon being agitated in water, a great portion of it separates into very minute particles, the rest being fine moss, or rotten twigs. It is easy to convert such a substance into a puddle, or semifluid, by mixing it well in water; and as every portion of bog contains a sufficient quantity for this purpose, and the revolution of the knives will divide and mix the bog and water so intimately, as to make a semifluid, having a tendency, like water, to run to a lower level (but of course by no means so great), the moss, or bog, which has been divided into such minute parts, will be easily carried off to a lower level, if we can get a stream of water to pass over it. It is intended to do so.

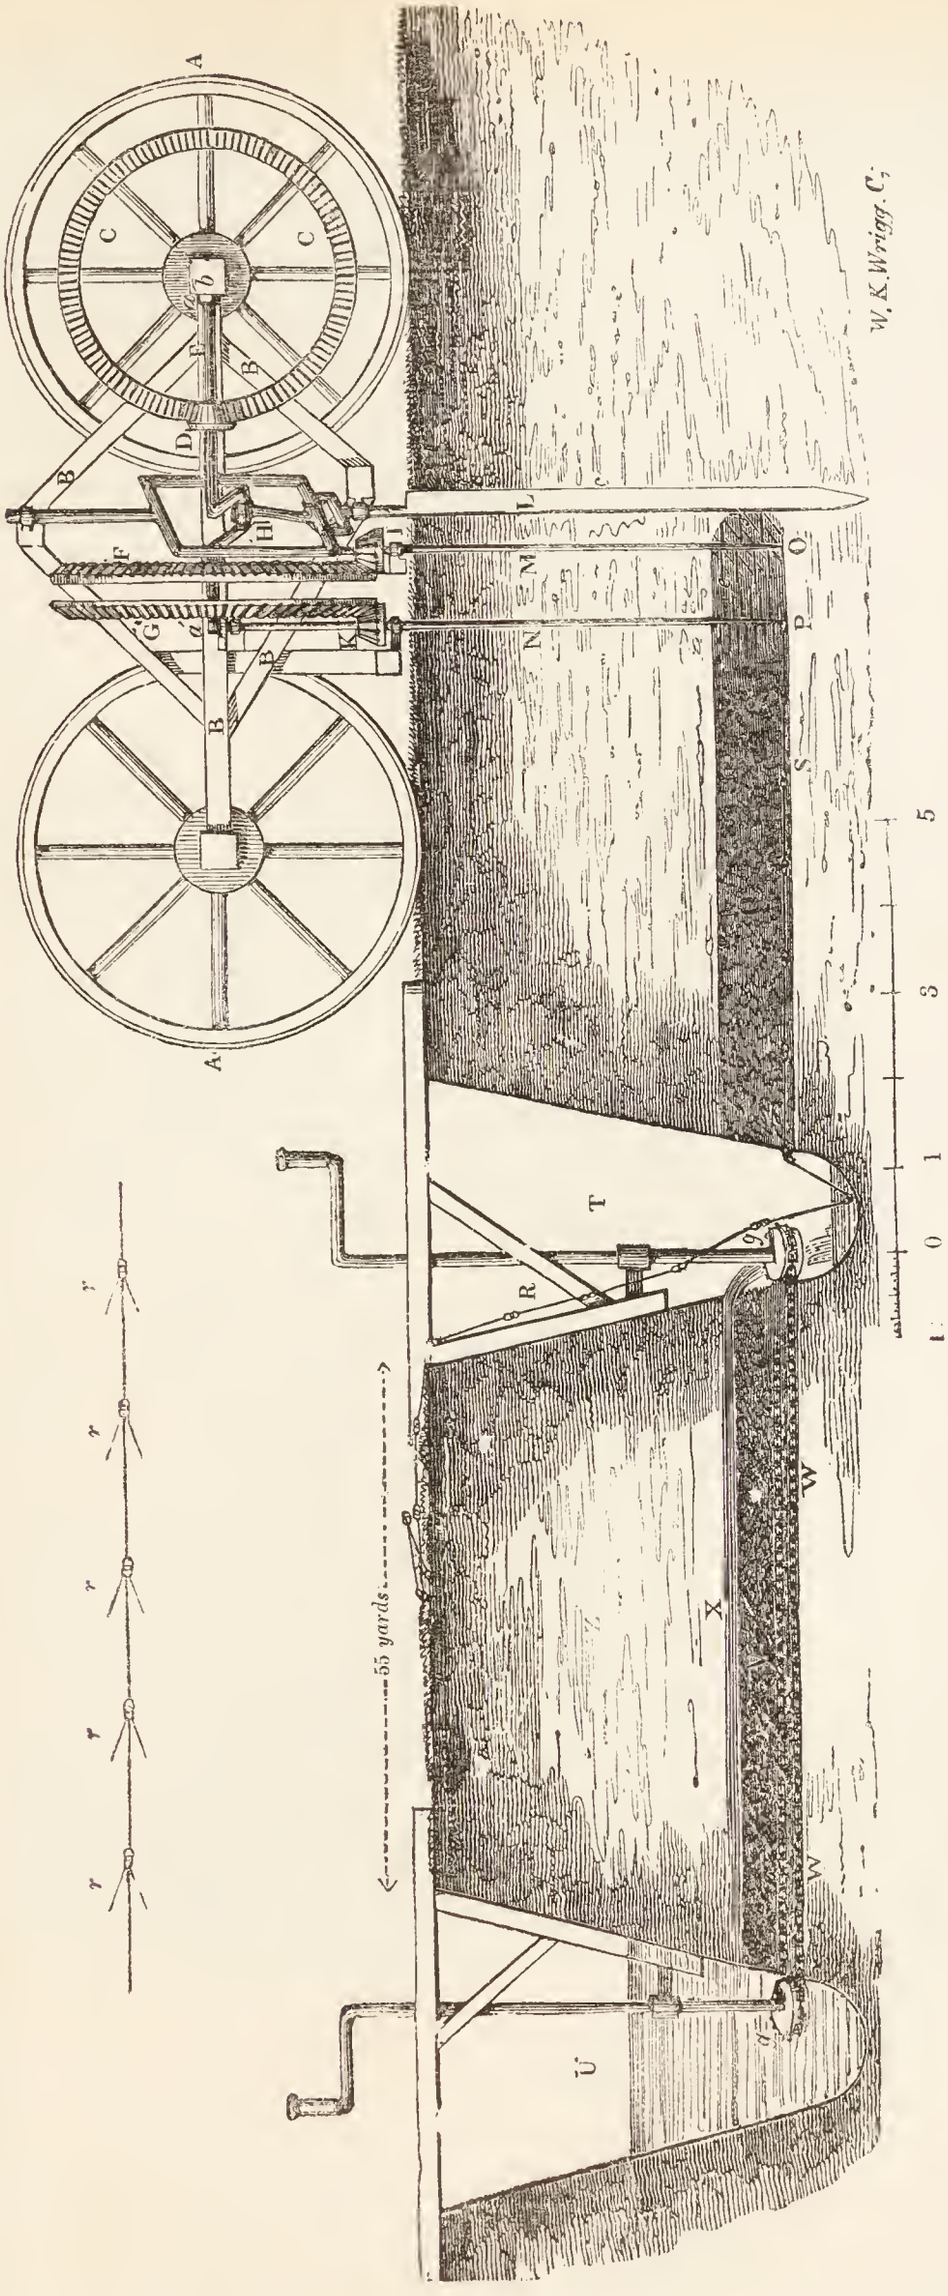
8469. *A chain*, R, made of wire, and in links, in order that it may accommodate itself to the turn out of the main drain T, into the minor drain Q, is attached to the lower part of the spindle N, as at S, by means of a ring playing upon the spindle, N, at perfect ease. Let us suppose the machine has now cut out the minor drain, from one main drain to another, as from U to T; we shall then have the chain extending through the minor drain V, an end being in each of the main drains U and T. The chain is then detached from the machine, and a fresh chain attached to it, making it ready to proceed with another cross minor drain.

8470. If the *puddle* made in the minor drain V is of a very semifluid nature, it is probable drawing the chain alternately backwards and forwards (which might be done by a labourer at each end) would bring a sufficient quantity of it out into the main drains, to cause an unoccupied space immediately under the undisturbed portion of the bog at X; thus making a passage for the water previously dammed up in the drain U, to pass over the puddle in the subterraneous drain V, and fall into the main drain T. As soon as this is effected, the drain may be left to the action of the water, which will very shortly carry away all the puddle out of it into the main drain T, from whence it may easily be cleared, without any expense.

8471. But should a *simple wire chain* not bring out the puddle quick enough, then a similar chain, but having fangs attached to it, as shown at *r r r*, *fig.* 1272., may be used, instead of the one before mentioned. The fangs are to be so arranged, that when they meet resistance moving in one direction, they open a certain distance from the chain, but upon meeting resistance moving in the opposite direction, they lie close to it. It will be unnecessary to describe how this may be accomplished, it will be so easily seen. Its operation in clearing out the puddle will be thus:—Having got it through the drain (and it will offer little more resistance than a plain wire chain, as the fangs will lie close), it is to be moved by men at each end, alternately backwards and forwards: each time it moves backwards, the fangs, from meeting resistance, opening, and bringing before them some portion of the puddle; thus, by a number of such movements, dragging out sufficient puddle to cause an unoccupied space, through which the water will rush.

8472. Or, *if the bog is very compact*, and the puddle very stiff, such as is likely to be the case in what is known by the name of "black bog," then the following method may be taken, which will give two men sufficient power to drag out the puddle from the subterraneous drain:—Suppose the wire chain R (without fangs) to be already dragged through the minor drain. Fastening one end of the chain W to the end of the chain R, it is drawn through and passed round the rag-wheels *g g*, which rag-wheels are connected with the winches, as shown in the drawing. Now it is evident, if the winches are turned, one portion of the chain will be moving in one direction, while the other portion is moving in the opposite one; and as the chain passes out of the minor drain it brings with it, between the links, and otherwise attached to it, portions of puddle, which fall off in the drain T, or are washed off in passing through the water in the drain U; the pins, or spikes, on the rag-wheel, as they pass through the several links, forcing off that portion of the stuff held between them. Besides this, that portion of the chain, passing out of the water in the drain U into the minor drain V, will carry with it a small portion of water, thus assisting the fluidity of the puddle, and consequently decreasing the resistance to the chain passing through. The quantity of stuff brought out of the minor drain by the revolution of the chain, will, after a few turns, cause the puddle in it to sink, and so leave a passage, as by the other methods, immediately under the undisturbed portion of the bog at X, for the water to discharge itself; in doing which it will continue to carry along with it portions of the minutely divided matter until the minor drain is cleared out.

8473. Let us now assume that *the puddle has been washed out* of the minor drain. It will be seen by the distribution of the knives fixed upon the spindles M N, the transverse section of the bog divided and puddled by those knives is a perfect circle, and consequently the transverse section of the drain is also a circle, a form best adapted to resist the tendency of the cir-



cumambient bog to collapse; but although the bog immediately surrounding the drain has not been changed in its consistency by any operation of the machine, yet, containing so much water as it does, it necessarily partakes in some degree of the nature of fluids; hence we find the bottom of drains made in wet spongy "red bogs," have as strong a tendency to rise at the bottom, as the sides have to approach each other. Partaking, then, as the great mass of the bog surrounding the minor drain does, of a fluid nature, it will have a tendency to fill up the space made by extracting the puddle, but, in doing so, it will slowly approach. Now, as the pressure upon the bottom, sides, and top, in fact, upon every part of the circle surrounding the vacant space, is equal, or nearly so, the surrounding matter will approach the centre of the vacant space with equal velocity; and as it approaches, the circle being narrowed, the mossy fibres composing the bog immediately adjoining it will be pressed nearer to each other; and thus, being forced to part with a considerable quantity of the water which kept them apart, will gradually acquire a greater compactness and resistance, as the circle narrows, until, in the end, the fibrous matter will be pressed so close as to resist the pressure of the surrounding bog forcing it into a smaller space. We shall thus have formed a tubular drain, though something less in its dimensions than the diameter of the circle made by the knives o p. I never yet saw sufficient water coming from a minor drain to fill a two-inch bore, and I have seen a great deal of bog draining, and paid much attention to it. Even when any considerable quantity is discharged, it is to be supposed not from the drainage of the bog immediately about it, but from its having crossed the course of some spring. I may remark here (though the remark is unconnected with the effects produced by this draining-machine), that, when this is suspected, means should be taken to discharge the waters of the spring as quickly as possible, if it is a bog spring; but, if a spring supplied from the upland, the water should be impounded for irrigation. In general, both these objects may be obtained with little trouble or expense.

8474. *Minor drains* should not only be sufficiently large to pass off the water from the bog immediately surrounding them, but also to prevent them from being easily choked. I think they ought not to be less than six inches in diameter, and by way of securing them this size, the diameter of the circle made by knives might be ten inches, thus allowing them four inches for collapsing. The bog immediately surrounding the drain would have to be pressed into three fifths of its original bulk, before it enclosed the drain so as to reduce it to six inches in diameter; but, before it was pressed into so much less space than it originally occupied, it would have acquired a compactness enabling it to resist the pressure behind it, and the drains would, in general, be more than six inches in diameter. According to the consistency of the bog, the diameter of the circle made by the knives might be regulated.

8475. *Mode of using the machine.* Having described the operation of the machine, it will be necessary to point out the methods of overcoming any obstructions that may pre-

sent themselves upon putting it in motion. We will, in the first instance, consider horses to be used for this purpose; in which case it will be necessary that the main drains, such as T and U, be made some time before the minor drains are commenced; in order that the bog z, lying between them, may be sufficiently consolidated to admit of horses, with proper pattens, working upon it. This will take place upon the edges of bogs in a short time after the main drains are opened; but in the interior the consolidation will take place slowly, for, from its very spongy quality, it will not part with its water so quickly as the denser bog on the edges. It is the general practice to make the main drains parallel to each other, and at a distance of about ten statute perches asunder; and yet, although so near, so strongly retentive is bog of water, that, in very soft spongy bogs, it would require at least two or three years to drain them sufficiently, by this means, to admit of horses working upon them. Upon the edges they would be sufficiently firm in a few months. The bog may always be rendered sufficiently dry by taking a large quantity in hand at once, so that, before the last of the main draining is finished, the banks between the first drains cut will be well consolidated; or, if a small quantity only is taken in hand, by waiting till it does consolidate.

8476. *The probable expense of working the machine* by horses will be first calculated, and afterwards a method shown by which the minor drains may be made without waiting for the main drains to draw off any considerable quantity of water from the bog; thus expediting its reclamation, without adding to the expense.

8477. *The weight of the carriage and its machinery* is about one ton, and, as the wheels are intended to be nine inches upon the sole, they will sink little under so small a weight. Two horses would move the carriage with ease, and from two to four more (according to the depth and size of the drains, for they must vary with the nature of the bog) would overcome the resistance of the saw and spindles M N, with their knives. If we say five horses on an average, we shall be perfectly safe. I believe a less number would do. To this must be added two men for driving. The draining-machine is to proceed in a straight line, passing over the main drains, from one division of bog to another, until a minor drain is made from one extreme of the bog under reclamation to the other extreme.

8478. *In cutting main drains* it is usual to make them open, but I should propose, that occasionally bog bridges be left, say at a distance of every eleven yards; that is, leaving an open drain for eight yards, and having a bog bridge three yards broad. Many advantages attend this plan, not appertaining to the usual method. In the first instance, the labour and expense is something less; they afford an easy passage for men or cattle to walk over; thus preventing, in a great measure, the injury done in leaping across, and so destroying the sides of the drain, and choking it with the bog stuff thrown into it by these means. Bog bridges, if placed at short distances, prevent the collapse of the drains, and would on this account, enable us to cut them at once sufficiently deep, without waiting, as is necessary now, for two or three years. Viewed in connection with this draining-machine, they would afford a ready passage for the horses, and so save labour and expense, and facilitate the operation.

8479. *The method of passing the horses and machine over the main drains.* As soon as the horses arrive at the edge of a main drain, the chains by which they are drawing the carriage may be lengthened, so as to allow them to turn out of the direction they were proceeding in, and pass over a bog bridge, which will always be within two yards of the line of a minor drain; supposing them to be a statute perch distant from each other, as is usual. There will be little inconvenience, or loss of time, in this. As soon as they are on the other side they may again be hooked to the carriage, giving them chain sufficient to reach over the drain; a pass for the carriage-wheels having been previously formed. The pass is to be made thus: — Suppose the main drain to be four feet six inches wide at the top. Two three-inch planks are to be provided, each one foot broad and eight feet long, and having ribs of iron fastened on each edge of each of the planks, to prevent the wheels of the carriage from slipping off in passing over the drain. The length of these planks will give a bearing of one foot nine inches on each side of the drain, which will be quite enough, as there can only be a pressure of five hundred-weight on a plank at one time. Their extremes are to be worked off to a chisel edge, in order to facilitate the carriage mounting upon them. The planks being placed over the drain before the machine comes up, there will be no delay, except taking the horses to the other side of the drain, and unhooking them from the carriage and hooking them to again. As soon as the machine has passed over the drain, two men are each to take up a plank (they will not be a hundred weight each) and proceed to the next main drain and make a pass. They may easily have this done by the time the carriage comes up, there being little more trouble than throwing down the planks, of course due care being taken to place them in the line of direction in which the carriage is to move. In passing over drains already made, that have no bog bridges, it will be necessary to connect with the carriage pass more planks, so as to allow the horses to walk over without difficulty: this may easily be done.

8480. *The number of men* required to clean out a sufficiency of the puddle from the minor drains, so as to give vent to the water through them, is the next consideration. Except in very compact "black bog," it will not be required to use the winches with the chain and rag-wheel; and as bog of this description bears but a small proportion to the spongy or "red bog," this method will seldom need be resorted to. However, to make sure, the calculation of the expense is made upon the assumption that it will always be necessary. The platforms used for working the chain and rag-wheel, together with their machinery, do not weigh two cwt. each; so that two men would be able to carry one at a time, from drain to drain, as they were required. Let it be observed, it will not be necessary to move both platforms when a fresh drain is to be cleared by them. Thus, if the drain the machine is forming is to be cleared after the one in which the chain is working, the platform over the drain T would not have to be removed; it would merely have to be turned round: but the platform over U would have to be carried double the distance of U T. Calculating the men would be twice the time in carrying it this distance that the draining-machine is in moving from drain to drain, and that two men, having got the chain through the drain, would be about the same time in working out the necessary quantity of puddle from a minor drain as the draining-machine is in puddling one; and that it would take them twice this time to insert the chain, and draw it out again; we have two men occupied five times as long in cleaning a drain as is taken to puddle one; consequently it would, upon this calculation, take ten men to clean out the drains as fast as they were puddled. We will allow twelve men for this portion of the business. It must not be forgotten, we are assuming *all* the drains will have to be thus cleared, although it is by no means probable. We shall be under the mark, if it is only calculated the horses would move the draining-machine at the rate of one mile per hour: however, we will make our calculation on this assumption. If the horses work eight hours a day, they will make eight miles of draining. We shall have the day's expenses then as under, calculating them from the highest rate of labour in Ireland, a country to which this machine is particularly applicable.

	L.	*s.*	*d.*
5 horses, at 2*s.* per day	0	10	0
2 men, making passes, at 1*s.*	0	2	0
2 men, driving, at 1*s.*	0	2	0
12 men, cleaning out drains, at 1*s.*	0	12	0
Wear and tear of machine, and pattens of horses, say	0	2	0
Cost of making eight miles of minor drains	1	8	0

Now there would require 160 perches of minor drains per acre, supposing them to be made a perch asunder, the cost of which would only be 1*s.* 9*d.* The present expense is about 14*s.* per statute acre for the same work.

8481. *The main drains cost now, on an average,* about 9*s.* per statute acre, making the whole expense 23*s.* By the use of this machine the expense of main drains and minor drains would be 10*s.* 9*d.*; thus at once doubling the profits of bog reclamation, so far as draining is concerned.

8482. *Objections answered.* It may be said, horses could not work upon a very wet bog till a long time after the main drains had been made; perhaps years. To meet this objection, among many other obvious means, a windlass, mounted on a moveable platform, might be used; the windlass to be placed over the main drain, next the front of the draining-machine; and the platform upon which it is mounted to be made so that it shall have a bearing against the side of the drain, sufficient to enable it to resist the reaction from the draught of the machine. Its form will be similar to the platform used for clearing out the puddle; but, perhaps, it will be necessary to offer a greater face of planking to the side of the drain. Its weight need not exceed from three to four cwt., so that it may be easily removed, as occasion requires. By attaching a rope from the windlass to the carriage, it of course can be dragged on; and the expense by this method will probably be about the same as when horses are used. If it is objected, that drains made at one operation, in such wet bogs as we now are speaking of, will soon close; it may be answered, that though the collapse will undoubtedly be great, yet, being something like equal on all parts, the circular form of the drain will most certainly prevent a perfect closure of the aperture. This, though true of arched drains, is not so of the shoulder drains now in use: for, while the former increase their resistance to the pressure surrounding them, the nearer the approach to the centre of the unoccupied space, the latter, whose sides are straight lines, decrease in their power of resistance, under the same circumstances: hence it is found totally impossible to make shoulder drains to stand, except in tolerably firm bog; and, to secure this, they are generally made in three operations. I by no means admit it; but we will suppose every drain was to close after a short time: before doing so, they most certainly would have discharged a great portion of the water from the bog, and have consolidated it considerably, so that there would be no grounds to fear the closure of a second set of minor drains made after the first set had drawn off the great body of water from the bog. Should even this be necessary, the expense of the minor drain would only amount to 3*s.* 6*d.* per statute acre. It will readily be admitted, that, where there is the slightest fear of a circular drain closing, a straight-sided drain could not possibly stand.

8483. *The profits of reclaiming bogs.* By the use of such a machine as is here described, the profits of bog reclamation would be much increased; but, as in conjunction with other machines the inventor of this has contrived one for carrying earth on bogs cheaper than by movable railroads now in use, and performing other operations in bog improvements (which he will take another opportunity to describe), there can be little doubt that bogs may be converted into land not inferior to some of the best upland, and that, too, so as to yield a profit of from 10 to 40 per cent, according to the particular circumstances under which the bog lies; thus not only yielding a handsome income to the reclaimers, but also as providing a large field for the employment of the labouring population.

THE END.
